Railway Mechanical Engineer

Volume 93 | January, 1919 | No. 1

CONTENTS

The Contents of Our January Issue

The publication of this issue of the *Railway Mechanical Engineer* was delayed for the purpose of giving our readers, as best we might, a review of the happenings in the mechanical department field for the year. The past year has been one of the most interesting in railroad history. Last year at this time the locomotive and car equipment on the railroads of this country was in very poor shape because of the extreme cold weather; the labor situation was extremely critical and large numbers of railway men had gone to France to do their part in relieving the transportation situation there. In this issue we publish a brief story of what was accomplished in France in the matter of handling the cars and locomotives under the jurisdiction of American railway forces. We give also a review of the labor situation and show what has been accomplished in improving the condition of cars and locomotives, together with the number of new cars and locomotives ordered during the year. In addition to this, the January *Railway Mechanical Engineer* contains a very complete article on the West Burlington shops of the Chicago, Burlington & Quincy, which represent, perhaps, the latest practices in railway shop construction.

Supervising Foremen Receive Increases

The compensation for the supervising forces in the mechanical department of the railways has at last been revised and as a general rule when these new rates are compared with what the workmen receive for an eight-hour day, they appear to be satisfactory. Contrary to the manner in which the increases in the workmen's wages was handled, this matter was handled by the regions or districts in which the roads were located rather than by establishing universal rates the country over. The latter method would be quite difficult to handle and have everyone satisfied, as the responsibility and effort required of foremen carrying the same titles vary on different roads. So far as we have been able to learn, however, the rates are sufficiently high to make the positions attractive to competent men. By making a study of the increases which have come to our attention it is found that they are based on a 10-hour day with time and a half over eight hours. This, of course, is a very fair way of approaching the determination of a proper rate, as very few supervising foremen can get through the week without spending many more hours on the job than are required of the workmen.

With the disposition of the Railroad Administration to limit all classes of wage earners to an eight-hour day there will be but little of the dissatisfaction which existed a few months ago when the men were receiving so much overtime, caused by the small differences between the earnings of the wage earners and the supervising forces. It is to be hoped that with this added incentive and with the knowledge that the Railroad Administration is out after a full day's work for a full day's pay, as indicated by Mr. De Guire's address, published in last month's issue, the output and the discipline in the railway shops will improve. The task ahead of the foremen is a difficult one. Had these men been granted their increases along with those granted the workmen last summer the feeling of disrespect and disregard of the foreman's authority would have been prevented to a large extent. It would have been possible to hold some of the competent foremen who found it to their advantage financially to return to the ranks and to have attracted able organizers and leaders of men to the supervising positions. While it will be acknowledged generally that it was a short-sighted policy to follow, the mistake must not be allowed to interfere with a courageous and conscientious policy on the part of the foremen. Any tendency toward Bolshevism and insubordination should not be tolerated. The shop supervisors must get their organizations back into good working shape just as quickly as possible by being absolutely fair with the men, by insisting upon proper respect and a fair output. The time has gone by when labor can be ruled with an iron hand. Courage, discipline and fair-mindedness are now the qualities which distinguish the successful supervisor.

Report on Standard Locomotives

In the annual report of Director General McAdoo, which was not released in time to incorporate in this issue, an outline is given of the reasons for standardizing locomotives. They sum up as follows:

"*First.*—To reduce to a minimum the time required to prepare drawings, patterns and dies and thus enable deliveries to begin more quickly than where separate drawings and patterns would have been necessary for each lot of locomotives allocated to a particular road.

"*Second.*—To insure quantity deliveries. This method of construction has resulted in delivery being made at a quantity rate, which would not have been approached had the locomotives been ordered to individual designs.

"*Third.*—It has also provided a supply of equipment, the parts of which are largely interchangeable, which is available for use anywhere in event of congestion. This removes the necessity of carrying a large stock of repair parts particular to the locomotive and avoids delay which results when repairs must be ordered from some distant owning road."

It may be safely said that thus far none of these aims has been reached. In the first case, new drawings, patterns and dies had to be made for these standard locomotives and it stands to reason that had the roads which needed locomotives been permitted to order locomotives to existing designs, which was so strongly urged last spring, it would have been unnecessary to prepare these new drawings, patterns and dies and that deliveries could have been made much more quickly and with less labor and expense. In fact, to realize anything on this particular point, which by the way considers only the manufacturers of locomotives, standardization would have to extend over many, many years.

The discussion of the first point covers to some extent the second—to secure quantity deliveries. In commenting on this point the director general says: "During five weeks, beginning July 20, an average of 13 1-5 locomotives per week were turned out at the Dunkirk plant (of the American Locomotive Company) while during five weeks beginning September 14, an average of 19 1-5 locomotives per week were turned out at the same plant." The answer to this is that had the roads been permitted to order locomotives to existing designs, as mentioned above, and had not the builders been required to prepare drawings, patterns, dies, etc., for the new standard designs, the average output during the five weeks beginning July 20 would have been larger than that cited by the director general and the railroads of this country would have received locomotives when they needed them most and not after the war was over.

Under the third point the director general says: "This removes the necessity of carrying a large stock of repair parts particular to the locomotive and avoids delay which results when repair parts must be ordered from some distant owning road." During the latter part of the year when the standard locomotives were being placed in service in large numbers, and at the present time, the reverse of this is true. Every road that handles a standard locomotive must enlarge its stock of repair parts in order properly to handle the standard locomotives. The director general in commenting on this point goes on to say: "The importance of this is forcefully illustrated by an instance where a leased locomotive was held out of service until over $4,800 rental had accumulated, waiting for a part which would cost not to exceed $30." This statement, the truth of which is not to be questioned, coming from the source it does, will appear to any practical railroad man as being utterly absurd. Any mechanical department officer that would permit such a thing to happen when he has the shop facilities usually found on a railroad with which to make the missing part costing $30, should not be permitted to hold a position of authority. At best it must be assumed that this was an extreme and isolated instance.

The thought the director general endeavors to convey by this statement applies more particularly to the standard locomotives at the present time than to leased locomotives, for the reason that the owner of a locomotive must have repair parts that are available for the borrowing road, whereas every user of the standard locomotives must either make the new repair parts or obtain them from the equipment manufacturers. As these locomotives are scattered throughout the country, much labor and expense will be involved to provide these parts properly to take care of the locomotives wherever they may be. This third point can only be realized, as in the case of the first and second, after standardization has been in effect for a large number of years, all of which seems to indicate that the director general in following such a plan was giving far more thought to the establishment of a permanent policy for the future than to the immediate problem of winning the war—the only purpose in establishing government operation.

The entire locomotive standardization program, it would seem, favored far more the builders of locomotive equipment than the railroads that are to use these engines. The advantages to the builders will be short-lived and were obtained, as shown above, at a sacrifice in the year's output, while the disadvantages to the railroads will exist 15 or 20 years, or for the life of the standard locomotives they operate. If standardization were to continue it would be 10 to 15 years before any beneficial effect could be obtained from the standard locomotives from a maintenance standpoint. Even after the government releases the control of the roads and the railroads have control of the purchases of locomotives, tools, taps, dies, patterns, etc., must be carried in stock to maintain these standard locomotives. On one road in particular a complete set of patterns will have to be made for the standard locomotives assigned to it, as no part of them is common to those of its own locomotives. Grates, pistons, cylinder heads, cylinders and parts, crossheads, driving boxes, shoes and wedges, ashpan casings, crown brasses, engine trucks, tender trucks and trailer truck brasses and boxes will have to be obtained to meet these new designs. In addition, many fittings are entirely different from those that have been used on that road for many years.

In the case of one road to which a number of the standard locomotives were sent, they were found to be inferior to the road's own locomotives of but slightly less tractive power, particularly in the amount of fuel used. This same road has had much trouble with the stoker equipment, which is of a different design from that used on the road's other locomotives. Engine failures have been caused on account of this, which have delayed traffic and necessitated the use of relief locomotives. The engines were held out of service waiting for repair parts with which to repair the stoker. If the road had had the privilege of specifying the equipment desired it would have ordered that with which its other locomotives were equipped and with which its engine crews were familiar and for which it had a stock of repair parts.

On another road several standard locomotives were delivered almost before the road knew it was to receive them. They were delivered under their own steam and one arrived with the grates burned out. As all grates had to be changed, the engines had to be held out of service until the work was done. The rod packing used on these engines was of a different design from any used on that road, although other standard locomotives were equipped with packing that conformed to its standards. As no packing was sent with the engines, delays were caused until the road procured the proper packing for the engines. One of the engines met with an accident and as there were no spare parts and no drawings of the standard locomotive, a draftsman had to go out on the road to the engine and make a sketch of the parts needed for patterns and forgings to make repairs. This required holding the locomotive out of service for some time.

It will be seen, therefore, that locomotive standardization cannot be considered as a war measure, as the advantages sought could not be obtained unless the war lasted many years. It seems to have been more a part of a well defined scheme for complete nationalization of the railroads in this country.

The Railway Crisis

The director general of railroads has just appeared before the Senate Committee on Interstate Commerce to explain the work of the Railroad Administration during the past year, and to tell why he thought it was necessary to extend government control for a period of five years. He has also made public that part of his report to the President covering the activities of the Division of Operation. Under ordinary circumstances we could well afford to congratulate ourselves upon the fact that the railways of this country made a splendid record during the past year in transporting the increased traffic, made necessary by war conditions, and in helping to win the war. No one wishes to take any credit from Mr. McAdoo or the Railroad Administration, but when the director general deliberately tries to make out a case for the Railroad Administration and show why it should be given a period of five years in which to develop the advantages of unified control under peace conditions, it clearly becomes our duty to disagree with him.

The *Railway Mechanical Engineer* has always been firmly of the opinion that a serious mistake was made when the government took over the actual operation of the railroads. This was unnecessary, as has been clearly shown by the results that have been obtained in Great Britain. That country, on the basis of the experiences in the Franco-Prussian war, made plans for the government control of its railroads during emergency as far back as 1871. When it entered the war in 1914, it took over the control of the roads, but left their operation in the hands of a board of railroad executives. The government simply guaranteed the earnings on the basis of 1913, the pre-war year, and lent all of its authority and power to the railway executives who were placed in charge of the actual operation. As a result, the English railways will probably go down into history as the best managed and operated of any of those of the countries which were engaged in the war.

In this country, a Railroads' War Board had been formed directly after our entry into the war and had given excellent results, considering the fact that it was hampered by the restricting and conflicting regulations of the federal government and 48 states. Two of the factors which were largely responsible for the government taking over control of the railroads were the financial difficulties in which the roads found themselves, because of the rapidly increasing costs and the fact that the Interstate Commerce Commission would not grant an increase in rates, and also because of the serious congestion which was caused, to a very great extent, by the fact that officers in various departments of the government were allowed to issue priority orders without regard to other departments and with no relation to the real order or necessity in which the material was actually required.

The government, by simply taking control and guaranteeing the earnings, and leaving the operation in the hands of the Railroads' War Board, with full responsibility, could undoubtedly have done all that the director general of railroads was able to do and not with the break-down of morale which followed when Mr. McAdoo made such radical changes last winter. One of the greatest shortcomings of the Railroad Administration has been that it has not given the thought which it should to the importance of the human factor in railroad operation. Whether it intended to have it so or not, the impression was widespread that it deliberately intended to discredit the officers. The effect of this upon the morale and discipline throughout the entire organization was disastrous. It is perfectly true that many of the things that were done by the director general, looking toward unification of operation and facilities, were productive of good results. It must be remembered, however, that many of these things had been proposed by the Railroads' War Board but could not be carried out because of laws and regulations under which the railroads were formerly forced to operate.

The labor problem, under private management, was a most serious one. There is no reason, however, why it could not have been solved just as well by railroad executives as by the director general, providing the Interstate Commerce Commission had granted the necessary increase of rates, and this the commission could have been forced to do by the government. One splendid thing has been accomplished by Mr. McAdoo and his Railroad Administration, and that is that so much publicity has been given to the railroad problem, that the public generally is thoroughly awakened to it and is beginning to take the intelligent interest that it should in its final solution. President Wilson frankly stated to Congress that he had no solution for the railroad question, but only a few days later Mr. McAdoo announced that it would be necessary to grant a five-year extension for government control and that if Congress did not take immediate steps in this direction, the roads would be turned back to their owners without any opportunity for remedial legislation. The announcement was also made that the President agreed with him as to this. Just why statements should have been made that it would be necessary to turn the roads back immediately to their owners if the extension was not granted has never been made clear, and there are not a few who suspect that Mr. McAdoo was trying to stampede Congress and the railway executives and force them to the five-year plan.

Fortunately, Congress was not stampeded and the Senate Committee on Interstate Commerce is now engaged in holding a series of hearings during which representatives of all of the important organizations or interests will be heard. Manifestly, it will not be possible to handle the matter to completion during the present session of Congress, which ends next March. The railroad problem, however, is of such tremendous importance to the nation at large that the President will be fully justified in calling a special session of the new Congress to continue the studies and develop the necessary legislation.

Many different plans have been put forward in order to provide the legislation which will be necessary before the roads can safely be returned to their owners. Unless some provision is made to guarantee their financial returns or to insure adequate revenues, it will be disastrous to return the roads to their owners. Moreover, the railroads must be relieved of the conflicting and restrictive regulation of the federal and 48 state commissions; this can possibly best be done by federal incorporation, thus bringing all of the railroads directly under the federal authorities and, at the same time, insuring that careful attention will be given to the issuance of securities which will tend to restore confidence on the part of the security holder and investors. In order to retain those features of unified operation that have given good results during the past year, it will be necessary to repeal the Sherman act, so far as it relates to the railroads. The central regulating authority will have to be more constructive and have a larger responsibility than is now given to the Interstate Commerce Commission. Doubtless, it will be necessary to reorganize and enlarge this commission, and the suggestion has come from other sources that a secretary of transportation be appointed, who will report direct to the President and be a member of his cabinet.

It is noteworthy that the Interstate Commerce Commission has gone strongly on record before the Senate Committee against government ownership and that it believes that it will be advisable to retain a certain amount of competition between the different roads, in order to develop initiative and give the public the best possible service.* One of the most difficult phases of the whole problem is the so-called "weak sisters". These are the weaker and less favorably located roads that cannot exist on rates that would give a good return to the stronger roads. Many suggestions have been made as to combinations which might be formed, and there have been strong advocates of dividing the country into various regions and unifying railroad operation in each region. On the other hand, there has been quite some opposition to this proposal, and the Interstate Commerce Commission in particular suggests that the problem might be solved in a more logical way by arranging for a combination of the weaker roads with adjacent strong roads. Such combinations would, of course, have to be carefully supervised, and it would be specially important not to allow any of the weaker roads to be isolated, so that they would have to stand by themselves.

Hundreds of suggestions are being made as to how Congress should handle the entire problem. It is of great importance that the return of the railroads to their owners should be accomplished with as little disturbance to the public as possible, and that there should be no attempt at experimentation, or in taking radical and unnecessary steps. The railroads of this country pay the best wages and give the best service, at the lowest cost, of any railroads in the world. Common sense would seem to indicate that it will be wise to remove those restrictions that have hampered the continued development of the roads and that, if necessary, the solution of the railroad problem be made in more than one step, if it is not possible clearly to determine the final solution without too much experimentation.

Cost of Locomotive Repairs

While it is extremely difficult with the statistics now at hand to obtain a precise idea of the increase in the cost of locomotive repairs during the past year, sufficient information is obtainable to show that it has increased at a tremendous rate. This is due, of course, very largely to the fact that on account of the war, prices of labor and material have increased greatly. It is also due to the fact that a very strong effort has been made during the past year to keep locomotives in repair and to build up a reserve of power for the winter months to preclude any serious shortage of power such as crippled the roads so badly during the extreme winter last year. The very trying experiences of last winter made it apparent that drastic steps must be taken to prevent its recurrence and when the weather became more favorable in the Spring the Railroad Administration was determined that locomotives should be repaired regardless of cost. The shop hours were increased to 70 hours a week, wages were very materially increased and a basic eight-hour day granted in order to keep the men on locomotive work. Engines were sent to foreign shops that were able to handle repairs in addition to their own; old locomotives that under ordinary conditions would have been scrapped were repaired and every step possible taken to improve the locomotive condition situation.

It has been difficult to get a very comprehensive idea of the increases in the cost of locomotive repairs due to the fact that most of the roads have included in their monthly statements back pay for preceding months. From those roads on which the amount of back pay was deducted from the cost of repairs it has been found that 100 per cent. increase in the cost of locomotive repairs per locomotive mile over pre-war conditions is a very conservative estimate. On one road in particular, the cost of repairs per locomotive mile for June, 1918, was 113 per cent. greater than in June, 1916. In August, 1918, it was 114 per cent. greater and in October, 1918, 91 per cent. greater than the corresponding months in 1916. For the first ten months of 1918 the costs were 76 per cent. greater than for the same period in 1916. This, however, does not show the real situation, as none of the back pay for the first part of the year was included in the comparison. On another road a fair estimate for the first six months of 1918 was 100 per cent. greater than for the same six months in 1916. The locomotives being now in such good condition, as reflected by the reports from Washington, which are published elsewhere in this issue, and the extreme demand for power removed, it is to be anticipated that the cost of locomotive repairs for the coming year should be less.

NEW BOOKS

Proceedings of the American Railway Master Mechanics' Association. Edited by V. R. Hawthorne, secretary. 528 pages, 33 plates, 6 in. by 9 in., bound in cloth. Published by the association, 746 Transportation building, Chicago. Price $5.

The fiftieth volume of the Master Mechanics' Association Proceedings, which has just been issued, covers the activities of the organization during the years 1917 and 1918. A large part of the book is devoted to an account of the convention of 1918, which includes several valuable committee reports. The report on the shop manufacture and repair of semi-elliptical springs covers the subject very thoroughly. The report on the design and maintenance of locomotive boilers is devoted principally to a discussion of the field for autogenous welding in boiler work. The committee on fuel economy and smoke prevention outlined briefly the problem of fuel economy on railroads and made specific recommendations concerning the methods of handling storage coal. The committee on train resistance and tonnage rating submitted data secured from train resistance tests and engine tests. Several important changes were made in the specifications, standards and recommended practices of the association. The development of feedwater heaters is covered very thoroughly in an individual paper by J. Snowden Bell.

Proceedings of the International Railway General Foremen's Association.—Compiled and published by William Hall, secretary of the association. 63 pages, 6 in. by 8¼ in., illustrated, bound in leather.

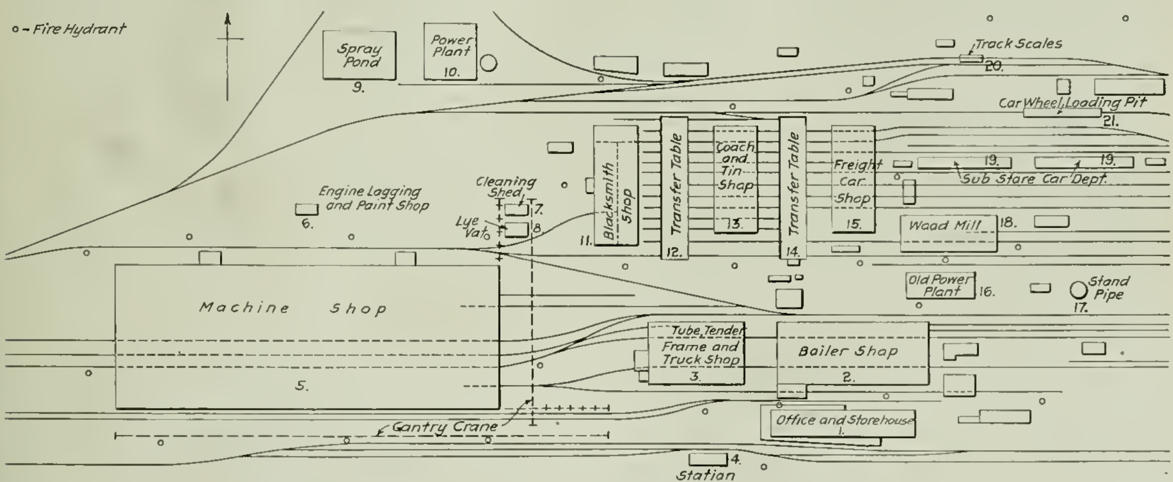
Although the International Railway General Foremen's Association did not hold a convention during 1918, it has in an endeavor to carry on its work of improving mechanical department conditions published the papers prepared by its members which would have been presented had a convention been held. The association is to be congratulated on thus attempting to keep alive its good work and its various members will undoubtedly appreciate the time and effort taken by the committee members in preparing papers for their benefit. The proceedings contain an address by President North, superintendent of shops of the Illinois Central at Chicago, by Robert Quayle, general superintendent motive power and machinery of the Chicago & North Western and by Dr. Frank Crane and in addition the annual report of the secretary-treasurer. The following subjects were discussed by various members of the association: What effect has the war had upon your shop methods and what changes for the better are the result thereof?—The mileage of a locomotive; its relation to the cost of shop and running repairs; who should determine when to shop an engine and who should furnish the work report?—Economical and necessary electrical equipment for railroad shops and roundhouses—Is the flat rate of pay for various classes of labor a success? Should the minimum rate accepted by various organizations be the maximum rate allowed by employers?—How best can greater output by unit of labor be obtained—and, How can uniform classification of repairs to locomotives be brought about?

West Burlington Shops of the C. B. & Q.

Equipment and Operation of New Erecting and Machine Shop, Blacksmith Shop and Power Plant

In 1917, the Chicago, Burlington & Quincy made extensive additions to its shops at West Burlington, Iowa. These included a new power plant, a blacksmith shop, and a combined machine and erecting shop which surpasses in size any similar structures that have yet been built. The expansion of the facilities at this point was made necessary by the increase in the amount of motive power in the district which the shop served and the crowding of neighboring shops. West Burlington is on the main line between Chicago and Omaha, and points farther West. The other principal shops on this line are at Aurora, Ill., 173 miles east of West Burlington and at Havelock, Neb., 336 miles to the West. Burlington, Iowa, four miles east of West Burlington is an important division point on the main line between Chicago and Omaha and is the center of a net work of feeders running throughout western Illinois, Iowa and Missouri. The shops are therefore centrally located with respect to a large amount of motive power.

The problem involved in enlarging the shop was one often met with, namely, to utilize existing facilities to the best advantage in connection with a large extension. The shops as they stood prior to 1917 were built in 1882. At this time a tract of land comprising 640 acres was purchased and the West Burlington shops were erected, much of the equipment being moved out from Burlington. The plant as built at that time comprised seven principal buildings; a storehouse



Plan of Tracks and Buildings, West Burlington Shops

List of Buildings

		Material	Size	Year built
1	Office and storehouse	Brick	55 ft. 8 in. by 301 ft. 6 in.	1882

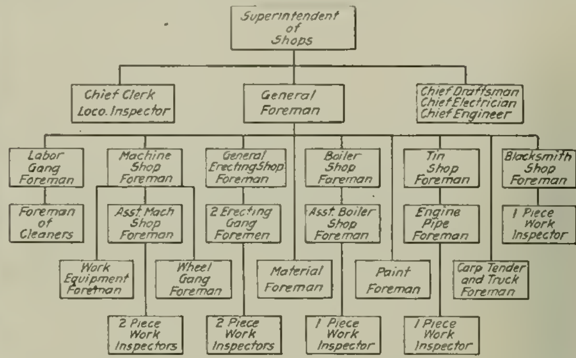
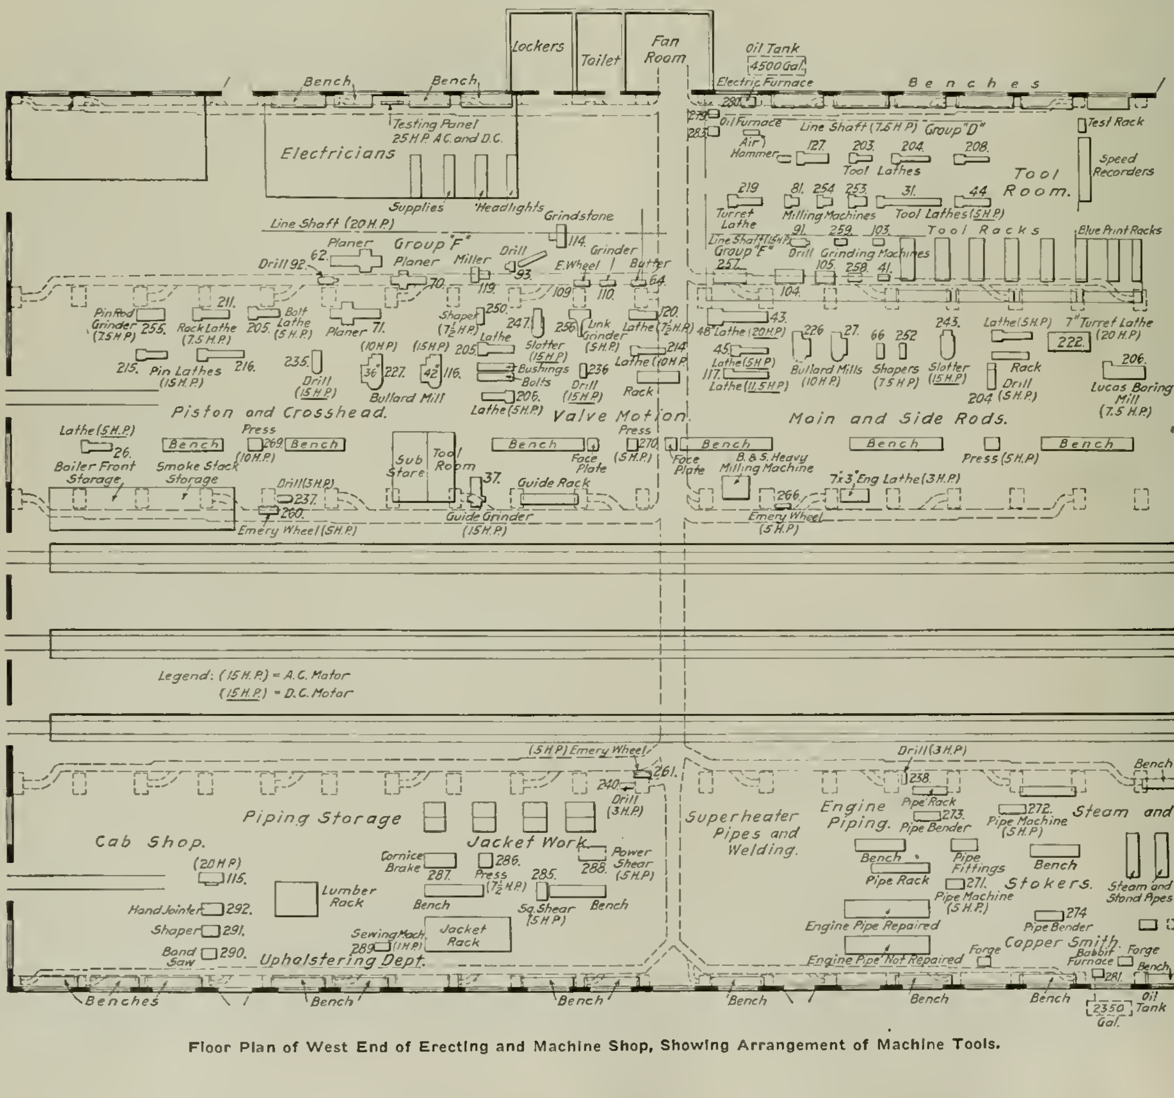
20	Track scales	Wood	8 ft. by 50 ft.	
21	Car wheel loading pit	Concrete	22 ft. 6 in. by 110 ft. 1 in.	

Bolt Department in the Light Machine Bay

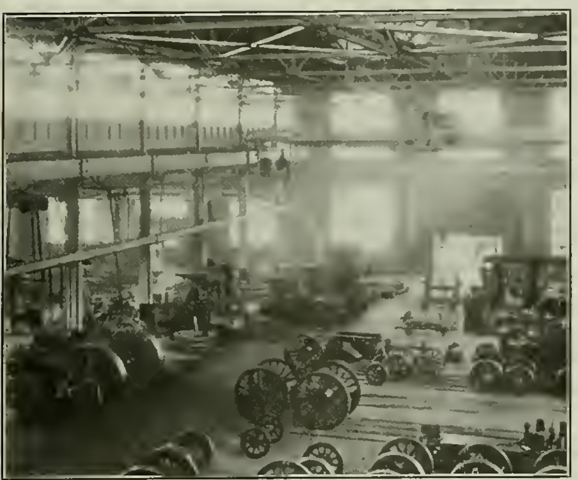


Organization Diagram for the Locomotive Department

and office, a machine and erecting shop with longitudinal pits, (now used as a boiler and tank shop), a boiler and blacksmith shop, (now the flue and tender truck repair shop), a coach shop, a freight car shop, a wood mill and a power house. The main entrance to the shops was from the east, and expansion in that direction was impracticable because the adjoining land was occupied by an iron foundry. The land at the west end of the shops was level and the location of buildings on that side would not inter-



Floor Plan of West End of Erecting and Machine Shop, Showing Arrangement of Machine Tools.



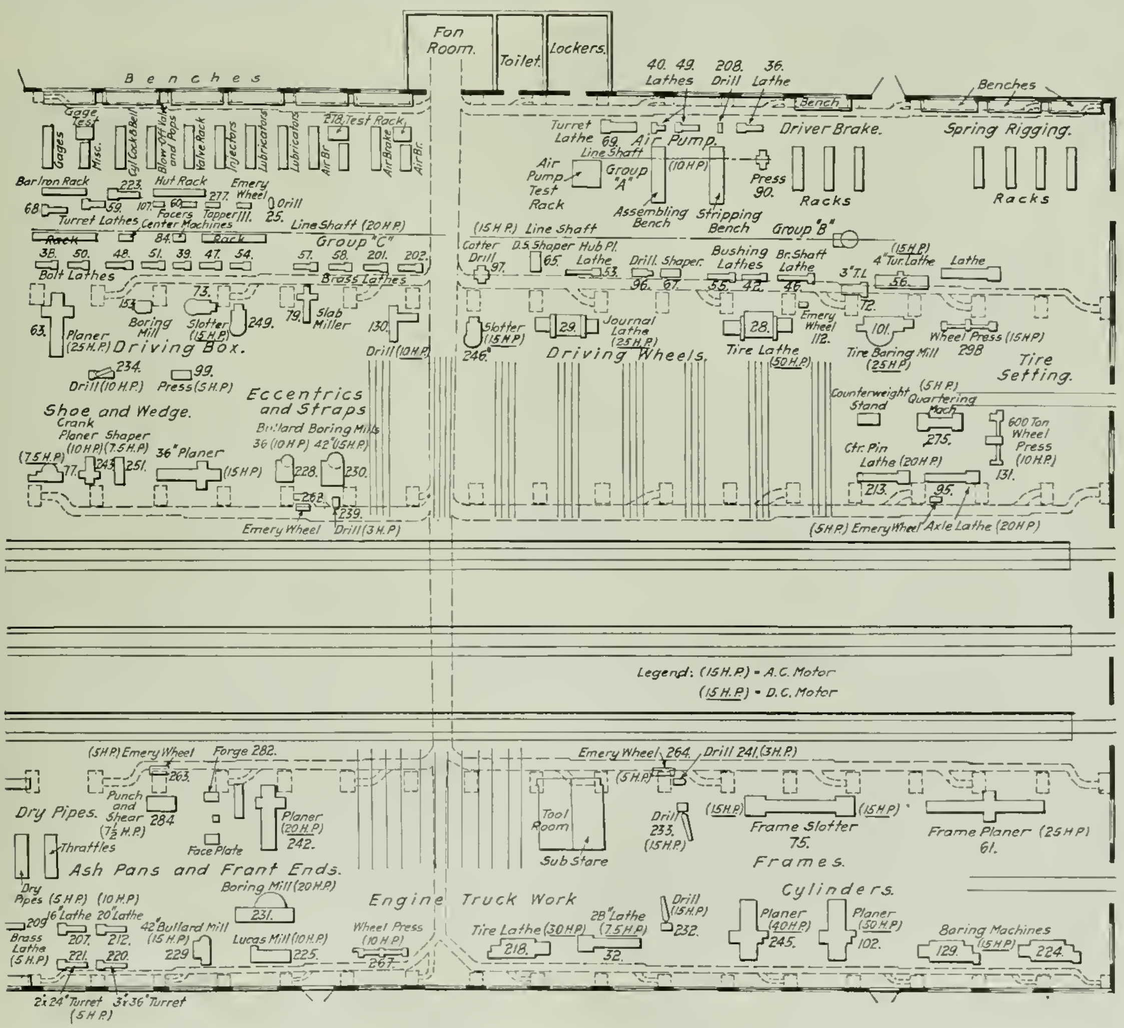
Wheel Department in the Heavy Machine Bay

fere with the car department to any appreciable extent, so it was decided to place the new shops west of the existing plant. A study of the requirements showed that but one department could be housed in the old shop buildings. It was therefore decided to build a combined erecting and machine shop, a blacksmith shop and power plant in the locations shown on the map below. The new erecting shop has a capacity of approximately 30 large or 45 small locomotives, including two or three being stripped and three or four being wheeled and finished.

STRUCTURAL DETAILS OF BUILDINGS.

The buildings in the new plant were erected by Westinghouse, Church, Kerr & Company, New York. The machine and erecting shop is a steel frame building 792 ft. long and 310 ft. wide. The total floor area is 5.65 acres. The entire floor space is made of concrete. The foundation is of concrete and the walls are concrete and glazed hollow tile. The roof is made up of three-inch Douglas fir planks, supported on fir purlins and covered with tar and gravel. The building is divided longitudinally into four bays, one for the erecting shop, two for heavy machines and one for light machines.

The erecting shop occupies a bay 100 ft. wide and three pits, spaced 30 ft. apart, run longitudinally through its entire length. There are four cranes spanning the bay, two of 125 tons' capacity with 15-ton auxiliary hoists on the



Floor Plan of East End of Erecting and Machine Shop, Showing Arrangement of Machine Tools.

upper runway and two of 15 tons' capacity on the lower runway.

On the south side of the erecting shop there is a bay 70 ft. wide served by one 15-ton crane. This part of the building contains some of the heavy machine tools, but the greater part of the space is used for overhauling engines, trucks, ash pans, steam pipes, superheaters, stokers and

Half-Gantry Cranes Along Side and End of Shop

stoker engines and cabs. A standard gage track leads into the east end of this bay.

A heavy machine bay is placed on the north side of the erecting bay. It is 70 ft. wide and has two 15-ton electric traveling cranes covering the entire area and has a stub track leading into it from the east. Along the north side of the shop is the light machine bay, 70 ft. wide. This section has no traveling crane but numerous jib cranes are provided for the heavier work. The tool room is located midway along

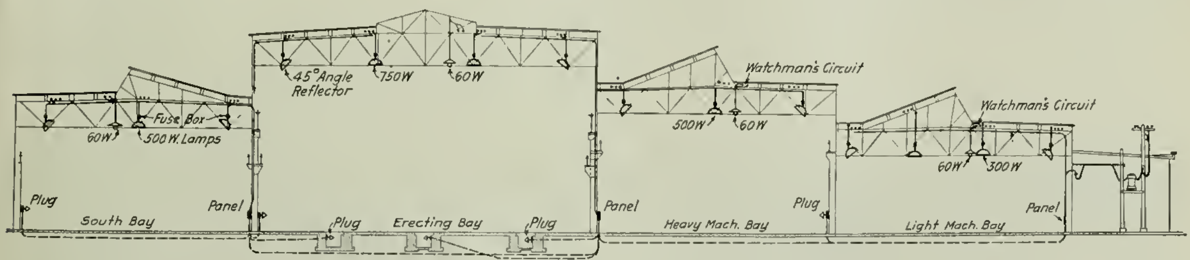
The Rod Department

this bay. In one corner there is a room for the storage of hand tools and blue prints, and directly above this is the foreman's office.

The walls of the shop have a large area of windows which are set in steel sash having sections pivoted horizontally to provide for ventilation. The natural light is increased by a double pitch skylight in the erecting bay and sawtooth skylights running almost the full length of the three remaining bays. A good idea of the uniform lighting across the shop can be gained by referring to the cross section of the building.

Interior of Erecting Shop

The shops are lighted at night by nitrogen filled lamps in enameled steel reflectors. The general illumination is ample for working on machine tools or around locomotives. Plug receptacles are provided, however, spaced 20 ft. apart in the erecting pits and 40 ft. apart on the walls and col-



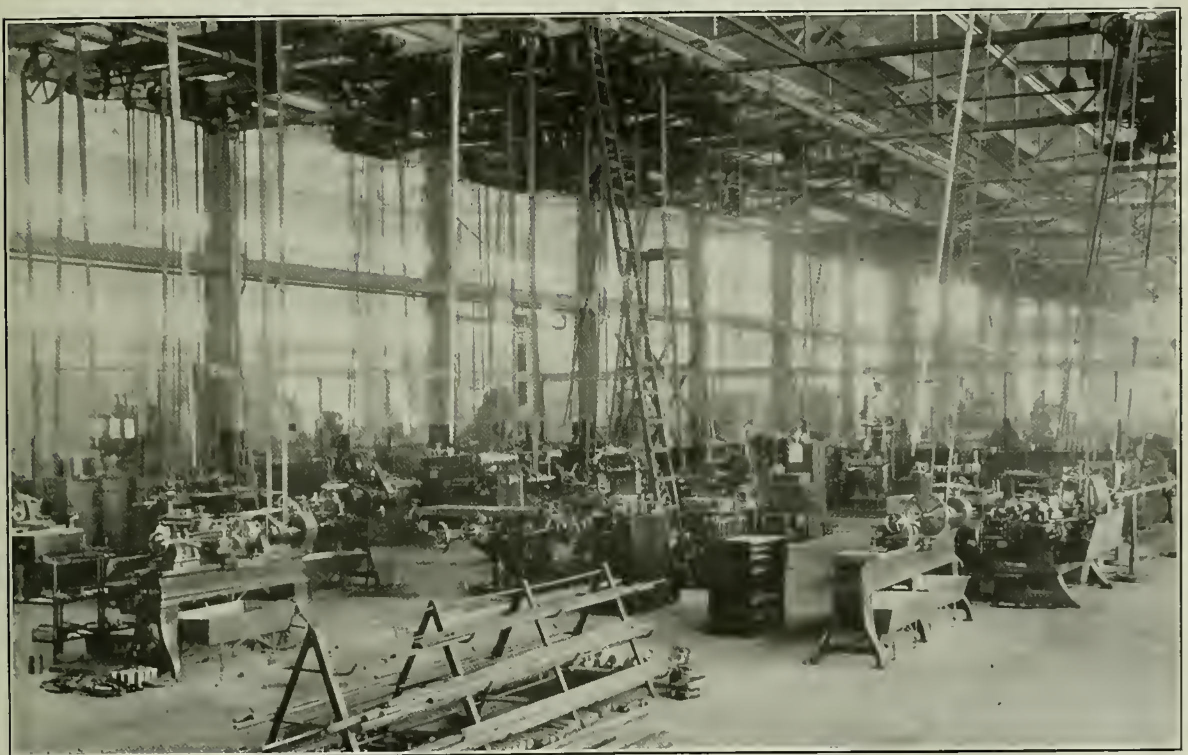
Cross Section of Shops, Showing Arrangement of Lighting Fixtures

umns. Data concerning the lighting installation is given in the following table:

DATA ON ILLUMINATION OF WEST BURLINGTON LOCOMOTIVE SHOPS

	Approximate height	Number of lamps	Size of lamps	Watts per sq. ft.	Approx. ft. candle intensity
Light machine bay	23 ft.	144	300	.78	5.5
Heavy machine bay	33 ft.	87	500	.78	5.0
Erecting shop	50 ft.	72	750	.68	4.5
South bay	33 ft.	87	500	.78	5.0

An indirect fan system of heating is used. The air is drawn in at two fan rooms which extend out from the north wall. The fan forces the air through the heating coils, which are supplied with exhaust steam from turbines, and one air compressor in the power plant and thence into concrete ducts under the floor. These ducts branch into smaller tile ducts which are carried up to sheet metal cowls with outlets about three feet above the floor. During extremely warm weather this system can be used for forcing air through the shop to create an artificial circulation. The water supply for fire protection is taken from two reservoirs about half a mile from the shop. The pumps discharge into a stand pipe 28 ft. in diameter and 60 ft. high, having a capacity of 275,000 gal. Hydrants are spaced from 200 to 400 ft. apart around the shop. A separate pipe line is provided for drinking water. The main toilet rooms are located in the additions, which house the ventilating fans, several auxiliary toilets being provided at convenient points in the shop. The wash rooms and locker rooms are on the second floor of the two additions.



Interior of the Tool Room

The blacksmith shop is a brick building with a steel frame and concrete foundation 250 ft. long and 90 ft. wide. A louver with pivoted steel sash windows in each side extends along the center to provide an outlet for smoke and gases. The roof is of the same type used on the erecting and machine shop.

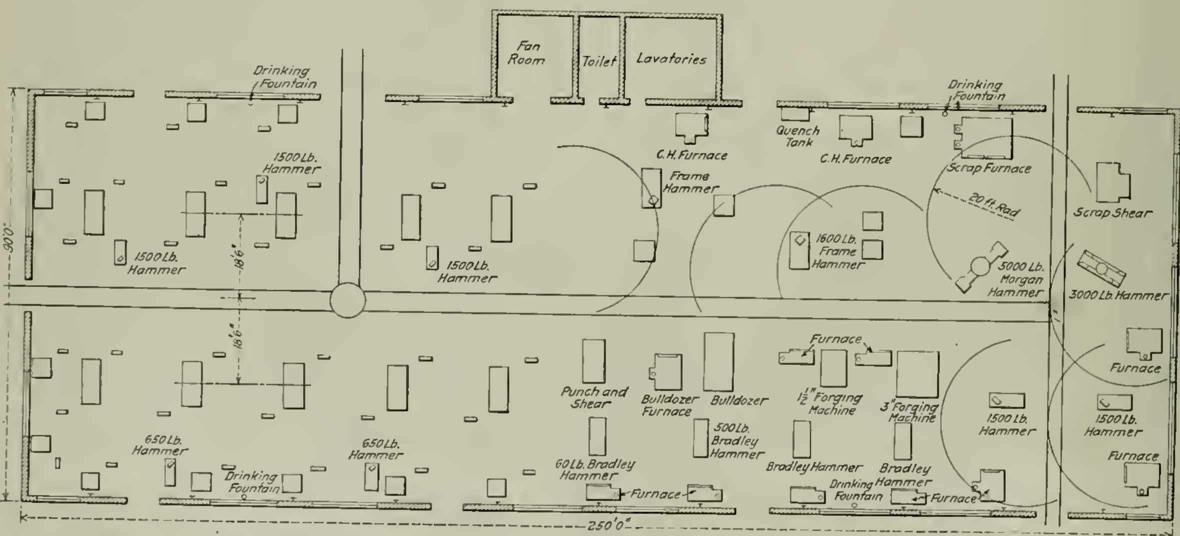
The power house is a steel frame brick building 118 ft. by 107 ft. with a basement under both the boiler and the engine rooms. It has a reinforced concrete roof covered with tar and gravel. The two buildings which are now used for the boiler, flue and tank work, are 125 ft. wide and 316 and 200 ft. long. The walls are of brick and composite wood and iron trusses support the roof, which is of wood with an asbestos covering.

DIVISION OF FLOOR SPACE BETWEEN DEPARTMENTS.

The proper division of floor space between the various departments of a locomotive shop presents a difficult problem. In determining the allotment it is necessary to consider

Frame and Cylinder Equipment in the South Bay

among other factors the class of repairs to be handled, the average period for the renewal of tubes and fireboxes, and the amount of manufacturing work to be done for other shops. Practically all the locomotives repaired at West



Floor Plan of the Blacksmith Shop

Burlington are given a general overhauling. Flues are removed after the engines have run about 80,000 miles, and fireboxes are renewed on the average every five years. The areas of the principal departments in the locomotive shop are given below:

Area of Shops

	Size	Area	Area per pit*
Erecting shop	100 ft. by 792 ft. =	79,200 sq. ft.	2,640 sq. ft.
Machine shop	210 ft. by 792 ft. =	166,300 sq. ft.	5,543 sq. ft.
Erecting and machine	310 ft. by 792 ft. =	245,500 sq. ft.	8,183 sq. ft.
Boiler and tank shop	125 ft. by 316 ft. and 125 ft. by 200 ft. =	64,500 sq. ft.	2,150 sq. ft.
Blacksmith shop	90 ft. by 250 ft. =	22,500 sq. ft.	750 sq. ft.
Total of four main departments		332,500 sq. ft.	11,083 sq. f.t

General Foreman's Office and Small Tool Stock Room

Relative Size Compared to Erecting Shop

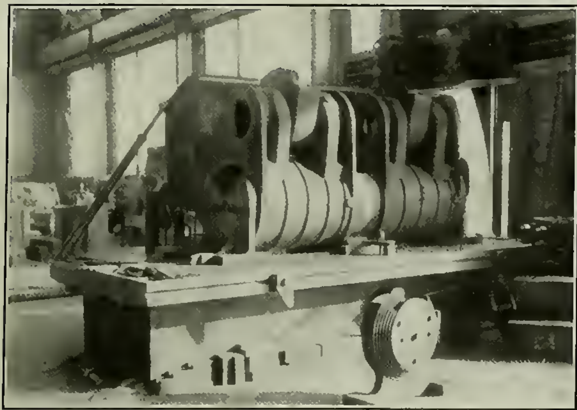
Erecting shop	100.0
Machine shop	210.0
Total erecting and machine shop	310.0
Boiler and tank shop	81.5
Blacksmith shop	28.4
	419.9

Relative Size of Main Departments

Erecting shop	23.8
Machine shop	50.0
Total erecting and machine shop	73.8
Boiler and tank shop	19.4
Blacksmith shop	6.8
	100.0

*Based on shop capacity of 30 locomotives.

The large area devoted to machine work is one of the striking features of the shop. The allotment was made with two objects in mind; first, to furnish ample space around all machines for the stock of parts undergoing repair, and second, to permit of arranging the machines in the order that would eliminate backward movements as far as possible. It



Cylinder Set Up on Jigs for Planing

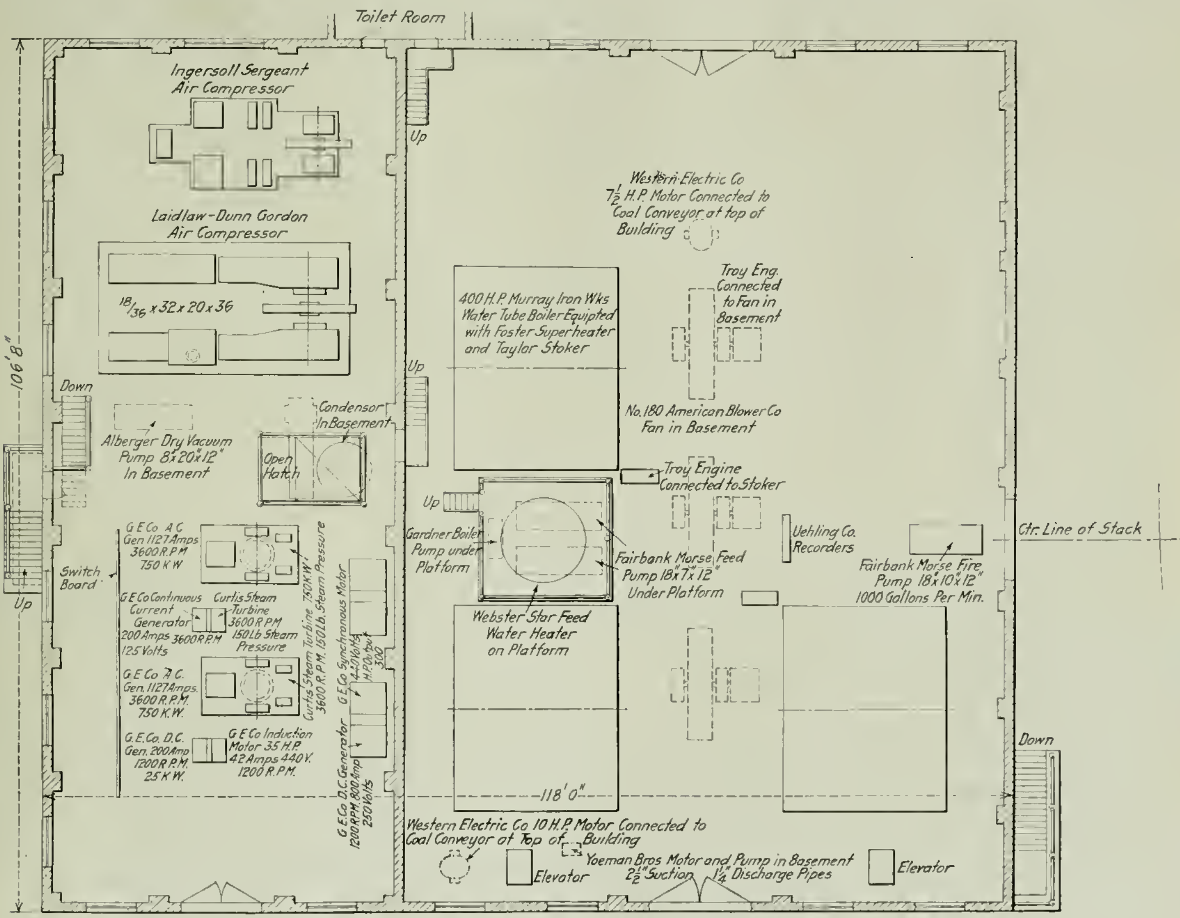
should be noted that the machine shop area includes also the sub-department in which the ash pans, front ends and superheater units are repaired, although this amounts to less than 10 per cent of the total floor space. Furthermore the shop finishes cylinders and other parts for some of the smaller repair points on the system. The space devoted to blacksmith work is relatively small by comparison with the average for older shops, although work for both locomotives and cars is handled here. This is undoubtedly to be explained by the increase in the parts for which steel castings are used, with a consequent reduction in the number of forgings that has occurred in recent years.

ORGANIZATION.

The organization of the supervising force in the locomotive department is shown in the diagram. This is closely in accord with general practice and little comment is necessary. It should be noted that piece work is in effect in practically all departments, which accounts for the small number of foremen in the main sections.

ROUTING OF PARTS BEING REPAIRED.

In locating the sub-departments a special effort has been made to group them in a logical order so that related parts are kept together, so that the distance material must be hauled will be reduced to the minimum and so that the parts will all be moving in the same general direction. The location of the machine tools in each sub-department has been studied and they have been arranged to permit material undergoing repairs to pass from one to another in regular order without any back movement. Thus the normal routing for the parts is from the erecting shop to the end of the sub-department nearest the stripping pit, and thence through the machines in rotation, coming out completed at the end of



Arrangement of Equipment in Power Plant

the department nearest the finishing pits. This arrangement is treated in detail in the description of the sub-departments later in this article.

Ample facilities have been provided for transporting the work in the shops and from one building to another. The erecting shop, as already noted, is served by two 125-ton cranes with auxiliary hooks for lifting 15 tons, and two cranes of 15 tons' capacity running on the lower track. The bay in which the heavy machines are located has two 15-ton cranes and the south bay has one of the same capacity. Along the south wall of the shop there is a track for a 10-ton half-gantry crane, extending nearly to the storehouse. Under this crane most of the heavy material such as cylinders, tires, etc., is stored. The east side of the machine and erecting shop is served by a 50-ton half-gantry crane which reaches the ends of the tracks into the shop and runs beyond the north boundary of the shop to the lye vats. As the runway for this crane extends a short distance under the runway of the 10-ton gantry it is easy to transfer the material by means of these two cranes from the material platform to cars or trucks that can be run into the shop. The flue shop and erecting shop are connected by two direct tracks and two others lead into the tender truck repair shop. A separate track goes to the boiler and tank shop, which can also be entered by two tracks at the east end. The blacksmith shop and erecting shop are joined by a board path over which electric storage battery trucks are operated and there is also a standard gage track extending from under the 50-ton gantry crane runway to the track through the center of the shop.

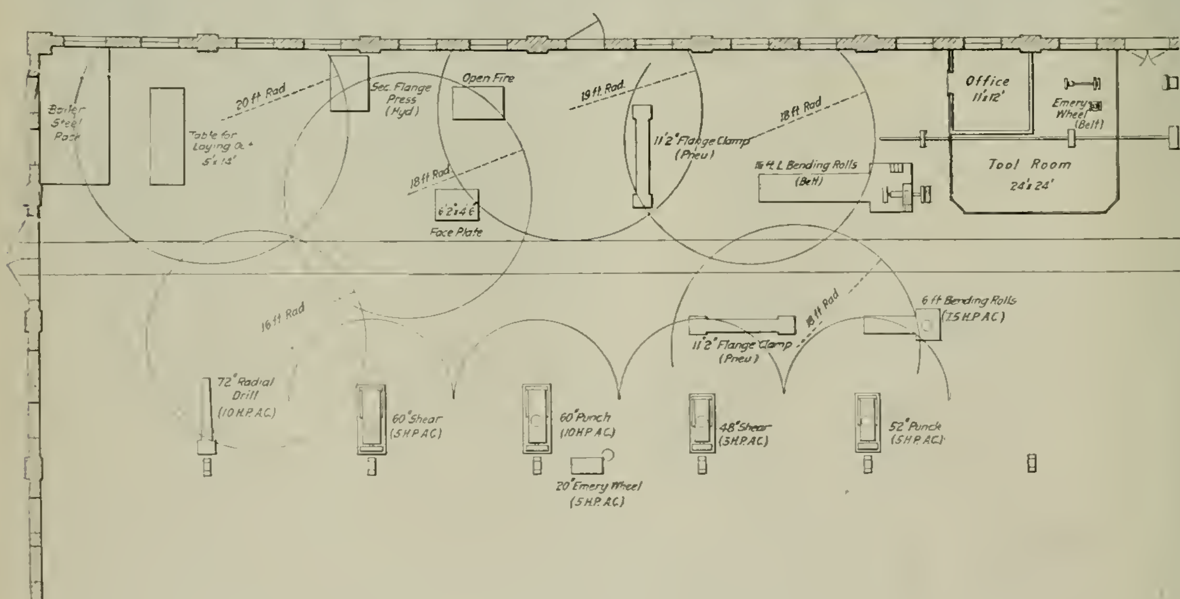
One of the things that frequently causes trouble in railroad shops is local congestion due to the inability to predetermine accurately how much room will be required by each department. In this instance, space has been left between most of the departments. This gives extra floor area for the material and provides leeway for future growth. The extra space has been apportioned with considerable judgment, for instance, it seems likely that the number of stoker fired engines will increase and therefore the stoker department has been allowed room to grow. On the other hand, the work on eccentrics and straps is handled in the smallest possible area because these parts are not found on modern locomotives. While no enlargement to the shop is planned further extensions toward the west or toward the north are quite feasible.

Ease of observation, important as an aid to supervision, has been given due consideration. The longitudinal arrangement of the pits in the erecting shop enables the foreman to see work being done on several engines from any point. By grouping the tools in the machine shop in single rows with a passageway between, the same object has been accomplished.

SHOP OPERATION.

ERECTING SHOP.

Locomotives awaiting repairs are stored on dead tracks in the yard east of the shops. They enter the erecting shop at the east end where the stripping is carried on. When the stripping is finished the locomotive is set on blocks in the center portion of the shop. If it is necessary to remove the boiler, this is placed on a car and taken to the boiler shop. Flues are cut out, placed on push cars and run to the flue shop. The wheels and driving boxes are rolled out under the 50-ton gantry crane, which takes them to the lye vat. The pedestal binders crossheads, links, hangers and similar parts are placed in containers to facilitate the cleaning. The front ends are stored in a rack adjoining the finishing pits.



Plan of Boiler Shop, Showing Location of Machine Tools.

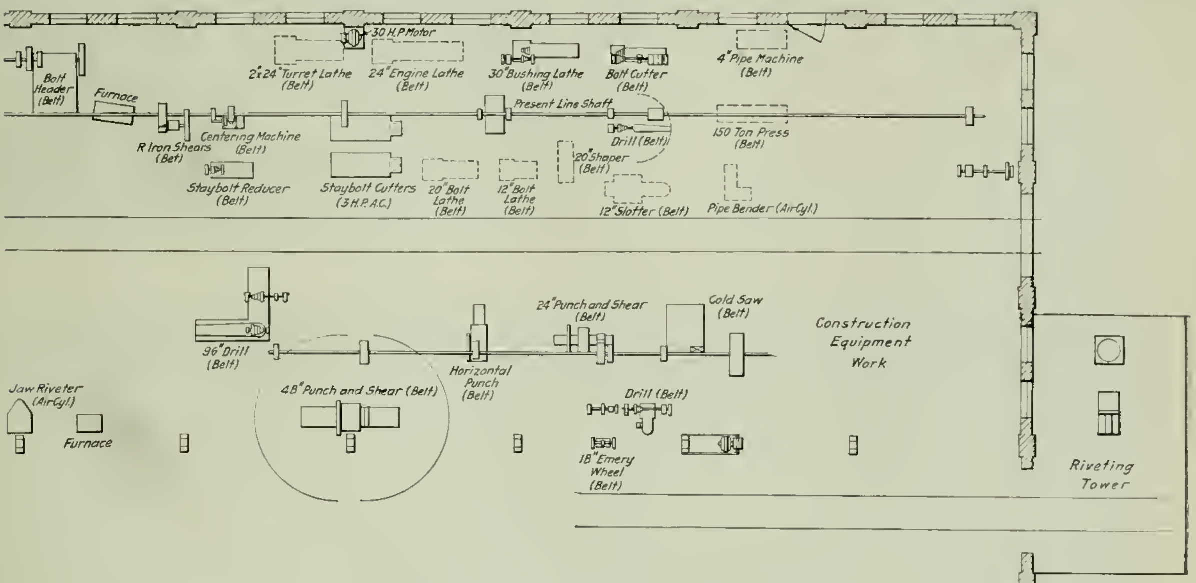
HEAVY MACHINE BAY.

Driving Wheels, Axles and Crank Pins.—The driving wheel department is at the extreme eastern end of the machine shop. From the lye vat the wheels are rolled in on a stub track and inspected. If the wheel centers need to be pressed off or crank pins pressed out, they go to a 600-ton wheel press on the left hand side. Beyond the press are located the axle lathe, crank pin lathe, and quartering machine. On the right hand side of the track are the stands for holding wheels while the tires are removed or set. The tires on truck wheels are removed and applied in this department, as there is not enough of such work to justify the duplication of the facilities. Beyond the mounting stands are located the boring mill for wheel centers and tires, a driving wheel lathe and a journal turning lathe. Next in order come the tracks adjoining the fitting bench where hub plates are applied and crank pins trued up. The eccentric cranks and eccentrics are fitted on a track next to the eccentric bench, and also adjacent to the driving box department. Wheels are fitted with driving boxes and cellars before they go to the erecting shop. There are 16 tracks for storing wheels, each 35 ft. long, and extending out into the erecting bay to facilitate handling.

Eccentric Department.—The eccentrics and straps are brought from the lye vat to the eccentric department which has a 36-in. Bullard vertical turret lathe, used mostly for turning up brass liners, and a Gisholt 42-in. boring mill used for eccentrics and straps.

Driving Boxes.—The boxes from the lye vat are placed on a platform south of the passage through the machine shop, where they are inspected. Those requiring new crown brasses go to the press, while others are taken to the planer. The crown brasses are shaped on the slotter and then pressed in. The box then follows the same course as those not requiring brasses, going to the planer to be faced on the shoe and wedge fit, and on the hub if necessary, and then to the boring mill. After being bored a clearance for the grease is cut on the back side of the box only on the slotter. The removed. The rods are next examined for cracks. If they need reboring they are sent to the horizontal boring mill. Next they go to the radial drill to have the taper knuckle joint pin fit reamed out, then the pins are fitted. After this operation the rods are set on a rack at the west end of the rod department and the bushings are fitted on a small boring mill. After the bushings are bored and pressed in, the rods are fitted together and trammed for length, being changed by the blacksmith if necessary. Knuckle joint pins and bushings and crosshead pins are turned up rough on a 7½-in. Libby high duty turret lathe. The sides of main rod straps are trued up on the surface grinder and main rod brasses are shaped to size on two 28-in. shapers with special attachments and bored out on a 36-in. Bullard vertical turret lathe. Side rod bushings are pressed in by a 100-ton hydraulic press.

Valve Motion.—The diversity of work involved in the repairing of valve motion makes it difficult to establish a routing for the parts, except in a general way. However, the majority of parts can be finished on one or two machines and as they are relatively light the handling presents no special difficulty. The rocker arms, lift shafts, bushings, valve



Plan of Boiler Shop, Showing Location of Machine Tools.

lateral play of the driving boxes is governed by the thickness of the hub liner on the wheel center. The flanges on each pair of driving boxes are made the same thickness. The man applying the hub plates takes this dimension off the box with the thickness of the shoe and wedge flanges and the distance over the frames and has the brass hub liners turned to the proper thickness to give ⅛ in. lateral clearance. Each half of the hub plate is put on with four wrought iron pins having a straight fit in the wheel center and a counter-sunk head. When the driving boxes are worn down ⅜ in. the face is counter-bored and a ½-in. sheet steel liner is put on with countersunk head bolts.

Shoes and Wedges.—All new shoes and wedges are finished on a planer near the driving box department. When these parts come from the engine after being laid off, they are faced on a planer in the light machine bay near the west end of the shop shown on the layout as No. 70.

Main and Side Rods.—The rods as they come from the locomotive are placed on rails resting on trestles, the main rods on one side and the side rods on another. They are then cleaned with waste, and grease cups and bushings are bodies, rings, etc., are handled on two lathes. Pins are roughed out on Jones and Lamson and Pratt and Whitney turret lathes. Pins are fitted on three lathes, one of 16-in. swing and two with a swing of 18 in. The drilling of heavy parts is done on a Baker high duty drill, while lighter work is handled on drill presses in the light machine bay. A planer in the light machine bay handles surfacing operations on links and similar parts.

Pistons and Rods, Crossheads and Guides.—The piston guide, and crosshead work is done at the extreme west end of the heavy machine bay. The machine tools include a 42-in. Bullard vertical turret lathe for turning piston packing, a 36-in. vertical turret lathe for turning valve chamber heads, packing, etc., a Baker high duty drill for miscellaneous drilling and reaming, two piston lathes and an Acme turret lathe. As the pistons come from the locomotive they are set on the floor and examined. The nuts are turned off in a lathe and the pistons are sent to the 250-ton press and the heads are taken off. The rods then go to one of the two lathes and are trued up or if necessary are replaced with new rods. The piston heads are turned up on a boring mill and come to this department finished except for the cylinder fit. The pistons are put on the rod and the outside is turned and grooved for the packing rings.

Crossheads are set alongside the pistons and rods. The shoes are taken off, and if necessary, the crosshead pin fit and the piston rod fit are reamed. The crosshead shoes go to the babbitt furnace to be relined and when they are returned are applied to the crosshead and the bolts are fitted. Then the complete crosshead goes to the planer where the shoes are planed to fit the guides; after which the crosshead pin is fitted. Then the piston rod is inserted and the key shaped to fit. As the final operation, the gland is fitted on and the packing is bored to size.

Crosshead guides coming from the locomotive are placed on a rack from which they are handled by a jib crane onto the surface grinder. After heing ground on the face and the sides, they are put back in another portion of the rack, until they are ready to be applied to the engine.

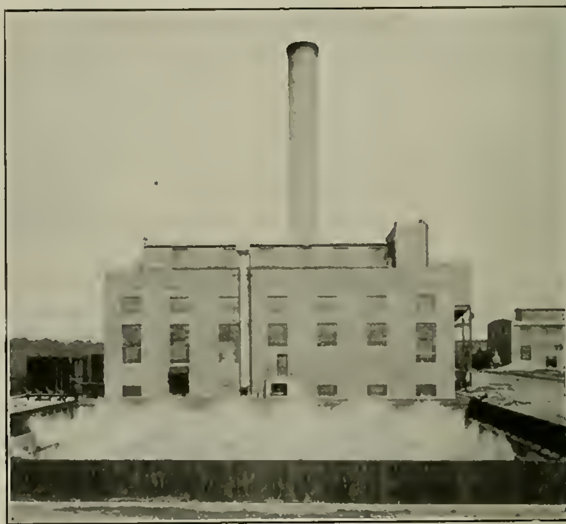
LIGHT MACHINE BAY.

At the extreme east end of the light machine bay the driver brake rigging and spring rigging is repaired. This is largely bench work with the exception of pins and bushings, which are handled on a Warner & Swasey hollow hexagon turret lathe and a Jones & Lamson flat turret lathe. Two engine lathes are used for turning up trunnions, etc., and there are also provided in this department a drill press and a hydraulic bushing press.

Next to the spring rigging department is the air brake department. At the east end air pumps are repaired. Three small engine lathes, a shaper and a drill press are conveniently located to do the work that must be handled on these machines. The lighter air brake parts as well as injectors, lubricators, pops, bell ringers, valves and gages are repaired at benches about half way down the shop. There are three brass lathes and one engine lathe serving this department. Just beyond the brass lathes is the bolt department. In this department there are five turret lathes, seven small engine lathes for fitting helts, a centering machine, a drill press, a nut facer, a 4-in. single spindle tapping machine and a three-spindle bolt cutter.

Tool Room.—The tool room is very completely equipped for light or heavy work. The smaller machines are belt driven from line shafting but the larger lathes have individual motor drive. There are two cylindrical grinders and one universal grinder. For repetition work such as pins, sleeves, sockets, flue rollers, etc., a Warner & Swasey hollow hexagon turret lathe is used. The repairs to speed recorders are handled at a bench with special fixtures in the tool room. Just beyond the tool room are several benches where machine tools, hoists, and similar machinery, are overhauled. In the northwest corner of the tool room is located a light Beaudry hammer and an oil furnace where chisels and other tools are made and put in shape. The main stock room for blue prints and hand tools is in the corner of the tool room. Above this is the foreman's office which gives a view of the entire north side of the shops. The walls are of glass to give a wide field of vision.

The west end of the light machine bay is occupied by the electrical department. Here repairs to headlight equipment,



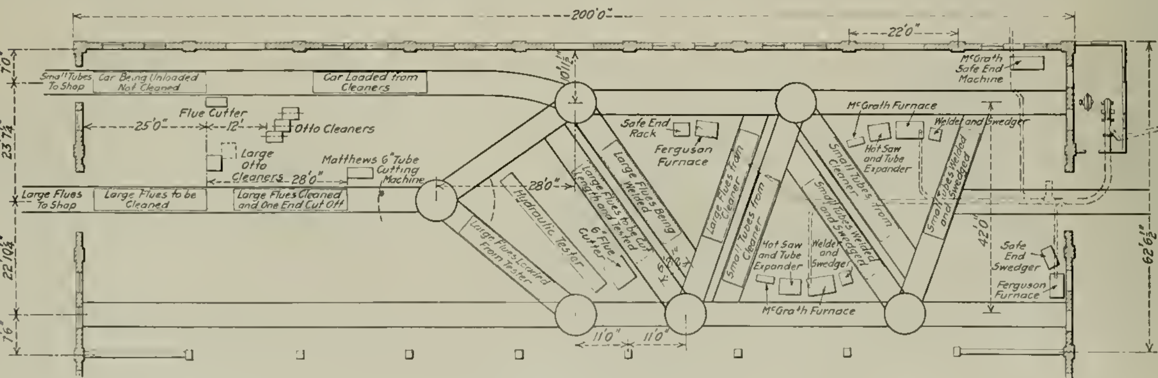
Power Plant and Spray Cooling Pond

motors, gasoline engines and section cars are carried on. A part of the space at this end of the shop is devoted to storage at the present time.

SOUTH BAY.

The large bay south of the erecting shop is equipped to handle the work on frames and cylinders, engine trucks and most of the auxiliary parts of the boiler and the machinery. All the tools in this section have individual motor drive.

Frames and Cylinders.—At the east end of the south bay, alongside the erecting shop, is located equipment for planing and slotting frames, consisting of a 60-in. planer, a double head frame slotter and a 96-in. radial drill. These machines are not kept busy on frame work, so they also handle other heavy parts of a miscellaneous character. The cylinder work is done on a group of machines located along the east end of the south wall in the south bay. This consists of a



Layout of Machines and Tracks in the Flue Shop three-spindle cylinder and valve boring machine, an 84-in. planer with reversing motor drive and a 96-in. radial drill. A notable feature of the work in this department is the extent to which jigs, fixtures and templets are used. Cylinders are finished in considerable numbers and a great deal of time is saved by the device used for lining up the cylinders for planing, which is shown in the illustration, and by the jigs for locating bolt holes not only around the cylinder bore, but also in the frame and saddle fits.

Engine Trucks.—The engine truck department has a

Exterior of the Blacksmith Shop

16-in. engine lathe for bolt work, a 42-in. lathe for truing journals, a Sellers 48-in. car wheel lathe driven by a 50-h. p. direct current motor, and a 400-ton wheel press.

Ashpans.—The ashpan department is equipped with a punch and shear besides numerous pneumatic tools. Adjacent to this department there is a sub-store for bolts, nuts, washers, rivets, etc.

Steam Pipes.—As the repairs of steam pipes, dry pipes and throttle valves and superheater headers is largely bench work, this department has but one machine tool, an Acme turret lathe, used for finishing dry pipe rings and similar work. There are a large number of ingenious fixtures used in grinding joints with air motors.

Stokers.—A considerable amount of space is devoted to stoker work, but as the majority of these parts are maintained to standard sizes, the machine work required is handled in other departments. The stoker engines are overhauled here and are tested before being installed on the locomotive.

Piping and Superheater Units.—The steam and air brake piping and superheater units are handled in the same department. The piping as it comes from the locomotives is thoroughly cleaned in the lye vats and is then placed on racks.

Cab and Upholstery Work.—The cabs used by the C. B. & Q. are mostly of wood with a steel front. To take care of the repairing a small wood working department has been installed at the west end of the shop. Here the cabs and seat boxes are overhauled.

Paint Shop.—A small stucco building north of the erecting and machine shop is used for the storage of paint and also for reworking boiler lagging. Another similar structure near the lye vat is used for reclaiming journal box packing and driving box grease.

BLACKSMITH SHOP.

The blacksmith shop is well equipped to handle heavy or light hammer work, general blacksmithing and bolt making. The heaviest steam hammer is one of 5,000-lb. capacity, with a double frame, which is used principally for making billets from scrap iron. Short pieces of bolts and flat bars are piled on boards and brought to a welding heat in the scrap furnaces and are then shaped into slabs under the steam hammer. These slabs are again piled together and made into billets. Iron of excellent quality is secured in this way. In addition to the 5,000-lb. hammer there is one of 3,000-lb., one of 1,600-lb., five of 1,500-lb., and two of 650-lb.

For making parts in considerable quantity there is a battery of Bradley hammers, including three 500-lb. and one 60-lb. size, a large bulldozer and one 3-in. and two 1½-in. forging machines. The Bradley hammers and forging machines are belt driven from a line shaft, while the bulldozer, punches and shears are direct connected. At the south end of the shop there is a small pneumatic hammer on which tools are dressed. The shop is well equipped with light and heavy jib cranes to facilitate the handling of the work. It is also equipped throughout with oil furnaces. The blast is furnished from two high pressure direct connected electric

Interior of the Flue Shop

driven blowers, each one of ample capacity to handle the entire shop equipment. The shop is also equipped with sanitary closets and washrooms for the convenience of the men.

POWER PLANT.

The power house supplies steam, compressed air and electric current for the entire plant and is equipped to raise the pressure on the water mains in case of fire. There is no high pressure pump for hydraulic apparatus, however, as all machines operated by hydraulic power have individual motor drive. This arrangement was considered more satisfactory since it eliminated the necessity for a line of high-pressure piping, which is often troublesome to maintain. The boiler room has six Murray Iron Works water tube boilers of 400 h. p. each, equipped with Foster superheaters and Taylor underfeed stokers. Space has been provided for four additional boilers. A boiler pressure of 150 lb. is maintained and the steam is superheated to 500 deg. F. A 4,000-h. p. Webster Star open type feed water heater is installed on a platform in the boiler room and an Alberger condenser in the basement under the engineroom. A spray pond of 500,000 gal. capacity, located 75 ft. west of the power plant, is used in connection with condensing apparatus.

The coal is dumped into a hopper underneath the track and is carried by a chain bucket type elevator into a conveyor that delivers it into overhead bunkers, where the coal is measured before being fed to the mechanical stokers. The ashes are collected in hoppers under the furnaces and are dumped into an ash car which carries them to the elevator pit. The elevator raises them to an overhead ash bin from which they are dumped into the empty coal car. The smoke stack is of brick, 12 ft. in diameter and 150 ft. high. Forced draft is supplied by three blowers driven by steam engines. The boiler room equipment operates non-condensing to supply the steam for feed water heating.

The electric generating equipment consists of two 750 kw. General Electric high pressure turbo generators, producing three-phase current at 440 volts and 60 cycles. The turbines are of the bleeder type, so-called from the fact that steam for heating is drawn off at a pressure of 4 to 5 lb., after passing the first stage of the turbine. A vacuum of 27½ in. of mercury is carried on the low pressure stage. To furnish direct current for the variable speed shop motors there are two 200-kw. motor generator sets, generating at 220 volts d. c. There is one steam turbine driven and one motor driven exciter. A central switch board is installed on the west wall of the engine room and an instrument board for the boilers is located on the east wall. These carry a very complete equipment of pressure and temperature gages and draft gages and also continuous CO_2 recorder for each boiler. A Venturi meter is used for checking the amount of water evaporated by the boilers.

There are two air compressors in the turbine room both operating at a pressure of 110 lb. per sq. in. One is an Ingersoll compound type of 1,350 cu. ft. per minute capacity, taken from the old power house. The other is a Laidlaw condensing cross compound high duty compressor, with a capacity of 3,650 cu. ft. of free air at 110 R. P. M. The fire pump is a Fairbanks-Morse, 18 in. by 10 in. by 12 in. underwriters pump having a capacity of 1,000 gal. per minute. The steam, air and electric lines are carried from the power house to the shop in a concrete tunnel.

The engine room is equipped with a ten-ton traveling hand crane which spans the whole width of the building. This crane is used to facilitate handling or repairs to equipment.

BOILER SHOP.

The boiler shop is located in the building formerly used as the machine and erecting shop. The boilers are placed on the south side, which is equipped with overhead cranes across the three longitudinal tracks. The machines are on the north side and are served by a monorail floor crane. The west end of the machine department is devoted to heavy plate work. Here are located the laying out table, bending rolls and flange fire, as well as the heavy punches and shears. At the center of the north wall is the office and tool room. In the space east of this the light machines, such as bolt cutters, lathes and small drill presses are located. Some of the tank work is being handled in the boiler shop, but eventually all the tender tank and truck work will be taken care of in the south half of the old boiler shop, just west of the present boiler shop.

FLUE SHOP.

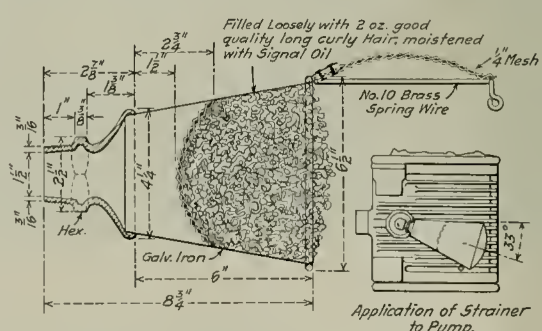
A unique arrangement of machines and tracks is used in the department where the tubes and flues are repaired. The layout of the shop is shown in the illustration below. Small flues after being removed from the boiler are loaded on push cars and enter the shop on the north track. The back end is cut off square and the flue is run through one of the Otto cleaners to remove the scale. As the tubes pass out from the cleaners they are placed on another push car. The clean tubes go down the track to the second turn table and are set on one of two diagonal tracks leading from it. Adjoining each of these tracks is the equipment necessary for applying safe ends, consisting of a small oil furnace, a hot saw and tube expander, a welding furnace and a welder and swedger. The flues pass through the furnaces and machines and when completed are placed on push cars on one of the diagonal tracks leading to the transverse track on the south side. The front ends of the tubes are heated with an oil burner to anneal them and they are cut to length and sent to the erecting shop to be reapplied.

Superheater flues are handled in a similar manner. The push cars enter the shop by the center track. The flues are cleaned and the back end is cut off, and the car is then set on the diagonal track next to the furnace. The safe end is inserted in the furnace but not welded, being swedged down to enter the flue for a distance of about one inch and welded to the flue with the oxy-acetylene torch. After the flues have had safe ends welded on they are cut to length and tested and are then annealed and put back in the boiler.

AIR PUMP STRAINER

BY E. A. M.

A simple air pump strainer, much more effective than the ordinary type which has so long been used, is shown in the drawing. In making it the casting from the old type strainer



A Simple Curled Hair Air Pump Strainer

is used, and in this is inserted a cone-shaped tube of sheet metal 6 in. long by 6½ in. outside diameter at the large end. A concave screen of ¼-in. wire mesh is inserted in the tube and soldered in place 2¾ in. from the inner end. The remainder of the strainer is loosely filled with curled hair, about two ounces being required for this purpose. The outer end of the strainer is closed with a hinged lid of 1/4-in. wire mesh, soldered to a light brass wire frame. A slot in the side of the tube is provided to take the latch formed on the end of the wire lid frame. In order to provide sufficient spring for the proper operation of the latch, about two inches of the frame at the latch end of the wire is left unattached to the netting. The lid is hinged to the strainer at a point opposite the latch.

PRESENT CONDITION OF LOCOMOTIVES AND CARS

Notwithstanding the fact that the number of locomotives actually built for the use of the railways in the United States during the past year and the four preceding years has materially fallen behind the 10-year average of 1907 to 1917 inclusive, and that there was an acute shortage of power apparent at the close of 1917, there is at the present time very little evidence of a lack of sufficient power to meet immediate requirements. This does not mean, however, that there is no need for new power. Old locomotives have been kept in service at a sacrifice in operating efficiency to preclude a repetition of conditions existing last winter. The number of locomotives built each year during the above-mentioned 10-year period for domestic steam railroad use has averaged approximately 3,300. For the past five years, beginning with 1914, the railroads have fallen behind this figure by an average of about 1,300 locomotives each year, a decrease which can be accounted for only partially by the increase in tractive effort of the locomotives built during recent years.

Aside from the fact that the unprecedented weather conditions of last winter, so far have not been repeated this season, the present fortunate situation is broadly attributable to three factors: (1) In general the power of the country is in much better condition now than at the beginning of any winter for several years past; (2) the application of economy and capacity increasing devices to existing equipment has increased the effectiveness for service of a large number of locomotives, and, (3) there are now retained in service many locomotives which, if new power were available, would and could economically be scrapped.

LOCOMOTIVES IN GOOD CONDITION

That the condition of power is much better than it was last year is evidenced by the fact that for several months past there have constantly been stored in serviceable condition from 800 to 1,000 locomotives, over half of them on the eastern roads, where extraordinary demands are most apt to arise. This improvement has been made possible by the increased working hours which have been in effect since last spring, the decrease in labor turnover during the latter part of the year, and the increase in the number of men employed on locomotive maintenance. Both of the latter are the result of the wage increases put into effect by the Railroad Administration.

Table I—Weekly Summary of the Condition of Power on the Railroads Operated by the United States Railroad Administration

Week ending	Number of locomotives: On lines	Number of locomotives: Serviceable	Number of locomotives: In or awaiting shops	Per cent of locomotives out of service for over 24 hours	Number of locomotives turned out of shops: 1918	1917	Increase	Number of locomotives: Being repaired for other lines	Number of locomotives: Stored serviceable	Number of employees in locomotive department: 1918	1917	Increase
August 3.........	62,764	53,665	9,999	14.4	5,329	4,462	867	190	924	261,915	241,104	20,811

What has been accomplished in increased shop output will be evident from an inspection of Table 1*, showing the condition of power for alternate weeks during a period of 18 weeks, for the months of August to November inclusive, which has been compiled from data collected by the equipment maintenance section of the Division of Operation of the Railroad Administration. For this period, which is practically one-third of the year, it is evident that the number of locomotives turned out of shops (including all engines out of service for repairs over 24 hours) is nearly 23 per cent greater than during the corresponding period of 1917, while the number of employees in the locomotive department has been approximately 9 per cent to 11 per cent greater than the number in service last year. Taking the country as a whole, the increase in output is more than accounted for by the increase in maintenance forces and the increase in working hours from the eight, nine and ten-hour days in effect in various parts of the country, to the 70-hour week, which was in effect on many roads from March to November 25. During the period covered by the table it also will be seen that there has been a gradual increase in the number of locomotives being repaired for other lines, the maximum shown being 284 during the first week in November.

Since November 25, when working time was reduced from 70 hours a week to a nine-hour day basis, followed on December 9 by a further reduction to an eight-hour day, there has been a decrease in output which has been felt more particularly in running repairs. The eight-hour day necessitates the employment of three shifts at engine terminals, with a consequent increase in supervision, where two shifts have heretofore been the rule. At present, in most cases practically the same number of men who have constituted the two shifts must be redivided into three. It will, of course, be possible gradually to build up these forces to overcome the present shortage as demobilization progresses. The power has been put in such good condition during the past summer and fall that the reduction in back shop output following the reduced number of working hours on the whole need give little immediate concern.

Since 1914, the conditions which have restricted the buying of new power have directed attention to the possibilities for increasing the capacity of a large number of existing locomotives by the application of economy and capacity increasing devices, most important of which are the superheater, mechanical stoker and brick arch. During the past four years not less than 10,000 old locomotives have been equipped with one or more of these devices. In some cases the conversion has made unnecessary the purchase of a new class of power to perform the service which these engines were becoming unsuitable for, but which they are now capable of performing satisfactorily. In such cases each converted locomotive has saved the purchase of a new one, while in others the saving in new locomotives has been in proportion to the increase in capacity effected by the change, which

*A detail report of the condition of power by regions for the week ending September 28, 1918, was published in the *Railway Mechanical Engineer* for November, page 605.

conservatively would be between 10 and 20 per cent. It is evident that these 10,000 converted locomotives have had a material influence in preventing an acute power shortage.

While the use of obsolete locomotives, to scrap which authorization has been secured or is contemplated, may be effective in preventing an acute shortage of power, it can be justified only to meet an emergency. With such locomotives in service it cannot truly be said that there is no shortage of power. In the interest of economical operation it is now imperative that there be a heavy purchase of new power in order that the three or four years' accumulation of scrap power may be gotten off the lines.

NO IMPROVEMENT IN FREIGHT CAR CONDITIONS

Although there has been some improvement in the percentage of bad order cars in the course of the year, it is doubtful if there has been any real improvement in the condition of freight cars such as noted in connection with locomotives. In the first place the number of new cars delivered to the railroads during the past year was less than half the number which were placed in service during 1917, and is hardly large enough to take care of normal replacements. The extreme need of equipment during the past year has therefore led to the retaining in service of a large number of cars which should be and will be retired at the first opportunity. These cars, unlike old locomotives, cannot be kept in condition to remain in service without causing an undue proportion of failures, and the need of retirement is therefore greater than in the case of motive power.

Those roads which had practically completed extensive reinforcement programs prior to our entrance into the war still have their equipment in excellent condition. Many roads, however, were only instituting such programs or had only partially carried them out before the pooling of equipment took the rolling stock out of the control of the owning roads. In such cases there has been very little opportunity during the past year to continue the betterment program, the proportion of cars on home roads being so small as to very seriously slow up this work.

The pooling of equipment has also tended to decrease the output of running repairs. It is a comparatively simple matter to supply material for the repairing of home line cars at outlying points where mill facilities are not available. Considerable delay is inevitable, however, where a very large percentage of the cars on the repair tracks belong to foreign lines, each requiring more or less special material.

Table II—Weekly Reports of Car Conditions for All Regions

Week ending	Oct. 19	Oct. 26	Nov. 2	Nov. 9	Nov. 16	Nov. 23
Number of roads reporting	139	139	138	139	139	139
Total revenue cars	2,478,704	2,441,111	2,434,255	2,437,344	2,430,606	2,447,922
Bad order cars—1918	140,328	139,548	135,462	134,874	132,853	130,048
Bad order cars—1917	131,036	132,501	128,957	129,414	124,162	123,056
Heavy repairs—1918	82,459	82,078	79,559	79,198	77,966	78,941
Light repairs—1918	57,869	57,470	55,903	55,676	54,887	51,107
Percentage of bad order cars	5.7	5.7	5.6	5.6	5.5	5.3
Average number of bad order cars repaired per working day	86,486	83,279	83,328	83,469	82,274	82,805
Heavy repairs	9,332	8,871	8,578	8,797	8,173	8,209
Light repairs	77,154	74,408	74,750	74,672	74,101	74,596
Number of cars transferred to other shops	5,075	626	589	253	485	524
Number of employees—1918	140,021	138,703	158,959	142,500	141,540	143,169
Number of employees—1917	118,758	123,156	124,256	124,521	123,966	124,319
Number of cars damaged in trains	13,605	13,060	12,446	12,364	12,255	12,668
Cost of labor	$126,630	$121,275	$90,464	$122,463	$128,925	$135,887
Cost of material	$154,708	$151,476	$170,532	$162,818	$179,972	$182,005
Number of cars damaged in yards	5,264	4,868	5,267	5,275	5,159	5,242
Cost of labor	$54,308	$46,823	$53,492	$49,959	$50,886	$52,406
Cost of material	$76,589	$61,135	$68,072	$66,920	$93,720	$70,987
Cars held to be dismantled	5,584	7,211	6,920	6,823	6,646	6,640

The destruction of the incentive of the pieceworker following the failure to adjust the piecework wage differential to correspond to the increase in hourly rates, has had a much more marked effect in reducing the output in the car department than it has in the locomotive department.

The effect of these adverse conditions is not reflected in the percentage of bad order cars, which has been maintained between 5 and 6 per cent, a figure approximately equal to the average for the country in 1917. An inspection of Table II*, however, shows that of the total number of bad order cars shown on the weekly statements of the maintenance of equipment section of the Division of Operation of the Railroad Administration for the six weeks ending November 23, from 58.7 per cent to 60.7 per cent are classed as needing heavy repairs. Of the corresponding daily output the number of heavy repairs has averaged a fraction above 10 per cent. It is evident, therefore, that there is an accumulation of cars needing heavy repairs, which eventually must be reckoned with. If this situation is to be improved some means should be taken to return the cars to the owning roads at the earliest possible opportunity, where in many cases material for reinforcing is already available, as in this way only can the greatest output be obtained for the labor expended.

Table III—Percentage of Bad Order Cars by Regions

Week	Oct. 19	Oct. 26	Nov. 2	Nov. 9	Nov. 16	Nov. 23
Eastern	6.3	6.4	6.2	6.3	6.1	6.1
Allegheny	7.1	7.1	7.1	7.0	6.7	6.4
Pocahontas	5.9	6.9	5.8	5.6	5.6	5.1
Southern	4.4	4.8	4.5	4.7	4.8	4.4
Central Western	5.0	4.9	4.7	4.8	4.8	4.7
South Western	3.1	3.1	2.9	2.9	2.8	2.8
North Western	5.7	5.4	5.4	5.2	5.3	5.2
All regions	5.7	5.7	5.6	5.6	5.5	5.3

Air brake conditions have been notably poor during the past year. This is due in part to a lack of proper facilities for testing and repairing brake equipment, to the necessity for employing many inexperienced men on this class of maintenance, and in part to a shortage of material.

Efficiency of Oxy-Acetylene Welds.—It has been proved in tests on boiler plate that the average oxy-acetylene weld has an efficiency in the neighborhood of 70 per cent, although tests have been made in which the efficiency has run much higher. This would be a fair comparison with a lap-double seam of the ordinary 44,000 lb. shear of rivets, using a tensile strength of 55,000 lb. for the plate.—*The Engineer, London.*

Record Claimed for Oxy-Acetylene Torch Cutting Out Rivets.—An operator employed by the Submarine Boat Corporation, Newark, N. J., claims a record, which was witnessed, timed and sworn to, of having cut out with his oxy-acetylene torch 123 3-inch countersunk rivets from an oil tank cover in 55 minutes. The work was so well done that the rivets came out with one stroke of the maul and punch. —*American Machinist.*

*For tables showing car conditions since the middle of July, see the *Railway Mechanical Engineer* for November, page 614, and December, page 656.

Our Railway War Forces Abroad

An Account of the Problems Encountered in France and the Shop Facilities for Erecting Equipment

THE January 3 issue of Railway Age contains a signed article by Samuel O. Dunn, editor of that paper, which gives the first account of what the Transportation Department of the A. E. F. has done since America entered the war. Mr. Dunn, who has just returned from England and France, was the first American press representative to visit Tours, the headquarters of the Transportation Corps, since the signing of the armistice. He was given full access to all sources of information as to what has been accomplished by

Repairing Locomotives at Nevers

our American railway men. The following, which is of particular interest to our readers, is taken from that article:

When the United States entered the war in April, 1917, the officers and employees of American railways knew extremely little—in fact, practically all of them knew next to nothing—about the way in which the railways of Europe were constructed, equipped and operated. Even as late as July, 1917, the transportation department was practically non-existent. One year later—in June, 1918—it had a personnel of 1,300 officers and 30,000 men, was operating

Locomotive Shops at Nevers

through eleven French ports, and over an extensive system of railways and inland waterways. It was running exclusively American trains, the first train which was exclusively American in equipment and personnel having been run on July 1, 1918, from Gievre to Nevers, a distance of 83 miles. When the armistice was signed, in November, 1918, the American Transportation Corps had a personnel of 1,970 officers and 53,136 enlisted men. In addition, 553 officers and 21,452 men were attached to it for duty, making a total personnel of 2,523 officers and 73,588 men.

What our railway men have done is to take over the operation, and maintain and enlarge the facilities of existing French railways to the extent necessary, first, to move our own armies and supplies to the front, and, second, to enable the French army to continue to carry on its part of the struggle with unimpaired energy and effectiveness. In order to enable the French railways to handle the vast additional traffic, it was necessary greatly to enlarge the facilities of the railways by building second, third and fourth tracks in some places; by building cut-offs in other places; by constructing numerous large yards and vast storehouses; by building shops to erect and maintain locomotives and cars, and by importing and putting in service large quantities of railway equipment and materials. Over 300 large construction projects (to be exact 316) were undertaken for the Transportation Corps. The total number of miles of new trackage actually built was 937, and the number of cars shipped from the United States knocked down and erected in France up to December 12, was 15,068. The number of locomotives from the United States put in service by our military forces in France was 1,105. Up to December 12 the complete record

Locomotive Repair Shop at Nevers

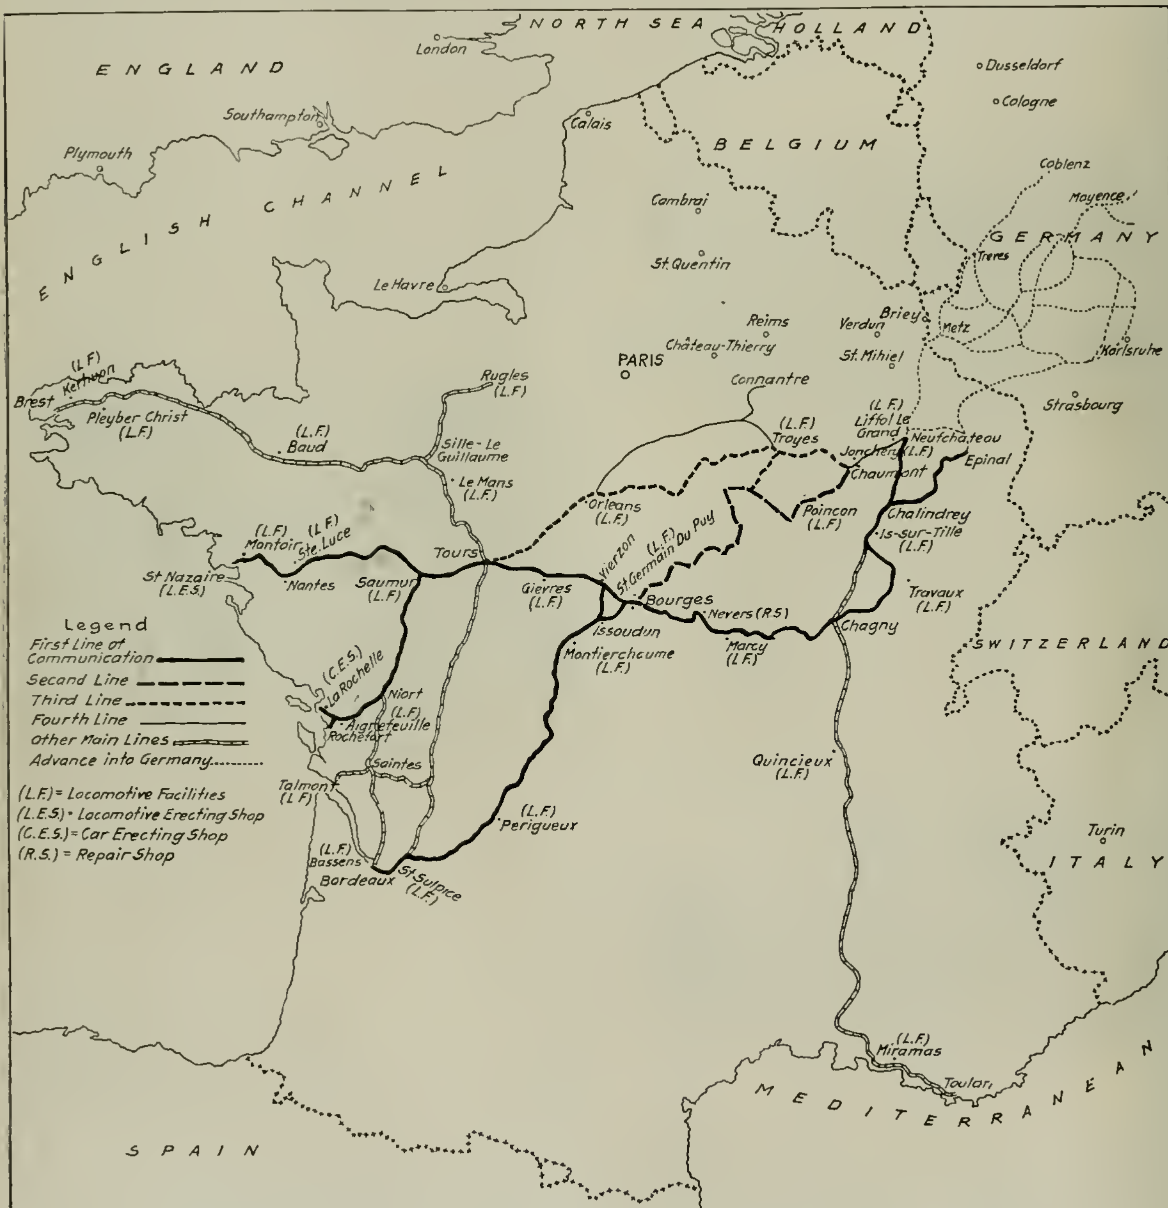
of the Transportation Corps with respect to the ordering, acquisition and erection of locomotives and cars was as follows:

	Locomotives			Freight cars		
	From U. S.	Other sources	Total	From U. S.	Other sources	Total
No. ordered	1,600	425	2,025	30,000	1,040	31,040
On sea	34	...	34	400	...	400
At port	139	...	139	747	...	747
At shop for erection...	19	63	82	1,238	...	1,238
Erected today (Dec. 12)	8	...	8	80	...	80
Erected to date	1,105	336	1,441	15,068	988	16,056

The magnitude of the work which the Transportation Corps has done is indicated, although only partially indicated, by the tonnage of supplies and the number of soldiers it has handled. Between June 1, 1917, and November 30, 1918, the total tonnage of supplies moved for the American Expeditionary Forces was 6,547,621 tons. What was accomplished is much better indicated by the increase in the tonnage handled per month and per day. In June, 1917, the tonnage handled was 24,524, or 817 tons per day, while in November, 1918, the tonnage handled was 920,972, or 30,699 tons per day. Plans had been made and were being carried out for providing a transportation capacity of 101,000 tons a day by June, 1919, if the war lasted until then. In the eighteen months from June, 1917, to November, 1918, inclusive, the number of troops transported into France was 1,865,440, and the number of animals, 53,117.

In the early part of August, 1917, General Pershing established the principle that there must at all times be kept on hand in France 90 days' supplies of all kinds for our troops. Forty-five days' supply must be available at base ports; 30 days' supply at intermediate storage points, and 15 days' supply at advance storage points, which were to be 50 or 60 miles from the front.

It was originally estimated that, on the average, there would have to be provided and transported 100 pounds of supplies daily for every American soldier in France. Ex-



Lines of Communication, American Expeditionary Forces. Light Dotted Lines Show Advance Into Germany

perience showed that this estimate was much too large, and later ones were based on an average requirement of 50 pounds per day per man. The actual consumption, after the army had become large, was about 40 pounds per man per day.

As the number of Americans in France and the amount of supplies which had to be furnished them increased by leaps and bounds, it became necessary rapidly to increase the number of ports used and greatly to enlarge the facilities of many of them. Five entire groups of ports finally were used. These were as follows:

Channel Group.—Le Havre, Fecamp, Hornfleur, Rouen, Cherbourg, St. Malo, Granville.

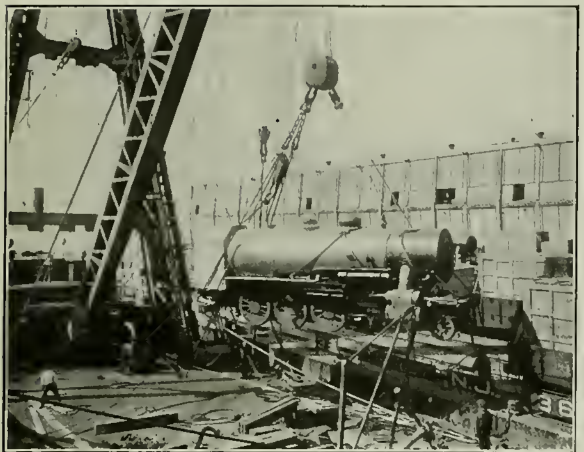
Brest Group.—Brest, Lorient, St. Brieuc.

Loire River Group.—St. Nazaire, Montoir, Donges, Usine Brulee, Nantes, Les Sables d'Alone, La Pallice, Rochefort, La Rochelle, Ponnay-Charente, Marans.

Gironde River Group.—Bordeaux, Pauillac, Blazefort, St. Loubes, American Bassens, French Bassens, St. Sulpice, St. Pardon, Bayonne.

Mediterranean Group.—Marseilles, Toulon, Cette.

The principal dock project was at American Bassens, near Bordeaux. The docks at this point consist of 10 berths of 410 feet each, served by four tracks along the front of the docks. Electric gantry cranes are used for unloading cargoes from ships and placing the supplies on cars. Immediately back of the docks are classification yards and warehouses. There is at present a covered storage capacity of 121,984 square feet and open storage capacity of 262,170 square feet.



Hoisting Locomotive from Lighter to Ship

The tonnage unloaded at the ports in November was divided among the various classes of supplies as follows:

Supplies	Tonnage	Per cent of total
Coal	207,644	22.55
Forage	68,154	7.40
Foods	177,791	19.30
Clothing	9,451	1.03
Oil	23,629	2.51
Other quartermasters' supplies	63,657	6.91
Transportation materials	89,721	9.74
Motor transportation	50,096	5.44
Engineering supplies	75,272	8.17
Ordnance	64,195	6.97
Medical	10,973	1.19
Signal Corps	3,114	.34
Air Service	9,166	1.00
Gas Service	2,883	.31
Troop property	993	.11
Red Cross	3,765	.30
Y. M. C. A.	2,148	.23
Naval	1,780	.19
Steel billets	54,379	5.91
Miscellaneous	3,161	.34
Totals	920,972	100.00

"Ordnance" in the above classification embraces munitions of all kinds; and it is a striking fact that ordnance constituted less than 7 per cent of the supplies transported. Of course, however, a vast work of transportation was carried on in the United States in handling the fuel and raw materials which were used in the manufacture of the ordnance which ultimately formed so small a part of the supplies unloaded and transported in France.

CAR AND LOCOMOTIVE SHOP FACILITIES

Besides providing facilities for taking care of both French and American equipment when it was in service, it was necessary for the Amercan Transportation Department to provide shops for getting it ready to put into service after it was received in France. The erection of locomotives and cars from the United States and the repair of those in France and Belgium by our transportation forces were begun in December, 1917. From that time up to the middle of December, 1918, the shop troops erected 1,055 locomotives from the United States, 99 for the French, and inspected and overhauled 359 from Belgium. They had also repaired 1,423 French locomotives. Records for the same period showed that 14,302 cars from the United Sates and 975 from other sources were erected, and that 45,993 were repaired for the French.

The large locomotive shop, where most of the work on locomotives is done, is at St. Nazaire. Locomotives for overseas shipment are erected and tested in the United States and then knocked down or partially knocked down for shipment. The knocked down locomotives are crated in sixteen boxes, the largest of which weighs 33,000 pounds. The partially knocked down locomotives are complete except rods, cab, stack, piping and odd fittings.

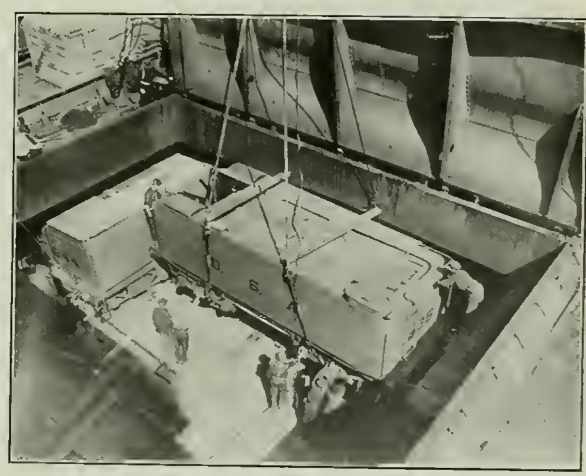
Arrangements were made to rent ten locomotive emplacements in Shop No. 1 from the Societe Anonyme des Ateliers et Chantiers de la Loire, nine emplacements in Shop No. 2 from the Societe Anonyme des Chantiers et Ateliers de Saint Nazaire (Penhouet) and the necessary storage and shifting tracks, all the above being located on the Bassin de Penhouet at St. Nazaire.

The main storage tracks located at Shop No. 1 include 14,600 feet of shifting and storage tracks and embrace 54,500 square feet of locomotive box storage. At Shop No. 2 the yard includes only 2,080 feet of track with no box storage, this yard being used principally for shifting.

The locomotive boxes are unloaded from the vessels by use of the French Titan cranes, loaded on flat cars and shifted to the locomotive box storage yard, unloaded by a 35-ton locomotive crane, and sorted out into complete locomotives, or held until the complete sixteen boxes are available. When sorted properly they are again loaded on flat cars, seven cars to a locomotive, and shifted either to Shop No. 1, close at hand, or Shop No. 2.

The locomotives under erection are handled in the French shops by two 100-ton electric cranes and are erected in proper sequence, that is, the drivers are placed, then the frames, the boiler, etc., until the locomotive is completed and ready to be sent to Montoir engine facilities to be tested.

The first locomotive was turned out at St. Nazaire shops October 27, 1917. Since that time, up to and including December 12, 1918, 1,032 locomotives have been completed.



Locomotive Tenders in Hold of Ship

This does not include 30 smaller type saddle tank locomotives completed at Rennes. The maximum daily output was obtained on September 6, when 14 locomotives were completed, this number consisting of seven partially erected type and seven knocked down type. The maximum weekly total was obtained during the week September 1 to 7, 1918, and was 69 locomotives. This number included 39 partially erected type and 29 knocked down type, and one saddle tank locomotive. The maximum monthly total was obtained in

September, 1918, and was 215 locomotives, 77 partially erected, 137 knocked down, and one saddle tank.

It is estimated that erecting shops No. 1 and No. 2 are capable of an output of 300 locomotives per month, 200 knocked down, and 100 partially erected. This capacity was never realized, as the locomotives were not received from the States in sufficient numbers, or were held up in ports.

When it was first proposed by the Transportation Department that locomotives should be shipped to Europe only partially knocked down, the Shipbuilding Board protested upon the ground that no ships were in existence which could stand up under the strain of such an immense concerted load. But boats were found which would stand up; and as many as 12 to 15 partially knocked down locomotives, together with their tenders, have been shipped to Europe in a single ship. This method of shipment has saved time and labor on both sides of the Atlantic, but especially after the engines have arrived in Europe. Gantry cranes which have been erected both at Bordeaux and St. Nazaire, have been used in transferring locomotives from the ships to the docks.

The large car erecting shops are at La Rochelle. These shops cover an approximate total area of 1,453,000 square feet. The buildings utilize an area of approximately 157,000 square feet. There are 34,325 feet, or about 6½ miles of track, which include two sets of erecting tracks, four sets of unloading tracks, one locomotive and crane repair track and three tracks for painting.

An erecting set comprises six tracks spaced at 17 feet, 58 feet, 30 feet, 58 feet and 17 foot centers. The two outside tracks at each side are crane and unloading tracks. The two middle tracks are the erecting track and crane track. The erecting track is covered for its entire length of approximately 1,300 feet and is divided into sections, according to the phases of construction, as follows: 200 feet, truck storage and erection; 450 feet, erection and riveting; 180 feet, flooring; 300 feet for side and end lining, and 220 feet for roofing. The painting facilities consist of three tracks, each 1,000 feet long, which were never covered as originally planned.

The 58-foot intervals between tracks, at the first approach to the plant proper, are used for storage of car boxes, but further along the various buildings are placed in this space. The buildings included are the power house, offices, shop buildings, waste sheds, store houses, machine and blacksmith shops and quarters.

Car parts are received from the United States crated in 100-car lots. The crates are sorted and stored until the parts for a 100-car lot are on hand. Erection starts with the assembling of trucks, which are then moved along the track to the erection position, where a frame, to which the outside fittings have been previously riveted, is placed on the trucks by two 15-ton locomotive cranes. The car then passes through the various phases of construction, each operation comprising a phase, being completed as nearly as possible at the same time, so that no delay occurs.

The first car was turned out at La Rochelle shop February 26, 1918. Since that time, up to and including December 11, 1918, 14,830 cars have been completed. The maximum daily output was obtained on September 26, 1918, when 150 cars were completed. The maximum weekly total was obtained during the week September 22 to 29, 1918, and was 700 cars. The maximum monthly total, obtained in September, 1918, was 2,370 cars. These totals include cars of all types, that is, flat, box, low and high side gondolas, refrigerator and Roger ballast cars.

Shop Labor Situation in 1918

Year Marked by Wage Advances and Decreases in Unit Production; Supply of Labor Now Improving

During the year 1918 changes took place in the labor situation that were little short of revolutionary. To understand the situation during the past year, it is necessary to look back as far as 1915 and 1916. In those years the industries in the Eastern states turned a great deal of their production over to war work, thus creating an unusual demand for men skilled in the mechanical trades. The wages paid in the war industries were higher than the prevailing scale and after a time affected the labor conditions on the railroads. Some of the most highly skilled mechanics were drawn away from railroad work by the prospect of higher remuneration and those remaining in the shops became dissatisfied with the relatively low rates of pay they received. The shortage of mechanics grew steadily worse during 1916 although in that year practically all the railroads increased the wages of the shopmen, the advances granted to the various craft in general varying from one to four cents an hour.

After the declaration of war there was a scramble among the mechanics to get into arsenals and navy yards and later in the year many of the men who had been employed on steel car work found lucrative positions in the ship yards. In June, 1917, the Railroad's War Board, realizing the necessity of maintaining the mechanical department forces, asked the Council of National Defense to define the policy with regard to the enlistment of machinists or other skilled railroad employees. It was felt at that time that there was danger of mechanics being drawn from the shops in such numbers as seriously to impair the efficiency of the railroads. The warning of the War Board was not heeded, consequently many of the best mechanics left railroad service and their places were filled by men who had had but limited experience. As these men in turn developed into skilled mechanics they likewise left the railroads to take better paying positions in war industries. This resulted in a very large labor turnover.

Roads Attempt to Maintain Shop Forces.

The railroads tried as best they could to keep the mechanics in their employ, and during 1917 granted numerous wage advances, ranging from two to eight and one-half cents an hour. One of the principal increases was that put into effect in the Southeast. According to a decision rendered by Secretary of Labor W. B. Wilson, on August 24, 1917, the shopmen in this territory received wage advances of six and one-half to eight and one-half cents an hour. The rates of pay for machinists, boilermakers and blacksmiths with the advances, ranged from 45 to 52 cents an hour. It is interesting to note that the wage increases granted in 1917 were in general higher on Western roads than on Eastern roads, in spite of the fact that the greatest shortage of mechanics was in the East. This was no doubt due to the fact that the Eastern roads had experienced serious losses in net revenues and being denied an increase in freight rates were not financially able to pay higher wages.

The shortage of mechanics caused discipline in the shops to slacken. The men became indifferent about their work, and production decreased very considerably. The percentage of men absenting themselves from work became very high and to counteract this tendency some roads inaugurated the practice of giving bonuses to men who were absent not more than two or three days during the month. The attempts to keep mechanics in the shops by increasing the wages did not have the desired results, consequently railroads in all sections of the country began to train women to do light work, both skilled and unskilled.

One of the factors that lowered the efficiency of the shops was the inadequate compensation the foremen received. Their earnings were often less than the average wages of the men under them, and with such conditions prevailing, it was difficult to secure competent men for supervisory positions. In fact, many foremen gave up their places and returned to work at their trade.

As the shortage of labor became more pronounced, the demands for wage increases grew more frequent. In December, 1917, the federated shop crafts on the Middle Western roads proposed rates of 62½ cents an hour for the locomotive shop crafts, 50 to 56 cents for carmen, and 44 cents for helpers, no increase to be less than 10 cents an hour. This tentative schedule was submitted to the members of the unions for their approval, but before the demands were presented to the roads, President Wilson assumed control of the transportation systems.

LABOR CONDITIONS AT THE BEGINNING OF FEDERAL CONTROL.

Such in general was the labor situation when the roads were taken over by the Government. The developments up to that time indicated clearly the conditions that would have to be met as long as the war lasted. The traffic was certain to be abnormally heavy, requiring motive power and rolling stock in good working order to handle it efficiently. The supply of labor instead of increasing, would decrease as more and more men entered military service. The problem therefore, was to secure increased output in spite of the constant depletion of the existing forces.

The absolute control over labor which the Government could exercise, made the problem less difficult for the Railroad Administration than it had been for the individual roads, and hope was expressed that the labor problem would be handled in a broad and thorough manner. However, the Railroad Administration has treated the labor question primarily as a *wage* problem and not as a *production* problem. The increased output required in the shops might have been secured through an increase in the production per man, either by working longer hours or by speeding up during the working period; or through an increase in the labor supply, by raising the wages sufficiently to attract labor from other fields, or by training women to fill those positions for which they are qualified. During the past year, the Director General and his staff have increased the hours of work and raised the wages, but they have made practically no effort to introduce women in railroad work and instead of placing a premium on high unit production, they have actually discouraged such measures by refusing to allow increases in piece work rates.

The wage problem was given consideration by Director General McAdoo soon after his appointment. A wage commission headed by Secretary of the Interior Franklin K. Lane, was appointed on January 18, to make recommendations for wage adjustments and on February 9 the Division of Labor was created with W. S. Carter as director. The first action that Mr. McAdoo took with regard to the labor situation in the mechanical department came in February. At that time he announced that the railroad shop employees, acting through A. O. Wharton, president of the railway department of the American Federation of Labor, had agreed that the hours of labor in the shops should be increased to 70 per week and that apprentices with three years' experience and helpers with five years' experience should be promoted to the rank of mechanic. It was also stipulated that mechanics were not to be denied employment for any cause other than inability to perform the work.

WAGE ADVANCES FOR MECHANICAL DEPARTMENT EMPLOYEES.

Director General McAdoo's promise to grant adequate wages was quite as effective in holding the men as any actual increase could have been, and comparatively few mechanics left railroad service during the early part of the past year. On May 25, the findings of the Railroad Wage Commission were made public. The commission recommended increases on a sliding scale ranging from $20 a month for those who, in December, 1915, received $46 or less, to $1 for those receiving $249. The Director General modified these recommendations and established a minimum rate of 55 cents an hour for machinists, boilermakers and blacksmiths. The employees of the mechanical department were not satisfied with the increases awarded by the provisions of General Order No. 27, principally because it took no account of the wage advances secured during 1916 and 1917. The disapproval of the findings of the commission was so strong that strikes took place in two shops. It was evident that the employees had expected to be awarded wages commensurate with those paid to mechanics in war industries. In hearings before the Board of Wages and Working Conditions, the representatives of the shopmen's organization asked for a rate of 75 cents an hour for car and locomotive shop men with over four years' experience and 56¼ cents for car men with less than four years' experience. Supplement No. 4 to General Order No. 27, issued on July 24, established a minimum rate of 68 cents an hour for mechanics, boilermakers, blacksmiths, sheet metal workers, molders and first class electrical workers, 58 cents an hour for car men and second-class electrical workers, and 45 cents an hour for helpers. It provided also for foremen paid on an hourly basis a rate 5 cents higher than their respective craft, and an increase of $40 a month for foremen paid on a monthly basis, with a minimum of $155 and a maximum of $250. For the sake of uniformity, all foremen were later placed on an hourly basis. The basic eight-hour day was established, and the increases were retroactive to January 1.

Other classes of labor in the shops were granted increased wages under the provisions of supplement No. 7, issued September 5, 1918, the minimum rates established being as follows: For stationary engineers, $110 per month; for stationary firemen and power house oilers, $90 a month; for locomotive boiler washers, 38 cents an hour; for power transfer and turntable operators, 33 cents an hour; for shop, roundhouse and storehouse laborers, 31 cents an hour, and for common labor 28 cents an hour. The rates specified in supplement No. 7 were not retroactive but were made effective September 1, 1918.

The increases in the wages resulting from the application of the new schedules, have been variously estimated at from 40 to 60 per cent. in the locomotive department, and from 40 to 90 per cent. in the car department. The increase would vary considerably in different shops, depending on the basis of payment previously in force. The supplements to General Order No. 27 made no provision for increases in the piece work prices, and this has resulted in the abolition of piece work in a large number of the shops.

EFFECTS OF HIGHER WAGES ON LABOR CONDITIONS.

In general the mechanical department employees were well pleased with the wages awarded by supplements Nos. 4 and 7. The migration of railroad shop employees to other industries practically ceased and many who had left railroad service returned to their former occupations. Director General McAdoo stated that he expected every railroad employee by faithful and efficient service to justify the large increases of pay granted to them. However, the evidence at hand indicates that this result was not secured. The shopmen were given an opportunity to increase their earnings very materially, but instead of working steadily after the new rates went into effect, many worked only enough days in each month to earn a small amount in excess of what they formerly received. The percentage of absentees in the shops was in some instances as high as 30 per cent. and to find 20 to 25 per cent. "laying off" was by no means unusual. While piece work systems were not abolished, the earnings under existing piece work rates were in most cases only slightly higher, and in some cases even lower than the established minimum wage for mechanics. Consequently when the higher rates went into effect, there was no longer sufficient incentive for men to increase their production to a point where they would earn more than the guaranteed rate per hour. On the few roads where the rates earned on piece work were considerably higher than the present wages, the system is still in effect and the unit production has not fallen off appreciably. Where the incentive has been removed, however, the output has fallen very markedly. Records of the average earnings on roads which had piece work systems before and since the wage increases went into effect are available. On one typical road the data showed that whereas the men in the car department, under the old piece work system, earned an average of 45 cents an hour, they were now earning 35 cents an hour, but were of course receiving the minimum rate of 58 cents an hour. On another road it was found that the output was but 60 per cent. as much per man as formerly, and 40 per cent. as much work was being turned out per dollar as before. These are by no means extreme instances, as in some cases the records for whole shops show that the men's earnings have dropped to from 20 to 30 per cent. of what they had been while the work was being done at the piece rate. It is probably no exaggeration to say that in the shops where piece work has been eliminated the output per man has decreased 30 per cent. and the labor cost of doing the work has increased 50 per cent.

OVERTIME AND PRODUCTION.

The experience gained during the past year demonstrates plainly that increasing the hours does not increase the output in proportion. In general as much work was done in a ten-hour day as in a 13-hour day, and the officers of one road stated that they expected to secure practically the same output with the shops running 48 hours a week that was obtained when the men were working 70 hours a week. It should be stated, however, that the eight-hour day has not been received with favor particularly by the car men, and under this condition the normal production cannot be secured.

In considering the records of the shops, the fact must not be overlooked that supervising officers were working under unfavorable conditions. The foremen, as a class, were underpaid. Many had given up their positions to return to work at the trade, and this tendency became even more marked after the issuance of General Order No. 27. Had the foremen been granted salaries commensurate with their responsibilities, the labor situation would undoubtedly have been improved. The inadequate wages not only made it difficult to secure competent men for the supervising forces, it also resulted in the foremen losing authority, as where the workers received higher wages than the supervising forces they feel the foremen are their inferiors, and obey instructions grudgingly. It was not until the first of November that the supervising forces were granted adequate wage increases. While the final wage scales for the foremen were in general quite satisfactory, they came too late. The most trying times had passed, and the roads had lost the full production that might have been secured had the foremen been able to exercise complete authority in the management of the shops.

The effect of the Government's attitude toward labor has been clearly shown in the mechanical department. One of the first significant changes was a marked increase in the number of men enrolled in labor organizations. Soon after the Railroad Administration announced that no distinction should be made between members or non-members of labor unions, the representatives of the American Federation of Labor sent organizers to the "open" shops. As a result of the activities of the federation, there is hardly a shop in the country in which a local lodge has not been formed. This movement has been furthered by the evident advantages of organized labor in enforcing its claims on the administration and by the widespread opinion among the workers that the organized crafts have been especially favored in the wage awards.

GOVERNMENT ATTITUDE TOWARD LABOR.

The removal of the power of determining wages from the officers of the individual roads had an unfortunate effect on discipline in the shops. The men became imbued with the belief that any favors they were to receive would be determined by the authorities at Washington and that the administration of discipline would likewise be governed by the central body. This resulted in flagrant cases of insubordination. Men refused to obey the orders of the foremen in the shops, denied the power of the supervising officers to discharge them, and whenever they were not satisfied with decisions in matters affecting wages or working conditions, carried the matter to Washington in the form of complaints or grievances. In general the men were inclined to give credit for all the benefits they received to the Railroad Administration, but placed all the blame for undesirable conditions on the local officers. The general effect of this situation on the morale of the workers can readily be appreciated.

SUPERVISORS TRY TO INCREASE PRODUCTION

Late in the year, the administration officers seem to have arrived at a realization that the men were not giving a fair day's work for a fair day's pay. Belated attempts were made to increase the production of the shops. The general supervisors of equipment visited a number of plants, and by personal appeal, endeavored to speed up the workers and restore discipline. These men have stated that the workers are not giving the Government the output which they had given to the railroads under private control, regardless of the fact that wages have been increased and working conditions improved. In one case following an unpopular reduction in the working hours, the men deliberately cut the output more than 50 per cent. The equipment inspectors have insisted that insubordination must cease, and that shopmen must obey their officers. This movement should result in better output in a short time under the present conditions.

Since the signing of the armistice the labor situation has undergone a rapid change. In the sections of the country where many war industries were located, there are now plenty of mechanics available. In other sections a slight shortage of skilled labor is reported. The working period in the shops has been reduced to eight hours per day, and where it is found that a single shift will not give the required output, the second shift is to be organized. This arrangement has been put in force in order to give employment to the maximum possible number of men during the reconstruction period. With the decrease in the demand for skilled labor there has come a change in the attitude of the workers. The unit production probably reached the low point during the last months of the year. During the coming months there should be a marked improvement in the morale and in the output of the shops.

German Railway Equipment for France.—Press despatches state that on December 29 Germany would deliver to France 2,600 locomotives and 70,000 cars.

Two More Standard Locomotives

Heavy 4-8-2 and Light 2-10-2 Types Are Well Proportioned and Have Essentially the Same Boiler

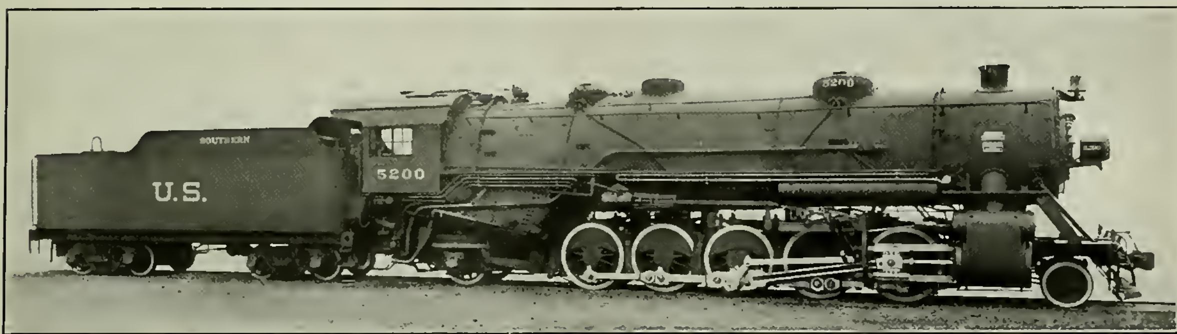
The first locomotives of the United States Railroad Administration standard heavy Mountain type and light Santa Fe type have recently been delivered by the American Locomotive Company.

The boilers used on these two types are practically identical; the size of the shell, the number and diameter of tubes and flues and the principal firebox dimensions are the same. The principal difference between the two boilers is in the slope of the mudring, the height of the center line of the boiler on the Mountain type locomotive making possible the maintainance of a deeper backhead with less inclination of the grate than was necessary on the 2-10-2 type. The design of both types conforms closely in the details used to the other standard types which have already been built, and a considerable measure of interchangeability exists in the details of the various classes.

The boiler provides ample capacity in each case. Stating the relation between the boiler capacity and the cylinder demand on the basis of Cole's ratios, the Mountain type locomotive has practically a 100 per cent boiler, while the boiler for the Santa Fe type is equivalent to about 109 per cent. The design of the boiler itself is well balanced, both as to the ratio of tube length to diameter and the ratio of grate area to heating surface. The latter relation checks almost exactly with Cole's assumption of 120 lb. of coal per square foot of grate per hour at the maximum boiler output.

In the table is presented a comparison of the principal dimensions of the standard 4-8-2 type locomotive with a few of the recently built locomotives of this type. It will be found that although the total weight of this locomotive is slightly less than that of the A. T. & S. F. locomotive,* the weight on the drivers is considerably higher, as is also the tractive effort, which exceeds that of any locomotive of this type previously built. It will also be observed that the cylinder stroke is longer than has usually been adopted for locomotives of this type, which accounts for the high starting tractive effort obtainable.

A similar comparison of Santa Fe types shows less of interest, as the comparison in order to be fair must be confined to locomotives of medium weight; the light 2-10-2 type is designed to keep within axle loads of 55,000 lb.



The Standard Light 2-10-2 Type Locomotive

Comparison of Principal Dimensions of Notable 4-8-2 Type Locomotives

Road	U. S. Std.	Santa Fe	N. Y. C.	N. & W.
Builder	American	Baldwin	American	N. & W.
Year built	1918	1918	1916	1916

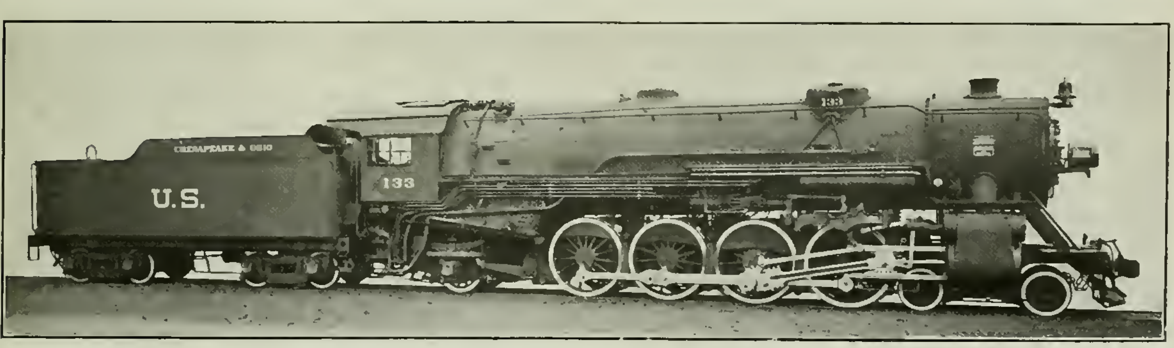
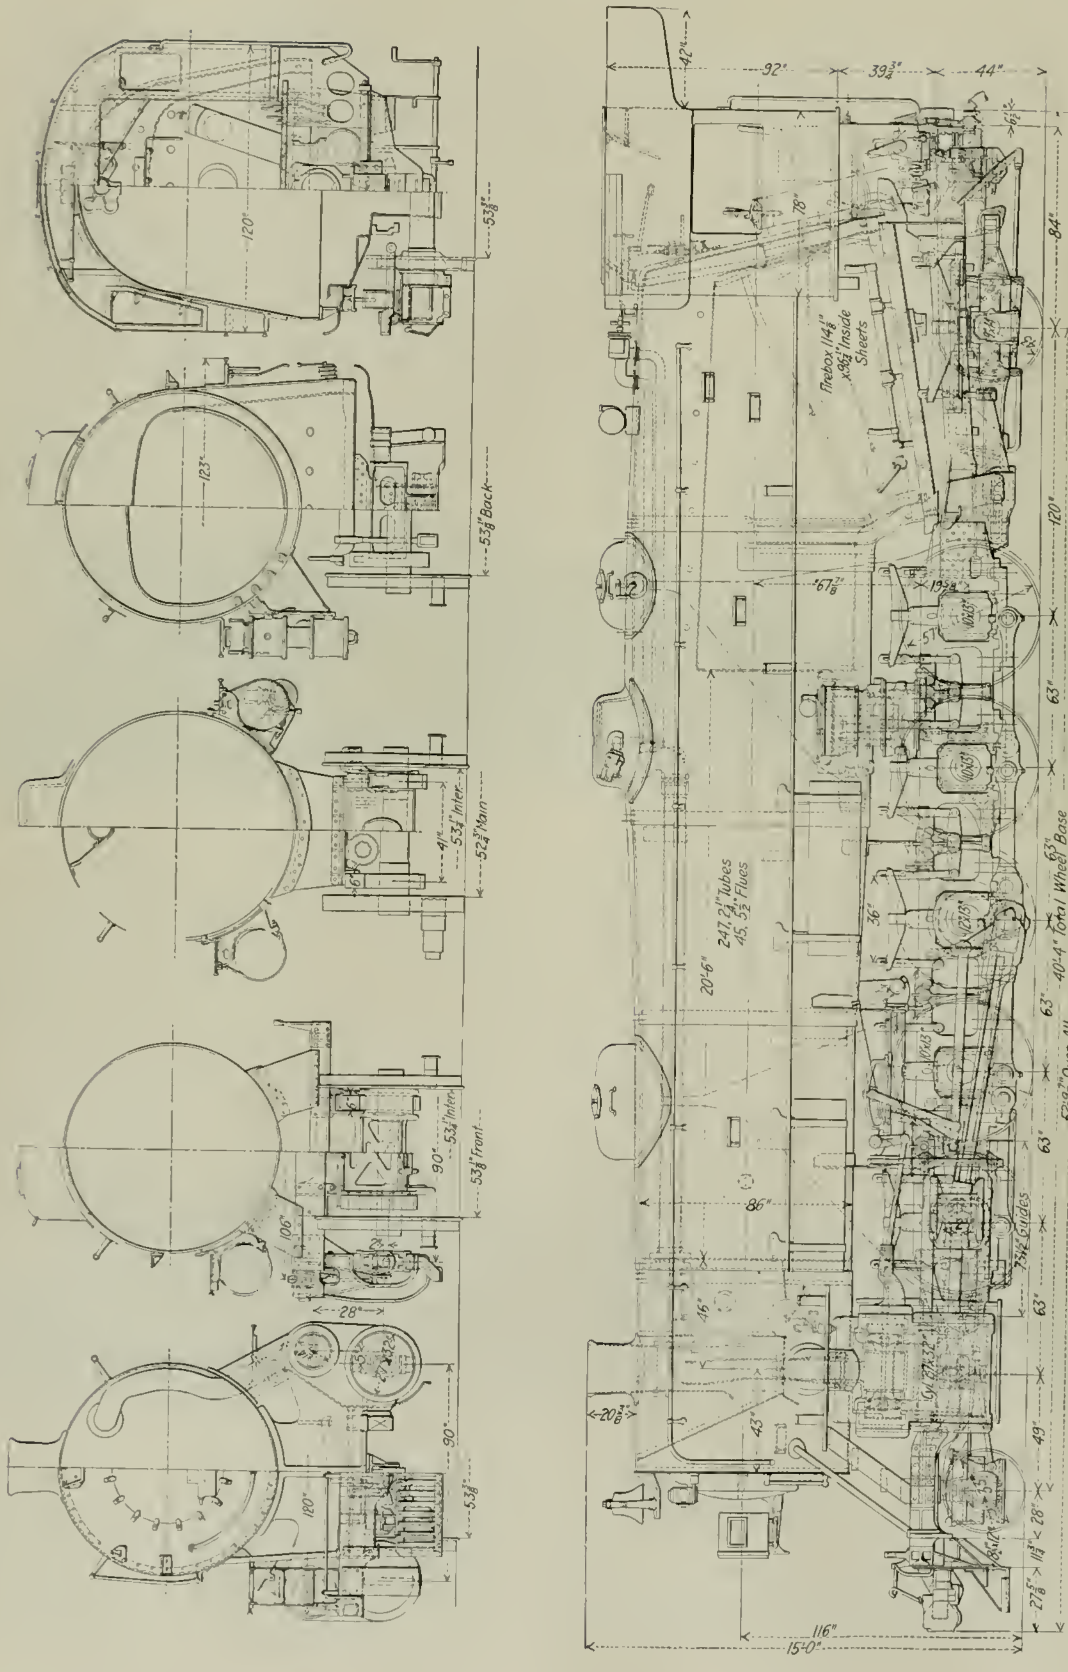
Grate area, sq. ft.	76.3	71.5	66.8	80.3



The U. S. Standard Heavy Mountain Type Locomotive

The tonnage rating charts for the two types were prepared by H. S. Vincent and are similar to those shown in the

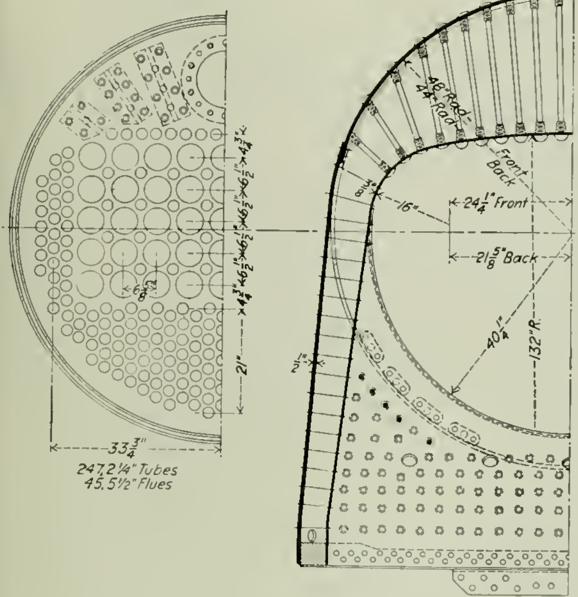
*See the *Railway Mechanical Engineer* for December, 1918, page 649.



Elevation and Cross Sections of the U. S. Standard Light Santa Fe Type Locomotive

Railway Mechanical Engineer for November, 1918, page 607.†

The boiler for both types is 86 in. in diameter outside of the first ring and is increased to an outside diameter of 96 in. at the firebox by a conical course just ahead of the dome.

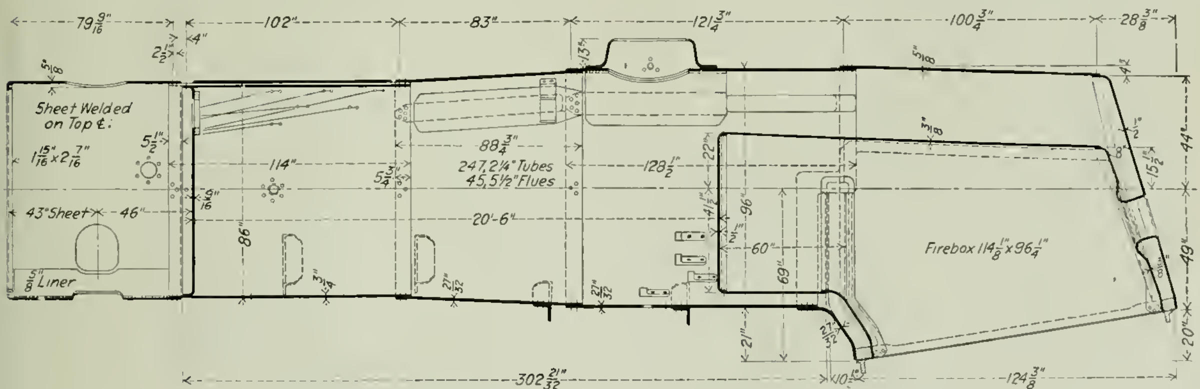


Firebox Section and Tube Sheet Layout

The longitudinal seam in the dome course is placed at the left side of the top center line, the dome pad being used as an inside welt strip for the portion of the seam in front of the combustion chamber. The dome is of pressed steel, standing eight inches above the top of the boiler shell on the 4-8-2 and 13 in. on the 2-10-2 type, and has a clear opening of 25 in. The seam on the conical course is placed to the right of the top center line, while the forward, straight course is closed on the top center line. The tubes and flues are 20 ft. 6 in. long, ending at the rear in a combustion chamber tube sheet which is placed five feet ahead of the firebox throat. Type A superheaters and Security Brick arches are used on both types of locomotives.

Both locomotives are fired with stokers, the 4-8-2 type being equipped with a Standard stoker and the 2-10-2 type with the Duplex. Both have Franklin power grate shakers and the 4-8-2 type is equipped with a Shoemaker firedoor, while the 2-10-2 type has the Franklin door. In both cases the throttle rigging is of the Chambers backhead type. On the Mountain type locomotives the boiler is fed by Hancock No. 13 non-lifting injectors, while on the 2-10-2 type the Ohio non-lifting injectors of the same number are used. The 4-8-2 type boiler is fitted with Consolidated safety valves, while the Santa Fe type has Coale valves.

The frames of both locomotives are similar in design, both having single front rails cast integral with the main frames and Commonwealth rear frame cradle castings spliced to the rear ends of the main frames. The frames of both types are six inches wide. The top rail on the Mountain type has a maximum depth over the pedestal of 7⅝ in., with a minimum depth of 6½ in. The lower frame rail is 5⅛ in. in depth over the ends of the pedestal binders and 4⅝ in. in depth at the minimum section. The standard pedestal taper in all cases is one in twelve. On the 2-10-2 type the top frame rail is 7⅛ in. deep over the pedestal with a minimum section 6 in. deep, while the lower rail has maximum and minimum depths of 4¾ in. and 4¼ in., respectively. The frame bracing is similar in both cases. Vertical crossties are bolted to the pedestal jaws of each pair of drivers except the rear, the forward casting also being attached to the inclined lower rail immediately back of the cylinders. Horizontal crossties are attached to the top rails of the Mountain type locomotive in front of the forward drivers and between the first and second, second and third, and third and fourth pairs of drivers. The front crosstie also supports the guide yoke. The bracing of the Santa Fe type is similar; starting with the guide yoke, which is located between the first and second pairs of drivers, transverse castings are attached to the top rails between each succeeding pair of wheels.



Longitudinal Section of the Boiler for the Standard Light Santa Fe Type

The cylinders of the Santa Fe type locomotive are the same diameter and stroke as those of the heavy Mikado type and, including the cylinder and valve chamber heads, are interchangeable with those used on the latter locomotive. The Mountain type cylinders do not interchange with any other type yet built, but the valves and steam chest covers used on these locomotives are interchangeable with those used on the

†The curves of hauling capacity are constructed for a car resistance of 4 lb. per ton. The chart may be used for any other car resistance or for any combination of resistances by converting them into terms of grade.

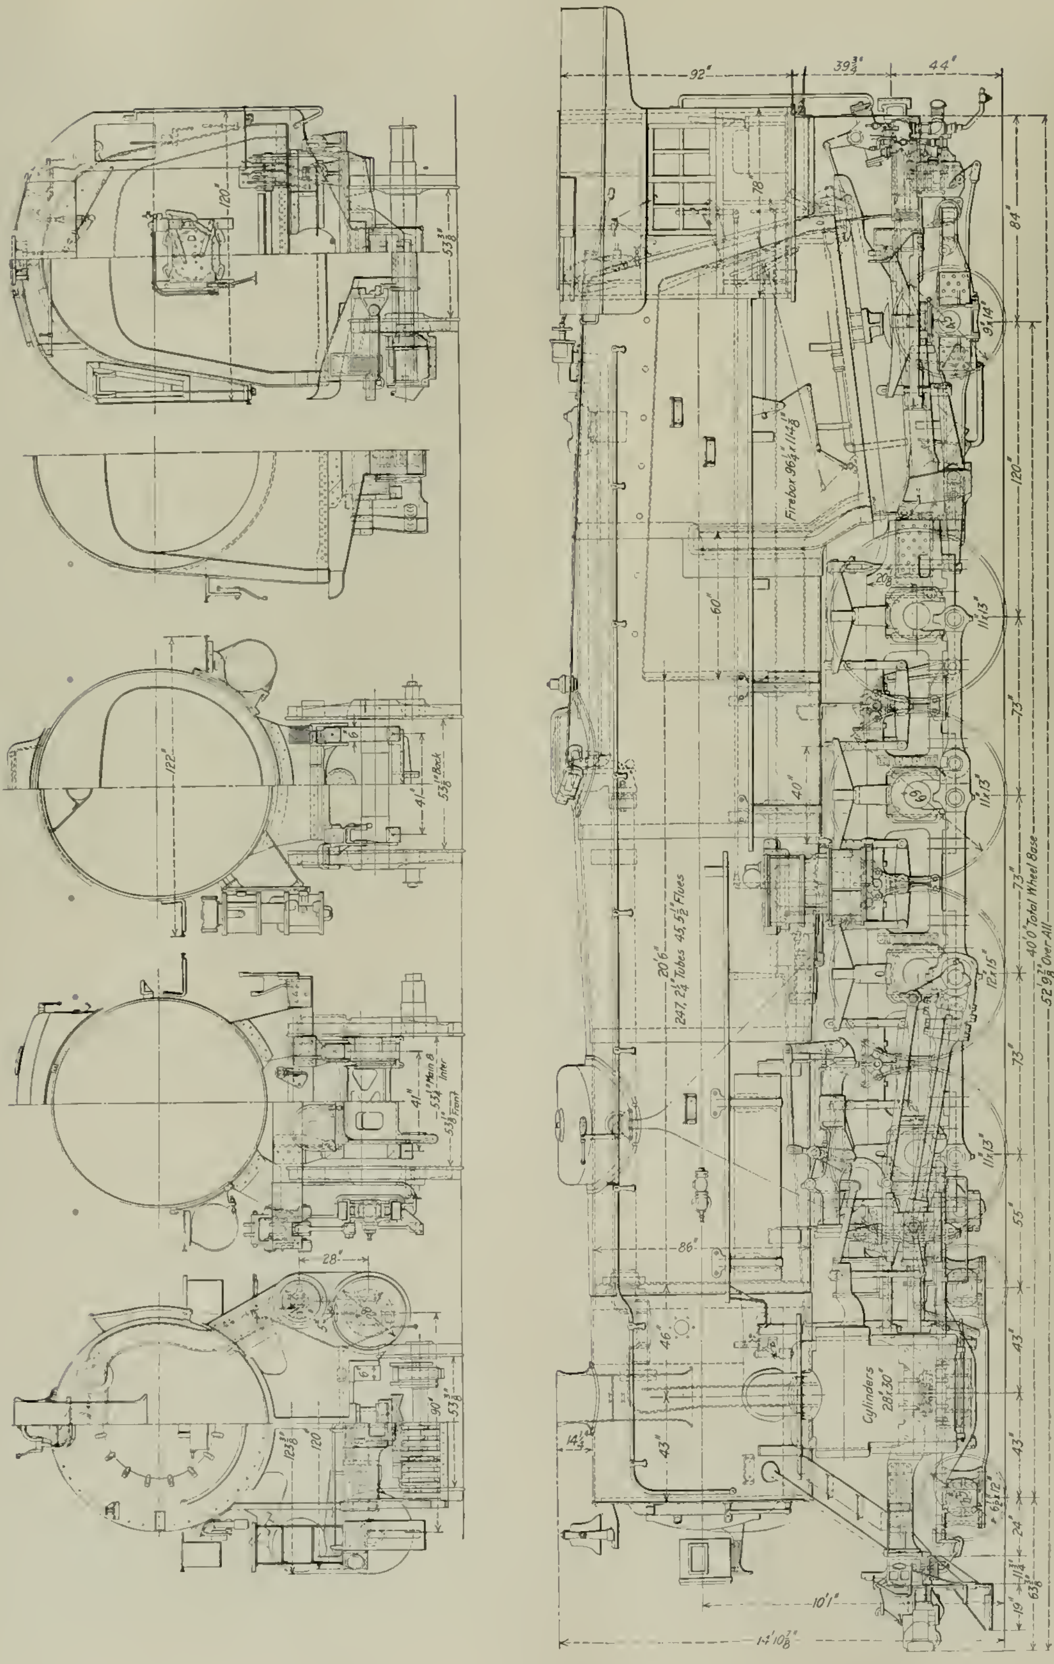
1 lb. car resistance = .05 per cent grade
1 degree curve uncompensated = .04 per cent grade

For example: Find the tonnage which can be hauled in passenger service by the 4-8-2 type locomotive, on 0.5 per cent grade combined with 4 deg. uncompensated curve at 40 m.p.h.

From Table III (see the November issue, page 610) the resistance of passenger coaches at 40 m.p.h. is 6.65 lb. per ton. The equivalent grade is then:

$$0.5 + (4 \times .04) + (6.65 \times .05) = 0.7925 \text{ per cent}$$

At the intersection of the ordinate for 0.7925 per cent grade with the drawbar pull curve for 40 m.p.h., we find 925 tons as the capacity of the locomotive.



Elevation and Sections of the Standard Heavy Mountain Type Locomotive

2-10-2 type, both the light and heavy Mikado types and the eight-wheel switcher. The crosshead body, with the exception of the finish for the wrist pin fits, the front end main rod clearance and the piston rod fit is identical for the heavy Mountain type locomotive, both the light and heavy Mikado type locomotives and the eight-wheel switcher. The crosshead shoes are not interchangeable. The piston and rod used on the light Santa Fe locomotive are identical with those used on the heavy Mikado type. Hunt-Spiller gun iron is used for piston and crosshead wearing shoes, piston and valve packing rings and cylinder and valve chamber bushings on both the Mountain and Santa Fe types. Paxton-Mitchell metallic packing is used for the piston and valve rods on both types.

On both the light Santa Fe and the heavy Mountain types the main driving journals are 12 in. in diameter by 13 in. long. The other journals on the Mountain type are 11 in. in diameter by 13 in. long and the driving boxes for these axles interchange with the main driving box for the light Mikado type locomotive, with the exception of slight differences in the finish of the crown brass, which is bored out 1/32 in. oversize for the Mountain type journals and 1/100 in. oversize for the main journals of the Mikado. The other journals on the Santa Fe type are 10 in. in diameter by 13 in. in length and the driving boxes used on these axles interchange with those of this size used on both the light and heavy Mikado type locomotives.

The leading trucks on both locomotives are of the constant resistance type, while the trailing trucks are of the Cole-Scoville type, the journals in both cases being 9 in. in diameter by 14 in. in length.

The Baker valve gear is applied on the Mountain type locomotives while the Santa Fe type are fitted with the Southern valve gear. In both cases the valve motion is controlled by the Ragonnet power reverse gear.

Both locomotives are served by tenders carrying the standard 10,000-gal. tank mounted on Commonwealth cast steel frames. The passenger tenders are fitted with equalized trucks having frames of the built-up type, while the trucks under the freight tender have cast steel side frames. In both cases the trucks are fitted with Woods roller side bearings. The connection between the engine and tender includes the Unit safety drawbar and Radial buffers, while the rear ends of the tenders are fitted with Westinghouse D-3 type draft gear.

Among the specialties are Everlasting blow-off cocks on the 4-8-2 type, Murden blow-off cocks on the 2-10-2 type, Ashcroft and Ashton steam gages on the 4-8-2 and 2-10-2 types, respectively, Detroit six-feed six-pint lubricators on both types and Leslie steam heat equipment on the 4-8-2

type. Greenlaw flexible pipe couplings are used on the 4-8-2, while the 2-10-2 is fitted with Barco couplings.

The principal dimensions and data for both types are given in the clearance and wheel load diagrams, which were prepared by F. P. Pfahler, chief mechanical engineer, Division of Operation, United States Railroad Administration, and in the following table:

General Data

	4-8-2	2-10-2
Gage	4 ft. 8½ in.	4 ft. 8½ in.
Service	Passenger	Freight
Fuel	Soft coal	Soft coal
Tractive effort	58,000 lb.	69,400 lb.
Weight in working order	352,000 lb.	352,000 lb.
Weight on drivers	243,000 lb.	274,000 lb.
Weight on leading truck	51,500 lb.	23,000 lb.
Weight on trailing truck	57,500 lb.	54,000 lb.
Weight of engine and tender in working order	547,500 lb.	540,300 lb.
Wheel base, driving	18 ft. 3 in.	21 ft.
Wheel base, total	40 ft. 0 in.	40 ft. 4 in.
Wheel base, engine and tender	75 ft. 8½ in.	76 ft. ½ in.

Ratios

Weight on drivers ÷ tractive effort	4.2	3.9
Total weight ÷ tractive effort	6.1	5.1
Tractive effort × diam. drivers ÷ equivalent heating surface*	637.0	629.6

Railroad Administration News

New Director General Not Named; Other Resignations; Circulars Issued from Washington and the Regions

As this issue goes to press no successor to Mr. McAdoo has been named although Walker D. Hines appears to be the preferred candidate. Mr. Hines has been with the Railroad Administration since it was formed a year ago, having been formerly chairman of the Board of Directors of the Atchison, Topeka & Santa Fe. He is the most logical successor to Mr. McAdoo, having followed through the year's developments with him.

During the month Judge Robert S. Lovett, the head of the Division of Capital Expenditures, resigned to return, after two months' rest, to the Union Pacific as its president. On December 20, Carl R. Gray, director of the Division of Operation, tendered his resignation, to take effect January 15. Mr. McAdoo delayed this abdication of the director generalship until after he presented his plea for the five-year extension plan to Congress. He then expects to go to California with his family for a rest.

EMPLOYEES WANT MCADOO TO STAY

Mr. McAdoo has received hundreds of letters and telegrams expressing regret because of his resignation as director general of railroads and appreciation of the work he has accomplished, from all classes of railroad service, from employees to managers and corporation officers. The employees, however, are most expressive of their desire to retain him as boss and many of them have backed up their words by concrete evidence. In addition to the numerous offers to "chip in" toward an adequate salary, four employees of the St. Louis-San Francisco enclosed certified checks for $1 each as a Christmas present.

The executive council of the railway department of the American Federation of Labor called on Mr. McAdoo on Saturday after his return from his southern trip, to present resolutions asking him to retain his office, and also another resolution, which was transmitted to the President, proposing legislation which would "provide a salary in keeping with the services rendered." The resolutions also protested against any plan to return the roads back to private control.

RAILROAD ADMINISTRATION NOT CANCELLING ORDERS

In reply to various inquiries that have reached Washington regarding rumors that the Railroad Administration had cancelled or was likely to cancel outstanding orders for equipment, officials of the Administration say that no cancellations have been made, except in the case of the recent orders for 600 locomotives, which were held up and then reinstated before the contracts were formally signed, and it is understood that none are proposed, although as reported last week an investigation was undertaken of the situation as to the outstanding car orders.

DIRECTOR GENERAL'S CHRISTMAS MESSAGE TO RAILROAD MEN

"Christmas this year will have a special significance to peoples everywhere. For the first time in four years the world is at peace and railroad men can be happy in the consciousness that they have contributed their full share to this result. I shall always remember the splendid way in which they applied themselves to the task of running the railroads at a time when their efficient operation was absolutely fundamental to the winning of the war. I am proud to have been associated with them in this great job.

"The railroads have not alone carried the tremendous burden thrown upon them by the war, but they are now in better shape than ever before in our history. For the coming winter I have no fear of their ability to do the work required of them.

"And now, as I am about to sever my connections with the officers and employees of the railroads, I want to assure them of my deep regret at being forced to take this step. Among the happiest memories of my life will be those connected with my work as director general of railroads. I shall always cherish the friendships I have formed with railroad officers and employees, and I take this opportunity to assure them that although I shall no longer be their 'boss,' I shall always be their friend."

RULES FOR INSPECTING AND TESTING STATIONARY BOILERS

The Division of Operation has issued Mechanical Department Circular 11 dealing with the rules and instructions for the inspecting and testing of stationary boilers, as follows:

Rule 1—These rules shall apply to all steam boilers and their appurtenances operated by railroads under Federal control, except the boilers of locomotives or boilers used solely for heating which carry pressure not exceeding 15 pounds per square inch.

Rule 2—The chief mechanical officer of each railroad will be held responsible for the general design, construction, and inspection of all boilers covered by these rules. He must know that all inspections are made in accordance with the rules, and that the defects disclosed by any inspections are properly repaired before the boiler is returned to service.

Rule 3—The working pressure of each boiler shall be determined by the mechanical engineer, using the formula commonly used in determining safe working pressures, and after a thorough inspection and report by a competent inspector. The minimum factor of safety allowed shall be four.

In determining safe working pressure, the maximum allowable stress shall be 7,500 pounds per square inch for staybolts, and 9,000 pounds per square inch for round or rectangular braces supporting flat surfaces.

Rule 4—Each boiler shall be given a serial number by the operating railroad. A metal badge plate showing this number and the safe working pressure shall be attached to each boiler.

Rule 5—Specifications of each boiler shall be kept on file in the office of the chief mechanical officer of the railroad. Within ninety days after this rule becomes effective, each railroad will file report (Form MD-25) with the chief mechanical officer of the railroad and a copy with the Assistant Director, Division of Operation, in charge of the Mechanical Department, United States Railroad Administration, Washington, D. C., for each boiler subject to these rules, giving all the data called for thereon.

Rule 6—Each boiler shall have at least one safety valve of sufficient capacity to prevent an accumulation of pressure more than five per cent above the working pressure and shall be connected direct to boiler.

Safety valves shall be set at pressure not to exceed six pounds above the allowed working pressure.

Working safety valve on boiler shall be tested each day boiler is in use. Failure of safety valve to open before an excess pressure of ten pounds has been reached must be immediately reported to the proper authority, and repairs made.

Not less frequently than once each three months all safety valves on boiler shall be tested and adjustment made, if necessary. At this test, as well as at all other tests where the safety valves are adjusted, two steam gages shall be used, one of which shall be in full view of the person adjusting the valves.

Rule 7—Each boiler shall have a steam gage, graduated to at least fifty pounds above the working pressure, connected direct to steam space of boiler, equipped with a suitable siphon and with not more than one cock or valve between boiler and gage. This cock to be located near steam gage.

Steam gages shall be tested at least once each three months, or whenever any irregularity is shown and shall also be tested before any adjustment is made of the safety valves. Each time gage is tested, siphon pipe and cock must be cleaned and examined.

Rule 8—Each boiler shall have at least three gage cocks and one waterglass, so located that the lowest reading shall be at least three inches above the lowest safe water line. Each waterglass shall be equipped with a valve at each end of glass and with a blowoff or drain at bottom of glass. Gage cocks, waterglass and water column valves, cocks and connections shall be maintained in an operative condition free from leaks and shall be cleaned of scale each time boiler is washed.

Suitable lights shall be provided for waterglass and steam gage.

ANNUAL INSPECTION

Rule 9—Before being placed in service and not less than once each twelve months thereafter, each boiler shall be subjected to a hydrostatic pressure 25 per cent greater than the working pressure and the boiler and appurtenances carefully examined while under pressure.

After hydrostatic pressure has been applied, a thorough inspection shall be made of every accessible part of the boiler. Manholes shall be removed to permit of interior inspection.

Boiler having lap joint longitudinal seams should be examined with special care to detect grooving or cracks at edge of seams.

Water tube boilers should be examined with special care to detect blistering on the tubes, tubes bending and leakage or corrosion where tubes are fastened to headers.

Soot and cinders shall be cleaned from furnace and combustion chamber and a thorough inspection made of the brick lining and setting, the fire wall-baffles and grates.

Threaded and flange joints on steam header, steam pipe and blowoff line shall be carefully examined for signs of corrosion or wasting.

After repairs are completed the boiler must be fired up, safety valves set, and boiler and appurtenances examined. All cocks, valves, seams, pipes, flanges and joints must be tight under this pressure.

All defects disclosed by any of the above inspections must be repaired before the boiler is returned to use.

A certified report of the inspection and repairs (Form MD-27) shall be filed with the chief mechanical officer of the railroad and a copy sent to the Assistant Director, Division of Operation, Mechanical Department, Washington, D. C.

Rule 10—Locomotive type boilers working under a pressure of 125 pounds or more shall have the staybolts tested at least once each month. Locomotive type boilers working under a pressure of less than 125 pounds shall have the staybolts tested at least once each three months. Vertical boilers working under a steam pressure of 100 pounds or less shall have the staybolts tested each time the hydrostatic test is applied. No boiler shall remain in service with five or more broken staybolts.

Rule 11—Boilers shall be thoroughly washed as often as water conditions require, but not less frequently than once each month. Special care shall be given to water tube boilers to prevent an accumulation of scale in the tubes and the tubes must be scraped, if necessary. At washout periods, soot, ashes and cinders shall be cleaned from furnace and combustion chamber, and brick lining, setting and fire wall examined.

SEMI-ANNUAL INSPECTION

Rule 12—Not less frequently than once each six months an inspection of the boiler under steam shall be made by a competent inspector. He shall test the safety valves, gage cocks and waterglass, blowoff valve, examine and test the feed pump or injectors, examine steam pipes for leaks, giving close attention to leaks around threaded joints, see that pipes are well braced, that all valves are operative, examine the setting of the boilers and the general condition of the boiler room, with especial reference to fire risks.

He shall report any defects found to the division officer in charge and to the local officer in charge so that prompt repairs can be made.

A certified report of the inspection and repairs (Form MD-26) shall be filed with the chief mechanical officer of the railroad and a copy sent to the Assistant Director, Division of Operation, Mechanical Department, Washington, D. C.

MISCELLANEOUS RULES

Rule 13—Boilers equipped with fusible plugs shall have plug cleaned of scale not less than once each three months.

Rule 14—Boilers in batteries connected to same steam header shall each have a suitable valve between boiler and header, which must be maintained in an operative condition.

Rule 15—Each steam outlet from boiler (except safety valve connections) shall be equipped with a suitable valve, which must be maintained in an operative condition.

Rule 16—Injectors and pumps must be kept in such condition that they will feed water into the boiler against the maximum pressure allowed on the boiler.

Rule 17—Feed water heaters shall be cleaned and inspected as often as water conditions require, but not less than once each three months.

Rule 18—Boilers with any of the following defects shall be withdrawn from service until after proper repairs are made: Cracks in cylindrical boilers or headers; bags or bulges in shells of external fired boilers or unstayed surfaces of internal fired boilers; bulges in arch or water tubes; more than one gage cock inoperative; safety valve inoperative.

Rule 19—Boilers showing indications of having been low in water or of mud burning shall not be used until after inspection by a competent inspector.

Rule 20—Where necessary to plug flues, the plugs shall be tied together with a rod not less than ¼ inch in diameter and a report of same made to the officer in charge, who will have proper repairs made.

Rule 21—When making internal inspection of one of a battery of boilers, another employee will be stationed outside of boiler, whose duty shall be to prevent steam valves from other boilers being opened into boiler being inspected.

Rule 22—The boiler room shall be kept in a clean and sanitary condition, old clothes, waste, etc., must not be allowed to accumulate in or around boiler room.

Rule 23—An annual certificate of inspection shall be posted under glass in a conspicuous place in the boiler room. This certificate shall show the number of the boiler, the allowed working pressure, the date of inspection and the signature of the inspector.

Rule 24—Inspection certificates may be made in triplicate and copy filed with state inspector of boilers, when desired.

The above rules shall become effective January 1, 1919, as minimum requirements and shall be put in full force on each railroad under federal control on that date. When a railroad has in effect additional rules which provide greater safeguards such additional rules may be continued in effect.

SHOPS ON EIGHT-HOUR BASIS

Frank McManamy, assistant director of the Division of Operation, has sent to the regional directors the following interpretation of the director general's order to reduce shop hours wherever practical to eight per day, stating that the numerous inquiries received and the different ways in which this has been put in effect clearly indicates it has not been uniformly understood:

"The purpose of this order was to reduce the hours worked in locomotive shops and roundhouses and in car shops and repair yards to a basis of eight hours per day on December 9. At roundhouses and other places where the work is continuous 24 hours a day three eight-hour shifts should be established. In shops where a single eight-hour shift will not properly maintain the equipment a second shift should be organized as soon as men can be obtained, pending which the work should be taken care of by necessary overtime in accordance with agreements with the employees.

"It is believed that under present conditions of business with increased force, which is available, that at practically all points shop work can be handled on the eight-hour basis without the necessity of requiring excessive overtime, and every effort should be made to do this."

TO RETAIN SKILLED RAILROAD MEN

The mechanical department of the Division of Operation is taking steps to prevent the possible loss of trained shop employees to the railroad service as a result of any reduction in force which may seem necessary at particular points. If the men are not needed at one place arrangements will be made to locate them elsewhere, as it is believed that more men instead of less men will be needed in the next few weeks. Frank McManamy, assistant director of the Division of Operation, has addressed a letter to the regional directors stating that a number of cases have recently been brought to his attention where in the readjustment of shop forces skilled workmen have been laid off.

"Every trained railroad employee represents a certain definite investment," Mr. McManamy said, "therefore, when reorganizations make reductions in forces necessary, all reasonable efforts should be made to retain these men in railroad service. Before a reduction in force is made at any point, steps should be taken to ascertain if the men to be laid off cannot be profitably used at some other point, either on that line or on some other line within your region, in which event transfer should be made and transportation provided.

"If the men cannot be profitably used in your region, this office should be advised, giving the number of skilled workmen to be released and their occupation, so that efforts may be made to place them elsewhere, thus retaining in railroad service, men who have been trained and are proficient in that line of work."

APPRENTICE SYSTEM MAY BE EXTENDED

Frank McManamy, assistant director of the division of operation of the Railroad Administration, has been designated by the administration to confer with the government Board for Vocational Education on plans for the co-operation of the Railroad Administration in the development and extension of the apprentice system for training railway employees. The board has been in existence for about a year, having been appointed for the purpose of investigating and recommending methods of vocational education. Mr. McManamy, held his first conference with the board early in December.

WAGE INTERPRETATION

Interpretation No. 2, to Supplement No. 7 to General Order No. 27:

Question:—Shall employees coming under the provisions of paragraph (a) Article V, Supplement No. 7 to General Order No. 27, paid on a tonnage or piece-work basis and earning in excess of 43 cents per hour (the maximum rate established) receive any portion of the increase provided for, if thereby such increase would establish a rate in excess of 43 cents per hour.

Decision:—Paragraph (2) Article V of Supplement No. 7 to General Order No. 27 specifically states, "Provided that the maximum shall not exceed 43 cents per hour." Employees paid on a tonnage or piece-work basis whose average hourly earnings, per day period, equal 43 or more cents per hour are therefore not entitled to any portion of the increase, but are guaranteed not less than 43 cents per hour.

The provisions of paragraph (2) Article VIII, Supplement No. 7 to General Order No. 27, protects higher rates and is to be observed.

MATERIAL STANDARDS FOR FREIGHT CAR REPAIRS

Frank McManamy, assistant director of the Division of Operation, has issued Mechanical Department Circular No. 8, prescribing material standards for freight car repairs as follows:

When renewing parts or applying betterments to freight cars owned by the railroads under federal control, if suitable material, either new or second hand, that is standard to the car, is in stock it shall be used. Where such material is not in stock, material standard to United States standard cars should be used if available.

1. *Bolsters*—Body bolsters, when renewals are made, should be either cast steel or built-up type.

Truck Bolsters—When renewals are made should be cast steel box girder type.

2. *Column Castings*—Truck column castings when used should be made of malleable iron or cast steel.

3. *Side Bearings*—If body or truck side bearings require changing or renewing, frictionless type should be used, interchangeable in capacity and dimensions with those used on United States standard cars.

4. *Side Truck Frames*—When necessary to renew side truck frames, cast steel U-shaped section, United States standard car type with separable journal boxes to be used.

5. *Coupler Operating Device*—Coupler operating device to be of type directly connected to coupler knuckle lock without use of clevis, link, chain or pin and to be interchangeable with operating device on United States standard cars where possible.

6. *Draft Gears*—(a) Friction draft gears, either Cardwell, Miner, Murray, Sessions Type "K," Westinghouse or similar gears, of not less than 150,000 lb. capacity with a maximum travel of 2¾ in.

(b) Spring draft gears, if used, to be at least equal in capacity to two M. C. B. Class "G" springs, interchangeable with friction gear without change in car construction.

(c) Clearance between coupler horn and striking casting to be three inches.

(d) Coupler to be key connected to draft gear.

7. *Hand Brakes*—If renewals are required on open top cars, hand brakes should be changed to drop handle type and so located as to be below top of car where construction of car will permit and of a type interchangeable with United States standard cars.

8. *Doors*—Side doors on box or stock cars (except double-deck stock cars) will be bottom supported, the attachments uniform with those on United States standard cars.

9. *Ends*—Box cars with weak constructed ends requiring two-thirds of end to be renewed, should be reconstructed as follows:

(a) Horizontal corrugated steel ends (two or three piece) having top section 3/16 in. thick and bottom section or sections ¼ in. thick and corrugations 2¼ in. deep.

(b) Vertical reinforced ends with four or five-inch Z-bars, securely fastened to place on end sills and end plates. End plates to be diagonally braced on inside of car, under roof, to side plates, or with reinforcements equivalent in strength.

(c) End lining to be 1¾ in. thick, tongued and grooved, extending from floor to end plate, with corners sealed with beveled corner strips 1½ by 1½ in., securely nailed to place to prevent possibility of grain leaks.

10. *Metal Strap to be Applied to Side Sheathing*—Double sheathed box cars will have applied to face of sheathing of car at side sill a small angle iron, channel iron or strap securely bolted in place to insure sheathing being held tight against side sill to prevent grain leakage; bolts to have single nuts and to be riveted over. Location of bolt spacing to be the same as on United States standard cars where practicable. Channel or strap to be painted on back with freight car paint before it is applied.

11. *Grain Door Nailing Strip*—Door post should have grain door nailing strips on inside face (approximately 1½ in. by 3½ in.), full height of door opening securely fastened to place with screws or heavy wire nails.

12. *Roofs*—When roofs are changed or renewed outside flexible type metal roof with mullions between roof sheets and with flexibility at eaves and ridges, made of 22 or 24 gage galvanized iron will be applied. Roofs should be interchangeable with United States standard cars having same length and width sheets. To permit the use of standard sheets, the following changes may be made:

(a) Increase or decrease in thickness, or omitting eave molding, fascia or both.

(b) Increase the width of roof flashing at eaves.

(c) Where cars are equipped with all-metal roofs, such construction may be continued when renewals are necessary, if considered desirable to do so.

13. *Preservation of Material*—When rebuilding or repairing wood or steel cars—On all-wood cars, wood preservative, freight car paint or its equivalent will be applied to all mortises and tenons; ends of posts and braces; and post and brace shoes at sills. Top of all sills will be painted, including face of side and end sills.

(a) On refrigerator cars, sills will be painted all over in addition to the above.

(b) When applying metal parts on outside of wood cars, both the wood and metal part shall be painted before applied, except when applying metal roofs. Before outside metal roof is applied it should be painted on underside.

(c) Steel cars, steel underframes, steel center sills or steel draft arms, when assembling should have red lead applied to the surfaces before one metal part is applied, lapping another.

In complying with the above instructions, it is imperative that careful consideration be given to preservation and reclamation of material. Material removed from one car, in order to standardize such car or a part thereof, fit for further use, shall be reclaimed and used in making repairs to other equipment.

REPAIRS TO FREIGHT CARS

The Division of Operation has issued a revision of Circular No. 20, regarding the limit of cost for repairs to freight cars in which rule No. 7 is changed to read as follows:

"When the cost of repairs in kind exceeds the amount which may be expended and betterments are not to be applied, repairs will not be made. The federal manager, or general manager on roads having no federal manager, will endeavor to secure an agreement with the owning corporation that such cars may be dismantled upon the basis of settlement established in the current Master Car Builders' Association rules. When such agreements have been secured he may authorize in writing that the car will be dismantled. If such an agreement has not been secured the car will not be dismantled, but will be held for disposition and the regional director advised."

DESIGNS FOR PASSENGER CARS

The Committee on Standards of the mechanical department of the Railroad Administration at a meeting in Washington last week agreed upon the floor plan and general designs of the proposed standard 70-ft. passenger coach and the 70-ft. combination passenger, baggage, mail and express cars. The general designs and the specialties selected follow very closely those approved for the proposed standard baggage cars.

ORDERS OF REGIONAL DIRECTORS

Rental Charge for Locomotives.—In Order 126 the Southwestern regional director announces that the rate for the rental of locomotives to industries and small lines has been set at one-tenth cent per pound of tractive power per day, with a minimum of $30 per day. This rate of rental will apply in all cases where locomotives are loaned to any such industries or small lines.

Working Hours in Shops.—In Supplement 1 to Order 141 the Southwestern regional director issued instructions regarding the period to be allowed for meals in roundhouses and other places where three eight-hour shifts are worked. Most of the agreements which are in effect provide for a lunch period of not to exceed 20 minutes, with pay, for men who are working one of the eight-hour shifts. Men who are employed in shops or roundhouses or other places where less than three shifts are worked generally have a meal period of not to exceed one hour without pay. These practices, pending further action by the Railroad Administration, will govern except when more favorable conditions are provided by the agreements in effect.

M. C. B. Brake Shoe Keys.—The Eastern regional director, file 500-70A348, advises that the executive committee of the Master Car Builders' Association calls attention to the fact that a great number of brake shoe keys are being made which do not conform to the Master Car Builders' standard, and which are made, in many cases, of inferior material. The substitute brake shoe keys are of numerous types, with the result that they work down from the lugs of the brake head and shoe, resulting in loss of the shoe and key. Brake shoes should not be applied unless the key is provided with a head, and of sufficient strength for the service, as is shown on Master Car Builders' Sheet No. 17, Volume 51, of the Master Car Builders' Association proceedings.

Placing of Common and Semi-Skilled Labor on an Eight-Hour Basis.—The Eastern regional director, file 1200-4-56A352, states that it has been brought to his attention that in applying Interpretations No. 1 to Supplements Nos. 7 and 8 to General Order No. 27 very substantial increases will be given to the various classes of common labor where heretofore paid on an hourly or daily basis. The indications are that labor conditions will be very much improved within the next week or two, and it appears that this would be an opportune time to place all maintenance of way, common and semi-skilled labor, also other classes of common labor, on an eight-hour basis.

Removal of Coal and Water from Engines.—The Eastern regional director, file No. 500-1-68A336, orders that when engines are moved dead to repair shops it is desired that coal and water be removed before shipment is made.

Violations of Safety Appliance Laws.—In Order 144 the Southwestern regional director states that numerous violations of safety appliance laws and of the director general's order No. 8 are being reported by traveling federal inspectors. He directs that immediate action be taken effectively to stop these violations; car and mechanical department heads should be given to understand that the federal laws and the orders of the director general must be observed.

Car and Locomotive Orders in 1918

The Railroad Administration and the Director General of Military Railways Are the Principal Buyers

The number of locomotives reported as having been ordered during the 12 months of 1918, according to figures compired by the Railway Age, was 4,888, of which 2,802 were on domestic orders for companies in the United States and Canada, and 2,086 were on orders for shipments to other countries. These figures compare with a total in 1917 of 6,142, of which 2,704 were on domestic orders and 3,438 were for export, principally to the war zone in France.

The leading feature in the locomotive market during the past year, as in every other essential industry in the country, was the predominance of government orders. Of the 2,593 locomotives reported as having been ordered for service in the United States (excluding the domestic orders for Canada), no less than 2,030 were included in the orders for standard locomotives placed by the United States Railroad Administration. Of the 209 locomotives ordered for roads in Canada 195, or practically all, were ordered by the Canadian government for the Canadian Government Railways.

Table I—The Locomotive Orders in 1918

Domestic—		
United States Railroad Administration	2,030	
Other railroad orders	525	
Industrials, etc.	38	
Total United States	2,593	
Canadian railroads	209	
Total domestic		2,802
Foreign—		
Director General Military Railroads	1,404	
Other foreign	682	
Total foreign		2,086
Total of all orders		4,888

Of the total of 2,086 locomotives ordered for export, no less than 1,404 were on orders for the United States military railroads, this figure excluding those orders that were cancelled after the signing of the armistice. The remainder of the orders for export also included a considerable number of locomotives for foreign governments—South Africa, England, Chili, China, Italy, etc.

The number of locomotives ordered for domestic service in 1918, inclusive of the Canadian orders, as will be seen from Table II, was greater than last year but not as great as 1916. It was greater than the totals of domestic orders in 1914 and 1915, which were poor years. It was only about 1,700 less than in 1912 and bears no comparison whatever to the big totals of 1905 and 1906. The orders for export were likewise not as great as in 1917. They bade fair to be much the same as those of that year, but the signing of the armistice put an end to the placing of further orders for the United States military railroads and resulted in cancellations of orders already placed, amounting to 1,500, in the latter part of November.

Table II—Domestic Orders for Locomotives Since 1901

Year	Locomotives	Year	Locomotives
1901	4,340	1910	3,787
1902	4,665	1911	2,850
1903	3,283	1912	4,515
1904	2,538	1913	3,467
1905	6,265	1914	1,265
1906	5,642	1915	1,612
1907	3,482	1916	2,910
1908	1,182	1917	2,704
1909	3,350	1918	2,802

Table III gives a resumé of the standard locomotives delivered to December 21, 1918. It will be noted from this table that the American Locomotive Company produced by far the larger proportion of the 678 that had been completed to date. The Baldwin Locomotive Works, which produced only 112, was engaged for several months almost entirely

				1918†	3,668	2,807	6,475

* Includes Canadian output.
† Includes Canadian output and equipment built in railroad shops.

compares with a total of 5,446 in 1917, of which 2,585 were for domestic service and 2,861 for export. In spite of the high rate of production which was attained at various times during the year the total was not as great as in the peak years of 1906 and 1907, when 6,952 and 7,362 locomotives were produced respectively.

FREIGHT CARS ORDERED IN 1918

Because of the 100,000 standard freight cars ordered by the United States Railroad Administration in 1918, of which, however, only about 12 per cent had been delivered to the end of December, the orders for freight cars in 1918 for domestic service in the United States and Canada were considerably in excess of those of 1917. They were not, however, as great as those of 1916, were only half those of 1912,

Table V—The Freight Car Orders in 1918

Domestic—		
United States Administration	100,000	
United States Army or Navy	740	
Other railroad orders	1,227	
Private car lines and industrials	12,146	
Total United States	114,113	
Canadian railroads	9,657	
Total domestic		123,770
Foreign—		
Director General Military Railroads	36,875	
Other foreign	16,672	
Total foreign		53,547
Total of all orders		177,317

and did not compare at all with those of the big years 1905 and 1906.

The orders for freight cars in 1918 totaled 177,317, of which 123,770 were on domestic orders and 53,547 were on foreign orders, principally for the United States Military Railroads in France. The orders in 1917 totaled 131,558 (excluding the 30,500 Russian cars which were cancelled), of which 79,367 cars were for domestic service and 34,167 were for export, principally for France and the Military Railroads.

The passenger car orders for 1918 were practically non-existent, war-time activities and presumably the omnipresent government desire for standardization not permitting the placing of such orders. The orders for passenger cars

Table VI—The Passenger Car Orders of 1918

Domestic, United States and Canada	131
Foreign	26
Total	157

totaled only 157, including 131 for domestic service and 26 for export, as compared with 1,167 in 1917, of which 1,124 were for domestic service, 6 for the United States Government and 37 for export.

As in the case of locomotives, the predominating feature during the past year, insofar as the orders for freight cars were concerned, was the great proportion the government purchases held to the total orders. Unlike 1917, there were few orders from governments of other countries. The government orders referred to were those placed by our own authorities, either the United States Railroad Administration or the Director General Military Railroads.

Table VII—Domestic Orders for Cars Since 1901

	Freight cars	Passenger cars		Freight cars	Passenger cars
1901	193,439	2,879	1910	141,024	3,881
1902	195,248	3,459	1911	133,117	2,623
1903	108,936	2,310	1912	234,758	3,642
1904	136,561	2,213	1913	146,732	3,179
1905	341,315	3,289	1914	80,264	2,002
1906	310,315	3,402	1915	109,792	3,101
1907	151,711	1,791	1916	170,054	2,544
1908	62,669	1,319	1917	79,367	1,167
1909	189,360	4,514	1918	123,770	131

The year opened very auspiciously with prospects for heavy orders from the railroads, which were soon dispelled with the announcement that purchases for our own railroads would be centralized and placed by the Railroad Administration. It was not until April, however, that orders for 100,000 standard cars were placed, divided as follows:

25,000	40-ton double sheathed box.
25,000	50-ton single sheathed box.
20,000	50-ton composite gondola.
5,000	70-ton low side gondola.
25,000	55-ton hopper.
100,000	

Quantity production on these orders was promised by the Railroad Administration for August, but was not reached until November, and up to December 21, the latest date for which figures are available at this writing, only 11,815 have been delivered.

The orders placed by the Director General Military Railroads totaled 36,875. The first orders this year were in February and totaled about 5,000. In July an order for 10,000 additional was divided among several builders, and

was shortly afterward supplemented by 20,000 more. In September an additional 40,000 cars were ordered, but immediately following the signing of the armistice this last 40,000 was cancelled before production had been begun on them. Table IX, giving a resumé of the orders on hand at the various car building plants of the country as of November 1, contains a column showing the status of the military orders on that date—that is, before any cancellations had taken place. From that column it will be seen that there were then outstanding orders for 85,834 cars. There had been shipped

On November 1 there had been shipped on these orders	20,400	2,575	6,368	8,463	252	2,742	8,943	11,457
Leaving to be shipped	215,214	83,259	24,957	9,076	664	97,258	108,216	106,998

These military cars have been an important factor in the year's business, but they have not been sufficient to impede the production of other cars, and it cannot be said that the car building plants have been particularly rushed at any time.

The resumé of freight car orders on hand on November 1 shows a total of 235,614 cars, of which only 20,400 had been delivered, leaving a total of 215,214 still to be delivered, divided about evenly between foreign and domestic orders. This total represents nearly double as many cars as have on the average been produced annually for the past five years inclusive of 1918. Even with the elimination of such orders for the United States Military Railroads as have been cancelled since November 1, the indications for a big year from the production standpoint in 1919 are very favorable.

The largest single order remaining is, of course, that of 100,000 cars for the United States Railroad Administration. As of November 1, only 2,742 of these cars had been delivered, a figure which had been brought up on December 21 to 11,815. The table headed Standard Car Deliveries to December 21, 1918, will show to what railroads these cars have gone.

FREIGHT CAR PRODUCTION IN 1918

The number of freight cars built in 1918, as shown in one of the tables, totaled 124,708, of which 81,767 were on domestic orders and 42,941 for the United States Military Railroads, or for other foreign service. The total production for 1918 was less than in 1917, when 151,401 cars were produced, of which 119,363 were for domestic and 32,038 were for foreign service. From the standpoint of domestic production, 1918 was one of the low years in the period from 1899 to date, but the production of cars for foreign service was by far the largest yet reported.

The production of passenger cars in 1918 was very low, the total of 1,573 being the lowest since 1901.

Northern Pacific Builds Box Cars

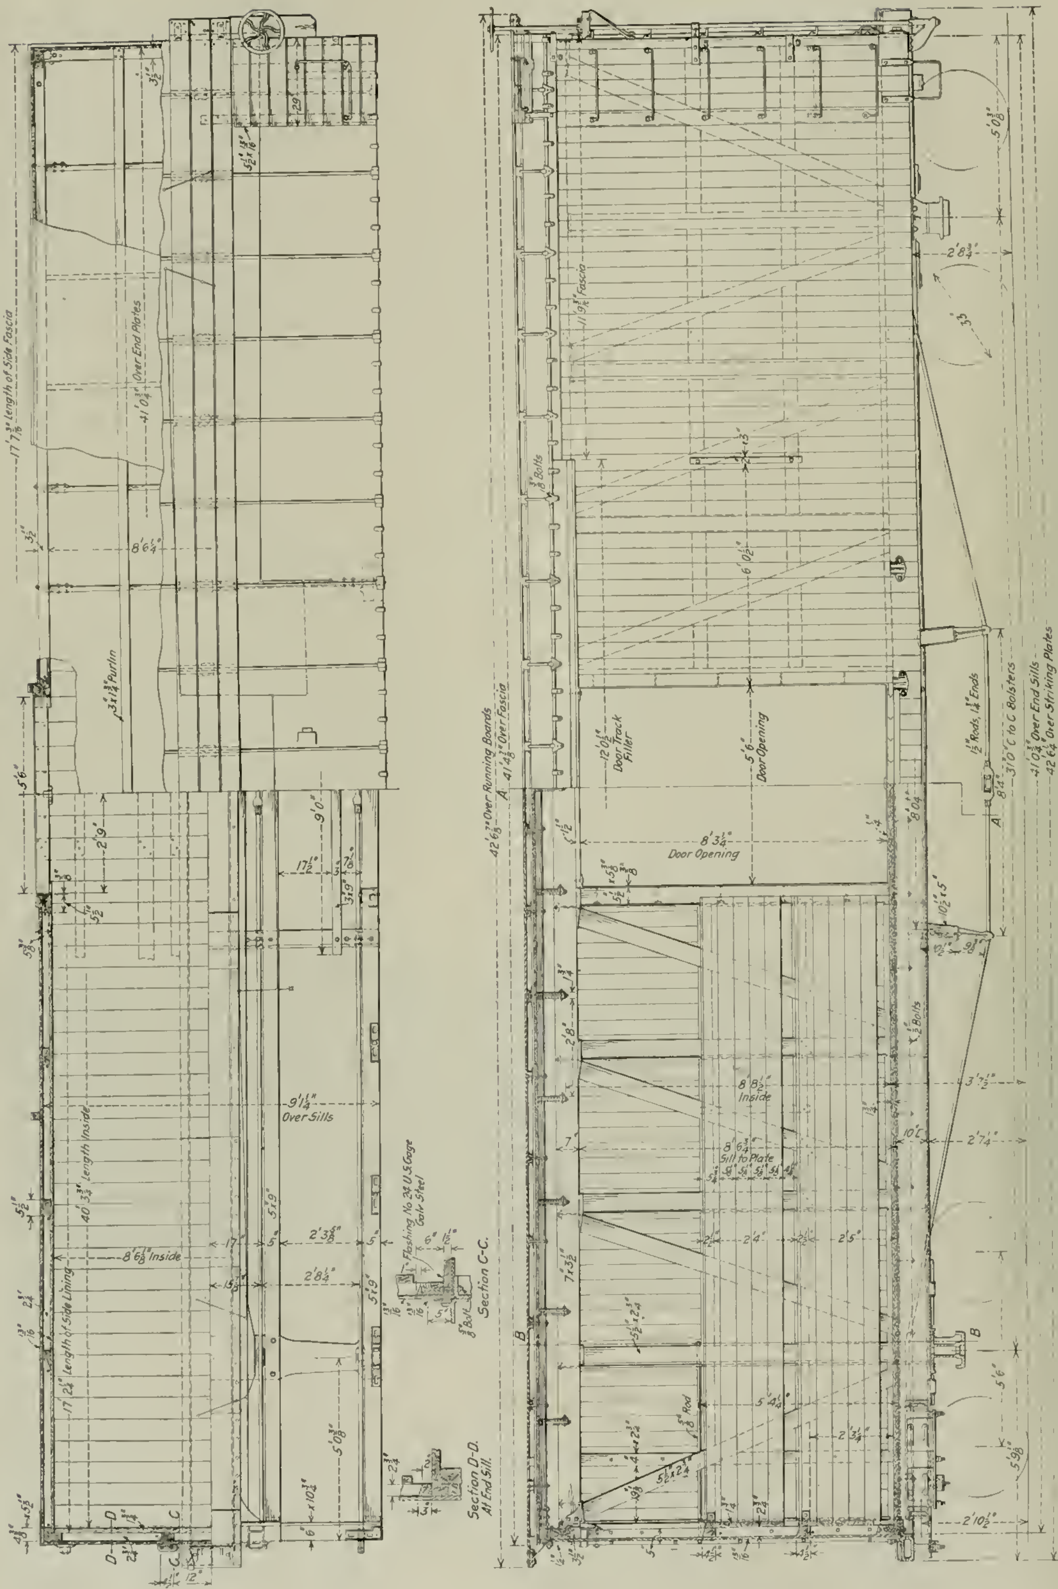
Interesting Design of Underframe and End on Cars Now Being Constructed in Company Shops

The necessity for saving steel in freight cars in every way possible, on account of the large numbers constructed, was quite generally realized during the war. The abnormal shortage in the supply of bars and plates resulted in many interesting designs of rolling stock being brought out. The extent to which wood can well be used varies, of course, with the type of car. The problem under war conditions was to keep down the amount of steel and at the same time provide a car that would not require much labor for upkeep. Man power was as essential as steel in the great conflict. For that reason it was not advisable to save a small amount of steel in building a car that would waste labor as long as it was kept in service.

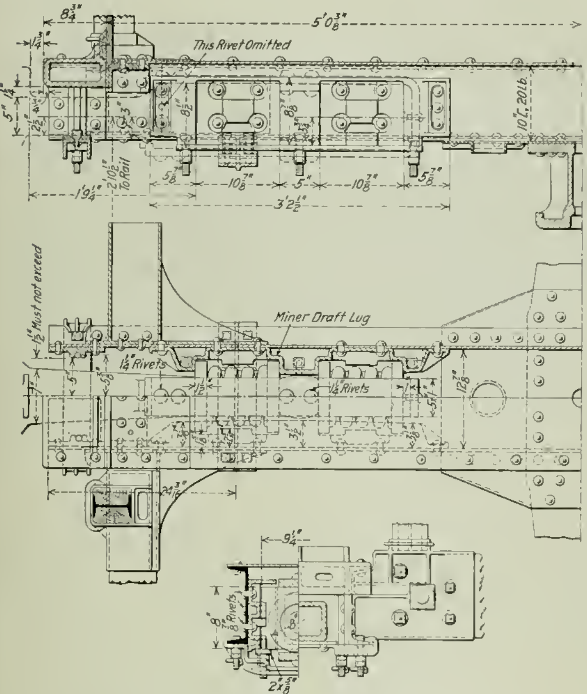
Northern Pacific Box Car of Wood Construction With Steel Center Sills and End Posts.

A good example of a car in which wooden construction is supplemented by the use of a moderate amount of steel in the parts where it is required to enable the equipment to withstand the present severe service conditions, is found in an order of 1,000 box cars of 80,000 lb. capacity now being built by the Northern Pacific. These cars are being constructed at eight different shops on the system where the necessary facilities are available and the building is being carried on as the regular work permits. The use of steel in these cars is confined almost entirely to the center sills and end posts. The cars are 41 ft. ¾ in. long over the end sills, 13 ft. 5½ in. from the rail to the top of the running board and 9 ft. 5⅜ in. wide over the eaves. They have a capacity of 2,990 cu. ft. and weigh 38,600 lb.

The underframe consists of a combination of a steel center sill with wooden side and intermediate sills and truss rods. The center sill is built up of two 10-in. 20-lb. channels, extending continuously the entire length of the car, with top and bottom cover plates. At each end of the channels there is a ¼-in. by 18⅜-in. top cover plate 11ft. ⅜ in. long and above the needle beams there are tie plates ¼ in. by 18⅜ in. by 18 in. On the under side the channels are reinforced for the entire distance between the rear draft lugs. At the center there is a ¼-in. by 18⅜-in. bottom cover plate 25 ft. 6 in. long, while at each end there is a diamond shaped bolster and center sill gusset plate with flanged edges which furnishes diagonal bracing for the body bolster. The draft lugs are of malleable iron of the Miner double pocket type arranged to house two M. C. B. class G springs. The center



Side Elevation and Plan of Northern Pacific Box Car line of draft is three inches from the bottom of the center sill channels. Sharon couplers with 5-in. by 7-in. shanks are used. The buffer castings are of cast steel riveted between the center sill channels and reinforced by a forged angle rivited to the cover plate and sills. The buffer castings and carrier irons are designed to permit the future application of a coupler with a 6-in. by 8-in. shank if desired. In order to bring the 5-in. by 7-in. shank coupler to the proper height a ½-in. filler plate is riveted to the top of the malleable carrier iron. By replacing these plates when worn the standard coupler height can readily be maintained.

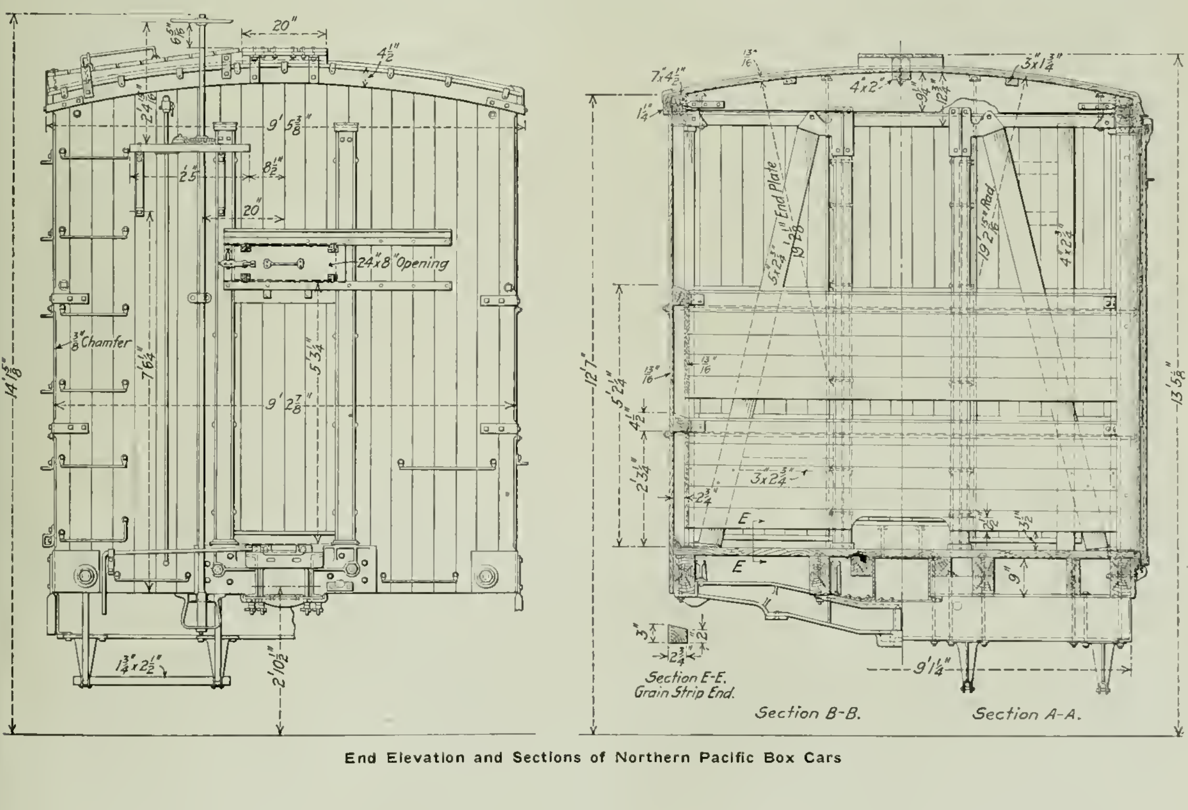


Details of Center Sill End and Draft Rigging

As the side sills are not elevated above the level of the center sills, a continuous end sill cannot be used. The two parts of the end sills, which are of a 6 in. by 10¾ in. section, are fitted into malleable iron castings riveted to the outside of the center sill channels, as shown in the detail drawing of the draft rigging. The two center end posts fit into pockets in these castings. The end sills have pockets bolted to them into which the four 5-in. by 9-in. longitudinal sills are fitted. The sills are supported by the cast steel body bolster, which extends under the center sill, and by two needle beams spaced 8 ft. apart. Just inside of each sill there is a 1½-in. truss rod with 1¾-in. upset ends. In order to strengthen the floor at the door openings, two 3-in. by 9-in. sills, extending 3 in. beyond the needle beams, have been located 7⅛ in. from the side sills. The sills, and all other wooden parts of the car as well, are of fir.

The end framing of the car consists of 4⅜-in. by 5-in. wooden corner posts and two intermediate posts made up of a 5-in. I-beam with wooden fillers on each side. These posts fit into pockets in the castings on the center sills, as already mentioned, and are gained on each side to receive the siding. The upper ends of the posts are set into castings bolted to the end plates into which the 2¾-in. by 5½-in. diagonal braces are also fitted. At one end of the car there is a sliding door 8 in. high and 24 in. wide, 5 ft. 3¼ in. from the floor. The end and side doors have Camel fixtures.

The side framing is made up of 2¾-in. by 5½-in. posts and braces. The door posts are 5½ in. by 5⅜ in. and are reinforced with a 5-in. by ⅜-in. plate flanged against the underside of the side plates and flooring. All the body rods are ⅝ in. in diameter with ends upset to ¾ in. The siding



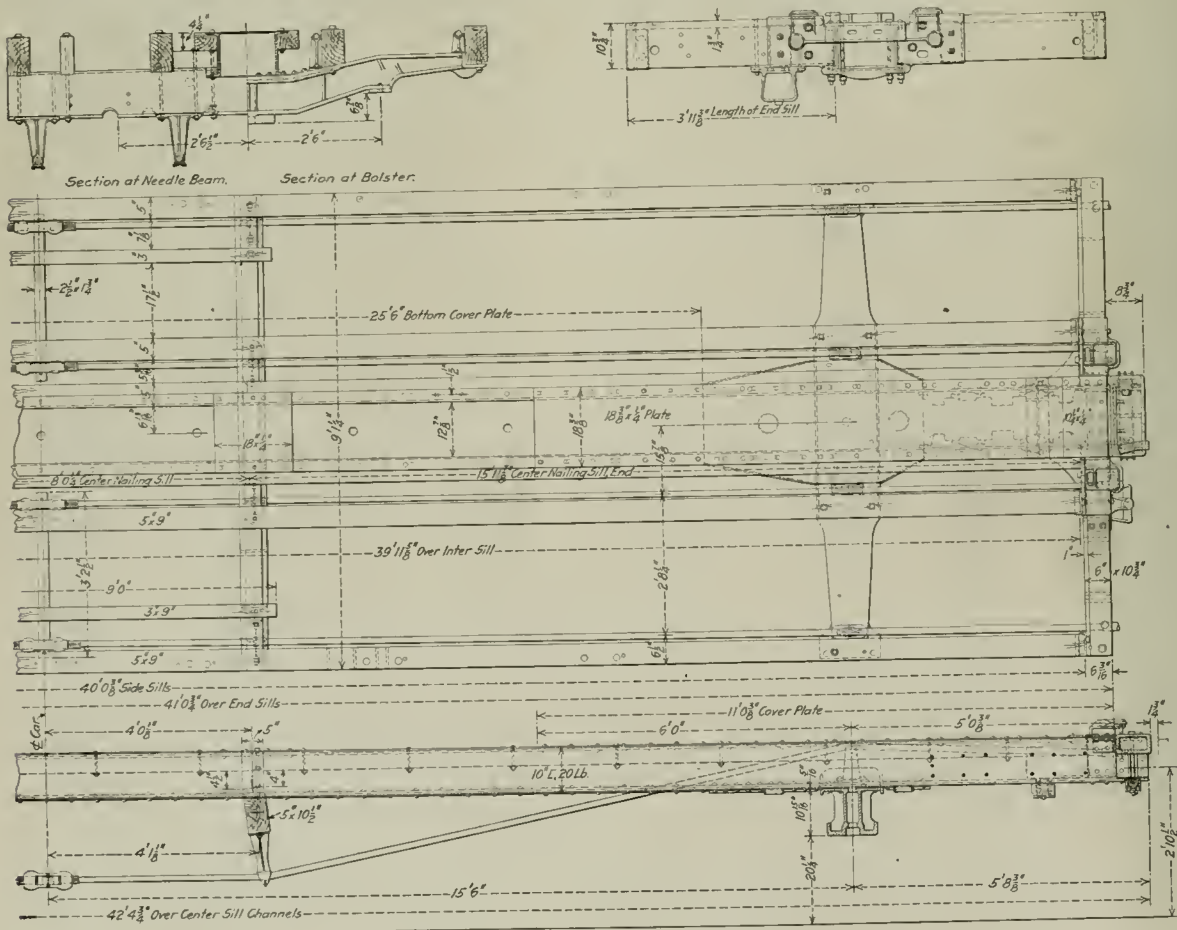
End Elevation and Sections of Northern Pacific Box Cars and the lining are 13/16 in. thick tongued and grooved with the exception of the end lining where 1¾-in. material has been used. There are two belt rails spaced 2 ft. 3¼ in. and 4 ft. 9¾ in. above the floor of a 4½-in. by 2¾ in. section beveled to 3½ in. by 2¾ in. The flooring is 1¾ in. thick, tongued and grooved. Two nailing strips bolted under the top flanges of the center sills, are provided to furnish support for the floor in addition to that given by the sills. The end sill construction makes it necessary to provide special means for insuring that the ends of the car will be grain tight. This is accomplished at the sides by gaining the end sills to receive the flooring. Between the center posts the flooring is laid on the cover plates and the siding is laid up along the edge of the floor. A high grain strip with a flashing of 24 gage galvanized steel under it is bolted into the corner and a filler is nailed between the siding and the rib on the buffer casting, as shown in section *C-C*.

The roof is supported on wooden carlines 1¾ in. wide and 9¼ in. high at the center, tenoned into the side plates. The roof is curved with a radius of 19 ft. 3 in. The roof boards are 13/16 in. tongued and grooved, laid diagonally and continuous from side plate to side plate. An outside metal roof built to Northern Pacific specifications is applied over them.

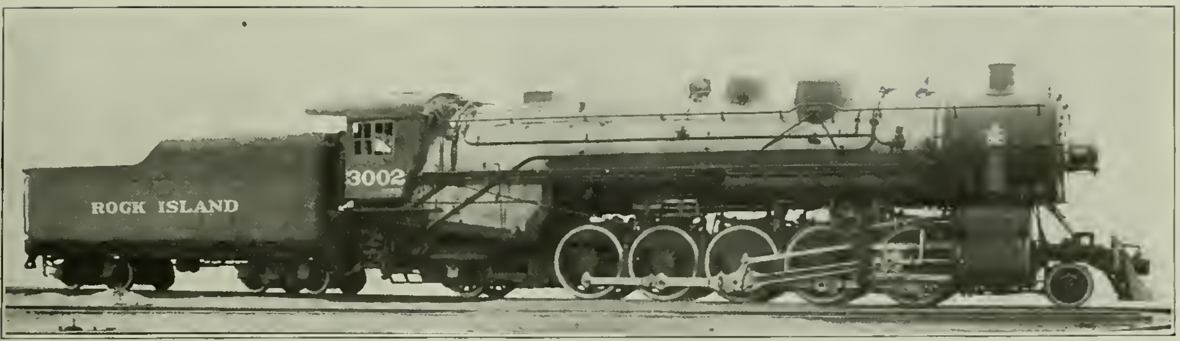
The brake equipment is the Westinghouse Air Brake Company's schedule KC-1012. In connecting the hand brake, the hand brake rod is fastened to one end of an increaser lever, which is fulcrumed at the other end and from an intermediate point is connected to the end of the cylinder push rod by a chain, giving a power ratio of five to two. Trucks of the Bettendorf type with chilled iron

End View of Northern Pacific Box Car

wheels are used under these cars. They are fitted with Barber lateral rollers and Stucki type *C* side bearing. No. 2 brake beams are used and an angle iron safety holder is bolted under the spring plank.



Underframe for the Northern Pacific Box Car

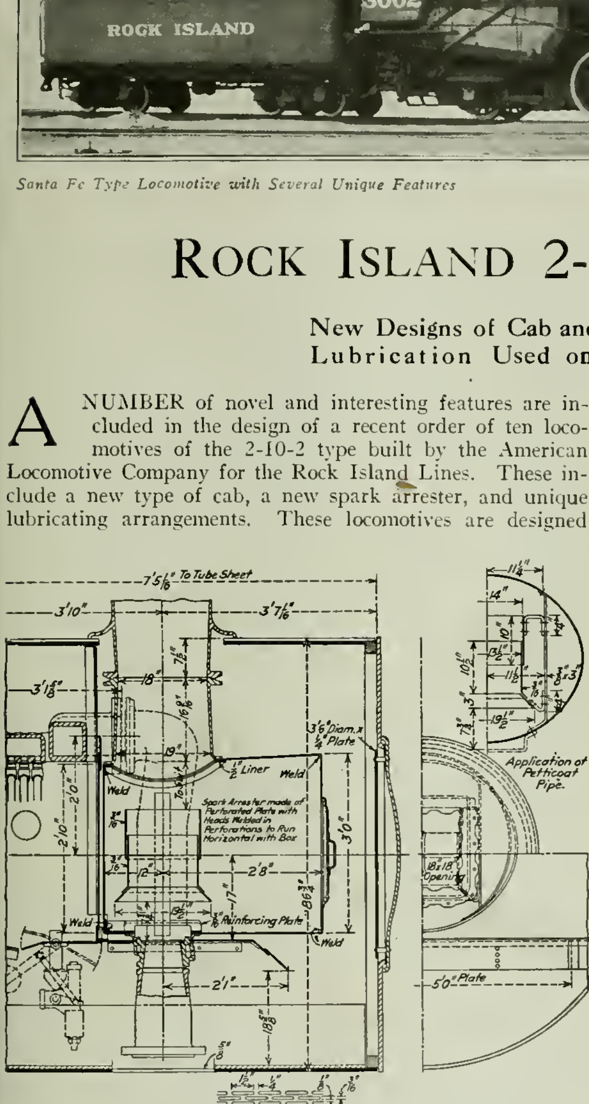


Santa Fe Type Locomotive with Several Unique Features

Rock Island 2-10-2 Locomotive

New Designs of Cab and Spark Arrester; Grease Lubrication Used on Crossheads and Trailer

A NUMBER of novel and interesting features are included in the design of a recent order of ten locomotives of the 2-10-2 type built by the American Locomotive Company for the Rock Island Lines. These include a new type of cab, a new spark arrester, and unique lubricating arrangements. These locomotives are designed

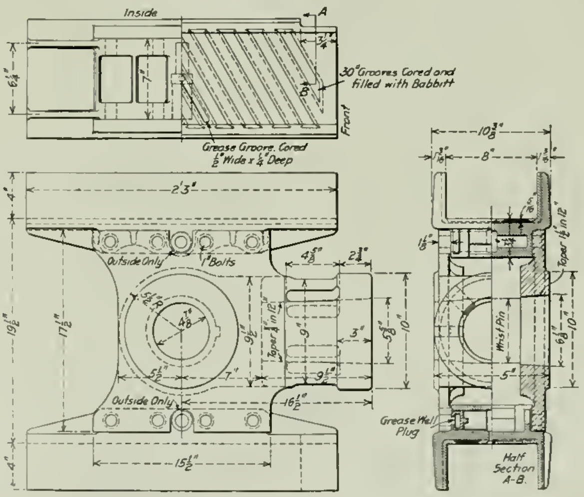


Front End of the Rock Island 2-10-2 Type Locomotives with the Security Spark Arrester.

for a load of 60,000 lb. on each pair of drivers. They are intended to traverse 16 deg. curves and have lateral motion driving boxes on the front axle. Both the front and rear pairs of driving wheels are fitted with Detroit flange lubricators.

The clearances permitted the application of a boiler of large capacity. The boiler horsepower is 96.2 per cent of the cylinder horsepower rating. In the design of the boiler few innovations have been introduced. It is of the conical extended wagon top type with a 5-ft. 4-in. combustion chamber and tubes and flues 2¼-in. and 5½-in. in diameter respectively, 21 ft. 3 in. long. A type *A* superheater with 46 units is applied. The firebox has a Security arch and is fired by a Duplex stoker. The grates are operated by the Franklin power grate shaker.

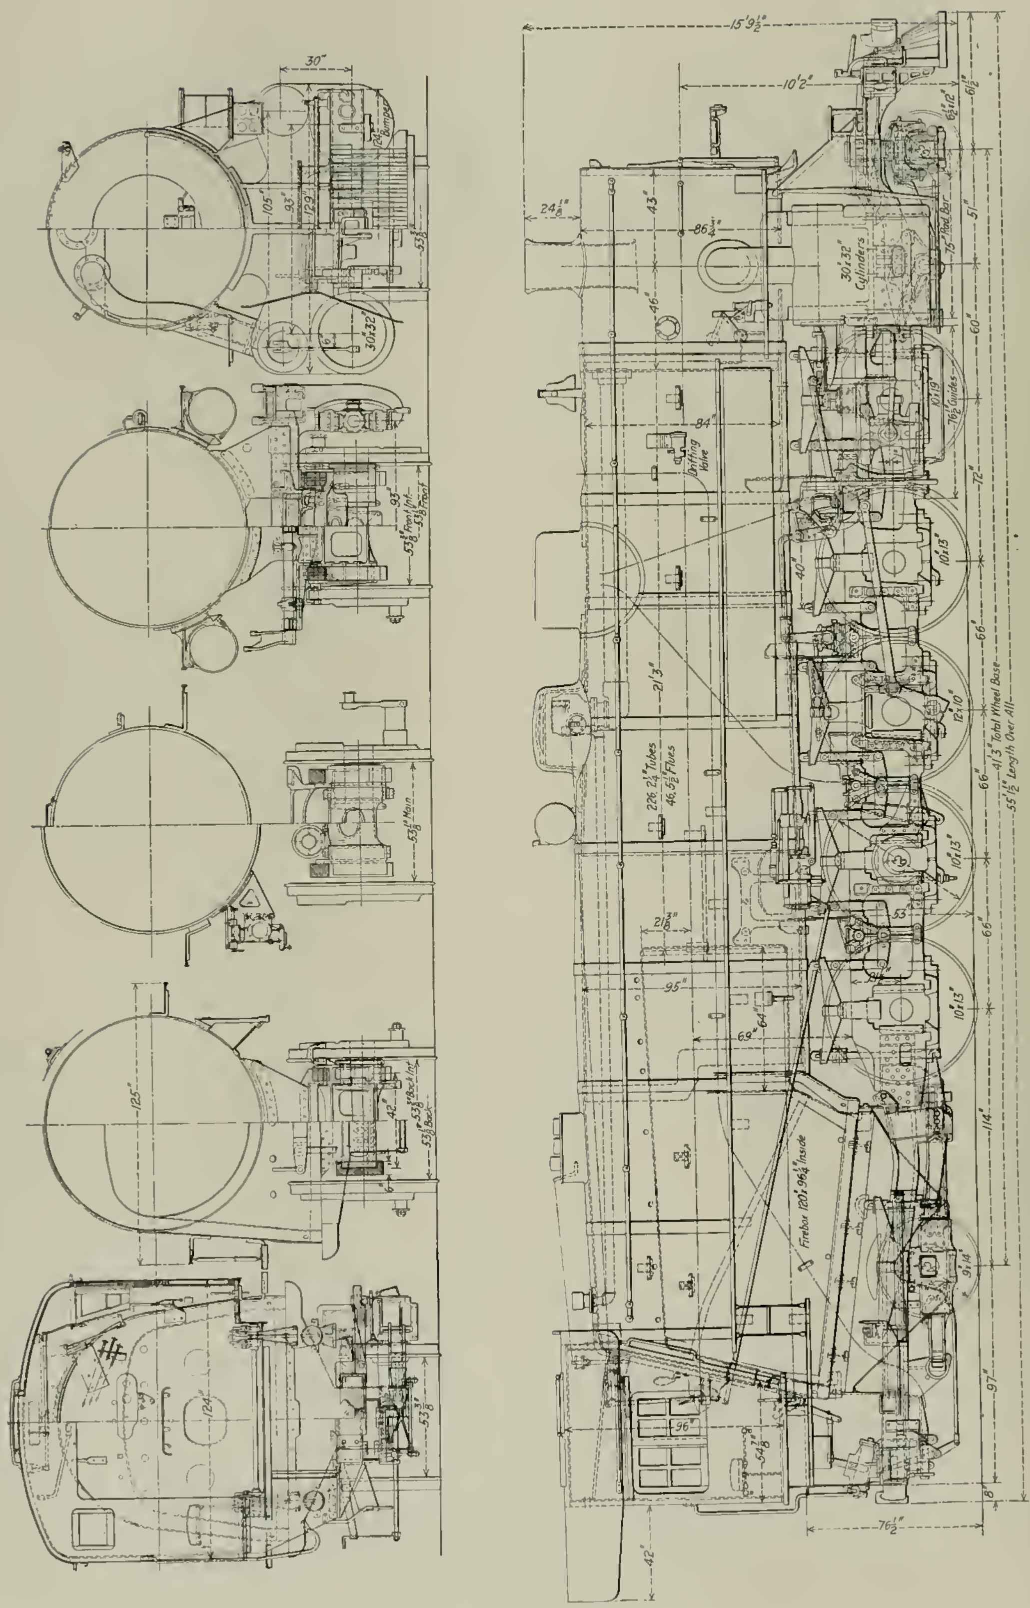
The Security spark arrester which has been in use for several years on the Rock Island Lines is used. This consists of a cylindrical or truncated conical box made of perforated plate or netting, closed at both ends and set between the nozzle stand and the stack extension. The box is reinforced around the openings where it is fastened to these parts. The petticoat pipe is supported on two braces inside the box. At the outer end a sliding door is provided which permits of readily inspecting the box or doing any work inside it. The entire box can be inserted or removed through the smoke-box door. The spark arrester is supported



Crosshead for the Rock Island 2-10-2 Type Locomotives

entirely between the nozzle stand and stack extension. The arrangement of the front end is clearly shown in the illustration.

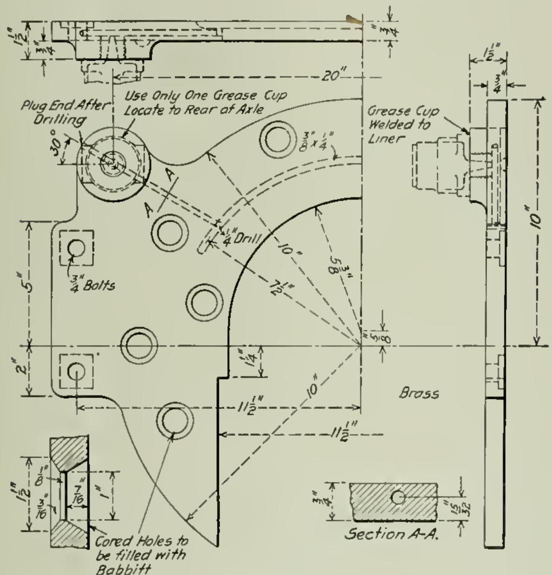
Several months ago the Rock Island applied a new type of cab to a Mikado locomotive. It proved so satisfactory that a similar design is being used on all new power. The front wall of the cab, instead of being vertical, is sloped at



Elevation and Sections of Rock Island 2-10-2 Type Locomotive the same angle as the back-head of the boiler and is set so that it projects forward only a few inches beyond the back-head. With this arrangement all the staybolts in the wrapper sheet are readily accessible for inspection or repairs. The angle of vision through the front cab window is also increased. The front part of the cab, which is eliminated in this design, serves no useful purpose but offers an opportunity for dirt to collect.

The main valves are of the piston type, 14 in. in diameter, and are operated by the Baker valve gear controlled by the Mellin power reverse. The valve chamber and cylinder bushings and piston and valve packing rings are of Hunt-Spiller gun iron. The piston rod packing is of the King type. The Nathan Manufacturing Company's drifting valve is used. A McCord force feed lubricator supplies oil to the valves and the lubrication of the air pump and stoker is provided for by the use of a Nathan two-pint two-feed hydrostatic lubricator.

A departure from the usual practice is the application of grease lubrication to the crossheads and trailer box hub-liners, both of which are illustrated below. The crosshead gibs are of gun iron with recesses in the wearing surfaces filled with babbitt. Grease is fed from a well at the center through a single hole to a groove extending across the face



Trailer Box Hub Liner.

of the gib. The hub-liner on the trailer box is fitted with two lugs to one of which is welded a grease cup. The cup feeds grease to the hub-face at a point behind the center line. An annular groove is provided to facilitate the passage of the lubricant.

The ashpan extends out several inches beyond the sides of the firebox and is flanged upward to the level of the mud-ring. This gives a large air opening and at the same time keeps live coals from falling out or being blown out at the sides of the pan. Electric welding has been used to some extent in the construction of the boiler. The door hole is welded, the sheets being flanged inward and welded together. The firebox sheets are also welded to the mudring at the corners.

The tender used with these locomotives has a flanged bottom and is similar to the design recently described in these columns.* It is carried on a cast steel frame. The air connections between the locomotive and the tender are made with Barco flexible metallic joints of the 3V type.

Among the specialties not already mentioned applied to these locomotives are Westinghouse *ET* No. 6 brakes with an 8½-in. cross-compound compressor, Commonwealth locomotive cradle castings, Miner *A*-18 draft gear, Chambers throttle valves, Pyle-National headlights, Economy radial buffers, Nathan non-lifting injectors, Sellers coal sprinklers, Ashton safety valves and Viloco *II* double type sander.

The principal dimensions, weights and ratios are given below:

General Data	
Gage	4 ft. 8½ in.
Service	Freight
Fuel	Bituminous coal
Tractive effort	71,900 lb.
Weight in working order	383,000 lb.
Weight on drivers	302,500 lb.
Weight on leading truck	26,000 lb.
Weight on trailing truck	54,500 lb.
Weight of engine and tender in working order	572,900 lb.
Wheel base, driving	22 ft. 6 in.
Wheel base, total	41 ft. 3 in.
Wheel base, engine and tender	80 ft. 2¾ in.

Water capacity	10,000 gal.
Coal capacity	16 tons

* Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.
† Includes combustion chamber and arch tube heating surfaces.

A Miniature Motor.—An electric motor of extremely small dimensions has appeared on the market in Germany. The motor is enclosed in a shell of 3 cm. diameter and 4 cm. length and weighs 150g. The shaft is arranged so as to hold tools that are required by dentists and surgeons, but the device should be of great use for other purposes, such as boring small holes in metals and rare stones. The motor can be driven by direct or alternating current, and runs at a maximum speed of 5,000 r.p.m.—*The Engineer, London.*

Locomotive Feed Water Heating*

Discussion of the Exhaust Steam and Waste Gas Methods of Preheating for Locomotive Boilers

BY H. S. VINCENT

II.

In a feed water heater using waste gases as the heating medium, due to the relatively slow absorption of the heat, it is necessary to greatly increase the heating surface over that required for an exhaust steam heater. This is usually accomplished by applying a large number of tubes of small bore, as by this means the maximum heating surface can be obtained in a given area.

Fig. 9 illustrates in diagrammatic form the heater on which the present study is based. This is composed of 320 tubes, one inch (outside diameter), 6 ft. long, with walls .095 in. thick, giving a total heating surface of 407 sq. ft. These tubes are surrounded by a casing through which the smokebox gases circulate. They are fixed at each end into headers, these headers being divided into ten compartments, in each of which are 32 tubes.

The feed water enters the lower compartment of one header, flowing thence through the 32 tubes to the opposite header, traversing in this way, the heater, ten times before passing into the boiler.

As a basis for determining the transmission of heat from waste gases into the feed water, we will consider the known evaporative capacity of a boiler tube under similar conditions.

When evaporating 54,400 lb. of water per hour, the locomotive under consideration showed a smokebox temperature of approximately 600 deg., and this temperature will be assumed in the present calculations.

From Bulletin 1017, published by the American Locomotive Company, we find that the evaporative value of tubes 2 in. diam. 18 and 19 ft. long, is respectively 79.5 and 81 lb. of water per hour. The difference or 1.5 lb. equals the evaporative value of that portion of the tube one foot long which is subjected to a gas temperature of 600 deg.

With steam at 205 lb. pressure and feed water at 60 deg., the B. t. u. content imparted to the water in the boiler, per second, is:

$$\frac{(1{,}198.5 - 28.08) \times 1.5}{3{,}600} = .488 \text{ B. t. u.}$$

for the total temperature difference; or a heat transmission of:

$$\frac{.488}{600 - 390} = .002325 \text{ B. t. u.}$$

per second per degree of temperature difference.

The heating surface in one foot of 2 in. boiler tube is .523 sq. ft.; therefore the conductance of the boiler tube is;

$$\frac{.002325}{.523} = .00445 \text{ B. t. u.}$$

per second, per sq. ft. of heating surface, for one degree temperature difference.

From tests made by Geo. L. Fowler, on a Jacobs-Schupert boiler when working at capacity, it was found that the average velocity of the flow of water parallel to the longitudinal center of the boiler, was about .65 ft. per second. This record was obtained at a point near the water leg, but we can assume without serious error, the same velocity at a point 18.5 ft. ahead of the back tube sheet.

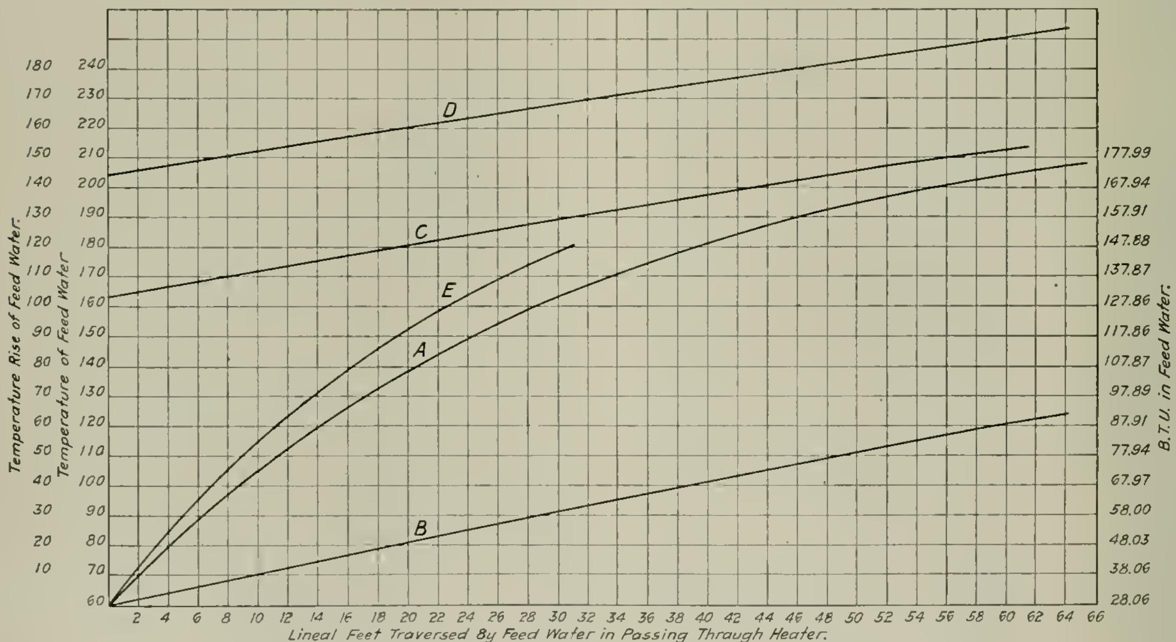

Fig. 6—Rise in Feed Water Temperature Per Lineal Foot of Feed Water Heater Pipes

*The first part of this article, discussing the exhaust steam method of preheating was published in the December *Railway Mechanical Engineer* on page 645.

The weight of water passing through the feed heater is 15.35 lb. per second; the volume per foot of the 32 tubes forming each pass is .1145 cu. ft. and the weight of water per foot entering the heater is 7.14 lb., the velocity in feet per second through each pass is:

$$\frac{15.35}{7.14} = 2.15 \text{ ft.}$$

Referring again to the experiment of Clement and Garland, Fig. 8 gives the relation found between the velocity of the feed water and the conductance of the metal in the tube plus the film on the water side. It is evident that this conductance is independent of the heating medium and that the low heat transmission with gases is due solely to the high resistance of the film on the gas side. The value of this resistance may be determined by the following method.

Reading from the Fig. 8 we find at a water velocity of .65 ft. per second, a conductance through the tube and water film of .1635 B. t. u. per second. The conductance of the boiler tube has been found to be .00445 B. t. u. As the resistance to heat transfer is the reciprocal of the conductance, we have:

$$\frac{1}{\frac{1}{.00445} - \frac{1}{.1635}} = .00458 \text{ B. t. u.}$$

or the conductance of the film on the gas side.

In the Clement and Garland experiment, the thickness of the tube walls was .134 in. with a conductance through the metal of 1.204 B. t. u. With tubes .095 in. thick, the conductance of the metal is:

$$\frac{1}{6.2 \times .095} = 1.697 \text{ B. t. u.}$$

Referring again to Fig. 8, in which the water film is plotted in relation to the velocity of the feed water, we find, for a water velocity of 2.15 ft. per second, a conductance of .227 B. t. u. Combining this with the conductance of the tube, we have:

$$\frac{1}{\frac{1}{1.697} + \frac{1}{.227}} = .200 \text{ B. t. u.}$$

or the total conductance of a tube .095 thick plus the water film. Carrying this further, knowing the conductance of the gas film, we have:

$$\frac{1}{\frac{1}{.200} + \frac{1}{.00458}} = .00448 \text{ B. t. u.}$$

or the conductance of metal, gas and water films.

Having established the conductance we can now determine the quantity of heat transmitted to the feed water by the proposed heater, using equation (5).

Assuming as in the case of the exhaust steam heater that the feed water enters the heater at a temperature of 60 deg., corresponding to a thermal content of 28.08 B. t. u. and with the average temperature of the heating gases 600 deg., the heat absorbed per lb. of feed water during its traverse through the first pass, or the first six lineal feet, is given by the following equation:

$$Q = \frac{k^{\circ} A\, hm\, L}{s\, w'} \quad \ldots\ldots (8)$$

s = Velocity of water in feet per second.
w' = Weight of water in L ft. of the heater.
L = Number of lineal feet through which the heat transfer is in progress.

Using the quantities as determined above:

$$Q = \frac{.00448 \times 40.7 \times (600 - 63) \times 6}{2.15 \times 42.84} = 6.37 \text{ B. t. u.}$$

Or at the end of the first pass the heat content of the feed water is 28.08 + 6.37 = 34.45 B. t. u. corresponding to a temperature of 6.64 deg.

By a similar step by step process it will be found that at the end of the tenth pass or 60 lineal feet, the thermal content of the feed water has risen to 88.76 B.t.u. corresponding to a temperature of 120.7 deg.

This increase in temperature and thermal value is shown graphically by curve *B* in Fig 6. It will be observed that

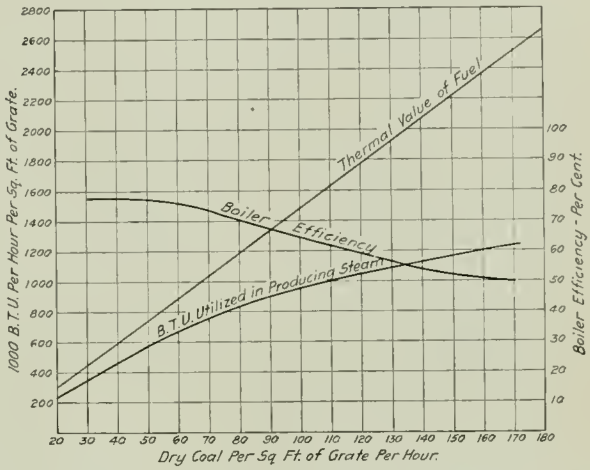

Fig. 7—Efficiency Curves of a Locomotive Boiler Without a Feed Water Heater

this curve is practically a straight line, indicating that in this type of heater the temperature rise is nearly proportional to the heating surface traversed by the feed water.

In the above calculations it has been assumed that the velocity of the gases through the heater will be equal to that through the boiler tubes.

The direct economy obtainable is given by equation (7).

Applying this equation, we find for a heater of the type

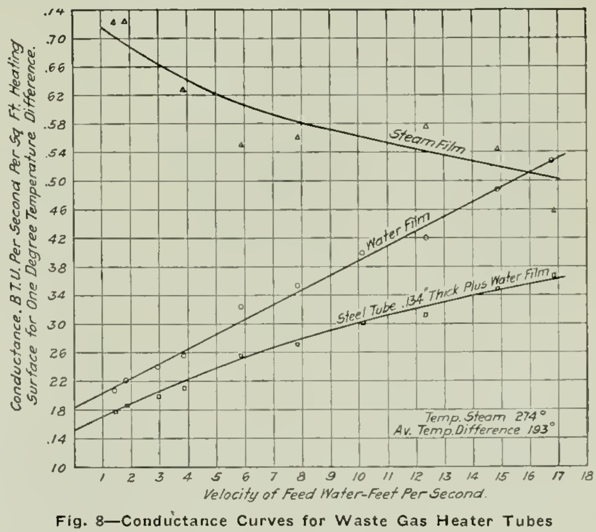

Fig. 8—Conductance Curves for Waste Gas Heater Tubes

and proportions illustrated by Fig. 9, a direct economy of:

$$100 \frac{1{,}170.42 - (60.68 - 20.48)}{1{,}170.42} = 3.4 \text{ per cent.}$$

In these calculations it has been assumed that a feed pump will be used for forcing the water through the heater, using 1.75 per cent of the total amount of steam generated.

The direct economy which is obtained by feed water heating with waste gases reduces the unit fuel consumption to:

$$\frac{120 \times 1{,}130.2}{1{,}170.42} = 116 \text{ lb.}$$

Referring to Fig. 7, it will be seen that the ordinate for a unit fuel consumption of 116 lb. crosses the boiler efficiency curve at 60 per cent, as the efficiency when burning 120 lb. is 59 per cent, the indirect economy equals 1 per cent, or a total economy for the waste gas heater of 4.4 per cent.

The relatively great difference in the temperature of the exhaust steam and the smokebox gases makes possible a further economy through arranging the heaters in series with the exhaust steam as the primary and the waste gases as the secondary heating medium. We have seen that the temperature of the feed water issuing from the exhaust heater having 30 lineal feet traverse, is 163.3 deg., with a total thermal content of 131.16 B.t.u. If this water on passing from the exhaust heater is made to traverse the waste gas heater, it will attain a final temperature of 213.65 deg. with a thermal content of 181.65 B.t.u.

This increase in temperature is shown by curve *C* on Fig. 6; it will be observed that with the decreased temperature head between the waste gases and the feed water, the curve still approximates a straight line.

The direct economy by series heating is:

$$100 - \frac{1{,}170.42 - (153.57 - 20.48)}{1{,}170.42} = 11.5 \text{ per cent.}$$

and the fuel consumption is reduced to:

$$\frac{120 \times 1{,}037.33}{1{,}170.42} = 106.5 \text{ lb.}$$

From diagram Fig. 7 the ordinate for a unit fuel consumption of 106.5 lb. crosses the curve at an efficiency of 62.7 per cent, or an indirect saving of 3.4 per cent; this, added to the direct economy, equals 15.2 per cent.

By placing the waste gas heater in series with the exhaust heater having a traverse of 60 lineal feet, the temperature of the feed water would be increased to 250.25 deg., and the thermal content to 218.76 B.t.u. The direct economy would be:

$$100 - \frac{1{,}170.42 - (190.68 - 20.48)}{1{,}170.42} = 14.5 \text{ per cent.}$$

The unit fuel consumption would be reduced to:

$$\frac{120 \times 1{,}000.22}{1{,}170.42} = 102.3 \text{ lb.}$$

From Fig. 7 the ordinate for 102.3 lb. crosses the efficiency curve at 64 per cent, therefore the indirect economy is 5 per cent, and the total economy 19.5 per cent.

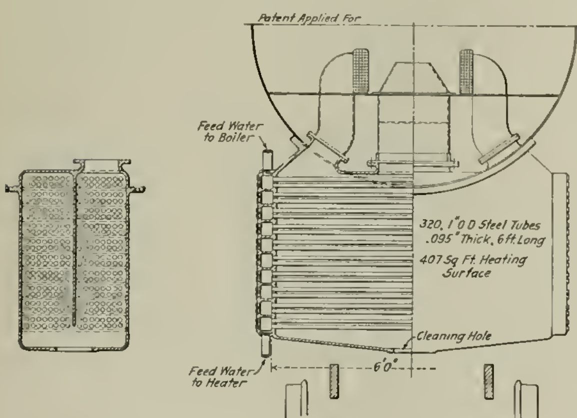

Fig. 9—A Type of Waste Gas Feed Water Heater

The constant steam consumption of 1.75 per cent, which has been assumed for the feed pump, may be increased when forcing the water through the two heaters in series, in which case the figured economy will be slightly decreased.

Table II presents a summary of the results obtained in this study of the various types of heaters, as compared with a locomotive not so equipped, but fitted with the ordinary injector. It will be observed that with the injector the water enters the boiler at practically the same temperature as from the exhaust steam heater having 30 lineal feet traverse, there is, however, with the injector no economic gain, as the heat given up by the steam is equal to the heat given to the feed water plus the external work done; this amounts to a loss in the present instance of approximately .7 per cent. In this table is shown the area of exhaust nozzle required with the various rates of combustion, to produce the necessary draft.

Table II

	Without heater	Exhaust steam heater 30 lin. ft.	Exhaust steam heater 60 lin. ft.	Waste gas heater 60 lin. ft.	Series heaters. Waste gas and exhaust steam 30 lin. ft.	Series heaters. Waste gas and exhaust steam 60 lin. ft.

The thermal balance sheet for the exhaust steam heater, having 60 lineal feet traverse, in series with the waste gas heater, is shown in Table III. This gives the percentage of total heat supplied by the boiler and the two heaters, also as divided between the engine and the feed pump, during one hour's operation. Instead of the boiler having to supply 63,669,760 B.t.u., as in the injector fed engine, fuel has only to be burned to supply 54,285,365 B.t.u., or a reduction in unit fuel consumption from 120 lb. to 102.3 lb. per sq. ft. of grate per hour.

Table III

Source of heat	Proportion of total heat supplied	Percentage of total heat supplied	B. t. u. supplied To engine	B. t. u. supplied To pump	B. t. u. supplied To engine and pump
Exhaust steam heater	144.19 / 1,170.42	12.31	7,837,747	142,779	7,980,526
Waste gas heater	46.49 / 1,170.42	3.97	2,517,689	46,046	2,563,735
Boiler	979.74 / 1,170.42	83.72	53,314,324	971,041	54,285,365
		100.00	63,669,760	1,159,866	64,829,626

CONCLUSIONS

Exhaust steam is superior to waste gases as a heating medium due to the low resistance of the steam film to the transmission of heat.

In a heater using exhaust steam the use of copper tubes is to be preferred to steel or iron on account of their higher conductance. Tubes should have walls as thin as is consistent with strength and wearing qualities.

Exhaust steam may be diverted for heating the feed water without detriment to the operation of the locomotive if the area of the exhaust nozzle is decreased to give the required draft. This can be done without any increase in back pressure on the pistons.

An exhaust steam heater such as is shown by Fig. 7, if fitted with copper tubes, will give an economy in fuel of about 11.8 per cent when using 13 per cent of the exhaust steam.

The economy of the heater using waste gases as a heating medium increases nearly in direct proportion to the heating surface. It is very difficult, however, to find space on a locomotive for a heater giving over 5 per cent economy.

High economy may be obtained by using exhaust steam and waste gases in series, but there is not sufficient room on a modern locomotive for such an application.

It is very desirable that further investigation be made of the heat transmitting property of the gas film.

TABLES FOR COMPUTING THE AREA FOR BOILER LAGGING

BY WILLIAM N. ALLMAN

For the purpose of determining the area in square feet required in lagging for boilers, cylinders or other heated surfaces to be insulated, the tables shown will be found convenient. As it is the general practice of the various lagging manufacturers to furnish lagging in six-inch widths, the tables are computed on this basis. In establishing the area required it will be understood there are perfectly flat surfaces, and also curved surfaces to deal with, and naturally, cylindrical or curved surfaces require lagging with curved faces. The thickness of the lagging for the cylindrical sheets is the basis for making the computations and the maximum thickness should always be used. By maximum thickness is meant the thickest end where a tapered sheet is used; for example, a block six inches wide by 36 in. long may be 1½ in. thick on one end, two inches on the other, in which case two-inch thickness is the one to consider.

Table I

Thickness of lagging	Concave Chord	Convex Chord
¾ in. to 15/16 in.	6 in.	6 3/16 in.
1 in.	6 in.	6¼ in.
1 1/16 in. to 1 7/16 in.	6 in.	6 5/16 in.
1½ in. to 1 15/16 in.	6 in.	6⅜ in.
2 in.	6 in.	6 7/16 in.
Over 2 in.	6 in.	6½ in.

Table II—Areas, in Square Feet, for Convex Blocks of Various Radii

In using Tables II and III it is necessary to refer to the key contained in Table I.

It is to be understood that in considering the area of a certain size block for a given radius that the ruling factor is the thickness, regardless of the radius of the particular boiler sheet. Considering the block mentioned above, namely, 36 in. by 6 in. by 2 in., we find in Table I that the convex chord for this thickness is 6 7/16 in. Referring to Table II (6 7/16-in. wide), we find that the area for a block 30 in. long is 1.34114, for a 6-in. block .26822, giving an area of 1.60936 sq. ft. for the entire block. Had the length been 36½ in., the area for a block ½ in. long (.02235) should be added, giving a total area of 1.63171 sq. ft. Should the length be equal to a figure not shown outright in the table, such as 36⅞ in., all that is necessary to do is to take the value of 30 in., 6 in., ¾ in. and ⅛ in. and add them together.

Table III—Areas, in Square Feet, for Straight Blocks, 6 In. Wide

Length in inches	Area in square feet	Length in inches	Area in square feet	Length in inches	Area in square feet
1/64	.00065	3	.1241	30	1.2501
1/32	.0013	4	.16667	40	1.6668
1/16	.0026	5	.20835	50	2.0835
⅛	.00521	6	.25	60	2.5003
¼	.01042	7	.29169	70	2.9169
½	.02083	8	.33336	80	3.3336
¾	.03125	9	.37503	90	3.7503
1	.04167	10	.4167		
2	.08333	20	.83334		

When figuring on lagging for domes and cylinders, which generally runs in one-half the width of the regular boiler lagging, or three inches wide, use just one-half the values shown in the tables.

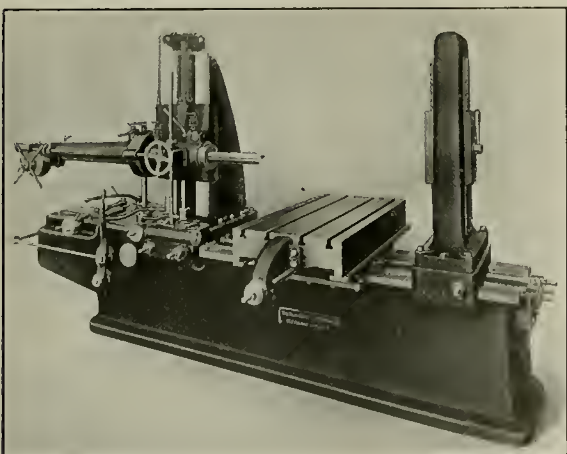
In considering the areas for flat sheets use Table III. In the case of flat sheets, the thickness of the lagging does not enter into the calculations, as the area is the same, regardless of whether it is one-inch thick or two inches thick.

The Need of Locomotives in China.—One of the pressing needs of China today is locomotives. The demands upon the railways have far exceeded the expectations of the builders. The locomotives bought in the first instance have proved too small, and it is now clearly realized by the technical advisers of China that they must standardize upon a type that will meet their needs for a long time to come. This question is being earnestly considered at the present time. Of the fifteen lines composing the system of Chinese Government railways, only one was built by the Chinese themselves; it is financed by the Chinese Government, and is operated exclusively by Chinese. The funds for the construction and equipment of the various other railway lines of China were furnished by foreign capital of various nationalities, but, according to the American authority, Charles Denby, special assistant to the department of state, not in a single instance has America so constructed and equipped any of these lines. As a result, today the Continental—European—design of locomotive is predominant in China. On some of the lines, notably those under English and, hitherto, German influence, not a locomotive other than those built in accordance with the prevailing design common to the nation financing the railway was purchased or even considered, either for initial or subsequent equipment—at least up to the time of the outbreak of the war. Only in the case of the Chinese financed and operated railway have American builders been given a free hand, with the result that an American design was adopted, and a thorough standardization of power effected. Out of the 638 locomotives in service on all lines at that time only 15½ per cent were of American design and manufacture; and on the English, Belgian, and French lines, which operated at that time 365 locomotives, or approximately 60 per cent of the total, only eight, or approximately 2.2 per cent were of American design and manufacture.—*Eastern Engineering.*

NEW DEVICES

THE BLOMQUIST-ECK HORIZONTAL BORING MILL

The working efficiency of any horizontal mill and drill depends entirely upon its ability to operate upon all classes of work at the highest speeds and coarsest feeds practicable, and at all times to produce a finished product of dependable accuracy. The Blomquist-Eck Machine Company, Cleveland, Ohio, in designing its new horizontal boring mill, has developed these points to a high degree by combining rigidity, accuracy, a suitable range of selective speeds and feeds with a high standard of material and workmanship. The various groups of mechanism form complete individual units and any unit can be inspected, removed or replaced without disturbing the alignment or any adjoining unit. The bed or base is of an unusually wide and deep box section, being cast entirely in one piece. The outer walls directly under the column are left intact, without cored openings, which adds greatly in resisting the lines of stress. Chip chutes are provided and so arranged that their walls give added strength. The bed (directly under the column) is reinforced by sections tied together and cast integral with the base. The bed is further reinforced by heavy deep ribs running lengthwise, and at right angles the three-point support or bearing is also incorporated in the construction.

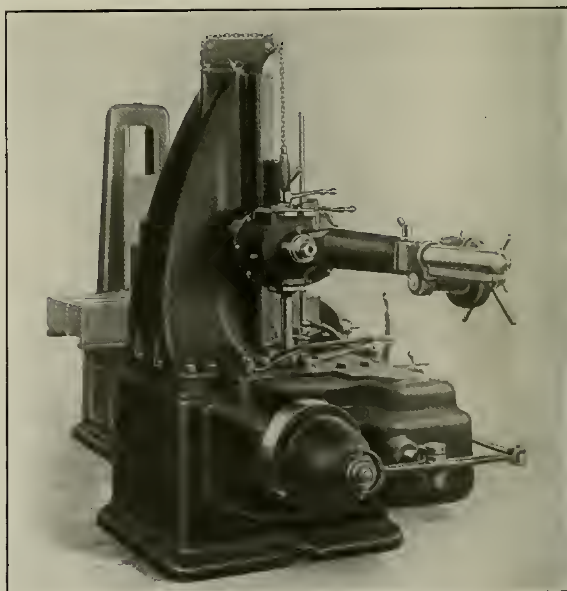


Blomquist-Eck Horizontal Boring Mill

The column is of a rigid box section, strongly braced internally by ribs in both horizontal and vertical positions. The base of the column has a liberal bearing upon the bed, eliminating deflections and spring.

The spindle saddle is designed with a liberal bearing surface on the face of the column, a long narrow guiding edge with single screw adjustable taper gib for adjustments on one side and square lock form with gib on the other side. The center of the spindle in the spindle saddle is placed as close to the column face (reducing overhang to a minimum) without sacrificing strength at a point most desired. The elevating screw which is between the column faces and the spindle, is so placed in relation to the narrow guide that the vertical movement of the saddle is direct and accurate. The units comprising the spindle and saddle are counterbalanced by a weight within the column.

The spindle is made from carefully selected high carbon steel, heat-treated, and is ground for its entire length. It is bored for a No. 5 Morse taper and is provided with an end thrust for operating in either direction. The spindle sleeve consists of a special hammered high carbon steel forging accurately ground inside and out. The front and rear spindle sleeve bearings are adjustable and tapered, being made of genuine government bronze. Either bearing can be adjusted to compensate for wear. Sight feed oil cups provide an adequate lubrication.



End View of Blomquist-Eck Horizontal Boring Mill

The boring bar support is raised or lowered in unison with the spindle saddle by a shaft and a set of planed steel bevel gears. The bar support or bearing proper is securely clamped by a lever binding bolt at any position..

The Method of Driving.—The close-coupled drive gear shafts, mounted on S. K. F. double-row, self-aligning ball bearings, transmit the power to the spindle in a direct and practical manner. All shafts are made of high carbon steel. Hardened steel ring spur gears, heat treated, are used wherever possible, and these are shrunk onto cast-iron hubs. The smaller spur gears in the drive are made of solid steel and heat treated. The bevel gears are made of hammered steel forgings planed from the solid. The speed changes are made by two levers at the front of the machine which operate the selective sliding gears. The entire driving mechanism is well located on the base and each individual shaft and bearing can be removed or replaced without disturbing any adjoining unit. Access to the entire unit may be had through an oil-tight top-plate cover, the removal of which permits an easy inspection when required. All gears run in a bath of oil, and in addition a positive cascade oiling system is provided for both gears and bearings.

The feed to the spindle in either direction, to the spindle saddle in raising or lowering upon the column, to the table saddle paralleling the bed, or to the table longitudinally upon its saddle, is introduced in the same direct positive geared manner as applied to the spindle drive. Shafts are made of high carbon steel mounted on S.K.F. ball bearings. The gears are of steel and heat treated. The feed mechanism in the base is arranged so any unit may be removed or replaced without disturbing any adjoining unit. All gears run in a bath of oil, and in addition a positive cascade oiling system is provided for bearings and shafts. The feed changes are made by two levers which are placed directly in front and at the top of the gear box. In addition there are three selective interlocking levers provided that engage either the spindle, vertical or table feeds. No two conflicting feeds can be engaged at the same time. In operating star feed facing heads or work of similar nature all feed levers can be positively locked in a neutral position.

Following are the principal dimensions of the machine:

Table and Saddle—The bed surfaces are designed and proportioned to compensate for any overhang of the table at the extreme front or rear positions. When the table is in either extreme position it is supported in the saddle practically three-fourths of its entire length. The saddle is gibbed to the bed by the square lock method having a long, narrow guiding edge with a taper gib for adjustment. The table is of an extra heavy pattern, long, wide and deep, being reinforced by heavy ribs. The table is securely gibbed by the square lock method, which in this instance resists any strains when the table is in an overhanging position.

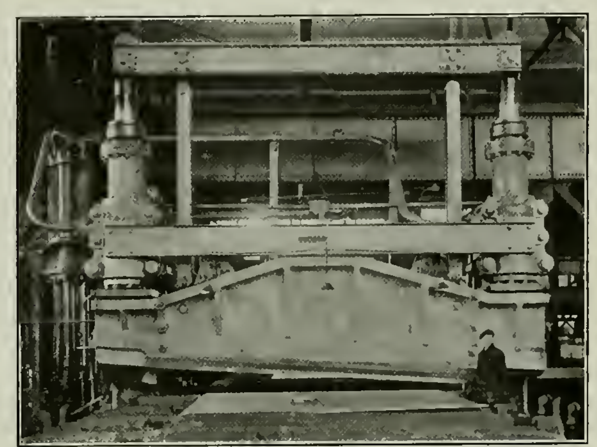
Power rapid traverse of a friction type is provided for all members operated by the feed. Regardless of whatever feed may be engaged, the rapid traverse always operates at one rate of speed in either direction. An adjustable safety friction leather washer in the clutch mechanism prohibits damaging any portion of the mechanism engaged. The clutch control is sensitive, and practically any amount of travel can be had. Hand adjustments to the spindle saddle, spindle travel, table saddle or table are provided in addition to the automatic feeds. All screws are fitted with graduated dials reading in thousandths of an inch.

Single friction clutch pulley drive operating at constant speed is regularly furnished. Constant speed or adjustable speed motor drive can be furnished. Any type of electrical control can be provided.

Diameter of spindle	3¼ in.
Travel of spindle	30 in.
Number of spindle speed changes	12
Range of spindle speeds in r.p.m.	16 to 196
Number of feed changes to spindle or table	9
Number of feed changes to spindle or table with back gears	18
Ranges of feed in inches per each revolution of spindle	.003 in. to .518 in.
Working surface of table	24 in. by 54 in.
Automatic longitudinal feed to table	36 in.
Automatic transverse feed or parallel movement of table with bed	37 in.
Maximum distance spindle nose to outboard bearing	5 ft. 5 in.
Maximum distance top of plain working table to center of spindle	27 in.
Diameter constant speed friction drive pulley	14 in.
Width of driving belt	4 in.
Weight crated domestic shipment (standard length) Approx.	11,600 lb.
Size of motor recommended	5 hp.

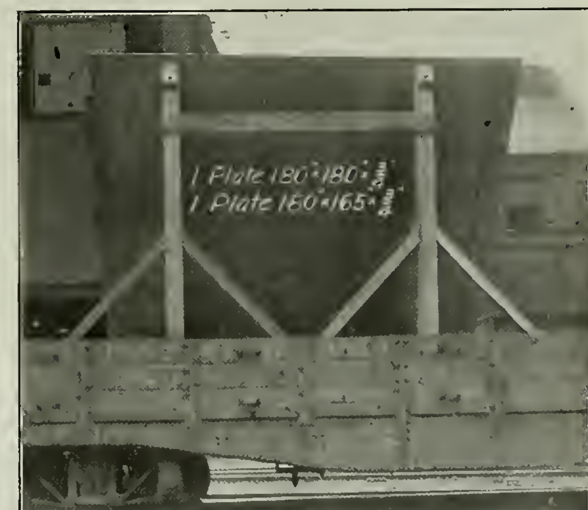
THE LARGEST PLATE MILL IN THE WORLD

The Lukens Steel Company, Coatesville, Pa., has for the fourth time in its history the largest plate mill in the United States. This company, at whose plant the first boiler plate in America was made in about 1820, had in 1890 a 120-in. plate mill, which was later rebuilt to the 134-in. size; in 1903 a 140-in. unit was placed in service, and now with its 204-in. No. 5 mill it has for the fourth time the largest



Hydraulic Shears 210 in. Between Housings, Having Capacity for 2-in. Plate

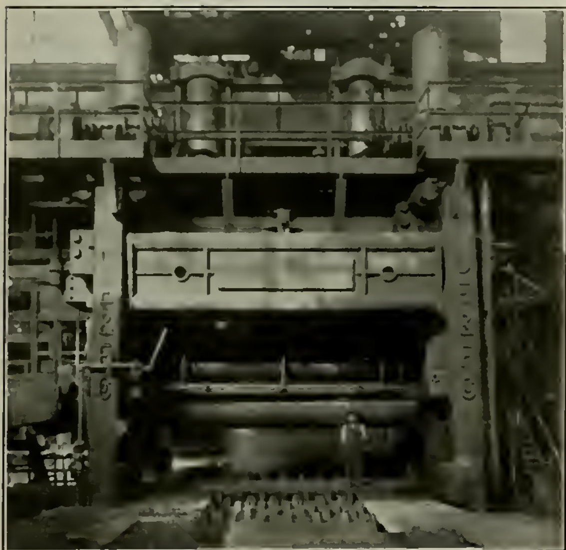
mill in the United States. This mill also exceeds anything in any other country, exceeding the 178-in. mill of the Witkowitz Works in Austria and the 168-in. mill in the British Isles. This new mill is capable of rolling plates up to 192-in. in width and circular pieces a few inches wider, with comparatively little variation in the gage at the center of the



Two Plates of Locomotive Firebox Steel Ready for Shipment to the Pennsylvania Railroad

plate. A novel device for handling and weighing the plates after shearing, designed by C. L. Huston, vice-president and mechanical engineer of the Lukens Steel Company, has been installed, and further devices are being planned to eliminate almost entirely all hand labor about the shearing department and to more accurately cut the plates than has been possible by methods heretofore in general use. Facilities have also been provided for flanging heads in one piece. For 15-ft. boilers the entire head is heated and flanged at one time, the work being done by the rolling process, which provides a better head than when heads of such diameter are made in two pieces.

When the construction of this large mill was contemplated attempts were made to build a 180-in. three-high mill after the accepted American practice. When it came to obtaining the chilled rolls of the size and weight desired, however, there was no manufacturer to be found in this country who could be persuaded to undertake the contract. Such a mill required chilled rolls of 50 in. in diameter, which was larger than anything the rollmakers had ever attempted. To overcome



The New No. 5 Mill for 192-in. Plates, Lukens Steel Company

this difficulty Mr. Huston proposed the adoption of the four-high reversing type of mill, the design of which was carried out in collaboration with the engineering staff of the United Engineering & Foundry Company. This new mill is built on the principle of the two-high reversing plate stand commonly used in the British Isles, being modified by having two large supporting rolls to back up the two finishing rolls in order to stiffen the mill and give it added strength to prevent the operating rolls from springing when wider than plates are being handled. This arrangement enables the use of operating rolls of smaller diameter and thereby overcomes the difficulty of obtaining the large chilled rolls. These operating rolls are 34 in. in diameter and have a working face of 204 in. with 27-in. necks. They weigh about 30 tons each. The 50-in. diameter backing rolls are made of cast steel, with 36-in. necks and weigh about 60 tons each.

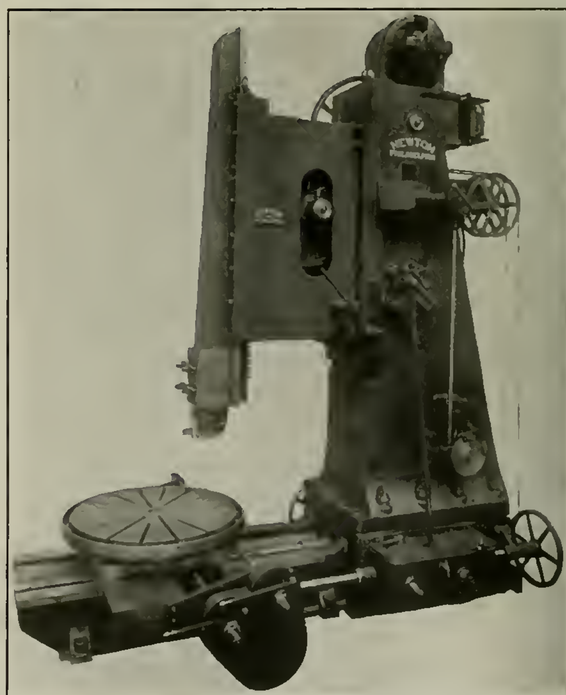
It was necessary to use a housing of a built-up type, as it is so large that the machining and transportation of such a housing cast in one piece would be impossible. Each housing weighs 400,000 lb. The mill stands about 40 ft. from the top of the screw cover to the bottom of the shoes, and is slightly over 42 ft. in height over all. The foundation of the mill is of concrete built on solid rock. The screw-down rig is driven by 150-hp. motors, one on each housing. The mill pinions are of cast steel, having a 42-in. pitch diameter and a 60-in. face. These pinions are connected to the working rolls by spindles 20 ft. long. Special provision was made for removing the smaller chilled rolls for grinding, which is done in a special grinding machine built by the Norton Company, the largest grinder ever built for this class of work.

The mill is driven by a 46-in. and 70-in. by 60-in. twin tandem compound condensing engine fitted with a jack-shaft and gear ratio of one to two. This engine was designed and constructed by the Mesta Machine Company. The plates after being rolled pass over the turnout table, 65 ft. long, to the straightening rolls, which were furnished by the Hilles and Jones Company after Mr. Huston's design. An inspection tilt-up device for raising the plates so that the bottom side may be inspected is provided, being operated by hydraulic cylinders. After inspections the plates are conveyed to the cut-off shear, which is hydraulically operated and which is 210 in. between housings.

The mill will handle ingots up to 60,000 lb. in weight. When it is operated to full capacity it is estimated that it will roll from 4,000 to 5,000 tons per week. To supply the increased metal to operate this new mill an addition to the steel plate mill of six basic open-hearth furnaces of 100 tons capacity each, has just been finished. With the other furnaces in operation and an additional two more which are contemplated, the Lukens Steel Company will have an estimated annual capacity of about 500,000 tons of finished plate. This company furnishes the majority of railroad locomotive boiler steel used in this country.

UPRIGHT GENERATING PLANERS

The Newton Machine Tool works, Inc., Philadelphia, Pa., having found that the term "slotting machine" does not suggest the possibilities of its equipment formerly known under that name, has called its latest design, which has recently been placed on the market, "upright generating planer." This machine, which is shown in the illustrations, has a stroke of 72 in., other sizes being built down to 36-in. maximum stroke. These machines are rack driven and are provided with a newly developed method of stroke control



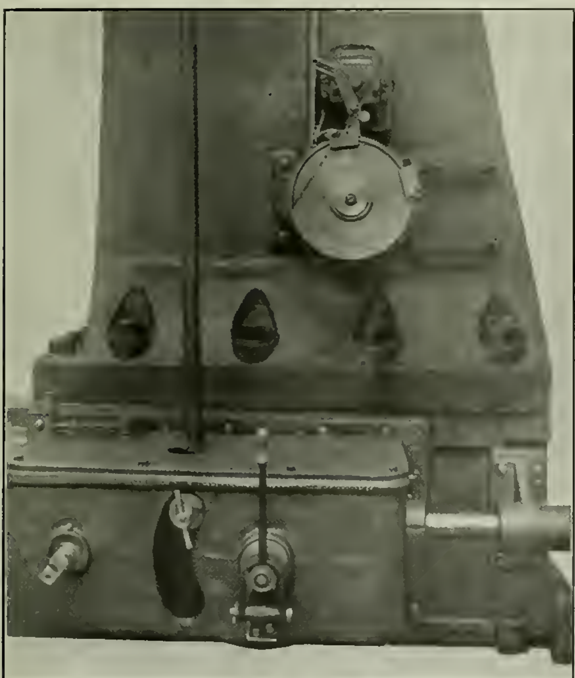
Newton Upright Generating Planer

disk, a close-up view of which is included with this article. The trips on this control disk can be operated by hand while the machines are in motion, which is desirable as the drift of the motor has to be compensated for.

This machine represents an entirely new development. It is rigid, conveniently controlled and is designed to insure permanency of alignment. The rams or cutter bars are counterweighted, having square bearings in the guides with taper side adjusting shoe and, on all sizes, the vertical clamping surface is solid and steel faced and equipped with suitable tool holding clamps. Beneath the ram or cutter bar is mounted a newly developed steel swiveling relief tool box apron, which can operate in any position of a complete circle.

The motion is transmitted from the motor to the broad face steel rack on back of the cutter-bar or ram through all steel spur reduction gears, whose coarseness of pitch and width of face increase with reduction of the gear speed. All gears are covered and on the operating side of machines, all gears are totally enclosed. The circular tables are heavily ribbed and of substantial construction and have full bearing on the saddle to which they are held by corner clamps. These tables are centered by a deep face, large diameter bearing. The oil pans are cast solid with circular tables and are graduated on the exterior into 360 degrees. The table saddles have narrow guide alignment control with centralized location of feed screw and taper shoe control of fit. Hand adjustment of the saddle is provided for from both ends of the cross slide.

All feed motions are independently clutched and the clutches have independent levers. The cross slide is of



Stroke Control Disc for Newton Upright Generating Planer

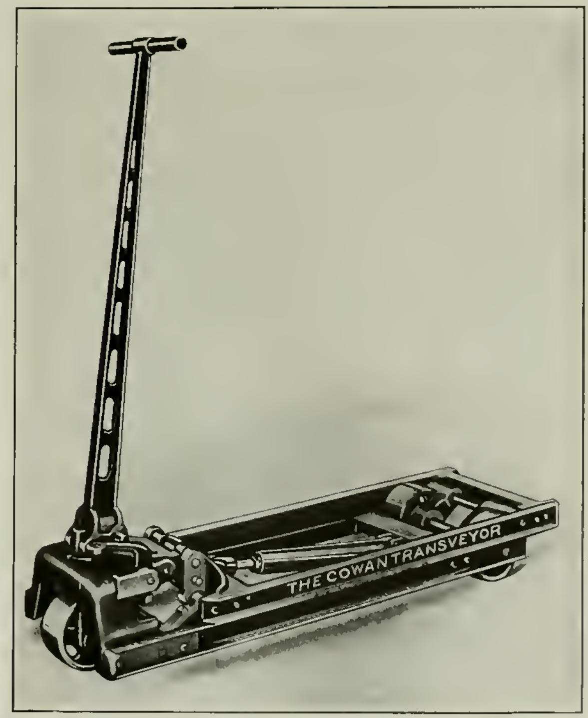
heavy box type section and has square bearings on the base with side adjustment taper shoe. Adjustment is from operating side, as well as from front of machine. The feed screws have bearings on each end to insure operation in tension. The feed motion is taken from a rocking friction box on the outside of which the pawl rod stroke adjusting screw is located. The circular, cross and longitudinal feeds are variable in rate and reversible through the use of pawl and ratchet wheel.

The cutter bar guide on the 36-inch stroke machine is cast solid with frame, and, therefore, does not have any vertical adjustment, while on the 56-inch to 72-inch machines inclusive, they are separate from the frame and have vertical hand-controlled adjustment to permit their being located in positions relative to cutter bars. The cutter bar guide adjusting mechanism is of tandem design to prevent dropping of guide in event of accidental breakage of counterweight ropes.

These upright generating planers are now built for reversing planer type motor drive only. The motor speed should be between 400 and 1,200 R. P. M. and the ratio should preferably be 3 to 1. Rapid traverse for table motions, can be provided as an extra, when desired, through incorporation of suitable mechanism and use of extra constant speed motor.

NEW TYPE OF TRANSVEYOR

The latest addition to the line of transveyors manufactured by the Cowan Truck Company, Holyoke, Mass., is its new Model G. This transveyor is of rugged construction and is an easy elevating machine. The leverage is



Cowan Type G Transveyor

such that the maximum load can be readily elevated by one man. It is made in several sizes varying in capacity from 1,000 to 3,000 lb. It is fitted with an improved locking device. This was chiefly designed to safeguard against the load becoming unseated when trucking over uneven floors. Various other improvements are incorporated in this new machine. The ease with which this transveyor elevates its maximum load, and its quick operation makes it particularly applicable to plants whose trucking requirements demand trucks of the above mentioned capacities.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions payable in advance and postage free; United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 7,400 copies were printed; that of these 7,400 copies 6,348 were mailed to regular paid subscribers, 57 were provided for counter and news company sales, 186 were mailed to advertisers, 66 were mailed to employes and correspondents, and 743 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 7,400, an average of 7,400 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

Employees of the Pennsylvania Railroad furloughed for military service, up to November 1, numbered 24,712, and it is announced that every one of these who returns honorably discharged can have his former position or another equally good.

Government regulation of steel prices was discontinued on December 31, following a meeting of the committee of the American Iron and Steel Institute with the War Industries Board in Washington on December 11. The steel producers have proposed a voluntary reduction in steel prices.

S. M. Felton, who as director general of military railways has had charge of the organization and despatch abroad of all railway forces and the purchase of all railway material for the American Expeditionary Forces, resigned on December 31, and will return to his railroad work at Chicago as president of the Chicago Great Western.

The Fuel Administration has in preparation a compilation of all rules and regulations promulgated during the life of the administration. This will be brought down to date January 1, 1919, and will be issued as soon thereafter as possible. It will be a bound volume of perhaps 500 pages. All persons desirous of obtaining a copy of this should communicate at once with the Bureau of Education, Washington, D. C.

The Professional Division of the United States Department of Labor, office at 16 East 42d street, New York City, invites employers of all classes who want university graduates in mechanical, electrical and civil engineering, and in chemistry, to make use of the facilities of that office in securing men who are retiring from the army or the navy. J. O. Winslow, special agent, in charge of the office, is making a list of engineers and other technically qualified men who are retiring from the military service and desires to have the names of all men of this class seeking employment. The record of each man is carefully investigated before registration.

The Engineering Index, published for 25 years in The Engineering Magazine and its successor, Industrial Management, an index to engineering periodical literature, has been acquired by the American Society of Mechanical Engineers, and hereafter will be compiled and published by this society. The first issue of the Index under its new management appears in the January number of The Journal. As heretofore, The Engineering Index will be regularly issued in three different forms: (1) As a part of The Journal of the Society; (2) as a separate monthly publication for libraries or individuals desiring to clip the items for indexing purposes, and (3) as an annual volume in which all the items for the year are collected.

MEETINGS AND CONVENTIONS

Railway Storekeepers' Association.—The fourteenth annual business meeting of the Railway Storekeepers' Association will be held at the Hotel Sherman, Chicago, on January 27, 28 and 29, 1919. The following subjects will be discussed at this meeting:

Fundamental principles of railway storekeeping, H. C. Pearce.
Unapplied material, committee report, W. D. Stokes.
Labor and labor saving devices, J. R. Mulroy.
Scrap and scrap handling, W. F. Jones.
The use, inspection and handling of lumber and cross-ties, M. E. Towner.
Conservation of material, J. G. Stuart.
Conservation of Cars, H. E. Ray.
Accounting for materials in the stores department, J. H. Waterman, H. E. Ray and U. K. Hall.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Jan. 14	The Preservation of Ties	H. K. Wicksteed	James Powell	P. O. Box 7, St. Lambert, Que.
Central	Jan. 10	Fuel Conservation. Election of Officers	V. C. Randolph	Harry D. Vought	95 Liberty St., New York.
Cincinnati	Feb. 11	....	....	H. Boutet	101 Carew Bldg., Cincinnati, Ohio.
New England	Jan. 14	Acetylene Welding	W. L. Bean	W. E. Cade, Jr.	683 Atlantic Ave., Boston, Mass.

Air Brake Association.—At a meeting of the executive committee of the Air Brake Association, held on December 5, in Pittsburgh, Pa., it was arranged to hold the 26th annual convention in Chicago on May 6, 7 and 8, 1919. The subjects adopted by the committee for discussion are as follows:

"Air Requirements for Pneumatically Operated Devices for Locomotives," C. H. Weaver, chairman.
"Cleaning, Repairing, Lubricating and Testing Freight Car Brake Cylinders," by Mark Purcell.
"Reclamation and Conservation of Material," T. L. Burton, chairman.
"Twenty Per Cent Overload Allowed on Heavy Grade Braking," by C. H. Rawlings.
"Holding Standing Trains and Cars on Grades," by R. J. Watters.
"Recommended Practice Report," H. A. Clark, chairman.
"M. C. B. Air Brake Defect Card."
"How Can Enginemen and Trainmen assist in Air Brake Maintenance," by H. A. Glick.

It was decided to invite car and locomotive builders each to send a representative to the convention for their information as to the best methods of installing air brake equipment.

June Mechanical Conventions.—At the meeting of the executive committees of the American Railway Master Mechanics' Association, the Railway Master Car Builders' Association, and the Railway Supply Manufacturers' Association at the Hotel Biltmore, New York, on December 20, arrangements were made for the holding of a mechanical convention at Atlantic City in June. Inasmuch as the convention is a postponed one, the previous decision to meet at Atlantic City was adhered to and the dates set are June 18 to June 25; the Master Car Builders' Association being held first, June 18 to 21, and the Master Mechanics' Association from June 23 to 25. While the executive committees felt that it would be advisable to hold all the sessions during one calendar week, it was not found feasible to make such an arrangement. Frank McManamy, assistant director, Division of Operation of the Railroad Administration, was present. The decision in favor of holding the usual exhibit of the Railway Supply Manufacturers' Association was strongly favored by all those present, the advantages to the younger men in railroad service and for visitors from other countries being very strongly presented. It was decided that all three associations unite in invitations to the representatives of foreign countries to attend the convention.

Headquarters, as in former years, will be in the Marlborough-Blenheim Hotel, and sessions will be held on the Million Dollar Pier. At a separate meeting of the executive committee of the Railway Supply Manufacturers' Association J. D. Conway was elected secretary-treasurer.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention, May 6-8, 1919, Chicago.
American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.
American Railway Master Mechanics' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.
American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.
American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
Chief Interchange Car Inspectors' and Car Foremen's Association.—W. R. McMunn, New York Central, Albany, N. Y.
International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.
International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.
International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York.
Master Car Builders' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 18-21, Atlantic City, N. J.
Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.
Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.
Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio. Convention, January 27-29, 1919, Hotel Sherman, Chicago.
Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

Personal Mention

GENERAL

E. Langham, general purchasing agent of the Canadian Northern Railway System, has had his jurisdiction extended to include all the Canadian Government Lines, with headquarters in Toronto, Ont.

George E. Murray, whose appointment as electrical and mechanical engineer of the Grand Trunk Western Lines, with headquarters at Battle Creek, Mich., has been announced in these columns, was born on December 8, 1884, at Decatur, Ill. He began railway work with the Wabash in 1903, and two years later went with the People's Gas & Electric Company, of Defiance, Ohio. He returned to the Wabash in 1906 to install the machinery and equipment in the new car shops at Decatur, remaining with that road until 1910. He then became connected with the Chicago & North Western, where he had charge of electrical equipment in shops, and subsequently was made chief electrician of that road, which position he held until he recently went with the Grand Trunk Western Lines, as noted above.

R. D. Quickel, having been released from military service, has been reappointed fuel agent of the Southern Railroad and associated roads, lines west, with headquarters at Cincinnati, Ohio, succeeding N. C. Kieffer, assigned to other duties.

Samuel J. Hungerford, general manager, eastern lines, of the Canadian Northern, has been appointed assistant vice-president of the Canadian Northern Railway System and the Canadian Government Railways, with headquarters at Toronto, Ont. Mr. Hungerford was born on July 16, 1872, near Bedford, Que. He was educated in the common and high schools and began railway work in May, 1886, as a machinist apprentice on the South Eastern and later served with its successor, the Canadian Pacific, at Farnham, Que. He was then machinist at various places in Quebec, Ontario and Vermont. From August, 1897, to February, 1903, he was consecutively chargeman, at Montreal; assistant foreman at Farnham, Que., locomotive foreman at Megantic, general foreman at McAdam Junction, N. B., and locomotive foreman at Cranbrook, B. C., on the Canadian Pacific. In February, 1903, he was appointed master mechanic on the Western division at Calgary, Alta. The following January he became superintendent of locomotive shops at Winnipeg, Man., and four years later was appointed superintendent of shops at the same place. In March, 1910, he became superintendent of rolling stock of the Canadian Northern and the Duluth, Winnipeg & Pacific, at Winnipeg, Man., and in May, 1915, was transferred in the same capacity to the Canadian Northern at Toronto, Ont. On November 1, 1917, he was appointed general manager, eastern lines, of the Canadian Northern, which position he held at the time of his recent appointment.

S. J. Hungerford

James H. Rader, gang foreman of the Atchison, Topeka & Santa Fe at Emporia, Kans., has been appointed apprentice instructor in charge of schools at La Junta and Pueblo, Colo. His headquarters are at La Junta. Mr. Rader entered the employ of the Santa Fe about nine years ago as a machinist apprentice. After serving his apprenticeship he worked as a machinist until February 26, 1917, when he was appointed assistant apprentice school instructor at Topeka, Kans., and on May 1, 1917, he became gang foreman at Emporia.

W. L. Robinson, supervisor of fuel consumption of the Baltimore & Ohio, Western Lines, Dayton & Union, and the Dayton Union Railroad, has been appointed superintendent of fuel and locomotive performance, and his former position has been abolished.

G. W. Seidel, superintendent of motive power and rolling stock of the Minneapolis & St. Louis, has been appointed superintendent of motive power of the Chicago & Alton and the Chicago, Peoria & St. Louis, with office at Bloomington, Ill., succeeding J. E. Ohearne, resigned.

C. D. Young, formerly superintendent of motive power of the Pennsylvania Railroad, eastern lines, with office at Wilmington, Del., has been appointed acting superintendent of the Schuylkill division, succeeding William Elmer. Mr. Young resigned in November, 1918, as superintendent of motive power to become a lieutenant-colonel in the transportation corps, engineers.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

C. A. Fisher, a locomotive engineman on the Spokane division of the Great Northern, has been promoted to road foreman of engines of the first district, Spokane division, with headquarters in Hillyard, Wash.

G. R. Galloway, master mechanic of the Baltimore & Ohio, at Lorain, Ohio, has been appointed general master mechanic of the Baltimore & Ohio, Western Lines; the Dayton & Union, and the Dayton Union Railroad, with office at Cincinnati, Ohio, succeeding P. H. Reeves, assigned other duties.

M. A. Gleeson, master mechanic of the Baltimore & Ohio, Western Lines, at New Castle Junction, Pa., has been appointed master mechanic of the Cleveland division, with office at Lorain, Ohio, succeeding G. R. Galloway.

Erik W. Lostrom has been appointed road foreman of engines of the Northern Pacific, with office at Duluth, Minn., succeeding Charles Emerson, promoted.

T. F. Perkinson, master mechanic of the Baltimore & Ohio, with headquarters at Baltimore, Md., has been transferred to Cumberland, Md., as master mechanic.

Zill Pierce has been appointed master mechanic of the Saratoga and Champlain divisions of the Delaware & Hudson, with headquarters at Colonie, N. Y., succeeding A. L. Moler, resigned.

J. A. Tschour, general foreman in the locomotive department of the Baltimore & Ohio, Western Lines, at Willard, Ohio, has been appointed master mechanic of the New Castle division, with office at New Castle Junction, Pa., succeeding M. A. Gleeson.

Charles W. Weaks has been appointed road foreman of engines on the Toledo division of the Pennsylvania Lines West, with headquarters at Toledo, Ohio, succeeding R. Palmer, promoted.

CAR DEPARTMENT

M. H. Quinn has been appointed general car foreman of the Erie lines east.

R. B. Freeman, car foreman of the Seaboard Air Line, with office at Monroe, N. C., has been appointed general car foreman, with office at Hamlet, N. C.

G. E. Smart, superintendent of the car department of the Canadian Northern Railway System, has been appointed general master car builder, with jurisdiction over all lines of the Canadian Northern and the Canadian Government Railways, with office at Toronto, Ontario.

G. M. Waddy, general foreman of the Erie at the Buffalo car shops, has been appointed general car foreman of the lines west.

SHOP AND ENGINEHOUSE

J. B. Tynan has been appointed superintendent of the locomotive shops of the Wheeling & Lake Erie at Brewster, Ohio.

PURCHASING AND STOREKEEPING

R. C. Harris, supervising engineer for the Pennsylvania Railroad, Western Lines, at Columbus, Ohio, has been appointed general storekeeper, with headquarters at Pittsburgh, Pa.

C. W. Kinnear, assistant engineer of motive power of the Pennsylvania Lines West at Toledo, Ohio, has been appointed assistant general storekeeper, with office at Pittsburgh, Pa.

C. H. Rothgery has been appointed storekeeper of the Baltimore & Ohio, Western Lines, with headquarters at Lorain, Ohio, succeeding W. H. Dean, transferred.

FEDERAL ADMINISTRATION APPOINTMENTS

S. A. Bramlette has been appointed representative of the Division of Labor of the Railroad Administration, with office at Washington, D. C. Mr. Bramlette will be assigned to conduct investigations and to represent the Division of Labor in other specific matters to which he may be assigned affecting employees of the railroads under federal control.

C. E. Chambers, superintendent of motive power of the Central of New Jersey, has been appointed mechanical assistant to Charles H. Markham, regional director of the Allegheny region of the United States Railroad Administration, with headquarters at Philadelphia, Pa., succeeding J. T. Carroll, resigned, to go to the Baltimore & Ohio.

E. A. Clifford, assistant general purchasing agent of the Atchison, Topeka & Santa Fe at Chicago, has been appointed assistant to the Regional Purchasing Committee for the Central Western region, with headquarters at Chicago.

C. M. Freeman, traveling engineer on the Sunset-Central Lines, has been appointed assistant fuel supervisor of the Central Western regional district.

F. W. Marquise has been appointed assistant to the manager of the Fuel Conservation Section of the United States Railroad Administration, with office at Washington, D. C., succeeding Edward C. Schmidt, major, Ordnance Department, United States Army, who was temporarily assigned to service with the Fuel Conservation Section, but has returned to the service of the War Department.

OBITUARY

T. W. Heintzelman, formerly general superintendent motive power of the Southern Pacific, died of pneumonia in San Francisco, Cal., on December 11. After serving the Southern Pacific in various capacities for about 28 years he retired on January 1, 1917, on account of ill health.

SUPPLY TRADE NOTES

Joseph T. Ryerson & Son, Chicago, announce the opening of an office in Philadelphia, located in the Widener building.

The Cleveland Milling Machine Company, Cleveland, Ohio, announces that W. P. Sparks is now acting as its representative at Indianapolis, Ind., with office at 316 Terminal building.

The records in the offices of the mechanical department of the El Paso & Southwestern at El Paso, Tex., were lost in a fire on December 5. F. B. Lister has requested the supply trade to send catalogues to replace those destroyed.

George T. Cooke has resigned as eastern sales manager of the Vapor Car Heating Company, Inc., to accept the presidency of the Union Metal Products Company, Chicago, with office in the Singer building, New York. Mr. Cooke was born in Chicago on May 28, 1883. After receiving a technical and mechanical training he entered the employ of the Pullman Company in 1901 as draftsman. Later he was made chief draftsman of the Calumet repair shops, and subsequently was promoted to chief inspector and finally mechanical inspector. In 1911, he left the Pullman Company to become southern manager for the Chicago Car Heating Company, at Atlanta, Ga., and in 1913, he was transferred to this company's New York office as eastern manager. When the Chicago Car Heating Company and the Standard Heat & Ventilation Company, Inc., were absorbed by the Vapor Car Heating Company, Inc., in 1917, Mr. Cooke was made eastern manager, in charge of sales and mechanical matters in the eastern territory, which position he held until December 1, 1918, the date of his connection with the Union Metal Products Company as president.

G. T. Cooke

H. E. Passmore, formerly with the mechanical department of the New York Central and later production manager of the Marble Cliffs Quarries Company, has been appointed sales representative of the reorganized Grip Nut Company.

Roswell P. Cooley, who has had charge of sales in the southwest, with headquarters at Chicago, has been appointed to succeed Mr. Cooke, and Nelson T. Burns, formerly with the New York Central, has entered the sales department, with headquarters at Chicago.

Cyrus J. Holland has been appointed western representative of the Wine Railway Appliance Company, Toledo, Ohio, with offices at 730 Peoples Gas building, Chicago, succeeding the vice-president, R. F. Tillman, who has been assigned to other duties, with headquarters in Toledo.

The Walworth Manufacturing Company, with general offices at Boston, Mass., and works at Boston and Kewanee, Ill., with branches in New York, Chicago and Seattle, has recently purchased the business of Hunter & Dickson Company, at 241-247 Arch street, Philadelphia, Pa., and is operating it as one of its branches.

J. K. Mahaffey has been appointed sales manager of the Pittsburgh district with office at Pittsburgh, Pa., for the Edison Storage Battery Co., Orange, N. J. Mr. Mahaffey has been with the Edison Company for the last two years. He was identified for several years with the General Electric Company and a number of other electrical concerns.

Bertram Smith, heretofore district sales manager at Detroit, Mich., has been appointed assistant general sales manager of the Edison Storage Battery Company, with headquarters at the main office, Orange, N. J. Mr. Smith has long been engaged in the storage battery business, having formerly been with the National Battery Company.

George Simons, who has been associated with the Edison Storage Battery Company for the past three years, has been appointed to succeed Bertram Smith as district sales manager at Detroit, Mich. He has had valuable experience in storage battery practice, and was for nine years associated with the National Battery Company, Buffalo, N. Y., and with the United States Light & Heat Corporation.

The Truscon Steel Company, Youngstown, Ohio, which for many years has been manufacturing pressed steel parts principally for use in its own products, announces the expansion of its business into the manufacture of pressed steel parts of all kinds. The work will be handled by the pressed steel department, headed by G. F. Danielson, as manager, who for 25 years has devoted his entire efforts to the manufacture of pressed steel products.

Major William L. Allison, who for the past 18 months has been in active military service, has been honorably discharged from the U. S. Army and has resumed his duties as vice-president of the American Arch Company. In addition, Major Allison has been elected vice-president in charge of sales of the Locomotive Feed Water Heater Company. Major Allison was one of ten majors graduated from the first training camp at Fort Sheridan, Ill. That he, along with many others, were denied the opportunity of overseas service was a great disappointment to him. Major Allison was born near Salisbury, N. C. He graduated from the Davis Military School of Winston-Salem, N. C. For over three years he was in government service as deputy marshal. For six years he was employed in various capacities in the Baldwin Locomotive Works, Philadelphia, and in January, 1904, he became mechanical engineer of the Atchison, Topeka & Sant Fe. He resigned from the Santa Fe to become mechanical engineer of the Franklin Railway Supply Company. He was later western sales manager of that company, the Rome Merchant Iron Mills, the Economy Devices Corporation, and general western sales manager of the American Arch Company. He became vice-president of the latter company in January, 1914, which position he still holds in addition to the vice-presidency of the Locomotive Feed Water Heater Company.

Major Allison

The Brown Hoisting Machinery Company, Cleveland, Ohio, announces the following changes in its organization: Harvey H. Brown, chairman of the board of directors; Alexander C. Brown, president; Melvin Pattison, vice-president, general manager and director; Robert G. Clapp, director; John F. Price, director, and Ewen C. Pierce, general manager of sales.

The Independent Pneumatic Tool Company announces the opening of a branch office and service station in Cleveland, Ohio, on December 15. A complete line of Thor pneumatic and electric tools and repair parts will be carried in stock at 1103 Citizens building, under the management of Hayden F. White, who has represented the company in Detroit, Chicago and Milwaukee districts for some years past.

William P. Dalton, formerly for many years chief engineer of the Schenectady plant of the American Locomotive Company, has been appointed assistant manager of the Schenectady works of the General Electric Company. For the last three years Mr. Dalton has been with the Washington Steel & Ordnance Company, engaged in war work. He was graduated from Cornell University in 1890.

John E. Galvin has been elected president of the Ohio Steel Foundry Company of Lima, Ohio. Mr. Galvin has been operating vice-president since the organization of the company in 1907. In 1916 he built a converter and electric foundry at Springfield, Ohio, for the manufacture of small steel castings and later sold it to the Ohio Steel Foundry Company. This plant is now known as the Springfield works of that company.

R. W. Burnett has resigned as master car builder of the Delaware & Hudson to become associated with the Joliet Railway Supply Company as assistant to the general manager, and with the National Car Equipment Company as vice-president, with headquarters at Chicago. Mr. Burnett was born at Farmer City, Ill., in 1868, and in 1890 became connected with the Union Pacific in the car department at Denver, Colo. In 1892 he went to the Pennsylvania as a car inspector at Chicago, and from August, 1892, to July, 1899, was successively foreman and general foreman of the car department of the Lake Shore & Michigan Southern, at Chicago. During the early part of 1900 he was employed as general foreman of the car department of the Long Island, going to the Central Railroad of New Jersey the latter part of the year as general foreman of the car department at Elizabeth, N. J. From 1904 to January, 1907, he was successively assistant master car builder and master car builder of the Erie at Meadville, Pa. On the latter date he went to the Canadian Pacific as assistant master car builder, being made general master car builder in 1909. He left the latter road in November, 1915, to become vice-president of the National Car Equipment Company, returning to railway service on September 1, 1917, as master car builder of the Delaware & Hudson.

R. W. Burnett

L. E. Schumacher, who for the past eight years has been chief inspector of the Westinghouse Electric & Manufacturing Company, at East Pittsburgh, Pa., has been promoted to works manager of the Krantz Manufacturing Company, of Brooklyn, N. Y., the latest subsidiary of the former company. Mr. Schumacher has been with the Westinghouse Electric & Manufacturing Company for 18 years, prior to which he was with the Niagara Falls Power Company. The Krantz concern makes safety switches, panel boards and floor boxes.

S. D. Rosenfeld has been appointed district sales manager of the Franklin Railway Supply Company, Inc., with offices at Houston, Texas. Mr. Rosenfeld has had wide experience in railroad work and has brought out several inventions that improved locomotive operation. He was born at Lincoln, Neb., and received his early education at that place. Upon leaving college he entered the service of the Chicago & North Western, serving in the machine shop and signal department, and then as fireman and engineer. In 1912, Mr. Rosenfeld resigned as locomotive engineer and entered the service of the Franklin Railway Supply Company as mechanical representative, which position he held at the time of his recent appointment.

S. D. Rosenfeld

Lieutenant Clarence E. Holborn was instantly killed in an airplane accident at Call Field, Wichita Falls, Tex., on December 3. Lieutenant Holborn, previous to entering the military service, had been in the advertising department of the Hyatt Roller Bearing Company, New York. After leaving school he entered the service of the Simmons-Boardman Publishing Company, publisher of the *Railway Mechanical Engineer*, and for a number of years was connected with it in various capacities in the business and advertising departments.

H. W. Clarke, who until December 15, was connected with the advertising service department of the McGraw-Hill Company at Chicago, has been appointed manager of advertising for the Chicago Pneumatic Tool Company, Chicago. Prior to his connections with the McGraw-Hill publications he spent eight years with the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., part of the time as a member of the sales and publicity departments, and later as western publicity representative, with headquarters at Chicago.

L. J. Kennedy, who for many years has been associated with the Consolidated Railway Electric Lighting & Equipment Company, died in Chicago on October 30. Mr. Kennedy was born in Watertown, N. Y., in 1880, but at an early age moved to Chicago and received his education in the public schools of that city. In 1900 he returned to the east and entered the employ of the Consolidated Railway Electric Lighting & Equipment Company as a machinist in the factory at Shelton, Conn. He was later employed as an inspector, taking care of car lighting equipment on various roads running into Chicago. Mr. Kennedy applied the first electric lighting equipment to the Golden State Limited and also to the Twentieth Century Limited. Later he had charge of the maintenance and operation of the lighting on those trains. After holding this position for some time, he was placed in charge of the manufacture and sales of the Consolidated company at Chicago, and later, when the Consolidated company discontinued its manufacturing in Chicago, Mr. Kennedy remained in charge of the sales only. In 1913 he left the employ of the Consolidated company to engage in boat building on the North Side of Chicago. Later he went to New Mexico on account of the health of his family and accompanied Pershing's Expedition into Mexico. In 1916, he returned to the employ of the Consolidated as sales engineer, but left the company again in 1917 to once more engage in the boat building business in which he was very successful in completing some large contracts for pontoons for the army.

Dr. Angus Sinclair

Angus Sinclair, D.E., founder and editor-in-chief of Railway and Locomotive Engineering, New York, died at his home in Millburn, N. J., on January 1, 1919, at the age of 78. Doctor Sinclair was born in Forfar, Scotland. He began his railroad career as a telegraph operator and later was a locomotive engineman on the Scottish Northeastern Railway. He attended evening high school and later for several years was employed in the Customs Department in Montrose, Scotland, and London, England. A love of adventure took him to sea, and, after some service as a marine engineer, he again took up railroad work in America, first in the service of the Erie, and afterward in the west, where he ran a locomotive on the Burlington, Cedar Rapids & Northern. During this period he attended the chemistry classes of the Iowa State University, making a specialty of water analysis, and was appointed chemist of the railroad, combined with the duties of roundhouse foreman. It was during this period that he first gave serious consideration to the problem of fuel economy and smoke prevention, on which he has since written extensively. In 1883 he joined the editorial staff of the American Machinist, a few years later becoming president of the publishing company. In 1887 the company, desiring to broaden its field, established the Locomotive Engineer, of which the late John A. Hill became editor. A few years later Doctor Sinclair and Mr. Hill bought this paper, now Railway and Locomotive Engineering, and since Mr. Hill's retirement from the partnership in 1897, Doctor Sinclair has been the sole proprietor and editor-in-chief.

Angus Sinclair

In 1908 the faculty of Purdue University, Lafayette, Ind., conferred upon him the honorary degree of Doctor of Engineering. About this time he was appointed special technical instructor in the mechanical department of the Erie Railroad. Doctor Sinclair has also been closely identified with the work of nearly all of the leading engineering societies in America and with some in Europe. He was the senior officer in point of continuous service of the American Railway Master Mechanics' Association, having been treasurer since 1900. Previous to that time he had served as secretary from 1887 to 1896. He was also a member of the Master Car Builders' Association, the American Society of Mechanical Engineers, and was instrumental in the establishment of the Traveling Engineers' Association, which was organized in his office in 1892. He was a delegate to three International Railway Congresses, at Washington, D. C., St. Louis, Mo., and Berne, Switzerland.

Doctor Sinclair is the author of a number of works on railroad subjects, some of which have become textbooks, including "Locomotive Running and Management," "Combustion in Locomotive Fireboxes," "Firing Locomotives," "Railroad Man's Catechism," "Twentieth Century Locomotives," and "History of the Development of the Locomotive Engine." His first published work, "Locomotive Running and Management," was begun while he was running a locomotive, and was made up entirely from personal observation. It has repeatedly been revised by the author and has passed through 26 editions, the last appearing in 1915. His work on "Firing Locomotives" has been translated into eight languages, including Chinese. In his long and varied career Doctor Sinclair has been a pioneer in the study and development of many practices pertaining to locomotive operation, which have now become well established, and his influence will long be felt in practical railroad operation.

The Whiting Foundry Equipment Company, Harvey, Ill., announces changes that have been made in its organization. The following men have left the company: F. A. Rundle, general superintendent; C. A. Hardy, sales manager; G. R. Brandon and P. A. Dratz, Chicago representatives. Samuel Moore, formerly general manager of the Bond plant of the American Radiator Company, is now general superintendent and the company will be represented in Chicago by George Ristine, formerly with the Pressed Steel Car Company. H. A. Wolcott, formerly with the McMyler Interstate Company, Cleveland, Ohio; E. V. Brown and Walter R. Hans have become members of the company's engineering staff.

Dr. Walter V. Turner

Dr. Walter Victor Turner, manager of engineering of the Westinghouse Air Brake Company, died at the Columbia Hospital, Wilkinsburg, Pa., Thursday morning, January 9. In the death of Doctor Turner the world has lost the greatest air brake expert of the age. Doctor Turner has had a most unique career, having by the fate of destiny entered on a work that has meant so much to American railroading. He was born in Epping Forest, Essex county, England, April 3, 1866. He was in the wool business in that country and came to America in 1888 to develop his education along those lines. He was secretary and manager of the Lake Ranch Cattle Company, Raton, N. M., in 1893. In 1897 this company failed and Doctor Turner entered the employ of the Atchison, Topeka & Santa Fe as a car repairer. In one month he was made gang foreman and three years later was made chief inspector. Having previously become interested in air brake apparatus through a bad wreck that occurred in the vicinity of his home, he made a very careful study of its intricacies in his new position and it was during the first year of his employ that he developed his first air brake patent. He soon gained a reputation for proficiency in air brakes and was placed in charge of the

Walter V. Turner

air brake instruction car on that road. From general air brake instructor he was promoted to mechanical instructor for the entire system, during this time having sold 22 patents to the Westinghouse Air Brake Company.

At the 1902 convention of the Air Brake Association, which was held in Pittsburgh, Doctor Turner was offered a position with the Westinghouse Air Brake Company, but refused. The offer was repeated again at the 1903 convention and in November of that year arrangements were made between the Air Brake Company and the Santa Fe to loan Doctor Turner to the former. That arrangement was continuously in effect to the time of his death. In 1907 he was made mechanical engineer; in 1910, chief engineer; in 1915, assistant manager, and in 1916, manager of engineering. The first task of Doctor Turuer with the Westinghouse Company was to develop the *K* triple valve, of which there are now over 2,000,000 in use. By his untiring energy and ingenuity the art of braking trains has developed by leaps and bounds. He has been granted over 400 patents and a hundred or more are still pending. Among his latest inventions the improved empty and load brake and the electro-pneumatic brake stand out pre-eminently. These made possible an increase of 300 per cent. in the capacity of the New York Subways. Doctor Turner was also an author, among the more important of his books being "Train Control—Its Development and Effect on Transportation Capacity," which was published in two volumes. He was awarded the Longstreth medal in 1911 and the Elliott-Cresson medal in 1912. He was a fellow of the Royal Society of Arts, England, and a member of the American Society of Mechanical Engineers, the American Electric Railway Association, Franklin Institute (Philadelphia), and the Pennsylvania State Chamber of Commerce. The degree, "Doctor of Engineering," was conferred on Doctor Turner by the University of Pittsburgh in 1918.

Doctor Turner's death was the result of complications, among them being enlargement of the heart and Bright's disease. He was injured two or three years ago in an automobile accident, to which he attributed his condition. He had been seriously ill since the middle of November. He leaves besides his widow, a married son and daughter.

William I. Thomson, electrical superintendent of the Safety Car Heating & Lighting Company, died at his home in Newark, N. J., on December 10 of pneumonia. Mr. Thomson was prominent in the field of railway car lighting engineering for many years, and to his efforts are due many important developments in car lighting electrical apparatus. He was born in Newark, N. J., June 26, 1876, graduated from Stevens Institute in the class of 1897, and served as chief machinist on U. S. S. Badger during the Spanish-American war. He was instructor in applied electricity at Stevens Institute from 1897 to 1900, and after working in the electrical construction department of the Manhattan Railway Company, New York, for two years he went to the Safety Car Heating & Lighting Company in 1902.

Fred C. J. Dell has been elected secretary of the National Railway Appliance Company, New York. Mr. Dell has acted in the capacity of secretary to the president of the company for the past two years, previous to which time he was connected with the American Electric Railway Manufacturers' Association as assistant to the secretary-treasurer. He held that position from March, 1911, to May, 1916, at which time he resigned to assume charge of the detail work of the exhibit committee for the 1916 convention of the American Electric Railway Association. In October, 1916, he was elected secretary of the American Electric Railway Manufacturers' Association, which position he still holds. He received his early training in the office of the vice-president and general manager of the Interborough Rapid Transit Company, where he was employed for a period of seven years.

CATALOGUES

PNEUMATIC HAMMER.—A six-page folder describing in detail the construction and operation of the Barr pneumatic high speed hammer has been published by H. Edsill Barr, engineer, Erie, Pa.

TANKS.—A list of the storage, pressure, car tanks, etc., for sale by the Walter A. Zelnicker Supply Company, St. Louis, Mo., with the dimensions and weight of each, is published in bulletin No. 252.

SMALL TOOLS.—Catalogue No. 40, listing taps, dies, screw plates and reamers manufactured by the Greenfield Tap & Die Corporation, Greenfield, Mass., has been issued by this company. It contains 288 pages, in which sizes, prices, dimensions and illustrations are given in convenient form.

TIGHT RIVETS.—The American Flexible Bolt Company, New York, has developed a new type of rivet, known as the American rivet, which is described in bulletin No. 301. It upsets from both ends, and because of this is claimed to make a tight rivet. Reproductions of actual photographs of plates sectioned for the purpose, are shown to illustrate this point.

ROME HOLLOW STAYBOLT IRON.—Bulletin No. 2 of the Rome Iron Mills, Inc., 30 Church street, New York, enumerates the advantages of Rome hollow staybolt iron and bears out a claim of economy with figures comparing the cost of this kind of staybolt iron per engine for the first year and each succeeding year, and the ultimate cost of solid iron, which must be drilled and frequently tested.

RESEATING MACHINES.—Bulletin G-2, recently published by the Lagonda Manufacturing Company, Springfield, Ohio, describes that company's electric, air, steam and water-driven reseating machines for boiler caps and headers. These machines are portable and are especially designed for use on boilers of the Babcock & Wilcox type, using ground joints between caps and cap seats in the headers.

HOISTING MACHINERY.—The equipment manufactured by the Brown Hoisting Machinery Company, Cleveland, Ohio, consisting of trolleys, traveling and portable cranes, electric hoists, etc., is presented in a complete and attractive catalogue, No. D-1919, containing 56 pages, 8½ in. by 11 in., and over 100 illustrations. A large amount of data is also given in tabular form as to prices, dimensions and clearances.

LOCOMOTIVE CONDULETS.—The Crouse-Hinds Company, Syracuse, N. Y., has designed several new condulets for use in electric headlight wiring on steam locomotives, which are listed and illustrated in bulletin No. 1000-1. A plan view and side elevation of a locomotive and tender wired with conduit and condulets, and sectional views of the installation are shown in the catalogue, with a list of the materials required. These drawings are complete insofar as it is possible to make them and they should be of value to anyone charged with the work of installing electric headlights.

FEEDWATER FILTER.—A multiple filtration feedwater filter and grease extractor designed for power plant work and manufactured by the Lagonda Manufacturing Company, Springfield, Ill., is described in some detail in Catalogue R, issued by that company. This is a compact, self-contained unit and the multiple filtration assures thorough cleaning by filtering and refiltering the water. The filtering element may be easily cleaned and used repeatedly. The catalogue contains a number of illustrations showing the construction of the filter and several installations, as well as a table of dimensions.

Railway Mechanical Engineer

Volume 93 February, 1919 No. 2

CONTENTS

Thermic Syphons for Locomotive Fireboxes

It is a well-known fact that firebox heating surface is much more productive as a steam generating medium than any other part of the boiler, and some attempts have been made to increase the firebox heating surface by using a horizontal water leg in place of a brick arch. This method did not prove successful, due to the fact that it provided in effect a cold blanket over the fuel bed which hindered rather than aided the complete combustion of the gases, the purpose for which an arch is used. The most recent development along this line is that of the thermic syphons, which are described elsewhere in this issue. They consist of two triangular water legs extending down from the crown sheet to the throat. The fire bricks are supported on the long side of these water legs and the syphons form in effect three combustion chambers above the arch. Thus, the additional heating surface is located in the hottest part of the firebox and divides the flame into three sections, thus increasing its total radiating surface. With these water legs placed above the arch the combustion of the gases should be far enough along to prevent the formation of soot and smoke. This is further checked by the incandescent arch which forms one side of each of the three chambers. A much larger amount of radiant heat should thus be absorbed from the burning fuel than has hitherto been possible and as the amount of heat obtained by radiation is far greater than that obtained by the contact of the hot gases with the heating surfaces, a greater amount of heat from the fuel is utilized. The circulation through these syphons being exceedingly brisk a large amount of heat should be absorbed. This not only increases the evaporating efficiency of the firebox, but affects the entire boiler, as better circulation throughout the boiler should be obtained. The first installation of thermic syphons was made on the Chicago, Milwaukee & St. Paul about six months ago and the tests, which are reported on another page, show that a marked increase in evaporative efficiency was obtained.

Fundamentals in Autogenous Welding

The development of both oxy-acetylene and electric methods of welding metals has been rapid during the past few years. In many cases all that was deemed necessary was to place the apparatus in the operator's hands and after a perfunctory course of instruction set him to work with the thought that welding troubles were over. Many roads soon found, however, that there is much to learn in the handling of the apparatus if successful results are to be obtained. Some roads have developed far more rapidly than others and are doing work which has been impossible on other roads. The chief reason for this is that they have given the problem very careful study and have sought to get down to fundamentals. They soon found that in order to get good work and to weld difficult jobs that thorough instruction was necessary and this cannot be over-emphasized, for the possibilities for saving money by these methods of welding are great if they are handled properly.

There appears elsewhere in this issue an article discussing some fundamental facts regarding the oxy-acetylene process, in which it is shown that there are right and wrong methods of handling the torch. Of particular interest is the analysis of the oxy-acetylene flame and how easy it is by the improper manipulation of the flame to make a soldering rather than a welding job; also, how important it is that filler materials of proper characteristics should be used in order to obtain satisfactory work. It is these things that must be carefully studied in the handling of any welding process if success is to be attained. The man that thoroughly knows the subject, knows the materials with which he works and how to get the best results from them, is the one who will make the greatest saving and produce the best work. It is of fundamental importance that this be considered in any attempt to develop autogenous welders in railway shops.

Employment of Returning Soldiers

We read much in the newspapers concerning what is to be done with the returning soldiers. Too many of us look upon it as a government proposition. To a certain extent it is, of course, but to a very large extent it is up to every individual employer of men. The government should so regulate the affairs of the country that business will improve. It should insist that every one of its departments that involves the occupation of men proceed with the necessary construction to provide markets for the materials from the workshops of the nation and to provide labor for the men. It is not doing so in its department of railroad administration—the contrary is true. Purchases are held down to a minimum in spite of a large amount of deferred maintenance. Attempts have been made, however, to increase the opportunities for employment on the railroads themselves by the introduction of the eight-hour day, which requires three shifts in 24 hours where before two were used. The individual employer of men where he can possibly justify additions to his forces should take care of the returning soldier and particularly the man who has enrolled from his immediate vicinity. Justice requires that this be done. Those of our boys who do come back have served our interests well. They have saved our nation from disgrace and sorrow. Our responsibility to them does not cease with their disenrollment from service. Everyone must seek to make their re-entry into civil life a success.

Patriotism of Belgian Railway Men

It is impossible for American railroad men, not having been subjected to the horrors of invasion during the war, fully to appreciate what it meant to their brothers in Belgium and northern France. We might have had our own ideas as to what we would have done in case our land were invaded but it is practically impossible to realize what it would mean to us. An interesting sidelight on what it meant to the railway men of Belgium and how their patriotism was put to test is vividly given in an article recently published in the Railway Gazette of London. At the time of the invasion the railway engine drivers took as many locomotives into France as possible. Comparatively few mechanics, however, escaped in this way and due to the congestion, by no means all of the engines. Those that were left refused to carry on the service. At first German employees were brought into the country, but later as Germany's demand for men grew and because of many accidents caused by the unfamiliarity of the Germans with the peculiarities of the road, a strong endeavor was made to get the Belgian railway men to work. The Germans offered large increases in wages and as high as $10 a day to the enginemen, but the Belgians steadfastly refused. They and their families were told that they would be deported into Germany, but still this did not alter their attitude.

Railway officers and hundreds of men were put in prison, towns were penalized, but still the men did not give way. Throughout 1916 the German administration in Belgium took every step to increase unemployment with a view of forcing the men through distress to work in Germany. The railway men, however, were more valuable to the Germans in Belgium than in Germany and instances of pressure brought to bear on them, which amounted to regular persecution, are too numerous to mention. At Tournai the railway men were condemned to four months' imprisonment for refusing to work on German engines. Finding them equally obdurate at the end of their sentence it was increased to a year's imprisonment, during which time they nearly died of hunger. At Brussels, despite threats and pleadings, the railway men would give no assistance and finally the Germans ordered the banks to cease any payments of money to their wives and families, the men being deported into Germany, leaving their families to live under charity or to starve. The railway men resisted to the end. They were true to their country and even though they were not privileged to fight on the battlefield, by their patriotism and refusing to work for the Germans, they served their country's cause loyally, despite the privations and persecutions to which they were subjected.

Developments in Locomotive Design

In this issue of the *Railway Mechanical Engineer* is published a description of two of the most recent developments in the design of locomotives, both of which are intended to increase the efficiency of the machine and to reduce its cost of operation. Both are particularly noteworthy and make one think of the wonderful development made in locomotive design and locomotive accessories during the past 10 years. Whence have these improvements come? Who was it that developed them, engaging the best talent in the country for the purpose? There is hardly an improved mechanical appliance on the locomotive today that was not fostered and nurtured and developed by our railway supply fraternity, which has become a tremendously important institution in the railway field of this country. True, many of the embryonic ideas were obtained from railroad men, but the process of investigation, study and development has been carried on by the supply interests. Their incentive, of course, is profit, but the competition has been so keen under past conditions that they have had to provide a product with real merit if they had any hope of success. Under this competition these products have been developed to a high state of efficiency and their savings in the cost of operation have been such that the railroads have found it profitable to buy them. To be sure the railroads have co-operated with the supply companies in working out the designs to a logical conclusion by placing a sufficient number in operation so that the weak points might be determined and corrected.

The manufacturers of these devices have had under private ownership an open and scattered field, so that if a group of men on one railroad could not be convinced that the device was worth trying, there was still plenty of opportunity for convincing others, where, perhaps, operating and maintenance conditions were more favorable, and there were very few meritorious devices that did not find an opening on some road in the United States. Under government control these manufacturers have but one chance to get their devices tried, and that rests with a central committee at Washington which, with such a large task before it, would naturally become over conservative. It is evident, therefore, that with this greatly narrowed field it will be far more difficult to introduce and develop improvements than was formerly the case. In order to get an idea of our condition 10 years hence, under the existing conditions, one has but to think of what has been accomplished during the past 10 years under private management. Would we have had the air brakes we have today? Would the brick arch have been in such extended use as it is today? Would an attempt have been made to introduce feedwater heaters, reverse gears, stokers, superheaters and the many other noteworthy improvements which have met with success? Does this nation realize what an important factor the railway supply interests have been in the development of railway equipment? To remove their incentive for further development and to make it more difficult for them to introduce improved devices will seriously retard further growth.

Equipment Standardization in England

As in the United States the germ of standardization has taken root in England. Sir John A. F. Aspinall, general manager of the Lancashire & Yorkshire Railway, in a presidential address to the Institution of Civil Engineers, strongly opposed this tendency. The conditions in England are somewhat like those of the United States as far as the necessity for having several designs of locomotives to meet the physical conditions is concerned. They are unlike the United States in that a comparatively small amount of equipment was interchanged between the roads before the war. There has been, therefore, no demand for standardized details of construction as there has been in this country. Sir John, however, appreciates the possibility of standardizing to this extent, but argues strongly against extreme standardization.

Assuming that the possibility of seven types might serve the requirements of the English roads he calls attention to the fact that these types will have to be split up into various classes to enable them to deal with the work in all parts of the country without reducing loads. But he says, "Assuming that the seven types will do all the work, the question of maintaining those types for a long period of years depends on the march of progress; and if you look back over a series of years you will find that each period of, say, 10 years on some lines and 15 years on others, calls for great changes in the locomotive brought about by changes in traffic conditions." Thus he goes on to show that the number of classes must be increased in the future, for true economy demands that the machines be kept absolutely up to date.

The individual railway companies have, as in this country, developed an admirable system of duplication which it would be very costly to change and he points out that inasmuch as it would be impracticable absolutely to replace the present designs with standard designs, the transition period would at least extend over 25 years. This will be very expensive—"As the money to be saved on new construction will be trivial and will be much more than wiped out by the interest on the greatly increased value of stores at workshops and outdoor locomotive sheds, necessitated by the introduction of new parts." He quoted the address of Alba B. Johnson,* president of the Baldwin Locomotive Works, before the Chamber of Commerce last year and finds confirmation of Mr. Johnson's views in the growth of locomotive power in the United States during the past 15 years. In speaking of standardization as a bar to progress he says:

"In pressing forward the all-important question of the further standardization of parts, nothing should be done to prevent the acceptance of new ideas which tend toward the improvement of conditions and the economy of operation, though a nicely balanced judgment will often be required to decide between the acceptance of some excellent new idea and the economy to be maintained by the retention of parts which are absolutely interchangeable.

"In the world of mechanism there can be no finality, and we ought not to look forward to finality if we are to keep pace with other nations. The brightest ideas of many minds may easily be killed by over-standardization, and one has but to look at the motor car industry to see how the inventive brains of many of our countrymen have been stimulated by the varied requirements of motor travel to produce some of the most beautiful mechanism in a number of forms, many of special engineering merit. One trembles to think how the too enthusiastic theoretical standardizer could in this case have put a stop to practical progress, and sterilized the best efforts in this great modern industry, while the well thought out standardization of many details and minor parts has helped the manufacturer to purchase parts in a competitive market."

*See *Railway Mechanical Engineer*, May, 1918, page 246.

It is exceedingly interesting to read the opinion of so great a man as our neighbor across the sea on this tremendously important problem. It coincides with the thoughts of our ablest men in this country. We have only to think where we would be today had standardization as it was promulgated the first of last year been enforced 10 years ago to realize where we will be 10 years from now if the present plan of the Railroad Administration persists.

All Sorts of Plans for the Railroads

Twice before, in recent history, railroad men, bankers, politicians and shippers have had an opportunity to air their theories of railroad regulation. Once, in 1914, before the Hadley commission, and once, in 1916-17, before the Newlands committee, but never before has there been such an opportunity as at present for general publicity for different theories of railroad regulation. During the entire month of January the Interstate and Foreign Commerce Committee of the Senate was in session, hearing whomsoever could speak with some show of authority on this question. Probably the most important testimony was that given by the Interstate Commerce Commission, the counsel and representatives of the railway executives, and the representatives of the Association of Owners of Railroad Securities. Naturally, the Interstate Commerce Commission was for an extension and a continuation of its authority with the right to fix minimum as well as maximum rates and to pass upon new issues of railroad securities.

The outstanding feature of the railway executives' plan was the creation of a new cabinet office with a secretary of transportation to fill this office. His duties would be that of assuming the responsibility for adequacy of rates. In addition, railroad companies would be permitted to incorporate under federal laws instead of state laws, and federal regulation would be substituted for state regulation.

The Association of Owners of Railroad Securities, which is an association formed by S. Davies Warfield, president of the Continental Trust Company of Baltimore, with a membership consisting of insurance company officers, savings bank officers, etc., is opposed to the secretary of transportation idea and to federal incorporation, but wants a law passed which will guarantee to the railroads rates sufficient to yield a minimum fixed return on their securities.

It will be seen that in all of these plans, the maintenance of healthy competition is essential. In other words, the dream of economies under a unified railroad administration is apparently recognized as a dream by nearly all the classes of men who are giving their views to the Senate committee. Even Clifford Thorne, representing various shippers, is opposed to government ownership and government operation. Only Mr. McAdoo and his successor in office, Walker D. Hines, continue to urge retention of the roads by the government for five years. The retirement of William G. McAdoo as director general, and the assumption of that office by the former assistant director general, Walker D. Hines, was effected without any immediately apparent change in policy of the Railroad Administration. Mr. Hines takes up the task of urging a five-year retention of the roads in the same vigorous spirit that Mr. McAdoo gave to it.

NEW BOOKS

Proceedings of the Traveling Engineers' Association. Edited by W. O. Thompson, secretary. 478 pages, 6 in. by 8½ in., illustrated, bound in leather. Published by the association, W. O. Thompson, secretary, care of general offices, New York Central, Cleveland, Ohio. Price $1.

This is the official report of the twenty-sixth annual meeting of the Traveling Engineers' Association, held in Chicago September last, which was one of the most successful conventions ever held by this association. The subjects discussed covered particularly the duties of traveling engineers and the opportunities they had for helping the nation win the war. Fuel economy was practically the keynote of the entire convention, and much valuable information was presented on this subject. Several interesting subjects of more technical interest were discussed, among them being proper maintenance of locomotives, superheater performance, improvement in the air brake service and maintenance, locomotive cab and cab fittings on modern locomotives, and engine failures. This volume contains an address by Frank McManamy, assistant director of operation, United States Railroad Administration, outlining the importance of the duties of the traveling engineer, and a paper on "The Railways in the War," by Samuel O. Dunn, editor of the *Railway Age*. Eugene McAuliffe, manager of the Fuel Conservation Section, presented a paper on railway fuel conservation.

The Starrett Book for Machinists' Apprentices. By Howard P. Fairfield, assistant professor machine construction, Worcester Polytechnic Institute, and Carl S. Dow, S.B., editor-in-chief Practical Mechanical Engineering and Practical Shop Work. Fourth edition, 176 pages, illustrated, 4½ in. by 7 in., bound in leather. Published by the L. S. Starrett Company, Athol, Mass. Price 50 cents.

While this book is essentially for the apprentice rather than the expert machinist, many machinists will find it of much interest and value, as it is intended to answer questions as to how to do the everyday work of the average machine shop. The aim in preparing the book was to select the elementary features most essential to the advancement of machinists' apprentices and students in technical and manual training schools. It is intended to give a portion of the instruction ordinarily given by the teacher or by more experienced machinists and will also serve as a reference book for data not to be memorized. The different classes of work are taken up separately; the most common errors are pointed out and the correct practice indicated. Attention is given to the proper use and care of tools, the reading of micrometers and verniers, bench work, lathes and lathe tools, grinding, belts, gears, etc. Distribution is being made exclusively through the hardware dealers handling Starrett tools.

An Investigation of Twist Drills. By Bruce W. Benedict and W. Penn Lukens. 139 pages, illustrated, 6 in. by 9 in. Bound in paper. Published by the Engineering Experiment Station of the University of Illinois, Urbana, Ill.

This bulletin contains an account of a series of experiments to disclose certain facts regarding the performance of metal drills. One-inch drills of several standard makes, and cast iron test blocks made in the shop laboratories, were used. The power required for different speeds and rates of feed was noted in all tests and the thrust and torque of the drill were recorded by special dynamometers. The economical helix angle, point angle, clearance angle, speed and feed were determined, and the effect of pilot holes was shown.

Some of the more important points brought out by the investigation are the following: The lowest power consumption was attained with helix angles from 35 to 40 deg., while in cast iron an angle of 30 to 35 deg. gave the best average endurance. For drilling holes at depths of more than 3 in. a drill with a large helix angle gives the best results. In general a point angle of about 110 deg. seems more satisfactory than the usual angle of 118 deg. A peripheral clearance of 6 or 7 deg. showed the maximum endurance. An edge angle of 130 deg. is recommended for all but the heaviest feeds. This angle may be decreased for light feeds and increased for heavy feeds. Drills with concave cutting edges and large chip spaces showed the lowest power consumption and the greatest endurance. The endurance of a drill may be increased from three to ten times by simply rounding the sharp corners at the edge. This has the effect of preventing the corners from burning.

Bulletin No. 103 may be had gratis from the Engineering Experiment Station, University of Illinois, Urbana, Ill.

COMMUNICATIONS

THE SUBTLETY OF STANDARDS

LOUISVILLE, KY.

TO THE EDITOR:

There is scarcely a word more heavily laden with deceit than that of STANDARD. Its meaning is sadly misinterpreted even by men of intelligence. It conveys to the lay mind that something long in dispute and unsettled has been agreed upon. We think of it as something carefully worked over, hammered and boiled down until nothing remains but the essence. It suggests a system or device or a method which may be followed by the unknowing and assumes that that which has long been in a state of unrest and turmoil is forever out of the way, pigeon-holed, ticketed and labeled and finished. Tamper with what you may, criticise as you feel disposed, but keep away from that which is immobile, permanent, fixed—OUR STANDARD. Whose Standard?

While investigating one of our big new U. S. Standard Mikado engines, I found the throttle lever altogether too short for easy handling for the average engineer. Cab fittings and their proper location are among our most troublesome things for the reason that no two men will agree as to the exact location of anything. It has been our plan to take several opinions under advisement and, by pooling the ideas, select the best average and go ahead. By this means we think we have attained a fair degree of success and our cab arrangement is said to be good, in fact so much so that we are occasionally beguiled into speaking of it as "our" Standard.

As a matter of fact every new engine suggests modifications of one kind or another, and in riding with our men from point to point we get information regarding cab fittings and fixtures which cannot be had in any other way. Our cab arrangement is excellent, for our engines and our men are pleased with it, but under no circumstances would we say it is adaptable to every railroad. Our house appears to be in order and we like our furniture, then why should we discard that which suits a majority of our operators to adopt a doubtful design of another's invention? Standard Practice data are useful, very useful, but they must not be substituted absolutely for an experience which has proven its practice.

"Just as soon as we have become accustomed to the new order of things we may like the Standard better," I hear some one say. Not so. It is impossible to get used to a short throttle lever and equally impossible to do one's best with an inconvenient arrangement of cab fittings. Whose business is it to correct these things and see that they do not appear on the next lot of engines? Which of the manufacturers will take the pains incident to obtaining the information it has taken us years to accumulate? Whose standard is it that we are trying to swallow without making faces? The deceitfulness of riches is not to be compared with the deception lurking in the word "Standard."

It has gotten some of us into ten or fifteen years of extra trouble which we will doubtless pass on to our successors, an unwelcome heritage. We can hardly hope to outlive it. Those "three reasons * for standardizing locomotives" is the strongest possible testimony to the subtlety of the word which seems to have tricked a lot of old heads into thinking that the impossible might be pulled once anyhow on the unsuspecting.

MILLARD F. COX.

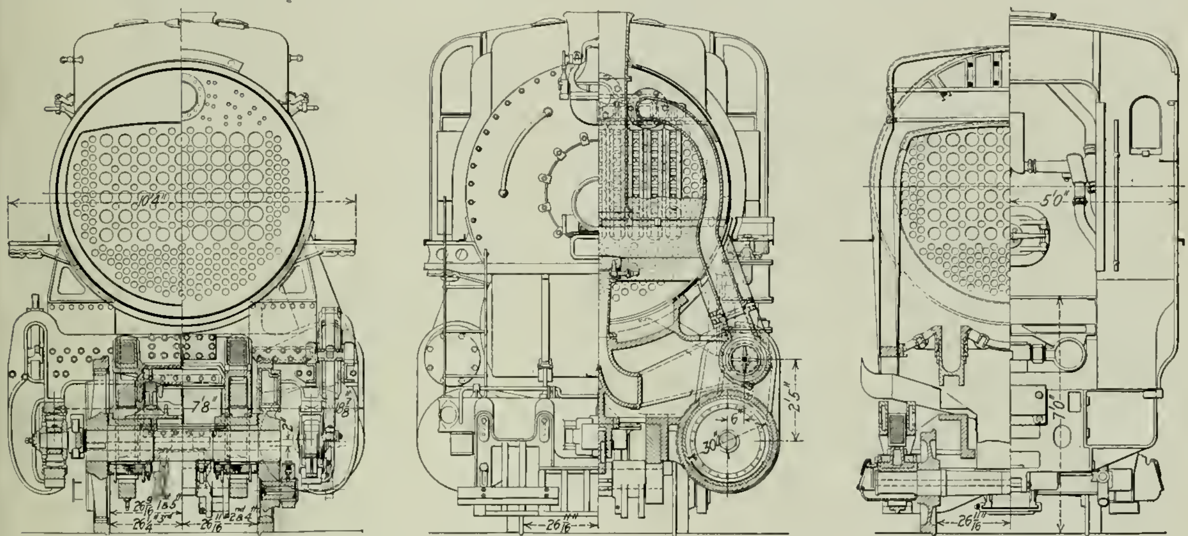
Pennsylvania Lines 2-10-2 Locomotive

New Features Include Four Point Suspension System, Two Radial Axles and Road or Switching Pilot

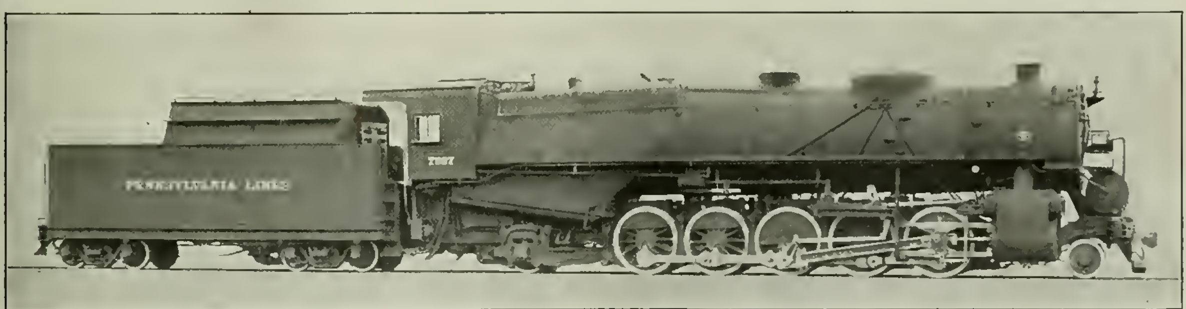
The Pennsylvania Lines West of Pittsburgh have recently received from the American Locomotive Company several locomotives of the 2-10-2 type which are notable for two reasons. The total weight is greater than for any engines of this type previously built, and yet they are able to operate on 23 deg. curves. Although these locomotives are extremely heavy they are in service on a division with low grades. All that have been received thus far are on the lines running from Conway Yard, near Pittsburgh, Pa., to Ashtabula, O., and Erie, Pa. The majority of the traffic being handled is ore moving from Ashtabula to Conway and coal from Conway to Ashtabula. The ruling grade on this line is 0.3 per cent, and the engines are handling approximately 85 loaded ore cars. The locomotives have a rating of 7,100 adjusted tons which amounts to about 6,000 actual tons.

The Consolidation type has long been the standard for freight service on the Pennsylvania Lines West of Pittsburgh. The recent designs developed practically the limit of the tractive effort obtainable with four driving axles. As the traffic conditions demanded heavier motive power it was felt that the increase in tractive effort which would be secured with the Mikado type would be so slight that it was best to go to the use of five driving axles. This 2-10-2 type, which is known in the company's classification as the N-1s, was therefore designed. Orders have been placed with the American Locomotive Company for 35 of these locomotives, and 25 are to be built at the Baldwin Locomotive Works.



Sections of Pennsylvania Lines West 2-10-2 Type Locomotive

Locomotives with five coupled pairs of driving wheels and a lateral motion driving box on the front axle cannot traverse curves sharper than 16 deg. In order to enable these engines to pass 23 deg. curves both the front and rear drivers are fitted with the Woodward floating axle. The tires on these wheels are set 53⅛ in. apart, and the main driving wheels have blind tires. In order to permit of coupling on sharp curves a pilot drawbar with a long shank is used and the pilot beam casting is cored out where the coupler enters, so that it can swing some distance on either side of the center line.

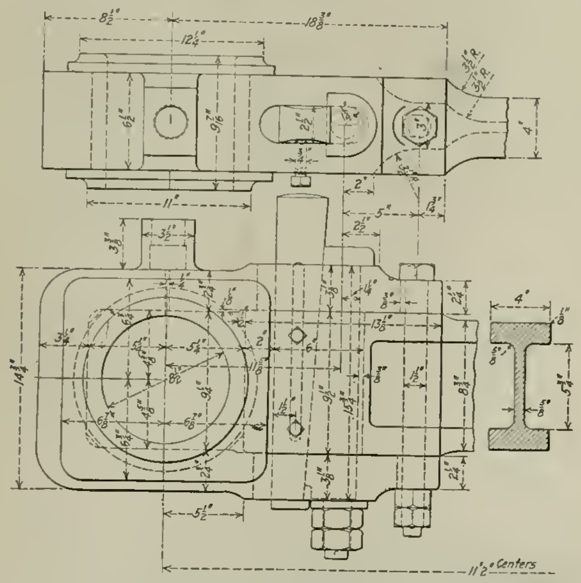


2-10-2 Type Locomotive for the Pennsylvania Lines West

While designed primarily as a road engine this type is well adapted for use in hump yard service. A unique design of cast steel road and switching pilot worked out by representatives of the Pennsylvania Lines West has been applied which makes it possible to use the engine in either service without the delay incident to removing the pilot and applying footboards or vice versa. Details of the pilot are shown in one of the illustrations.

The equalizing system is a very unusual departure from standard American practice. Instead of the three point suspension introduced by Eastwick & Harrison in 1838, which has been universally used in this country for many years, a four-point suspension has been adopted. The leading truck is equalized with the front pair of driving wheels, the three center pairs of driving wheels on each side are equalized together and the rear pair of drivers are equalized with the trailing truck.

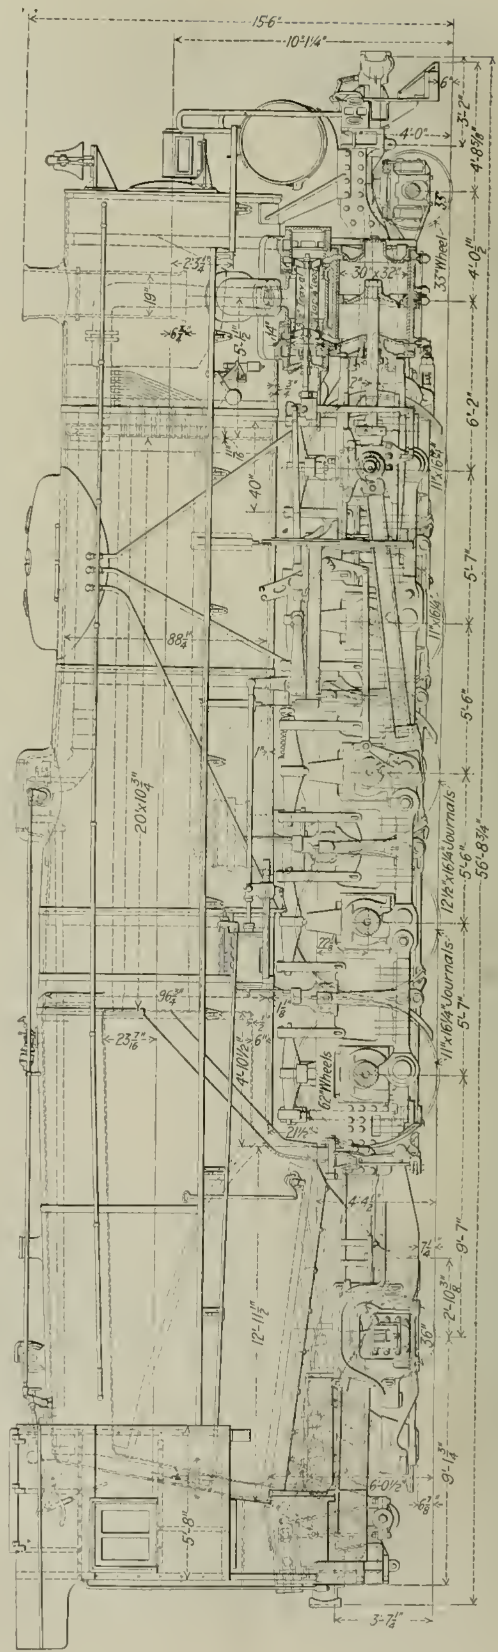
The valve motion which is of the Walschaert type, has an extremely long travel. While a full gear travel of seven inches has usually been considered the maximum that could be attained with this type of valve motion the design used on these engines gives a travel of 8½ in. The long travel is secured without excessive angularity by the use of a long radius rod and a long link combined with an eccentric crank of large throw. A similar arrangement has been in use for some time on a Consolidation locomotive, and the results ob-



Back End Main Rod; Pennsylvania Lines West 2-10-2 Locomotive

tained have demonstrated that the theoretical advantage of the long travel is borne out in actual practice. The steam lap of the valve is 1⅛ in. and the lead ¼ in. The 14-in. piston valve has a long spool and the passages to the cylinder are made as short and direct as possible. The cylinders, which are 30 in. in diameter with a 32-in. stroke, have a Z-shaped piston with a cast steel center and a cast iron bull ring. The cylinder lubrication is effected by a two-feed force feed lubricator which is attached to the left steam chest. A two-feed hydrostatic lubricator located in the cab is provided to supply oil to the air pumps and the cylinders of the stoker engine.

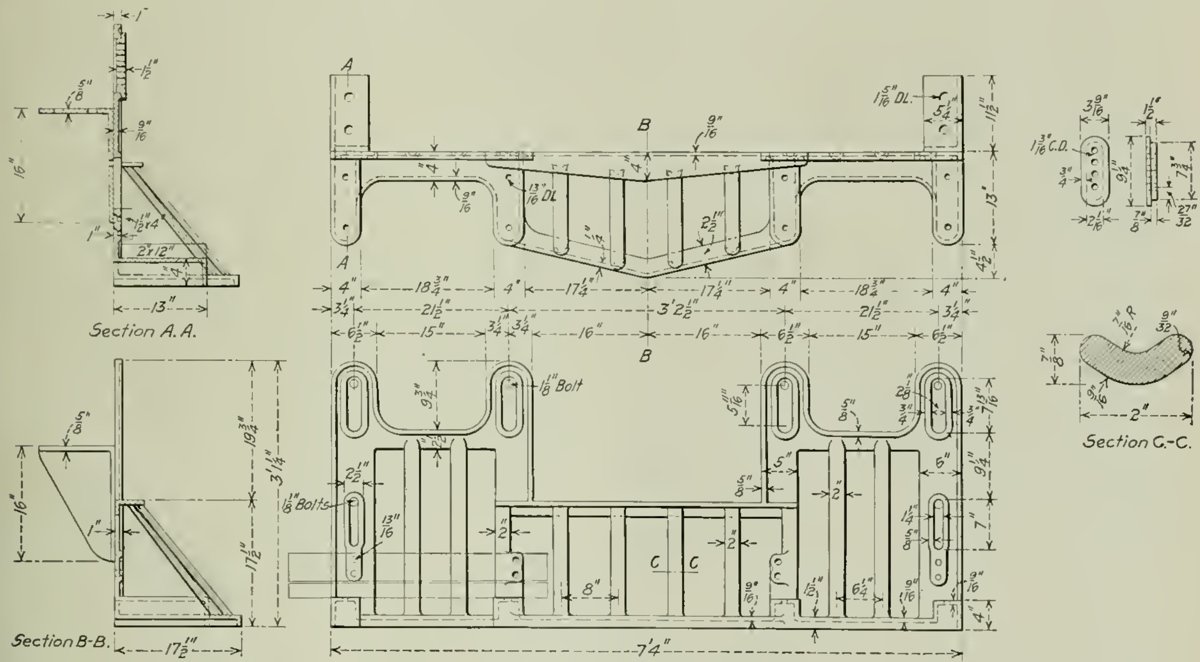
The boiler has been designed with a view to securing adequate firebox volume, and a large fire area through the tubes. The firebox is fitted with a brick arch and has a combustion chamber approximately 5 ft. long. There are 54 flues of



Elevation of Pennsylvania Lines West 2-10-2 Type Locomotive

5½ in. diameter, and 196 tubes 2½ in. in diameter. While the total heating surface is decreased by the use of the larger tubes, experiments have demonstrated that as tubes are lengthened beyond a certain point the evaporation does not increase proportionately. The most desirable ratio of length to internal diameter is approximately 100, and by using 2½ in. tubes this ratio is secured. Although the locomotives are now operating with a boiler pressure of 205 lb., the boiler is designed to carry 250 lb. The weight on the driving wheels is sufficient to permit of securing additional tractive effort, still maintaining a satisfactory factor of adhesion. The Crawford underfeed stoker is applied to these locomotives. The driving cylinder is placed in inclined position on the left side of the engine.

The location of the main reservoirs presented a difficult problem. It was finally decided to place a 36-in. diameter reservoir ahead of the cylinder saddle. The braces leading from the smoke box to the frame are steel castings, which also serve to support the reservoir. A three-rung ladder leads from the pilot beam to the running board. The air piping is arranged under the running board bracket, which is designed especially to receive it. Two sets of 13-in. by 12-in. brake cylinders are set between the first and second drivers, both working on the same levers and operating the shoes on all five pairs of driving wheels. An 8½-in. cross compound compressor is used. Among the specialties applied are Pyle National headlight, Commonwealth locomotive cradle, and Delta trailing truck, Ragonnet power reverse gear, and Barco flexible joints.



Cast Steel Pilot for Both Road and Yard Service

The principal dimensions and ratios of the locomotives are as follows:

General Data

Gage	4 ft. 8½ in.
Service	Freight
Fuel	Bit. coal
Tractive effort	80,942 lb.
Weight in working order	435,400 lb.
Weight on drivers	351,300 lb.
Weight on leading truck	23,100 lb.
Weight on trailing truck	61,000 lb.
Weight of engine and tender in working order	642,400 lb.
Wheel base, driving	22 ft. 2 in.
Wheel base, total	41 ft. 11½ in.
Wheel base, engine and tender	82 ft. 7¼ in.

Ratios

Weight on drivers ÷ tractive effort	4.34
Total weight ÷ tractive effort	5.38
Tractive effort × diam. drivers ÷ equivalent heating surface*	701.67
Equivalent heating surface* ÷ grate area	89.4
Firebox heating surface ÷ equivalent heating surface,* per cent	5.21
Weight on drivers ÷ equivalent heating surface*	49.1
Total weight ÷ equivalent heating surface*	60.9
Volume both cylinders	26.18 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	273.1
Grate area ÷ vol. cylinders	3.06

Cylinders

Kind	Simple
Diameter and stroke	30 in. by 32 in.

Valves

Kind	Piston
Diameter	14 in.
Greatest travel	8½ in.
Outside lap	1⅛ in.
Inside clearance	⅛ in.
Lead in full gear	¼ in.

Wheels

Driving, diameter over tires	62 in.
Driving, thickness of tires	3½ in.
Driving journals, main, diameter and length	12½ in. by 15 in.
Driving journals, others, diameter and length	11 in. by 15 in.
Engine truck wheels, diameter	33 in.
Engine truck, journals	6½ in. by 12 in.
Trailing truck wheels, diameter	36 in.
Trailing truck, journals	7½ in. by 13⅞ in.

Boiler

Style	Conical Belpaire firebox
Working pressure	†205 lb. per sq. in.
Outside diameter of first ring	90¼ in.
Firebox, length and width	80 in. by 144 in.
Firebox plates, thickness— Back and sides ⅜ in., crown 7/16 in., throat ½ in., tube 9/16 in.	
Firebox, water space	6 in.
Tubes, number and outside diameter	196, 2½ in.
Flues, number and outside diameter	54, 5½ in.
Tubes and flues, length	20 ft. 10¾ in.
Heating surface, tubes and flues	4,302 sq. ft.
Heating surface, firebox, including arch tubes	423 sq. ft.
Heating surface, total	4,725 sq. ft.
Superheater heating surface	1,618 sq. ft.
Equivalent heating surface*	7,152 sq. ft.
Grate area	80 sq. ft.
Center of boiler above rail	10 ft. 1¾ in.

Tender

Tank	Rectangular water bottom
Frame	Cast steel
Weight	207,000 lb.
Wheels, diameter	33 in.
Journals, diameter and length	6 in. by 11 in.
Water capacity	10,000 gal.
Coal capacity	20 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.
†Designed to carry 250 lb. per sq. in. pressure.

Recent Papers on Fuel Conservation

Abstracts of Railway Club Papers Prepared by Fuel Experts Describing Methods for Saving Coal

PAPERS on fuel conservation were presented recently at the New England Railroad Club and the Southern and Southwestern Railroad Club by Robert Collett and B. J. Feeney, respectively, both of the Fuel Conservation Section of the Railroad Administration. A letter was also circulated by Joseph Harrington of the Fuel Administration, on the removal of soot by burning salt. All three of these are abstracted below:

IMPORTANT POINTS IN FUEL CONSERVATION

BY ROBERT COLLETT
Assistant Manager Fuel Conservation Section, U. S. Railroad Administration

A recent request from General Pershing called for six million tons of fuel to be shipped abroad. Our present shipbuilding program was estimated to require fourteen million tons of coal, merely to make and transport the steel. And for the eight million tons of vessels, it will require five tons of coal for each ton of shipping which leaves the ways. Each 15,000-ton ship that leaves our harbors for Europe consumes about 3,000 tons of coal or 12,000 barrels of fuel oil. Before the war, ships coaled abroad and made the round trip. Now the reverse is true. We can readily see, therefore, that the need for conservation, aside from cost is such as to challenge our best efforts. By reason of the large corps of fuel inspectors under the Federal Fuel Administration, aided by the railroad fuel inspectors, who have also been given federal authority, the general quality of the fuel has been, and will continue to be, very much improved. The miners have responded wonderfully. Better car movement has also helped.

ORGANIZATION.

It is our recommendation that one general man without other duties than fuel conservation, be charged with general supervision, reporting to the chief operating or chief mechanical officer; if to the latter, it should be understood by all departments that matters so requiring will be referred to the chief operating officer whose support, it is needless to add, will be given all practicable suggestions. The particular reason for this is, that many features vitally affecting fuel performance can only be handled as a system matter. The monthly fuel cost should be furnished at the earliest possible date after the close of each month to all divisional as well as general officers, and be made a subject of discussion at staff meetings. The plan of having fuel conservation committees, as a number of roads now have, is a good one.

Where practicable, each road foreman of engines or supervisor should have a certain number of crews and engines and be thoroughly familiar with the fuel costs in such service. We will assume one road foreman of engines with an assistant, and one traveling fireman—which is more supervision than is usually provided—has 50 engines in service at all times under his direction. At present costs these 50 engines are worth, if at all modern, we will say $40,000 each, or a total of $2,000,000. We will estimate they will burn 300 tons of coal each month at $6 per ton, a fair average for New England; this gives a fuel cost of $1,800 per engine per month, a total of $90,000 per month, or $1,080,000 per year. This supervision then is virtually responsible for the proper operation for every minute it is in actual service, of $2,000,000 worth of machinery and the proper use, so far as the work of the crew is concerned, of $1,080,000 worth of fuel annually. It is very natural, therefore, they should be anxious to make a good return for their stewardship.

PERSONAL EXPERIENCES ON A LARGE ROAD.

Several years ago the writer was assigned to the work of fuel economy on quite a large railroad, reporting directly to the general manager. In this experience I early learned that the one thing that goes further than anything else in obtaining results, is the unqualified support of the officers—from the chief operating officer down—which should be manifested by a personal interest *in*, and familiarity *with*, what is going on in the work. The important factors which it was my duty to study and control, as outlined by the general manager, were as follows:

Waste of fuel by reason of engines being delayed on the road.
Waste of fuel by engines being kept under steam unnecessarily at terminals.
Improper handling of the engine.
Excessive use of fuel by firemen.
Engines not in good condition.
Fuel not up to contract specifications.
Shortage of coal reaching pockets.
Fuel used for other purposes and improperly charged to engine use.
Any other matters that may require attention.

Locomotive Performance Sheet.—By the performance sheets we were enabled to make a very close study of fuel distribution, that is, the charges to individual engines and other miscellaneous purposes. A daily record was kept by charging the coal consumed on each trip, including that used at terminals, against the gross ton-miles in freight service and passenger car miles in passenger service for the trip. We found that no matter how closely we watched the distribution feature and although the law of averages worked out very satisfactorily for a given class of service, we could not depend on the performance sheet alone to locate excessive consumption. There are so many factors that can influence the performance even on similar runs, that a very close personal knowledge of the conditions of all of the locomotives and also close contact with the crews, shop forces and despatcher's office is necessary.

Waste of Fuel by Engineers Kept Under Steam Unnecessarily at Terminals.—It had been the practice with us and it is not at all uncommon for the mechanical department to keep engines ready for service at all times. This method was reversed and the transportation department gave three hours' notice for the required engines. All of the time above three hours the engines were held under steam, was charged at a rate determined by tests for the various class of service and considered as excessive fuel used at the terminal. This is a matter for local handling, but requires very close watching. Firemen instructors should spend a certain portion of their time educating fire-tenders and there should be terminal fuel committees, consisting of the master mechanic, yardmaster, and others. Proper division officials should be looked on as responsible for economical use of fuel at terminals, including stationary plants.

Improper Handling of Engines.—Engineers are quite naturally anxious to make a good performance. The statement has sometimes been made that "You can't teach an old dog new tricks." That is not my experience. Any man who can successfully hold down a job of running an engine over a period of years, I maintain not only *can*, but has the disposition *to* learn the most economical methods of operation. We will presume a man is not quite so skillful with the reverse lever and throttle or injector as some other men. Let the road foreman or supervisor go with him and say, "We want to see, or the boss wants to know, what is the best that can be done on this run in the way of fuel. I may make a few suggestions, but I will take the responsibility for making the time, etc." He may even handle the engine or fire for a part of the way. Let a note of commendation come back from the general manager or superintendent on the good performance and you will find that it will have the effect of encouraging any man to make a close study, as to how he can improve his methods. Another thing, the enginemen see things neglected which to them seem of great importance, and which causes them to believe that fuel economy is not really so much the desire of the management, or they would have been corrected. It is desirable that the crews be advised as to what steps are taken to remedy defective conditions which come under their observation and to which they call attention.

Excessive Use of Fuel by Firemen.—Not unlike many other roads, our plan was to give new firemen a letter to be signed by three different engineers, when in their opinion he was qualified. We found they did not always ride with crews who were the best instructors. We then arranged to select the crews they should ride with and whom we knew would train them properly. We also established the first, second and third year progressive examinations and made a rule that as nearly as practicable, the road foreman of engines would approve the application of new firemen before they entered the service for pay. In the past eighteen months scarcely any rule would apply in the employment of new men, but speaking in general it is possible to attract good men for the position of locomotive firemen.

I believe it worth while to maintain a competent force of traveling firemen or firemen instructors. There are always firemen on every division of the railroad who are very skillful, and the other firemen should be taught their methods. Everything depends on the new firemen getting a proper start and this has not been given enough consideration on the average railroad. The treatment accorded by the engineer, especially with new men, is important.

Engines Not in Good Condition.—Aside from the support of general officers and thorough co-operation between all departments, the condition of the locomotive is the greatest factor in the economical use of fuel. We will pass the matter of design and well known appliances with the statement that appliances, of whatever nature, tend to make the engine more complicated and require that they be properly maintained and operated. Certain devices operating under 100 per cent condition guarantee a certain result, but it is sometimes found that practically all of the benefits of the investment are lost by reason of lack of attention to detail, in its care.

Definite front-end and nozzle arrangements should be established and maintained at standards proven to be the most economical for the grades of fuel to be used. Air openings through ash pans should not be less than 15 per cent of the grate area, and preferably more than this. Tight steam pipes, front ends, tight valves and cylinder packing, grates properly maintained and first class steam distribution are the more important items. Engines cannot be in too good condition. If properly encouraged and especially if they know just what it means in dollars and cents in fuel costs, engineers will assist by their reports in keeping engines in good condition.

It is a good plan for the road supervision to ride engines for the first trip out of shop or during the breaking-in period, giving the shop superintendent or master mechanic a detailed report. These reports can be gone over at the staff meetings of the shop superintendent or the master mechanic with their foremen. We should also commend them for their good work. There should be the closest co-operation between the road supervision and the terminals and shops. It has been often stated that if all of the unnecessary work occasioned by improper reports could be avoided, all of the necessary work could be done.

SUGGESTIONS FOR FUEL SAVING

BY B. J. FEENY
Supervisor, Fuel Conservation Section United States Railroad Administration

The railroads are playing a very important part in the conservation of fuel, as they fully realize the importance of so doing not only because it is a part of the government conservation program, but also on account of the great increased cost of fuel, coupled with the increased cost of labor and materials. At all fuel conferences great stress is laid on the necessity of good locomotive maintenance, constant education of enginemen and firemen, hearty co-operation and a more complete and thorough understanding of the importance of fuel conservation by operating officers. All these things can be accomplished if an effective organization is put on each railroad. There should be a general staff officer in charge of fuel conservation, who should give his entire attention to the conservation of fuel on locomotives, in shops, at terminals, at water stations and for all miscellaneous purposes. He should also give attention to the preparation of fuel received, to its quality and should direct its transportation to and its handling at fuel stations.

Constant and good supervision is necessary to promote fuel conservation, so that all users of fuel may be taught to use it economically in the shortest possible time. We must constantly train our enginemen and firemen so that they will get the highest degree of economy which is consistent with good practice. They should know that every available bit of energy is produced by the fuel that is burned. What good results could be accomplished if the engineers and firemen would have in mind the saving of coal from a point of working the engine to the best advantage, with a view of getting results in the most economical manner. The enginemen should have the assistance of all officers and employees who have anything to do with the purchase, handling and preparing of fuel for use. Fuel economy starts with its purchase and ends at the cinder pit.

The coal on the tender should be used while it is in the best condition and should not be carried on tenders from shopping to shopping. Any practical device that will move coal forward to the fireman should be put on the locomotive tender. Shoveling coal forward, in the absence of a coal pusher, will answer the purpose. The supplying of coal to locomotives should be similar to the method of supplying oil. Daily experience indicates that the coal ticket as prepared by the engineer is not dependable; the coal chute foreman is the best judge of the amount of coal delivered to each engine.

An important subject that should be followed up is the firing up of locomotives in advance of leaving time. The practice of keeping locomotives under steam should be discontinued. Where a locomotive is fired up a long time in advance of leaving time, the front end netting becomes stopped up and the fire becomes dirty, which often results in the engine not steaming and failing on the road. To provide a safe margin, two or three hours before leaving time is early enough to start a fire in a locomotive intended for any service. Any small defect that heat would produce would make itself apparent in sufficient time to permit workmen to correct it or furnish another engine without delay.

There are advantages other than saving of coal in permitting engines to cool off. Workmen are offered more opportunity to work around cool engines; and they permit any character of inspection and good workmanship. The liability of engines moving while under steam is eliminated and there is no expense for engine watchmen to put water in locomotives standing partly fired, which causes damage to flues and firebox; it also avoids unnecessary moving of engines. There is not an element of locomotive maintenance that does not in some degree affect fuel consumption. We should organize and concentrate roundhouse forces so that all work is done on washout and monthly boiler inspection days. This also will allow for quick turning of power on all other days.

In starting fires in locomotives considerable green coal falls through the openings in the grates. After an engine is taken out of the roundhouse the ash pans should be dumped and the coal reclaimed. In many instances there is enough green coal left in the ash pan to haul one thousand tons of freight one mile. Locomotives tying up at points where no roundhouse facilities are available should have their fires banked when the engine is placed at rest and the fires should not be cleaned until two hours before the listed time. This allows the fire cleaner an opportunity to work with cold ashes instead of a hot fire. The ashes remaining in the locomotive all night prevent air from passing through the grates and flues, consuming fuel and reducing the temperature of the boilers with bad effects on the fire-box and flues.

The covering of stacks on locomotives when fires are knocked out should receive more attention, as locomotives with stacks covered retain steam pressure from five to seven hours longer than when they are left uncovered and air is allowed to circulate through the flues. It also prevents the flues from sweating, which often causes engine delays.

The front end inspection of locomotives through the smoke box door should be extended to making inspection through the smoke stack. Many locomotives are in service today with petticoat pipes out of line or hangers and bolts loose, table plates loose, and with holes in them, blower pipe out of line, air pump exhaust pipe out of line, exhaust tips gummed or loose or with bridges in them. Experience has taught that just opening the front door and making an inspection from that point has not given the desired results. Periodical inspections of front ends for air leaks should also be put into effect.

A great many of the older locomotives are running today with draft sheets set so close to the tubes that gases strike them with such force as to stop the flow through other tubes, thus causing excessive heat at the fire door. All draft sheets should be set far enough away from the flue sheet so that the gas, after reaching the end of the flues may travel freely to the atmosphere.

The uniform drafting of locomotives should receive the necessary consideration, in order that the benefits resulting from the proper sizing of coal and the proper handling of it by engineers and firemen may be secured. Records show that firemen who do well on certain locomotives are absolute failures on other engines of the same class, on account of the variation of exhaust tips and other front end irregularities. Often times poor performance is secured where competent firemen are doing their best. Some railroads have already adopted uniform nozzle openings. A record should be kept showing the size of the nozzle opening in every engine and every change in the size of the nozzle should be recorded. A reduction of 1/8 in. in the diameter of the nozzle will waste one ton of coal over an average division.

The saving of coal and the increased efficiency to be produced by testing superheater units at regular intervals of 30 days will no doubt more than offset the expense of examination. Superheater units leaking can waste large quantities of fuel though the locomotive may perform apparently satisfactory service. All flues should be thoroughly cleaned. Many times this work is apparently done, but a closer investigation develops that the tubes are given a "lick and a promise" cleaning only. When flue cleaning is done in this manner, engines will not steam freely and will be wasteful of coal. Such a condition will not exist if there is a capable inspector around.

Much emphasis must be laid on the necessity of keeping boilers clean and free from scale. Tests indicate that 1/16 in. of scale will increase the fuel cost 15 per cent. Good feed water is not always obtainable, but for the sake of economy railroads can well afford to spend money for purifying plants, or any practical means of treating water in tender tanks or locomotive boilers. With any of these treatments, regular and good boiler washing is of vital importance. The inspection of boilers after being washed out is very important. Fuel and labor saving devices must always be kept in best of condition; failure to do so will result in vast waste of fuel. Representatives of the manufacturers should be called on when devices are not giving proper results.

Steam heat pipes on locomotives should be covered from the source of supply in the cab to the rear of the tender. Many locomotives are in service today with 45 ft. of steam heat pipe uncovered and the connection between the engine and tender so low as to be dragging in the snow. In some cases the tender leaks and the drippings fall on the steam heat pipes, condensing the steam in addition to the loss by radiation. Consider how much condensation this 45 ft. of exposed pipe will create on a locomotive on a cold, stormy day, fanned by the winds. The loss does not stop here; in severe weather, on long passenger trains, steam traps and pipes become frozen, due to excessive condensation and it becomes necessary to delay passenger trains to thaw the pipes and again get steam through the train. These delayed passenger trains delay other trains on the road. The steam pipe to the air pump should be placed under the locomotive jacket and all other locomotive steam pipes exposed to the weather should be covered.

Every pound of unconsumed coal that finds its way to the ash pit is a direct loss. Supervisors of fuel can procure good results by meeting engines on arrival at the cinder pit and making clear to the enginemen and firemen the amount of fuel lost by not keeping fires in proper condition.

Close attention must be given to the fuel used at stationary power or heating plants, at terminals, roundhouses, pumping stations, and elsewhere. A large share of fuel is used at these places and frequently wastefully used. A large loss of fuel is sustained due to exposed steam surfaces; in many places steam pipes are laid in or on the ground without any protection from the weather, causing wasteful condensation. When conduits are not available these lines should be located overhead and covered. Cover all steam pipes, connections, boilers and manifolds, and stop all air leaks in boiler settings. There should be a more general use of CO_2 recording apparatus and draft gages in connection with the investigation of fuel conditions in power plants. Efforts here will yield a large return.

Compressed air is the most expensive power to produce that is used for railroad shop and yard service. All air lines leading from compressors should be so arranged that each department can be cut out when working hours cease, or when it is no longer required. Fuel bulletin boards should be established at all district terminals. These boards should be used exclusively for fuel bulletins, circulars and graphic statements. Railroads that publish employees' magazines should see that each publication gives some space to the subject of fuel conservation. Coal gates and coal chutes should be stenciled, "Save Fuel," also other places where coal is handled or used. If every railroad man will but realize his personal responsibility to do his utmost under existing conditions, and if he will in his daily work steadily apply the good practices with which he is familiar, avoiding the poor practices and encouraging others to do likewise, enormous savings in fuel will result.

REMOVE SOOT BY BURNING SALT

Joseph Harrington, administrative engineer, United States Fuel Administration, at Chicago, describes a method for removing soot from the furnace walls and heating surfaces which was called to his attention by C. J. Causland, electrical engineer of the Pennsylvania at Chicago, and Jerome Kohout, chief chemist of the Commercial Testing & Engineering Company, Chicago. He says:

"One of the most difficult problems which conservation engineers in the State of Illinois encounter in the burning of local coal in both steam boilers and house-heating furnaces, is the removal of the excessive deposit of soot and tarry substances on the cold heating surfaces of the boilers. This tar or soot has an insulating value far in excess of any commercial insulator. One 1/32 in. of soot on a boiler reduces the transmission of heat approximately 10 per cent, and 20 per cent for 1/16 in. In view of the well known fact that heating surfaces quickly become covered with soot as thick as the foregoing, the great importance of some method of removing it becomes apparent.

"This process is in brief, the application of common salt to the fire under conditions which will produce dissociation of the sodium and chlorine from the salt and the subsequent combination of these elements with the carbon of the soot to form a substance which then passes off as a gas or drops off of the heating surface. The practice is briefly as follows:

"The fire is put into good condition with a substantial body of hot fuel. Common salt, previously dried, is then thrown or sprinkled onto the incandescent fuel bed in a quantity depending entirely on the size of the furnace. In the case of a household furnace a pound at a time is ample, in the case of a large power plant boiler, four or five scoopfuls may be required. The dampers are kept open so as to maintain the furnace temperature and the salt is allowed to remain until the fumes have entirely disappeared.

"Immediately upon charging the salt, the furnace becomes filled with dense white fumes which may require as much as half an hour to entirely disappear. If results are not secured on the first application, it should be repeated as many times as necessary. Once the heating surface is thoroughly cleaned, a small application every few days is usually sufficient to keep it so."

U. S. R. A. Mechanical Department

Abstract of Mr. McAdoo's Report to the President of the Work and Accomplishments of This Section

On February 9, 1918, Frank McManamy, chief inspector of locomotives for the Interstate Commerce Commission, was appointed manager of the Locomotive Repair Section of the United States Railroad Administration. On July 1, 1918, he was promoted to assistant director of operation, in charge of the mechanical department and his jurisdiction extended to include car repairs, supervision of mechanical standards, and of tests of new devices. Later he was given jurisdiction over the enforcement of federal laws for the promotion of safety for employees.

Methods Adopted for Improving Equipment.—On account of the competition of high wages paid by the shipbuilding plants and war industries generally there was a considerable shortage of skilled mechanical workers in railroad shops. Immediate relief could only be secured by working a greater number of hours. Railroad shops on many of the important lines were placed on a basis of 70 hours per week, and the remainder on 60 hours per week, which was approximately an average increase of 20 per cent in shop hours. In June all shops were placed on the 60-hour-per-week basis, which continued until the signing of the armistice, when arrangements were made for readjusting the hours, which were reduced on November 25 to nine, and December 9 to eight hours per day.

Co-ordination of Locomotive Repairs.—A check of the repair shops indicated that their combined capacity was ample to take care of all of the locomotives if they were properly distributed. Plans were immediately perfected to send locomotives to the nearest available repair shop, regardless of ownership, and to distribute the work so that each shop could be worked to capacity. Under this plan, since January 1, we have transferred 2,065 locomotives to the shops of other railroads under federal control, where they had been given heavy classified repairs; otherwise, these locomotives could not have been kept in service.

Comparison of Motive-Power Conditions.—Accurate comparison of motive-power conditions with one year ago is difficult, because of the varying methods of rendering reports prevalent on the different lines. The improvement in the condition of locomotives is perhaps best indicated by the fact that, notwithstanding the tonnage handled during the year has been the heaviest ever known, there are now stored in good condition and ready for winter service, 1,189 locomotives, while one year ago there was not a single serviceable locomotive in storage. This improved condition is due to the co-ordination of shopwork.

Condition of Freight Cars.—The general condition of freight cars has also shown a substantial improvement since the organization of the mechanical department. The percentage of bad-order cars to revenue cars on line has decreased from 7 per cent in July to 5.3 per cent, which is a decrease of approximately 43,000 in the number of bad-order cars.

GENERAL CONDITION OF EQUIPMENT AND TERMINAL FACILITIES

One of the prime causes for the necessity of government control of railroads and one of the most serious conditions the Railroad Administration was called on to correct when assuming control, was the general bad condition of locomotives and cars. As the Railroad Administration had at that time no mechanical department organized to check up shop practices and handling of equipment at terminals, the Interstate Commerce Commission promptly placed at the disposal of the Railroad Administration the records and personnel of its Bureau of Locomotive Inspection and Bureau of Safety.

The reports showed that in addition to the congestion caused by failure of shippers to unload cars promptly that a serious situation existed on account of the number of bad-order cars at various terminals and also on account of the general defective, run-down condition of motive power.

Prompt handling of locomotives was seriously hampered by the condition of roundhouses and the lack of facilities at many points to make running repairs to large modern locomotives. Roundhouses built 20 or more years ago for locomotives in service at that time were still being used to house locomotives more than twice the size for which they were designed. Repairs had to be made either out of doors or in open roundhouses with the temperature below zero. Steam pipes, injectors, air pumps, and even cylinders froze and burst, and in many cases locomotives were actually frozen to the track in roundhouses and could not be moved.

Only two methods for improving the general condition of equipment existed; namely, to increase the shop facilities and forces or to use more efficiently the facilities and forces which were available. Increasing the facilities and forces under war conditions was clearly impossible; this left as the only practical means of improving equipment conditions the adoption of some plan whereby existing facilities and forces could be made to produce greater results.

The plan of considering the condition of equipment as a whole and taking steps to improve it by uniformly increasing shop hours on all railroads in the country and utilizing to their full capacity the facilities of all shops which could only be done under federal control is really what improved the condition of the locomotives and cars.

STANDARDIZATION OF EQUIPMENT

The standardization of locomotives and cars is an ideal which has long been striven for by the various organizations of railroad officials, and much has been done by them to bring about this result. Complete accomplishment has never heretofore been possible because of an absence of authority to enforce standards which might be agreed upon. This has now been accomplished by the preparation and adoption of standard designs for different types of locomotives which are suitable for all classes of service and by standardization of freight and passenger equipment.

Standardized Locomotives.—In addition to the vigorous action which had been taken to improve the condition of existing equipment, the necessity of adding to the available stock was recognized and designs were worked out for standardized locomotives and orders placed for their construction.

The locomotives were built from standardized designs for various reasons, the principal of which are as follows:

First. To reduce to a minimum the time required to prepare drawings, patterns, and dies, and thus enable deliveries to begin quicker than where separate drawings and patterns would have been necessary for each lot of locomotives allocated to a particular road.

Second. To secure quantity deliveries.

This method of construction has resulted in delivery being made at a quantity rate which could not have been approached had the locomotives been ordered to individual designs. The increase in the rate at which standardized locomotives can be turned out is clearly shown by the following comparison of two of the principal shops of the American Locomotive Company during a portion of July and August when the locomotives built were of individual design with a similar period in September and October when they were building standardized locomotives. During five weeks, beginning July 20, an average of 13⅗ locomotives per week were turned out at the Dunkirk plant, while during five weeks, beginning September 14, an average of 19⅘ locomotives per week were turned out at the same plant. For Schenectady, during the five-week period beginning July 20, an average of 8 locomotives per week were turned out, while for the corresponding period beginning September 14 an average of 13 2-5 locomotives were turned out. It will be seen that the increased production due to the standardized locomotives was about 50 per cent.

Third. It has also provided a supply of equipment, the parts of which are largely interchangeable, which is available for use anywhere in the event of congestion. This removes the necessity of carrying a large stock of repair parts peculiar to the locomotive and avoids delay which results when repair parts must be ordered from some distant owning road.

Standardized Cars.—The freight car situation was handled along the same lines as were the locomotives. In addition to the designs for freight cars, for which orders have been placed, designs have been prepared for all-steel box cars of 50 tons capacity, refrigerator cars of 30 tons capacity, general service gondola cars of 50 tons capacity, steel frame stock cars of 40 tons capacity, flat cars of 55 tons capacity, oil tank cars of 7,000 gal. capacity, oil tank cars of 8,000 gal. capacity, oil tank cars of 10,000 gal. capacity, acid tank cars of 7,000 gal. capacity, acid tank cars of 8,000 gal. capacity, and acid tank cars of 10,000 gal. capacity. While no cars have actually been built from these drawings, they are available at any time that the traffic needs show them to be desirable.

Complete plans and specifications of all steel baggage cars, in both of 60-ft. and 70-ft. lengths, have been prepared, and tentative plans prepared for 70-ft. steel coaches, and for steel passenger and mail, passenger and baggage, passenger, baggage and mail cars.

STANDARD PRACTICES

Standard practices have been established and circulars of instruction issued for mechanical work covering the following matter, which will result in more efficient and economical operation of locomotives and cars: Repairs and betterments to freight cars, painting freight cars, installing field ranges in cars, locomotive maintenance, care of journal boxes, inspection of ash pans and spark arresters, lubrication of locomotives, repairs to refrigerator cars, and superheating of locomotives.

Rules have also been promulgated for the inspection and testing by the inspection forces of the railroad companies of all stationary boilers used, which will make it possible to save the insurance premiums now paid on such boilers.

CONSOLIDATION OF MECHANICAL TERMINAL FACILITIES

Under private operation, at many points complete organizations for the maintenance of a comparatively small number of locomotives or cars were maintained side by side, which resulted in a duplication of work, heating plants, and supervising forces. Wherever a saving could be made without adversely affecting efficiency, such useless facilities were eliminated. Such consolidations have been made at 417 points and the annual saving effected thereby amounts to $2,363,535.95. Additional consolidations are now under way.

In connection with this work extensive investigations were conducted covering shop and engine-house operation, resulting in changes and improvements which have materially increased the output. For example, at one large shop the output of locomotives receiving classified repairs increased over 50 per cent, and increases ranging from 10 to 25 per cent were secured in many shops. It was also possible by rearranging the method of handling work in engine houses to release hundreds of employees that were sorely needed in other departments, and the saving effected in engine-house operation by such reduction in force, while not obtainable for all railroads, on one railroad alone amounted to $1,061,332.68 per annum.

The condition of motive power on all lines under federal control has shown a gradual improvement, and the locomotives in service are in much better condition than they were one year ago. In addition to the improved condition of power in service there are now in white lead 1,021 locomotives in the various regions. These locomotives have received classified repairs and are being held in reserve for winter service. There are also being placed in storage for service during the winter months 150 new standardized locomotives which were recently received from the locomotive builders.

NEW DEVICES FOR LOCOMOTIVES AND CARS

On account of the vast number of new devices for use on locomotives and cars which were submitted, a comprehensive plan for handling this question was necessary. Detailed instructions were issued by circular establishing rules for the submission of such devices for the consideration of the Railroad Administration and a committee on appliances was created to conduct necessary investigations and to pass upon the value of all devices or appliances thus submitted. Up to date 692 such devices, which cover practically everything used in locomotive or car construction, have been submitted. One hundred and thirty-five of these have been examined, ten of which have been recommended for test under service conditions. These tests will proceed under the direction of the mechanical department.

EDUCATION OF RAILROAD EMPLOYEES

It has long been recognized that the service rendered by railroad employees is capable of substantial improvement by proper training of employees along industrial lines, and many railroads have in existence plans for furnishing additional training for their employees.

The Railroad Administration is in sympathy with this work and plans are being considered for establishing a system of technical training for railroad employees in connection with the Board of Vocational Education. It is also believed that this work may be profitably extended to employees who have been injured in the service to an extent that prevents them from following their usual vocation, but with proper training may fill other responsible positions.

ORGANIZATION

The work of the mechanical department, Division of Operation, has been conducted with a total force of approximately 60. Of these, 28 are considered as field men whose duties are to conduct investigations concerning shop practices and shop output and to furnish first-hand information relative to the efficiency of the work performed and the general condition of the equipment. They are also used to conduct investigations and handle disputes between shop men and railroad officials which have not reached the point where they should be referred to the Division of Labor.

The office force, in addition to handling ordinary correspondence, receives, checks and compares the reports showing the general condition of equipment, the assignment of locomotives to shops for repairs as well as the assignment of new locomotives received from the builders. It also includes the mechanical engineering staff, which checks up the designs for locomotives and cars, receives reports of failures of standardized locomotives, and corrects faulty construction. The mechanical engineering staff also acts as a clearing house for information concerning standard designs of locomotives and cars, distributes drawings and other data necessary to the proper standardization of equipment and keeps the practices up to the standard.

NEW TYPE OF LOCOMOTIVE FIREBOX

By the Introduction of Thermic Syphons the Evaporating Efficiency of the Boiler Is Materially Increased

THE Chicago, Milwaukee & St. Paul has recently completed a series of road tests of a locomotive equipped with a new type of firebox. The principal feature of the design consists of two water legs extending longitudinally from the throat of the boiler to the crown sheet. The trials were conducted with one locomotive so equipped and another of the same class with a firebox of the usual type. The results showed that the new design caused a noteworthy increase in the boiler efficiency with a corresponding decrease in the fuel consumption. The performance, as developed by the tests, is summarized in the adjoining table. Locomotive 7142 had the ordinary type of boiler, while engine 7615 had the new type of firebox.

The boiler tests conducted at Coatesville in 1912 proved conclusively that the water evaporated per square foot of heating surface in a locomotive boiler is much greater in the firebox than in the boiler tubes and flues. The maximum evaporation per square foot of tube heating surface is estimated at about 10 lb. per hr., while the corresponding figure for the firebox is 55 lb. per hr. Since these important facts have been demonstrated, the tendency in boiler design has been along the line of increased firebox heating surface. It is a difficult matter to secure more than a very limited increase in the area of the sheets in the usual design of firebox. To overcome this difficulty J. L. Nicholson of the Locomotive Firebox Company, Chicago, recently patented a new design of firebox. The salient features of this design are the water legs in the firebox, known as Nicholson Thermic Syphons.

The syphon is formed from a single sheet rolled to shape and closed by welding along the front edge. The sides are set four inches apart and joined to the crown sheet, extending from a point about 18 in. from the front edge to about 6 in. from the rear. The front edge of the water leg is parallel to the tube sheet; from the back of the crown sheet it slopes downward toward the throat of the boiler. The cross section of the leg is increased at the lower edge to form a segment of a circle six inches in diameter, which joins a 6-in. tube extending into the lower portion of the tube sheet. The syphons thus form a support for the sectional brick arch. Fig. 1 shows the side elevation and plan of the firebox on which the

GENERAL RESULTS OF TESTS

	Engine 7142	Engine 7615	Decrease, Engine 7615 Per cent
Pounds coal fired per thousand gross ton miles, actual	124.36	93.64	24.7
Pounds coal fired per thousand gross ton miles, equated	124.36	86.63	30.3
Pounds coal fired per locomotive mile	271.9	218.9	19.4
Average tonnage hauled	2,190.0	2,340.0	6.8*
Pounds of water used per thousand gross ton miles	670.72	596.22	11.1
Pounds water evaporated per pound of coal fired	5.39	6.36	18.0*
Equivalent evaporation per pound of coal fired	6.54	7.74	18.3*
Equivalent evaporation per pound of dry coal	7.28	8.60	18.1*
Equivalent evaporation per pound of combustible	8.37	10.49	25.3*
Boiler efficiency	57.65	73.75	27.92*

* Increase.

tests were made, equipped with the syphons. Fig. 2 shows another method of installing thermic syphons in locomotive fireboxes. In this case, instead of flanging the neck of the syphon out and welding it into the throat sheet, a separate diaphragm plate is used, the syphon being formed with a separate neck and expanded into the diaphragm plate, also being riveted and welded as shown. This is for the purpose of giving more flexibility to the installation, and also to enable the manufacturers, by eliminating the flanged portion of the neck and making the neck long enough to fit extreme cases, to standardize the manufacturing forms and dies.

Test Conditions and Methods

The test runs were conducted between Milwaukee and Portage, Wis. The distance westbound was 91.8 miles and eastbound 89.1 miles. There was no attempt to control the makeup of the test trains. The tonnage was limited to what the engines could handle on the ruling grade, and trains were run as extras with whatever cars were available. Two trips eastbound and two westbound were made with each locomotive, the same engine crew being used on all the tests. A road foreman of engines acted as cab observer and all other readings were taken by employees of the test department un-

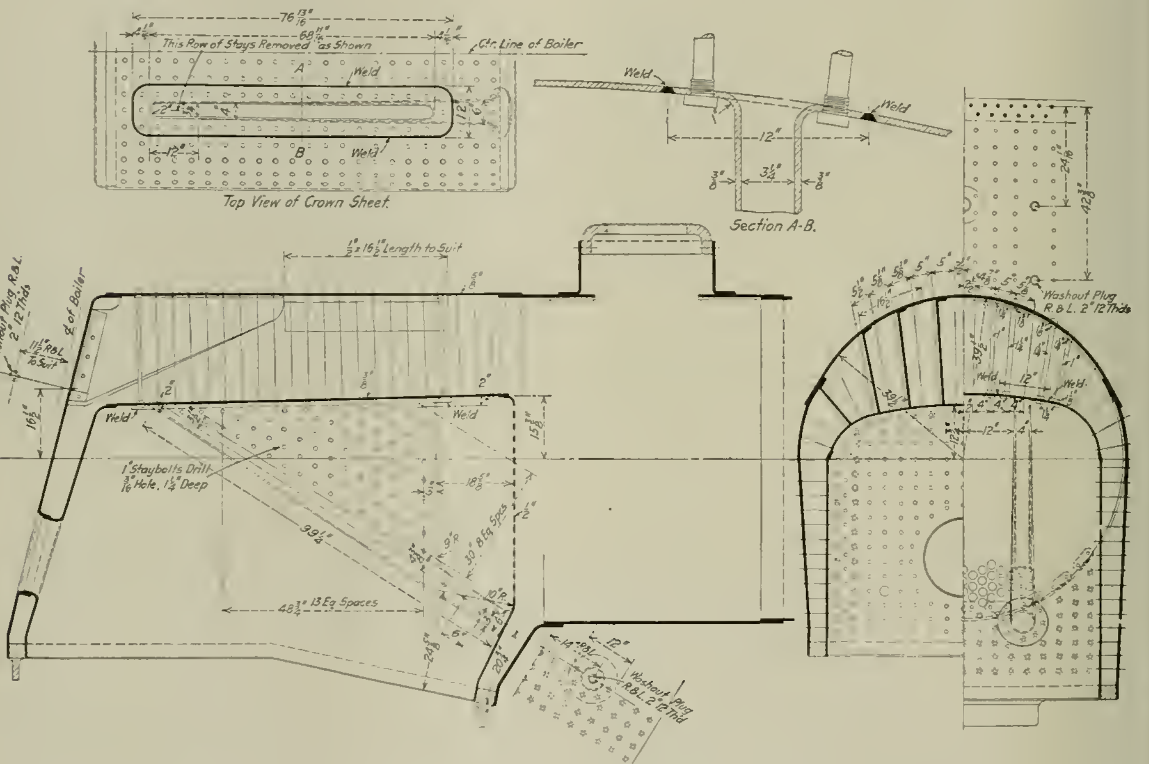

Fig. 1—Firebox of Chicago, Milwaukee & St. Paul Locomotive Equipped with Nicholson Thermic Syphons

The locomotives tested were of the Consolidation type, using saturated steam and equipped with piston valves and Walschaert valve gear. They were alike in all respects except that the firebox of locomotive 7615 was equipped with the Nicholson Thermic Syphons supporting the brick arch, while 7142 had a brick arch supported on four 3-in. arch tubes. Both had recently received heavy repairs.

The engines were coaled at the chutes, no attempt being made to select the coal. The amount used was obtained by weighing the tender at the end of each run with all water emptied out of the tank. Sacked coal was used while at terminals and standing or switching on the road.

Samples were taken from the tender during each trip and were later analyzed. The average analysis was as follows:

Analysis of Coal as Fired

Eng. No.	Moisture	Volatile combustible	Fixed carbon	Ash	B. t. u. per pound coal
7615	10.00	35.02	38.75	16.23	10,184
7142	10.21	37.36	40.80	11.63	11,008

The coal consumption and firing rate are shown below:

Coal Consumption

Eng. No.	Test No.	Total lb. coal fired	Average lb. coal fired per hr.	Lb. coal per hr. per sq. ft. of grate	Lb. coal fired per 100-car mile	Lb. coal fired per locomotive mile	Lb. coal fired per gross 1,000 ton-miles

	Ave.	24,584	4,401	90.18	510.8	271.9	124.36

From an operating standpoint the boiler performance of both locomotives was satisfactory, although it was noticeable

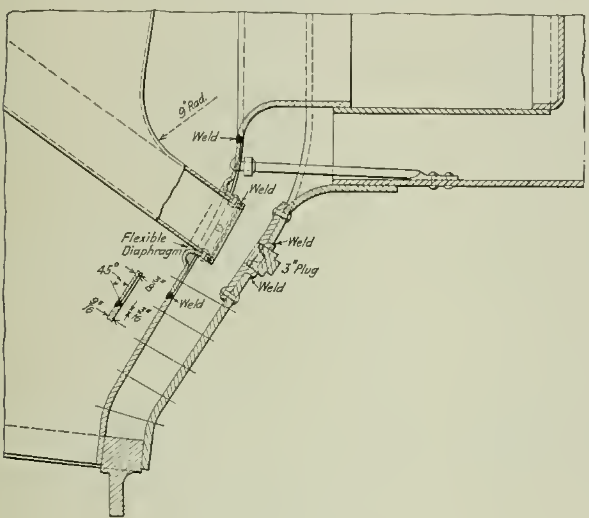

Fig. 2—An Improved Method of Applying the Thermic Syphon to the Throat

that the boiler of engine 7615 was more responsive to the demands made upon it than that of engine 7142.

It will be noted that the average boiler horsepower developed by locomotive 7615 was 807.4, as compared with 834.8 horsepower for engine 7142. This is to be accounted for by the fact that engine 7142 consumed 12.4 per cent more water per thousand gross ton miles. Neither of the locomotives was forced to the limit of the capacity of the boiler. Engine 7615 developed a maximum boiler horsepower of 1,015 on the grade from Milwaukee to Brookfield. This is at the rate of 10.62 lb. equivalent evaporation per square foot of heating surface per hour.

Both locomotives had double exhaust nozzles with 3½-in. tips at the time these readings were taken. On the last round trip with engine 7615 the tips were enlarged to 3-11/16 in. diameter, which reduced the vacuum somewhat. The front end temperatures were obtained by means of a Hoskins pyrometer. It is thought that owing to an improper adjustment of the recorder the temperatures recorded for engine 7142 are too low.

No analysis was made of the front end gases, so it is impossible to tell exactly what changes in combustion conditions were brought about by the changes in the firebox. The reduction in the coal consumption, the increase in the evaporation and the marked absence of smoke indicates that the syphons tend to improve combustion conditions by breaking up the stream of gases and securing a better mixture of the combustible gases and the air.

In considering the increased boiler efficiency secured by the use of the Nicholson Thermic Syphons it should be noted that engine 7615 was working at a lower rate of evaporation

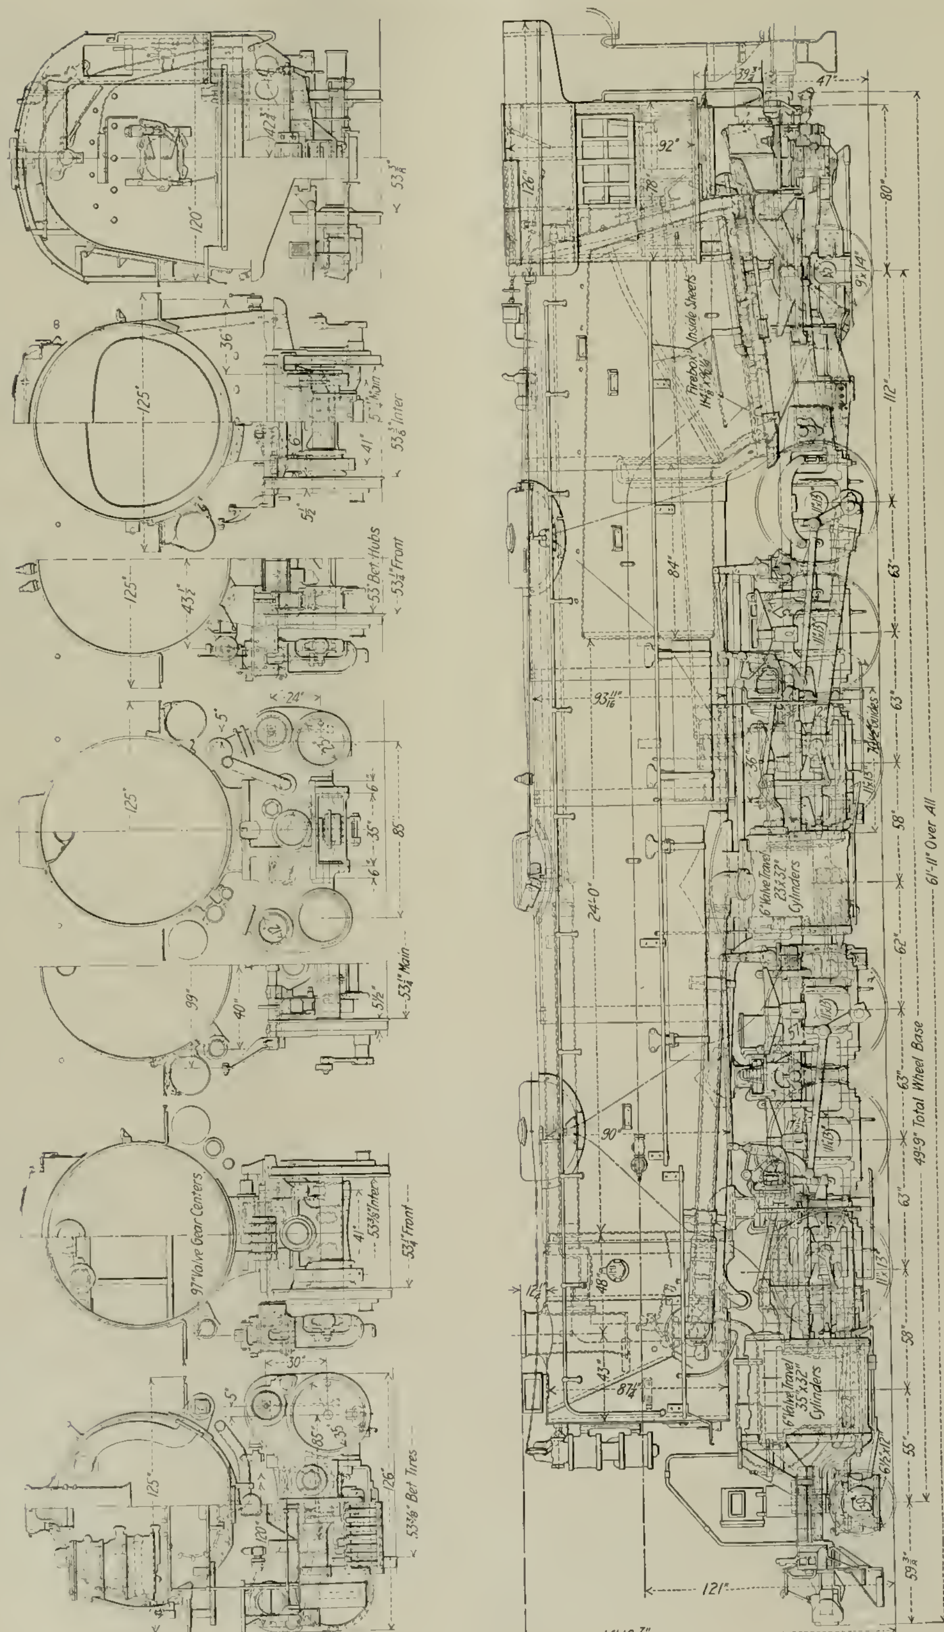
than engine 7142 and also at a lower rate of combustion, which made a favorable condition for obtaining bigher boiler efficiency. In this connection, however, it should not be overlooked that this was not due to operating conditions favoring engine 7615, as the average tonnage hauled by this locomotive was 6.8 per cent greater than that hauled by engine 7142. Making due allowance for the favorable evaporation and combustion rates, there remains a gain in economy which cannot be attributed entirely to the increased firebox heating surface. There is evidently a further saving due to the increase in the radiating surface in the firebox, to the more intimate mingling of the combustible gases with air in the firebox and to the more rapid circulation through the boiler. It is estimated that the rate of flow through the syphons is so fast that all the water in the boiler passes through them every five minutes. Such rapid circulation will cause the water to remain at more nearly uniform temperature throughout the boiler. This should result in a decrease in the boiler troubles due to unequal expansion and contraction.

The cost of application of the Nicholson Thermic Syphons is low, and it is anticipated that the maintenance charges will be negligible compared with the savings effected. The syphon requires no more attention than any other part of the firebox and when properly applied is practically fool-proof and accident-proof. The first installation has been in service for four months and has given no trouble from mud or scale. The rapid circulation has kept the syphons clean and has apparently resulted in throwing the mud and scale into the back water leg, where it can easily be removed. Up to the present time there has been no evidence of scale in the syphons, and no leak or trouble of any nature has developed at the seams or stays. The C. M. & St. P. is now planning to install the syphons on several additional locomotives.



Elevation and Sections of the United States Railroad Administration Standard 2-6-6-2 Type Locomotive

Standard 2-6-6-2 Type Locomotive

**Weights: Total 448,000 lb., Drivers 358,000 lb.;
Tractive Effort Compound 80,000 lb., Simple 96,000 lb.**

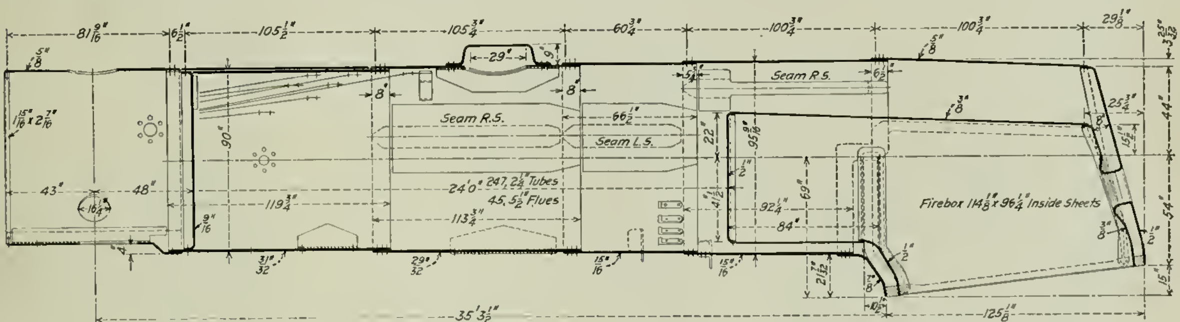
The first of the standard Mallet type locomotives designed by the United States Railroad Administration has recently been turned out by the Schenectady works of the American Locomotive Company, for delivery to the Chesapeake & Ohio. The locomotive is of the 2-6-6-2 type, the lighter of the two standard Mallet types, and orders were placed for 30 of these locomotives.

The locomotive has a weight on drivers of 358,000 lb., 2,000 lb. less than the maximum permissible within the axle load limit of 60,000 lb. The cylinders are 23 in. and 35 in. in diameter by 32 in. stroke and the locomotive is designed to deliver a tractive effort of 96,000 lb. simple and 80,000 lb. compound. In the table will be found a comparison of the principal dimensions and data for a number of Mallet locomotives of the 2-6-6-2 wheel arrangement, of which the standard locomotive is the heaviest both on drivers and in total weight.

The boiler has an outside diameter at the first ring of 90 in., increasing to 95 9/16 in. at the fourth ring just forward of the firebox. The dome is located on the second ring from the front and is 9 in. high.

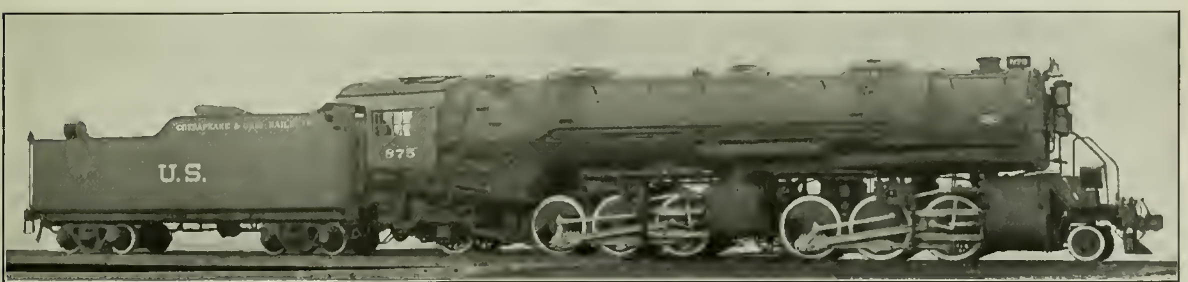
The firebox has a combustion chamber extending forward into the barrel of the boiler 84 in. from the throat sheet, making the tubes 24 ft. long. It is fitted with a Security brick arch carried on five arch tubes and is fired by a Standard stoker. The fire door is of the Shoemaker power operated type and the grates are operated by Franklin power grate shakers. The boiler is fitted with the Locomotive Superheater Company's Type A superheater with 45 units.

In general the detail design of the frames follows that of all the other standard type locomotives which have been built. The top rails for both high and low pressure units are 6 in. wide, with a maximum thickness of 5 in. over the pedestals and a minimum thickness of 4½ in. The lower rails have a maximum and minimum thickness of 3½ in. and 3 in. respectively. The high pressure frames are designed with splice joints at the rear for attachment to a Commonwealth frame cradle which includes in one casting the frames, rear deck plate and trailer equalizer fulcrums. The high pressure cylinders are supported on a single front rail which is cast integral with the main frames.



Boiler for the Standard 2-6-6-2 Type Locomotive

The low pressure frames are designed to receive the articulation joint, which is of the Baldwin universal type, hinged for movement about a horizontal axis transverse to the center line of the locomotive and provided with a ball joint pin connection at the high pressure unit end. The low pressure cylinders are supported by double rails, both of which are bolted to the main frame. The frames of both units are spaced 41 in. from center to center, while the cylinders have a spread of 85 in. Owing to the size of the low pressure cylinders the face of the lower rail bolting flange is only 20½ in. from the center line of the locomotive, thus requiring an offset in the front frame rail. This is provided by bolting the front rail to the inside face of the lower rail extension of the main frame and reducing the lateral thickness of this section to 3 in. where it is joined under the cylinder to the front rail. The section of the extension under the cylinders is 11 in. deep, while that of the front rail has a vertical thickness of 7 in. The upper front rail is bolted and keyed to the top of the main frame over the front pedestal. The section of the main frame here is 13 in. deep with horizontal slots for the splice bolt nuts over the pedestal.



The Railroad Administration Standard 2-6-6-2 Type Locomotive

The cylinders and valve chambers throughout are bushed with Hunt-Spiller gun iron. In the design of the high pressure cylinders is incorporated the Mellin intercepting valve which completely controls the admission of steam, either exhaust from the high pressure cylinders or steam direct from the boiler, to the low pressure receiver pipe. Piston valves

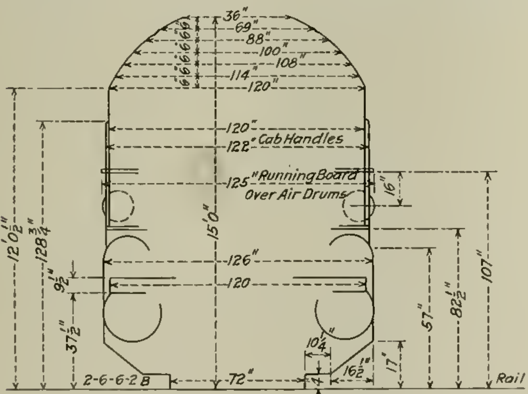
are employed with both the high and low pressure cylinders. These valves are 12 in. in diameter and have a maximum travel of 6 in. The valves for the low pressure cylinders are



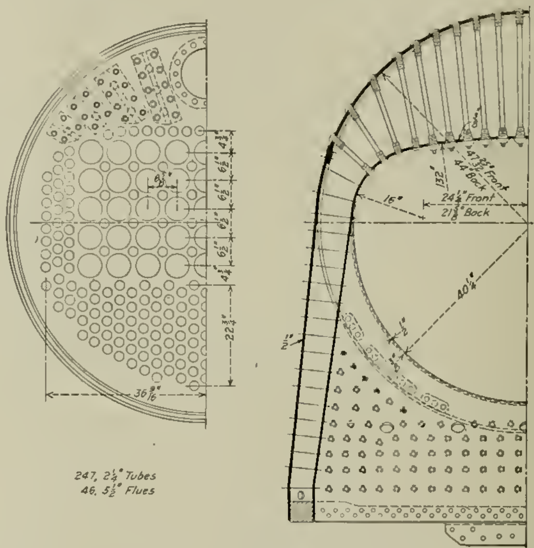
Clearance Diagram for the Standard 2-6-6-2 Type Locomotive

double ported while those for the high pressure cylinders are the same as are used on the 0-6-0 type switchers.

The high pressure piston specifications call for either rolled or cast steel of dished section, while for the low pressure pistons the center of which has a diameter of 30¾ in., exclusive of the bull ring, cast steel only is specified. Hunt-Spiller gun iron bull rings and packing rings are used

distribution is controlled by the Baker valve gear and the Chambers back head type throttle. The locomotive is fitted with a Lewis power reverse gear.

The driving journals throughout have a diameter of 11 in. and are 13 in. long. The driving boxes are interchangeable on all journals, except that the crown brass for the main journals is finished with a clearance of 1/100 in. instead of 1/32 in. The same driving box is also used on the heavy Mountain type locomotive, with the exception of the main journals, and on the main journals of the

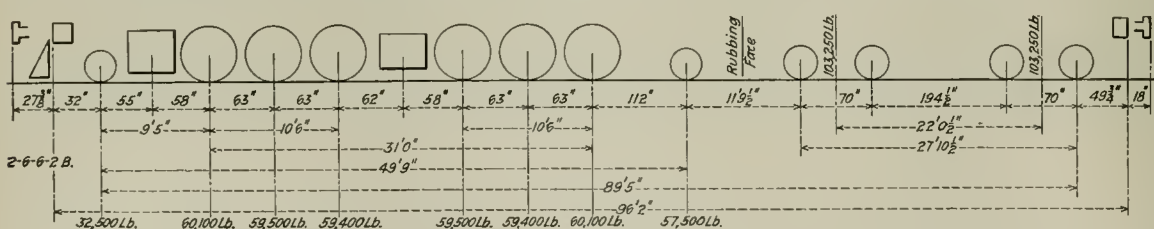


Tube Layout and Firebox Section—Standard Light Mallet Type Locomotive

light Mikado type locomotive. The engine truck is of the constant resistance type and the trailer truck is of the Cole-Scoville type.

The tender tank has a water capacity of 12,000 gallons and a coal capacity of 16 tons. It is carried on a Commonwealth cast steel frame, and is one of the three standard types which have been designed to meet the requirements of all of the standard locomotives. The trucks have cast steel side frames and are of a design which is used on all the standard freight locomotives. The Unit Safety drawbar and Radial buffers are used between the engine and tender.

Among the specialties with which these locomotives are equipped are four Coale three-inch open safety valves, No.



Weight Distribution Diagram for the Standard Light Mallet Type Locomotive

on both high and low pressure pistons. The design of the crossheads is the same in detail as that employed on all previously built standard locomotives, and is interchangeable with that on the 0-6-0 switchers. Paxton-Mitchell packing is fitted both on the valve stems and piston rods. Steam

13 Nathan non-lifting injectors, Nathan bull's-eye lubricators, Ashton steam gages, Okadee flanged blow-off cocks and Barco flexible pipe joints.

On the diagrams, prepared by F. P. Pfahler, chief mechanical engineer, Division of Operation of the Railroad Administration, will be found the clearances and actual wheel load distribution for these locomotives. Other dimensions and data are as follows:

ENGINE FAILURES—CAUSES AND REMEDIES*

It has been said that the engine failure reports form one of the best barometers of the efficiency of the mechanical department, and this is indeed the case where all detentions and reported failures are carefully investigated *before* they are recorded. Where the engine failures charged depend, however, on the reports of conductors or on interpretations of the rules by the despatcher's or trainmaster's clerk, the accuracy of the charge is often open to question.

An engine failure on the line of road is an expensive proposition, more far reaching in its effects on the movement of trains than is generally believed by mechanical men who have had no road experience, often so upsetting the despatcher's pre-arranged schedule that we cannot be surprised if he loses his temper and feels like charging every delay, regardless of cause, as an engine failure.

*Abstract of a committee report presented at the 1918 convention of the Traveling Engineers' Association.

DEFINITION OF WHAT CONSTITUTES AN ENGINE FAILURE

1. All delays waiting for an engine at an initial terminal, except in cases where an engine must be turned and does not arrive in time to be cared for before leaving time.

2. All delays on account of engines breaking down, running hot, not steaming well, or having to reduce tonnage on account of defective engine, making a delay at a terminal, a meeting point, a junction connection, or to other traffic.

DELAYS THAT SHOULD NOT BE CONSIDERED AN ENGINE FAILURE

1. Do not report cases where engines lose time and afterwards regain it without delay to connections or other traffic.

2. In cases where a passenger or scheduled freight train is delayed from other causes, and an engine (having a defect) makes up more time than she loses on her own account, should not be called an engine failure.

3. Do not report delays to passenger trains when they are less than five minutes late at terminals or junction points.

4. Do not report delays to scheduled freight trains when less than 20 minutes late at terminals or junctions.

5. Do not report delays when an engine is given excess of tonnage and stalls on a hill, provided the engine is working and steaming well.

6. Do not report delays on extra dead freight trains if the run is made in less hours than the miles divided by ten.

7. Do not report engine failures on account of engines steaming poorly, or flues leaking, on any run where the engine has been delayed on side-tracks other than by defects of engine, or on the road an unreasonable length of time—say, 15 hr. or more per 100 miles.

8. Do not report an engine failure for reasonable delays in cleaning fires and ash-pans on the road.

9. Do not report failures against engines that are coming from outside points to the shops for repairs.

10. Do not report cases where an engine is held in the roundhouse for needed repairs and called for by the operating department, they being informed that the engine will not be ready until a stated time. Failure to provide that engine before the stated time should not be called an engine failure.

11. Do not report broken draft rigging on engines and tenders caused by air being set on train, account of bursted hose or breaking in two.

12. Do not report delays to fast schedule trains when the weather conditions are such that it is impossible to make the time, provided that the engine is working and steaming well.

13. Do not report delays when an engine gets out of coal and water, caused by being held between coal and water stations an unreasonable length of time.

If rule No. 2 is correctly interpreted there is no need for the 13 qualifying rules. However, if an engine apparently fails on the line of road, it is charged as an engine failure, although the engine may be in perfect condition and the delay due entirely to other causes, such as mishandling on the part of the crew, either engineer or fireman, excessive tonnage, weather conditions, or any of a hundred possible causes, any of which may result in a poor engine performance and for which the engine or its condition is least of all responsible.

The true cause of the poor performance should be determined by a full investigation, which, however, may not be possible immediately and, consequently, when determined several days may have elapsed before the cancellation of the charge is requested. This being the case, it appears to this committee, in justice to the mechanical department, it would be much more equitable were all doubtful cases simply shown as delays on the "morning report" and these delays then promptly investigated and where the failure is established it be so reported on a subsequent report, or else a monthly report compiled, showing all failures and delays.

Any criticism to be of value must be constructive; therefore, as a first step toward the elimination of engine failures, we would recommend a closer relationship between all departments of a railroad, "get-together" meetings about once a month where engine and train performance can be freely discussed and wrong practices corrected.

We would also recommend that the mechanical department be kept advised as far ahead as possible of any power requirements, so that fitting preparation can be made, as where no such system obtains the roundhouse foreman will sometimes take a chance when pressed for power and let an engine go on the assumption that perhaps it can make just one more trip.

A check of the various engine failures extending over a period of two years, shows as follows:

Failures in Two Years Per 1,000 Miles of Road

Air brake and piping	15
Ash pan and rigging	5
Axle, driving, broken	2
Brake rigging	3
Boiler studs	1
Boiler checks	4
Blow-off cocks	3
By-pass valves	2
Cylinder packing	9
Cross-heads	2
Cylinder heads broken	5
Crank pins broken	3
Draft gear	4
Flues leaking	24
Frames broken	7
Follower bolts	1
Foaming	1
Grates and rigging	4
Guides and guide bolts	5
Head lights	6
Hose, air and water	3
Injectors	1
Journals, hot	21
Lubricator	1
Pins, hot	14
Piston rods broken	6
Relief valve	1
Stokers	12
Springs and rigging	6
Tires slipped	31
Terminal delays	39
Valve gear—Stephenson	17
Valve gear—Walschaert	16
Wrist pins and nuts	3
No steam	11
Man failures	13
Total	329

In the list above presented is it not clearly established that if the provisions of the Federal Inspection Laws were fully complied with in letter and spirit at least half of these failures would have been eliminated, and by the same token would it not appear that one of the logical remedies for engine failures is a strict compliance with the inspection rules? An analysis of the above reported failures shows that at least 50 per cent of the mechanical failures should have been preventable and practically all of the man failures likewise.

In this report we will consider only the principal failures, such as are common to all railroads.

Air Brakes and Piping.—An air compressor should be overhauled periodically just the same as a locomotive, but, unfortunately, as the moving parts are hidden and the compressor capacity is usually in excess of average requirements, they are frequently allowed to run until failure results. Some railroads make a practice of numbering air compressors and keeping a mileage record of them, and when the allotted mileage has been made, they are overhauled. The pipes and connections to the air compressor become strained, due to the variations in expansion, the universal use of flexible joints would go far toward preventing pipe failures.

Hot Journals.—Periodical and regular inspection is the logical remedy.

Hot Pins.—The present systems of crank pin lubrication are crude, to say the least. Poor fitting bearings are, of course, responsible for many hot pins, but irregular lubrication is responsible for much more. Heavy grease is a makeshift, not an efficient lubricant.

Cylinder Packing.—With the advent of superheater engines, such failures are becoming more common. Regular periodical inspection, together with the application of a reliable drifting valve, would go far toward reducing this.

Flues Leaking.—This is often due as much to the manner in which the engine is fired, pumped or handled as to any mechanical defect, and much can be done by education and co-operation of the enginemen. Flues should be inspected each trip on arrival and if their condition is such as to make it doubtful if the engine can make a successful trip they should be removed. One road failure will often cost more than the renewal of an entire set of flues.

Broken Rods and Straps.—Rods and rod straps seldom break at once. It would, therefore, appear that closer inspection for cracks would be advisable. It is found that rod, piston, crank pin and axle failures on old locomotives which have been modernized are becoming more frequent, and investigations lead to the belief that some of the failures are due to increasing the tractive effort of the old locomotives without correspondingly increasing the strength of the parts that must stand the increased strain. Fully 80 per cent of the side rods break in the jaws at the knuckle joint connection. This would indicate that our knuckle joints are fitted too snug laterally so that when lateral wear develops in the driving wheels it sets up stresses in rod jaws. By allowing sufficient play in the jaws to compensate for lateral wear in drivers, much of this stress would be relieved.

Stokers.—Ninety per cent of the so-called stoker failures can be traced right back to neglect on the part of firemen and are due either to lack of proper care in lubrication, to excessive wetting down of coal, or to allowing the hopper or feed trough to get clogged. Education and discipline is all that is needed here.

Slipped Tires.—During the past two years 31 failures due to slipped tires were reported. Of these 18 were man failures, pure and simple, and caused by excessive and unnecessary braking. There is room for more education, especially on E. T. equipment. All enginemen do not realize that the straight air will creep on if the automatic valve is not properly handled, and yet, even if ignorant, there is no excuse, as the small gage will always tell what is going on, if consulted.

Terminal Delays.—Failures are charged for any delay to engines at terminals, regardless of cause; therefore, the only logical way apparently of correcting them is to adopt the method in vogue on some railroads, viz.: make a double inspection, one on arrival and the other prior to departure. This, to many, may appear unnecessary, but the fact remains that all men will overlook something sometimes.

Walschaert Valve Gears.—All of the failures charged were due to poor design in so far as the fastening of the union link arm is concerned, and should not be classed as defects to the gear itself.

Steam Failures.—In nearly every instance, the alleged failures were due to inexperienced firemen, and this brings up a subject on which volumes could be written, viz.: the proper training of enginemen, a subject so broad, however, that it should not be handled in this report. In the same class can be placed the man failures, all of which though charged against the engine, were due entirely to inexperience or ignorance on the part of the men.

Let it be understood that this report is not intended to reflect discredit on the enginemen when speaking of ignorance or inexperience, but rather on the methods in use on too many of our railroads. New devices are continually being applied and too often men are expected to familiarize themselves with these with no other instructions than that contained in descriptive pamphlets. One ounce of ocular demonstration is worth a pound of reading in such cases. We feel that all new methods or devices should be thoroughly explained and demonstrated to the men whose duty it is to operate or work with them, before we can place ourselves in position to criticise. Every roundhouse where repairs are made can be fitted up with instruction rooms, containing charts or models or both, and certain hours or dates can be set when instruction will be given. Then if the men do not take these opportunities, action can be taken in case of man failure.

Railroad Administration News

Walker D. Hines Appointed New Director General; News of Interest to the Mechanical Department

THE appointment of Walker D. Hines, assistant director general of railroads and formerly chairman and general counsel of the Atchison, Topeka & Santa Fe, to the director generalship was announced by Mr. McAdoo at Los Angeles on January 11, and Mr. Hines entered upon the duties of his office immediately.

In announcing Mr. Hines' appointment Mr. McAdoo said: "Mr. Hines has been my assistant at Washington since the beginning of government control and has a thorough knowledge of the organization and administration of the railroads under federal control as well as the fundamental problem involved in the railroad situation. His ability and experience admirably fit him for the great trust and responsibility with which the President has honored him. Aside from his obvious qualifications Mr. Hines is in full sympathy with the policies which have guided the Railroad Administration and with the views of the President on the railroad question. I am sure that Mr. Hines will have the hearty support of the fine army of railroad officers and employees and I can ask nothing better for him than that they shall give him and the country the same loyal and effective service they rendered during my term as director general."

Walker D. Hines

It was announced that Mr. Hines will receive the same salary, $25,000 a year, which he has received during the past year as assistant to Mr. McAdoo and which was fixed for the directors of the departmental divisions of the Railroad Administration. In accepting the office Mr. Hines stated that he will carry forward the policies followed by Mr. McAdoo during the past year. He issued the following statement to railroad officers and employees:

"The President has appointed me director general of railroads, effective at once. I wish my first official act as director general of railroads to be this statement to officers and employees:

"Having been a part of Mr. McAdoo's organization from its first day, his policies are my policies and I intend to carry them out and to do so through the existing railroad organizations of the Railroad Administration.

"The responsibilities of the work cannot be exaggerated and there can be no success in it without your confidence and support.

"I shall gain and justify your confidence by prompt and fair treatment, but until you get a chance to know me and judge me by my works I want you to take me on faith and from the very first day help me to give the government the best possible service and the people the best possible transportation. You and I have been fellow workers in the hard work of the past year and I ask you to join me in giving the public even in time of peace the valiant and faithful service that you gave so heartily in time of war."

Mr. Hines was born February 2, 1870, at Russellville, Ky. He entered railway service in 1893 as assistant attorney of the Louisville & Nashville. He later became first vice-president of the road, following which he entered general law practice. In 1906 he was appointed general counsel of the Atchison, Topeka & Santa Fe and became chairman of the executive committee of that road in 1908.

As there is little probability that Congress will approve the five-year extension plan which has been strongly advocated by both Mr. Hines and Mr. McAdoo, it is believed in Washington that Mr. Hines' tenure of office will be short and that one of his principal duties will be to wind up the affairs of the Railroad Administration.

One of the first official acts of the new director general was the appointment of W. T. Tyler as director of the Division of Operation to succeed Carl R. Gray. Mr. Tyler entered railway service with the Wisconsin Central in 1883 as messenger. He has followed railroading consistently since that time, having been assistant to the vice-president in charge of operation of the Northern Pacific before he went to Washington last January as Mr. Gray's senior assistant.

During the month Thomas C. Powell, recently manager of inland traffic of the War Industries Board and formerly vice-president of the Cincinnati, New Orleans & Texas Pacific and the Alabama Great Southern, was appointed director of the Division of Capital Expenditures, succeeding Judge Robert S. Lovett. Mr. Powell was born in 1865 and since 1884 has been engaged in railroad service on lines connected with the Southern Railway System, starting as mail clerk for the Cincinnati, New Orleans & Texas Pacific.

INTERPRETATION OF WAGE ORDER

Director General McAdoo has issued the following interpretation No. 8 of General Order No. 27:

As there seems to have been a misunderstanding on some railroads as to the application of General Order No. 27, the said order is hereby interpreted to apply to all persons in the employment of the railroads earning less than $250 per month in December, 1915. Where such persons have not been granted the increases provided for in General Order No. 27 such increases will be made applicable retroactive to January 1, 1918, and until superseded by supplements thereto.

LOCOMOTIVE SPECIALTIES

The Central Advisory Purchasing Committee of the Railroad Administration has decided on the specialties to be used on the orders placed some time ago with the American Locomotive Company and the Lima Locomotive Works for 600 locomotives for 1919 delivery. Practically the same specialties will be used that were authorized for the locomotives ordered for 1918.

STANDARD LOCOMOTIVES DELIVERED TO JANUARY 18, 1919

Alabama & W. Point & Western Ry. of Ala.	2		0-8-0	American
Atlantic Coast Line	5		0-6-0	American

ORDERS OF THE REGIONAL DIRECTORS

Railway Storekeepers' Association.—The Eastern regional director quotes a letter received from H. B. Spencer, chairman, Central Advisory Purchasing Committee, as follows:

"A meeting of the Railway Storekeepers' Association will be held at the Hotel Sherman, Chicago, Ill., on January 27, 28 and 29, 1919. The status of the association has been approved by the director general, and this is the first meeting which has been held since the railroads were taken under federal control. In view of the important economies which it is confidently expected to effect through the re-organization of the stores department which has been undertaken, and the desirability of having all of those who are charged with the duty of procuring, handling and distributing the material obtain the benefit of personal discussion of the many questions involved, we would appreciate it if you will request your federal managers to arrange to have as many of their purchasing and stores department officers as possible in attendance at this meeting. It is believed that this will greatly assist in the introduction of uniform practices, which it is the desire to establish as speedily as possible."

The Master Boilermakers' Association.—The Eastern regional director states that the Master Boilermakers' Association will hold its convention at the Hotel Sherman, Chicago, Illinois, May 26, 27, 28 and 29, 1919. As this organization has been recognized and encouraged by the railroads on account of its educational value, approval has been given for the holding of the convention. Please arrange for master boilermakers, boiler shop foremen, general boiler inspectors and others employed in a similar capacity to attend, as far as they can be spared without detriment to the service. Each road should follow its usual practice with respect to allowance of time and expenses and furnishing transportation for men who may properly be permitted to attend this convention.

Location of Air Pumps on Locomotives.—The Eastern regional director and the Southwestern regional director have issued orders stating that when air pumps are applied to locomotives, care should be taken that they are so placed as not to obstruct the vision of men on the locomotives; as locomotives receive Class 1, 2 or 3 repairs the pumps should be properly located.

Passes for General Chairmen of Committees of Employees' Organizations.—The Eastern regional director states that it has been decided that it will be the policy of the Railroad Administration to issue annual railroad transportation to the general chairmen of committees of employees' organizations, where the application is properly made and it can be shown that such chairman actually represents the class of employees he claims to represent. This will include also the granting of the necessary leave of absence in the usual manner during the incumbency of such chairman to enable him to carry on the business of his Association. It will be proper to honor requests of this character where annual transportation over the home road only is desired. Requests for off-line transportation should be forwarded to the Director of Operation.

Time Allowed for Lunch to Shopmen on Eight Hour Shifts.—The Eastern regional director states that pending further action by the United States Railroad Administration, the following will govern except when more favorable conditions are provided for by agreements in force: Men employed in shops or roundhouses where three shifts are worked and who work one of the three shifts, will be allowed a lunch period of not to exceed 20 minutes, with pay. Those employed in shops or roundhouses or other places where less than three shifts are worked are to have a meal period of not to exceed one hour, without pay.

Elimination of Sunday and Holiday Work.—The Eastern regional director reproduces a letter from the Director of Operations which is self-explanatory:

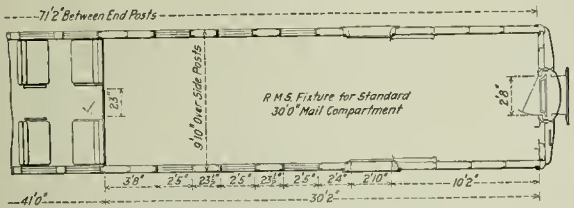
"If you have not already done so, won't you please immediately arrange for a thorough investigation and study to be made on the roads in your region with respect to the elimination of Sunday and holiday work, in order to carry out the desire of the director general as expressed in Supplement No. 13 to General Order No. 27.

"In order that the director general may know what progress is being made, and that his wishes in the matter are being fully met, I believe it advisable that you have your federal managers make reports from time to time indicating to what extent they have found it possible to either wholly eliminate or reduce to the minimum Sunday or holiday work."

Car Inspectors Needed.—The Eastern regional director states that C. B. Young, manager, Inspection and Test Section, 610 Southern Railroad building, Washington, D. C., is in need of car inspectors at plants building cars for the United States Railroad Administration and asks that railroads forward to him the names of men who are at present in their employ who would make good inspectors on car construction, and who could be spared temporarily to take up this work.

STANDARD PASSENGER CAR EQUIPMENT

THE Committee on Standards for Locomotives and Cars of the Railroad Administration has approved the general arrangements for the passenger; passenger and baggage; passenger, baggage and mail, and passenger and mail cars, the floor plans of which are shown in the illustrations. No other drawings, nor the specifications have been drawn for this equipment because of the uncertainty as to whether any of these cars will be built. All the cars are 70 ft. in length and are of the same general design. The



Half Floor Plan of U. S. R. A. Passenger and Mail Car

illustrations show the complete floor plan of the passenger car and half plans of the other cars, as the passenger end of all cars is the same. The designs for these cars will follow in a very general way that of the 70-ft. baggage car, a description of which was published in the *Railway Mechanical Engineer* for October, 1918, on page 561.

The following is a list of the specialties recommended by the committee for the standard passenger carrying cars:

Inside finish: Water and fireproof, ¼ in. mahogany window sills. Three star Agasote below wooden window sill and steel above.

Ceiling: Upper deck water and fireproof—three star Agasote ¼ in. thick. Lower deck water and fireproof—Agasote 3/16 in. thick. Deck to be painted with slush paint. Ceiling to be painted light color enamel of approved shade.

Ceiling decoration: Single plain sap green color line on lower and upper deck. Line only varnished over to hold decoration.

Window sash: Brass sash complete with fixtures as shown on Baltimore & Ohio blueprint No. 10,745. All windows to be double sashed except toilet room windows. Sash to raise 18 in.

Deck panels: All swinging deck panels to be equipped with T. U. Company's Eclipse ratchet. No deck sash to be used, swinging panels only at ventilators.

Window glass: American polished plate 3/16 in. thick, except in saloons and lavatories, which are to be equipped with pressed prism design 0-1, with smooth surface outside.

Door glass: American polished plate ¼ in. thick.

Window shades: Railway standard mercerized on inside, pantasote on outside. Width of curtain goods in windows not more than ¼ in. less than distance between window casing. Color of shade to be selected.

Shade fixtures: Rex, all-metal shade roller. Curtain Supply Company, ring type No. 88.

Shade rolls: Rex, all-metal shade roll.

Seats: Hale & Kilburn, walk-over type, high back, with head rest, steel ends, wooden arm rests, No. 197, or its equivalent.

Seat covers: Seat covering to be selected later.

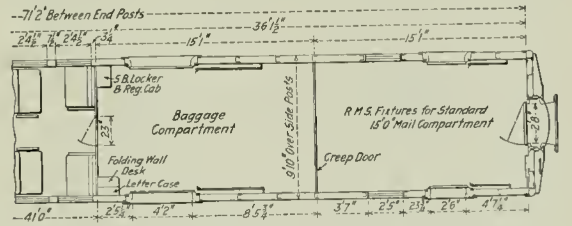
Ventilation: Clere story deck, eight per car. Utilities ventilator 100 per cent, Peerless 90 per cent, Garland-Honeycomb 75 per cent.

Water coolers: White metal, North Pole sanitary drinking fountains with filter attachment, arranged suitably to design of car.

Wash stands: White metal. Plumbing under wash stands to be open with nickel fittings. Wash stands fitted with Adams & Westlake throw-over lever type of faucets and drain fixtures of Pullman standard.

Water supply: Pullman standard air pressure water system. Galvanized steel piping. Cold water only. Metal tank box insulated.

Heating system: Chicago Car Heating Company's vapor system to be guaranteed by manufacturers to register an inside temperature of 70 deg. when the outside temperature is 20 deg. below zero. Holes through center sills for train line sufficiently large to prevent chafing of pipe due to expansion or contraction. Piping so applied as to give ample clearance



Half-Floor Arrangement of U. S. R. A. Passenger, Baggage and Mail Car

between all body and truck parts when cars are rounding 170 ft. radius curve. Same to include extra heavy pipe for train line.

Steam hose and couplings: Steam hose to be 1⅝ in. by 24 in. Couplings to be of the S-4 type.

Steam pipe: Train pipe 2 in. wrought iron. Pipe and fittings extra heavy. Piping inside of car 1¼ in. standard pipe.

Foot rests or guards: Pullman type, perforated steel.

Wrecking tools and cases: Steel box fitted with No. 6 sledge, axe, saw, fire bucket, hack saw, six hack saw blades, cold chisel and steel bar, located to comply with state laws.

Hardware: To be of the Pullman type.

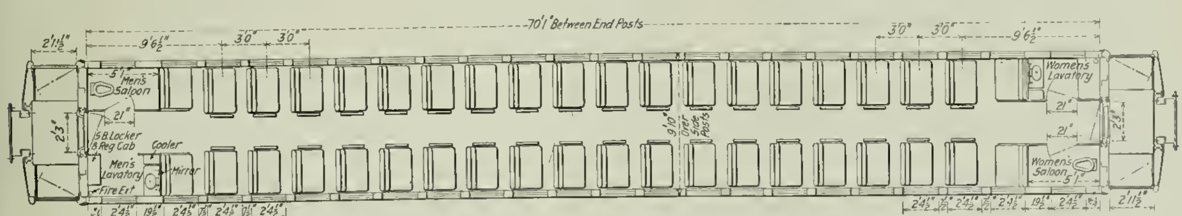
Floor covering: Floor covering to be of plastic material, thickness to meet linoleum ⅝ in. to the top of chanarch, and then an aisle strip of green or red linoleum laid so that the top will be on the level with the inlay and of suitable color to harmonize with the interior finish of the car, chanarch to be 22 B.W.G. gage galvanized. Brass strips to be placed on either side of the linoleum as shown on Baltimore & Ohio blueprint No. 31,189.

Equipment: One deck sash opener. One step box (Dunbar).

Basket racks: Three-section continuous type.

Coat and hat hooks: In saloons and lavatories.

Check holder: Fitch.



Floor Arrangement of the U. S. R. A. Standard 70-ft. Passenger Car

Platform and end of car: Cast steel integral with body bolster as manufactured by Commonwealth Steel Company, or built-up type of approved design.

Gates: Each car to be equipped with safety gates, Pullman type, and permanently attached at each end of car.

Steps: Steps to be of steel with metal safety treads of abrasive material and have no nosing.

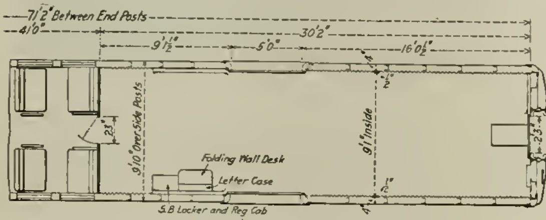
Draft gear: Miner friction class 5-A-P.

Buffer device: Miner friction, Class B-10, or equivalent.

Diaphragm upper buffer: Fowler upper buffer spring.

Vestibule: Wide type Pullman standard, with Imperial wide face plate.

End doors: Mahogany with finger guards.



Half-Floor Arrangement of U. S. R. A. Passenger and Baggage Car

Diaphragms: To be of steel. First choice Dunbar, Style C. Second choice, Pullman. Third choice, Rex.

Vestibule curtains: Pullman, first choice; Acme Automatic, second choice.

Vestibule shield: Pullman or Acme revolving type.

Vestibule curtain, hook and handle: Rex, first choice; Robertson Safety, second choice.

Vestibule trimming: Enameled body color.

Vestibule grab handle: All handholds, grabs, to be smooth wrought iron, ⅞ in.

Trap doors and lifting device: First choice to be T. U. Company's National high station platform type, arranged to open up after and outside of vestibule doors. Second choice, Edwards, and third choice, Pullman.

Air brakes: The Universal, common standard, high-speed automatic brake equipment, schedule UC-1-18, shall be used without electric features and with type K-1 automatic slack adjuster placed on brake cylinder. J. M. expander ring. Ten pound spring type retaining valve and one conductor valve.

The air brake shall develop a nominal brake power of 90 per cent of the complete light weight of the car with 60 lb. cylinder pressure, and be capable of 150 per cent braking power in emergency.

All parts of truck and foundation brake gear to withstand stresses in accordance with M.C.B. standards; 1¼ in. extra heavy brake pipe to be used. All pipe fittings except those regularly included in the air brake schedule shall be "Extra quality individually tested pipe fittings for railroad air brake service." All air pipe to be blown out before pipe is assembled.

Hand brakes: Miner or Western Railway Equipment, or Lindstrom improved.

Braking and signal cord: Signal cord, ¼ in. steel cord, braided green. Conductor's cord, ¼ in. steel cord, braided red, both applied along center of car upper deck supported.

Painting: U. S. Standard.

Roof: Steel. To be of material which has been thoroughly sand blasted, painted and sanded on the outside.

Trucks: Cast steel.

Truck wheel base: 11 ft.

Center plates and center pins: Cast steel separable, arranged for application to cone bolster locking center pin.

Side bearings: Frictionless rolled side bearings for six-wheel passenger trucks. Miner first choice, Perry second choice, Woods third choice.

Equalizers: Wrought iron.

Wheels: 36 in. rolled or forged steel.

Pedestals: Cast steel.

Journal boxes: National Malleable Castings Company's pedestal type complete with lids for axles with 5 in. by 9 in. journals.

Journal bearing keys: To be drop forged M.C.B. dimensions suitable for axles with 5 in. by 9 in. journals.

Brake shoe: Diamond S.

Floor insulation: To be 1 in. quilted hair felt with paper on both sides.

Insulation, super-structure: Body insulation to be ¾ in. quilted hair felt with paper on both sides applied to inner surface of the side walls and end sheets.

Saloon hoppers: Dayton Company's Eckert No. 8 with porcelain hopper chute as manufactured by Dayton Manufacturing Company, or Pullman Standard (Duner). Hopper in women's lavatory to have double lid and men's lavatory to have single seat with horseshoe opening. Toilet paper holder, Pullman type, to be applied in each saloon.

Designating signs: Pullman style, to show location of each toilet, one illuminated sign to read "Men" in end of car where men's toilet is located. Sign to be placed inside of car on bulkhead. Same method to be used at ladies' end and sign to read "Women."

The Standard Refrigerator Car*

The Designs Have Been Based on Results of Investigation Made by the Department of Agriculture

BY M. E. PENNINGTON
Food Research Laboratory, Bureau of Chemistry, U. S. Department of Agriculture

A SHORT time ago the Railroad Administration issued Mechanical Department Circular No. 7,** the opening paragraph of which reads as follows: "In order to insure the greatest possible degree of efficiency in refrigeration and conservation of foodstuffs, refrigerator cars having trucks of 60,000 lb. capacity or over, will, when receiving general repairs or being rebuilt, be made to conform to the following United States standard refrigerator car requirements." Then follow specific details and references to blueprints for the construction of the car in general, its insulation, ice boxes, and the many details of a refrigerator car.

Considering the fact that we have in this country more than 100,000 refrigerator cars, and that ultimately all will probably conform to the essentials just laid down by the Railroad Administration, it may not be amiss to review the circumstances which have led to the issuance of this circular.

In the latter part of the nineties and early hundreds the difficulties in the distribution of our perishables attracted an increasing amount of attention because the length of the hauls increased as more distant markets demanded supplies, and the losses from decay in transit kept pace with the distance traveled. Some of the shippers applied to the United States Department of Agriculture for assistance, among them the Georgia peach growers. In 1903 G. Harold Powell and his associates undertook to investigate the matter. They studied the effect on ripening of cooling the fruit quickly after picking and before loading in the car, as well as the development of decay in transit. Precooling, however, was not a reliable remedy because the insulation of the refrigerator cars of the south was, and is, insufficient to retain the chill imparted to the fruit and the air circulation in the cars was, and is, inadequate to transfer the refrigeration from the ice bunkers to the center and top of the load.

From Georgia peaches the investigators were called to California oranges. The industry was severely handicapped because of decay in transit. Again the inadequacies of the refrigerator cars were apparent. The investigations of the temperature in cars in transcontinental trips brought out the differences in various parts of the car and their relation to excessive decay in the middle and upper part of the load.

In 1908 the Food Research Laboratory, which had been studying the effect of long cold storage on poultry, extended the work to the handling of fresh goods in the packing houses and in transit. We soon found that standardized methods at the packing house did not give standardized results at the market; in other words, the refrigerator cars were a variable factor. It was not and it is not uncommon to find chickens on the floor at the bunker hard frozen, those quarterway of the car in a good chilled condition and between

*Abstract of a paper read before a joint meeting of the American Society of Mechanical Engineers and the American Society of Refrigerating Engineers.

**See *Railway Mechanical Engineer*, December, page 663.

the doors green struck, although the condition of the packages was practically uniform when they were loaded.

Then began the study of the construction of these cars. In 1913 the results were published as Bulletin No. 17 of the United States Department of Agriculture. The conclusions presented in that bulletin outline fairly well the lines of work since followed by the investigators and which have led to the information on which the construction of the standard refrigerator car is based. The concluding paragraph of the bulletin says, "It is eminently necessary that such questions as the most efficient and economic size of the refrigerator car, the exact amount of insulation required to insure the maintenance of low temperatures, or, conversely, to protect the contents of the car against frost, the equalization of temperatures in all parts of the car, and many others, be pressed for more exact and far reaching answers." The bulletin points out the importance of roof and floor construction in relation to insulation efficiency, especially the waterproofing of the floor, and also the efficiency of the wire basket bunker which permits of abundant air access to the refrigerant.

By the early spring of 1916 we had ready quite a number of experimental cars built by four roads in as many shops. The details of construction varied widely. This we considered advisable because we first had to establish the fundamentals of construction, such as the type of bunker and the action of floor racks, regardless of the car itself.

AIR CIRCULATION

It did not take long to decide that the basket bunker, insulated bulkhead and a rack four inches off the floor, with lengthwise stringers and cross slats about three inches wide and about two inches apart, are essential for the distribution of the refrigerated air. The wire basket hanging free in the end of the car permits the warm air entering at the top to flow without obstruction over the entire surface of the ice, and as it cools, to fall to the floor. At the floor it is not pocketed, but finds a ready exit under the rack, and so along the car floor and up through the load, gathering heat as it goes and carrying it to the upper bulkhead opening where again the ice has a chance to absorb it.

If we place thermometers in the air of the car to determine its temperature at the lower bunker opening, again at the middle between the doors, then at the ceiling, midway of the car, then at the ceiling quarter way, and finally about 10 in. in front of the upper bunker opening, we find a steady rise in temperature, the upper bunker opening thermometer being the highest. Generally we find from two to four degrees difference between the air in the upper middle part of the car and that at the upper bunker opening. If the thermometers are similarly placed in a car equipped with a box bunker with open bulkhead and without the floor rack, the graduations of temperature in the upper part of the car are just reversed. Here the temperature at the upper bunker opening is ordinarily from two to four degrees lower than at the middle of the car. This observation has been made again and again and is further confirmed by the performance of a box bunker combined with solid bulkhead and a floor rack, with which there is good cooling in the top of the load at the bunkers, but unsatisfactory results in the upper middle parts of the load.

Even more striking are the results obtained when salt is added to the ice in the basket bunker combined with the insulated bulkhead and floor rack, or the standard type bunker, as it is now termed. So rapid is the removal of the very cold air from the bottom of the bunker that fruit and eggs may be rapidly cooled throughout the car without frosting the packages at the bulkhead. Of course, the bulkhead insulated with one or two inches of a standard insulator is an essential if the packages against it are to be protected from the frigid air close to the ice and salt, but that this protection is not due entirely to the bulkhead is proved by the pocketing of the cold at the bottom of the bunker when the box bunker with an insulated bulkhead is salted. Then the packages at the bottom of the load, next to the bunker, are frosted. In other words, there is no force to the air movement and it cannot be distributed with sufficient rapidity to prevent the intensive chilling of itself. With the standard bunker and floor rack and a lading such as cantaloupes or oranges, as much as 9 per cent of salt may be safely used in the initial icing, and the same percentage or a little less may be used on the two successive days, by which time the load is cooled throughout. It is unnecessary to point out the great advantages accruing to the transportation of such perishables as berries, peaches and cherries by this ability to cool them rapidly while rolling. It is also of benefit to eggs, which, because of the character of the commercial package and the tight load, are exceedingly slow to cool in the ordinary car, the top and middle of the load being but little affected.

The question of insulation has been more complex. We have not only a compound wall, but one which is continually in vibration and which is moving constantly. To this constant movement of the insulator must be added the difficulties of making it continuous because of the framing of the car and the use of tie rods and bolts which offer heat runways.

INSULATION

The thermometers which were fastened tightly against the lining of the car very promptly and consistently indicated that roofs and floors must be better protected than the walls, and in the case of the floor and the lower part of the walls it is imperative to waterproof. Comparisons of cars having varying amounts of insulation, loaded with representative commodities, showed that for the safety of the load, as well as economy in loading and in refrigerant, it is necessary to have the equivalent of two inches of pure cork board in the side walls and ends, at least two and one-half inches in the roof and at least two inches in the floor, the insulation in the floor to be continuous from side to side and end to end. In other words, the insulation on the floor must not be broken by sills and it must be at least two inches of pure cork board.

It has not been possible, heretofore, to waterproof the floor. Consequently there has been wet insulation and a serious loss of efficiency. Therefore the findings of the department emphasize the need of cork board in the floor.

THE GOVERNMENT STANDARD REFRIGERATOR CAR

Such essentials of a refrigerator car as an adequate amount of insulation and air circulation had been agreed upon by the investigators prior to government control of the railroads, and certain lines had incorporated some or all of the findings into their new and rebuilt cars. In the standard refrigerator car* developed by the Railroad Administration, so far as possible, the trucks, draft gear, framing and other general construction features are standardized with the United States standard double wall box car. The essentials upon which rest efficiency in protecting perishables against heat and cold have followed very closely the findings of the investigators of the Department of Agriculture. The plans include unbroken insulation on both floor and roof. On the walls the insulation is continuous from door post to door post. It was not possible to devise a scheme by which the insulation could be run over the belt rails, but the exposed surface was reduced. All the insulation is applied in a solid mass, unbroken by air spaces. It is supported by pressure and not by direct nailing. The excess space afforded by the framing is left on the inner side, under the lining, to receive such nails as the shipper cannot be prevented from driving into the walls and which have played havoc with the insulation. Bolt heads and tie rod exits are protected by insulation. The bunker is a woven wire basket holding approximately 10,000

*See *Railway Mechanical Engineer*, December, page 663.

lb. of ice, surrounded by a 2-in. space and separated from the body of the car by a bulkhead carrying at least 1 in. of insulation, and last, but far from least, is a floor rack, 4 inches in the clear, built of 2-in. by 4-in. runners with 1-in. by 3-in. cross slats 1½ in. apart. This rack is hinged to the side walls. Each half may be turned up and the doorway section folds back to facilitate cleaning the car. The length of the car over end sills should be about 41 ft. and the loading space 33 ft.; it must not be more than 33 ft. 3 in.

FUTURE DEVELOPMENTS

On the basis of a standard car the department is now predicating a standard icing service which should save foods and money. It is also working on standardized methods of stowing loads and the standardization of packages. The ability quickly to cool certain commodities in transit by the use of salt with the ice has given a new impetus to orchard, field and packing house handling, while the reasonable assurance of proper care in transit of such products as dressed poultry lends a stability to the industry which is much needed. There has been much discontent on the part of shippers of products requiring intensive refrigeration because they could not obtain such cars as the large meat packers are using. The United States standard refrigerator car will carry meat hung from rails quite as successfully as the cars built especially for meat. In addition it will carry package loads on the floor under the meat better than the meat cars. An important difference in the standard car as compared with the meat car is the reserve of ice in the bunkers which are often amply supplied when the tanks of the meat cars need replenishing. Neither is there visible in practicable results the advantages supposed to accrue from the retention of the brine, provided coarse rock salt is placed *on top of the ice* and so forced to bore its way through the whole mass before finding an exit. We have wasted much salt in the past, as well as ice and foodstuff for lack of knowledge.

For every standard car turned out of the shops there will follow a saving of food, a saving of money and a saving of labor. To that end the Department of Agriculture has worked long and patiently and to that same end the Railroad Administration has now issued Mechanical Department Circular No. 7, and has also indicated its intention of reminding the railroads of the instructions.

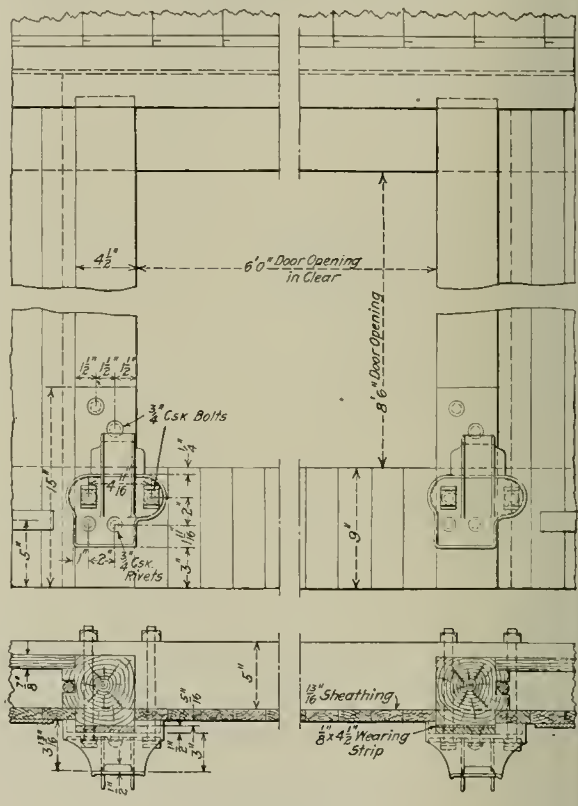
Truly, facts, faith and friendly co-operation have brought about a consummation long and earnestly desired.

MAKING BOX CARS EFFICIENT GRAIN CARRIERS

BY E. K. HOGAN

Investigation shows that a large majority of all the leaks of grain from box cars occur between the car sheathing and the side sills, due to the tendency of the sheathing to spring away from the sills under load. Nails do not effectively and permanently hold sheathing boards firmly and tightly to the sills under the strain to which cars are subjected.

One successful remedy for this condition has been the application of sheathing straps of flat iron, size ¼-in. by 1½ in. to the sides of the box cars. These straps are fastened by bolts through the side sills together with rods that extend through both side and intermediate sills. It has been the observation that no more adequate protection against sheathing leakage than these straps can be applied to a car. In applying straps of this kind it will be found that iron of the dimensions given above is much more desirable than straps

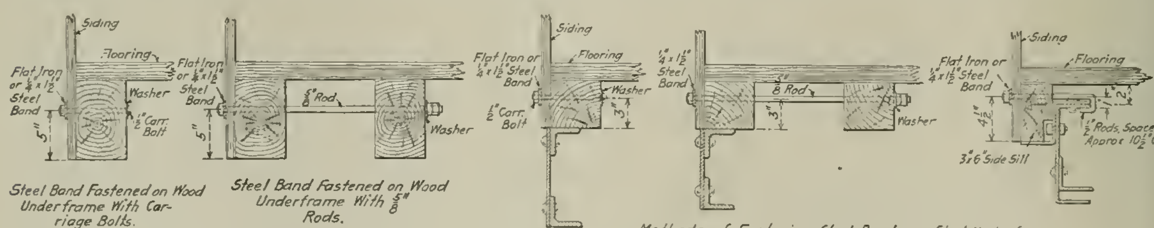


Box Car Door Guides with Steel Plate Attachment Bolted to the Door Posts

of greater width, which would not shed moisture as well and might cause the sheathing to rot under the straps.

On some steel underframe cars the sub sill is of such light weight or the frame of such construction as to preclude the application of bolts to hold the sheathing straps. This difficulty has been met by the use of J-bolts, as shown in Fig. 1.

Some grain losses are ascribed to the prevalence of warped, twisted and loose grain strips. It has been our experience that this leakage is primarily due not to faulty grain strips but to the fact that flooring is improperly and insecurely fastened to side sills. Flooring fastened by nails to the side sills will in course of time spring up at the ends, which per-



Methods of Preventing Box Car Sheathing from Working Loose from the Side Sills mits grain to run underneath floor and over the inside edge of side sill.

The only remedy that would overcome this condition would be to bolt the flooring to the side sills, and it is the recommendation that straps of flat iron, the same size as those applied to the sheathing, be applied to the flooring along the side sills just inside of the post line. These straps should be fastened by bolts extending down through the sills. This method would be much more secure than placing bolts through the grain strips, which are in short lengths and liable to split. The use of sheathing and floor straps, both bolted through the side sills, together with adequate door protection, would make cars of wooden construction grain tight.

Many experiments have been made by railroads to discover a box car side door that will successfully perform its functions. As a result the up-to-date box car usually has a strong, durable side door. The greater problem really has been to hold it properly to the car. Success in this depends largely on the door post and the door guides. Grain doors are nailed to the door post and when removed the nails are left in the post which weakens it considerably and lays it open to moisture and rot. Because of this all door posts should be equipped with a well fitted nailing strip of at least 1¼-in. stock covering the entire inside face of the post.

Insecure doors and grain leakage is often caused by door posts being burst out because of rotten tenons or other reasons. A remarkably good arrangement to strengthen the door post has been successfully applied by one road to all of its box cars. This is shown in Fig. 2. The door post, besides being tenoned into the side sill, has an outside extension down to the bottom of the sill. A wrought iron plate is fastened to the door guide by means of two rivets. This plate extends up the post, to which it is secured by two bolts. The two bolts through the door guide pass through the side sill, one of them also passing through the extension of the door post. This not only holds door post in place but makes it impossible to pry or hammer down the door guide to gain entrance to the car. It is a more economical and as satisfactory as any of the so-called "burglar proof" door fixtures on the market.

Grain spoiled or damaged by water on account of leaky roofs is so much grain lost. To avoid breaks and leaks a roof must be flexible. It is contended that the most satisfactory roof yet discovered is the steel roof of heavy gage metal. Without taking issue with this assertion I wish to describe a method of applying the much derided light metal roof which has been found to make it wear 50 to 75 per cent longer. A single board wood roof is first laid over the purlines, crosswise of car. This is given a heavy coat of Baco or Sarco preparation and covered with one layer of plastic paper, over which the roof sheets are laid. It has been found that the tar in the paper is an excellent lubricant and preservative of the metal. This preparation, besides its waterproofing qualities, prevents nails that become loosened in the board roof from wearing their way up through the roof sheets.

Lumber for Car Construction*

Selecting Proper Grades to Secure Strength and Lasting Power, Increasing Service by Preservatives

BY DR. HERMANN VON SCHRENK

A GOOD many years ago I went abroad to study questions of economies in maintenance. The most impressive fact which I came back with was the striking view point that most of the European engineers had of the necessity of a thorough comprehension of the materials that they were working with and their high degree of respect for what they were working with. They furthermore, did not hesitate to change their methods of using material, provided some way was shown to them by which they could bring about not only greater economy but increased fitness and adaptation. We in this country have been prone to stick to precedent. The tendency to continue methods simply because they have been in use a great many years is characteristic of much of our railroad practice. We are rather slow to change, particularly when it comes to the question of using material. It is not astonishing that we have got into such habits, because in the first place we have had such an enormous amount of raw material and it has been easily available. If there is one lesson that the war has taught us it is that we have been slipshod in the use of our material.

One of the chief difficulties in the construction of cars, referring of course entirely to lumber, has been the extremely vague way in which most of the lumber used in a car has been described and the even vaguer appreciation on the part of those who are repairing cars as to what might be expected of various kinds of wood. The lumber men and the officers of most of our roads specified one or two kinds of wood because they had always been used. White oak and white pine were the woods that were most readily at hand in the earliest days and were long recognized as the best. Consequently for years they were specified and used and they are still being specified. This is a remarkable fact; it is not only the case with the railroads but also with the government. I was present at a meeting revising government specifications for lumber and it was found that they called for clear white pine an inch and a quarter in thickness, dressed on both sides—lumber which has not been manufactured for a great many years.

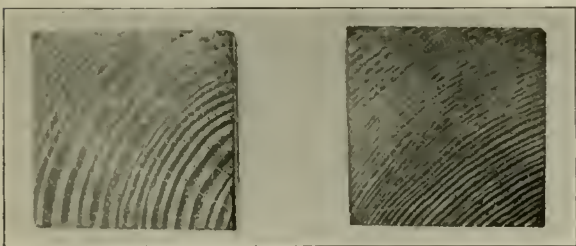
Now what has been done for the average man interested in the construction of cars that might enable him to get better service out of the material? The best way in which he can do that is to specify more closely the kind of lumber that he wants for his construction and to specify it so that he will get a reliable class of material. The specifications under which lumber was bought in the last year on one of our biggest trunk line railroads was "yellow pine, long leaf, grade B or better." It is against that kind of practice that I would caution you.

As a result of a long series of studies made in co-operation with the American Society for Testing Materials and the U. S. Forest Service, a standard specification was adopted by which yellow pine lumber could be visually inspected instead of describing it. I have a chart which was furnished me by the engineers of the United States Forest Service, having four pieces of long leaf yellow pine (Fig. 1). They are all botanically long leaf pine, but you will notice the modulus of rupture varies from 11,110 lb. to 4,660 lb. per sq. in. There is not any way in which you could identify these as long leaf pine; you would have to accept it under

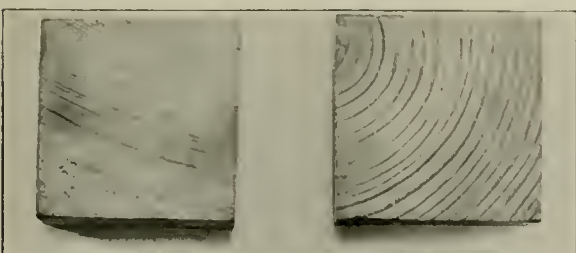
*From an address before the Western Railway Club.

the usual specifications, but notice the difference in the quality which is furnished. From this you will get an idea as to what grade of pine ought to be specified, particularly from the standpoint of strength. If you want a piece of timber in a car where strength is required as in sills, posts or braces, the specifications should call for a dense piece of pine instead of the ordinary long leaf pine, because in specifying that you will get a strong piece, as you will see from the chart. The term "long leaf" does not take care of that.

After the density rule had been developed some members of the M. C. B. Association raised the question, "Are we sure when we specify this grade of dense pine, that we will also get a stick which will last?" A few years ago the poorest as well as the best grades of southern pine were put under a testing machine to determine their strength and were also submitted to decay producing influence, in order to see whether there was any relationship between the strength and the lasting power. It was discovered that the strong pieces were also the ones that had the greatest length of life. The results of these tests are shown on the curve in Fig. 2. This demonstrates clearly that if you obtain a good, dense-grained piece of southern pine, you will also obtain a long-lived piece. In making experiments with car sills for the last few years, I have been impressed with the fact that those in which a high



Modulus of Rupture	11,110 lb.	Modulus of Rupture	10,750 lb.
Specific Gravity	.639	Specific Gravity	.598
Per Cent Summerwood	55	Per Cent Summerwood	52
Rings per inch	10	Rings per inch	23



Modulus of Rupture	4,660 lb.	Modulus of Rupture	5,520 lb.
Specific Gravity	.432	Specific Gravity	.440
Per Cent Summerwood	....	Per Cent Summerwood	25
Rings per inch	32	Rings per inch	10

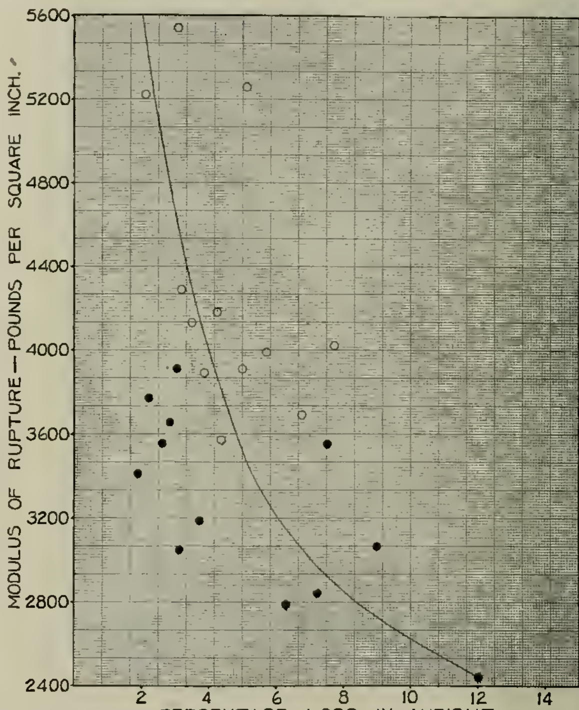
The two upper blocks show typical sections of timber with a large percentage of summerwood. Both have high density or specific gravity and a high modulus of rupture, although the rings per inch vary greatly. The two lower blocks show a small percentage of summerwood. The specific gravity is low in both cases and the modulus of rupture shows the ultimate strength is only about one-half as great as for the dense wood. The tests were conducted on small, clear specimens of green material.

Fig. 1—Samples Illustrating the Properties of Yellow Pine

percentage of failure was found were the pieces that fall in the low part of the curve. The pieces which brought the car to the shop were in very rare instances the pieces that were in the high points of the curve.

A third series of tests was made to determine whether we had to specify long leaf pine at all. The question was raised two years ago in one of the committee meetings of the M. C. B. Association as to whether it was safe to use pine lumber other than the strict long leaf variety brought from Louisiana, Texas, Alabama or Georgia. Without going into details I will state that it makes no difference whatever what kind of pine tree the lumber comes from, whether it is lobolly, short leaf or long leaf: all have equal lasting power or strength, provided they are of the same density and provided they are all heart wood. In other words, exclude young saplings and you will get as long life out of one as out of the other, provided it has the same density. The comparative resistance to decay of heart wood and sapwood is well brought out in the samples as shown in Fig. 3.

A great deal has been said about the possibility of increas-



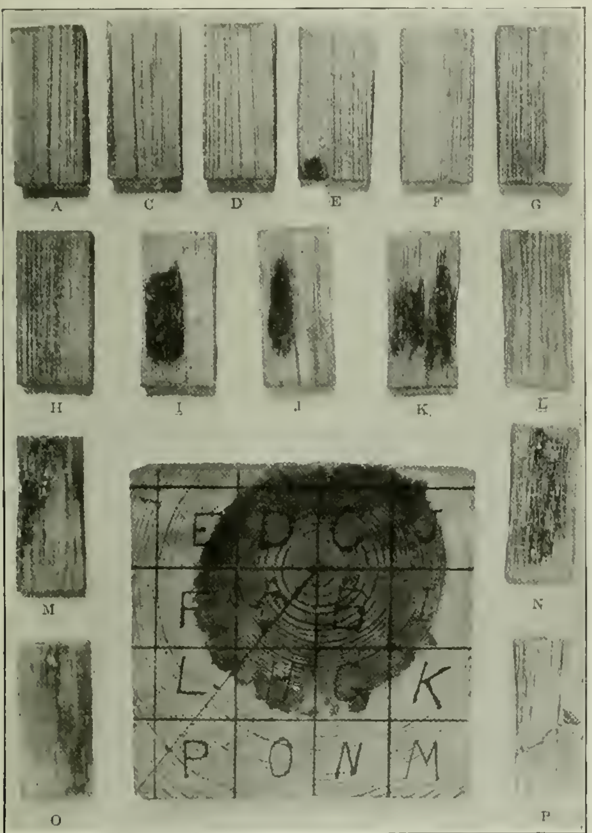
Two samples were taken from the same piece. One was broken in the testing machine and the other was subjected to decay producing influences for 18 months, after which it was dried and weighed. The percentage loss of weight indicates the amount of decay that had taken place. The strongest pieces also showed the highest resistance to decay.

Fig. 2—Curve Showing the Relation Between Strength and Resistance to Decay of Southern Pine

ing the service of lumber after we buy it by some kind of preservative treatment. It is rather surprising that the car men are so far behind the rest of the engineers in availing themselves of that opportunity. There are only two roads, the Burlington and the Santa Fe, so far as I know, that make a practice of creosoting sills and flooring, particularly of stock cars. I recently examined some cars that the Burlington built, over five years old, none of which have come back for repairs. They have creosoted sills and creosoted flooring, and in all of the cars the creosoted parts are in just as perfect condition as the day they were first put out. Now, if the Burlington can get such service out of creosoted lumber, is it not a shame for us to get three or four years' life out of material, when we might increase the length of life we ordinarily get five or six times?

Do not understand me as advocating anything less than a system of impregnation which will force the preservative into the timber. At the present time that is not very practical because our supply of creosote is short, but when normal conditions are restored I do not see why we cannot have a widespread treatment of car parts which are not subject to mechanical stresses, but in which lasting power, namely the protection against decay, is a vital factor. The ordinary scheme which I have seen applied here and there, the spraying of a preservative on timber, I personally have little use for, because a perfect impregnation is not obtained. The expectation of a prolonged life cannot be secured, so the spraying of the preservative onto the car is more or less a useless proceeding and a false protection. Putting it over joints and tendons when pieces are put together may be of some slight protection, provided the lumber is absolutely bone dry, but the practice of putting preservatives on promiscuously should be discouraged rather than encouraged.

One other factor in car construction that will assume increased importance in the near future is a more careful selection of kinds of woods for special types and purposes. I have referred to the fact that we have used only one or two kinds of wood in the past; we are still doing that to a large extent at the present time. There are a good many woods



This illustrates the rapid deterioration of the sapwood and the resistance to decay of the heartwood. The letters on the small blocks correspond with those on the larger block.

Fig. 3—Blocks of Shortleaf Pine After Being Subjected to a Wood-Decaying Fungus for One Year

available which ought to be used more widely than they are at the present time. Beech is one of them that is rapidly coming into use. I know of one road that has used beech very freely mixed with various kinds of red oak. If used in places where the material is not subject to decay, for instance, in the interior of finished cars, for posts and braces, particularly in the upper section of the car, it ought to give just as good service as oak. With the great trouble we have had in getting car lumber the increased supply of beech available for construction, particularly for box cars, is going to make a very welcome addition to our depleted stocks.

There is another wood which, when our tropical commerce becomes re-established, will play a large part in the construction of refrigerator cars. That is the balsa wood, weighing about 7 lb. per cu. ft., or about half the weight of cork.

The field for the saving of lumber in various lengths and sizes is too big to more than refer to. If there is one place in railroad construction where closer adaptation of different sizes and lengths and particularly grades of different lumber can be obtained than in the car repair shop I do not know where it is. I recently tried to compile a list of the requisitions as issued by the car department on one of the eastern lines for different uses in repairs of freight cars and tried to correlate them by substituting grades which I knew would serve the purpose of the railroad equally well as some of the other woods. I hate to tell you the difference in cost.

With the increased refinement in the grading and manufacturing of various kinds of lumber, I believe it to be the duty of every man interested in repairs of cars to study with the greatest care the revised grading rules which have been established by the various lumber manufacturing associations, for hardwood as well as pine and fir. These associations issue also engineering manuals, and no car man ought to be without them. If that were done such specifications for lumber for cars as I have found in use on some railroads would become practically impossible. One of the biggest railroads running out of Chicago in its specifications simply gave two words to the discussion of the timber, said a few words about the dimensions and practically told the man who was going to furnish the lumber, who was the purchasing agent, to use his wits. They wanted some wood; that is about all the specifications said. If you look over your own specifications and ask yourself, to what extent that example has been followed, you will know what ought to be done.

DISCUSSION

A. LaMar (Penn. Lines): I would like to ask whether balsa wood can be secured for car construction?

Dr. von Schrenk: Practically all that is available is used for life preservers. The wood, however, will probably be very much more plentiful when our shipping facilities are rearranged. It is found in Brazil, Costa Rica and the West Indies. It is heavily impregnated with paraffine because it is very short lived otherwise. It is a remarkably strong wood considering its light weight and it is an almost perfect insulator. As soon as it is available in larger quantities it ought to be of great value as lining for refrigerator cars.

G. S. Goodwin (C. R. I. & P.): Dr. von Schrenk has mentioned preserving lumber for car construction. Would he stop with the sills or would he apply preservatives to the posts, braces, siding and roofing?

Dr. von Schrenk: That would have to be determined by the type of car and by the grade of lumber being used. It might be advisable to use it in the first place in stock cars or in any cars where the wood is subject to a maximum degree of deterioration because of decay. The requirements are different for the lumber used in different parts of the car, because some pieces in a car are destroyed mechanically by abrasion, by shocks due to the impact of one car against the other or by other factors which cause the material to break mechanically. The other cause of depreciation is rot or decay. Against mechanical destruction no amount of preservation will avail; against decay, preservation will bring about excellent results. Obviously it is a very foolish proceeding to expend money on preservation of those parts of a car that would be subject to a very short normal life due to shock or breakage. I found the places in cars where it would pay to use preservative to be the sills in all types of cars and all flooring, and possibly also the posts in cars which are subject to continuous moisture, particularly stock cars. I doubt whether it would pay, unless a low grade of sap lumber were used, to treat all parts indiscriminately. In some types of roof construction it would undoubtedly pay to treat the roof boards also, particularly where there is more or less leakage. That may mean that you want to use two different types of preservative. In the case of sills and flooring in stock cars, the only thing that you could afford to use would be creosote. In the case of posts or roof boards which would not be subject to the wetting and drying you could well afford to use the cheaper zinc chloride. It would have the additional advantage that the material would not be disfigured, and it would probably give a sufficiently increased length of life to pay for the original investment.

H. S. Sackett (C., M. & St. P.): The railroads should be more insistent and more careful in demanding a better class of material for car sills, car framing and other parts where strength is important. One of the mistakes that railroads generally make in the use of wood is that they do not season it properly before they use it. We are not giving wood as good a chance as we do other materials. I know that the railroad officers do not like to see a lot of lumber piled up around the yards, but if they could be impressed with the added service obtained from properly seasoned wood, they would not object to larger lumber piles.

In many cases the railroads are using a better grade of wood than is necessary and that is one field in which we can develop great economies. It has been the custom of the railroads generally to use clear material for car siding. In Douglas fir we use No. 2 clear and better and in yellow pine B and better, not only for the construction of new cars, but also for the repair of old cars. By far the larger part of the material is used for the repairing of old cars which may have a life of five or possibly ten or twelve years. The Chicago, Milwaukee & St. Paul is considering the use of "sound knotted" material for car siding. Clear material costs about $36 a thousand and sound knotted material would cost about $24. I do not see why a good sound knot should be objectionable in car siding. I do not mean encased, loose, unsound or black knots.

Dr. von Schrenk: I cannot see any objection to using that class of material. I think that it is simply another case of precedent. All you care for in the siding of a double sheathed car is to keep it weather tight, and it does not make any difference particularly what the outside looks like.

Mr. Sackett: In the use of southern long leaf yellow pine the question of how much sap should be allowed has always come up, whether used for a carsill, car framing, stringer or other purpose. In the Douglas fir, the question of sap has not been so prominent, probably because the sap in the Douglas fir is not of the same character as the sap in the yellow pine—it does not rot so quickly. I should like to ask Dr. von Schrenk's opinion with regard to that. In the case of carsills for example, assuming in the yellow pine it was required that 85 per cent of the material should be heart wood what would be the equivalent in the Douglas fir? In other words, what is the comparative life of the sap in the two woods?

Dr. von Schrenk: If in the pine 85 per cent girth measurement was required to be heart wood, I should be inclined to require the same in the fir. I am judging from recent experience with bridges that had pine and fir timbers. In the same length of time they were both practically in the same state of decay. It should be rather easier to conform to the requirements in the fir, owing to the smaller percentage of small timbers.

ALL-STEEL COACHES FOR THE EGYPTIAN STATE RAILWAYS

BY FREDERICK C. COLEMAN

Thirty all-steel third-class passenger coaches have been put into experimental use on the Egyptian State Railways, and these are now being largely used in connection with the transportation of military personnel. The leading features of the design are clearly shown in the photographs. The cars are 65 ft. 0 in. long over the platforms and have a maximum width over the belt rail moulding of 9 ft. 7⅞ in. The cars have a light weight of 73,360 lbs., and are designed to carry 107 persons seated. The trucks have Fox pressed steel frames, with a wheel base of 8 ft. and 4¾ in. by 9 in. journals.

The panelling and framing is of steel throughout, finished on the inside with asbestos board. The coaches may be freely washed out with a hose without any risk of water lodging so as to cause corrosion. The floors are of Decolite cement, provided with wash-out plugs, and experience in the hot climate of Egypt has proved them to be quite as cool in hot weather as the ordinary wooden type of coaches. The all-steel coaches have the added advantage that they can be cooled down more readily after sun-down than the wooden coaches as a result of the system of air circulation between the outer and inner walls.

Egyptian State Railway Steel Passenger Coach

The underframe and body are incorporated into one structure. The body side pillars are connected at the bottom through the side sills to the boxed ends of the underframe crossbars, except at the bolsters, and at the top they are connected direct to the carlines, a method of construction which makes for several strong girdles completely around the body and frame. These are further stiffened by diagonal braces between the backs of the seats fixed to the pillars at their upper ends, and to the underframe crossbar flanges at their lower ends. A test load distributed along the floor caused practically no deflection. Free air circulation is provided throughout in the body between the outer and inner linings. The asbestos lining is carried inside the body sides and the lower roof with a free air space of 8¾ in. at the roof centre. As previously mentioned, the design is so arranged that there is no place for lodgment of moisture in the panels and frame, and as a further means of preventing corrosion the bodies are arranged in such sections that they can be thoroughly stoved after they are prepared for erection. These coaches are built for the 4 ft. 8½ in. gage, and the draw-gear, buffing gear, brakework,

Interior of a Partially Finished Coach Showing the Steel Frame Work

journal boxes, wheels and axles, trunks and other details, such as windows, louvres, seats, lavatory and other fittings, have been arranged to accord with the standard practice of the Egyptian State Railways. The existing timber coaches have tare weights per passenger of from 836 to 992 lb. As compared with these the steel coaches have each an average of 685 lb. per passenger. This advantage in weight is due in a measure to the reduced thickness of sides which permit an extra passenger on the transverse seats. Without thus utilizing this extra seating space or by giving each passenger additional room the tare weight would then show about 810 lb. per passenger. The makers claim that this result will certainly be improved upon when orders for steel coaches are given in the same quantities as is usual in Great Britain for timber coaches, and experienced builders are given a free hand in design and manufacture. Such large orders will permit of the scantlings of the required sizes being more readily obtained, and the net result will be that the railways will undoubtedly benefit, and obtain even lighter coaches than has been possible in existing circumstances. Briefly summarized, the all-steel coaches have the following advantages when compared with the timber coaches as used on British and Colonial railways. They are lighter in structure, with increased capacity; they are stronger and better able to resist wear and tear; they have proved to be quieter in running; they are more economical in first cost and maintenance; there is no danger from fire, and the strong construction of the ends, which have strong vertical girders with very rugged corner pillar pressings, will prevent telescoping. These all-steel coaches were built by the Leeds Forge Company, Limited, of Leeds, England, and the designs were prepared and developed by the builders in collaboration with R. G. Peckitt, the chief mechanical engineer of the Egyptian State Railways, Cairo.

ANNUAL REPORT OF I. C. C. BUREAU OF SAFETY

The following is an abstract of the annual report of W. P. Borland, chief, Bureau of Safety of the Interstate Commerce Commission, for the fiscal year ending June 30, 1918:

The following analysis affords opportunity for ready comparison of the results of inspections of safety appliances on railroad equipment with previous years:

	1914	1915	1916	1917	1918
Freight cars inspected	790,822	1,000,210	908,566	1,100,104	1,059,913
Per cent defective..	5.79	4.77	3.72	3.64	3.92
Passenger cars inspected	26,746	33,427	27,220	29,456	25,732
Per cent defective...	1.04	2.85	1.82	.85	.56
Locomotives inspected	32,761	38,784	31,721	37,199	33,806
Per cent defective...	4.98	4.06	3.66	2.69	2.18
Number of defects per 1,000 inspected.	67.48	57.23	45.56	41.16	44.01

It is to be noted that the present report indicates the maintenance of the low percentage of defects found in equipment inspected which has obtained for the past three years, which is all the more remarkable considering the increased traffic, congested conditions existing during the months of December, January, and February, abnormal weather conditions of last winter, scarcity of labor and materials, etc.

Table I presents a classified summary of the defects reported by the commission's safety-appliance inspectors. Analysis shows that the condition of air-brake equipment, to which attention was directed in the last annual report of this bureau, has not improved. Out of a total of 49,270 defects reported, 24,707, or practically 50 per cent of the whole number, are defects to the visible parts of air brakes. The number of air-brake defects reported per 1,000 cars inspected was 22.07, as against 19.01 for the previous year. The number of freight cars inspected in 1918 was 1,059,913, as against 1,100,104 in 1917, showing a decrease of 40,191 in the number of cars inspected; but the number of air-brake defects reported increased from 22,181 in 1917 to 24,707 in 1918, an increase of 2,526.

This is a condition that demands serious attention on the part of those who are responsible for the maintenance of this equipment, as both safety and economy in train operation require the maintenance of air brakes to the point of their maximum efficiency. On level roads, where braking conditions are less severe than on roads having steep mountain grades, there is a tendency to neglect air-brake maintenance, thus imposing an excessive burden on the inspection and repair forces of the latter roads in order to provide for the safe movement of cars received in interchange. No logical reason for this tendency ever did exist, as a proper compliance with the provisions of the safety-appliance laws requires that brakes be maintained to the same degree of efficiency on level roads as on roads having steep mountain grades. Now that the roads are being operated by the federal government as a unified system the disappearance of this tendency may be looked for.

Table II represents the condition of the air brakes on trains as they left the terminals after terminal or standing tests had been made, and illustrates the importance of these tests. What is often believed to be a 100 per cent air-braked train is in fact much less. The standing test is the only reliable and efficient method of ascertaining the condition of the individual brake, on which, if found to be inefficient, adjustments can be made at once which will insure an adequate brake. A standing test should be made of each and every train before it leaves its terminal, and no car should be permitted to go forward which has an inoperative or inefficient brake.

The Eighth Circuit Court of Appeals in a recent case held that every hauling or handling of a defective car for any other purpose than repair is forbidden by the terms of the proviso of section 4 of the act of 1910. That is, that a defective car cannot be handled for the purpose of delivering its load to the consignee even when unloading is necessary for repair, unless it be affirmatively shown that such delivery involves no more movement or handling of the car than unloading it or transferring its load.

TABLE I.—Classified Summary of the Number of Defects Found per 1,000 Cars and Locomotives Inspected During the Fiscal Year Ending June 30, 1918

Couplers and parts	4.21
Uncoupling mechanism	4.50
Visible parts of air brakes	22.07
Handholds	3.33
Height of couplers	1.22
Steps	.52
Ladders	1.07
Running boards	1.92
Hand brakes	4.89
Safety railings	.02
Footboards	.16
Pilot beam sill steps	.02
Handrails	.02
Steps for headlights	.01
Power brakes	.004
Asb pans	001
All classes	44.01

TABLE II.—Summary of the Results of Terminal Tests of Air Brakes from July 1, 1917, to June 30, 1918

Trains	1.017
Cars	30,701
Air cars	30,699
Non-air cars	2
Brakes cut out	323
Brakes that did not apply	1,431
Brakes that operated	28,945
Cars not controlled by air	1,756
Cars controlled by air	28,945
Percentage of cars controlled by air	94
Brakes with excessive piston travel	148

The receipt of cars in interchange with defective safety appliances has been one of the common mistakes of the carriers, under the erroneous belief that such cars could be handled to a repair point without liability for the penalty. There are several decisions holding that a defective car can only be moved for the purpose of repair by the carrier upon whose line it became defective, the most recent of which is by the Sixth Circuit Court of Appeals, in which it was held that the necessary effect of the clause "and such equipment shall have become defective or insecure while such car is being used by such carrier upon its line of railroad," as used in the proviso of section 4 of the act of 1910, is to limit the right of hauling a defective car for repairs, without penalty, to the carrier upon whose line of railroad the car was being used when the equipment became defective.

In this connection attention is directed to Circular No. 7 of the Division of Transportation of the United States Railroad Administration, a portion of which relates to the offering in interchange of cars having safety appliance defects, under which the law as interpreted by the various courts will be observed together with the elimination of the dangerous practice of offering defective equipment to connections, thereby insuring the maximum of safety in operation and at the same time expediting traffic.

It is as yet too early to express definitely the degree of success attained under General Order No. 8 of the Director General of Railroads, in comparison with the former method of instituting suit for the penalty for violations under the statute. Under the former system there was a double purpose served by prosecutions for the penalty, that of publicity in defending such suits and the disciplinary measures taken by the carrier to prevent subsequent cases being filed. On the other hand, the remedy at present is that of discipline of employees, which it is believed will be efficacious when promptly and justly administered. Great care, however, must be taken to place the responsibility on the proper party regardless of position, so as not to permit the shifting thereof from officials to employees or evasion in any manner.

In addition to their regular inspection work during the past fiscal year, our inspectors investigated 91 train accidents and assisted in conducting a number of tests of safety devices. One of these tests, that of the automatic straight air brake, required the services of 10 inspectors for a period of more than two months. During the past winter also 42 inspectors were employed from January 1 to March 14 in investigating for the Railroad Administration the serious congestion of railway traffic which prevailed during that period. Performance of this special work will account for the fewer number of cars inspected shown in this report than is shown in the last annual report of this bureau. In the performance of all the exacting duties imposed upon them, our inspectors have displayed marked ability and have fully maintained the high standard of excellence which has always characterized their work.

INVESTIGATION OF SAFETY DEVICES

During the year plans of 88 devices were presented for consideration; 93 devices were examined and opinions thereon transmitted to the proprietors. Of the number examined, 74 were so impracticable or crude that they were considered worthless; 10 were devices which were not intended primarily to promote safety and which would not affect the safety of railway operation sufficiently to warrant further consideration; 3 possessed meritorious features, but as a whole required further development before being entitled to serious consideration; and 6 possessed merit as safety devices warranting some degree of commendation. Of the devices examined which were commended, two were handbrake devices, one was an air-brake attachment, one was an automatic connector, one was a water sprinkler for locomotives, and one was a door for box cars.

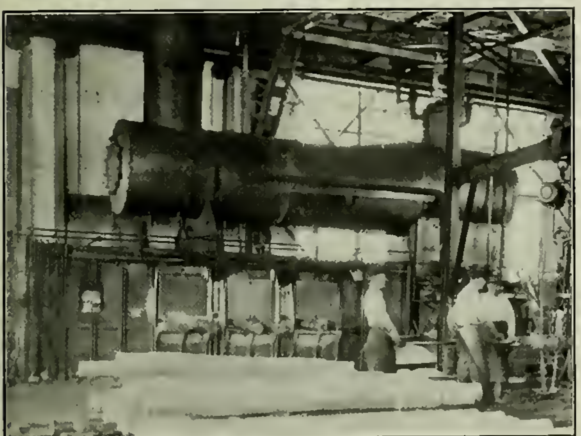
The automatic straight air-brake system mentioned in last year's report, which was submitted by the Automatic Straight Air Brake Co., New York, has been subjected to thorough tests during the year. The brake apparatus was first installed on a 100-car test rack in New York City and an elaborate series of tests was made. These tests demonstrated that the apparatus was sufficiently developed to warrant its trial under service conditions on a road having heavy traffic and mountain grades, and after the rack tests had been completed the brake apparatus was installed on 100 steel hopper cars on the Virginian Railway. These cars were loaded with coal. Standing and running tests were made with trains of 50 cars and 100 cars each, various arrangements of cars equipped with the present types of brakes and the new brake apparatus being used in these trains.

The purpose of these tests was twofold; namely, to determine whether the automatic straight air-brake apparatus would operate synchronously with brake apparatus in common use and to determine whether the new brake could be depended upon properly to control long trains on heavy grades as well as in general service. In these tests synchronous action with brake apparatus now in common use was obtained under a number of varied conditions and circumstances, and the flexibility of the system in controlling long trains, as well as smooth operation and the absence of severe shocks, were amply demonstrated. Many of the intended functions of the brake were substantially accomplished. The more important of these are (1) providing uniform brake cylinder pressure, irrespective of piston travel; (2) compensating for brake cylinder and brake pipe leaks; (3) greater availability of the emergency feature; (4) a graduated release feature, permitting flexibility of control; (5) prompt serial action in application and in release.

SHOP PRACTICE

UTILIZATION OF WASTE HEAT FROM BLACKSMITH FURNACES

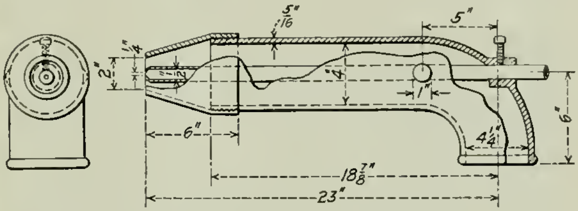
No one who has been around blacksmith shops can have failed to notice the flames from the furnaces rising out of the stacks. This is such a familiar sight that it is taken as a matter of course: but on second thought it is quite evident that the flames must carry away a great deal of heat that has never been utilized. At the same time that this heat is going to waste, fuel is being burned in some adjacent power plant to furnish steam for hammers, shears and blowers in the blacksmith shop. When there is such urgent need for fuel economy, why would it not be well to utilize the heat of the furnaces to generate steam for the smith shops?



Locomotive Boiler Set Over Furnace to Supply Steam to Hammers

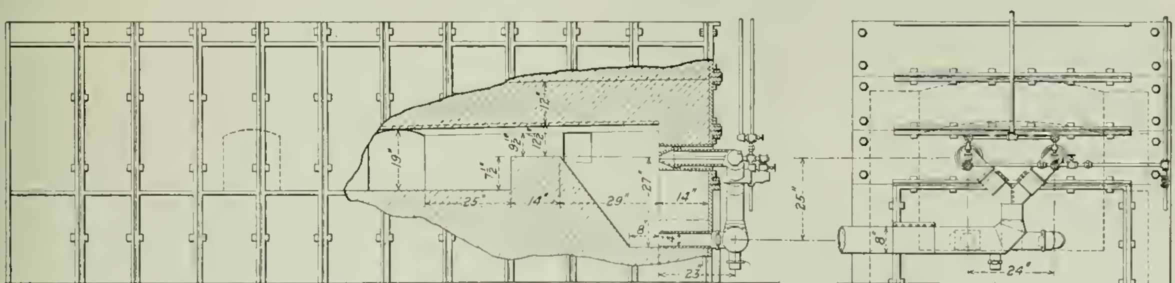
This is by no means a new idea. Boilers mounted over furnaces are to be found in shops built many years ago. The very limited extent to which this practice has been followed in shops recently constructed might lead to the conclusion that it has proved a failure. That such is not the case is fully demonstrated by the operation of the two blacksmith shops of the Atchison, Topeka & Santa Fe at Topeka, Kan. In these shops the heat from the furnaces is used to generate steam in locomotive boilers which supply the steam hammers and also a few steam-driven tools. In the interest of fuel economy in railroad shops, a description of the plant may not be out of place.

The furnaces over which the boilers are placed burn fuel oil. They are equipped with combustion chambers and the furnace proper varies from 8 ft. to 12 ft. in length. A view of the cross-section of the furnace is shown in the illustration. The oil is sent in through two burners in the end under a pressure of about 12 oz. from a fan blast. An auxiliary air supply enters the combustion chamber just below the burners. These burners are also fitted with steam jets which can be used to atomize the oil in case the air supply fails. As an alternative the furnaces can be readily and quickly changed to burn coal. Several features of this furnace are covered by a patent issued to George Fraser, foreman of the blacksmith shop.



Detail of the Furnace Nozzle

The flames from the burner strike directly on the point of the bridge wall of the combustion chamber. This has proved to be a great help in securing a neutral flame. If there is any tendency for carbon to deposit it gathers on the brick-work and not on the iron. After passing down through the neck of the furnace the flame is directed upward into the firebox of the locomotive boiler, through the flues and out the stack. The photograph below shows clearly the way in which the boilers are mounted over the furnaces. Very few changes were made in the boilers to adapt them for this service. They are fed by boiler feed pumps operated by the hammer driver who watches the water level to see that it



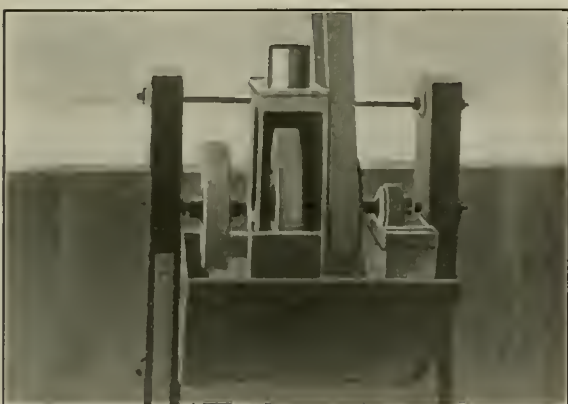
Arrangement of the Furnace, the Waste Heat of Which Is Used for Generating Steam does not get too low. The water glass is situated so that it is always in view of the hammer operator. Steam is taken from the highest point in the dome. All the boilers are connected together; the maximum pressure carried is 100 lb. per sq. in. It ranges generally between 75 and 85 lb. The stacks over the boiler are 75 ft. high without brick lining and have a damper near the smoke box instead of at the top of the stack. In operating the furnaces the blast is varied until a balanced draft condition is secured. This makes it easy to work around the furnace as the flame does not shoot out and work can be put in or taken out without disturbing the burners.

In the blacksmith shop at Topeka there are seven boilers placed over furnaces. These supply steam for 17 hammers, varying in size from 5,000 lb. to 150 lb. There is no other source of steam supply for the smith shop. While, of course, some of the small furnaces are not fitted with boilers or stacks, all of the larger ones are so equipped. The operation is very satisfactory and there is no question that the plant effects large savings in both fuel and money.

RECLAIMING BULL'S-EYE LUBRICATOR GLASSES

After lubricator glasses have been in service for some time the inner surface becomes rough and discolored. A glass in this condition causes difficulty in seeing the oil as it is fed. The Atchison, Topeka & Santa Fe has installed at the Topeka shops equipment for regrinding these glasses to avoid the necessity of replacing them when they become rough. The installation has now been in service for some time and the results secured are very satisfactory.

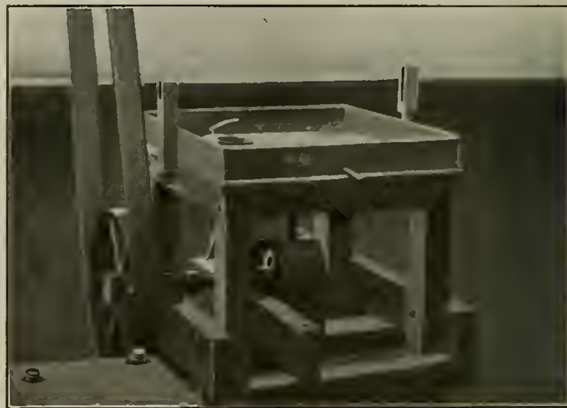
The machines used are quite simple and are shown in the illustrations below. The first grinding is done on a flat cast iron disk about 19 in. in diameter mounted on a vertical



Stone, Felt and Wood Wheels on Which Glasses Are Polished

spindle which revolves at the rate of 200 r. p. m. Sharp sand and water are used on this disk as an abrasive and the glass is ground down until a true surface is secured. A set of three wheels mounted on a single spindle are used for the finished grinding. The first wheel is a black cragleith stone which gives the glasses a smooth finish. The polishing is done on a felt buffing wheel and a willow wood wheel on both of which pumice stone and water are used. The three wheels revolve at about 350 r. p. m.

Glasses which have been scratched or chipped can be reground as well as those that have become roughened or discolored by use. They cannot be ground down below a certain thickness, which is about one inch; for that reason, limit gages are used to determine when the minimum allowable thickness has been reached. In shipping the glasses to the shop where they are to be reclaimed they should be packed in an orderly manner in boxes filled with sawdust. The machines used in reclaiming lubricator glasses are simple and comparatively inexpensive. It does not require



Machine for Rough Grinding Glasses

a very skilled operator to secure good results, and the saving effected at the present price of material is sufficient to justify such an installation on any road operating several hundred locomotives.

LOADING AND GLAZING OF GRINDING WHEELS

In replying to a question as to the relation of the speed of grinding wheels to "loading" and "glazing" Chas. H. Norton writes in "Grits and Grinds" as follows:

Loading is not caused *by* slow speed. It can be caused *with* high speed as well as *with* slow speed, but *is not caused by the speed.* If the wheel is forced into the work so deep and so quick that the material to be ground is crowded into the open spaces, filling them full before the bond can be worn away by friction, the wheel will be loaded, whatever its speed. But in practice it is usually impossible to cause this when the wheel is revolving at high speed, because the higher speed cuts smaller chips when removing an equal amount of metal in the same time. However, it sometimes happens that there is insufficient power to keep the wheel up to its full speed when the operator forces it quickly into the work; it will sometimes be slow enough to cause the particles to tear off chips so large that when they are forced hard into the spaces they will hold the bond in place instead of wearing the bond away.

If the chips are too large for the spaces and are forced into them, the bond cannot wear away because the chips have become the wearing surface, and until these chips are removed the bond must remain, since it is underneath the chips. This is a well known law with files and milling cutters. If a file is forced to the work too hard, it will fill with steel; the same is true of milling cutters.

The cause of wheel loading is not slow speed but *overwork*, whatever the speed. It is more difficult to overwork the wheel at high speed than at slow speed. Therefore, it is more unusual. When wheels are not overworked the slower the speed the faster the bond will wear away. The faster the wheel speed, when not overworked, the slower the bond will wear away and the longer the cutting particles will remain intact. Thus, when the speed is sufficiently high to cause the cutting particles to wear faster than the bond, we get the glazing effect.

Safeguards in Railroad Shops

A Description of Some of the Safety Devices Used at the Various Shops of the Southern Pacific

BY FRANK A. STANLEY

THE application of safeguards for workmen in railroad repair shops involves some elements of difficulty not commonly attached to the installation of safety devices in the general machine plant and factory. In the first place, there is an essential difference in the character of the equipment as a whole in the two classes of establishments referred to and there is, further, an equally important difference in the general method of installation due of course to the peculiarities of the work conducted therein. The recognition now for some years given to the necessity for suitable guards for machine tools and other apparatus has led the builders of this equipment to incorporate many such devices in the design of the machines themselves thus doing away with the necessity for the purchaser to develop a system of safeguards for such equipment. This advance in tool design is naturally more conspicuous in the cases of the smaller and medium sizes of machines.

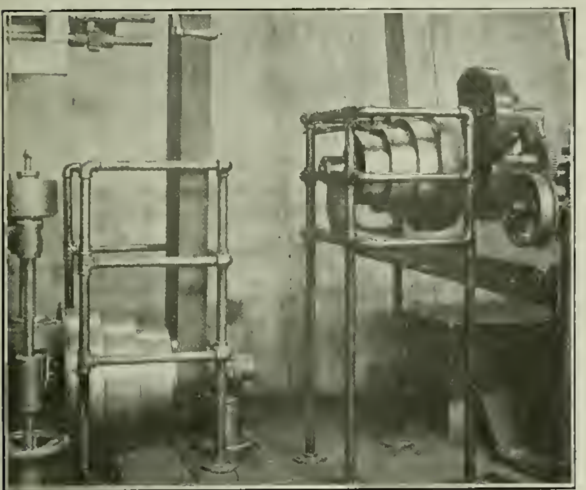


Fig. 1—Pipe Railing for Protecting Belts

With the railroad shop the machine shop proper is only one of several departments where closest attention is constantly demanded if workmen are to be kept free from injury. The erecting floor may be a prolific source of danger unless progressive measures are applied toward protecting the men working about the pits and elsewhere in the department. Outside of the shops, about the yards are various points where safeguards must be erected and maintained, such as railings for washing pits, screens for work undergoing chipping, etc., etc. To be sure, the dangers to the eyes of mechanics about railroad shops is not peculiar to these places, but it does undoubtedly exist in greater degree than in almost any other kind of plant, a fact that has been demonstrated by the necessity for eye protecting goggles in large numbers. These, where consistently adopted, have gone far toward the complete elimination of eye accidents. This can be no better illustrated than by reference to the experience of a conspicuous eastern repair shop which in one recent year prior to the campaign for the adoption of eye protective measures suffered a total of over four thousand injuries of varying degree, which the following year were reduced almost to zero by the adoption of goggles which the men were forced to wear when working at points of danger to the eye.

WHAT ONE SYSTEM IS DOING

Certain characteristic features of the Safety First campaign in the way of safeguards developed and adopted in different shops of the Southern Pacific are shown in the illustrations that follow. These include machine guards, for shop and wood working departments, yard safety devices, appliances for minimizing possibilities of accidents about the erecting pits, and so on.

The guards in Fig. 1 are for enclosing the driving belts and pulleys of two machines; the one at the right a shaper, the other a vertical boring mill. In both instances the railing is made of piping extending to a height that will effectively prevent any likelihood of a passing workman catching his clothing in either the belts or pulleys. The pipe enclosures are stiffly constructed and with machines placed with their driving cones and belts in fairly close position in respect to each other this form of guard is of especial advantage as it in no way interferes with the convenient shifting of belts on pulleys.

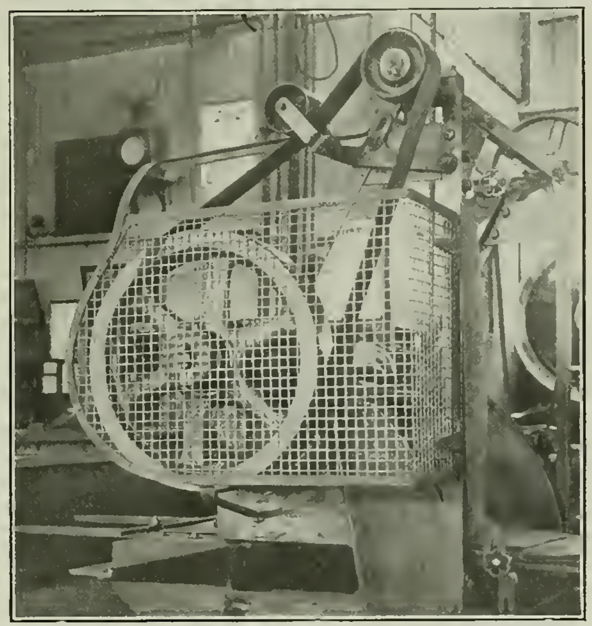

Fig. 2—Hinged Guard for the Fly Wheel of Copper Shop Shears

The guard in Fig. 2 is a hinged screen for the flywheel and driving belt of a shear in the copper shop. A guard of similar pattern is used over the pulley of the sprue shears used in the brass foundry. Another foundry guard is shown in Fig. 3 which shows a row of grinding wheels ten or a dozen in number, all protected by heavy plate covers which nearly surround the wheels. The frequency of serious accidents from unguarded wheels is too well known to require discussion here. The type of guard shown prevents broken wheels from flying across the shop and while protecting the workman from injury it in no way hampers his use of the wheel. Wheel covers of this kind are readily made in such shops from available material and they are easily proportioned to conform to the dimensions of the grinding wheels employed on the floor stands.

Special guards are erected on heavy lathes for enclosing

Fig. 3—Guards for Grinding Wheels

the feed drive at the end of the bed and the back gears at the rear of the spindle. The end guards are made up of a coarse wire screen riveted to a steel angle frame which is of sufficient size to extend from the base to the top of the head stock. The sides of the guard are wide enough to completely

Fig. 4—Protected Motor and Belt in the Pattern Shop

close in the feed cone and belt at the front and there is no possible way in which the operator's hands or clothing may become caught in the mechanism. The guard for the back gearing is made of sheet steel covering completely the gear teeth and extending well down over the faces of the gear wheels. Both guards are hinged to give ready access to the interior when desired.

In order to properly protect the operator from being injured by the rapidly revolving bar stock extending out from the spindle of turret lathes, a system of small pipe guards has been arranged. There are six longitudinal rails extending out from the machine, being supported by pipe standards from the floor, which completely surround the revolving rod.

APPLICATIONS IN WOODWORKING DEPARTMENTS

Referring now to some of the protective devices installed in the woodworking shops, Fig. 4 illustrates the application

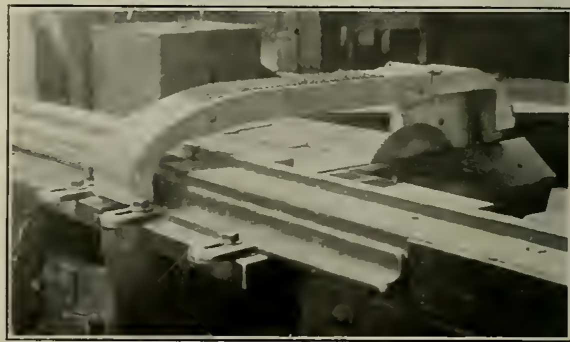

Fig. 5—Draw Cut Saw Guard in the Cabinet Shop

of a guard rail system and swinging screen gate for enclosing a motor and belt in the pattern shop. The belt here is run at an angle of about 45 deg. to the overhead shafting, and in

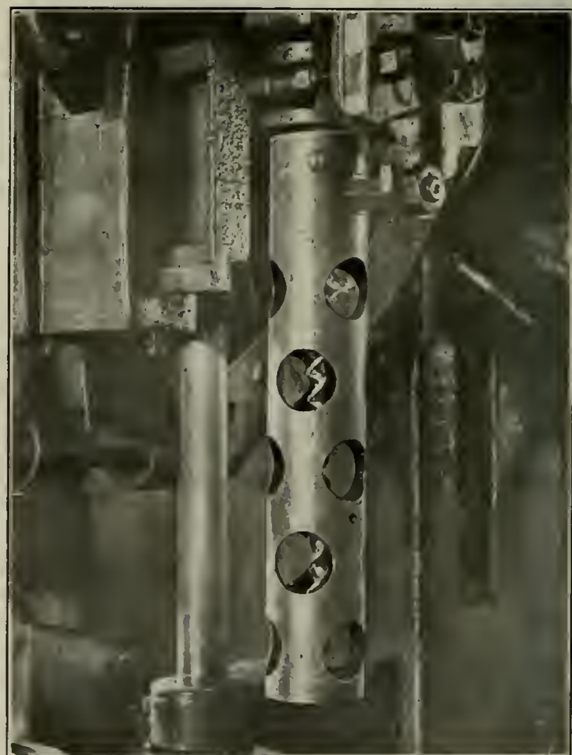

Fig. 6—Wood Boring Bit Guard

this position, if unguarded, it would be a constant menace to those obliged to pass under it. The lower portion of the belt is surrounded by the high pipe fence which is built around the motor. The remainder of the belt for a height of, say, seven feet is paralleled by a sloping guard which just clears the underside of the belt and which has at each side a pair of rails to provide protection along the belt edges. The enclosure

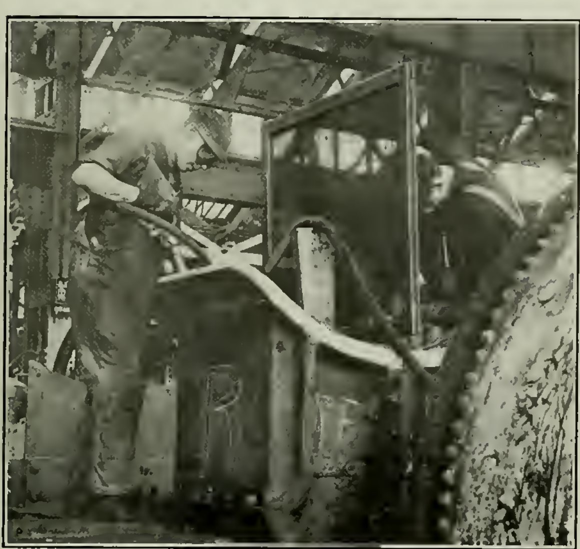

Fig. 7—Protecting Screen Between Men Clipping Cylinder Saddles. Note Also the Goggles

for the motor itself is formed on the front side by the wire gate which swings open when unlocked to give access to the machine.

Saw guards are generally provided and require little explanation. Fig. 5 shows a guard for a circular saw in the cabinet shop. Another feature of this department is the use of a rubber mat in front of the saw which is placed here to prevent the workman from slipping while he is operating the saw.

An interesting form of guard for a wood bit used in the mill shop is shown in Fig. 6. This safety appliance consists of a steel tube containing a number of holes through which the chips may work out when boring. The tube is located over the spindle which carries the bit and is attached to a bracket by which it is prevented from rotating, and by which it is moved up and down. It encloses the bit at all times, and when the bit is at work boring through the wood the chips are ejected from the tube through the liberally placed holes shown in the illustration.

SAFEGUARDS ABOUT THE ERECTING FLOOR

Reference has already been made to the necessity for protective goggles in railroad shops. A still further measure of protection, and one almost as valuable as the goggles themselves is the adoption of the portable wire screen which, as in Fig. 7, is placed at any convenient point to prevent chips made by one man from striking another nearby. This scheme can be developed further in the yard where chipping or cutting rivet or bolt heads is done, by making a portable screen with a substantial base which will prevent the chips or heads from flying about. Still another device used for stopping metal parts that would otherwise fly to a considerable dis-

Fig. 8—Pipe Connections Placed at an Angle Away from the Operator When Making Connections

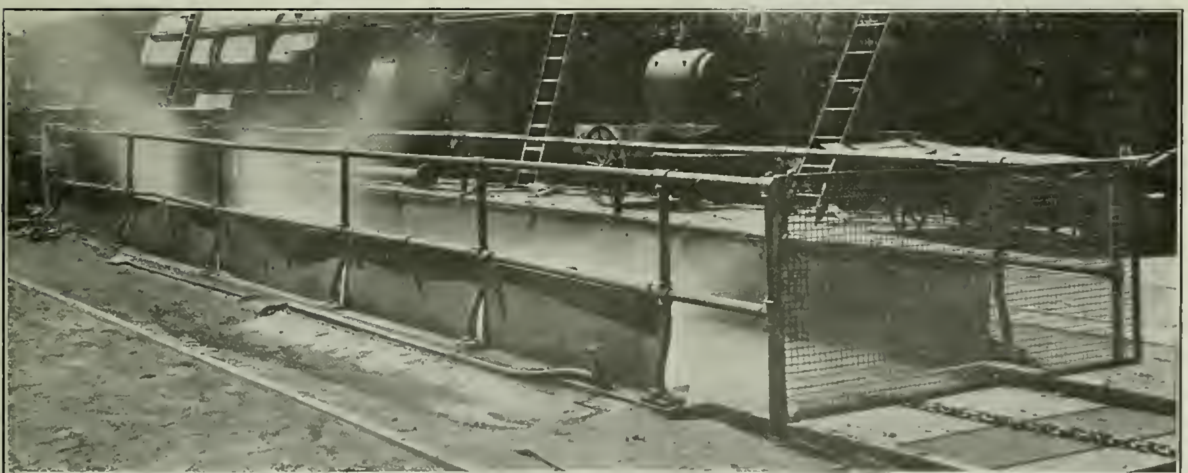

Fig. 9—Safety Railing Around the Lye Pit

tance is the wire basket which is held under rivet heads which are being cut off by hand chisel and sledge.

One of the unsatisfactory features of many erecting floors is the system (or lack of system) of steps, ladders and stagings for enabling the men to climb about the ends and tops of boilers and fireboxes. Not only are the makeshift rigs often dangerous to those obliged to use them, but they are to an equal extent the cause of lost time and effort. In this shop a portable stairway which is a substantial and reliable structure, has proved very effective in saving time and trouble. It is equally applicable to the front, end or sides of the locomotive.

Another interesting safety measure adopted at this shop is that, as shown in Fig. 8, of setting the floor hose connections at an angle so that they do not blow directly in the face of the operator when connections are being made.

Fig. 9 shows a substantial safeguard for a large lye pit. This has, in addition to the two-high pipe rail an end gate which swings open to allow the dipping cars to be run in and out with the material to be washed. Along each side the space under the lower rail is enclosed by sheet metal as indicated in the illustration.

AIR BRAKE DEVICES AT BRAINERD SHOPS

The Northern Pacific does a large amount of air brake repairing at the Brainerd, Minn., shops. In order to expedite the work, many special devices have been developed, a few of which are described below. One of the most useful tools in the air brake department is the machine for grinding the bushings of triple valves shown in Fig. 1, which was

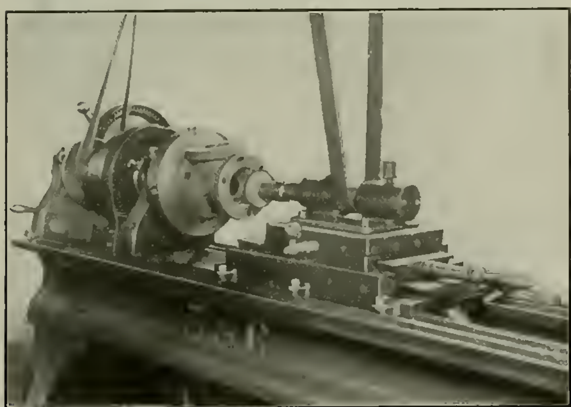

Fig. 1—Lathe Arranged for Grinding Triple Valve Bushings

made from an old brass lathe. In ordinary service the pistons of triple valves move principally between service and release positions and this causes the ring to wear the bushing through a small portion of its length. When triple valves are repaired at Brainerd shops the bushings are ground on this machine to make them truly cylindrical. The body of the valve is attached to a removable face plate which can be centered by means of screws. The grinding wheel is mounted on an extended spindle, carried on the cross slide and driven from an overhead counter shaft. By centering the bushing, setting the wheel to take a light cut, and moving it back and forth while the body is slowly revolved, the bushing can be made true and smooth without removing any more metal than is necessary. By changing face plates the machine can be adapted to any type of lathe. The uneven wear of bushings is the frequent cause of irregular action in triple valves and a machine for grinding them should form part of the equipment at least in the larger shops.

Another useful device for repairing triple valves is a press for closing the grooves in the piston shown in Fig. 2. The base is made of cast iron with a hole through the center and a counter-bored recess at the top. The bottom die is placed in the recess and the piston is set on it with the stem extend-

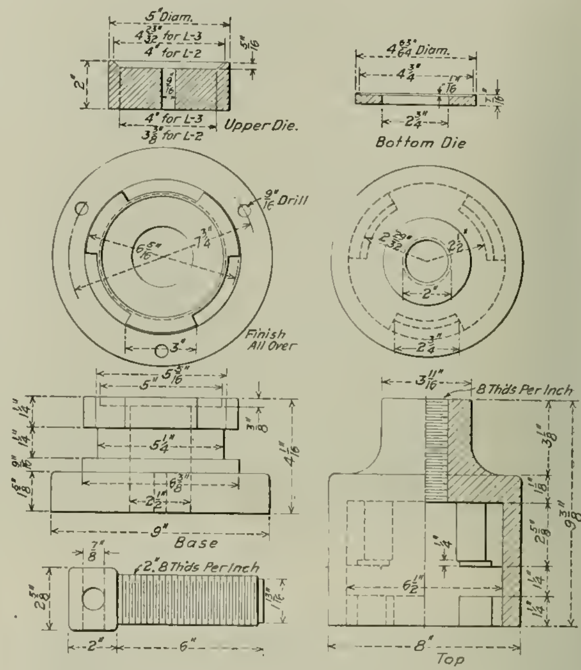

Fig. 2.—Press for Closing Triple Valve Piston Ring Grooves

ing down into the base. The upper die is placed on the piston and the top is set over it and turned to lock it to the lugs on the base. By turning down the screw in the top the

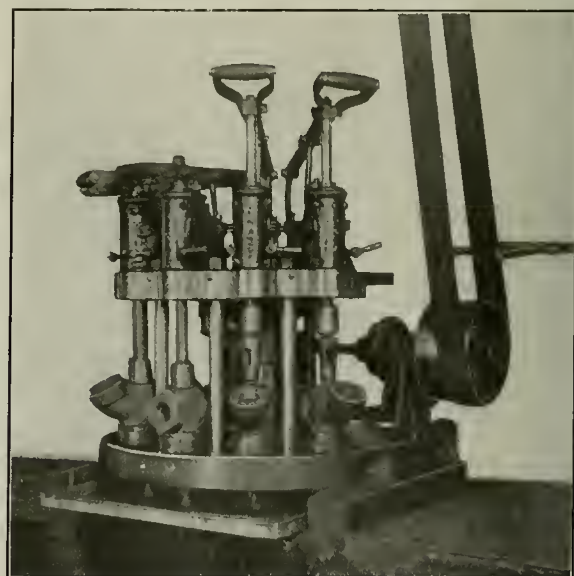

Fig. 3—Five Spindle Angle Cock Grinding Machine

piston can be compressed and the grooves closed. It has been found that the operator soon becomes skilled in using this device so he can get a good fit in a very short time. The dies shown in the illustration are the sizes used for *L*-2 and *L*-3 triple valves.

The angle cock grinding machine shown in Fig. 3 was originated on the Northern Pacific. It is convenient to operate and grinds the cocks very rapidly. The plugs are fastened to five vertical spindles which are revolved and reversed by a segmental gear. At the same time a trip lifts the plug from the body at regular intervals. The spindle can be raised by means of a handle and when at the top point it is thrown out of gear and held by a latch so that the bodies and plugs can be changed without stopping all the spindles. One of the excellent features of this machine is that the grinding compound is kept away from the gears and bearings. As many as 300 angle cocks have been ground in one day.

Oxy-Acetylene Welding Problems*

Discussion of the Flame Structure and Methods of Handling; Careful Training of Operators Necessary

BY W. L. BEAN
Mechanical Assistant, New York, New Haven & Hartford

It is my desire to present certain phases of the oxy-acetylene process which may have escaped the attention of those who have not had opportunity to study it in all its details. The use of the process in railroad work alone has grown since 1912 fully 25 times in volume. Methods of handling and applying oxy-acetylene in railroad work should, however, be scrutinized and properly supervised if the results are to match up with the rapidly mounting expenditures necessary daily, and monthly, and yearly to carry on the work. Since the process depends on two gases, acetylene and oxygen, a few facts, with respect to each, may be mentioned, I trust, with interest and profit.

Acetylene

Acetylene, which, as is known by all, is generated by chemical reaction between water and calcium carbide, is a gas of remarkable qualities. Briefly, its most outstanding characteristic, and the one which puts it head and shoulders above all other commercial gases, is its high carbon content which is 92.2 per cent of its total weight, and which gives such a high flame temperature, especially when burned with pure oxygen. Furthermore, the endothermic nature of acetylene further increases the flame temperature.

It is this characteristic which prevents the common gases, such as ordinary illuminating gas, natural gas, benzine, gasoline, kerosene, Pintsch and Blau gases, etc., from competing with acetylene for welding any metals, but those with low fusing temperatures; and from cutting steel or iron with the greatest economy. Comparative temperatures attained by burning acetylene and other fuels supplied by air are shown by the tabulation below:

Fuel Gas Flame—Temperature in Air

Alcohol	3,092 deg. F.
Marsb gas	3,362 deg. F.
Hydrogen	3,452 deg. F.
Coal gas	3,542 deg. F.
Water gas	3,632 deg. F.
Acetylene	4,652 deg. F.

Naturally when flames are supported by oxygen instead of air, the temperatures attained are much higher. This is of interest because it is sometimes difficult for those in charge of oxy-acetylene work to understand why it is necessary to use oxygen instead of air for welding work:

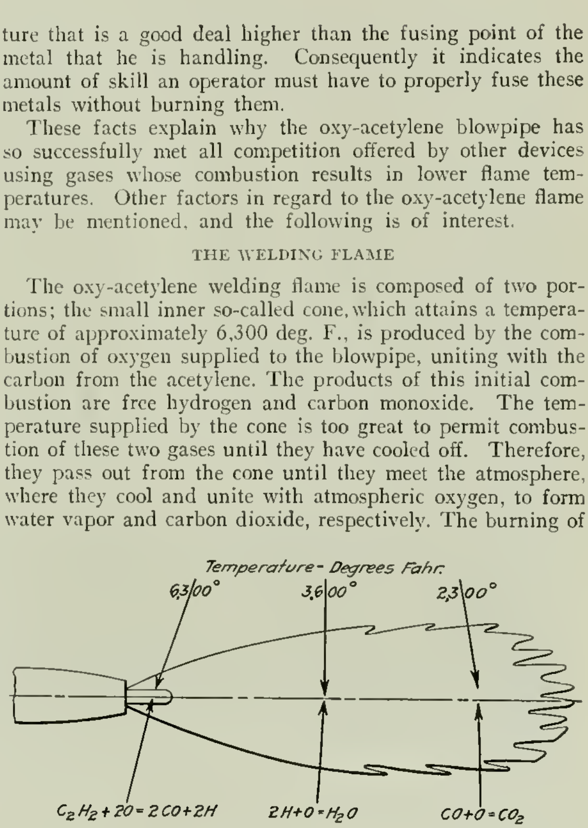
Coal gas burned in oxygen	3,960 deg. F.
Hydrogen burned in oxygen	4,388 deg. F.
Acetylene burned in oxygen	6,300 deg. F.

It is to be noted that acetylene burned in air gives a higher flame temperature than either coal gas or hydrogen burned in oxygen. My object in bringing up this subject of flame temperatures is to show that a welder handling a blowpipe has an extremely hot flame to handle; a temperature that is a good deal higher than the fusing point of the metal that he is handling. Consequently it indicates the amount of skill an operator must have to properly fuse these metals without burning them.

These facts explain why the oxy-acetylene blowpipe has so successfully met all competition offered by other devices using gases whose combustion results in lower flame temperatures. Other factors in regard to the oxy-acetylene flame may be mentioned, and the following is of interest.

The Welding Flame

The oxy-acetylene welding flame is composed of two portions; the small inner so-called cone, which attains a temperature of approximately 6,300 deg. F., is produced by the combustion of oxygen supplied to the blowpipe, uniting with the carbon from the acetylene. The products of this initial combustion are free hydrogen and carbon monoxide. The temperature supplied by the cone is too great to permit combustion of these two gases until they have cooled off. Therefore, they pass out from the cone until they meet the atmosphere, where they cool and unite with atmospheric oxygen, to form water vapor and carbon dioxide, respectively. The burning of



Temperatures in the Oxy-Acetylene Torch Flame

the hydrogen to create water vapor is at about 3,600 deg. F., and the carbon monoxide burns forming carbon dioxide at about 2,300 deg. F. That is of particular importance in welding alloys or metals like copper, which oxidize pretty rapidly, and it is one feature that stands out in favor of the oxy-acetylene flame as compared with the electric process, for although the electric process has the advantage of generating a great deal less heat—and thus reducing contraction stresses—the metal is not protected from the atmospheric oxygen as it is with the oxy-acetylene flame. The outer, cooler, enveloping flame acts as a shroud, which keeps the atmospheric oxygen from uniting with the metals being welded, thereby performing a valuable work. The products of the combustion, which forms the cone, hydrogen and carbon

*Abstract of a paper presented before the New England Railroad Club.

monoxide have strong affinities for oxygen, thereby assisting in preventing any excess of oxygen from uniting with the metals.

These features all contribute to making the oxy-acetylene blowpipe the wonderful device that it is, and the subject of flame temperatures is dwelt upon here with the practical consideration always in mind that the successful operator and his supervisor should know these elementary things in order to properly handle their work. If the operator does not know them, he will, with the best of intentions, spoil or render inferior most of his welds, and his supervisor may stand by and watch and not know what is going on because he cannot recognize what he is looking at. Examination of hundreds of test specimens and likewise hundreds of observations of welding operations convincingly shows that the great majority of blowpipe operators underheat the body metal; that is to say, the piece being welded, and, on the contrary, they overheat the wire or filler metal. An operator who plays the small cone directly on the filler wire is burning it. He cannot do otherwise. Such a workman invariably runs the burnt metal upon the underheated surface of the piece he is trying to weld, and gets an adhesion, but not a weld. He has, as a result, a combination of two weak elements; viz., burned metal attached by surface adhesion to the body metal.

This point cannot be too strongly emphasized, as it is the cause of more inferior welds than any other one thing. The skilled operator works the end of his filler wire in a puddle of the metal, agitating the molten metal and thereby distributing the heat. Also, he constantly moves his welding cone so as not to overheat the molten metal and so as to permit moving the wire through the latter without the wire encountering the welding jet. The welding cone should approximate, in its movements, a half circular arc. The welding wire should be melted by heat from the puddled metal plus radiated heat from the cone, but never by being enveloped by the latter. The function of the acetylene in cutting, being merely to raise the metal to the temperature where the oxygen can take hold of it, has led a good many to attempt to use as a substitute a cheaper gas than acetylene, but because of the high flame temperature of the acetylene—consequently the ability to localize the heat in a relatively small jet—there is really more economy in paying the higher price for acetylene—that is, economy in oxygen—than there is in using other fuel gases, even though the other gases cost nothing.

OXYGEN

The development of the oxy-acetylene process was retarded by the high price of oxygen. In 1910 oxygen was commonly sold at from four to six cents per cubic foot and still largely produced by the potassium chlorate process. The big possibilities commercially, however, stimulated production and a cheaper chemical process using bleach powder and some other reagents had a short life, the cost being about 2½ cents per cubic foot. The electrolytic and liquid air processes, however, control the market at present and are likely to continue, especially the latter. In 1912 the price of oxygen had dropped to about 2 to 2¼ cents per cubic foot, in quantities, and now most railroads buy it for 1½ cents or slightly less. Therefore, it is one article of importance which has decreased in price during the period of the war, and, as it is the item of largest expense in welding, especially in cutting operations, railroads have a better opportunity than ever before to make large and profitable utility of the process. It is true that carbide has increased in price, and so has labor, but not more than like items entering into costs of doing work or reclaiming materials by other methods.

APPARATUS SELECTION

Naturally with the development of the process there comes opportunity for refinement in the selection of apparatus to suit given conditions and the ultimate results depend on the choice made.

For oxy-acetylene operations in small shops or for temporary work at remote points, compressed acetylene in portable cylinders is best adapted to the work; but in large shops, where a relatively large amount of work is done regularly within a restricted area, full advantage should be taken of the economies of stationary apparatus connected to a piped system. Experience indicates that railroad shop installations of oxy-acetylene equipment should consist of stationary instead of portable apparatus when the volume of welding and cutting requires the services of two or more operators regularly.

Compressed acetylene costs 1½ to 2 cents per cubic foot, f. o. b. charging station. Freight or express charges must be borne by the railroad both on the filled and the empty drums, whereas, in using a generator, the cost per cubic foot is ¾ to 1 cent per cubic foot, depending on carbide price, and there is no expense for transportation except in one direction, and also there is less weight to be handled per foot of gas delivered by the generator as compared to the compressed acetylene. Also the slowness of releasing the compressed, or dissolved gas, especially on heavy work, causes operators to set cylinders aside as empty when they still retain from 10 to 20 per cent of the *nominal gas charge.* This is especially true in cold weather. This feature, of course, raises the cost of the gas per actual cubic foot delivered to the blowpipe. The cost is also affected by the admixture of varying amounts of acetone to the discharged gas.

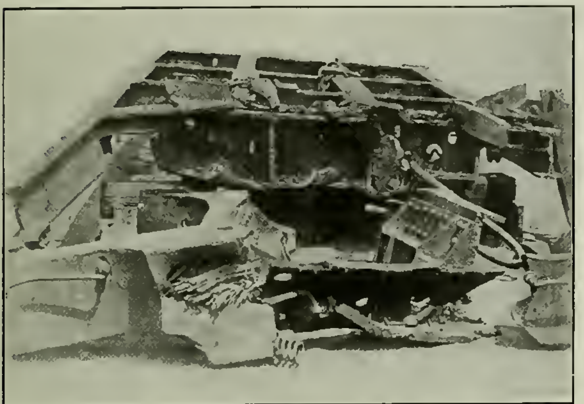
Acetone, by reducing the flame temperature, requires the burning of more acetylene to do a given amount of welding

Repaired Cast Steel Tender Underframe

than is needed when acetylene, free from acetone, is taken directly from a generator. These several features combined produce an actual cost for compressed acetylene of 2½ to 3 cents per cubic foot.

Aside from the above considerations, there remains a number of matters concerning ease and efficiency of operation. When an acetylene generator is installed, it delivers a continuous supply of gas to a shop through a pipe line at a constant pressure, thereby eliminating the need of regulators or reducing valves which have the following disadvantages: First cost, maintenance cost, and the time required for adjusting pressure and for connecting and disconnecting from cylinders.

Under the constant supply system the operator is at once relieved of all concern as to gas supply, since the handling



A Wrecked Cast Steel Tender Underframe Repaired by Oxy-Acetylene Welding

of cylinders from the storehouse to the shop and back again, and from job to job, is eliminated. He is also not concerned with regulating the gas pressure, as that is done by the generator, and he need not, and, in fact, cannot, change the pressure. That cuts out the regulator expense and annoyance. In fact the operator has his hose and blowpipe and can move from job to job without any more apparatus to carry or adjust than in the case of a man using an air hammer supplied by a pipe line.

Blowpipes are carefully designed by manufacturers and should not be altered by railroad shop men. If orifices are changed the proportion of mixing of oxygen and acetylene is disturbed with consequent effect on combustion. In this connection it is important to point out the need for using gas pressures and welding and cutting nozzles suitable for the heaviness of the work done. The average railroad shop worker, and that includes foremen, generally assumes that if a little is good a whole lot more is better, and so, one can daily observe operators welding thin plates with cones big enough for a locomotive frame job, or cutting an ash pan sheet, with 75 lb. oxygen pressure instead of 25 lb. Likewise, in using a cutting blowpipe, too large nozzles are used. When one cuts a ⅜-in. plate with 75 lb. oxygen pressure and a nozzle to match that pressure, fully two-thirds of the oxygen is absolutely wasted and the cost increased at the rate of $4 to $6 per hour of operation. There is a lot of money being wasted in everybody's railroad shop, especially on cutting, by using nozzles and pressures that are too big for the job, and a lot of alleged savings that are going by the board on that account.

There must be education and real supervision along these lines, or else the volume of poor and at the same time expensive work cuts down the benefits deplorably, below what they should reasonably be. The average net savings in money, in ordinary locomotive and car shop work, should conservatively and easily average $1 per blowpipe hour.

Of course, not all jobs of work are, or should be done by oxy-acetylene, solely to secure a reduction in first cost. The better quality of a welded job with longer life and less trouble in service, may warrant spending more money welding it than to do it in some other way. For example, some shops can rivet firebox seams cheaper than to weld them, but they find it pays to weld. Hence, the back shop saving in money does not tell the whole story. Likewise, all are familiar with large savings in time consumed by repairs whereby equipment has been released for service more quickly than otherwise possible.

I would like to speak of a job that the men on the New Haven did this summer on a Commonwealth tender frame for a Santa Fe type engine. Just after those engines came one of them got into difficulty with another one, and when the dust had all settled there was about six or seven feet of each end of the Commonwealth frame that was pretty well pulverized. The frame was taken to the shop. I don't need to dilate on the possibilities of last June in getting a frame of that sort from the foundries—at East St. Louis, I believe they are. It looked as if that engine was going to be tied up for the rest of the summer. But the job of welding these broken members was tackled. In addition to the broken portions on the ends the balance of the frame had a nice gentle wave to it, just like a warped board, and you can all appreciate what a job it was to pull that thing back into line. It had to be done by cutting the members to limber it up enough, so that the balance could be bent and the frame straightened, and then these cuts rewelded. Such portions of the damaged ends as could, were rejoined one to the other, and in some places, where they were about the size of a piece of cake, we had to fill in with plates shaped to fit. As I recall, the job altogether took about six weeks' time, and it cost about the same as a new frame, but the engine was in service probably two or three months earlier than would otherwise have been possible, and so we felt it was worth while.

IMPORTANCE OF WELDING ACCESSORIES

Boilermakers know that it would be folly to build a fine locomotive in all particulars except the firebox, and then to make the latter out of tank steel, or to build the engine according to approved practice and then put in staybolts made of common merchant bar iron. Just as unwise is it to equip a shop with high-grade oxy-acetylene apparatus and then give welders common iron to use as "filler" metal, or to set them to welding a gray iron casting with scrap packing rings for "filler."

The different metal parts of a locomotive vary greatly in their chemical and physical characteristics, and likewise those characteristics usually change more or less when the metals are heated to a welding temperature. On that account "filler" metals and fluxes designed to produce metal in the weld as nearly as possible of the right make-up should be used.

Charcoal iron wire of great purity is best for firebox work, and no flux is needed, but it is not the best practice to weld a cast-steel mud ring with that metal, which has 48,000 lb. tensile strength, when the mud-ring steel probably has a strength of from 60,000 to 75,000 lb. per sq. in. Is it not better to use on such work a "filler" of proper carbon content to give the weld high tensile strength, and to be otherwise specially adapted to the work?

It is not sufficient to use a "filler" of the same grade as the metal to be welded, or to use one which might seem even better in quality than the object to be welded. For example, any cast iron to be found on a locomotive, no matter how good it may be for the purpose it was made, does not make a good "filler" on a casting where it is important to get a clean, strong weld, which works well under a tool. The reason is, that on cast iron work a special alloy "filler" iron containing from three to four times as much silicon as is found in ordinary foundry castings, is needed. The excess silicon replaces that of the welded casting, oxidized in the making of the weld, and since the silicon controls, to a large extent, the proportion of combined and free carbon in the casting, it cannot be removed without hardness resulting.

A great majority of railroad shops have generally indifferent results in welding cast iron, even where they use approved practices insofar as blowpipes, skillful welders, proper fillers and fluxes, etc., are concerned, because they don't take the proper care in preheating and annealing. It is necessary on a cylinder job, for instance, or any job of any magnitude, where the casting has any complication to it, or any great mass, to heat it slowly, and weld it, and then let it cool slowly. It may be necessary even to let the job stand for 48 or 60 hours covered up from the air to let it gradually cool down. If it is allowed to cool rapidly it will not only warp but it will be as hard as flint. I find that the foremen as a general rule are so anxious to hurry the job that they lose time or lose the weld by not being willing to let the men on the job take the requisite time to do it,—and I don't mean time in the welding itself but in getting ready and in letting the thing cool down slowly afterward. Oxy-acetylene welding, to be carried on with the best of success, must include the use of "fillers" and fluxes specially compounded to meet the needs of the different metals to be welded. This applies to all forms of iron and steel, forgings, plates, shapes and castings; and to copper, brass, and aluminum.

SELECTION AND INSTRUCTION OF WELDERS

The use of pure gases, efficient blowpipes, and proper fillers and fluxes does not insure good welds unless operators are competent. Probably more failures of welds have resulted from unskillful and unintelligent craftsmanship than from any other one cause.

Not all proposed operations of welding are possible or advisable, but when men of some mechanical skill and knowledge of the metals and the demands which service will place on the weld are given correct and sufficient instruction, a great variety of jobs can be done successfully from every standpoint. The principle that years of apprenticeship are necessary for the training of boilermakers or machinists, and but three days or a week should be ample for a welder, has prevailed in some quarters and does yet, although the logic is not clear, and surely is not borne out in practice.

Those railroad men who recognized at the start the value of the oxy-acetylene process and who persistently applied intelligence and ingenuity to the problems attending its use achieved much success, and to those men much credit is due for proving beyond argument, by long records of welds in service for years, that the process is peculiarly adaptable to locomotive and car repairs. Those gentlemen know what constitutes real welding, and what intelligence, skill, and practice is needed in the make-up of a good operator.

On account of the fact that results in welding are very largely dependent on the skill of the operator, and because the welds can vary even more in actual structure than in external appearance, it is necessary to place blowpipes in the hands of men who have a knowledge of the particular piece being welded, as to its physical nature and the service to which it is to be subjected. Moreover, men who can be successfully instructed in the elementary chemistry of the subject will have a finer appreciation of the need for careful blowpipe regulation, the preparation of the work, the use of fluxes, the application of suitable special filler materials, the effects of expansion and contraction, and all other details which have to do with the efficiency and economy of the operation.

Men who are intelligent, who take a natural pride in workmanship, who are uniform in disposition, who are anxious to become proficient, should be the ones entrusted with the blowpipe, and the additional wages which such men command will prove a most excellent investment.

LOCOMOTIVE ELECTRIC HEADLIGHT WIRING

An interesting and well-arranged method of wiring locomotives for electric headlights has been developed by the Pennsylvania Lines West in connection with the electric headlight program on that road. Every effort has been made to provide a system which is free from the possibility of short-circuits and which will occasion the least amount of trouble when a locomotive is being stripped for repairs. The generator is located just ahead of the cab, a steam connection being made from the blower line through the cab with a union joint just outside of the cab.

Three classes of service, namely, road, shuttle and yard service, are provided for. Fig. 1 shows the general arrangement of the wiring and fixtures for locomotives in shuttle and yard service. These are similar to the arrangement for locomotives in road service with the exception of the wiring to the tender, which is eliminated. Fig. 2 gives the wiring diagrams for the three classes of service. They are fundamentally the same. The diagram for locomotives in shuttle service is different from that of the diagram for locomotives in road service in that it provides for the headlight and classification lamps for the tender. The diagram for yard service is different from the diagram for shuttle service in that no dimmer resistance is required. The circuits are controlled by single-pole push

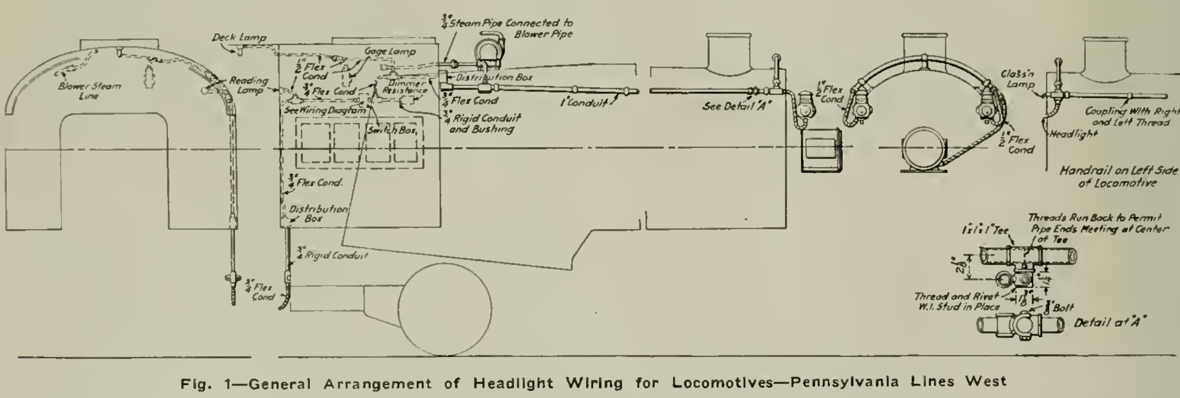


Fig. 1—General Arrangement of Headlight Wiring for Locomotives—Pennsylvania Lines West

button switches which are located on the side of the cab within easy reach of the engineer. For road service three switches are provided. The top one is the main operating

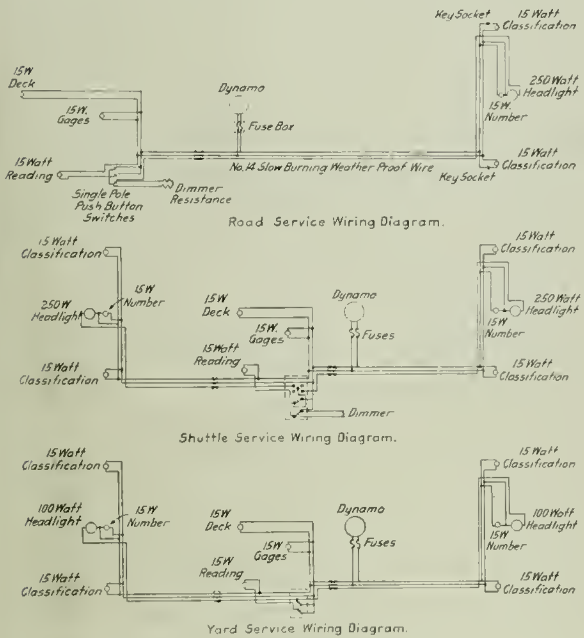

Fig. 2—Wiring Diagrams for the Three Classes of Service

switch energizing the entire system. The middle one governs the circuit to the reading lamp, which is located on the side of the cab back of the engineer. The lower switch throws the dimmer resistance in or out as required. This provides a very convenient arrangement and eliminates any possibility

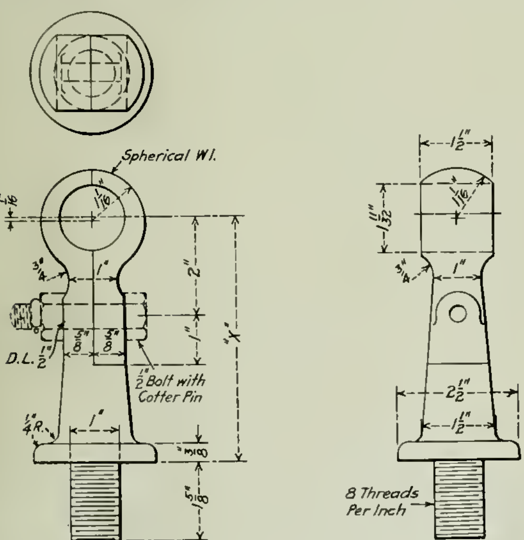

Fig. 3—Details of Hand Rail Column

of the headlight being thrown out of service by mistake when it is desired to cut in the dimmer resistance. It will be noted that a key socket is provided at the classification lamps. This is done for the purpose of insuring proper inspection of the lamps when it is necessary to turn the lights on or off. The deck and gage light, together with the headlight and number light are on the main circuit and are always lit whenever the circuit is closed. They are wired in parallel so that the failure of one light will not break the main circuit.

The wiring diagram for locomotives in shuttle service is substantially the same as that for road service with the exception that the main switch is of the "one-off, two-off electrolier" type, in order to require only one dimmer resistance

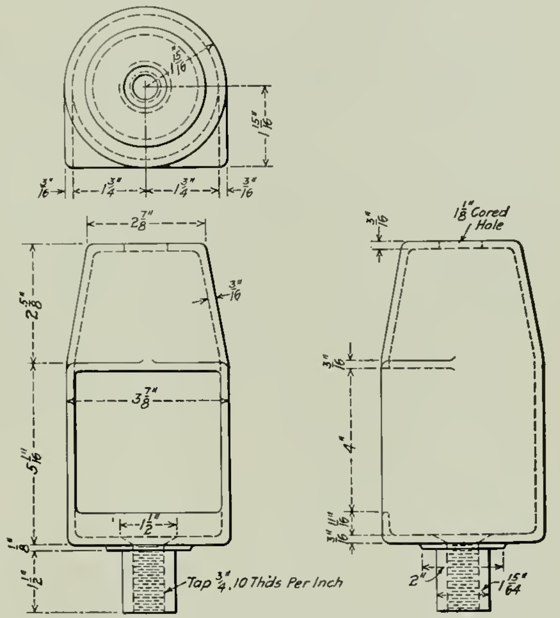

Fig. 4—Cab Lamp Used on Pennsylvania Lines West Locomotives

for both front and rear headlights and still permit them to be wired in parallel. The wiring diagram for locomotives in yard service is similar to that for shuttle service with the ex-

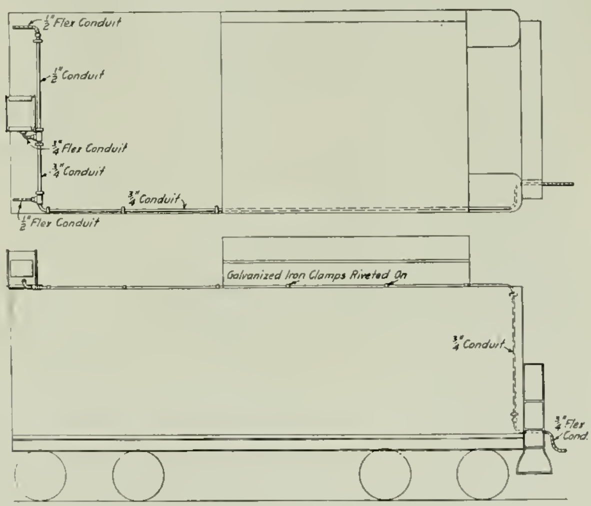

Fig. 5—Arrangement of Wiring on Locomotive Tender

ception of the dimmer resistance, as headlights for this class of service are of less intensity than those for road service and no dimming of the light is required.

The entire wiring is well protected from abrasion and chances of short-circuiting by a double sheathed conduit where it is exposed. The leads from the generator pass through a fuse box into a cast iron condulet, from which they pass back to a distribution box on the outside of the cab and forward through the handrail to the front of the locomotive. It is to be noted that condulets are provided at both ends of the handrail in order that the connections may be easily broken when stripping the locomotive. In fact, this principle has been followed throughout the entire system. It is also to be noted that the handrail columns have been modified. The column is split, as indicated in Fig. 3, to permit the easy removal of the handrail with the wires intact. At the front of the locomotive the wiring passes from the condulet to the right-hand classification lamp and also over the top of the boiler through the handrail to the classification lamp on the other side and to the headlight and number plate, one-half inch flexible conduit connecting the headlight with the condulet. The locomotive distribution box is of a design particularly adapted to the service and is made by the Central Electric Company. This box is attached to the front of the cab, the wires from inside and outside the cab terminating there, there being suitable connections for the wires. When it is desired to remove the cab from the locomotive the wiring both in the cab and on the locomotive can be left intact, the only operation necessary being that of disconnecting the locomotive wires from the distribution box. The cab wiring is run through flexible conduit attached to the roof of the cab. The cab lamp, which is shown in Fig. 4, is made of cast iron and it is held on a cast iron arm which is fastened to the backhead of the boiler and so located as to permit the rays of light from the lamp casing striking the water glass and gages. Only one lamp is used to illuminate the backhead of the boiler. The deck light has a spring grip socket and is located on the roof of the cab. The reading light, as stated before, is located at the side of the cab directly behind the engineer. On locomotives for shuttle and yard service the wiring passes through a ¾-in. flexible conduit down to the bottom of the cab where another distribution box similar to that at the front of the cab is located. The wires between the locomotive and tender pass through a ¾-in. flexible conduit up the side of the tender on the inside, and back to the light at the rear of the tender, as indicated in Fig. 5.

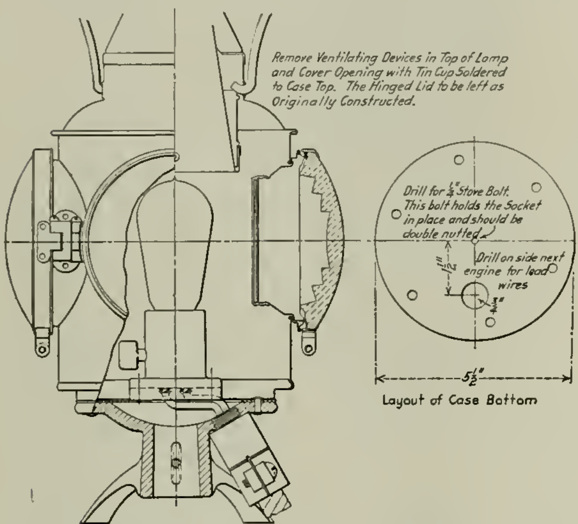

Fig. 6—Arrangement of Classification Lamp for Electric Lighting

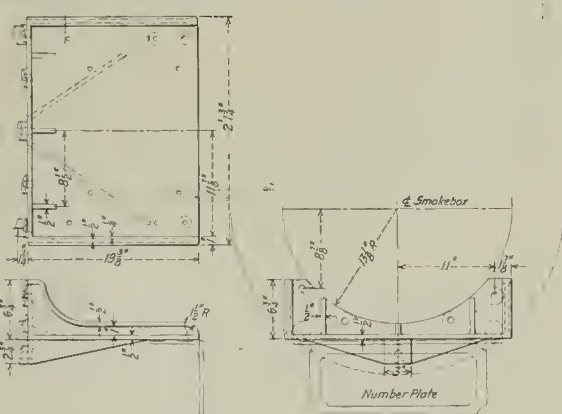

Fig. 7—Bracket for Locomotive Headlight

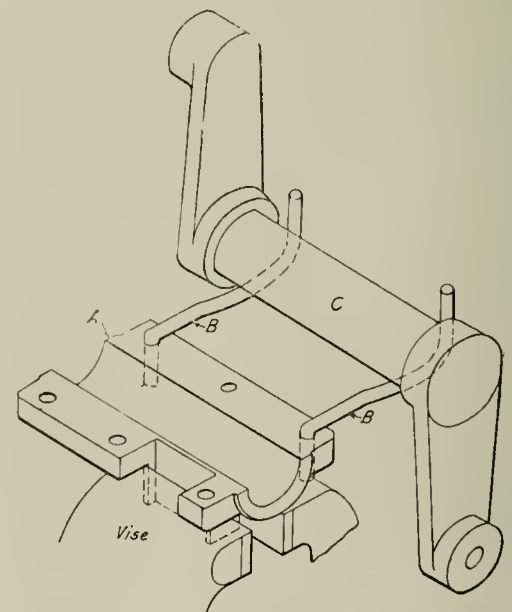
It was found necessary to make some changes in the construction of the classification lamp, which are indicated in Fig. 6. The bracket for the headlight and number plate is shown in Fig. 7.

FITTING ROCKER SHAFT BOXES

BY A. G. JOHNSON
Chief Draftsman, Duluth & Iron Range, Two Harbors, Minn.

As a means to facilitate the fitting of rocker shafts in their boxes the arrangement shown in the illustration has been devised and found successful. The rocker box is held in the vise as shown, it being ready for scraping or spotting. If, as it is often necessary, the rocker arm *C* has to be lifted to and from the bench every time it is desired to spot the box two men will be required to handle it. In addition to this it is heavy work and takes time. By providing two ¾-in. rods, as shown at *B*, bent to fit into the bolt holes of the box, the rocker shaft can be lifted out and rolled back out of the workman's way and at the same time be easily handled. With it in this position the box can be spotted and the shaft tried as many times as necessary without much time or physical strength and without the danger of denting or marring the bearing or the box.



Method of Holding Rocker Shafts While Fitting the Boxes

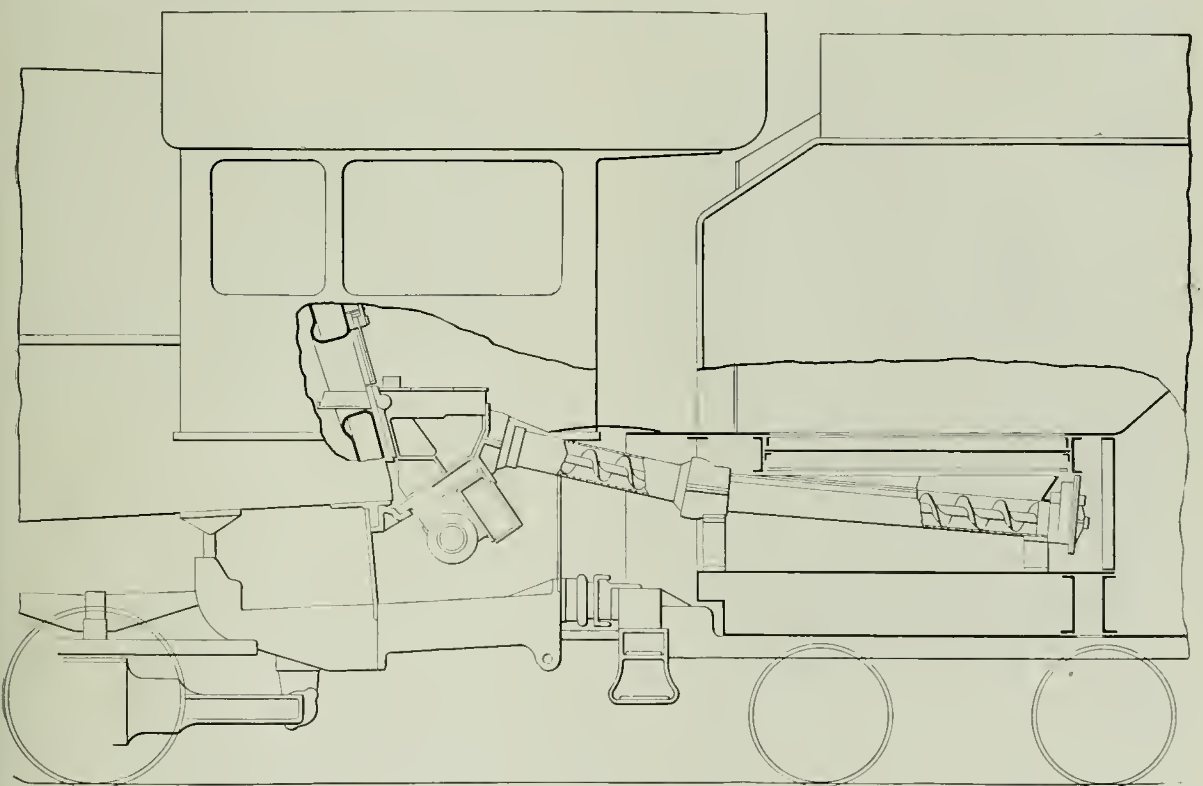
NEW DEVICES

THE ELVIN MECHANICAL STOKER

A mechanical stoker, in which the entire distribution of the coal in the locomotive firebox is effected by mechanically operated shovels, without the use of steam jets, has been developed by the Elvin Mechanical Stoker Company, New York. One of these stokers has been in road service on the Erie for the past three months with results which have demonstrated the feasibility of the method of distribution employed and which indicate an economy in the use of coal equal to, if not exceeding that obtainable by hand firing under favorable conditions. The locomotive equipment consists essentially of three parts: the stoker proper, the agitator and feed control on the tender and the screw conveyor between the engine and tender. The equipment is designed to handle the usual grade of prepared stoker coal.

The stoker proper is assembled in a complete unit which is mounted on the back boiler head and braced to the mud ring by cast brackets. The proportions of the machine and its location on the backhead are shown in one of the drawings. The one design is adapted to backheads of varying slopes by the insertion of filler blocks of suitable taper between the stoker and the boiler head. The stoker consists essentially of two distributing shovels operating through the fire door opening and an elevator for bringing the coal from the conveyor to the level of the shovels.

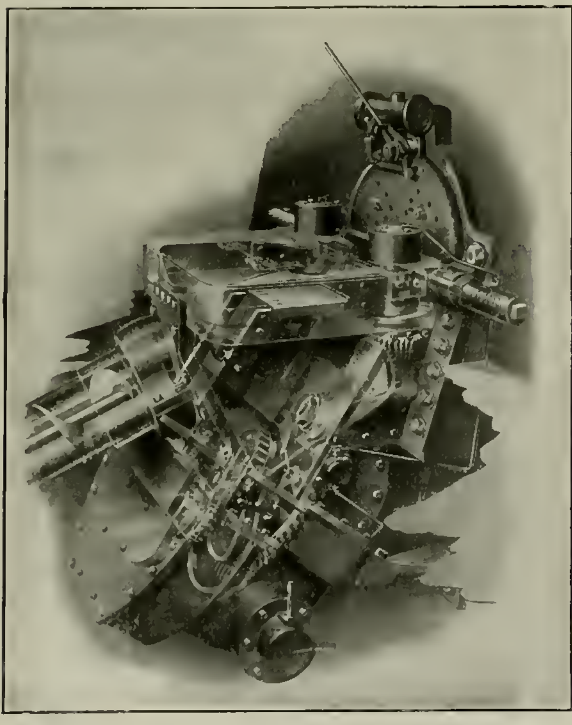
The distributing shovels are mounted on vertical shafts, the lower ends of which carry segmental bevel gears. These gears are driven by bevel segments carried on the upper ends of a pair of centrally pivoted drive arms, the lower ends of which carry steel rollers running in the grooves of a double-faced flat cam. The cam is driven by a worm gear from the main stoker shaft and revolves in a plane approximately parallel to the usual inclination of the backhead of the boiler. Each revolution of the cam completes a cycle of shovel operation; that is, one shovel moves around into



Elevation Showing the Location of the Stoker Equipment on the Locomotive the firebox and returns to remain idle while the other shovel performs the same movement.

Upon the cam is mounted a spur gear which, through a meshing gear of one-half its diameter, drives the elevator crank shaft. The elevator is thus raised and lowered twice during each revolution of the cam, one for each of the two shovels. The elevator, which moves up and down on an inclination parallel to the cam, has an approximately level top surface measuring 7 in. by 12 in. In its lowest position coal as it is delivered by the screw conveyor falls directly on the top of the elevator. As it moves up, a long apron extending downward from its back side forms the front wall of a V-shaped pocket in which the coal accumulates until the elevator again returns to the lower end of its stroke. As the elevator is gear driven directly from the cam, its movement synchronizes perfectly with that of the shovels. The crank is set so that the elevator reaches the top of its stroke just as a shovel is swinging over it. A slight inclination of the top of the elevator compensates for the small amount of downward movement which has taken place before the shovel has moved completely across its top. One of the shovels thus picks up the pile of coal from the top of the elevator at each stroke and carries it forward into the firebox.

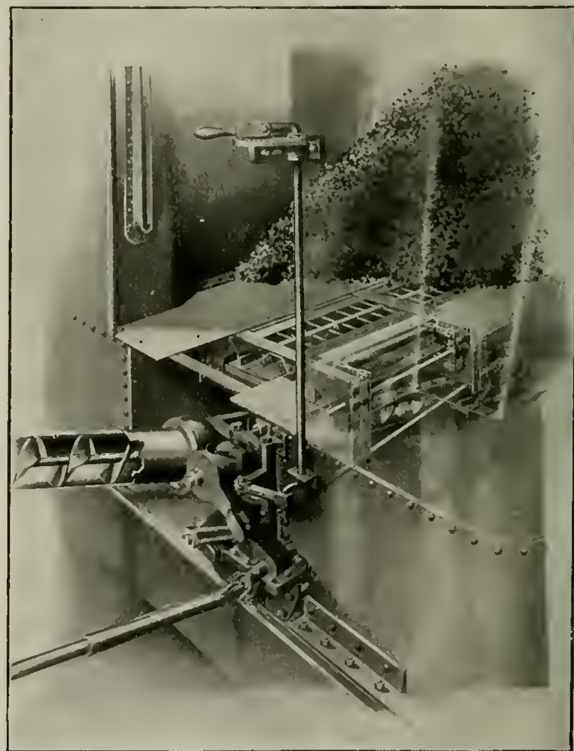
The upper part of the stoker casing forms a box-shaped chamber known as the shovel box, which is covered by



Phantom View of the Elvin Stoker Attached to the Back Boiler Head

hinged lids. The forward end of this box is open to the firebox and the shovels swing therein. The total height of the box is 5½ inches over the cover. The stoker thus uses the lower 5½ inches of the firedoor opening and that part of the door opening above the stoker is closed by a butterfly door, which is used for inspection and hand firing if necessary.

The shovels are L-shaped, with a flat bottom and a back, the maximum height of which is 4½ in. This is reduced to a height of 1¼ in. around the end of the shovel to permit a portion of the coal to be retained in the shovel until the end of the forward throw. As will be seen from one of the drawings the shovels are pivoted at either side of the fire door, and are swung through an arc of about 140 deg. The use of a cam drive has made possible the attainment of the speed variations required in the course of the forward swing of the shovel to accomplish the picking up and distribution of the fuel without shock and with constant uniformity. In action the shovel movement is uniformly accelerating until the charge of fuel has been picked up, or until the shovel has passed over the elevator; then the movement is rapidly accelerated until the shovel tip has entered the firebox when



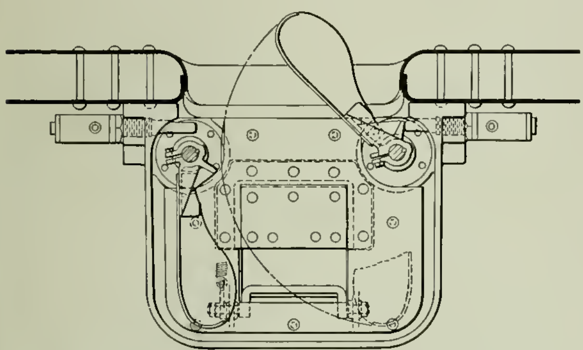
Phantom View of the Tender Equipment of the Elvin Stoker

it is rapidly decelerated. During this deceleration the fuel slides forward on the shovel and off the end where the back is reduced in height and at a tangent to the back of the shovel; but as the back is moving in an arc the effect is to spray the fuel throughout the remaining travel of the shovel, and that portion of the fuel held by the 1¼-in. vane is projected parallel to the backhead when the shovel stops.

The changes in the speed of the forward movement of the shovels have the effect of distributing the fuel uniformly over the entire grate area. The distribution is capable of variation, by changes in speed of the stoker engine; an increase in speed throws a greater amount of the fuel toward the front of the firebox, while a decrease fires heavier to the rear. Irrespective of the speed of the shovels, however, a portion of the fuel is always held by the shovels to fire the back corners of the box. In practice it is found that there is a certain speed which will give the proper distribution under normal conditions and the stoker should be operated at this speed, except when occasionally it may be advisable to fire heavier at the front or rear of the firebox. In practice the speed of firing is about 34 shovels per minute, or a cam speed of 17 r. p. m. The amount of fuel fired is independent of the shovel speed, and the distribution is not affected by the quantity.

All working parts of the stoker, with two exceptions, are run on ball bearings in a dust-proof casing, and are in a constant bath of oil. The oil level is maintained at a point above the main worm shaft and the oil is pumped to the highest bearings to return by gravity. The connecting rod driving the elevator, being outside the stoker casing proper, is provided with graphalloy bearings which require no oil and give long service without attention. The stoker is operated by a No. 3½ Dake reversing engine, which is rated at 7½ h. p. at 100 lb. pressure. The steam line to the stoker is provided with a regulating valve which is set for 25 lb. and is blocked for a maximum of 60 lb. The whole of the stoker mechanism is designed to withstand the maximum power of the engine without failure, and the engine will stall before any part of the mechanism can be unduly stressed.

The conveyor extends from the stoker rearwardly under the coal space of the tank and is in two parts. It is supported rigidly upon the tank, and the portion between the engine and the tank is arranged to swivel to compensate for curvature and to telescope for varying lengths of coupling. The rear end of the conveyor screw is carried in a trough



Top View of the Stoker with the Cover Removed from the Shovel Box, Showing the Elevator at the Top of Its Stroke

and between engine and tank it is carried in a pipe. The conveyor is driven from the rear through gearing enclosed in dust-proof casings. The drive is taken through worm gearing from the main stoker shaft, enclosed in the stoker casing and running in oil. A universal slip joint shaft transmits the power from the engine to the tender.

Under the floor of the tank and above the conveyor is the feeder which consists of an agitator, a deflector and a feeder plate. The agitator is a grating with a double row of 3⅛ in. openings, and is operated from a rock shaft which also moves the feeder plate. The feeder plate is located under the deflector plate so that when operating full stoke the openings in the plate register fully with openings on either side of the deflector plate, first on one side and then on the other.

A simple mechanism on the rock shaft, which operates the agitator and feed plate, provides for varying the throw of the shaft and the size of the plate openings which register with the deflector plate openings, thus controlling the quantity of coal fed to the conveyor, which runs at constant speed. This device is controlled by a handle operating on a quadrant on the front of the tank, where it is readily accessible to the fireman. The range of feed varies from zero to the maximum, which is 12,000 lb. of coal an hour.

The conveyor is designed to carry the maximum coal feed when running one-third full. This makes the movement of the fuel easy as the action of gravity tends to roll the coal along ahead of the screw, and it reduces the danger of clogging to a minimum. The ease with which the coal is moved may be tested by turning the engine over by hand, which can easily be done with the whole device under full load.

The stoker maintains a very thin fire over a greater part of the grate area, which gradually becomes heavier toward the front, rear and sides of the box, where the heaviest fire is needed. The thin character of the fire is clearly indicated by the fact that within a very few minutes after the throttle has been closed and the stoker stopped, the only fire still burning is around the outside of the firebox, while the central portion of the grate is dead. On starting the stoker, however, the thin charges of coal immediately ignite over the entire area of the grate and a uniformly hot fire is maintained as long as the stoker continues to operate. The rapid building up of the fire and the steam pressure following the starting of the stoker has made possible a saving in standby losses, as little need be done, either to maintain the fire or the steam pressure during detention time on the road beyond the minimum necessary to start the train. A characteristic of the distribution of the coal which also tends toward economy is the projection of the lumps forward under the arch while the finest of the coal is retained in the shovels to be deposited in the back corners of the box furthest from the most violent action of the draft. Comparative freedom from large cinders is a noticeable feature of the operation of the locomotive equipped with this stoker.

TEST DATA

The Erie locomotive to which the Elvin stoker was applied is of the Santa Fe type with the following dimensions:

Size of cylinders	31 in. by 32 in.
Diameter of drivers	63 in.
Weight on drivers	337,400 lb.
Total weight of engine loaded	417,200 lb.
Total heating surface	5,660 sq. ft.
Superheating surface	1,389 sq. ft.
Total equivalent heating surface	7,743.5 sq. ft.
Tractive effort	83,000 lb.
Grate area	88 sq. ft.

A series of tests were made with this locomotive, employing a dynamometer car and accurate means for correctly determining the quantity of coal and water used. These tests were made on the Second district of the Meadville division between Meadville, Pa., and Kent, Ohio, during the month of November last, under prevailing temperatures of 32 deg. F. This division has a ruling grade both east and westbound of one per cent and is generally rolling in character with little to distinguish between the physical characteristics of the division east and westbound. A brief summary of the results of these tests is given in the table.

Average Results of Elvin Stoker Tests on the Meadville Division of the Erie Railroad

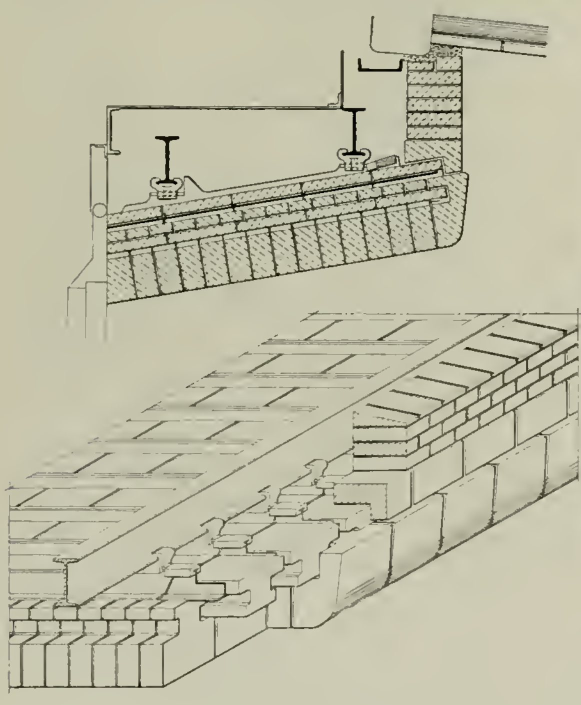
Length of run, miles	89.3
Time on road, hr. min.	9:50
Detentions, hr. min.	3:57
Running time, decimal hr.	5.88
Actual M's (1,000 lb.)	4.243
Adjusted M's	5.133
Total actual M's (inc. eng. and ten.)	4.816
Average drawbar pull, lb.	24,362
Average speed, m.p.h.	15.56
Average temp. superheated steam, deg F.	693
Million ft-lb. of work	11.482
Total coal as fired, running time, lb.	25,679
Coal as fired to do 11,482 million ft.-lb. work, lb.	25,679
Equivalent evap. per lb. dry coal, running time, lb.	8.60
Equivalent evap. per lb. dry coal, combustible, lb.	9.59
B. t. u. per lb. of coal as fired	13.157

It was developed during the tests that practically perfect distribution of the fuel was obtained under all conditions. The fire was maintained at a uniform level without the necessity of using the rake or shaking the grates, notwithstanding the variable operating conditions met on this division. The engine arrived at terminals with approximately six to ten inches of fire on the grates, except a point immediately under the arch at the forward end of the firebox, where the fire was somewhat heavier.

No difficulties were encountered in cleaning the fire at terminals because of the comparative absence of clinker. The results of the tests indicate very favorable evaporation per pound of coal fired. Under ordinary circumstances locomotives of the Santa Fe type on this division require coaling and fire cleaning between terminals. During the tests, however, it was unnecessary on any of the trial trips to clean the fire on the road and the grates were operated only to relieve the accumulation of ashes. On two occasions it would have been easily possible to make a round trip without attention to the fire other than shaking the grates. This condition is in a measure attributed to the absence of moisture which is injected into the firebox with most of the other types of locomotive stokers now in use. The locomotive will handle tonnage trains over this division with the use of less than one tank of coal.

DOUBLE SUSPENSION ARCH FOR STATIONARY BOILERS

It is usually desirable to operate stationary boilers for long periods without shutting them down. When working at high capacity it is not an infrequent occurrence to have the arch give way, and this often happens when it is extremely inconvenient to take the boiler out of service. There has recently been devised by the Liptak Fire Brick Arch Company, St. Paul, Minn., a type of arch for stationary boilers which is intended to overcome such difficulties. This is known as the Liptak Double Suspension Arch. It is made up of two layers of interlocking bricks, suspended from cast



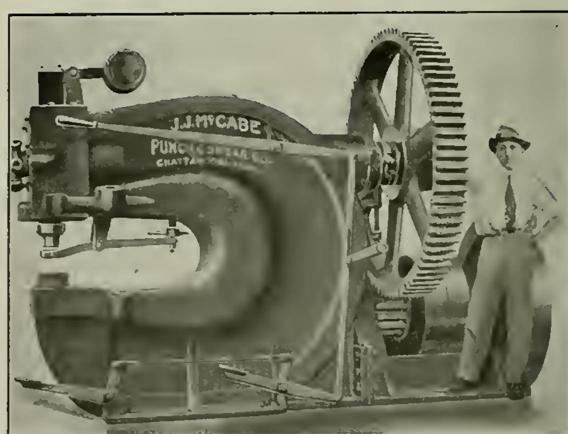
Double Suspension Arch for Stationary Boilers

iron supporting beams which in turn are fastened by clips to transverse I-beams. The perspective drawing accompanying this article shows the construction clearly. It will be noted that the upper arch furnishes almost complete protection for the cast iron supporting beams. Even if the lower arch is completely burned away the boiler can still be operated until the time when it can be shut down without inconvenience.

The lower arch can readily be renewed by the boiler room force as it is simply necessary to slide new lower arch bricks into the grooves of the reserve arch. This eliminates the services of an experienced mason, which are not always available. In case the end blocks are completely burned away, exposing the ends of the cast iron supporting beams to such an extent as to damage them, it is not necessary to renew the entire beam as replaceable tips are provided. The rear bricks in any arch are the first to give out. With this type it requires only a short time after the boiler is cooled down to renew the rear blocks and place the boiler in condition for service. It should be noted that the L-shaped blocks resting on the reserve arch and supporting the brickwork from the arch to the boiler header do not interfere with the lower arch. This permits the renewal of the lower brick without disturbing the rear wall. One of the important advantages of this type of arch lies in its adaptability. It can be built for any width and length to suit the requirements of all types of boilers and stokers. It is claimed that the Liptak arch has a long life and will stand high overload. Arches of this type have been in service for several months and the only repairs required have been the application of new rear blocks.

HEAVY PUNCH AND SHEAR

An improved design of heavy pattern punch and shear machine has been recently developed by the J. J. McCabe Punch & Shear Company, New York City. The illustration shows a machine having a 36-in. throat. The 50-in. machine is of the same general type. Particular attention has been given in the construction of the machine to rigidity to withstand heavy service, the frame having a heavy rib on the back. The head is driven by cam and rollers of carbon steel, which doubles the power during the working stroke and eliminates friction and wear. The clutch is of a new



Heavy Duty Punch and Shear

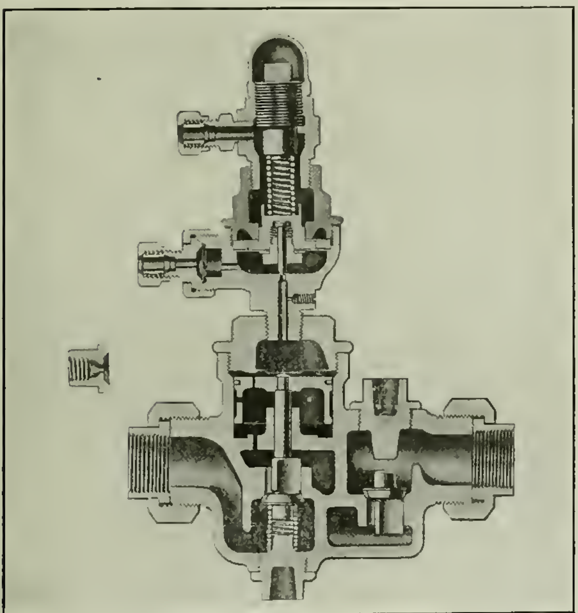
style, being made entirely of steel and equipped with an automatic stop so that the machine may be stopped at any desired point of the stroke. It is operated by either a hand lever or two foot levers arranged conveniently to the operator. The bearings of the machine are of hammered steel forged from the billet, the main bearings having heavy bronze bushings with facilities for taking up the wear. This machine will punch a two-inch hole through one-inch plate and will shear 1½-in. plate, 8-in. by 1⅛ flat bars, 2¼-in. round bars, or 6-in., by 6-in. by ¾-in. angles. The regular equipment provided consists of tight and loose pulleys for belt drive, a punch and die holder, and one punch and die of any size desired up to the full capacity of the machine.

PARASITE RESERVOIR GOVERNOR

The use of compressed air on locomotives for pneumatic devices other than the air brake, such as reversing gear, bell ringers, water scoops, etc., has reached a stage where it is considered necessary by some roads to protect the supply of air for the air brake from becoming depleted from the operation of these so-called "parasites." To accomplish this protection the Westinghouse Air Brake Company has developed a device known as the "Parasite" reservoir governor, which is so designed as to permit charging of the "Parasite" reservoir (or reservoir from which the parasites are supplied) from the main reservoir, only when the main reservoir pressure is above a certain predetermined amount sufficient to safely operate the brakes. The air-operated devices on the locomotive are thereby prevented from "robbing" main reservoir pressure, and, in consequence, the brake system itself.

This governor consists of a diaphragm portion and a body or valve portion which embodies a piston, a spring valve and a non-return check valve. Pipe connections are made, as illustrated, from the main reservoir and the brake valve feed pipe to the diaphragm portion and from the main reservoir to the body portion, and also from the parasite reservoir to the body portion.

When charging the parasite reservoir, air will flow from the main reservoir to below the diaphragm and tbrough the



Governor for Regulating the Pressure of the "Parasite" Reservoir

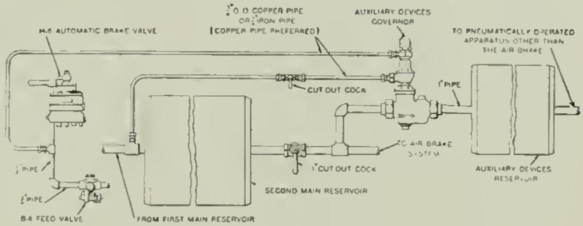
feed valve to the top of the diaphragm, but the diaphragm valve will remain seated until the main reservoir pressure reaches that for which the regulating spring is adjusted, plus the pressure on the brake valve side of the feed valve, when the valve will unseat, allowing air to flow to the top of the piston in the body.

The piston is thereby moved downward, opening the valve below it, at the left, and allowing main reservoir air to flow directly to the parasite reservoir past the non-return check at the right.

When air is being taken from the parasite reservoir for the operation of the parasites the pressure will fall a like amount in both reservoirs until it reaches that for which the governor head is set, when the diaphragm valve will seat and prevent further flow of air from the main reservoir.

Should the pipe between this governor and the parasite reservoir break, air in the main reservoir will not be lost because the diaphragm valve will seat as soon as the pressure in the parasite reservoir drops to that for which the governor head is set. Should a main reservoir pipe break, the non-return check valve 5 (at the right) will prevent the loss of parasite reservoir air.

Thus, should the parasite reservoir pipe break or the pressure become reduced abnormally through operation of the

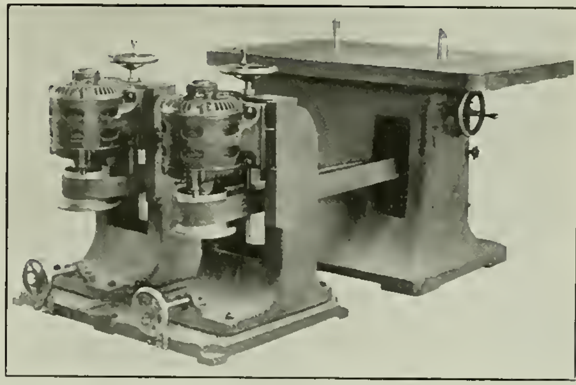


Connections for the "Parasite" Governor

parasites, the parasite reservoir governor would prevent the loss of main reservoir air below a point necessary for the operation of the brakes. Furthermore, should main reservoir pressure be lost through the breakage of a main reservoir pipe or be reduced abnormally from any other cause, the Parasite reservoir governor would prevent the loss of parasite reservoir pressure, thereby making it possible to reverse the engine if provided with a pneumatic reversing gear, or to operate the other parasite apparatus.

NEW MOTOR DRIVE FOR DOUBLE SPINDLE SHAPERS

The Oliver Machinery Company, Grand Rapids, Mich., has developed an interesting and useful compact motor drive for double spindle shapers. As shown by the illustration, standard vertical motors are used, one for each spindle. Each motor is mounted on vertical gibbed ways and is adjusted in height by means of a handwheel and screw to accommodate any height of the spindle which may be required



New Motor Drive for Double Spindle Motors

by the work at hand. Each motor stand can be adjusted longitudinally and the motors are controlled independent of each other, thus permitting the use of but one spindle when two are not necessary. This new arrangement takes up a small amount of floor room, occupying space seven feet long by five feet wide. Standard vertical motors of any type can be used, there being no need for a special built-in motor. The arrangement can be applied to old shapers as well as new and any kind of starting units can be furnished.

WE GUARANTEE, that of this issue, 7,700 copies were printed; that of these 7,700 copies 6,872 were mailed to regular paid subscribers, 57 were provided for counter and news company sales, 192 were mailed to advertisers, 25 were mailed to employees and correspondents, and 554 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 15,100, an average of 7,550 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

The Canadian Railway War Board announces that freight cars of Canadian roads may now be allowed to go into the United States. During the pressure of the past year this use of Canadian cars has been forbidden. Arrangements have now been made with the United States Railroad Administration whereby Canadian cars will be promptly returned to their owners.

S. M. Felton, president of the Chicago Great Western, and until December 31 director general of military railways, was awarded the distinguished service medal by the Secretary of War on January 18, on the recommendations of Gen. Peyton C. March, chief of staff, for "especially meritorious and conspicuous service in supervising the supply of railway material and the organization of railway operation and construction troops."

In the week ending January 4, locomotives in service on lines in the Northwestern region numbered 8,004, making the efficiency 85.2 per cent. The number of freight cars on the Northwestern lines during the week totaled 370,052, compared with an ownership of 334,615. Bad order cars numbered 20,886 (or 5.6 per cent), as compared with 18,916 (6.5 per cent) for the same week in 1918. Freight cars in outside shops totaled 208. The number of employees in service in car repair shops totaled 21,275 (working an average of 47 hours in the week), as compared with 17,537 in the same week of 1918.

Upon the recommendation of General Pershing, a distinguished service medal has been awarded to Brig. Gen. William W. Atterbury, formerly vice-president of the Pennsylvania Railroad, "for exceptionally meritorious and distinguished services." As director general of transportation in the face of almost insurmountable obstacles he organized and brought to a high state of efficiency the transportation service of American Expeditionary Forces. The successful operation of this most important service, upon which the movements and supply of the combat forces were dependent, was largely due to his energy, foresight, and ability.

The National Railways of Mexico, according to a report from Monterey, are being rehabilitated under plans which are making a fair degree of progress. All bridges on the main lines are now repaired and in use, and many of the stations have been rebuilt in a permanent manner. The roadbed is reported in fair condition. The number of locomotives in service is about 500, of which 100 belong to industries along the line and are used in the freight service of their owners. About 250 more locomotives are awaiting repairs, delay having been incurred in getting the repair parts from the United States. To handle even the minimum volume of traffic about 1,000 locomotives ought to be constantly in use, and the question of acquiring some new ones is now under consideration.

The Present Position of German Rolling Stock

In almost every direction, says an article in a recent issue of Engineering (London), Germany finds herself in a most serious plight, and the shortage and disrepair of rolling-stock is not the least important factor. Before the war Germany had about 700,000 freight cars and 30,000 locomotives. The number of the latter, as of the former, has certainly been increased during the war, through seizures in Belgium and France; but on the other hand some 4,000 locomotives may be looked upon as at least temporarily unavailable, being at present stranded in often remote occupied territory. As far as a portion of these 4,000 engines is concerned, it is doubtful whether they will ever return. Some 8,000 locomotives are badly in need of repair. Thus the 5,000 locomotives which have to be handed over, according to the terms of the armistice, represent about one-fourth of those available, and efficient. Apart from this there is some doubt as to whether or not the locomotives of the Alsace-Lorraine State railways are included in the above 5,000 engines. The proportion of increase and decrease as regards freight cars may be taken to be about the same as with the locomotives. The question then remains as to what extent German works will be able to make good the compulsory surrender of these 5,000 engines, for of the purchase of locomotives from abroad there can be no question at present. The capacity of the German locomotive factories is at the present moment, with some reserve, put at 2,500 large locomotives per annum. This estimate, of course, is subject to sufficient raw materials and other necessities being available as well as a sufficiency of skilled and trained and willing labor. If it really were possible satisfactorily to overcome these and other difficulties, and also in other ways to return to an ordered state of affairs, and entirely to ensure and rely upon the large left-Rhine production of raw materials for the whole reconstruction period, it would take the

German railways two or three years to recover from the blow which their defeat has entailed. During this considerable period German industry would be entirely debarred from export of full-size locomotives and confined to narrow-gage engines, of which it can supply some 1,500 in the year. The position is made additionally difficult, because Germany has to deliver up efficient locomotives, so that those which remain include all those more or less unfit for use. The repair of these, in addition to that of the 8,000 locomotives referred to above, will be very difficult to effect, but as the state railways are compelled to exercise the greatest economy these repairs will probably first be proceeded with.

It is being suggested in Germany that firms which have not formerly gone in for the building of locomotives, of which the majority have been engaged in war work, might with advantage take up the manufacture of locomotives, as has already been done by the Allgemeine Elektricitäts Gesellschaft.

As regards the building of freight cars the capacity of the German works during the last few months of the war has been put at 50,000 per annum. In case all necessary raw materials which are nearly all produced within the country, be made available and the industry not be handicapped by other adverse circumstances, the above-mentioned capacity might perhaps be increased by 50 per cent. Even then it will take Germany three years to replenish her stock of freight cars.

Changes in M. C. B. Interchange and Loading Rules

The Master Car Builders' Association has recently issued Circular No. 25 announcing certain changes in the 1918 Code of Interchange Rules. A second paragraph has been added to rule 8, which specifies that when repairs are made to cars of private ownership equipped with a receptacle for cards, a copy of the billing repair card shall be inserted in the receptacle. A new rule, No. 23, has been formulated, which provides for the periodical repacking of journal boxes. Rule 120, with some modifications, has been reinstated, effective January 1, 1919, to provide for the disposition of cars belonging to private car lines and railroads not under federal control which require extensive repairs for which the owners are responsible. The circular also contains two interpretations of Article 11 of the rules of interchange for 1918.

The loading rules of the Master Car Builders' Association as revised for 1918 have been approved by the Railroad Administration and are now ready for distribution. Numerous changes have been made in the present volume. The size of the pages has been increased to 5¼ in. by 7½ in. in order to permit the use of larger and clearer cuts. The general rules for loading material have been grouped in the first section and following these are the complete instructions regarding the handling of various commodities. All the rules governing the loading of each commodity are grouped together so that it is not necessary to refer to various portions of the book. In case railroads desire to provide copies of the rules for shippers, any of the sections will be printed in pamphlet form by the association. The Car Service Section has issued a circular instructing the railroads to refer any questions regarding loading that may arise to the secretary of the M. C. B. Association.

MEETINGS AND CONVENTIONS

Master Boilermakers' Association.—The 1919 convention of the Master Boilermakers' Association will be held in Chicago May 26, 27, 28 and 29 at the Hotel Sherman. This will be the first convention since 1916, the association having suspended activities on account of the war. The subjects to be discussed at the convention, together with the committees, follow:

1. Proper method of threading radial stays and tapping the hole in the boiler for them.
   Is it necessary to give radial stays the same lead as the tap with which the holes were tapped?
   Committee: H. J. Raps, chairman; Andrew Hedberg, J. J. Keogh, J. B. Smith, T. J. Reddy.
2. Which is the better time for drilling tell-tale holes, before or after application of the bolts?
   Which is the better method for drilling in either case?
   What is the best style of drill for opening up tell-tale holes in old staybolts?
   Does it pay to use a high speed drill for this purpose?
   What is the best lubricant for the drill?
   Committee: L. R. Porter, chairman; A. N. Lucas, S. M. Carroll, Bernard Wulle, C. E. Erwin.
3. Effect of proper upkeep of ash pan and front end draft appliances on fuel economy.
   Method used in determining proper design for various classes of locomotives.
   Committee: George Austin, chairman; E. J. Nicholson, Fred Bayer, H. F. Weldin, George Hewitt.
4. What is the best method for scaling superheater flues in the boiler?
   What is the best method of rattling flues?
   What is the best method of handling flues in and out of the rattler?
   How many revolutions per minute should the rattler make for 2-in. and for 5⅜-in. flues?
   Describe method for safe ending superheater flues.
   Committee: Frank Gray, chairman; W. J. Murphy, Andrew S. Green, John Harthill, J. J. Mansfield.
5. What is the best style grate for bituminous coal?
   Where should the dump grate be located, (a) in road engines, (b) in switch engines?
   What should be the percentage of opening in grates?
   What should be the percentage of draft opening in ash pans compared with area of grates?
   Committee: W. H. Laughridge, chairman; L. M. Stewart, T. P. Madden, C. P. Patrick, C. A. Nicholson.
6. What should be the minimum distance between the grates and the lower part of arch tubes for different classes of locomotives?
   What is the proper distance from the door sheet to the brick arch and from the crown sheet to the brick arch for the various classes of locomotives?
   Committee: C. L. Hempel, chairman; W. F. Fantom, A. E. Brown, E. W. Young, G. B. Usherwood.
7. What is the best method of bracing locomotive tenders? Describe method used.
   Committee: Thomas Lewis, chairman; E. J. Sweeney, J. J. Orr, J. P. Malley, J. T. Johnson.
8. Oxy-acetylene and electric welding.
   Committee: H. J. Wandberg, chairman; B. F. Sarver, L. M. Stewart, T. F. Powers, J. J. Davey.
9. What is the advantage of cutting off stay ends with oxy-acetylene over old method of nippers and chisels?
   Committee: W. S. Larason, chairman; John McGarrigal, J. B. Tynan, E. H. Hohenstein, A. E. Shaule.
10. General discussion.

Central Railway Club.—At the January 10 meeting of the Central Railway Club the following officers were elected for the ensuing year: President, Frank C. Pickard, master

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Feb. 3	Storage of Coal and Spontaneous Combustion	D. H. Pudney.......	James Powell ...	P. O. Box 7. St. Lambert, Que.

mechanic, D., L. & W.; vice-presidents, H. T. Malcolmson, superintendent, T. H. & B.; L. C. Fitzgerald, shop superintendent, Erie, and M. W. Hassett, master mechanic, New York Central. H. E. Myers, master mechanic, Lehigh Valley, was elected to the executive committee. The retiring president, W. H. Sitterly, general car inspector, Pennsylvania, was added to the list of past presidents, who are also members of the executive committee.

Master Mechanics' Association.—At a meeting of the executive committee of the American Railway Master Mechanics' Association, held in Chicago on January 3, W. J. Tollerton, general mechanical superintendent of the Rock Island Lines, was appointed president of the association to fill the vacancy caused by the resignation of F. H. Clark. C. F. Giles, superintendent of machinery of the Louisville & Nashville, was appointed first vice-president, and C. H. Hogan, assistant superintendent motive power, New York Central, was appointed second vice-president. The position of third vice-president was left vacant and will be filled by election at the time of the next annual meeting of the association.

The June Mechanical Convention.—J. D. Conway, secretary of the Railway Supply Manufacturers' Association on January 23, sent out circular No. 1 extending an invitation to manufacturers of and dealers in railway supplies to exhibit at Atlantic City in June, and giving full details as to the exhibit arrangements.

In his circular Mr. Conway says:

"This is the first exhibition that has been held for three years. The railroad associations have expressed their earnest desire that our association should make a full exhibit, and the United States Railroad Administration gives its unqualified approval of it. Invitations are being extended in the name of the three associations to all foreign trade bodies in this country, and, through the embassies at Washington, to all foreign governments (except the Central Powers), inviting them to send delegates or representatives to attend the conventions and examine the exhibits. The opportunity presented by an exhibition at this time for both the domestic and foreign demand is exceptional."

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention, May 6-8, 1919, Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Master Mechanics' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. R. McMunn, New York Central, New York, N. Y.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention May 26-29, Hotel Sherman, Chicago.

Master Car Builders' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 18-21, Atlantic City, N. J.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C. Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

Personal Mention

GENERAL

N. Bell, formerly master mechanic of the Minnesota and Iowa divisions of the Illinois Central with headquarters at Waterloo, Iowa, who has just returned from military service, has been appointed to the same position, succeeding O. A. Garber.

C. H. Dyson has been appointed fuel agent of the Baltimore & Ohio—Western Lines, the Dayton & Union Railroad, and the Dayton Union Railway, with headquarters at Cincinnati, Ohio.

A. L. Greburn, assistant superintendent of rolling stock of the Canadian Northern, with office at Toronto, Ont., has been appointed general fuel agent of the Canadian National Railways, with office at Toronto.

W. F. Kaderly, general superintendent of the Georgia Southern & Florida, the Hawkinsville & Florida Southern and the St. Johns River Terminal, has been appointed superintendent of motive power of the Southern Railroad, Lines East, with headquarters at Charlotte, N. C., succeeding E. C. Sasser, resigned.

William Gemlo, master mechanic of the Minneapolis & St. Louis at Marshalltown, Iowa, has been promoted to superintendent of motive power and rolling stock, with headquarters at Minneapolis, Minn., to succeed G. M. Seidel. Mr. Gemlo was born at Glasgow, Canada, on September 28, 1868. He began railway work with the Minneapolis & St. Louis as a locomotive fireman in September, 1888, and served in that capacity until October, 1896, when he was promoted to locomotive engineer. In June, 1907, he was appointed roundhouse foreman, and two years later traveling engineer. In October, 1913, he was promoted to master mechanic at Marshalltown, Iowa, which position he held until his recent appointment as superintendent of motive power and rolling stock.

W. Gemlo

E. E. Ramey has been appointed superintendent of fuel and locomotive performance of the Baltimore & Ohio, Eastern Lines; the Coal & Coke; the Wheeling Terminal Railroad; the Western Maryland; the Cumberland Valley, and the Cumberland & Pennsylvania Railroad. The position of supervisor of fuel consumption has been abolished. A photograph, and a sketch of Mr. Ramey's career were published in the *Railway Mechanical Engineer* for May, 1918, on page 294.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

O. A. Garber, master mechanic of the Illinois Central at Waterloo, Iowa, has been transferred to Memphis, Tenn., succeeding W. H. Watkins, granted a leave of absence.

W. B. Kilgore, road foreman of engines of the Baltimore & Ohio, Western Lines; the Dayton & Union Railroad, and the Dayton Union Railroad, with office at Dayton, Ohio, will also assume the duties of trainmaster of the Wellston sub-division, succeeding W. E. Duffey, who has been transferred.

P. T. O'Neill has been appointed division master mechanic of the Chicago, Milwaukee & St. Paul with headquarters at Spokane, Wash., succeeding Fred Lowert, who has been transferred to the St. Paul shops at Tacoma, Wash. Mr. O'Neill was formerly superintendent of motive power of the Idaho & Washington Northern at Spirit Lake, Idaho, and after that line was purchased by the St. Paul he was appointed general foreman at the Spirit Lake shops and later transferred as general foreman to the Tacoma, Wash., shops.

CAR DEPARTMENT

George W. Ditmore, assistant master car builder of the Delaware & Hudson, has been appointed master car builder of that road, the Greenwich & Johnsonville, the Wilkesbarre Connecting Railroad, and the Schoharie Valley Railroad, with headquarters at Colonie, N. Y. The position of assistant master car builder has been abolished. Mr. Ditmore was born on February 17, 1878, at Jermyn, Pa., and was educated in the high school of his native town. He began railway work on June 1, 1897, as a journal packer at Carbondale, Pa., on the Delaware & Hudson, and later served as car repairer. One year later he was promoted to car inspector and served in various other capacities in the car department. In March, 1902, he was appointed an interchange car inspector at Green Ridge yard, Scranton, Pa., and then served as foreman of car inspectors and repairers at the same place and at Buttonwood, Wilkes-Barre, Pa. On December 1, 1913, he was transferred to Carbondale as shop foreman and about four years later he was promoted to division car foreman of the Pennsylvania division. Since November, 1918, he served as assistant master car builder until his recent appointment.

G. W. Ditmore

PURCHASING AND STOREKEEPING

G. W. Alexander, storekeeper of the Central of Georgia, has been appointed general storekeeper with headquarters at Macon, Ga. He was born on February 21, 1886, at Senoia, Ga., and was educated in the high schools. He began railway work in 1905, as a receiving clerk in the freight agent's office of the Central of Georgia, at Atlanta. In 1907 he was appointed ticket agent at Bremen, and then to 1909 was mechanical clerk to the general foreman at Cedartown. From 1909 to 1912 he held different clerical positions in the division storekeeper's office at Macon, and later was appointed division storekeeper at Cedartown. He subsequently served as division storekeeper at Savannah, and from 1914 to April, 1918, as division storekeeper at Macon, in charge of the Macon, Southwest and Chattanooga divisions on the same road. In April, 1918, he became assistant to the Southern Regional Purchasing Committee of the United States Railroad Administration, with headquarters at Atlanta, Ga., and now returns to the Central of Georgia as general storekeeper.

J. H. Nichols has been appointed general storekeeper of the New York, Chicago & St. Louis with headquarters at Cleveland, Ohio.

E. A. Workman, storekeeper of the Baltimore & Ohio Eastern Lines, with office at Keyser, W. Va., has been appointed storekeeper of the Maryland district, with headquarters at Camden station, Baltimore, Md., succeeding O. V. McQuilkin, deceased.

C. L. Nash has been appointed division storekeeper of the Mobile & Ohio with headquarters at Tuscaloosa, Ala., succeeding T. S. Edgell who has been transferred to other duties.

W. J. Diehl, general storekeeper of the Mobile & Ohio, with headquarters at Mobile, Ala., now also has jurisdiction over the Gulf, Mobile & Northern.

Charles W. Yeamans, assistant engineer of the Chicago & Western Indiana, has been appointed purchasing agent of that road and the Belt Railroad of Chicago, with headquarters at Chicago, succeeding R. Benson, transferred. Mr. Yeamans was born at Akron, Colo., on August 12, 1886. He began railway work on May 1, 1905, as a clerk in the engineering department of the Chicago, Burlington & Quincy, with headquarters at Chicago. Two years later he was promoted to chief clerk to the engineer of track elevation. On May 1, 1910, he resigned to go with the Chicago & Western Indiana in charge of the field construction office, with headquarters at Chicago. During the construction of Clearing yard between 1913 and 1915 he was material agent, having full charge of the ordering of materials, their inspection and distribution. Later he became chief clerk in the engineering department, and on May 1, 1918, was appointed assistant engineer in the construction department, which position he held until December 1, when he received his appointment as purchasing agent.

C. W. Yeamans

FEDERAL ADMINISTRATION APPOINTMENTS

A. F. Duffy, assistant manager of the Safety Section, Division of Operation, of the Railroad Administration, has been appointed manager of the section, succeeding H. W. Belnap, deceased.

F. F. Gaines has been elected chairman of the Board of Wages and Working Conditions of the Railroad Administration, succeeding G. H. Sines, and A. O. Wharton has been elected vice-chairman succeeding Mr. Gaines, in accordance with the plan of rotation in office every six months, decided upon at the time of the organization of the board.

J. C. Turner has been appointed representative of the Division of Labor. Mr. Turner will be assigned to conduct investigations and to represent the Division of Labor of the Railroad Administration in other specific matters to which he may be assigned, affecting employees of the railroads under federal control.

Supply Trade Notes

The French government has conferred upon Samuel M. Vauclain, first vice-president of the Baldwin Locomotive Works, the title of Chevalier of the Legion of Honor.

Ernest Baxter has been appointed general sales manager of the Kansas City Bolt & Nut Company, with headquarters at Kansas City, Mo., succeeding L. L. Middleton, promoted.

Edward F. Carry has resigned as chairman of the Port Facilities Commission at Washington to return to his office at Chicago as president of the Haskell & Barker Car Company.

Harry F. Worden, sales manager of the Bryant Zinc Company, with headquarters at Chicago, died in that city on January 14, after a short illness brought on by an attack of acute indigestion.

Alden R. Ludlow, formerly vice-president of the Liquid Carbonic Company of Chicago, has since January 1, 1919, been acting as second vice-president and sales manager of the Air Reduction Company, Inc., New York.

Kenneth C. Gardner has been appointed assistant manager of sales for the Central district of the Pressed Steel Car Company, with headquarters at Pittsburgh, Pa., succeeding Henry P. Hoffstot, who has resigned to become president of the Koppel Industrial Car & Equipment Company.

Joseph B. Weaver, vice-president and general manager of the Harlan & Hollingsworth Corporation, Wilmington, Del., has been appointed vice-president in charge of the manufacturing department of the Pullman Company with headquarters at Chicago.

A. A. Heller, treasurer and general manager of the International Oxygen Company, New York, has given up his active managerial duties, and Eugene Schoen has been appointed general manager for the company. Mr. Heller, as treasurer, continues in charge of the financial departments of the business.

Edward D. Hillman, secretary and engineer of the National Railway Appliance Company, New York, for the past two years, resigned from that company on January 1, and has accepted a position with the new Consolidated Steel Corporation, 165 Broadway, New York.

Captain George A. Post, Jr., of the Ordnance Department, U. S. A., has received an honorable discharge from the military service and has returned to the service of the Standard Coupler Company, as assistant to the president, with headquarters at 30 Church street, New York.

John C. Kuhns has left the service of the Oxweld Railroad Service Company to become identified with the Burden Iron Company, of Troy, N. Y., as manager of railroad sales. His headquarters will be at the Railway Exchange building, Chicago. Mr. Kuhns was formerly purchasing agent of the Illinois Central.

Automatic straight air brake equipment, developed by the Automatic Straight Air Brake Company, New York, is now being manufactured by the American Car & Foundry Company, for both passenger and freight cars. It is reported that within 60 days the installation of these brakes will begin on freight and passenger cars in regular service.

The Vanadium-Alloys Steel Company of Pittsburgh and Latrobe, Pa., maker of high-speed and alloy tool steels, has leased commodious offices and warerooms at 566-568 West Randolph street, Chicago, where will be carried a large stock of "Red Cut Superior" high-speed steel in all the standard sizes and shapes of bar stock, also treated bits for tool holders.

L. L. Body has been appointed manager of railway, street railway and marine sales of the Glidden Company, Cleveland, Ohio. Mr. Body has been identified with paint and varnish interests for many years. He began his career with the Sherwin-Williams Company in 1902, where he rose to the managership of railway and marine sales in 1912. In 1915 he severed his connection with Sherwin-Williams to become sales manager of the Master Builders' Company, Cleveland.

William T. Lane has been appointed district sales manager of the Franklin Railway Supply Company, Inc., with offices at San Francisco, Cal. Mr. Lane has spent his entire business career in the railway supply field. For the past seven years he has constantly been in touch with locomotive development. On leaving college he went as an apprentice with the Franklin Portable Crane & Hoist Company. His next position was as draftsman for the Franklin Railway Supply Company, Inc., and then chief draftsman. In 1915, he was made mechanical engineer of this company, which position he held at the time of his appointment as district sales manager, as noted above.

Wm. T. Lane

The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., is planning to erect several new buildings at Essington (South Philadelphia), Pa., to take care of turbine an delectric generator construction work that this now being handled at East Pittsburgh. It is planned to build at Essington all the large and important apparatus manufactured by the Westinghouse Company, and it is probable that in the future a building will be erected for the construction of electric locomotives, in which work the Westinghouse Company co-operates with the Baldwin Locomotive Works.

Lieutenant T. W. Jenkins, U. S. N. R. F., has been appointed manager of railway sales of the American Rolling Mill Company, Middletown, Ohio. Previous to the entry of the United States into the European war, Mr. Jenkins was in charge of sales of castings and forgings for this company. When the war broke out he was given indefinite leave to re-enter the navy, from which he had resigned in 1913. Lieutenant Jenkins served as an engineering officer on the navy transports throughout the war. Upon cessation of hostilities he was relieved from active duty to return to the commercial field.

W. C. Lincoln has been appointed engineer for the National Railway Appliance Company, New York. Mr. Lincoln was originally employed by the American Locomotive Company at Schenectady, leaving that company's service to enter Union University. After graduation and the completion of the General Electric Company's test course, he was assigned to special railway work by that company. Subsequently he took up and completed the engineering extension course, after which he was connected for some time with the consulting engineering department. Mr. Lincoln later entered the railway engineering department and in 1913 was transferred to the General Electric Company's Philadelphia district as commercial engineer in the railway department, after which he entered the service of the Railway Improvement Company as electrical engineer.

W. C. L. Lamot, of Antwerp, advises that he is about to return to that city and would like to get in touch with any American firms who desire to establish an agency in Belgium. Mr. Lamot was established in Antwerp from 1907 until the outbreak of the war as an importer, exporter and shipping agent on his own account and had extensive business connections in both the industrial and commercial world. Since 1914 he has been acting as general merchant and commission agent in London, supplying many Belgian and British airplane, munition and engineering works. To facilitate matters he has given the *Railway Mechanical Engineer* a list of his connections as well as references. His present address is 22 Northumberland avenue, London, W. C. 2.

The Grip Nut Company, Chicago, has been reorganized with the following officers: Francis H. Hardy, chairman of the board of directors; William E. Sharp, president; Chester D. Tripp, vice-president; Herman A. Brassert, vice-president; Truman F. Miller, secretary and treasurer. The directors of the company include Messrs. Hardy, Sharp, Tripp, Brassert and Thomas G. Deering. William E. Sharp, who has been elected president of the reorganized corporation, began his railway career as an apprentice in the car department of the Erie in April, 1889. In October, 1892, he was promoted to general foreman of the car and locomotive department of the same road, with headquarters at Chicago. He left the Erie in 1898 to become assistant superintendent of the Armour Car Lines. In April, 1901, he was promoted to superintendent of those lines. He resigned that position in 1911 to enter the railroad supply business as vice-president of the Grip Nut Company. He was elected president in September, 1916, and became president of the reorganized corporation in November, 1918.

W. E. Sharp

The Electro-Dynamic Company, of Bayonne, N. J., which formerly manufactured the electric car lighting equipment for the Consolidated Railway Electric Lighting & Equipment Company, New York, has bought the entire stock in trade, assets, good will, etc., of the latter company, and will continue to manufacture and sell the "Axle Light" equipment formerly sold by the Consolidated, together with all repair parts for the Consolidated equipment now in service on the railroads. The Electro-Dynamic Company is controlled by the Submarine Boat Corporation and is known in the railway field as the manufacturer of the Edco interpole motors for railway shop use, machine tools and submarines. A separate department of the Electro-Dynamic Company has been created, known as the axle light department, to handle this work. There will be no interruption of the former Consolidated business.

Charles H. Wilson, who has been in active military service in France as a lieutenant of engineers, has been honorably discharged from the army and has resumed his duties as representative of Fairbanks, Morse & Co., Chicago. He was one of the survivors of the U. S. SS. "Lincoln," which was sunk by a German submarine 400 miles off Brest, France, while on a return trip to the United States. During his service with the American Expeditionary Forces Lieutenant Wilson, who was a reserve officer prior to the entry of this country in the world war, was attached to the British tank corps as mechanical officer and was later with the U. S. tank corps. On his return he was assigned for duty in the organization of tank corps units here, afterwards being on duty with engineer replacement troops. Prior to his entry into military service Mr. Wilson was located in Houston, Texas, as southwestern representative for Fairbanks, Morse & Co., with which company he has been associated for 14 years. He will now make his headquarters at St. Louis.

The Consolidated Steel Corporation, formed recently to handle the export trade of several independent steel producers, has opened offices in the City Investing building at 165 Broadway, New York. E. A. S. Clarke, former head of the Lackawanna Steel Company, is president of the export concern. The other officers are H. H. Barbour, vice-president, formerly of the Lackawanna Steel Company; W. Hesselman, secretary and controller, and A. Van Winkle, treasurer. Mr. Hesselman was controller of the Lackawanna company, and Mr. Van Winkle was secretary to Mr. Clarke when he was at the head of that concern. The traffic manager is William Heyman, formerly foreign freight agent for the Delaware, Lackawanna & Western Railroad. The independent steel companies represented in the organization are the Bethlehem Steel Corporation, the Brier Hill Steel Company, the Lackawanna Steel Company, the Lukens Steel Company, the Midvale Steel & Ordnance Company, the Republic Iron & Steel Company, the Sharon Steel Hoop Company, the Trumbull Steel Company, the Whitaker-Glessner Company and the Youngstown Sheet & Tube Company. The board of directors of the new export company is made up from the executives of these companies.

Nathaniel M. Rice has been elected a vice-president of the Pierce Oil Corporation, in charge of lubrication, with headquarters at 420 Olive street, St. Louis, Mo. The managers of the railroad lubricating, stationary engine lubricating and automobile lubricating departments will report to and receive instructions from Mr. Rice. Mr. Rice was formerly connected with the St. Louis-San Francisco, having occupied the position of purchasing agent, and later that of third vice-president. He was born December 28, 1863, at Rome City, Ind., received his early education in the public schools at that place, and in May, 1887, entered railway service as a brakeman on the Gulf, Colorado & Santa Fe. He served in various capacities in the transportation and store departments, and on April 1, 1901, he was made assistant general storekeeper of the Atchison, Topeka & Santa Fe Coast Lines, which connection he held until April 1, 1903, when he became general storekeeper in full charge of material, fuel and stationery, serving the entire system. In November, 1913, he was appointed chief purchasing agent of the St. Louis-San Francisco, with headquarters at St. Louis, Mo., and in September, 1916, was elected third vice-president of that road.

N. M. Rice

CATALOGUES

Boiler Tube Cleaners.—A general catalogue, X-4, has been issued by the Lagonda Manufacturing Company, Springfield, Ohio, describing in detail the boiler tube cleaners and accessories and other boiler room appliances manufactured by this company, and stating the work for which each type of cleaner is best adapted. All are illustrated and a number of sectional views are shown with the parts named.

Tool Holders.—Tool holders manufactured by the Gisholt Machine Company, Madison, Wis., for use in turret and engine lathes equipped with turret tool posts, are illustrated and described in a six-page folder issued by that company. Complete dimensions, sizes and prices are given. These holders were designed to make possible the use of worn down tools to the last inch or so, a fact which is of importance with the prevailing price of tool steel.

Graphite Products.—The United States Graphite Company, Saginaw, Mich., has published general catalogue No. 20, which gives detailed information about the line of lubricating graphite, greases, paints, etc., manufactured by this company. It also includes the report of tests made by the chief engineer of the Interborough Rapid Transit Company of New York, to determine the efficiency of graphite under actual operating conditions, and a number of microphotographs and curves.

Electric Industrial Trucks.—Three types of electric industrial trucks designed for different services, including a carrying truck, an elevating platform truck and a tractor, manufactured by the Buda Company, Chicago, are described in its bulletins, 327, 328 and 329, respectively. These give a general description of the construction and specifications for each type, as well as illustrations and drawings. Bulletin 326 contains a brief description of the mechanical features common to all three types.

Mallet Articulated Locomotives.—Record No. 91, published by the Baldwin Locomotive Works, Philadelphia, Pa., is devoted to a non-technical description of Mallet articulated locomotives, illustrated with two sectional drawings. Instructions are given for the proper handling of these locomotives, as well as formulas for calculating their tractive effort. The booklet also contains a number of illustrations of various locomotives of this type, both for foreign and domestic roads, with their dimensions and general data.

Rust Preventives.—The Dearborn Chemical Company, Chicago, has issued a booklet entitled "The Prevention of Rusting or Corrosion of Iron and Steel," for the purpose of presenting evidence of the success that has followed the use of No-Ox-Id, a rust preventive developed by the Dearborn Chemical Company, as well as to describe other Dearborn products, including Dearboline, a preparation for cleaning machined parts of emery or grease, Klean-Kleen, for use in cleaning metal during various stages of manufacture, and cutting, quenching and drawing oils, etc.

Iron and Steel Products.—A new edition of the Interstate Blue Book has been published by the Interstate Iron & Steel Company, Chicago. This book contains 204 pages and gives complete information regarding all Interstate products. Bars, bands, angles, channels, tees, flats and special shapes are shown with sizes listed for both wrought iron and high or low carbon steel, and the many other products of the company, including wire and wire products, staples and rivets are fully illustrated and described. The book contains the National Iron and Standard Steel classifications of price extras, as well as a number of weights and gages and other valuable information conveniently arranged for ready reference. The alloy and special analysis steels from the South Chicago plant are also described.

Turret Lathes.—The Gisholt Machine Company, Madison, Wis., has issued a 102-page, 7¾-in. by 9½-in. catalogue, TLC-1, describing Gisholt turret lathes. It was the purpose in preparing this catalogue to show particularly what kinds of work these lathes will do. It contains over 100 illustrations, including a number of close-up views of the lathes actually at work, followed by 22 pages of line drawings showing parts which are successfully finished on Gisholt lathes; the time for finishing these parts is given under each drawing. A general description of the machine is also given, together with specifications and dimensions, and the last part of the book is devoted to standard tools for the lathes, boring bars, reamers, tool holders and chucks. The turret on carriage and gap lathes, as well as the motor driven lathes, are illustrated and described.

Westinghouse Instruments and Relays.—The Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., has issued a revised edition of catalogue 3-B, listing and describing Westinghouse switchboard, portable and precision instruments, ammeter shunts, transformers and relays. The catalogue contains 104 pages, 8½ in. by 12 in. and gives complete information about each instrument, describing the principle of operation and construction, as well as the work to which the instruments are especially adapted. Wherever possible each particular type of apparatus is listed on only one page and where more than one page is required, the several pages are confined to a description and listing of only one particular type, so that it is not difficult to find desired information. Several new types of apparatus are listed for the first time in this edition.

Tool Steels.—The Carnegie Steel Company, Pittsburgh, Pa., is now offering to the trade a new line of electric carbon tool steels made in five grades, containing different proportions of carbon, which are intended for utilization in the manufacture of tools where heretofore alloy steels have been used. A catalogue has been issued describing these steels and presenting practical information for the steel user, without going into an extended discussion of the theories of heat treatment. It contains a chart in colors of heat and temper colors which is a direct reproduction by color photography from test pieces heat treated to the temperatures shown. It affords a direct comparison by the blacksmith in the shop whereby it is possible to eliminate the effect of different lighting conditions. Pages devoted to reproduction of labels of the five grades also specify the various uses for each different grade of steel, and permit the selection of the proper grade for any particular use.

"Under Frame" Car Lighting Equipment.—The Safety Car Heating & Lighting Company, 2 Rector street, New York, has issued a 28-page book as a reference for the man who operates "under-frame" equipment. It is called Operation of Safety "Under-Frame" Car Lighting Equipment. The object of the book is to state briefly and concisely the essential points regarding the installation and operation of "under-frame" dynamos and type F regulators. The first part is given over to such subjects as installation of dynamo and suspension, lining up dynamo, belt lengths, measuring of belt lengths, application of belt fasteners, care of under-frame suspension, operation of Safety type F dynamo regulator, method of adjusting automatic switch with car in yards, etc. The latter part of the book is given over to assembly and detail drawings and each detail part is numbered and named. The book is complete and well worth the attention of any one interested in car lighting equipment.

Railway Mechanical Engineer

Volume 93 | March, 1919 | No. 3

CONTENTS

The Trying Times During Readjustment

The men in supervisory capacities on American railroads are being put to a test by what may be considered not necessarily a period of reconstruction, but the result of conditions occasioned by the war. The manner in which these men meet these new problems will show the stuff they are made of. We all well appreciate how the conditions have changed, we all know also that certain changes must come if railroading is to be conducted along economic lines. It is the broad and far-sighted man who sees in these present conditions a swing of the pendulum towards the reactionary and who will foresee its return swing towards more stable and logical conditions. The war has wrought changes in old-time methods of railroading, which, under ordinary circumstances, would have taken years to bring about. Some of these changes have come to stay, others have not. We must take the good from what has come and learn our lessons from the bad. It is no time to give way to discouragements nor to have a spirit of hopelessness. We all must realize that what is fundamentally wrong will eventually be corrected, and everyone must put his shoulder to the wheel to correct the wrong and to further that which is right. Form your own conclusions as to what is right and best and have the courage of your convictions.

Give More Attention to Lumber

In buying steel, the railroads specify within the narrow limits the allowable percentage of impurities and the physical properties required and tests are conducted to insure that the material meets the specifications. Lumber, on the other hand, is usually bought without any precautions being taken to insure that it will have the necessary strength and lasting power, although the properties of different specimens from the same species of wood may vary widely considering the large sums the railroads spend for lumber for use in cars, the scant attention that has been given to its selection and to methods of getting the maximum service from the material is remarkable.

Often-times some of the common practices in purchasing lumber that have been in effect for years, can profitably be changed. For example, one road has found it advisable to specify No. 1 common for sills, even though it is necessary to cull out almost one-third of the material and use it for sill splices, draft timbers, etc. The same road has also found that by reducing the customary allowance of one-half inch for finishing on sills, side plates and other long timber, about eight per cent is saved. These instances will serve to show that a consideration of the methods of buying timber now in use may reveal possibilities for effecting considerable savings.

Coaling Stations Affect Fuel Consumption

The conservation of fuel is a matter that on most roads is handled by the mechanical department. It is probably due to this fact that the greatest attention is paid to methods of saving through improvements in the motive power, while the preparation of the coal and the operation of the fuel stations receive only passing consideration. The importance of the proper operation of fuel stations in securing the economical use of coal, was strikingly brought out at a recent meeting of the Western Railway Club by J. G. Crawford, who presented data to show that if the plants were improperly operated, as much as six per cent of the fuel might be wasted.

To secure the best grade of fuel for locomotive service as delivered on the tender, the coal loaded at the mine must be checked to insure that the lump and screenings are well mixed, the metal bottoms of the coal pockets must be kept bright, and each pocket must be completely emptied every few days. If these precautions are observed, the engines will receive a fairly uniform grade of well cracked mine run coal. On the other hand, if the chute pockets are not cleaned thoroughly and systematically, the metal bottoms will become rusty, and coal will accumulate, with the result that some engines will receive egg coal, others cracked mine run, and still others screenings.

The fuel performance under the latter conditions will not be as good as if the engines had received a uniform grade of mine run coal. Tests conducted at the University of Illinois, show that two inch lump coal is 98 per cent as efficient as mine run, and that two inch screenings are 90 per cent as efficient as mine run. It would make no difference whether the two inch lump and two inch screenings were obtained by screening mine run at the mine or whether they resulted through separation of mine run at the coaling station., Therefore, under the first assumed condition, the efficiency of the coaling station would be 100 per cent, and under the second condition, assuming that the engines received one-half the time two inch lump, and the other half, two inch screenings, the efficiency would be only 94 per cent, or the average of 98 and 90 per cent. The amount to be saved by closer supervision of coaling stations will not average six per cent, but nevertheless on most roads it will be found to be a very appreciable item. There are other conditions that make it advisable to give close attention to the coaling plants. There will be more delay to trains and more engine failures where some locomotives receive all lump coal and others all screenings, than if each engine received a uniform grade. Furthermore, the gradual oxidation of accumulations of mine coal which have remained in the chute undisturbed for some time may cause fires due to spontaneous combustion.

Wages of Railway Shop Employees

The New York State Department of Labor issues regularly a bulletin reviewing the labor situation in the shops and factories of the state. A statement of the average weekly earnings in December, 1918, in representative New York state factories, including all employees in both office and shop, indicates that employees in car, locomotive and railway repair shops are among the very best paid shop employees in the state. In December, 1918, their average weekly earnings amounted to $34.07 as compared to an average of $23.18 for 55 industries. Only one other class of employees, those engaged in the manufacture of pig iron and rolling mill products, received a higher weekly wage; these employees earned $37.97 a week. Employees in the boat and ship building establishments received an average weekly wage of $32.01 and those employed in structural and architectural iron work $30.21.

It is of special interest to compare the conditions in December, 1918, with those of December, 1914. In December, 1914, the average weekly earnings for employees in car, locomotive and railway repair shops was $14.34. Employees in 11 other industries received higher wages. For instance, employees in factories making beverages received $18.58; miscellaneous stone and metal products, $18.47; automobiles, carriages and airplanes, $18.07; printing and book making, $17.03; pig iron and rolling mill products, $16.63; boat and ship building, $16.16; structural and architectural iron work, $15.31; flour, feed and other cereal products, $15.10; slaughtering, meat packing and dairy products, $14.88; drugs and chemicals, $14.57; paints, dyes and colors, $14.43. The average of the 55 industries under consideration was $12.56.

In 1915 the railroad shop employees averaged $16.21 per week and were outranked by nine other industries, the average weekly earnings for the 55 industries being $13.49. In December, 1916, the average earnings for the railroad shop employees jumped to $19.28 as compared with an average of $15.51 for the 55 industries. The railroad shop employees were outranked by only three other industries, the best paid workers being those making pig iron and rolling mill products who received an average weekly wage of $21.76. In December, 1917, the railway shop employees advanced to an average weekly earning of $23.10 and, as in 1918, were outranked by only one other industry—pig iron and rolling mill products. The average weekly earnings for the 55 industries in December, 1917, was $17.71.

Doubtless the contrast between the wages received by railroad shop employees and employees in other industries is still more marked in other parts of the country where competition for labor is not so great. The rates for railroad shop employees have been standardized throughout the country and there are undoubtedly many districts where these employees rank as the very highest paid employees in any industry. It would be interesting to know to what extent this is appreciated by the railroad shop employees themselves, and whether they are giving adequate returns for the wages received. If not, energetic measures should be taken to see that they are thoroughly instructed in their tasks and sufficient supervision should be provided to insure a full day's work for a full day's pay. The public generally has watched closely the increased wages given to railroad employees, and it will look to these employees and their officers for increased efficiency and service.

Piecework Being Abolished in Railway Shops

One of the last acts of Director General McAdoo was to issue an order instructing the railroads to have the shopmen vote as to whether piecework should be retained and that the policy of the shops in this respect should be governed by the will of "a substantial majority." Having at the beginning of 1918 given the trade unions entree on all railroads to develop their organizations, and later encouraging them by increasing the hourly wage without granting a corresponding increase in the piecework rate, the results of this ballot could easily be predicted. There is probably today no railway shop operating under the piecework system. If there is we should be very glad to know about it. The New York Central System, on which the piecework system had been successfully operated both from the standpoint of the men as well as the road, has discarded it entirely. The employees on other large systems likewise have ruled piecework out of existence.

There is not a reader of this paper but will appreciate what the discontinuance of piecework means to output and the cost of repairs. After the increases of Supplement No. 4 to General Order No. 27 removed the incentive for the men to work piecework some very interesting data were obtained. One road found that the output was but 60 per cent. as much per man as before the supplement went into effect and 40 per cent. as much work was being turned out per dollar as before. Another road making a comparison of the last three months of 1917 with the corresponding period in 1918 found a decrease of 28.5 per cent. in the car department in the actual earnings of the men based on the piecework rates in effect in 1917. On still another road the average actual piecework earnings of a labor committee man dropped from 59 cents in March, 1918, to 24 cents in October of the same year, for which he received 58 cents. This gives an indication of what has been done in decreasing the output by not giving the piecework rates the same consideration that the hourly rates received.

The economic value of a man to the world at large is governed primarily by three things: namely, the time he devotes to increasing the world's wealth, the diligence with which he does his work during that time and his cleverness in performing it. Under the hourly rate only one of these qualifications is required of the worker—that is, the time he puts into his occupation. Piecework on the other hand not only demands the time of the workman but provides an incentive for diligent work performed in a skilful and able manner. Fundamentally, therefore, we cannot expect as large an output under day work as we might expect under piecework. The incentive for increasing the output of a man, which has been removed by the abolition of piecework, can to some extent be reclaimed by an increase in the supervision, and where labor is plentiful, by the process of elimination and reorganization for the purpose of getting the best men and the most diligent workers in the shop. The piecework system was so generally used in the shops of the railroads, particularly in the car department, that the reorganization and re-education of the supervising forces is necessary. It is this feature that requires the most careful thought by the railway managements today. Under the existing conditions the workmanship of the men must not only be carefully watched, but it will be necessary to see that they give a full day's work for a full day's pay. There is no use crying over spilled milk. We all must make the best of conditions as they exist and the successful man is he who adjusts himself to those conditions and makes the most of them. Pitch in therefore, recognize the task ahead of you and for your own self respect meet it and make the most of it.

Dissatisfaction with Wage Increases

Several anonymous letters have been sent to the *Railway Mechanical Engineer* by our readers commenting on the injustices that have been occasioned by the various wage orders promulgated by Mr. McAdoo during his year's tenure of office as director general of railroads. In practically every case these letters appear to contain true facts, but we cannot use them as it is against the policy of this publication to print anonymous communications in its columns. We know there are injustices, many of them, but injustices must be expected when any attempt is made to solve, along theoretical lines, the question of the compensation of railroad labor as it existed in 1917. The large amount of overtime worked last year and the varying retroactive periods for different classes accentuated the inequalities in readjustments. The supervising forces were, to use the "doughboy" expression, "out of luck," and many of them when the shops are working 10 hours a day will be still "out of luck," but on an eight-hour day basis there will be comparatively few instances where the remuneration of the supervising forces will be out of proportion to the mechanic. For instance, at 68 cents an hour a mechanic working eight hours a day, six days a week, will average $141.44 per month. The gang foreman at a rate of 73 cents an hour will receive $152 per month. This compares very favorably with the rates paid other foremen, these ranging anywhere from $215 to $350 a month. There are some glaring inconsistencies, however, on some roads, in the case of the roundhouse foremen. The men, receiving 68 cents an hour, are required to work only eight hours, while the foremen receiving between $250 and $275 per month are required to work 12 hours. In the case of an average wage of $265 per month, the foremen will actually be working at an hourly rate, based on overtime after eight hours, less than the mechanics under them. Every one will appreciate the importance of the roundhouse foremen's duties and the "grief" they have to bear. It takes a particularly good man to handle the job. Where are the railroads going to get these men if such discriminations are allowed to exist?

The application of the back pay, extending back to January 1, for the workmen, and July 1, for the supervising foremen, has caused the greatest dissatisfaction. In one instance which was brought to our attention the operator of a wrecking train crane received a total income for 1918 of over $4,000, which, of course, was caused by the excessive overtime he put in during that year. His foreman received less than $3,000 for the same period, and if the same overtime obtains during 1919 the crane man will still exceed his foreman. In another case a traveling crane operator handling a crane over seven pits drew $1,100 back pay, while as a general rule foremen received less than half that amount, and so it goes, according to the varying retroactive periods. Take the car inspector: Formerly, at 35 cents an hour, with a 12-hour day and seven days a week, he would average $127 per month. With his increase to 58 cents and for the same working period he received $246 a month, but now with eight-hour shifts he receives an average of $140 a month, an increase of $13 a month.

While it thus seems that the supervising shop forces are pretty well taken care of on an eight-hour day basis, except possibly in the case of some local discrepancy, it would seem from what we have been able to determine that the master mechanics have not been, perhaps, treated as kindly. The importance of their position should not be underestimated. They bear the responsibility of providing power in proper condition for the operation of the trains. By their most loyal support and work was the excellent record of moving trains accomplished last year. They have a difficult and trying position to fill, acting as the intermediary between the mechanical and transportation departments and between the officers and the men. It is by their efforts and tact that interdepartmental relations are properly maintained. It is true that they have not organized as have the shop men and many of the foremen, but that should not stand in the way of their proper recognition.

Present Condition of Freight Cars

While the general statistics available have shown a gradual improvement in the bad order car situation, they do not reflect the actual condition of the freight cars in this country. In fact, it has been stated that freight cars are in a very bad condition. The good record in the number of cars in bad order is due primarily to the fact that during the past year every effort has been made to keep the cars running and, to gain this end, repairs have been made which might come under the head of temporary repairs. Those cars requiring heavy repairs have been neglected and allowed to accumulate. In addition to this many cars reported in good order should be in the repair shop receiving a general overhauling. This hand-to-mouth policy has been carried on for so long that a vast amount of work is now required to build up the available freight car mileage to what it was when the Railroad Administration took over the roads over a year ago.

With the cars distributed all over the country without regard to ownership, as was the case last year, it has been impossible to maintain them in as good condition as formerly. With the railroads in the hands of private owners and with the car service rules such that cars reached their home roads more often, it was possible for the home roads to make improvements and properly repair their cars. Foreign roads without the necessary repair parts are obliged to a certain extent to make make-shift repairs in order to keep the cars moving, and it is not to be expected that the cars will be maintained as well as when they are on the home roads.

H. L. Shipman, equipment inspector of the Santa Fe, in a paper before the Western Railway Club recently stated that formerly there was a normal percentage of from 35 to 40 per cent of the box cars on the home lines, whereas at the present time this percentage has fallen as low as from 7 to 12 per cent. On one particular road in the east this same tendency has been noticed, but the figures are not quite as good. For three years prior to government operatiou that road maintained an average of 52 per cent home cars on its lines, whereas under federal control the average was only 14 per cent. During the same three-year period cars repaired were distributed about equally between home and foreign cars. During 1918 under government control only 22 per cent of the cars repaired were home cars and 78 per cent were foreign cars. This is the chief reason for the cars being in such poor condition.

The problem now is to get the cars home as quickly as possible in order that they may be given proper attention and repaired according to the standards of the owning lines. It is quite important that this be done, not only from the standpoint of the condition of the cars but from the standpoint of the government itself, for, according to law, it is responsible for returning the roads to their owners in as good condition as when they were received. Where $50 to $75 has been spent on the cars in order to get them off the repair track, only to become bad order again within a week or two, anywhere from $400 to $500 must be spent to put these cars back into first-class condition. The wear and tear on the cars has been very hard during the past year because of the congested condition of the railroads and the haste with which the cars passed through classification yards. Charges of careless practices in switching have frequently been made and an enormous amount of damage has been caused by such practices, all of which must be repaired before the car situation will be what it should be. Every effort should be made to correct such practices.

The Railroad Administration realizes the necessity of getting the cars home for proper attention as is indicated by Car Service Section Circular CS-53, which permits the short-routing of cars home, and further by Circular No. 27, recently issued by W. T. Tyler, director of the Division of Operation, which states that the present conditions with respect to car supply present an opportunity for a relocation of equipment more in accord with ownership than has been practicable during war conditions, under which each unit has been used with the sole purpose of meeting the then existing traffic demands, and further, for providing for the return to the owning road when desired for rebuilding or application of betterments, cars which can be put in safe condition for movement at reasonable cost. With these corrective measures taken it is now up to the individual roads to get the cars home and repair them. With the great reduction in traffic requirements and with the availability of cars for repairs, every measure should be taken to repair them. There should be no retrenchment in the purchase of material nor in the working hours of the shop until the car situation has materially improved.

NEW BOOKS

The Starrett Data Book for Machinists. By H. P. Fairfield, J. N. Bethel, H. H. Edge and J. C. Spence, collaborating editors. 177 pages, illustrated, 4½ in. by 7 in., bound in leather. Published by the L. S. Starrett Company, Athol, Mass. Price 50 cents.

As the title of this book implies, it is a compilation of data regarding machine shop practice and the materials of manufacture, arranged in convenient tabular form, to enable the machinist to finish work with a greater degree of efficiency and accuracy. The information is complete and covers a wide range of work and materials used, as well as weights, measurements, speeds, etc. Measuring instruments are illustrated and their uses described. It was the aim of the publishers to make the book of the greatest value to the largest possible number of practical machinists throughout the country, and the four editors were selected not only because of their knowledge of machine shop work, but because each represents a different field with its own peculiar problems and methods. Machinists should find the book of much assistance in their everyday work.

COMMUNICATIONS

INADEQUATE MAIN BOXES

To the Editor:

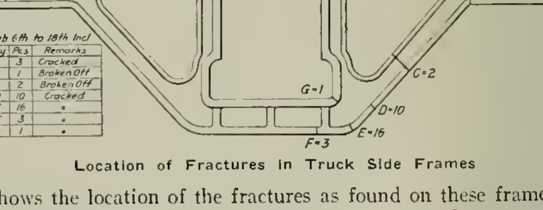
The one defect more than any other, that is knocking out the heavy power on the railroads of this country today is inadequate main boxes. The short sighted policy of equipping the heavy power with main boxes of the same weight, size and bearing as the rest of the driving boxes, has undoubtedly been a serious and costly mistake. I have seen locomotives just out of the repair shop, equipped with new machinery and driving boxes, develop a bad pound in their main boxes, due to worn shells, in less than four months, making it necessary to renew these boxes if it was desirable to keep locomotive in first class condition. You can not have a 100 per cent locomotive when equipped with defective main boxes. There can be no reasonable doubt, that if heavy freight locomotives were equipped with main boxes of a size, weight and bearing commensurate to the power developed in the cylinder of the locomotives, they would run as long without renewal as any other driving box. The loss in efficiency; the cutting out of the rod bushings; the strain on the entire locomotive as well as the cost of repairs, would seem to demand a more adequate main box. In fact, some roads have already begun to equip heavy power with heavier main boxes.
J. H. Buck.

SAFE LIMITS FOR WELDING TRUCK SIDE FRAMES

To the Editor:

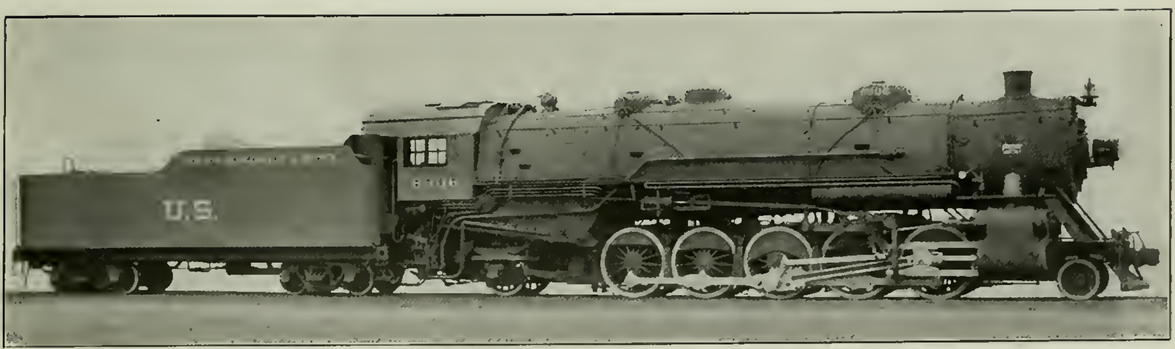
The practice of electric welding car castings has become quite general on most railroads of this country during the past two or three years. There is no question as to the saving that can be effected by this process but there is a question as to how far we can safely go with the electric welding of car castings, especially truck sides and truck and body bolsters. Some roads are limiting the welding to cracks not over 1½ in. in depth, while other roads are welding truck frames, bolsters, etc., that have been entirely broken.

During the past few weeks a record has been kept of the truck frames that have been found cracked and broken under cars arriving at our Kent shops for repairs. The sketch



Location of Fractures in Truck Side Frames

shows the location of the fractures as found on these frames, covering a period of two weeks. A total of 36 frames were found either cracked or broken. The one frame cracked at point *B* had been previously electric welded; the workmanship on this weld had been improperly performed as the casting was not chipped before the welding was done, the welded metal being simply applied to the outside of the casting at the fracture. One of the frames which failed at point *C* had also been previously electric welded in a similar manner. The fractures on these frames varied from ½ in. to 2 in. deep. Only a few frames were found where the fracture extended into the web of the casting. It would be interesting to learn whether other roads have had similar trouble with welded side frames.
W. W. Warner.



Standard Heavy 2-10-2 Locomotive

Heaviest Administration Single Unit Type; Total Weight 380,000 lb., Tractive Effort 74,000 lb.

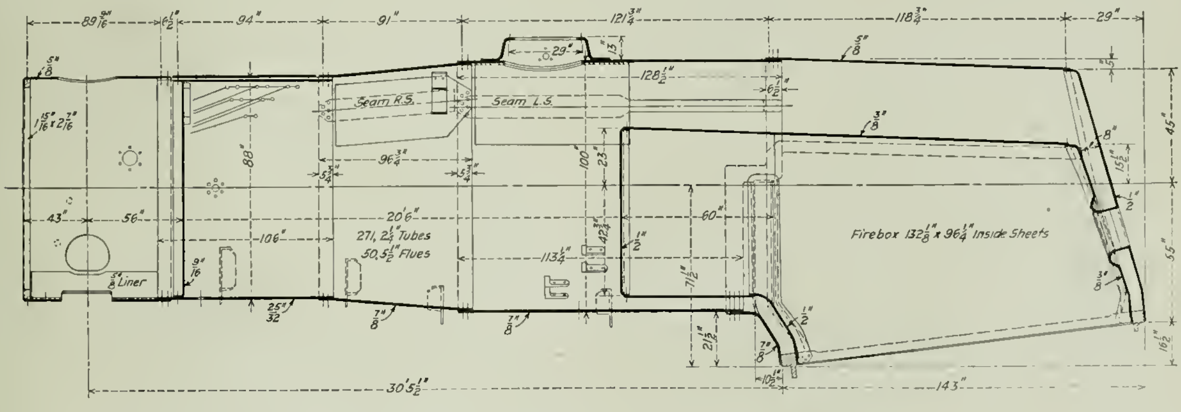
THE first locomotive of the Railroad Administration's standard heavy 2-10-2 type was recently completed at the Brooks Works of the American Locomotive Company for the Chicago, Burlington & Quincy. This locomotive was designed on the basis of driving axle loads of 60,000 lb. and has a total weight on drivers of 293,000 lb. The total weight of the locomotive in working order is 380,000 lb. and it is capable of exerting a calculated maximum tractive effort of 74,000 lb.

The design of this locomotive possesses no unusual features, the type of details throughout being similar to those used in the construction of other standard locomotives which already have been described. Interchangeability of parts between the various types has been effected wherever stresses and dimensions would permit. The relation of boiler capacity to the cylinder demand, calculated in accordance with Cole's ratios, shows ample boiler capacity both as to heating surface and grate area. The steam generating capacity is 104 per cent of the cylinder demand at a piston speed of 1,000 ft. per minute; the size of grate also shows up favorably, the ratio being 102.3 per cent.

As this is the heaviest single unit type of freight locomotive included among the Railroad Administration's standards it is of interest to compare it with a number of other heavy locomotives of the same type. By an inspection of the table it will be seen that it can by no means be ranked among the heaviest or most powerful 2-10-2 locomotives which have been built, although there have probably been none of better balanced design from the standpoint of boiler capacity.

The boiler barrel is of the telescopic type, with an outside diameter at the first course of 88 in., increasing to a maximum diameter of 100 in. There are three courses, the middle one of which is conical; the third course is 113¼ in. in length and the dome is located on this course.

The firebox includes a barrel combustion chamber, the tube sheet of which is 60 in. ahead of the throat sheet, thus providing for tubes 20 ft. 6 in. in length. The firebox is fitted with a brick arch carried on five tubes and is fired by a Hanna mechanical stoker. Other equipment includes the Franklin butterfly firedoor and power gate shaker.

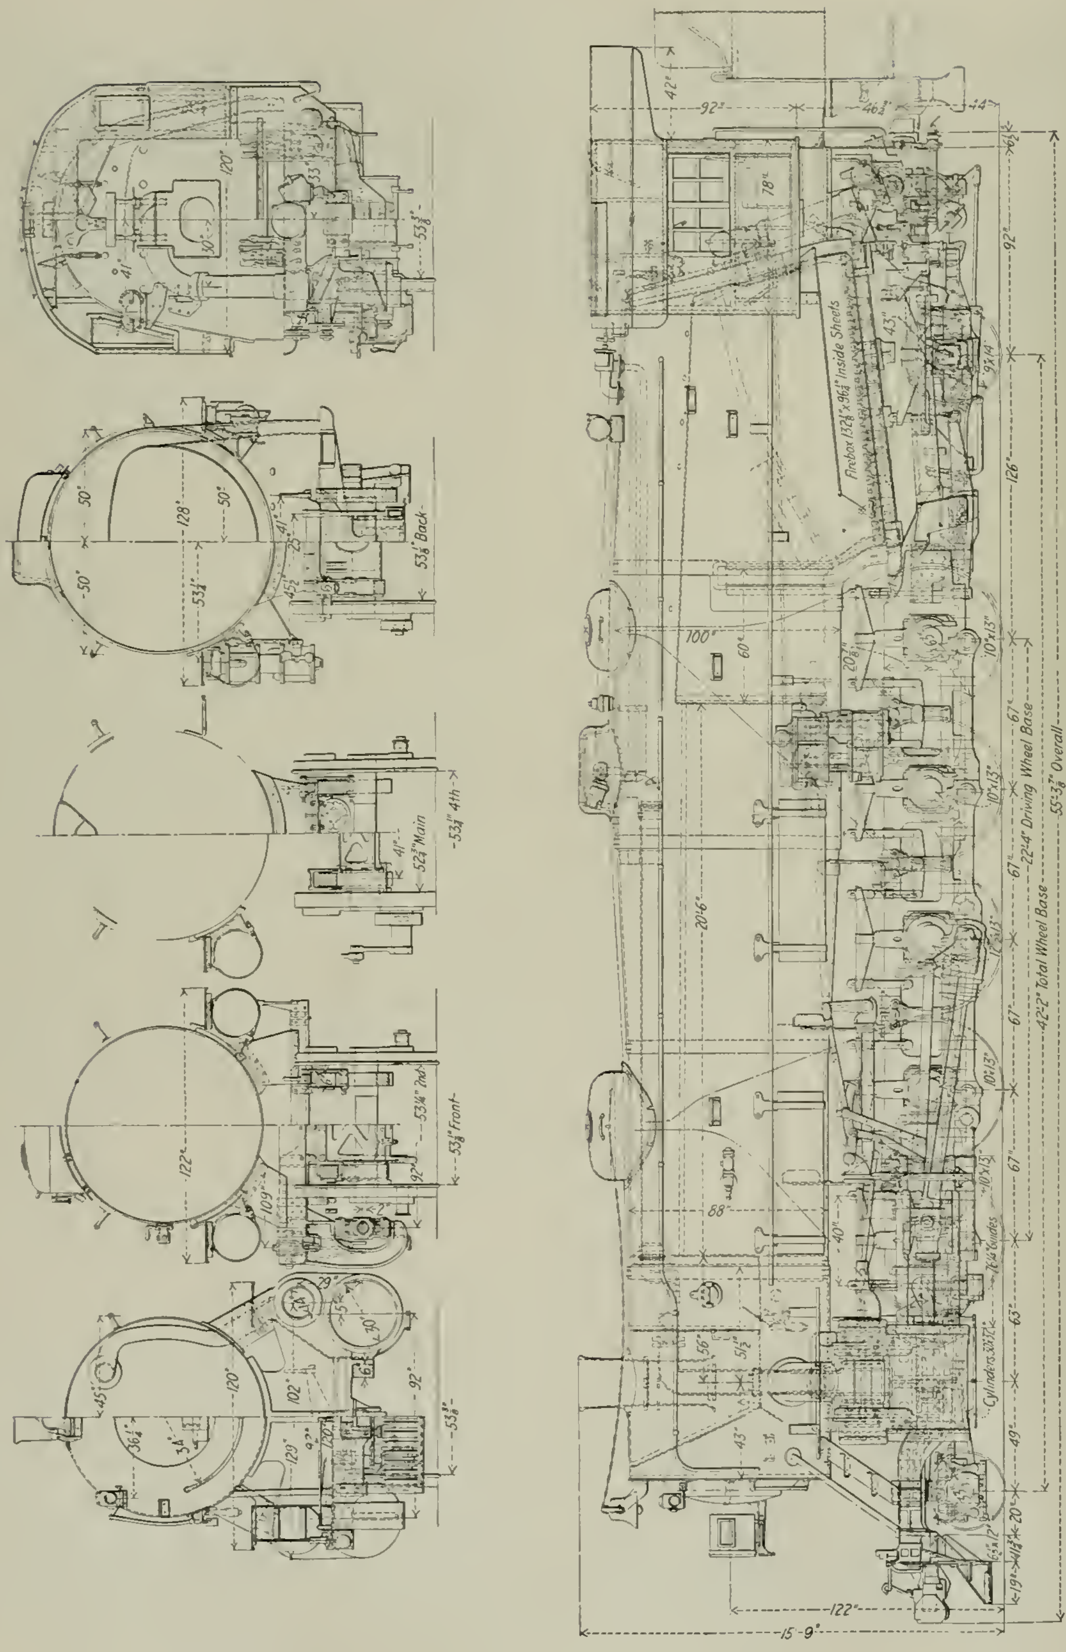


Longitudinal Section of the Standard Heavy 2-10-2 Type Boiler

The tube sheet is laid out for 271, 2¼-in. tubes and 50, 5½-in. flues for a 50-unit type A superheater. The tubes are spaced ¾ in. apart while the flues are one inch apart.

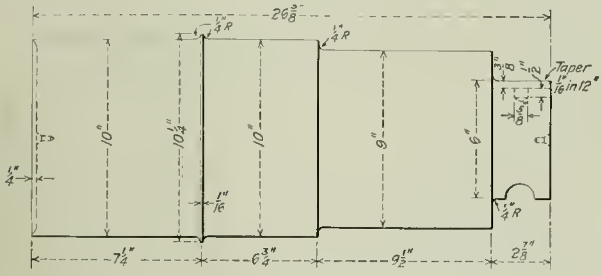
The general features of the frame design are identical with those of other single unit standard locomotives. The cylinders are carried on a single front rail cast integral with the main frame, and a Commonwealth cradle casting is spliced to the main frames just back of the rear driving pedestals.

The frames are six inches wide and have a maximum depth of top rail of 8⅜ in. over the pedestal jaws. The minimum depth of the top rail is seven inches. The maxi-



Elevation and Sections of the United States Railroad Administration Standard Heavy 2-10-2 Type Locomotive

mum and minimum depths of the lower rail are 5½ in. and 5 in., respectively. The front rail under the cylinders is six inches wide and tapers from a depth of 12¾ in. at the rear to 11½ in. at the front of the cylinder fit.



The Main Crank Pin for the Railroad Administration Heavy 2-10-2 Type Locomotive

The driving axles have journals 10 in. in diameter by 13 in. in length with the exception of the main, the diameter of which is 12½ in. The axles and driving boxes having

Firebox heating surface ÷ equiv. heating surface,* per cent	6.3	5.2	5.0	5.0	5.4
Grate area ÷ volume cylinders	3.3	3.1	3.2	3.4	3.5

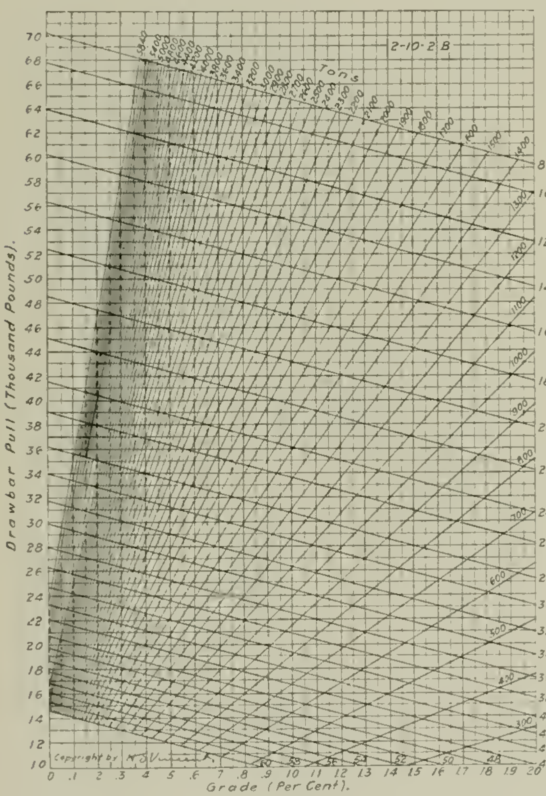
*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

engine truck details, including the center pin, pedestal, pedestal crosstie, swing bolster, swing frame and link are also identical with those used on the trucks of both Mikado type locomotives and the light Santa Fe type. With the exception of the radius bar these details are also used on the light Mallet locomotive.

The trailer truck is of the Cole-Scoville type and as a whole is not interchangeable with any other class of locomotives. The frame, however, is identical with that used under the light Santa Fe type, both Mikados and the light Mallet locomotives.

The cylinders are shown in detail in one of the illustrations, and are typical of those on the other classes of single unit type engines. They are 30 in. in diameter with a stroke of 32 in. and are fitted with pistons of single plate dished section similar in design to those used on all the standard locomotives. The valve chambers are designed for the use of 14-in. piston valves. As on the other standard locomotives Hunt-Spiller gun iron is used for cylinder and valve chamber bushings, piston and valve bull rings and packing rings, and crosshead shoes. The steam distribution of these locomotives is effected by the Southern valve gear and the locomotive is fitted with the Lewis power reverse gear.

Among the principal specialties with which these loco-



Tonnage Rating Chart Prepared for the Standard Heavy 2-10-2 Type Locomotive

motives are equipped are Chambers backhead type throttle, Ashton 3½-in. open safety valves, Hancock No. 13 non-lifting injectors, Everlasting blow-off cocks, Detroit six-feed lubricators, Barco flexible pipe joints and Radial buffers and Unit safety bar between the engine and tender.

The tonnage rating diagram was prepared and is copyrighted by H. S. Vincent. The curves of hauling capacity are constructed for a car resistance of four pounds per ton. The chart may be used for any other car resistances by converting them into terms of grade as follows:

1 lb. car resistance	=	.05 per cent grade
1 deg. curve uncompensated	=	.04 per cent grade

For example, find the tonnage capacity of the locomotive at 20 m. p. h. on .6 per cent grade combined with five-degree uncompensated curve and with a train resistance of five pounds per ton.

The combined resistance in terms of grade is:

$$.6 + (5 \times .04) + (1 \times .05) = .85 \text{ per cent.}$$

At the intersection of the ordinate for .85 per cent grade with the drawbar pull curve for 20 m. p. h. we find 2,100 tons as the capacity of the engine.

The clearance and wheel loading diagrams were prepared in the office of F. P. Pfahler, chief mechanical engineer of the Division of Operation of the Railroad Administration.

The Resistance of Materials

The Effect of Sudden or Abrupt Changes in the Section on the Distribution of the Unit Stresses

BY G. S. CHILES AND R. G. KELLEY

I

In the testing of sample or test pieces of material for the purpose of determining its various properties such as tensile strength, etc., it has long been recognized by engineers that the actual stretch or extension of the test specimen as well as the value obtained for its ultimate strength is affected to a considerable extent by its general form or contour. It is also quite generally understood, that in pulling specimens in a testing machine, it is of prime importance to maintain a truly axial pull, since otherwise an undesirable bending stress is set up which affects to a greater or lesser degree the results obtained. These facts have become more in evidence as the use of the extensometer or strain gage has gradually become more extensive; two strain gages attached to the opposite sides of a test bar often exhibit a considerable variation in readings due to the presence of a bending stress.

As a general rule these facts have been recognized and accepted merely as a characteristic feature of the testing of materials and have not been taken into consideration or put into practical application to any great extent in the actual design and construction of members employed in engineering structures and machines. As a matter of fact, this time-honored practice of applying values determined from tests upon specimen bars whose form is such that they will offer the maximum resistance, to the design of actual details admits of more or less inaccuracy and may be entirely misleading as regards results desired, since the form which offers the maximum resistance can seldom be utilized. When, however, it is desired merely to make comparisons of the relative resistances of different materials, the employment of test bars of such form provides a convenient means of obtaining accurate data.

The object of this article is to review briefly some of the data relative to the effect of abrupt changes of section under "static" and "dynamic tests" which has already been presented by various authorities and also to submit the results of some additional experiments dealing with this phase of engineering science which were carried out by the writers. While these experiments were not performed with such a degree of exactness as to permit of the derivation of formulae or laws, it is hoped the results will contribute in some small degree to the store of information relative to this subject by visualizing the mechanics of stress distribution.

It is customary in designing members in which there are sudden or abrupt changes of section such as bars, plates, etc., having drilled or punched holes, threaded bolts, or members similar to those shown at *a*, *b* and *c* in Fig. 1, to employ as the working value of the fibre stress the value for the average fibre stress determined by dividing the axial load in pounds by the minimum cross-sectional area expressed in terms of square inches. This practice is based upon the assumption that the distribution of stress is uniform throughout the section. However, for values up to the elastic limit of the material, a point which is considered by some engineers to represent the maximum desired range of stress, the stress is not uniformly distributed over the cross section but is considerably greater at some points thereof than at others, especially at parts which embody a rapid change of form such as a cross section immediately adjacent to the edge of a hole or to a boss or a shank. This non-uniform distribution of stress also occurs in irregular, curved or abrupt sections or surfaces. Due to the fact that the intensity of the stress is greater at the edge of a restricted area, the material at that point will be stressed beyond its elastic limit at a lower value of the total load than would be the case were the change from the larger to the smaller section made more gradual and less abrupt.

EFFECT OF GENERAL FORM ON ULTIMATE STATIC STRENGTH

In the case of good test specimens of ductile materials, such as wrought iron and mild steel, the flow of metal preceding rupture and causing local contraction of section often extends longitudinally over a distance of from six to eight times the diameter or width of section. The process of failure under a static test is a gradual one due to the progressive breaking down of the material as the maximum stress is transmitted from point to point upon the yielding of the metal under the increasing load thrust upon it by the failure of the metal at some other part of the cross section to withstand the stress to which it is subjected. In the case of steel, the part of the cross section which is subjected to the greatest stress intensity will yield first, throwing a portion of its load upon the material in the remaining portions. As the particles successively fail the load upon the remaining particles is continually increased in amount and the process of failure gradually becomes accelerated. As, under similar conditions, the same action takes place in members other than test specimens, this explains why in some instances members in which the length of reduced sections are short as compared to the transverse dimensions require a greater load to cause failure under a static test than members having similar reduced sections which have a greater ratio of length to transverse dimensions. The process of metallic flow becomes more difficult as the length of the reduced section is shortened and, in general, the value of the breaking load is increased.

The importance of the size of the test piece has long been recognized and is usually specified so as to afford a fair comparison of results.

The foregoing will explain why it is desirable when convenient to specify that the form of the specimen bars which are to be submitted for static tests shall be such that the length of the test section is not less than from eight to ten times the greatest transverse dimension and, in the case of bars having enlarged ends, that the change of section shall not be abrupt. Although due consideration is usually given to the form of the specimen and the effect of its general form upon the values determined by the static test, these features are frequently disregarded in the actual design and fabrication of the various members which are to constitute the structure or the machine.

A common instance of this may be found in the case of riveted joints, where the metal left between the holes is usually subjected to tensile stress. It has actually been determined by experiment that the metal in these sections will support a greater load per square inch of cross-sectional area under static test than a full section elsewhere in the same specimen, which is of sufficient length to permit of free local flow. Kennedy in a report on riveted joints before the Institute of Mechanical Engineers * produced evidence to the effect that the tensile strength of a strip of mild steel plate in which a number of holes had been drilled might reach a value as high as 12 per cent greater than that of an undrilled strip. Where the holes are punched instead of drilled it appears that the remaining metal adjacent to the holes is greatly weakened. It is distorted and overstrained by the shearing action and is rendered less capable of plastic deformation due to the hardening effect of the overstrain.

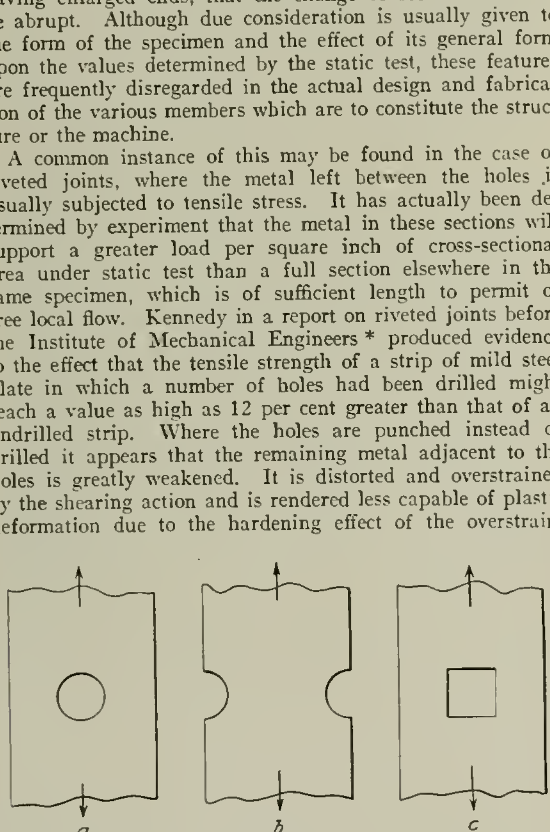

Fig. 1

The hardened portion thus receives an undue proportion of the stress and the strip will fail under a smaller load than it would were the stress uniformly distributed over the cross-section. This is a case of ductile and non-ductile material in the same cross-section.

The ultimate strength of members having irregular or abrupt sections under a static test becomes, then, in a measure a function of the ductility of the material. For non-ductile materials such, for example, as cast iron, fracture will occur at or near the minimum section as a result of the unequal distribution of stress. In the preceding discussion the two statements, "will support a greater load" and "will fail under a smaller load," it should be remembered, dealt respectively with ductile material which had not been overstrained, and with material which had been overstrained by punching the holes, thus acting more like non-ductile material. In the case of ductile materials, although the first deformation will take place at those localities where a restriction of sectional area occurs, *i. e.*, the edge of a hole, an edge adjacent to a boss, or an enlargement of sectional area, rupture under static test will be apt to occur at some cross-section other than that having the greatest stress, for the reason that at or near this cross-section the contraction

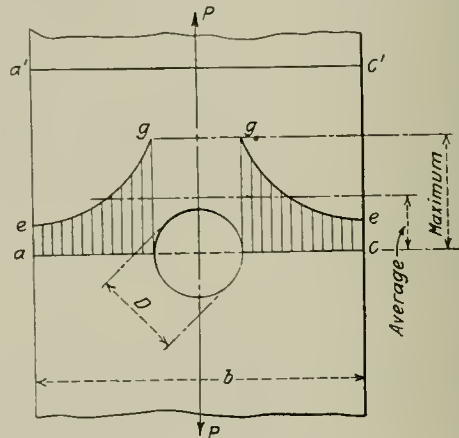

Fig. 2

of sectional area which precedes rupture is prevented to a considerable extent by the projecting sections of the member.

The tensile strength is reckoned on the original area of the test piece and not on the final area at the point of fracture. If we would term the tensile strength based upon the original area the nominal tensile strength and the real tensile strength the value obtained by using the area at the moment of fracture, then the difference between the nominal and the real tensile strength would depend upon the reduction in area. If we could prevent the test specimen from contracting, we would raise the nominal tensile strength and this is really what happens in a perforated bar or one having an abrupt change of section. Since only ductile materials have an appreciable contraction of area the above applies only to ductile material. In non-ductile or only slightly ductile material the perforated strip, when pulled in a testing machine, will usually break through the hole and the total pull will equal the product of the net area of the section by the tensile strength of the metal.

It should be remembered that the test pieces under discussion above have a non-uniform stress distribution due to their generally irregular or abrupt form. In the ductile material plastic deformation would take place and cause a uniform stress distribution but this is prevented or retarded by the irregular form. In the non-ductile material, there being practically no plasticity or local flow the stress distribution does not become uniformly distributed and the particles soon start to fail at the high stress point. This is more of a progressive break as explained above.

STATIC TESTS AND ACTUAL SERVICE TESTS

As regards the action of materials when subjected to those tests which, for convenience, we will style dynamic, or tests in which the specimen is subjected to the action of intermittent forces whose frequency of application varies more or less rapidly with time, the results are somewhat different.

*See Proceedings of the Institute of Mechanical Engineers, 1881-1885.

Materials whose properties as determined by ordinary static tests may indicate that their use is entirely justified yet fail or otherwise prove unsatisfactory in actual service.

Wöhler, in his classical experiments, clearly demonstrated that loads which were sufficient to produce only a moderate amount of permanent set even when allowed to remain in action for an indefinite period of time, would eventually cause failure if applied and removed at frequent intervals. He further found that by alternately applying loads of opposite sign, such as alternating a tension load with a compression load, the period of time required for failure was shortened.

The experiments of Wöhler and others show that a steel

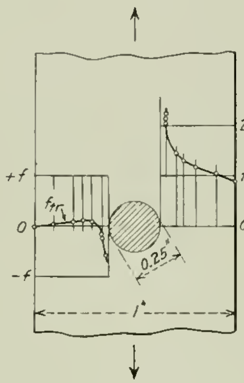
Fig. 3



Hole Fitted with Pin.

Fig. 4

bar having an ultimate strength of 60,000 lb. per sq. in., if loaded from zero to 40,000 lb. will probably break after a few thousand applications. If the upper limit is reduced 5,000 lb., so that the load varies from zero to 35,000 lb., the bar will withstand a much larger number of load applications; if this range of stress is reduced 5,000 lb. more, say from zero to 30,000 lb., it may take several million repetitions to cause failure and if loaded from zero to 25,000 lb. it will perhaps last indefinitely. If the stress varies from 25,000 lb. to 40,000 lb. per sq. in. the bar will also last indefinitely. Similar steel subjected to a stress which changes from 16,000 lb. compression to 16,000 lb. tension will fail, but if the stress changes from 14,000 lb. compression to 14,000 lb. tension the piece will probably stand an indefinite number of repetitions.

It is evident, then, that the strength of a material as determined by an ordinary static test is but one of several properties which may be essential to meet actual service requirements and it is by no means a correct indication of the ability of such materials to resist shocks or alternating loads. Thus while members having abrupt changes of general form, such as bolts and especially bolts with rolled threads, frequently fail under static loads at sections other than at the root of threads, in service failures which are brought about by gradual deterioration of the metal known as "fatigue," fracture usually occurs at those localities in which there is a sudden reduction of sectional area and under loads lighter than would be necessary to produce failure in a static test.

Static tests of arch bar trucks, when carried to failure, almost universally result in shearing the journal box bolts. In actual service failures it is the bottom arch bar which almost always fails, in the majority of cases at the lower radius near the column casting, although occasionally it fails at other sections and a few failures occur in the top arch bar. Many railway men with years of experience testify they have never known of a case of the journal box bolts actually shearing in service, yet if the static tests were accepted as indicative these bolts are the very parts that should be strengthened.

STRESS DISTRIBUTION IN TENSION MEMBERS

The effect upon the stress distribution across the section of a tension member, of a hole drilled through the member has been carefully investigated by several authorities. The stress diagram, Fig. 2, represents graphically the results obtained by Preuss * in the course of an investigation relative to the effect of a punched hole upon the stress distribution across the section of a flat bar. The hole, of diameter D, was centrally located, and the tension was exerted along the vertical axis of the bar of width b. The ordinates under the curved line eg represent the stresses at any point across the section of the bar. Preuss ascertained that the maximum stress, which occurs at the edge of the hole, is not materially affected by the magnitude of the diameter of the hole and that it is from 2.1 to 2.3 greater than the value obtained for it on the assumption of uniform stress distribution throughout the section most weakened by the punched hole. He also found that the minimum stress, which occurs at the outer edge of the bar, decreases as the diameter of the hole is increased.

Professor Croker and Lieutenant W. A. Scoble of the Royal British Navy, have investigated (1) the stress distribution across the section of a tension member having a drilled hole, (2) the stress distribution when the hole in the tension member was fitted with a pin, and also (3) the stress distribution when the load was applied through the pin.

Figs. 3, 4, 5 and 6 are reproduced from a paper on "The Design of Pin Joints Based on Ultimate Strength"† by Lieutenant Walter A. Scoble, R. N. V. R., which appeared in *Engineering*, London, April 20, 1917. In Fig. 3 case (1) is illustrated, a plate tension member of one inch width having a 0.25-in. hole drilled at the center of its width. The intensities of the stresses across the narrow section of the test specimen, indicated by the line *oo* through the center of the hole, are plotted from *oo* as a base. The longitudinal

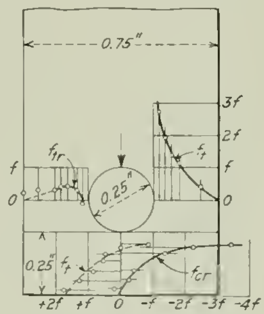
Load Applied by Pin.

Fig. 5



Case 2.
Load Applied by Pin.

Fig. 6

stress on the section *oo*, that is, the tension in the same direction as the pull, is indicated by the curve f_t at the right of the hole. The stress at right angles to the longitudinal stress, is denoted by the curve f_{tr} at the left.

Instead of the uniform distribution of stress usually assumed in such cases by the designer, the stress intensity is variable across the section and increases from the edge of the plate to the edge of the hole, where it may reach a value three times as great as the stress intensity at the edge of the

*Experiments on Distribution of Stresses in Punched Flat Bars, Zeits des Vereins Deutsches Ingenieure, Vol. 56, No. 44.

†Paper read at the Institution of Naval Architects, March 28, 1917.

plate. For the ratio of this maximum stress to the mean value of the stress across the entire section they find that their results for one central hole may be expressed as

$$\frac{\text{Maximum stress}}{\text{mean stress}} = \frac{3C}{C+1}$$

where C is the ratio of the plate width to the hole diameter.

The value of the longitudinal stress on a normal section of the plate at any distance l from the center of the hole might otherwise be stated as

$$f_{(l)} = \frac{f}{2}\left(2 + \frac{r^2}{l^2} + \frac{3r^4}{l^4}\right)$$

where f is equal to the mean value of the stress over the entire width of the plate and r is the radius of the hole. From the above it will be noted that at the edge of the hole, where r equals one, the longitudinal stress is

$$f_{(l)} = 3f,$$

or three times the mean value of the stress over the entire width of plate.

The longitudinal stress is accompanied by a stress at right angles, having a value which may be expressed as,

$$f_{(r)} = \frac{3f}{2}\left(\frac{r^2}{l^2} - \frac{r^4}{l^4}\right)$$

At the edge of the hole, where r and l are each equal to unity, the radial stress is zero.

In the course of an investigation of this phenomenon Prof. Croker and Lieutenant Scoble carried out a series of tests upon a bar one inch in width and 0.186 in. in thickness and perforated with a drilled hole whose diameter was gradually increased for each test. The load, in each case, was 100 lb. and the results obtained are presented in Table I.

Table I.

Test No.	Diameter of hole at center of bar, in.	Stress values in lb. per sq. in. $f_{(l)}$	f	$f_{(eh)}$
1	1/16	549	584	1,470
2	1/8	547	620	1,560
3	1/4	568	724	1,770
4	3/8	570	868	1,850
5	1/2	613	1,035	2,040

Note
- $f_{(l)}$ = stress at a long distance from centre of hole.
- f = mean value of stress over entire width of section.
- $f_{(eh)}$ = stress at the edge of the hole.

In Fig. 4 a tension specimen similar to the one shown in Fig. 3 was used except that the central hole was fitted with a pin. This specimen was then subjected to pull as in the previous test. The longitudinal tension, through the section *oo* was very similar to that found in the specimen with the hole not fitted with a pin. The pull on the plate caused the plate to press on the pin and the radial stress at right angles to the longitudinal stress was changed. Near the pin the plate is now in compression changing to tension a short distance out. Compression is shown below *oo*, tension above.

In Figs. 5 and 6 the tension, instead of being caused by a pull on the test specimen as in the two previous cases, was due to a load applied to the ¼-in. pin. In Fig. 5 the pin was small compared to the breadth of the plate and a considerable amount of overlap (0.7-in.) was allowed. The longitudinal tension or axial tension, f_t above *oo*, across the narrow section *oo* varies still more than in the previous cases. The section directly below the hole was also investigated and a very intense compression, f_{cr}, was found where the pin pressed on the plate. This compression diminishes rapidly as the distance from the edge of the hole increases, disappearing at about half way from the edge of the hole to the edge of the plate. The tangential stress, f_t, below *oo*, or the stress parallel to *oo* is not very high in this case.

In Fig. 6 the diameter of the hole is greater compared to the breadth of the plate, the plate in Fig. 6 being only 0.75 in. wide as against one inch in Fig. 5. The amount of the overlap is also less, being 0.25 in. The axial tension, f_t above *oo*, across the narrow section is greater at the edge of the hole than before and becomes zero at the edge of the plate. The radial compression due to the pressure of the pin on the plate, f_{cr} below *oo*, is much more intense, decreasing to zero in this case at the lower edge of the plate. The tangential stress, f_t, below *oo*, from the edge of the pin to the lower edge of the plate is like that across a section of a beam, in that near the hole the plate is in compression, changing to tension about one-fourth of the way down from the hole.

In all the above examples, such as a tension member with hole, or plate fitted with pin the stress distribution was very unequal and the stresses of greatest intensity were localized at the region near the hole.

(*To be continued*)

RAILROAD ADMINISTRATION NEWS

Additions to the payroll of the railroads in 1918, largely as the result of wage increases ordered by the director general, are now estimated at approximately $642,000,000, or about 37 per cent. This, however, is the total increase in the payroll and is affected to some extent by the change in the number of employees. All of the increases, however, were not in effect for the full year and the total on a yearly basis is estimated at $810,000,000, not including the perspective large increase for the train service employees.

OVERTIME NOT CONSIDERED AS SALARY

Interpretation No. 9, relating to general order No. 27, gives a decision on the following question: If an employee covered by the provisions of general order No. 27 and subsequent wage orders issued by the director general in connection therewith, whose salary is $250 or less per month, is required to work overtime, and in a given month his total wage, including overtime, amounts to more than $250, is it the intention to restrict his earnings per month to $250?

The decision is that overtime is not to be considered as salary.

PIECE WORK BEING ABOLISHED

In accordance with instructions issued by Director General McAdoo just before he left Washington the shop employees on the various roads voted on the question of the abolition of the piece-work system. As a result of the vote piece work has been discontinued on the Pennsylvania lines, east and west, Philadelphia and Reading, Baltimore & Ohio, Delaware, Lackawanna & Western, Cumberland Valley, Long Island, New York Central, Norfolk & Western, Chicago, Burlington & Quincy, Michigan Central, Lehigh Valley, Erie, Chesapeake & Ohio, and Central of New Jersey. The Railroad Administration is following a policy of reducing the shop hours at many places where there is a surplus of labor in preference to laying off men, and the Pennsylvania shops at Harrisburg and Altoona, and shops on the Baltimore & Ohio, Hocking Valley and other roads in the Eastern region have been placed on a 40-hour week basis. While the number of employees has been reduced at various shops on many roads, there is still a shortage of men on a large number of roads, and efforts are being made to transfer men from places where there is a surplus to where there is a demand for them. It is stated that places are being made for all returning soldiers and that in some cases they are replacing inexperienced men employed during the war.

CARS TO BE RELOCATED IN ACCORDANCE WITH OWNERSHIP

W. T. Tyler, director of Division of Operation, has issued Circular No. 27, which states that present conditions with respect to car supply present an opportunity for:

(a) Relocation of equipment more in accord with ownership than has been practicable during war conditions, under which each unit has been used with the sole purpose of meeting the then existing traffic demands.

(b) Providing to a greater extent for use by the owner of equipment of its accepted standards.

(c) Providing for the return to the owning road when desired for rebuilding or application of betterments, cars which can be put in safe condition at reasonable cost.

To accomplish the above, regional directors are instructed to direct federal managers and all concerned in the proper handling of cars in accordance with the following, without abandoning the principle of common use of cars:

1. In general, cars should be loaded to or in the direction of the home road. This will not apply to cars under direction of the Refrigerator and Tank Car Department of the Car Service Section at Chicago, or those under direction of the Eastern Railroads Coal Car Pool at Pittsburgh.

2. The Car Service Section will, as may be agreed upon with regional directors, relocate equipment according to ownership by regions so far as practicable.

3. The regional directors will then relocate the same cars on the basis of ownership so far as practicable.

(Date)....................

New Form for Reporting Conditions of Locomotives

4. Any railroad will accept its own equipment empty at any junction point.

5. Any cars already placed on storage tracks because of surplus will not be moved so long as relocation orders placed as provided in paragraphs numbered 2 and 3 can be filled from other available supply; or as may be specially directed.

6. When roads desire to rebuild their cars, regional directors should make application through the mechanical department of the Railroad Administration, and upon its approval the Car Service Section will authorize the owners to call upon holding roads (as determined from car records) for the return of the cars in such numbers and at such times as their shop operations require. These cars are to be moved on billing stating the authority and that they must not be diverted.

7. In carrying out the policies here indicated caution should be observed by regional directors so as not to bring about burdensome empty car mileage.

The Car Service Section in Circular CS-53 has issued the following instructions: When the terms of Division of Operation Circular 20 or Revisions thereof, movement of freight equipment to the home road is requested by proper mechanical department officer such equipment shall be promptly billed and moved to owners via direct routes. The full routing, including junctions, must be shown, billing to carry the following notation: "Billed via short route. Authority Division of Operation Circular 20, revised, and Car Service Section Circular CS-53. Not to be diverted." The originating line will be held responsible for proper short routing via Federal controlled roads.

LOCOMOTIVE AND CAR DELIVERIES IN 1918

According to figures made public by Director General Hines, there were 2,622 locomotives shipped to railroads under federal control during the year ended December 31, 1918. Of this number, 744 were constructed under orders of the Railroad Administration, while 1,410 were contracted for prior to government operation. In the total were 200 Russian decapods, constructed for the Russian government, but never delivered owing to the situation which arose in that country. Of the total number of locomotives delivered during the calendar year 1918, 540 were assigned to the Allegheny region, 375 to the Central Western region, 902 to the Eastern region, 236 to the Northwestern region, 105 to the

Pocahontas region, 361 to the Southern region, and 103 to the Southwestern region.

For the calendar year 1918 there were 700 passenger cars delivered to Class I railroads, while for the same period 40,850 freight cars were delivered. Of the freight cars built during the year 15,230 were U. S. R. A. standard cars. Of the total number of freight cars delivered, 8,683 were built in railroad shops.

LOCOMOTIVE EQUIPMENT CONDITION REPORT

A new form for reporting (weekly) the condition of locomotives has been issued as shown on page 127, to be used commencing with the report for Saturday, March 1.

ORDERS OF THE REGIONAL DIRECTORS

Shop Supervision.—The Eastern regional director quotes from a letter received from W. T. Tyler, director, Division of Operation, dated January 27, as follows:

It is stated that in some of the shops where a change has been made from piecework to hourly or daily basis, the piecework checkers, usually clerks or office men, have been put in the position of foremen at foremen mechanics' rates. I suggest the advisability of cautioning federal managers against leaving any opportunity for criticism in connection with this matter.

Inspection at Interchange Points Covering Loading.—Circular No. 422 issued by the southern regional director says that there has been some duplication of inspection at interchange points covering loading, bracing, stability of packages and general condition of freight offered in interchange. Such inspection and records must be made only by the receiving railroad.

Associations Approved.—The Southern regional director, file 841-6, advises that the director general has approved the Chief Interchange Car Inspectors' and Car Foremen's Association. Similar orders have been issued by the Southwestern and Northwestern regional directors.

General Foremen's Association.—The Northwestern regional director, file 61-1-20, advises that employees who are members of this association be allowed to attend the annual convention, which will be held in the fall of 1919, where they can do so without detriment to the service; transportation should be furnished and necessary expenses allowed.

THE VALUE OF INSULATION AND LOSSES IN B. T. U.'S

BY WILLIAM N. ALLMAN

The question of fuel conservation is one that is now being urged very forcibly upon power plant engineers and operators, and it is quite surprising to note what a large portion of the energy may be saved and converted into useful work by the proper use of insulation.

By the term insulation is meant the proper protection of heated surfaces to prevent the loss of heat, which is measured in terms of British thermal units, and which losses are often underestimated. We have often noted that great care is exercised in guarding against losses in electrical distribution and water leakage and against undue loss in steam pressure between the source of power and the prime movers, yet little or no attention is given to the proper insulation to guard against B. t. u. losses, which are now acknowledged as a vital factor in power plant operation, and so much so that engineers everywhere are now very much engaged in studying these conditions and locating those places where losses may be reduced with a consequent saving in the coal pile.

Steam piping running from boilers to engines and auxiliaries, and hot water lines from heaters and feed pumps, make up a big area of heat radiating surface and so offer opportunities to effect immense savings.

It has been estimated that the loss of heat from bare or poorly insulated pipes represents a loss in fuel ranging from 25 to 75 per cent, and for the reason that this is invisible it can hardly be realized. On the other hand, if it were in the form of a liquid and were visible, steps would be quickly taken to prevent such a loss. Although the eye cannot detect the escape of heat, scientific tests show that a tremendous waste occurs through radiation and poorly insulated pipes.

A large percentage of heat that would be lost if pipes and other apparatus were left bare can be saved by applying the right kind of insulation and thereby preventing unnecessary loss of heat by radiation. It is of importance to select insulation adapted to the service involved to obtain the maximum efficiency, and it is therefore necessary that the proper thickness of insulation be installed. The loss by radiation varies with the difference between the temperature of the steam and the surrounding air and upon the conductivity of the pipe and its covering and upon the extent of the exposed area. An insulation that would allow no heat to escape through it would, of course, be rated as 100 per cent efficient, but this condition does not exist. The efficiency of an insulating material is expressed in terms of percentage, which is the per cent saving realized by insulating a heated surface over what would be lost if the conductor were left bare or uninsulated.

The rate of flow of heat through a certain thickness of material and at a certain difference in temperature determines the conductivity of the material. The relative efficiencies of insulating materials are obtained by comparing their conductivities under similar conditions.

Heat is also frequently wasted where sections of insulation are not closely joined, either on a length of piping, or at its connections with fittings or specialties. All joints or seams in pipe insulation should be carefully sealed. This is especially true where use is made of insulation of a cellular type, allowing circulation of air through longitudinal cells parallel to the pipe.

Different methods of conveying heat and power from one building to another have been developed with widely different resulting efficiencies and costs. One method of distribution has been to surround underground pipes with some form of insulation that rapidly depreciates after installation. Another construction is the tunnel method, with pipes properly insulated, which is efficient but extremely expensive. Again, pipes are very often run overhead out of doors, the insulation being protected by some form of weatherproof jacket. This method is inconvenient as well as not presenting a very neat appearance, and unless very thick insulation of high insulating value is used the results are not what they should be. The underground system with the lines out of sight as well as out of the way and where they cannot interfere with traffic and plant operation should be the most acceptable, provided that the cost compares favorably with other systems and that its insulating value will not depreciate very rapidly.

Table I shows the amount of heat, in B. t. u.'s, lost where pipes are uncovered. It will be seen that a considerable loss of fuel will be occasioned in the course of a year with uncovered pipes, which could be considerably reduced by proper insulation.

There are numerous places in the power plant where savings may be effected by proper and judicious use of insulating materials and elimination of leaks. Items that should receive special attention are leaky baffle walls in boiler settings, infiltration of air through the furnace walls, bare steam pipes, boilers, cylinders, etc. Unless baffle walls are made tight there will be a loss of heat, as the heat which should be passing over the heating surface of the boiler will be short-circuited to the chimney. Cracks in boiler walls may not be very apparent, yet the admission of air through them is more than enough to lower the efficiency of the boiler. This air leakage may easily be detected with a sheet of paper, say, two feet square, having a small hole in the center of it about one inch in diameter, glued to a square wooden frame made of about one-inch stock. Place the frame over the wall and seal the edges all around, then hold a candle or torch in front of the hole. If there are leaks in the setting the flame will be drawn towards the hole in the paper. This matter of air leakage is extremely important, and yet very easy to correct. The application of proper insulation not only prevents the infiltration of air, but reduces the loss of heat from the boiler walls as well. It should be borne in mind that cold air that leaks in through the walls absorbs heat until it reaches the temperature of the furnace gases, and hence wastes heat that would otherwise perform useful work.

TABLE I—TOTAL HEAT LOSS IN B.T.U.'S PER HOUR PER LINEAL FOOT OF BARE PIPE OF DIFFERENT SIZES AND AT VARIOUS TEMPERATURES

Size of pipe in in.	Area (in sq. ft.) of pipe surface per lin. ft.	Temperature Differences (Degrees "F")

More horsepower from the coal pile is the one big problem that confronts all power plant engineers. As an illustration of what and where losses may occur in the average power plant, Table II, extracted from Joseph W. Hays' treatise on "How to Build up Furnace Efficiency," is shown. A large amount of heat is shown under the head of preventable losses which may be converted into useful work.

TABLE II—FUEL WASTES BETWEEN THE MINE AND THE MACHINE

	Direct Fuel Wastes	Preventable losses, B.t.u.	Non-Preventable losses, B.t.u.
1.	By weather waste between mine and factory..	....	290,000
2.	In bandling at tbe plant	290,000	....
3.	In the ash (non-preventable)	....	284,200
4.	In tbe ash (preventable)	1,136,800	....
5.	By radiation (non-preventable)	....	284,200
6.	By radiation (preventable)	852,600	....
7.	By incomplete combustion	204,908	....
8.	In chimney to maintain draft	....	3,410,400
9.	On account of air leakage in furnace and boiler setting	2,842,000	....
10.	On account of excess air drawn through grates	2,842,000	....
11.	Due to heating moisture in air and coal.....	....	426,300
	Totals	8,168,308	4,695,100
	INDIRECT FUEL WASTES—HEAT ENERGY LOSSES		
12.	Due to short circuiting of gases in passages of boiler	322,732	....
13.	Due to soot on heating surfaces	1,126,561	....
14.	Due to scale in boiler	1,452,293	....
15.	Due to incorrect correlation of load to draft	1,116,800	....
16.	Due to inability of boiler to reduce temperature of gases below that of the steam in boiler	....	1,280,907
17.	Due to leakage of water and steam	216,685	....
18.	Due to friction and radiation in steam pipes (non-preventable)	....	216,685
19.	Due to friction and radiation in steam pipes (preventable)	866,742	....
20.	With engine exhaust	....	7,627,331
21.	Due to cylinder condensation and radiation..	715,063	....
22.	In friction at engine (non-preventable)	....	119,177
23.	In friction at engine (preventable)	59,588	....
24.	In transmission from engine to machine (non-preventable)	....	231,000
25.	In transmission from engine to machine (preventable)	231,000	....
	Totals	6,107,464	9,475,100
	Grand totals	14,275,772	14,170,200
	Totals of all losses preventable and non-preventable		28,445,972 B.t.u.
	Delivered to the machine		554,028 B.t.u.
	Received from mine		29,000,000 B.t.u.

Note—One ton of coal at the mine is assumed to contain 29,000,000 B.t.u.'s. The items show where the losses occur and their relative magnitude in the average boiler and engine practice.

Now let us ask the question: In the face of all the facts and the serious questions that now affront us, why is fuel wasted, especially when it is one of the most vital factors of the present day in power plant operation? Why is it that the operators are not more persistent in their efforts to locate where the losses occur and then seek a means of reducing them and of putting their plant on a high efficiency basis? We all have heard and no doubt are familiar with the term "passing the buck," and the writer is of the opinion that if this were eliminated from the fireman up to the manager and if everyone would bear in mind that fuel is now the most costly thing they have to deal with, then and then only will the maximum efficiency be realized.

The selection of the proper insulating material with due reference to its insulating efficiency and durability should follow a careful analysis of the conditions and requirements of the case in question. The greatest savings, of course, are to be had by properly insulating the high pressure and high temperature steam lines. Inspect the equipment and ascertain all of the uninsulated surfaces such as steam chests, cylinder heads and all other hot surfaces, which in the aggregate result in high heat losses.

Table III shows what losses may be expected in uninsulated surfaces.

TABLE III—HEAT LOSSES FROM UNINSULATED HOT SURFACES

Temperature of Surrounding Air 70 Deg. F.

Steam pressure (gage)	Steam temperature (deg. F.)	Difference between temperature of steam and surrounding air (deg. F.)	Loss per sq. ft. per hour (B.t.u.)	Waste of of coal in lb. per sq. ft. per year	Number of sq. ft. of surface that wastes a ton of coal in one year
0	212	142	334.0	293	6.82
10	240	170	425.0	372	5.38
25	267	197	522.5	458	4.37
50	298	228	644.0	564	3.55
75	320	250	737.5	646	3.10
100	338	268	820.0	718	2.79
150	366	296	960.0	840	2.38
200	388	318	1,079.0	945	2.12
250	406	336	1,184.0	1,036	1.93

Above figures based on 10,000 B.t.u.'s available per pound of coal, or equivalent to a boiler efficiency of 70 per cent, using coal with an assumed heat value of about 14,000 B.t.u.'s per pound.

The figures are conservative, as both the boiler efficiency and the heat value of the coal are high and a lesser boiler efficiency or inferior grade of coal would cause even a greater waste in pounds of coal.

The loss of steam through open petcocks of steam traps or through leaky traps is extremely large. Leakage is generally due to parts of the trap binding or sticking, worn valve or seats, improper adjustments, defective or worn-out expanding members, etc. It is important that traps and their parts should be frequently and carefully inspected. Steam traps with large surfaces are very often left uninsulated, which results in a considerable loss due to radiation. This loss may be prevented by the application of suitable insulation.

Fuel Conservation Circular No. 14, recently issued by the United States Railroad Administration, is right to the point and the 34 suggestions under the heads of Plant Design and

Equipment, Maintenance and Operation, should be read very carefully by all concerned in the operation of power plants.

The United States Fuel Administration is making every effort to bring home to fuel users the gravity of the situation and the importance of coal and power economy. Only by the whole-hearted co-operation of all power plants, large and small, can the desired savings be effected.

In general, encourage those who work in boiler plants, engine rooms, factories, etc., to be continually on the lookout for heat and fuel losses. Such losses are not difficult to detect. Steam waste can readily be seen and heat felt. If those who discovered steam leaks or loss of heat would take the time and trouble to see whether or not it can be conserved, and then look for the remedy, not only would the nation's fuel be conserved, but the efficiencies of plants and the profits of owners would be increased.

A Unified Mechanical Department*

Suggestions for Co-ordinating the Efforts of Shop, Operating and Mechanical Engineering Branches

BY W. U. APPLETON
Superintendent Motive Power, Canadian Government Railways, Moncton, N. B.

A SYSTEM for regulating and combining the various branches of the mechanical department into one organization that will produce satisfactory service in the general repair shop and the operating branch, obviously, must be broad and definite in its principles. Harmony between the various officers is essential and the relationship between the branches must be very intimate. Success cannot be obtained if the general repair shop and the operating departments are not closely allied; if the shop superintendent is working with the one object of output and the operating officers are not making every effort to obtain the greatest mileage from the locomotives consistent with good service and economy, failure is sure to result.

In order to get results, it is necessary that we should have that co-operation whereby the shop superintendent and all his subordinate officers are giving the same attention to proper repairs as to output, and it should be the object and pride of every master mechanic and his subordinate officers to obtain the greatest mileage between shoppings with the least number of failures.

To repair a locomotive quickly, cheaply and properly, should be the ambition of the shop superintendent.

To maintain it in service with a minimum expense and the greatest number of miles between failures and shoppings, should be the aim and object of the master mechanic.

When locomotives are sent to the shop there should be some system of defining the class of repairs required, and the writer believes that three classes as described below is the best method and sufficient to take care of all repairs:

No. 1—General repairs, including a new firebox, a new cylinder or other such extra heavy repairs.

No. 2—Ordinary general repairs.

No. 3—Specific repairs that may be carried out at the roundhouse or shop.

Abbreviations as follows should be used in conjunction with the numbers to describe specific repairs:

No. 1 Repair	Convers.	means conversion to superheater, etc.
	Boil.	means new boiler.
	F. B.	means firebox.
	Cyl.	means cylinder one or two.
	Fra.	means frames.
	Int.	means internal examination.
	Ext.	means external.
	Der.	means derailment.
No. 2 Repair	Int.	means internal examination.
	Ext.	means external.
	Der.	means derailment.
	T.	means new tires.
No. 3 Repair	T. T.	means tires turned.
	Fr. W.	means frame welded.
	An. T.	means annual test.
	Int.	means internal examination.
	TU.	means fixing up tubes.
	DB.	means driving boxes.
	Der.	means derailment.

No. 1 or No. 2 repairs should not indicate any difference in the condition of the locomotives when turned out of the shop as far as the Operating Department is concerned, as the distinction is only made for the information and assistance of the shop force in effecting repairs, and either of these repairs should represent a locomotive in first class condition in every respect, and capable of making the standard mileage of its class, according to the physical characteristics of the division on which it is employed and the service it is in.

The condition of all parts of the locomotive should be as nearly balanced as possible in order to obtain the greatest mileage with the least loss of service. It is false economy to turn locomotives out of the shop represented as having received the above classes of repair, with certain parts somewhat worn, because they have been renewed a short time previous to shopping. For instance, it may seem wasteful to renew tubes or some part of the machinery that is apparently still capable of making considerable mileage, but as these parts will become defective and make renewal necessary before those that were brought up to standard of shop practice, the result usually is an engine out of service when badly required, delay in effecting repairs and higher cost of doing so on account of lack of facilities at engine-houses as compared with shops.

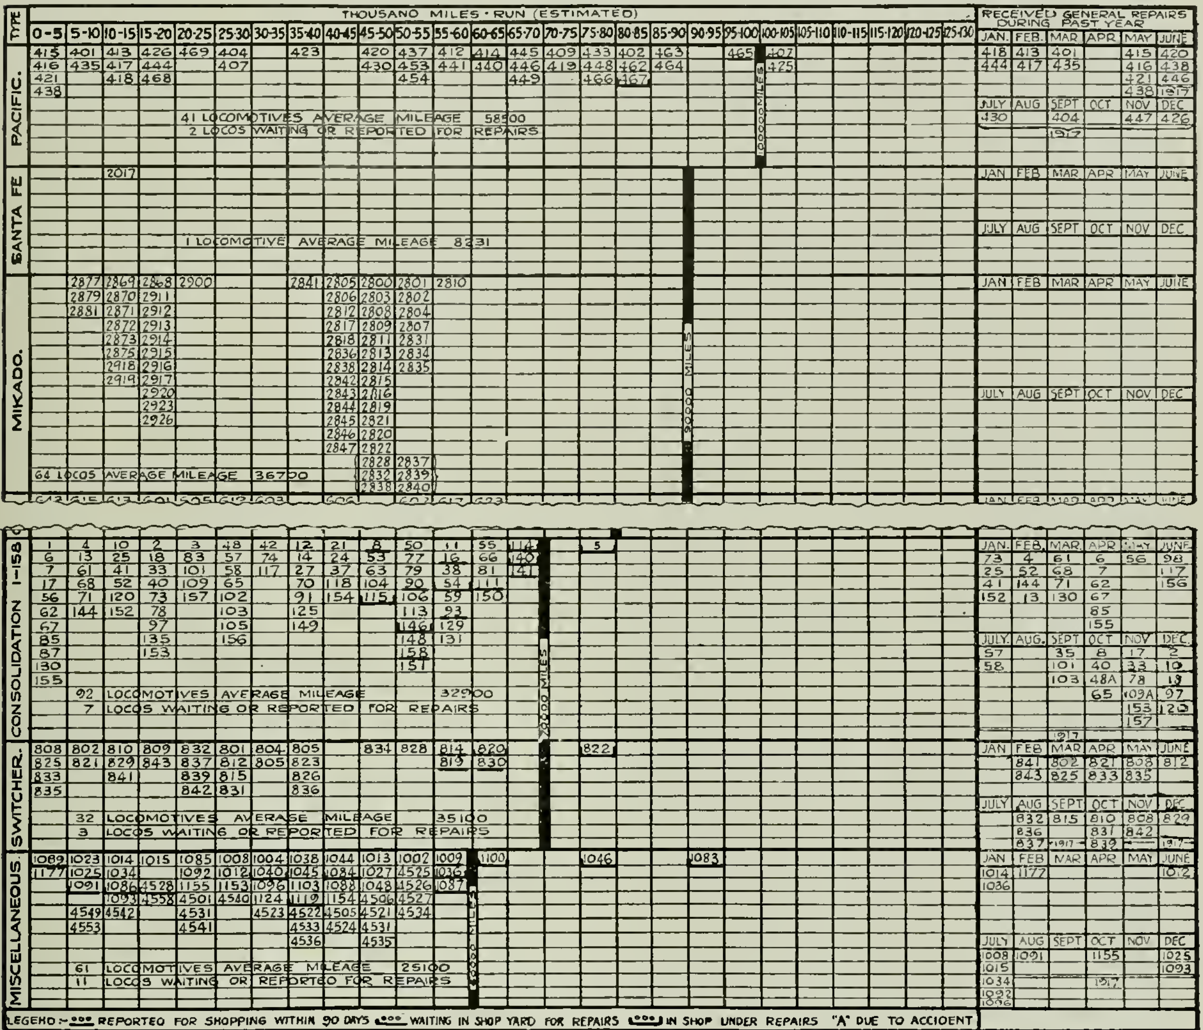
No. 3 repairs differ entirely from those referred to. This class represents specific work and may be done at engine-houses or shops. It is sometimes the result of an accident to or failure of some particular parts, but is generally due to ordinary wear and tear of certain parts of the locomotive that are subject to the most severe service. The parts subject to the greatest wear would not, if the locomotive is properly maintained while in service, represent sufficient work to justify a No. 1 or No. 2 repair, and in order to enable these parts to continue their work until the locomotive is generally worn to the extent necessary to justify a shop repair, it is usually economical to effect such repairs.

The latter class of repairs generally consists of partial renewal of tubes and flues, rod bearing work, lining up wedges, examination of pistons and valves, refitting main driving boxes, removal of lateral play from wheels, and sometimes tire turning. The parts requiring attention will, of course, be found to vary considerably with the different classes of locomotives as well as with the different classes of service they give and the subdivisions on which they are employed. In some classes of locomotives on some subdivisions the tubes and flues will run from shopping to shopping with very little trouble, while others on the same division or the same class on another division will require partial renewal when little more than half the required mileage has been accomplished.

The constant introduction of larger power is so changing conditions as to make the question of doing No. 3 repairs at

* From a paper read before the Canadian Railway Club.

engine-houses one of considerable controversy and the question naturally arises as to the best method of taking care of this work. In the writer's opinion the No. 3 repair should take care of this work except on the smaller and medium classes of power. At engine-houses where there is a heavy fluctuation in traffic it is an advantage to have a No. 3



No. of Locos. Tributary to Moncton Shops.

Fig. 1—Canadian Government Railways Form Showing Conditions of Locomotives

be continued and not confused with the heavier repairs under classes 1 and 2, this being important in order to determine the condition of the power at all times based on mileage made according to class of repairs, and to avoid expenditures on the power that should not be necessary.

Facilities at engine-houses are generally inadequate to repair gang, as it enables those in charge to hold their staff together and they can be employed to advantage on running repairs when necessary.

In general repair shops where the work is done on schedule and arranged so that the engines will be turned out at regular intervals and No. 3 repairs cannot be taken care of without interfering with the regular work, it is a debatable question as to the advisability of breaking up the organization in order to take care of this work, although under existing conditions there is usually no alternative. The changing conditions will, no doubt, make it necessary to provide certain space in general repair shops for this class of work, where it may be done at lower cost than at engine-houses. Where locomotives have to be hauled or worked a long distance to get to the general repair shop for such repairs, it might be advisable to provide a small shop for this class of repair if the number of engines tributary to it is sufficient.

To enable the shop superintendent to plan his work and maintain his schedule, it is only fair that he should be given all the advice possible as to the class of repair, and a list of the important parts that require replacement at least 30 days in advance of the locomotive coming to the shop. While it may not always be possible to do this on account of engines being damaged in accidents, there is no reason why it cannot be done to a very large extent in ordinary service. A form for reporting the work, shown in Fig. 2, has been found to be very satisfactory.

When making out this report of shop repairs required, master mechanics should devote particular attention to the note advising them to describe any unusual defect.

We all know that when a group of engines is built from the same drawings, even though all the parts are duplicate in every respect, no two of these engines will behave alike in service, but that each individual machine will have its own peculiar virtues and vices. For instance, one engine may jig and ride badly, perhaps the fault is more apparent at certain speeds than at others, and again it may vary with the position of the reverse lever and according to whether the engine is working hard or light. There are several things which might cause this trouble, and unless full particulars are given the real cause may be overlooked, but if the master mechanic will take particular care to describe the defect with all the symptoms he will give the shop superintendent a chance to determine the seat of the trouble.

On taking over an engine from the shop after repairs, the operating department should keep a very sharp lookout for any defect which may be actually present or beginning to develop, and these defects should be completely reported to the shop superintendent within 30 days of the date the engine goes into service. What too often happens is that the operating department will run the engine until there is a failure and then endeavor to throw the whole blame for the failure on the shops, whereas they are really as much to blame as the shops for not reporting the defect earlier.

There are some kinds of defects which often manifest themselves on an engine from the shops, which will disappear after a few days or a few weeks in service, and the operating department often makes the mistake of neglecting to report these defects, as they feel confident that the engine will come round to her work after a week or two in service. Very often their judgment proves correct, but the best policy in cases of this kind is to report the defect immediately, keep a strict watch on it and if no improvement is noticeable within a very short time the defect must be rectified to avoid any chance of engine failure.

The standard maintenance regulations in force on most roads, if faithfully carried out, will prevent a very large percentage of ordinary running failures, but there is a class of failures which cannot be guarded against by any such regulations. I mean failures due to faulty design and poor material. To deal with the failures of this kind is, obviously, the business of the (mechanical) engineering department, and their first and greatest effort should be to locate the prime cause of the failure. Very often the actual part which fails is not the part which is at fault, and if we go ahead blindly and strengthen this part, the evil will not only break out in another place, but very likely with worse results. The maxim of the engineering department should be first to find the root of the trouble and then rectify it.

To determine the mileage that should be obtained from the different classes of locomotives, considerable study and investigation is required, and, in the writer's opinion, a minimum mileage requirement should be established for all sub-divisions for the various classes of locomotives according to service, after receiving a No. 1 or No. 2 repair. If this is not done there is every possibility of locomotives being shopped for expensive repairs before actually required, while others, overdue for shopping on a basis of work done, remain in service, a source of trouble and expense to everybody. We make tests and establish standards as to tonnage that locomotives of the same class shall haul and they are not arbitrary for all divisions irrespective of grades and curves; then why require a locomotive to make as much mileage with the same repairs in way-freight service on a heavy division as in through service on a light division?

Fig 2—Form for Reporting to Shops Advance Information Concerning Repairs Required by Each Locomotive Shopped

Locomotives in assigned service will, I am satisfied, make more mileage at less cost than those in the pool, and in a given time—say 18 months—the assigned engine will possibly make the greater mileage, due to its receiving more care and attention which will keep it in continuous service; but in a rush of traffic for a short period the pooled engine will make the greater mileage. Where traffic is fairly steady I believe that the assigned system is the best, but where heavy fluctuations in traffic have to be met, it might entail too great a capital outlay. I have known a locomotive in assigned service, when the engineer was taking an interest in his work, to make 55 per cent more mileage than a locomotive of the same class in the same service and on the same division, in the pool.

The movement of power from one division to another should be done only under the advice of the motive power department, because otherwise it would possibly result in some roundhouses having a high percentage of power over the shopping period and others with a similar proportion of power just out of the shop.

In order that we may have a comprehensive idea of the condition of our power at all times, the monthly statement illustrated in Fig. 1 has proved to be of considerable value. The form is self-explanatory and it is easy to get an idea of the condition of any particular locomotive, of the general condition of a particular class of locomotive, of the number of locomotives due for shopping, etc.

It will be noticed that in the mileage established for different classes of locomotives there is no provision made for the class of service in which the locomotive is engaged, and it is therefore necessary sometimes to reduce the mileage required for locomotives working under severe conditions, such as way-freight service on a heavy division. It is a difficult and unsatisfactory matter to make rigid laws in such cases and the rules are necessarily slightly elastic.

To sum up, co-operation between the various branches of the mechanical department depends very much more on the men than on the system, and if the heads of the different departments all pull together with the idea of attaining greater efficiency and their subordinates back them up, it will not be difficult to get results.

The operating department should be very careful and very complete with their reports of repairs required when sending locomotives to the shop and should promptly report any defects in engines turned out of the shop.

The shops department should work conscientiously with the idea of making all locomotives good for their full mileage, and should pay special attention to any peculiar or unusual defects reported by the operating department.

The (mechanical) engineering department should be ready at all times with advice and assistance to the shops and operating departments, and when investigating any defects should spare no pains to get right at the root of the trouble before attempting to eliminate it.

Steam vs. Electric Locomotives*

Intelligent Comparison of the Two Types Requires a Knowledge of the Characteristics of Each

The tractive effort of the simple locomotive can be easily calculated from the following formula:

$$TE = \frac{0.85 \, P \times C^2 \times S}{D}$$

where TE = rated tractive effort at rim of driving wheel in pounds.
P = boiler pressure in pounds per sq. inch.
C = diameter of cylinder in inches.
S = stroke in inches.
D = driving wheel diameter in inches.

The maximum tractive effect in general corresponds to about 22 per cent adhesion between the drivers and the rail. Loads on the locomotive must be of such a maximum value that there is a small percentage of tractive effort available for possible starting under maximum grade and load conditions. The locomotive must be rated in terms of maximum load in tons for the division over which it operates, and this maximum tonnage must be corrected for temperature during the winter months. This rating is mentioned because it corresponds somewhat to the continuous rating of the electric locomotive, which we will take up and discuss further on in this article.

The torque of the motor is the pull which it can exert at one foot radius from the center of the armature shaft, i. e., at any point in a circumference of a circle 24 in. in diameter. The formula for the electric locomotive is:

$$TE = \frac{T \times 24 \times G \times \text{gear efficiency} \times N}{D \times g}$$

Where TE = tractive effort
T = torque of motor
G = number of teeth in gear
g = number of teeth in pinion
D = diameter of driver in inches
N = number of motors

The above formula is a general one and considers gearing as the mechanical connection between the motors and the drivers. So as to provide a ready means of enabling the railroad man to calculate the tractive effort and to know the performance of the electric locomotive under consideration, a set of curves are drawn, known as the characteristic curves. These curves show the relation between the current taken by the motor, the torque development and the revolutions. This data is then used to make up a set of curves for the complete locomotive, so that it is possible to read off the total current taken by the locomotive, the pounds tractive effort and the corresponding speed. The tractive effort is obtained by the formula given, and the miles per hour equals

$$\text{r. p. m.} \times D \times \frac{g}{G} \div 336$$

It is apparent that the tractive effort depends on the amount of current which passes through the motors, this current value being at the control of the engineer. There is a practically unlimited supply of power available at the power house compared to that developed by one steam locomotive, and the maximum power the electric locomotive is capable of developing does not depend on a fixed condition as in the case of the boiler of the steam locomotive. It is possible, therefore, to take advantage of extra adhesion with the electric locomotive. This extra adhesion may be natural or caused by the application of sand, and a value as high as 35 per cent has been obtained.

It is not possible to maintain this high maximum tractive effort continuously, which the steam locomotive is capable of doing, on account of resultant damage to the motors, but there is a tractive effort which can be maintained continuously by the locomotive. This leads up to what is meant by the continuous and hourly rating of an electric locomotive.

The tonnage rating of the steam locomotive corresponds, as nearly as the two entirely different machines can be compared, to the continuous rating of the electric locomotive. The continuous rating is fixed, but in a different way from the tonnage rating. The tonnage rating means that this is the maximum load it is safe to haul if the train is to be gotten over the road—allowance being made for a reduction in tractive effort due to poor coal and other factors.

With the electric locomotive, it does not mean that if the continuous rating is exceeded the locomotive will not be able to take the train over the road. It will pull the train and do it on schedule, but it may be at the expense of overheating the motors, and the question of whether damage will result depends on the time the overload is maintained. In addition to the continuous rating, there is the hourly rating which is higher than the continuous rating. Starting with the engine cold, the hourly rating represents the tractive effort which the locomotive could exert for one hour without overheating the motors. The hourly rating is a rating which

*Abstract of an article by A. J. Manson, Westinghouse Electric & Mfg. Co., appearing in the February number of the Railway Electrical Engineer.

does not exist in the steam locomotive. In the latter, the tractive effort depends entirely on the mean effective pressure in the cylinders, while in the former it depends on the amount of current passing through the motors. The current flowing through the motors causes the fields and armatures to heat, on account of the resistance of the conductors. This heat is conducted away by the iron and by radiation, and the whole motor becomes heated. A certain constant current flowing through the motor continuously, will result in a certain temperature rise above the surrounding air, the extent of this depending on the value of the current.

While the electric insulation used in the motor will not be injured if an occasional temperature of 100 deg. C. is reached in service, the ratings of the motors are for a much lower temperature rise—namely, from 60 to 70 deg. C. by thermometer. A continuous current which will give 60 deg. C. rise in temperature is the continuous current rating, and the tractive effort corresponding to this continuous current rating is the continuous tractive effort rating of the locomotive. The hourly rating would be the higher current (and the tractive effort corresponding), which in one hour would give the 60 deg. C. rise. Likewise there can be an indefinite number of ratings for any particular time from say 5 to 10 minutes up to the continuous time. It is the practice, however, to give only the continuous and hourly rating. A very much larger current can be taken for a shorter time without exceeding the allowable temperature rise, and so it is possible to rate the locomotive at a much larger tractive effort for a short time performance.

The tonnage rating of the steam locomotive is the rating for a particular division (varying with different service con-

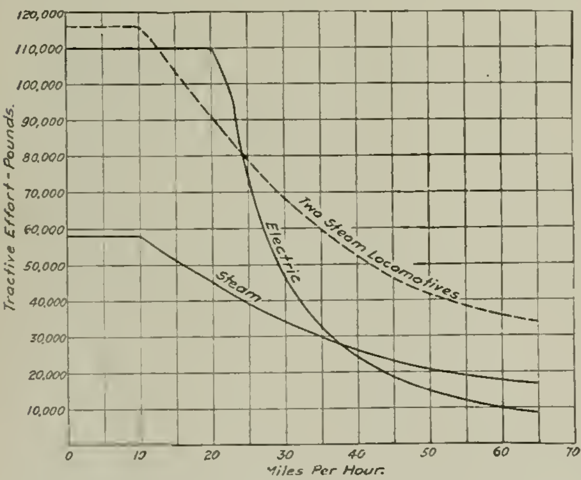

Fig. 1—Relative Tractive Effort of Steam and Electric Locomotives of the Same Weight Operating at Various Speeds

ditions) and is governed by the maximum grade, or by the pull which will be required of the locomotive. The load will be governed by this maximum condition. In the case of the electric locomotive, high tractive efforts can be exerted for short periods of time so that the loading does not depend upon the maximum grade encountered, but upon the whole profile. The load will be governed by what the temperature of the motors will be at the end of the run—not by what the maximum pull may be for 5 or 10 minutes. Therefore, it becomes possible to give the electric locomotive a higher tonnage rating for the same weight upon the drivers than would be possible with the steam locomotive.

There is one more very important point which should be thoroughly understood and appreciated, when considering the electric locomotive, and that is the "horsepower" rating. Horsepower is the product of the tractive effort and the speed. It is a direct measure of the locomotive's capacity to do work. Tractive effort tells how much trailing load can be handled, but it is the horsepower that measures the hourly ton-miles. Electric locomotives excel steam locomotives in this regard. They have the ability to carry the maximum tractive effort to speeds, two or more times that of the steam locomotives.

To better understand what has been covered in the foregoing discussion, an actual comparison has been made of the tractive effort and the horsepower of a steam and an electric locomotive of equal weights, both designed for heavy passenger service over mountain grades. The data of weights, etc., is given in the table. The steam locomotive is of the very latest design, embodying arch tubes and super-

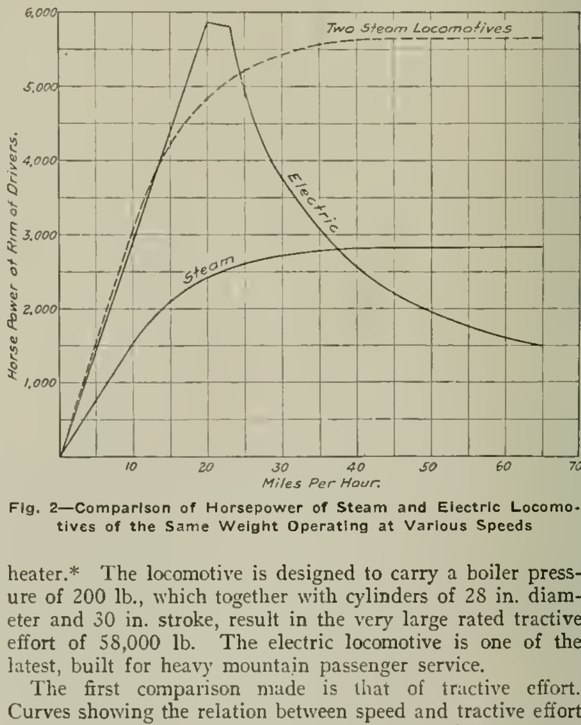

Fig. 2—Comparison of Horsepower of Steam and Electric Locomotives of the Same Weight Operating at Various Speeds

heater.* The locomotive is designed to carry a boiler pressure of 200 lb., which together with cylinders of 28 in. diameter and 30 in. stroke, result in the very large rated tractive effort of 58,000 lb. The electric locomotive is one of the latest, built for heavy mountain passenger service.

The first comparison made is that of tractive effort. Curves showing the relation between speed and tractive effort for the two types are shown in Fig. 1. The maximum tractive effort of the steam locomotive is 58,000 lb., while that of the electric is 110,000 lb. Reference to the data in the table shows that the weight on the drivers is 330,000 lb., so that the 110,000 lb. tractive effort for starting is based on 30 per cent adhesion, a conservative value for the electric locomotive. This maximum tractive effort in the case of the electric locomotive is carried out to a speed of 20 miles per hour, while the steam locomotive cannot maintain its maximum beyond 10 miles per hour. The electric locomotive curve drops rapidly, and at 38 miles an hour both types are the same. To better appreciate what this large tractive effort of the electric locomotive means, a curve has been drawn in, showing what the tractive effort would be for two steam locomotives operating as a double-header. The dotted curve is slightly higher for the maximum tractive effort, but in practical work the one electric could start the same train as the two steam locomotives, and would have an advantage over them up to a speed of 24 miles an hour. When it is considered that on heavy passenger mountain service, speeds do not greatly exceed this figure, it becomes clear that the one electric locomotive is nearly equivalent to the two steam locomotives.

*The U. S. R. A. standard heavy Mountain type.

It must be remembered that the two steam locomotives could maintain this speed continuously with a tractive effort of 80,000 lb., while the electric locomotive could not on account of the electric motors requiring a current much above the continuous rating.

Since horsepower is such an important factor, Fig. 2 has been drawn, showing the relative horsepower for the two engines chosen. Here the comparison is even more striking, and the great advantage of the electric locomotive is easily recognized. This electric locomotive of the same weight as the steam, has a maximum developed hp. rating at the rims of the drivers of 5,860 hp. compared to 2,825 hp. for the steam locomotive. And when compared with two steam locomotives it shows, for the working range, the ability to deliver the equivalent in hp. Of course, the continuous

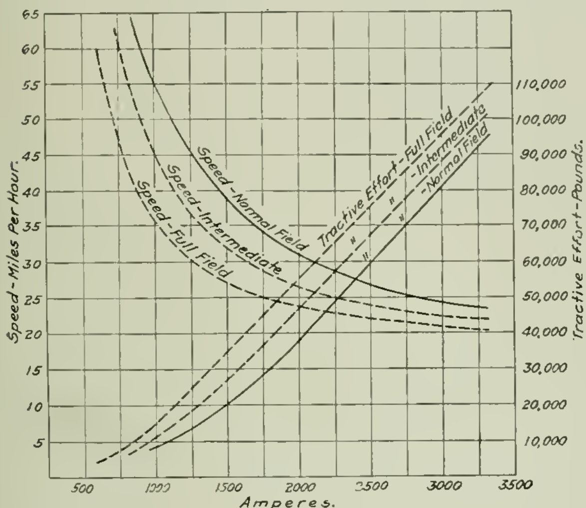

Fig. 3—Characteristic Curves for 266-Ton Electric Locomotive

rating must not be lost sight of, and for the electric locomotive this is 3,200 hp. The increase in horsepower is due to the increased speed for the same tractive effort. Referring to Fig. 1, assume there is a passenger train requiring at certain sections or grades, a tractive effort varying from 50,000 lb. to 40,000 lb. At 50,000 lb., the speed of the steam locomotive would be 16½ miles per hour—the electric, 29 miles per hour—nearly double. At 40,000 lb., the steam locomotive would be 24.5 miles per hour—the electric, 32.

COMPARISON OF STEAM AND ELECTRIC LOCOMOTIVES OF EQUIVALENT WEIGHTS

Characteristics	Steam	Electric
	4-8-2	4-6-2—2-6-4
Weight—engine and 14 ton tender....	268.5 tons	266 tons
Weight—engine only.................	352,000 lb.	532,000 lb.
Weight—engine on drivers......	243,000 lb.	330,000 lb.
Number of pairs of drivers..........	4	6
Weight per pair.....................	60,500 lb.	55,000 lb.
Wheel diameter, inches..............	69	68
Total wheel base engine and tender...	75 ft. 8.5 in.	79 ft. 10 in.
Maximum tractive effort.............	58,000	110,000
Maximum horse power.................	2,825	5,860
Continuous horse power..............	2,825	3,200

Characteristic curves showing the relation between speed, tractive effort and the current taken by the locomotive, are supplied by the electrical manufacturers. The set of curves for the electric locomotive under consideration are shown by Fig. 3. From these curves the tractive effort at any speed can be read off directly. It is noted there are three speed curves and three tractive effort curves corresponding. This locomotive uses "field controls," thus reducing resistance losses. The tractive effort and horsepower curves covered the "normal field condition." To show, briefly, what is gained with this field control, consider the continuous horsepower rating of 3,200 hp. With normal field this corresponds to a speed of 34 miles an hour and a tractive effort of 35,000 lb. If a greater tractive effort is necessary continuously the speed can be reduced by operating on full field when a speed of 24.5 miles per hour is obtained at a tractive effort of 49,000 lb.

ANNUAL REPORT OF THE I. C. C. LOCOMOTIVE INSPECTION BUREAU

The seventh annual report of the chief inspector of locomotive boilers for the fiscal year ended June 30, 1918, covers the work done under the locomotive-boiler inspection act as amended to apply to the entire locomotive and tender and all their parts and appurtenances.

TABLE I—LOCOMOTIVES INSPECTED, NUMBER FOUND DEFECTIVE, AND NUMBER ORDERED OUT OF SERVICE

	1918	1917	1916
Number of locomotives inspected.....	41,611	47,542	52,650
Number found defective..............	22,196	25,909	24,685
Percentage found defective..........	53	54.5	47
Number ordered out of service.......	2,125	3,294	1,943

Table I shows, in concrete form, the number of locomotives inspected, the number and percentage found defective, and the number ordered out of service on account of not

TABLE II—NUMBER OF ACCIDENTS, NUMBER KILLED, AND NUMBER INJURED, BY COMPARISON

	1918	1917
Number of accidents............................	641	616
Increase over previous year..........per cent..	4.1	...
Number killed	46	62
Decrease from previous year........per cent..	25.8	...
Number injured	756	721
Increase over previous year.........per cent..	4.8	...

meeting the requirements of the law. Table II shows the total number of accidents due to failure from any cause of locomotives or tenders and all parts and appurtenances thereof and the number killed and injured thereby.

Table III shows the total number of persons killed and injured by failure of locomotives or tenders, or any part of appurtenance thereof, during the three years ended June 30, 1916-1918, classified according to occupations.

A summary of the accidents and casualties resulting therefrom during the year shows an increase of 4.1 per cent in the number of accidents, with a decrease of 25.8 per cent in the number killed, and an increase of 4.8 per cent in the number injured.

The decrease in the number of locomotives inspected during the year is due to the fact that a substantial percentage of the inspectors of locomotives were engaged in special work during most of the year. During the months of November and December, 1917, almost all of the inspectors were engaged, at the request of the Interstate Commerce Commission, in checking the congestion at terminals in an effort to see that locomotives were promptly furnished so that the coal movement might be facilitated and the fuel shortage relieved; and during the months of January, February, and March, 1918, were performing similar work at the request of the director general of railroads, and this work contributed materially toward breaking the blockade and expediting the movement of coal and other freight. It is also due in part to the fact that a number of inspectors of locomotives were permanently transferred to the service of the director general of railroads because of their general knowledge of equipment and their training in conducting investigations.

The period covered by this report represents what is admitted to have been the most difficult in the history of American railroads to properly maintain locomotives. This is primarily due to the war conditions which made it necessary to use to their maximum capacity all locomotives that were serviceable, and to return to service many locomotives that had been out of service for years awaiting disposition and which, in some cases, were put in service without having been thoroughly repaired. Proper maintenance of locomotives was also made difficult by the large number of mechanics that entered military service. The excessive demands for power resulted in the use of many locomotives that were in violation of federal laws, but the results of this practice were clearly demonstrated during the past winter.

These conditions rendered the work of the inspectors exceedingly difficult, and considerable pressure from various sources was brought to bear on them to prevent the enforcement of the law where locomotives were sorely needed. The shortage of power made it necessary in every case for inspectors to exercise the utmost good judgment and discretion in their work in order to avoid any possibility of causing additional congestion which an inflexible enforcement of the law might have brought about. The fact that the enforcement of the locomotive inspection laws during this trying period did not unnecessarily hamper the movement of traffic, but on the contrary the work of the inspectors, in hundreds of instances, facilitated the operation of locomotives and the movement of trains, is evidence not only of the discretion and judgment of inspectors in their enforcement of the law, but also of the wisdom and farsightedness of its framers, because it is generally admitted that the law and the work of the inspection bureau was of substantial benefit during the past winter, and when we consider, in addition to this, the fact that the general condition of locomotives has improved during the year, due, in part, to the work of the inspectors, the results become particularly creditable.

TABLE III—THREE-YEAR COMPARISON OF CASUALTIES CAUSED BY FAILURE OF LOCOMOTIVES, TENDERS AND APPURTENANCES, CLASSIFIED BY OCCUPATIONS

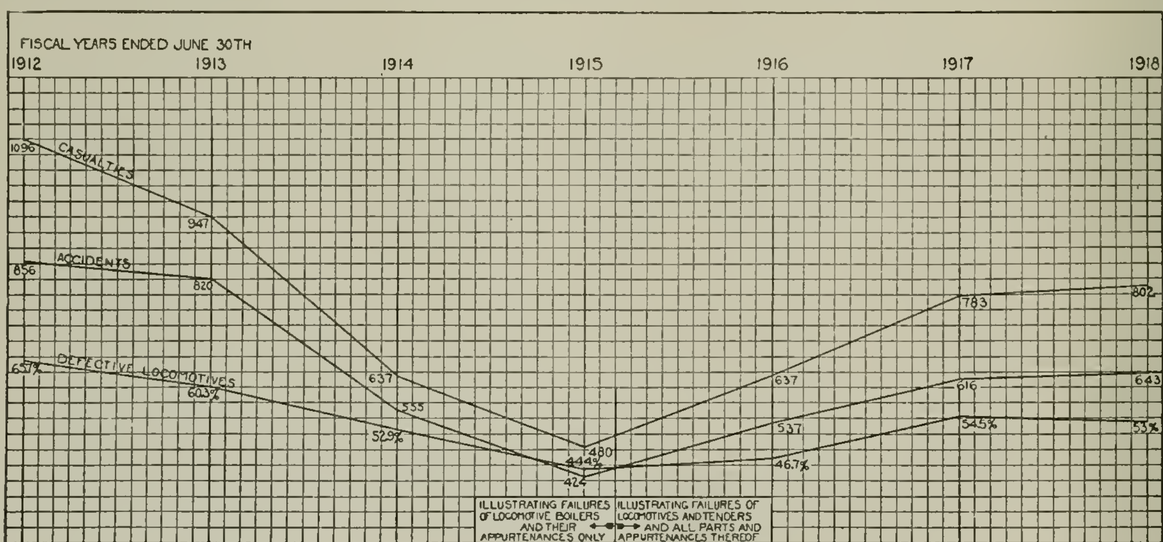
During the year 353 applications were filed for extension of time for removal of flues under the provisions of Rule 10. Investigation showed 18 of these locomotives in such condition that no extension could properly be granted. Forty-two were in such condition that the full extension requested could not be granted, but an extension for a shorter period was allowed. Thirteen extensions were granted after defects disclosed by our inspectors had been repaired. Sixty-two applications were withdrawn for various reasons, and the remaining 218 were granted for the full period asked for. It will be noted that the number of applications for extension of time for removal of flues decreased about 50 per cent. This is largely due to the modification of the rule which was recommended to the Commission and approved by it.

As provided in Rule 54, 3,124 specification cards and 8,080 alteration reports were filed.

The locomotive headlight case, which has been pending for approximately three years, was finally disposed of June 7, 1918, by the withdrawal by the complainant and at the complainant's cost, of bill in equity No. 226, United States District Court, District of Indiana, *New York Central Railroad Co. v. United States*, in which it was sought to restrain the Interstate Commerce Commission from enforcing its order. This withdrawal was made after arguments on the bill had been heard by the court and the position of the complainants declared to be unsound.

In the sixth annual report recommendations were made that locomotives should be equipped with automatic fire doors and that a steam connection to air-operated power reverse gear should be applied. It is not considered necessary to repeat these recommendations at this time for the reason that both recommendations have been adopted by the United States Railroad Administration, and all standard United States locomotives are being so equipped, and it is expected that these recommendations will be generally followed on locomotives passing through the shop for general repairs, so far as material and labor are available.



Relation of Defective Locomotives to Accidents and Casualties Resulting from Locomotive Failures.

Standard Equipment Specialties

The Distribution, by Classes of the Special Equipment Used on Government Cars and Locomotives

The specialties applied to the standard cars and locomotives built for the Railroad Administration have been published in the *Railway Mechanical Engineer* from time to time during the year. In order to give a better idea of the distribution of the use of these specialties among the various classes of equipment the accompanying tables have been compiled. A few minor changes were made in the original lists showing the distribution of the orders, primarily on account of delivery.

The companies receiving orders for the specialties for the locomotives are shown in the table under the various specialty items and on which class of power these specialties are used. In case one specialty is used on all locomotives, such as the American Arch Company arch, it is so designated.

The table showing the specialties for the cars includes only those for the cars which have been built thus far, as information is not obtainable as to just which of the specialties will be applied to the other cars.

LINING AND FLOOR RACKS FOR CARS HANDLING PERISHABLE FREIGHT

The car service section of the Railroad Administration issued Circular CS-43 (revised), dated January 30, covering the use of refrigerator and box cars to be used in the transportation of perishable freight.

Refrigerator Cars.—(1) Railroads will supply refrigerator cars for shipment of fruits and vegetables to the extent of their ability. A certain percentage of this class of cars belonging to the various railroads is already equipped with false floors or floor racks. It is contemplated eventually to equip in this manner all such cars owned by roads under federal control, and also cars of the following refrigerator lines: Pacific Fruit Express Company, Santa Fe Refrigerator Despatch, American Refrigerator Transit Company and the 'Frisco Refrigerator Line.

....
(Name of station.)

.... RAILROAD
(Name.)

UNITED STATES RAILROAD ADMINISTRATION

Instruction Card for Return of Cars

2. It will not be practicable for the railroads to equip a sufficient number of cars to fully meet the requirements of the present season. Therefore, if refrigerator cars owned by federal-controlled roads, or cars belonging to any of the above named refrigerator lines, not equipped with floor racks, are offered for loading fruit and vegetables, shippers, if they so desire, will be privileged to construct and place in cars suitable racks of standard type, in accordance with specifications shown on accompanying print. Racks when so placed will become a permanent part of the car.

3. Railroads will reimburse shippers for the value of floor racks placed as above described at the rate of fifty cents per linear foot of rack. This reimbursement will be made by the road on which load is first placed in car following installation of floor racks.

4. Any *lining* desired by shippers in refrigerators in addition to floor racks must be placed by them at their own expense, and in such manner as not to damage the car or insulation.

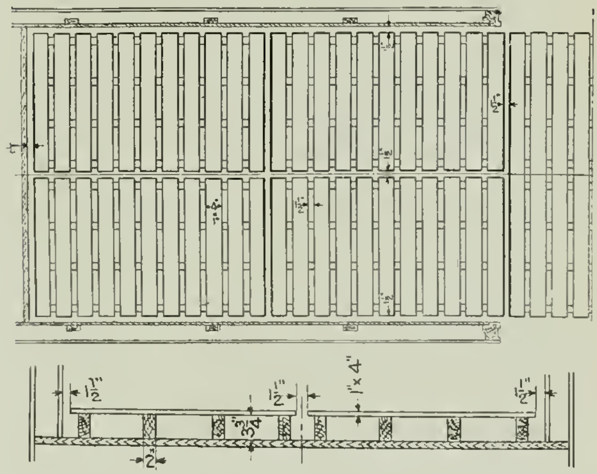
Box Cars.—(5) When railroads are unable to meet the demand for refrigerator cars for above named shipments, if shippers elect to make use of box cars, and if in their opinion such cars require lining, they (the shippers) will be given the privilege of equipping the cars with such lining entirely at their own expense.

6. In the interest of promoting shipments and conserving food supply, it is suggested that the lining of box cars, when done, conform to the following standard furnished by the Bureau of Markets, United States Department of Agriculture, which, it is believed, will give the best results:

"False floors, side and end walls shall be installed providing an unobstructed space for air circulation down between the car and walls and false end walls, and from there under the false floors to the doorways. This ventilating space must be kept clear of hay, straw, manure, shavings, and everything except the necessary false-floor supports. There shall be a space between the car side walls and the false side walls of not less than four inches at the top and six inches at the bottom.

"Each doorway shall be tightly boarded not less than 24 in. from the floor upward, the boards being nailed to the inside of the door frame to keep out cold winds."

7. For the same reason it is further requested that shippers make it a practice to use box cars for the shorter hauls, reserving refrigerator cars for loading to the more distant points. Railroads will supply refrigerator cars preferentially as compared with box cars, for the longer runs.



Arrangement of Floor Racks for Cars Handling Perishable Freight

8. Box cars that may be lined by shippers will be furnished with a board on either side, of uniform dimensions (24 in. by 30 in.), with lettering of suitable size, reading as shown in the illustration.

9. These boards will be furnished by the railroads. Lined box cars so boarded will be returned free, with lining, to point of origin of load, and should be waybilled to such point, consigned to party or firm whose name the board bears. They may be loaded all or a part of the way

on return trip with any suitable freight. They must not be loaded out of direct line, and care should be exercised to avoid damage to lining in loading or unloading.

10. It must be understood that cars thus lined and boarded are subject to demurrage, either while awaiting loading or unloading.

11. The privilege of equipping box cars as above will extend from November 15, 1918, to April 1, 1919. In the event of failure to return lining to shippers within three months from the last named date, roads on which it was originally placed in cars will refund to party furnishing same the sum of twenty-five dollars per car in full payment for the value of the lining, but only when installed in conformity with the specifications named in paragraph 6. In the case of box cars the term "lining" will be understood as including false floor as well as lining of side and end walls.

12. Roads on which cars are equipped should keep an accurate account, showing date, number and initial of car and name of shipper to avoid any misunderstanding in making settlement in case of loss.

13. After April 1, shippers will be required to promptly remove from cars any lining which belongs to them. Failing to remove such equipment, the work of removal will be performed by the railroads, but the latter will not be responsible to owners for the material or its value after removal.

14. Provisions herein contained which relate to reimbursements to be made to shippers become effective coincidentally with the effective date of tariff provisions of the various railroads authorizing such reimbursement.

JOURNAL BOX PACKING

In response to an inquiry for information regarding the use of substitutes for journal box packing, published in the *Railway Mechanical Engineer* a short time ago, several roads have replied. A brief abstract of the replies follows:

Road A.—We have experienced some trouble in using the cotton journal box packing. It has been found to be short material and has not been giving us the service that we should receive. We have been using cotton packing on freight equipment for some time, but the past year we have had a very poor grade of material.

Road B.—This company has been using cotton waste for journal box packing for some period of time, and we find that if it is kept up to the journal we have no trouble. This waste is inclined to sag a little more than good wool and requires a little more attention. We have been very successful with its use.

Road C.—We did not change our practice during the war but used cotton waste for packing all journal boxes, which has been the practice on this line for the past fifteen years.

Road D.—We have to date made no changes from our pre-war practice. We are using cotton waste for freight cars and a 75 per cent wool and 25 per cent merino waste for passenger cars and tender trucks. We have obtained very satisfactory results.

Road E.—We have not made any changes in our standards for journal box packing. We use cotton waste for packing journal boxes of freight cars and a composite wool cotton and fibre waste for passenger cars and locomotives.

Road F.—It has always been the practice of this road to use wool waste for passenger car journal box packing and a journal box packing composed of wool waste and cocoanut fibre for freight equipment cars. We have not deviated from this practice during the past year, but we have frequently been furnished with wool waste which was of inferior quality to that called for in our specification and were often obliged to take this material, although we did not consider it satisfactory for journal box packing.

The following is taken from our specifications for journal box packing: The material desired under Grade A is curled vegetable fibre, so curled as to impart to it the maximum resiliency; wool and cotton threads free from large lumps of any one component part and thoroughly machined and intimately mixed with the curled fibre in the following proportions. Grade B to have the same quality of wool and cotton as Grade A, without the vegetable fibre.

	Grade A	Grade B
a. Vegetable fibre	15 per cent	0 per cent
b. Wool waste	45 per cent	60 per cent
c. Cotton waste	40 per cent	40 per cent

The vegetable fibre should be Tampico, cocoanut or some approved equivalent, clean, long, strong, well curled and sufficiently elastic. The wool threads should consist of new yarn or thrums from the product of looms weaving Brussels, Axminster and Ingrain carpets and other high-grade woolen fabrics. Muck yarn shall not be used. The cotton waste should consist of white and colored new cotton threads.

Road G.—We have tried several substitutes for wool, but have not been able to secure satisfactory results and have insisted on and secured a journal box packing to the following specification: A shredded carpet stock containing at least 50 per cent net wool content, the balance of the mixture composed of cotton and long merino threads, 2 inches and over. The whole being well machined, free from knots, flyings, jute, sticks, paper or other deleterious substances. Oil, grease and dirt not more than 10 per cent. Moisture not to exceed 10 per cent. Cotton not more than 20 per cent. This is proving very satisfactory.

Road H.—This road has tested, in service, a number of different kinds of journal box packing and our tests indicate that a combination of wool, cotton and vegetable fibre gives the best results. The standard packing now used by this company consists of about 85 per cent wool, 7 to 8 per cent cotton and 7 to 8 per cent vegetable fibre.

Road I.—We have for several months on this road been using wool waste, which is partially made up of shredded carpet. This waste is composed of approximately 67 per cent wool and 33 per cent cotton, and is satisfactory.

Road J.—While a good grade of packing is, of course, better than a poor grade, I believe that 90 per cent of the hot box trouble could be eliminated with the average packing that is used if boxes were given the proper attention. Two of the main troubles have been, first, allowing cars to run until the packing at the back of the journal became dry and glazed; also in extremely cold weather the packing works to the front of the boxes reducing the surface of the journal which is lubricated until the hot box is unavoidable. Second, rebrassing cut journals instead of changing wheels.

The greatest advance that has been made in years in the prevention of hot boxes has been in the discovery that where lubrication is failing or friction is increasing from any cause, the center of the journal on the end becomes dry before the journal becomes hot. A dry journal center is almost an infallible sign of an impending hot box and calls for one of three actions (always examine brass and journal):

1. If caused by dry and glazed dope, with brass and journal in good condition, repack box.
2. If the brass is worn or defective with the journals in good condition, rebrass and repack.
3. If the journal is cut, change the wheels.

Where there is a plug of waste in the front end of the box (I think these will soon all be removed by all roads), a dry spot cannot, of course, develop; but frequently a greasy wheel with a new brass is an indication that a brass has been applied to a cut journal. This journal may run cool if the car is empty, but not when it is loaded.

One cause of an unnecessary number of hot boxes is the practice of applying brasses to cut journals when the wheels should have been removed. This was quite general a year ago, and there has been a great deal of it up until the last few months. A car stops off at various sidings and repair tracks to have brasses changed and thus takes several weeks to get over the road, and it is very difficult to learn what is going on until some person complains of the long delay to a car of important freight. I am fully convinced that if all roads followed these matters closely the hot boxes could be reduced 90 per cent.

We have spread our wheel storage tracks and cut the sides of our wheel cars down so that wheels can be stored without the flanges of the wheels striking against the journals.

A feature in connection with changing or examining the brass is the importance of using two jacks. When only one jack is used the weight on the opposite journal, especially if the car is loaded, usually causes the wheel to raise from the rail with the result that the man usually goes for help and has to use blocks to force the wheel down. In many cases this makes it necessary to drive the brass in with a bar or hammer, damaging the lining as it is forced past the collar and sometimes when there has been end wear on the brass removed, the new brass and wedge are not properly seated, resulting in a brass bearing on one end with the certainty of a hot box.

If a jack is placed under the opposite box and raised just enough to take the weight, the wheels remain on the rail; also if the brass removed is end worn the wheels, being free on the rail, can easily be moved over to allow the new brass to enter. I have seen three or four men take an hour to change a brass with one jack where one man could have done the work in a few minutes with two jacks.

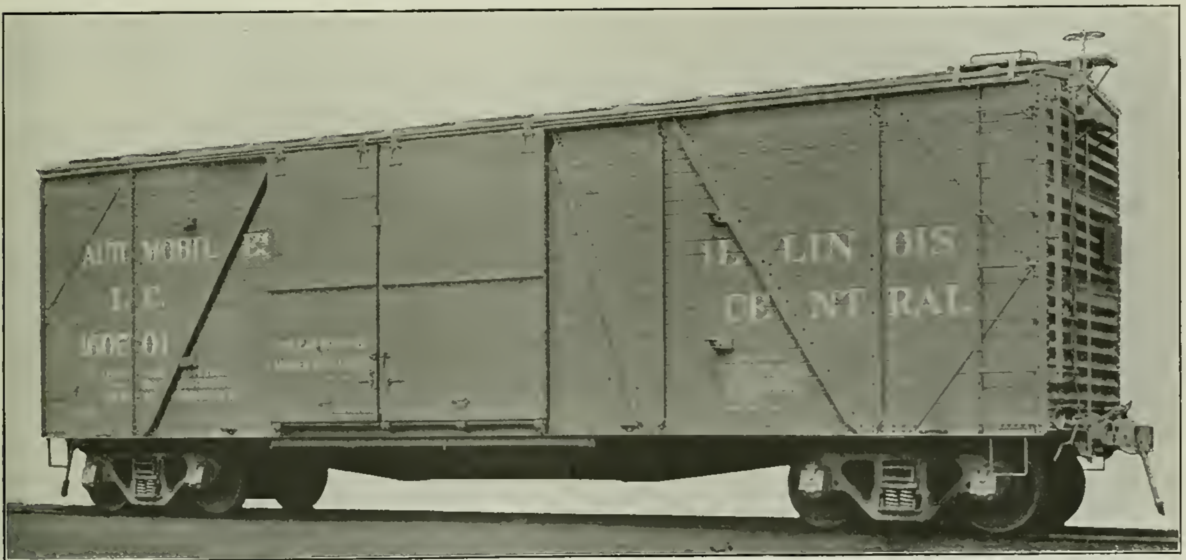
Automobile Cars for the I. C.

Single Sheathed Type of 80,000 lb. Capacity; Designed Particularly for Carrying Various Kinds of Lading

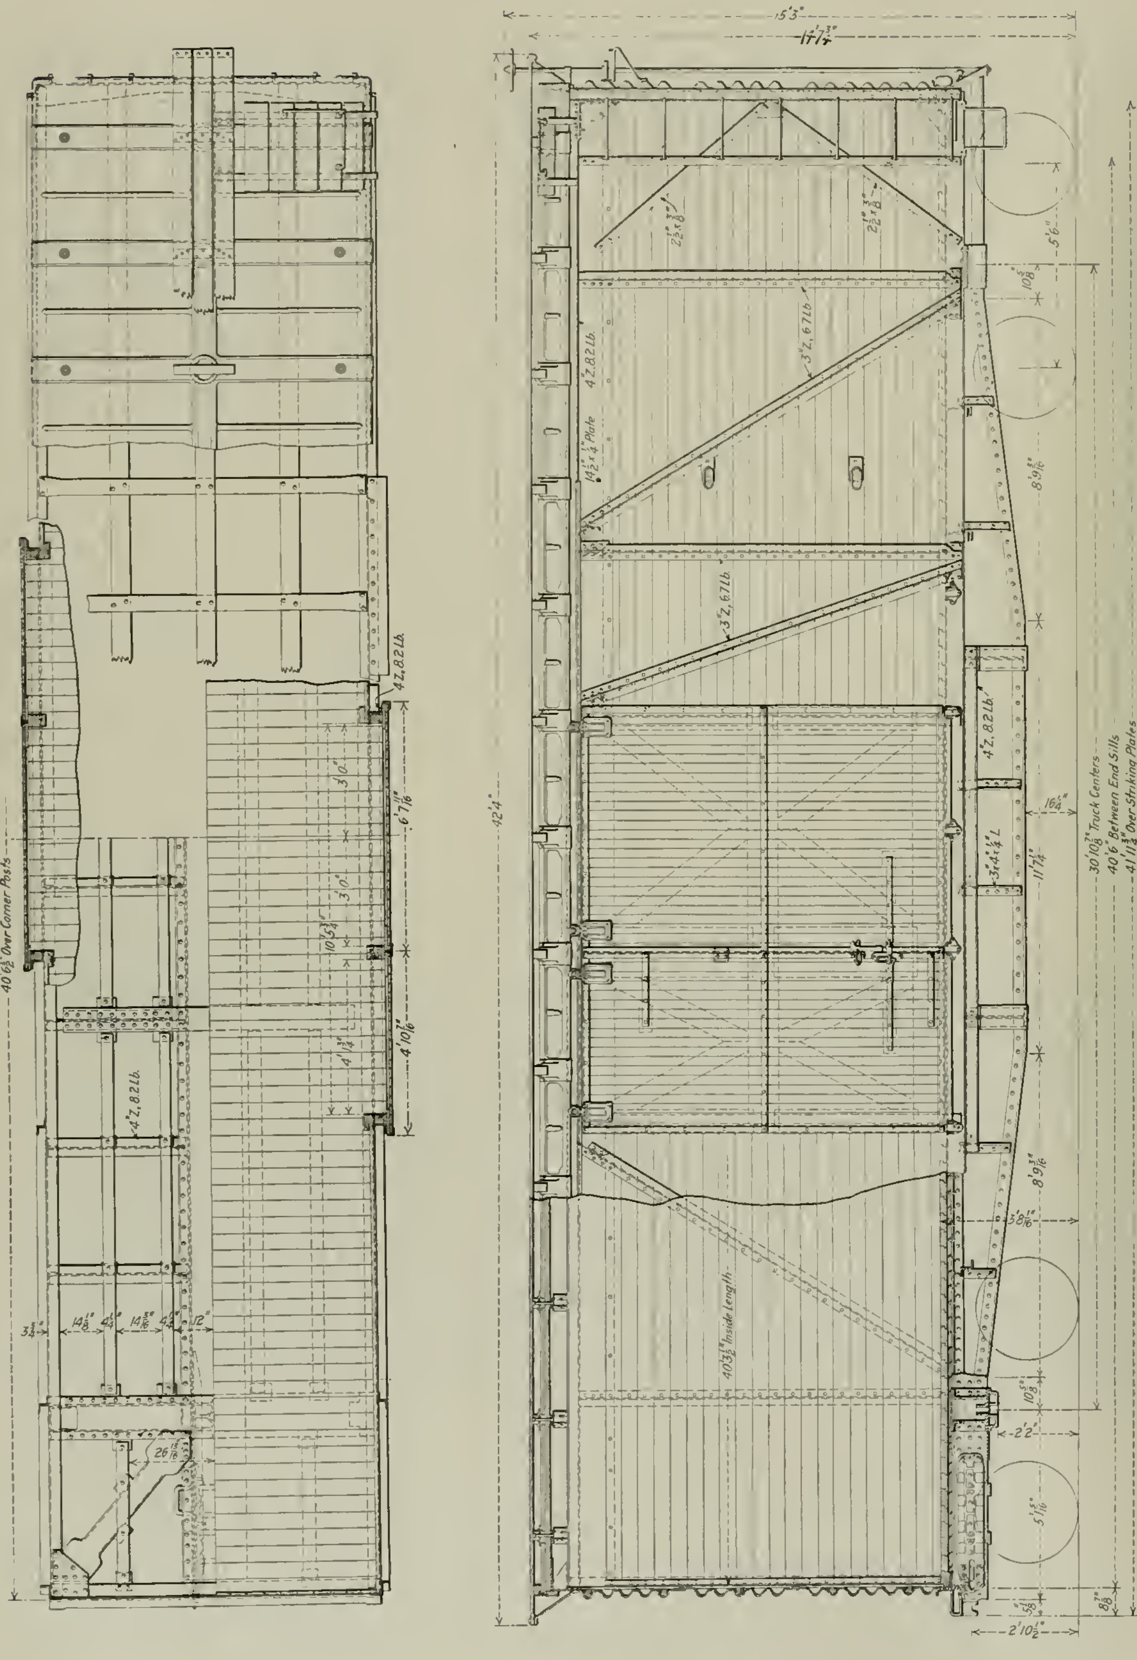
Persistent efforts have been made by many roads during the past few years to secure freight cars which are adapted for many kinds of lading. This policy, if consistently followed out, would undoubtedly bring about a reduction in the empty car mileage and an increase in the average carload. The growing tendency to design cars built for a special traffic, so that they are adapted for various kinds of lading is well exemplified by an order of five hundred 40-ft. automobile-furniture cars of 80,000 lb. capacity recently delivered to the Illinois Central by the Standard Steel Car Company. While designed primarily for automobile and furniture loading, these cars are suitable for almost any commodity that is handled in box cars, excepting grain.

These cars have a light weight of 48,000 lb. They are 40 ft. 3½ in. long and 8 ft. 6⅛ in. wide inside. The height from the floor to the under side of the carlines at the side is 10 ft. ¼ in. The cubical capacity of the car is 3,435 cu. ft. The length over the corner post is 40 ft. 6½ in. and over the striking plates 41 ft. 11¾ in. The width at the ends is 8 ft. 9⅝ in., and between the steel side door posts 10 ft. 5¾ in. The extreme height to the top of the brake mast is 15 ft., 3 in., and to the top of the running board 14 ft. 8 1/16 in. The top of the floor is 3 ft. 8 1/16 in. above the rail.

The underframe is of the fishbelly type. The web plates are 5/16 in. thick and 24¾ in. deep at the center, and 10 11/16 in. at the draft sill, extending continuously from end sill to end sill, being spaced 13½ in. apart. Along the bottom of each web plate is riveted a 5-in. by 4-in. by ⅝-in. angle, with the long flange horizontal. The top chord angles are 3½ in. by 3½ in. by 5/16 in., and to them is riveted a top cover plate 5/16 in. thick and 21 in. wide, extending the full length of the sills. From the inside of the end sill to a point 21 in. beyond the center line of the body bolster, the center sill web is reinforced by a plate 5/16 in. thick extending the full depth of the sill, having at the top, flanges



Illinois Central Single Sheathed Automobile Car

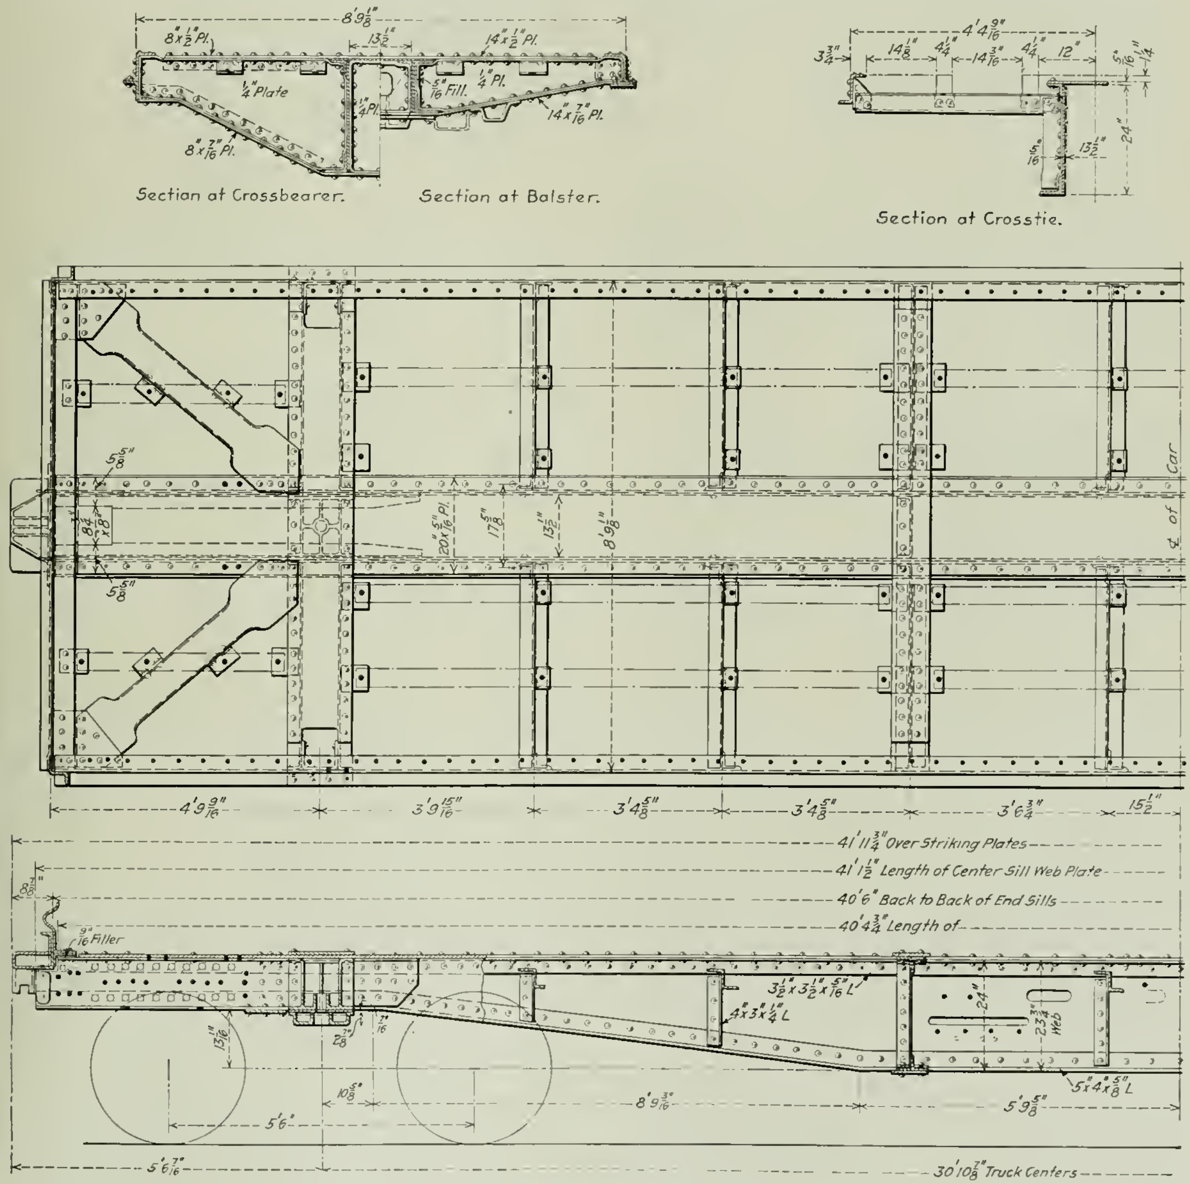


Plan and Elevation of Single Sheathed Automobile Car for the Illinois Central

3 in. wide extending inward. These stiffeners are riveted to the inner side of the center sill web plate and to the cover plate. The web plates are also reinforced between the bolsters by vertical stiffeners of 4-in. by 3-in. by ¼-in. angles, which are spaced approximately 3 ft. 6 in. apart and serve also as supports for the floor beams. Malleable iron cheek plates of the double pocket type are riveted inside the draft sills. The couplers have a 5-in. by 7-in. shank and 8½-in. butt. A cast steel yoke having an ultimate strength of 450,000 lb. is used. It is attached to the coupler by a key and is fitted with one M. C. B. class *G* draft spring and one Harvey friction spring. The Carmer release rigging and Imperial centering attachment are used.

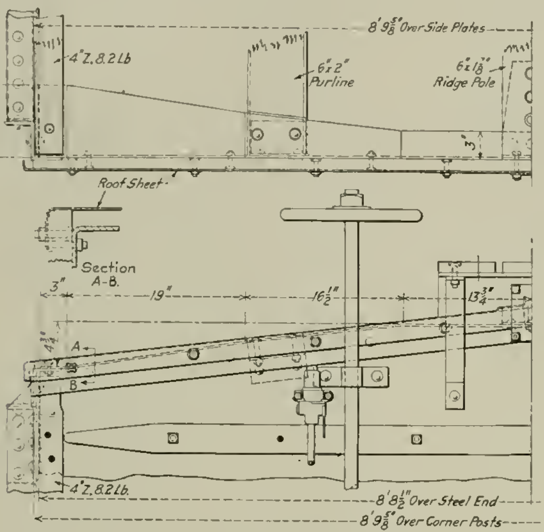
The body bolster is of a box section. The diaphragms are of ¼-in. pressed steel plate with 3-in. flanges all around and are spaced 8 in. back to back. At the outer end of the diaphragm there is a spacer made of a 7/16-in. bent plate. The spacers between the center sills at the bolsters are of cast steel. The top bolster cover plate is 14 in. wide and ½ in. thick extending from side to side sill. The bottom cover plate is 14 in. by 7/16 in. and extends the full width of the car. The cast steel body center plate is fastened under the bottom cover plate and is riveted through the bottom chord angles on the center sills and also to the center sill spacer casting.

The end sills are 8-in., 18.75-lb. channels. To the back of these channels is riveted a 5-in. by 3-in. by ⅜-in. angle by which the end sill is fastened to the top of the center sill. The striking plate is a steel casting riveted to the end sill and to the webs of the center sill. There are two cross bearers on each side of the car, spaced 10 ft. apart. The diaphragms are of ¼-in. plate with a 3-in. flange all around, reinforced at top and bottom by 3-in. by 2½-in. by 5/16-in. angles. A pressed steel filler made of ¼-in. plate is fastened between the center sills at each cross bearer. The top cover plate is ½ in. thick and 8 in. wide.



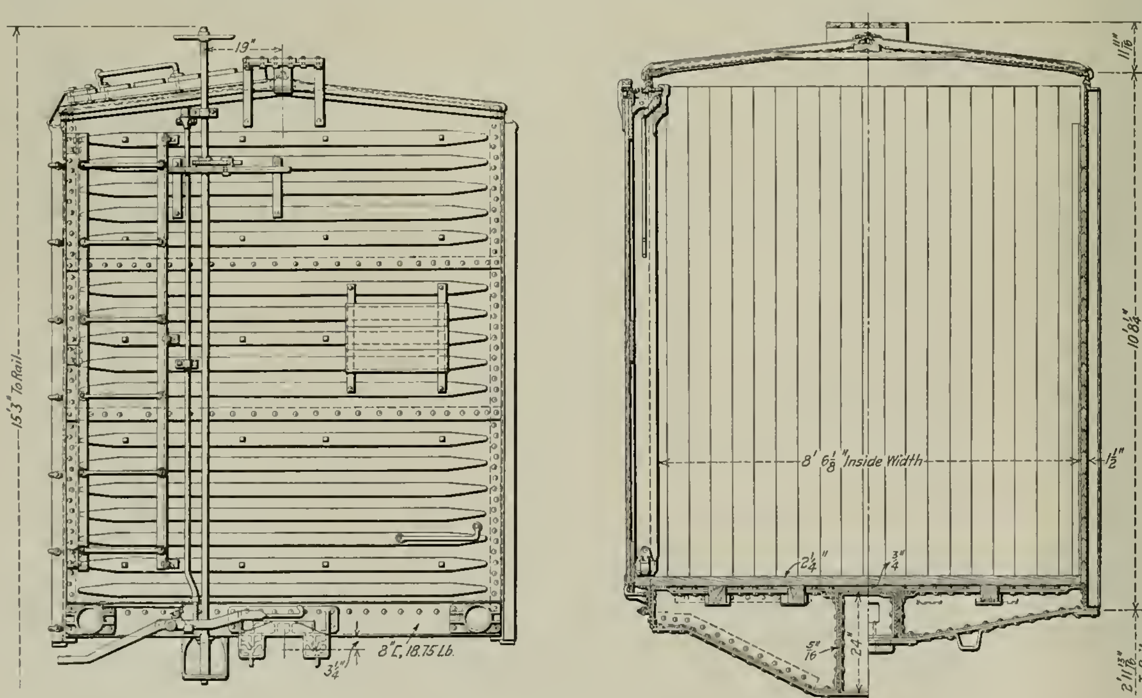
Underframe for the Illinois Central Single Sheathed Automobile Car and extends out almost to the side sill, while the bottom cover plate is 7/16 in. by 8 in. and is fastened directly to the side sill.

The side sills are made up of a 6-in., 16.67-lb. Z-bar of



Arrangement of End Plates and Roof Sheets

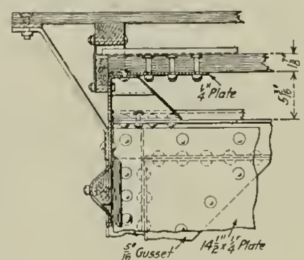
a special section incorporating a grain lock, extending from end sill to end sill. This Z-bar is reinforced under the door opening and for a short distance beyond at each end, by a



End View and Section of the Illinois Central Automobile Car

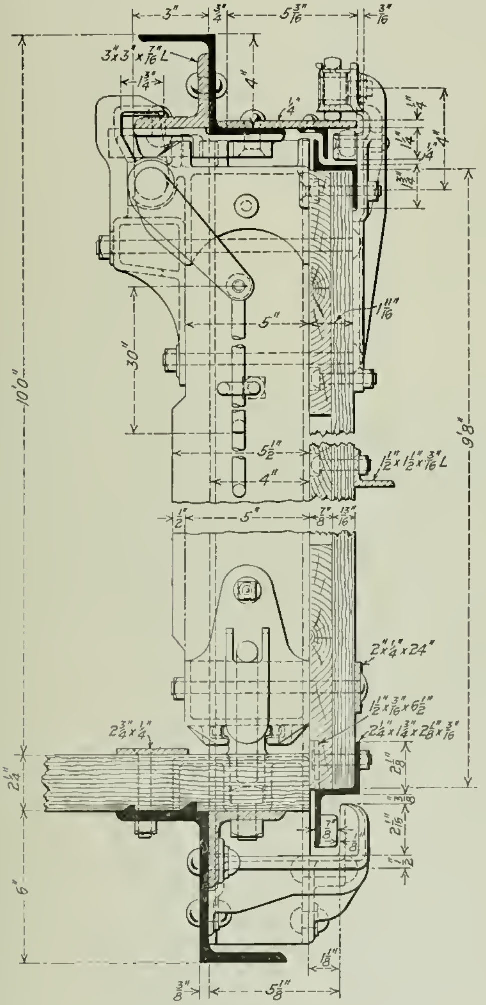
4-in., 8.2-lb. Z-bar riveted to the lower flange of the 6-in. Z-bar. The two sections thus form a channel which fits over the end of the cross bearer, the cross bearer bottom cover plate being riveted to the lower flange. The bottom cover plate of the body bolster is likewise fastened to the outwardly extending flange of the 6-in. Z-bar and a malleable iron jacketing casting is placed beneath the cover plate. The side sills and end sills are riveted together at the corners and are reinforced by a 5/16-in. plate. There are diagonal braces extending from the corner of the underframe to the intersection of the center sill and body bolster, made up of 3/8-in. plate 12 1/4 in. wide, flanged in the center to a channel section. There are six floor beams on each side of the car made of 4-in. Z-bars riveted to the center sill stiffeners and to short sections of 4-in. by 3-in. angles riveted to the side sills.

The corner posts are 4-in., 8.2-lb. Z-bars and the side posts and braces are 3-in., 6.7-lb. Z-bars, with the exception of the door posts, which are of the same section as the corner posts. The posts and braces are joined at the top of the 14 1/2-in. by 1/4-in. side plate girder which extends from the end post to the door posts and is riveted to the web of the 4-in. Z-bar side plate. The side plate is reinforced at the center by a 3-in. by 3 in. by 7/16-in. angle riveted to the web of the Z-bar and overlapping the side plate girder for a distance of 2 ft. at each end. The end posts are braced by 2 1/2-in. by 3/8-in. diagonal end straps and also by flanged corner angles made from 5/16-in. plate.



The end is of the Murphy pressed steel type, the two lower sections being of 1/4-in. plate and the upper sections of 3/16-in. plate. The bottom section is flanged inward, and is riveted to the 5-in. by 3-in. angle on the inner side of the end sill. Five transverse furring strips are provided to hold the end lining.

The floor of the car is supported on yellow pine stringers 4½ in. wide and 4 in. high. Between the body bolster and the end sill there is but one stringer on each side, but in the center of the car there are two. The stringers are continuous over the floor beams, but end at the cross bearers to which they are attached by short sections of Z-bars riveted to the upper flange. The flooring is 2¼-in. yellow pine, shiplapped, bolted to the side sills and nailed to the stringers. The siding is 1½-in. by 5¼-in. yellow pine, tongued and grooved, bolted to the posts and braces. The lower course of the siding fits over one of the ridges on the side sill, thus forming a grain lock. The siding extends to the



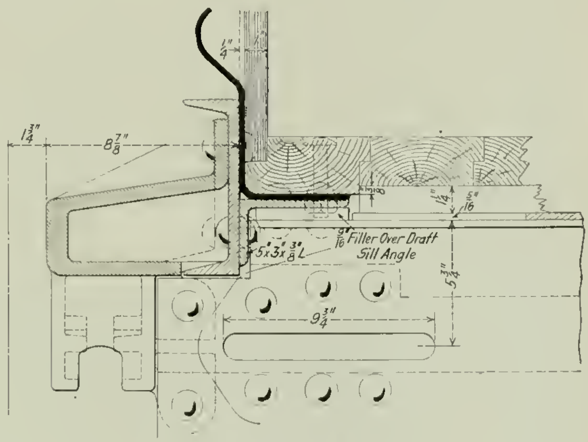
Side Door Post and Sections of Side Framing at Door

steel end sheet and an angle iron is fastened in the corner where it meets the 1-in. end lining, this angle being bolted through the side lining and the web of the corner post and also to the corner board in the end lining.

The door posts are spaced 10 ft. 5¾ in. apart, and are staggered, the distance from the center line of the car being 3 ft. and 7 ft. 5¾ in. respectively. There is a movable center door post of white oak, 4 in. by 5½ in., with top and bottom shoes of malleable iron engaging malleable housings, one on the side plate and the other in the floor. When the center post is moved over adjacent to the door post, there is a clear door opening of 10 ft. 1¾ in. When it is brought over to the point where the two doors meet it is automatically locked in position and can be bolted to the frame of the smaller door leaving an opening which is six feet wide.

The doors have steel frames made up of Z-bars at the top and bottom and angle irons at the sides with a transverse reinforcing angle across the center. The stiles, rails and braces are ⅞ in. and the sheathing is 13/16 in. thick. Camel door fixtures are used throughout.

The roof is supported on 13 carlines made of ¼-in. pressed steel plate and riveted to the top flange of the side plate Z-bar. The roof is of the all-steel type with galvanized sheets of No. 16 U. S. gage. The trucks are of the Vulcan cast steel type with cast steel truck bolsters equipped with Barber lateral rollers and a drop forged truck center plate. Brake beam safety bars made of 3-in. by 3-in.



Section Through End Sill

angles are attached to the spring plank. The air brake is the New York Air Brake Company's schedule CF-C-10 with J. M. expander ring.

SHOPPING RECORD FOR PASSENGER CARS

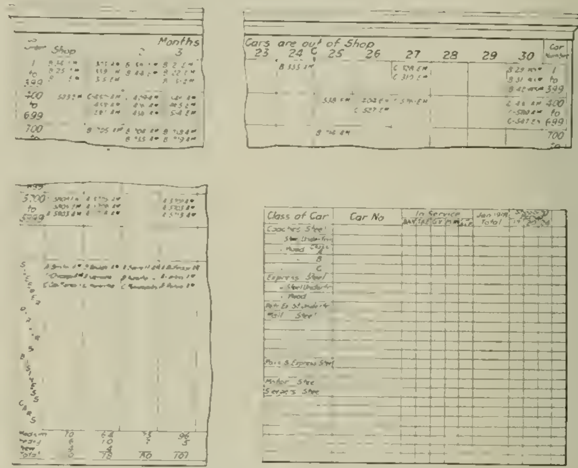
In the offices of passenger car shops it is necessary to keep records of the shopping of individual cars from which to prepare lists of equipment due for shopping. The usual form of book record is not entirely satisfactory for this purpose, as it does not make readily available the general data which are often of extreme importance. For instance, if information is desired concerning the number of cars which will be due for shopping in any particular month, it is necessary to check the records of every car unless separate statements are prepared on which this information is shown. The Chicago, Milwaukee & St. Paul has in use at its Milwaukee shops an ingenious arrangement called the passenger shopping record board, which makes it easy to compile such data and shows the condition of the equipment almost at a glance.

In order to give a clear explanation of the working of this device it is necessary to state some of the general rules governing the passenger car work. The road makes a practice of overhauling cars at regular intervals as follows: steel cars 17 months, steel underframe cars 20 months, wooden cars 24 months. The cars may receive light repairs for some special reason, but this does not affect the shopping period.

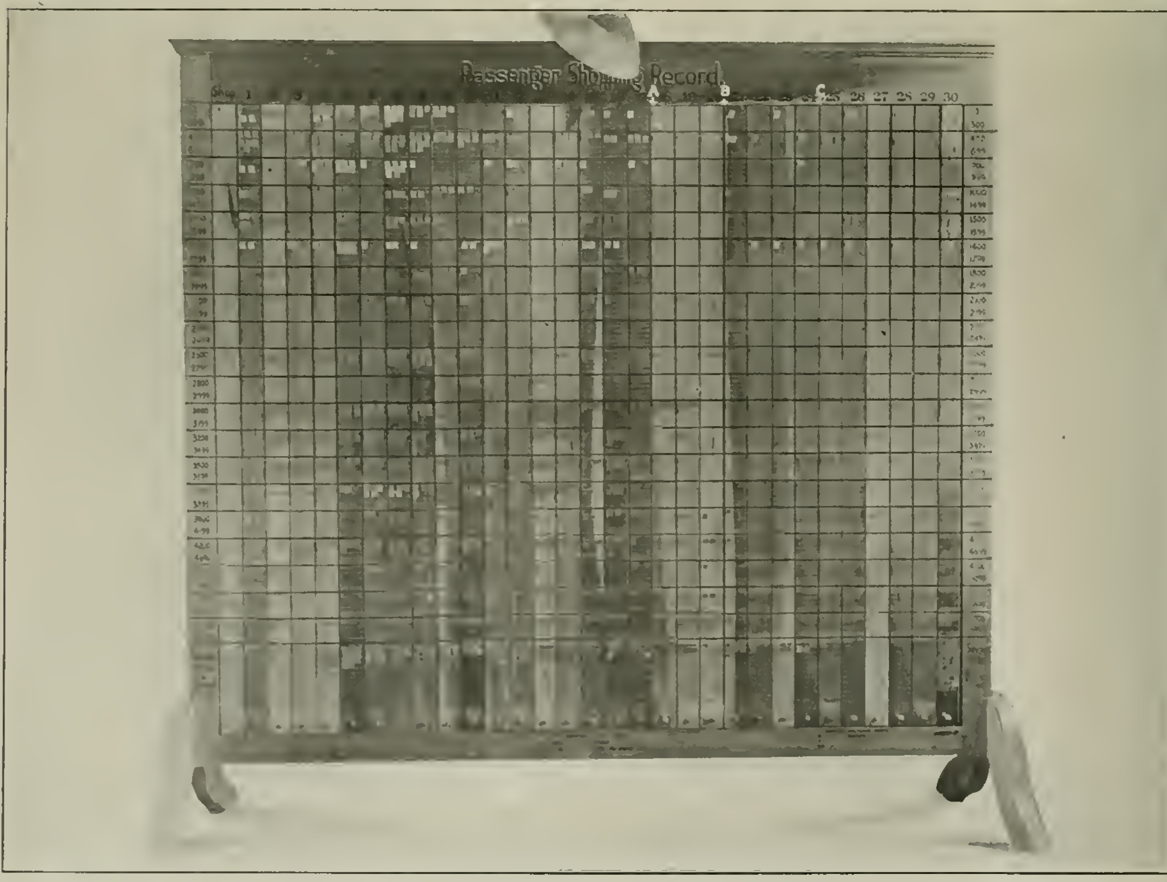
There are four shops where general repairs are made located at Milwaukee, Wis., Minneapolis, Minn., Dubuque, Iowa, and Tacoma, Wash. Repairs are classified as medium or heavy repairs and rebuilding, and some new cars are built.

The shopping record furnishes information concerning the cars and the last shopping in a convenient form. The record is kept in a frame approximately 8 feet high and 9 feet wide, this large amount of space being necessary, as the road has 1,670 passenger cars. The frame carries 31 narrow vertical panels in which are inserted small cards, each of which represents a passenger car. These panels slide in grooves along the top and bottom of the frame and those at each end are held in place by latches and can be removed if desired. The panel at the extreme left carries cards for the cars in the shops, the next has the card for all cars out of the shops one month, and so on across the board, the last panel carrying the card for all cars out of the shops 30 months or longer. The panels are divided into sections for the various series of cars, and in this way the different types as steel coaches, wooden coaches, express cars, etc., are separated. The cards, which are inserted in slots in the face of the panels, are of three different colors, red for steel cars, blue for steel underframe cars and white for wooden cars. On each card there are distinguishing marks to show the type of car (steel, steel underframe or wood), the number or name, the shop at which it was last repaired and the class of repairs it received. For example, a typical notation would be as follows: A-5718-A-M. The prefix *A* indicates that this is a steel car due for shopping at intervals of 17 months, the number shows that it is a tourist sleeper and the suffix *A-M* that it received its last shopping at Milwaukee, and was given medium repairs. If this card was shown in panel No. 7 it would indicate that the car had been repaired seven months before.

At the top of the frame between panels 17 and 18 is a letter A, indicating that steel cars beyond this point are due for shopping. It is easy to check over the red cards in



Monthly Blueprint Record of Car Repairs



Board for Keeping Record of Passenger Car Repairs the panels to the right of the letter and determine the number of steel cars which require repairs. Similarly, the limits for the steel underframe and wooden cars are shown after 20 and 24 months, respectively. When a car comes into the shop for classified repairs, the old card is removed from the rack and a new card is made out and placed in the shop panel. At the first of each month the board is changed. Panel No. 30 is removed and placed in the shop column, moving each board one column to the right. Cars overdue for the shop and not yet brought in are replaced in panel No. 30, and cars still undergoing repairs are replaced in the shop column.

The passenger shopping record is located in the office of the general supervisor of passenger cars. While this is convenient for the main shop, it is desirable to have the same information available in the other shops, and for that reason the record as it stands at the first of each month is reproduced on a tracing, and blue prints are sent to all shops on the system. This blue print also has a list of the classes of cars, the numbers and the roads to which they are assigned. In addition it has a summary of the repairs for each month and a statement of the number of cars overdue for repairs, with comparative figures for the two preceding months. From the description given above, it is easy to see how readily the shopping record in this form can be analyzed to obtain any information desired as, for instance, the number of cars of any series overdue for the shop, the number of steel or wooden cars that will fall due for shopping in any particular month, etc. On any road having a large number of passenger cars, such a device will prove very useful.

Freight Car Repair Standards

Government's Requirements Ambiguous; Interpretations Needed If Extravagance Is to Be Avoided

BY A MECHANICAL ENGINEER

A CLOSE study of the effort to establish "Material Standards for Freight Car Repairs," as outlined in U. S. R. A. Mechanical Department Circular No. 8 cannot but serve to convince the unprejudiced reader that it contains many ambiguities which are difficult of interpretation, that in many cases its observance is impracticable, and in other cases if followed would accomplish the introduction of the specified standards only at an expense totally unwarranted by the actual benefits realized. The introductory clause of this circular reads: "When renewing parts or applying betterments to freight cars owned by railroads under federal control, if suitable material, either new or second-hand, that is standard to the car, is in stock, it shall be used. Where such material is not in stock, material standard to United States standard cars should be used, if available."

Interpreting the above clause in strict accordance with its reading, it would appear that should parts "standard to the car" not be in stock they may not be manufactured or purchased even if readily available by manufacture or purchase, and regardless of all considerations of economy of repairs "material standard to the United States standard cars should be used, if available." Just what does "if available" mean, and to permit the observance of the most elementary principles of economy should not the conclusion of these general instructions have read, "*if readily applicable to the cars to be repaired?*"

Some of the rules set forth appear to be particularly impracticable of application and unwarranted.

Rule No. 3 reads: "Side bearings—If body or truck side bearings require changing, or renewing, frictionless type should be used, interchangeable in capacity and dimensions with those used on United States standard cars."

The committee appointed to consider the general subject of freight car repairs doubtless acted in accordance with its best judgment in deciding to extend the use of a device standardized for new cars by adopting it for repairs to cars in service. Nevertheless, it would seem that frictionless side bearings had not received a sufficiently strong majority endorsement by railroad mechanical department heads to warrant anything more than their recommended use in freight car repairs where conditions permit application without radical change in body or truck bolsters. Any one with a knowledge of the varying side bearing conditions obtaining on the multiplicity of freight car designs in service today can appreciate the problem involved in replacing the ordinary rub side bearings with the frictionless type interchangeable in dimensions with those used on United States standard cars. In many cases such replacement could not be effected for lack of space between the bolsters at the point of attachment of the side bearings; in other cases because the side bearings are cast integral with the bolsters.

As to the stipulated "interchangeability in capacity" with frictionless side bearings used on United States standard cars, an investigation will show that frictionless side bearings have not been and are not rated in accordance with capacity, the efforts of each individual designer being all in the direction of the development of devices whose several parts would continue to function properly and which could be maintained in working condition at minimum cost under the maximum side bearing loads generally obtaining.

Rule No. 4 reads: "Side truck frames—When necessary to renew side truck frames, cast steel U-shaped section, United States standard car type, with separable journal boxes, to be uesed."

The superiority of the cast steel side truck frame to the built-up arch bar type in rigidity, ultimate strength and durability no doubt justified its selection for the United States standard cars, but from the standpoint of supply available for quick repairs there are many who will question the propriety of designating the U-shaped section to the exclusion of the several T-shaped section designs that have given satisfactory service.

With respect to the specified exclusive use of the cast steel truck side frame for renewal of side frames in service: The intent and purpose of rule 4 evidently is the gradual elimination of all arch bar side frames and their replacement by the cast steel U-shaped section United States standard car type. A rigid adherence to this rule would obligate all railroads to immediately secure and carry a stock of the standard cast steel frame. Further, the wording of this rule is so indefinite that it seems necessary that supplementary instructions be issued stating the extent of failure which would constitute sufficient cause for renewal; that is, what proportion of the several members of the arch bar side frame should fail to warrant complete replacement with the cast steel side frame in preference to making easy and quick repairs by renewal of one or more of the individual parts.

The very extensively used M. C. B. arch bar side frame, being a built-up structure composed of solid rectangular bars, columns and column bolts, is very seldom subject to failure in its entirety, and as all of its component parts have been M. C. B. standards for many years and as such are carried in stock by all railroads, this type of side frame lends itself to quick and economical repairs.

The quite extensive adoption and use in recent years of cast steel side frames of the pedestal type, requiring a design of journal box differing from the strictly M. C. B. standard type, presents an obstacle to the use of the standard side frame required by rule No. 4 in making renewals that could be overcome only by entire disregard of all consideration of economical repairs. It can be readily seen that in replacing a failed side frame of this pedestal type with the United States standard car type it would necessitate scrapping the journal boxes or assigning them to storeroom stock for a possible future need which might never develop.

Rule No. 6 reads: "Draft gears—(a) Friction draft gears, either Cardwell, Miner, Murray, Sessions Type 'K' Westinghouse, or similar gears, to be of not less than 150,000 pounds capacity with a maximum travel of 2¾ in.

"(b) Spring draft gears, if used, to be at least equal in capacity to two M. C. B. Class 'G' springs, interchangeable with friction gear without change in car construction.

"(c) Clearance between coupler horn and striking casting to be 3 in.

"(d) Coupler to be key connected to draft gear."

Clause (b) of rule 6 seemingly permits the use of spring draft gears of a minimum capacity of 60,000 lb., but the qualifying stipulation reading "interchangeable with friction gear without change in car construction" effectually nullifies this seeming concession, as the most casual investigation will show that no known modern arrangement of draft castings suitable for tandem or twin M. C. B. class "G" springs can be designed so as to likewise provide for friction draft gears.

This qualification being present in rule No. 6, the use of friction draft gears becomes obligatory on steel reinforcements (either draft arms or through center construction) applied to wood underframe cars, or in the replacement of spring draft gears on steel cars where suitable draft attachments standard to the car are not in stock.

The difficulties and expense incident to replacing spring draft gears, either tandem or twin, on the many steel cars so equipped, by friction draft gears are too obvious to dwell upon, and if investigated would convince operating officials of the entire impracticability of this clause of rule No 6 and the enormous expense entailed.

Metallic draft arms in the past ten years have been found a very satisfactory, adequate and economical means of reinforcing wood underframe cars, but under rule No. 6 such draft arms must now be used in conjunction with friction draft gears. This brings about the concentration of the entire buffing shock on the center line of draft, with a resultant moment of force about the neutral axis of the section of draft arms above the bolster (which is limited by the design of the car) of such magnitude that stresses will be set up in the metal that are in excess of its elastic limit. This condition does not obtain with a 60,000-lb. capacity spring draft gear and a 2-in. coupler horn clearance, because the buffing shock delivered on the center line of draft is limited to the spring capacity, after which, with the coupler horn in contact with the striking plate the eccentricity of shock is very materially reduced. In other words, in using spring draft gears with metallic draft arms and two-inch coupler horn clearance it is possible to keep within the M. C. B. maximum ratio of unit stress to end load of .15, while in many cases it is not possible to meet this requirement with friction draft gears. Are we to eliminate an altogether satisfactory and economical method of reinforcing wood underframe cars which, when used in conjunction with spring draft gears can be designed to meet a very essential M. C. B. requirement, but which in many cases cannot be so designed when combined with a friction draft gear in an underhung draft rigging?

The foregoing is predicated in the case of spring draft gears on a clearance of two inches between the coupler horn and striking casting. Clause (c) specifies a three-inch coupler horn clearance, but when and how this is to be obtained is left to the ingenuity of the railroad making repairs. On many existing designs of underframes its reduction to practice would result in overstressing the center or draft sills between end sill and bolster.

The statement is ventured that in the opinion of many mechanical department heads spring draft gears are entirely satisfactory on any design of adequate steel reinforcement for wood underframe cars and that the greatly increased cost of applying friction draft gears to equipment of limited life and value is not justified.

Rule No. 8 reads: "Doors—Side doors on box or stock cars (except double deck stock cars) will be bottom supported and the attachments uniform with those on United States standard cars."

While there may be but few railroad men who will question the superiority of the bottom hung side door to the top hung door, it is difficult to understand the viewpoint of the committee on car repairs in making the bottom hung door an absolute requirement for repairs. In many cases this would necessitate extensive alterations at the side plate and side sill, and possibly involve rebuilding the doors themselves at a cost many times greater than that involved in merely replacing all the original door fixtures.

Rule No. 9 reads: "Ends—Box cars with weak constructed ends requiring two-thirds of end to be renewed should be reconstructed as follows:

"(a) Horizontal corrugated steel ends (two or three-piece) having top section three-sixteenth inch thick, and bottom section or sections one-fourth inch thick and corrugations 2¼ in. deep.

"(b) Vertical reinforced ends with 4 or 5 in. 'Z' bars securely fastened to place on end sills and end plates. End plates to be diagonally braced on inside of car, under roof, to side plates, or with reinforcements equivalent in strength."

While a certain latitude is permitted in renewing weak constructed ends because of the two different methods stipulated, an analysis of clause (a) of this rule discloses the fact that it becomes necessary to use one proprietary structure, notwithstanding the fact that the U. S. R. A. specifications for new cars permit the alternate use of three different types of steel ends. To those railroads to whose cars another design of steel end might be more economically applied the injustice of this very narrow restriction is most apparent.

Rule No. 12 reads: "Roofs—When roofs are changed or renewed, outside flexible type metal roof made of 22 or 24 gage galvanized iron with mullions between roof sheets and with flexibility at eaves and ridges, will be applied. Roofs should be interchangeable with United States standard cars having same length and width sheets. To permit the use of standard sheets, the following changes may be made:

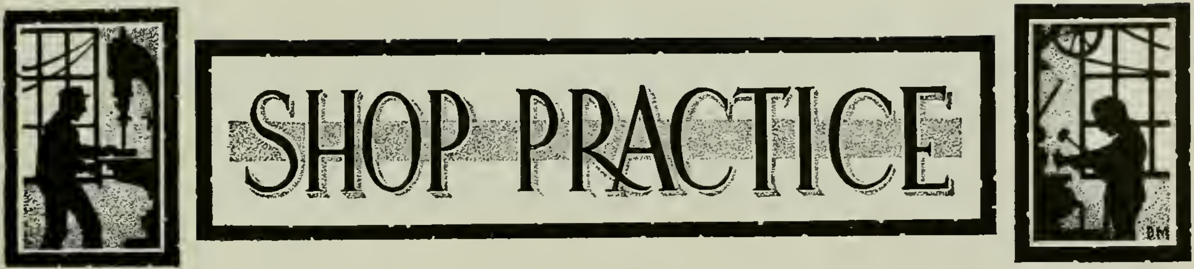
"(a) Increase or decrease in thickness, or omitting eave molding, fascia, or both.

"(b) Increase the width of roof flashing at eaves.

"(c) Where cars are equipped with all metal roofs, such construction may be continued when renewals are necessary, if considered desirable."

The effect of this rule on freight car repairs and its practical application is largely a question of interpretation. Taken by itself its observance is required only "when roofs are changed or renewed," but when linked up, with the introductory clause of the circular, it apparently becomes necessary to remove without regard to expense a partly worn-out all-wood or inside metal roof.

There are many who endorse the benefits and economy to be derived from standardized freight cars and locomotives building and hereafter built, while there are also many who oppose such rigid standardization as has been adopted for United States standard cars, but those who advocate standardized new equipment could not pursue a plan better calculated to discredit their views than by acquiescence in the enforcement of Mechanical Department Circular No. 8. If held to be mandatory and put into execution, it would add such a burden of increased cost of freight car maintenance as to rival the increase in direct labor operating costs already imposed by government control. It is an abortive attempt to extend standards never originally contemplated for anything but new cars of one general predetermined design to some two million (2,000,000) cars of a multiplicity of designs now in service without regard to the enormous cost involved, and it would seem that the Railroad Administration in approving it had acted with a very indefinite knowledge of what its actual reduction to practice would mean.

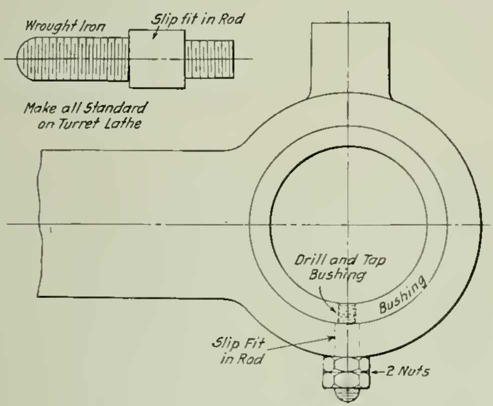


AN IMPROVED KEY BOLT FOR PARALLEL RODS

BY J. H. HAHN
Assistant Roundhouse Foreman, Norfolk & Western, Bluefield, W. Va.

The illustration shows an improved key bolt for securing the bushings in locomotive side rods. The bushings are applied in the usual way and the rod and bushing drilled, the bushing being tapped to receive the key bolt, which is applied with a stud driver and screwed up to the shoulder good and tight. The rod and the bushing is drilled in one operation and, owing to the fact that the hole in the bushing is smaller than the hole in the rod, a drill having two sizes is made especially for the purpose. Also in tapping the bushing a small case hardened bushing that serves as a guide for the tap is inserted in the bushing and, after tapping the hole in the rod bushing, is removed.

On the heavier classes of locomotives considerable trouble is experienced with the bushings getting loose, and whenever



Key Bolt for Holding Bushings in Side Rods

this happens it becomes necessary to remove the rods and shim the bushings, and when a middle connection side rod has to be removed for loose bushings it means quite an item for labor and time the engine is out of service. This rod key bolt was designed to eliminate a great deal of this trouble. If, when this key bolt is used, the bushing gets loose in the rod it can be held firmly in place by tightening the inside nut shown on the stud and locking it with the lock nut. As an additional precaution a cotter can be applied to the end of the stud. This will securely hold the bushing and permit additional mileage. As a matter of fact this can be repeated until the bushing becomes too large for the pin when, of course, it will become necessary to apply a new bushing.

The writer has applied quite a number of these key bolts and has always found them satisfactory. The key bolts can be made on a turret lathe and carried in stock ready for use.

RAILWAY WOMEN EMPLOYEES

The annual report of Director General McAdoo to the President contains a summary of the number of women employed and the character of the work for the dates of January 1, April 1, July 1, and October 1, 1918. The total number of all classes of employment has increased as follows: 60,555 on January 1, 65,854 on April 1, 82,370 on July 1, and 101,296 on October 1. The occupations served by the women are divided into 21 classes, which are shown in the following table, with the number of employees in each class on October 1, 1918:

Attendants	2,390
Bridge tenders	12
Car department	684
Clerical or semi-clerical	73,285
Cleaning	5,555
Elevator operators	97
Messenger service	736
Personal service	2,796
Roundhouse work	1,365
Shopwork	5,091
Signal service	220
Station agents, assistants and agent operators	377
Supervisors of women employees	113
Switch tenders and other yard work	50
Telegraph operators	2,396
Telephone operators (train orders, blocking and reporting trains)	2,613
Track work	872
Train service	100
Warehouse and docks	1,461
Watch women	518
Other service	565
Total	101,296

It will be seen from the above that the largest group is included under "clerical or semi-clerical," in which there are 73,285, or about 72 per cent of the total number. Of the remainder, 11,864, or 11.7 per cent, were employed chiefly in mechanical department work, being divided as follows:

Car department:	
Coach and car carpenters, helpers and apprentices	65
Coach and equipment painters	52
Coach and car repairers	46
Pattern makers, helpers and apprentices	3
Upholsterers and seamstresses	124
Other car work	394
Total	684
Cleaning:	
Car cleaners	3,704
Stations and offices	1,286
Shops	284
Other cleaners	281
Total	5,555
Messenger service:	
Day work	727
Night work	9
Total	736
Roundhouse work:	
Calling crews	66
Cleaning headlights and lanterns	20
Roundhouse clerks	204
Supplying engines	27
Wiping engines	1,000
Turntable operators	48
Total	1,365
Shopwork:	
Blacksmiths, helpers and apprentices	35
Boilermakers, helpers and apprentices	6
Coppersmiths, sheet-metal workers, pipe fitters, helpers and apprentices	14
Electricians, helpers and apprentices	36
Laborers (inside work)	3,316
Laborers (outside work)	1,314
Machinists, helpers and apprentices	370
Total	5,091

While the total number of women employees increased from 60,555 on January 1 to 101,296 on October 1, an increase of 67 per cent, the number employed in the classes pertaining particularly to the mechanical department, as above mentioned, increased from 5,978 on January 1 to 11,864 on October 1, or an increase of 98½ per cent.

INTERESTING SHOP DEVICES AT TRANSCONA

BY S. LEWIS
General Foreman Blacksmith, Canadian Government Railways, Transcona, Man.

No department of a modern shop engaged in either manufacturing or repair work has any greater effect on the output of the plant than the tool department. The Canadian Government shop at Transcona, Man., appreciates this fact, and is well equipped with modern tools and jigs for facilitating work and for reducing the cost of production. Every encouragement is given the men by the management to devise special devices for doing their work easier and in a shorter space of time. The following is a description of three devices that have given particularly good results.

JIG FOR MAKING GREASE PLUG NUTS

Fig. 2 shows a simple and effective jig for boring, facing and tapping nuts for grease plugs, which was designed by J. Darlington, foreman of the machine shop at this point. This device, which is attached to an ordinary drill, has two

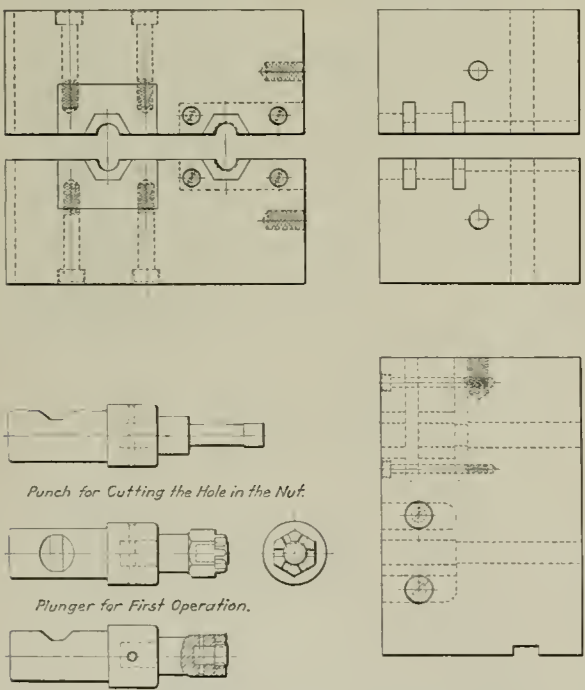


Fig. 1—Dies and Plungers for Making Castellated Nut

sliding V-blocks on top, which hold the hexagonal nut during the operation. These blocks are operated by adjusting screws as indicated in the illustration, which enable tne operator to locate the nut directly over the center of the hole in the jig.

In the base of the jig there is a brass bushing which acts as a steady rest for the boring bar, in which are located two cutters, the lower one boring the nut and the upper one facing it. Both operations are performed with one setting.

An ordinary tap, arranged as indicated in Fig. 2, is used for tapping the nut. The square head of the tap fits into

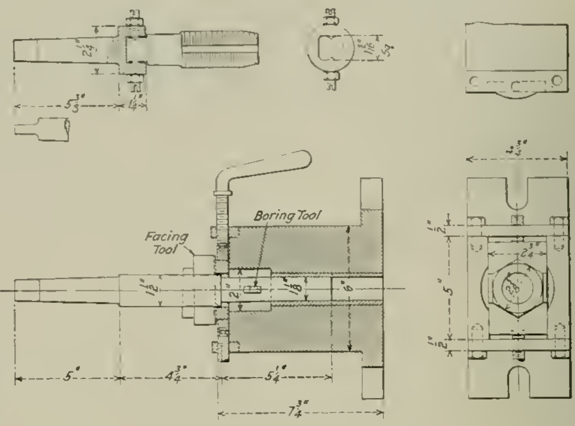

Fig. 2—Jig for Finishing Hex-Nuts

a socket and is held in place by two screws, having lock nuts, which are located on opposite sides of the socket.

Previously this work was done on a lathe, and it took from

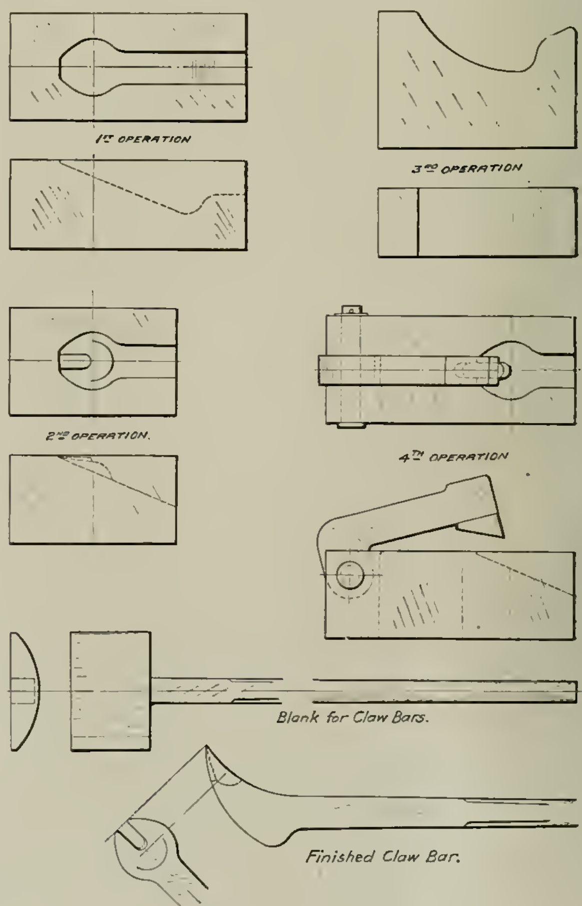

Fig. 3—Dies for Making Claw Bars

14 to 15 minutes to properly finish it, but with this jig on an ordinary drill this nut can be finished in 3½ minutes.

DIES FOR MAKING CASTLE NUTS

A set of dies and plungers used on a 2½-in. Ajax forging machine for making 1-in. castle nuts is shown in Fig. 1. With this equipment these nuts can be produced in one heat with three blows and without wasting the stock. The dies are made in two pieces to facilitate machining operations, and so that the working parts may be renewed without difficulty. The body of the dies is of mild steel, and is made from scrapped axles, while the working parts are made of Peerless *A* steel, which is hardened in air.

The first operation is performed by the plunger, two views of which are shown at the bottom of Fig. 1. It upsets and forms the castellated grooves in the head of the nut. It is of simple construction, being made in three parts, so that the wearing parts may be easily renewed. The body is made of mild steel and the other parts of 60-point carbon steel. The outside of the plunger is provided with six wings on the outside and has an inserted member for forming the inside of the nut. The punch for cutting the hole is shown above the forming plunger. Its functions are to complete punching the hole in the nut and at the same time sever the bar from the nut. It is made in two parts, the body being mild steel and the punch 60-point carbon steel. The diameter of the bar stock used for making the nuts must not exceed the root diameter of the thread in the finished nut.

CLAW BAR DIES

Fig. 3 shows a set of dies used under the steam hammer for making claw bars. These were designed by George Weston, blacksmith at this point. Four sets of dies are required for this work. The first operation gives the necessary deflection to the prepared blank. The second operation more completely forms the nose of the tool. The third operation definitely shapes the head of the bar, and the fourth operation completes it. The claw bars are made from scrap tire steel and weigh about 28 lb. The dies are simple and produce a very satisfactory bar at small expense.

Spot Welding Railroad Tinware

Illinois Central Finds Process Applicable on Wide Range of Work; Cost Materially Reduced

A LARGE proportion of the sheet metal work used on railroads is subjected to rough usage and for that reason it must be strong if it is to give satisfactory service. In order to secure the required strength, the joints in many cases must be riveted. Riveting is slow and therefore an expensive operation, especially when the rivets must be soldered to prevent leakage. The process of spot welding has been applied to the manufacturing of sheet metal ware during the past few years with great success. As the simplicity of the process and the great strength of the joints seemed to make it well adapted for railroad work the Illinois Central about a year ago investigated the possible savings that could be effected and purchased a 10 kw. automatic welding machine, manufactured by the Automatic Electric Welding Machine Company, New York.

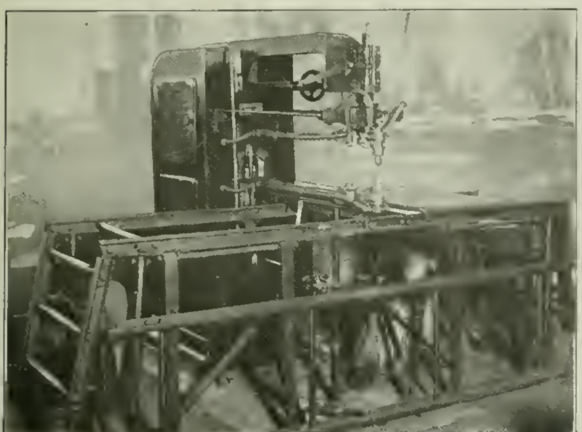

Fig. 1—Automatic Spot Welder of 10 kw. Capacity Used at Burnside Shops

A general view of this machine is shown in Fig. 1. It consists of a case containing the electrical mechanism with two arms extending from the front to which the electrodes are attached. The lower arm can be moved vertically by a screw engaging a crosshead at the front of the frame. The upper arm is stationary, but the electrode is mounted on the end of a bell crank operated through a horizontal rod from a cam in the body of the machine. This machine has a three speed transmission driven by a ½-hp. 220-volt A. C. motor. A hand wheel at the left of the upper electrode varies the speed to give one revolution in one, two or four seconds. On the cam shaft is a magnetic clutch operated by a pedal switch on a flexible cable. If the operator presses his foot on the switch once, the machine makes one weld, but if he holds his foot on the switch one weld will follow another at regular intervals, depending on the speed for which the machine is set.

The cam action is transmitted to the bell crank through a lever and then through a horizontal pressure rod. The lever has an adjustable fulcrum providing a lift of ¼ in. to 1½ in. for the upper electrode. The pressure of the electrode on the work is changed by a hand wheel which varies the stress on the spring in the pressure rod to the bell crank. The electrodes are cooled by a continuous flow of water. The points have a Morse taper fit and are adjustable for various types of work.

The time during which the current flows is regulated by a hand wheel on the right side directly opposite the speed control. The time can be varied by small increments from zero to two seconds which makes it possible to weld from the thinnest stock up to ⅜ in. on this machine. The capacity is dependent on three factors, the amperage of the transformer, the current between the electrodes and the length of time the welding current flows, all of which are automatically controlled in the machine, after the original adjustment has been made. The machine when once set for the gage of stock involved is automatic in its action. The amperage, pressure and time are adjusted by a foreman or electrician thoroughly familiar with the work of electric spot welding, after which any operator capable of feeding the work can secure perfect welds. The automatic features of the machine are important in reducing the cost of labor and in eliminating the waste due to burning or imperfect welds resulting from poor judgment on the part of the operator.

The machine installed at Burnside has proved well adapted for work on railroad tinware. It welds bright tin and black sheet iron very readily. The parts must be flat so that a good contact will be made between the contact points and the surfaces must be free from rust. Galvanized sheets are more difficult to weld satisfactorily, but by using a slow speed and a comparatively low current with small contact points the zinc coatings can be pierced and a good junction secured. In making ventilator screens it has been found quite feasible to weld brass screens to the galvanized frame.

Table I—Savings Effected by Welding Kettle Ears

Fastening Kettle Ears by Riveting	
Punching	$0.68
Riveting	1.53
Soldering over rivets	.68
Total labor	$2.89
Rivets	.50
Solder	.30
Total labor and material	$3.79
Number of ears riveted	576
Fastening Kettle Ears by Welding	
Labor	$1.20
Number of ears welded	576

The savings effected by welding can best be illustrated by citing a few examples of typical jobs. In fastening kettle ears on buckets, the former method was to rivet them on, covering the heads with solder. Spot welding is much quicker and the cost is only 32 per cent of the cost of the riveting. A detailed statement of the cost of doing this work is given in Table I.

Table II—Welding Compared with Other Tin Shop Methods

Name of part	Cost by former methods: Labor	Material	Total	Number made	Cost of welding	Number welded
Lamp chimney baskets	....	....	$10.56	100	$3.52	100
Sheet iron lamp shades	. ..	....	1.57	500	.85	500
Switch lamp lens bands	$20.00	$1.50	21.50	3,000	12.21	3,000
Stove pipe elbows	....	....	14.40	250	7.20	250
Ventilator screens	6.43	1.31	7.74	450	2.38	450
Split keys	52.00	10.00	62.00	20,000	30.32	20,000

Another typical operation to which spot welding has been applied is making the tops for water glass lamps. These were formerly soldered at a cost of $3.40 per thousand for labor and $.40 for material. The same quantity can be welded at a cost of $.85 for labor. On this job there is an additional saving in the material from which the parts are made. When solder was used it was necessary to make the tops of tin, but sheet iron can now be used. The cost of other typical parts are tabulated in Table II.

The manufacture of flat split keys is one of the principal jobs handled on the spot welder. To expedite the work a special attachment shown in Fig. 2 has been devised. The framework holds a stationary disc, the edge of which is set between the welding points. Above this disc is a movable disc with recesses around the edge, of the same size and shape as the end of the cotter. Above each of the recesses is a spring which holds the parts when they are placed in the slots. At each revolution of the cam shaft the disc is advanced the distance between the slots by a ratchet operated by an electrically controlled valve, thus bringing the two pieces making up the key into position between the electrodes. A contact is then made and the parts are welded after which the ratchet advances them one notch further. The welded cotter then passes over an opening in the stationary disc where a finger on a rod attached to a lever on

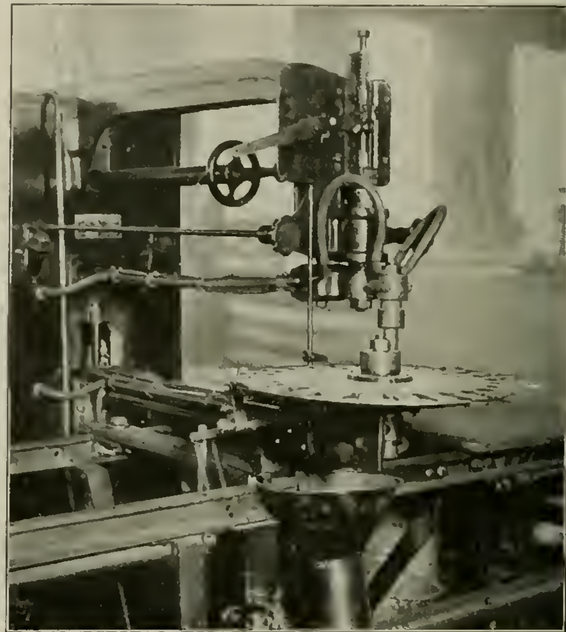

Fig. 2—Attachment for Welding Split Keys

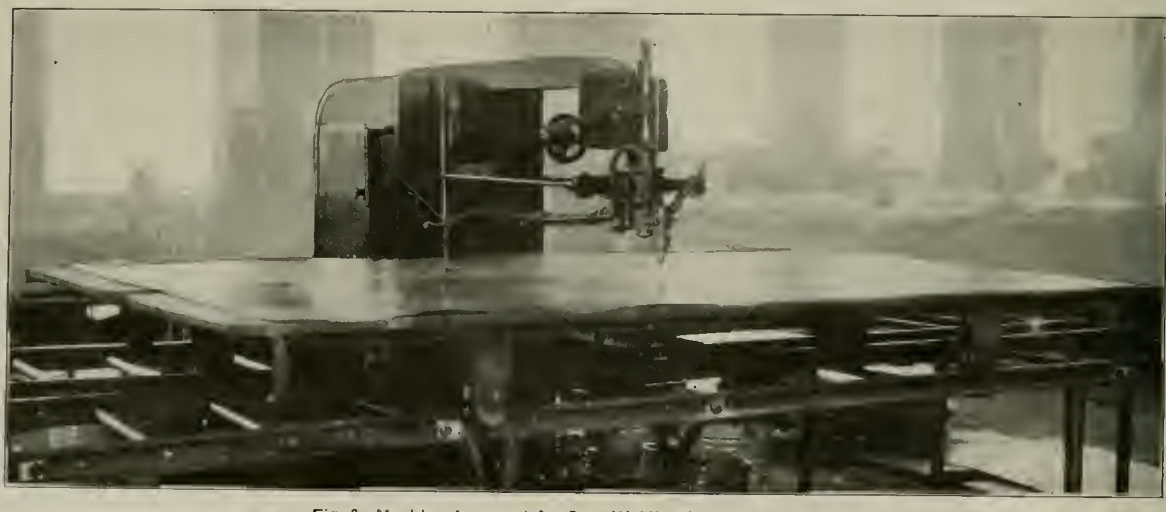

Fig. 3—Machine Arranged for Spot Welding Locomotive Jackets

the upper arm of the machine strikes it, causing it to drop into the receptacle beneath. The parts can be welded as fast as the operator can feed them. As many as 5,000 cotters have been made in seven hours.

Another important job for which special attachments have been made is the welding of locomotive jackets. The large sheets are placed on rolling tables as shown in Fig. 3 and are simply lapped and welded together along the edge at intervals of about ¾ in. to 1 in. The description of some of the typical parts made by spot welding as given above will serve to show the adaptability of this machine. Further developments are to be expected and devices of this type will probably become important adjuncts to railroad tinshops.

WHEN THE SEWING CIRCLE FAILED TO MAKE GOOD

BY HARVEY DE WITT WOLCOMB

Jim Haskins, the general foreman of the big shops of the Northwestern Railroad at Warren, was puzzled. Not alone puzzled, but disgusted also. He had just returned from his daily morning conference with the "Old Man," at which certain shop matters had been discussed and orders issued which Jim knew were contrary to the general policy of the shop. Heretofore the "Old Man" had always claimed that he did not care what the men or foremen did outside of shop hours; but this morning he had said that if big Bill Munson, the foreman of the boiler shop, did not cut out neglecting his family he would soon be looking for a new job. Bill Munson was a particularly good foreman, always on the job, a good mechanic himself and able to handle men. He actually obtained more work from two men than it was formerly possible to get from four men.

While Jim Haskins, as general foreman, worked with Bill practically every day in the week, he had never taken the trouble to look into his private family affairs and as long as the boiler shop was handled so efficiently, there was no need to investigate the man's home. Subconsciously, Jim Haskins felt that some one was trying to run Bill Munson off the job. By several remarks which the "Old Man" had made lately he knew there was a storm brewing. But why? Personally, he couldn't see one reason why Bill Munson wasn't the most valuable foreman they had. He had told the "Old Man" so, but he wouldn't have it that way. Jim had even quoted facts and figures to prove how much better Munson was than his predecessor, but to no avail. The "Old Man" had brought up little occurrences which Jim Haskins could remember when they were mentioned, but which had had no great weight on the management of the shop.

But now the "Old Man" was quoting these little things and placing so much emphasis on them that things actually looked bad for the boiler foreman. After Jim had left the office the thought suddenly struck him—where had the "Old Man" heard this stuff? Surely Munson had not said anything about his family affairs—Jim himself had not said anything about it—so where was the leak? To take such dirty, low-down, underhand methods to run a man off the job made Jim Haskins mad. He was a fair and just man himself. That was why he was so popular with all the shop men and was so successful as a shop manager. And he could not for the life of him understand why the "Old Man" would countenance any such doings.

Starting the day under these circumstances made Jim so disgruntled that he was on the war path all day. Try as he might, he could not get anything on the boiler department. Joe Kelly, the machine shop foreman, who Jim secretly knew was a wonderful man in the "Old Man's" estimation, but who was actually the poorest foreman he had, spoiled a driving axle, bored a set of driving boxes for the wrong wheels, nearly spoiled a new set of frames and was so careless that, driven to exasperation, Jim had to tell him frankly that if the machine department did not show a decided improvement it would soon have a new foreman. Under the conditions that morning I am not sure of all that Jim told the machine shop foreman, but he was in no mood to talk softly or mince his words, so you can wager that what he did say was forceful and to the point.

During the day many things came up which nearly drove Jim crazy, but he managed to pull through and was glad to go home where he could light his pipe and read his paper in peace.

As his wife was clearing off the supper dishes she remarked that the Munsons might move out of town. Being absorbed in his paper, Jim paid but slight attention to her remark and passed it by unnoticed. After finishing her work his wife brought out her mending and when Jim was refilling his pipe she remarked that Joe Kelly, the machine shop foreman, was talking about buying a home. Continuing she said: "Joe is a valuable man to the company and is sure of promotion and that is the only reason why he hesitates to purchase a home. He might just get nicely located and the company would move him to a better position."

"Yes, move him, but not to a better position if he don't mend his careless methods," grunted Jim. His wife noted that Jim was in no mood to talk, so the balance of the evening he was permitted to read his paper with no further interruptions.

The next morning as Jim started for the "Old Man's" office, he wondered what would be discussed. Engine failures were being held down to the minimum and the output was good. As he had had a good night's rest and the shop affairs were moving smoothly, Jim felt good natured. He even felt inclined to go in the boss's office, slap him on the shoulder and say, "Well, old timer, we've got them on the hip now. Everything is moving O. K."

But the minute he stuck his head inside the office door he could see trouble was brewing. The "Old Man" didn't waste any time, but started right in on Jim and bawled him out good and proper. To say that Jim Haskins was surprised is putting it mildly. He was dumbfounded! Since his appointment as general foreman at Warren he had doubled the shop output, had cut down engine failures, had reduced the pay roll, got along fine with the men and had carried on several improvements that were much to the advantage of the place, and now the "Old Man" was telling him what a poor stick he was. He told him all about his trouble with the machine shop foreman and informed him that the machine shop foreman was not responsible for such mistakes, but that he, the general foreman, was the one to blame. The "Old Man" even went so far as to say that the machine shop foreman would not be discharged, but if any such disgraceful recurrences came to his notice, the general foreman would have to do some explaining.

Can you imagine how Jim Haskins felt after a call-down like that? One day the "Old Man" wanted to discharge the best foreman on account of some trivial family affair and the next day he wouldn't allow the dismissal of a foreman who was the biggest failure in their organization. Poor Jim wondered who was stuffing the "Old Man" with all his misinformation. He tried to explain his position, but the "Old Man" would have none of it. Jim welcomed the opportunity to get out of the office when the chief clerk told him that something had just gone wrong with the turntable.

And again Jim's day was spoiled. He had started out in the morning well satisfied with conditions—in fact in fairly good humor, but the "Old Man's" talk had changed him into a frame of mind that was far from pleasant. He did not try to take any spite out on his foreman, but just the same he felt ugly enough to bite a ten-penny nail in two. He put in a most unpleasant day and was glad to escape to his home where he could eat his supper and enjoy a quiet smoke.

Again, as on the previous night, his wife ventured a remark that Joe Kelly had decided to buy that home. Subconsciously Jim felt that his wife had said something before about Joe Kelly. The Kellys were not neighbors of theirs, yet his wife seemed to mention their name a great many times. Puffing at his pipe like one of the big Mallets pushing a train up the hill, Jim reviewed in his mind all the occurrences of the past few days at the shop. Suddenly a thought struck him with such force that he yelled at his wife so loudly he nearly scared the poor woman out of a year's growth.

"Say," he said, "where do you hear so much about Joe Kelly, anyway?"

"Why, our sewing circle met this afternoon and while I was out in another room I overheard the master mechanic's wife telling how mean they used poor Joe Kelly at the shop. She said that it was a shame to pick on a good man like him and not to pay any attention to the disgraceful actions of a man like that Bill Munson. She also said that the Kellys were going to buy their home.

"By jimanetti," thought Jim, "I've got it! I've got it! It's that bunch of old hens who are trying to do poor Bill Munson. Some woman has an axe to grind and she is playing a smooth game." With that Jim began to question his wife and from her he could piece out a pretty good story of how this woman and that woman was working through her husband to try to influence the inside workings of the busy terminal at Warren. As Jim thought over the situation and recalled many little things which had been pulled off in the shops he could see the propaganda of the busy and ever watchful ladies' sewing circle. The master mechanic's wife was a prominent member. She was just foxy enough to work on her husband so that she influenced many of the orders he issued.

After turning the entire situation over in his mind several times Jim finally decided that the best way to fight fire was with fire.

The next morning he had a long talk with Bill Munson. During their conference they had several good laughs, and while Bill at first refused to follow Jim's instructions, he finally gave in.

Well, to make a long story short, Bill Munson's wife joined the sewing circle. She became a very prominent member and worked her way into the good graces of the master mechanic's wife.

Jim Haskins noted that the complaints about the boiler department seemed fewer and fewer. About two months after Jim Haskins awoke to the fact that wives play an important part in the management of a shop. He was agreeably surprised one morning by having the master mechanic remark that the boiler department was so efficient that he had recommended an increase for the foreman, Bill Munson.

Right there Jim Haskins smiled to himself, for he knew that instead of running a good man off the job, the sewing circle had actually been the means of securing him an increase in wages.

Increase in Coal Production.—Bituminous coal production in the United States during 1918, as reported by the National Coal Association, amounted to 587,500,000 tons, an increase of approximately 36,000,000 tons, or nearly seven per cent, over the production in 1917, which was in itself a record.

A CONVENIENT STAND FOR AIR PUMPS

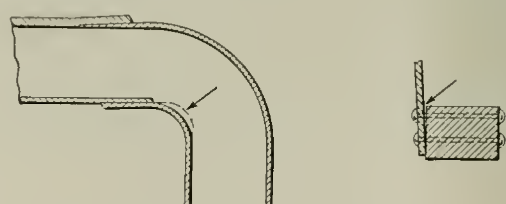
In overhauling air pumps it is desirable to have them mounted so that the cylinders can be placed either vertical or horizontal as desired. The stand shown in the illustration below, which has been in use for some time in the Joliet shops of the Elgin, Joliet & Eastern, makes it easy to bring the pump into any position. The stand is supported by a heavy post bolted to the floor. Near the top of this post is pivoted a disc made up of two plates riveted together to obtain the required stiffness. Behind the bottom of the disc and attached to the post are rollers which help to support the plate and make it easy to turn. There is also a cross piece attached to the post with a pin in the cross piece fitting into holes in the rear plate, thus holding it securely in any position. This stand is particularly suitable for cross compound pumps.

A Stand Used for Holding Air Pumps When Making Repairs

MAKING MUDRING CORNERS TIGHT

BY JOSEPH SMITH

No one knows better than the roundhouse man what a hot, dirty job is occasioned when an engine is reported with the back mudring corners leaking. Not only this, but many times it means a serious delay in engine service. By carefully noting the reasons for this condition we have come to the conclusion that 95 per cent of the troubles are due to



Imperfect Fit at the Mud-Ring Corners

the fact that, as shown in the illustration, there is a space of ¼ in. to ⅜ in. between the sheet and the top of the mudring. Cracks frequently occur in the sheet around the corners at the top row of rivets, and while welding them will help for a little while, it is finally necessary to cut out the sheet and weld a new piece in. This trouble could be eliminated if, when fitting the firebox to the mudring, the corners were well heated and set up tight before riveting.

Machining Locomotive Driving Boxes

Time and Effort Will Be Saved by Doing Accurate Work; Special Devices and Tools That Will Assist

BY M. H. WILLIAMS

The machining of locomotive driving boxes is quite an item in railway shops, and on account of the number that must be repaired the question of special machines and appliances for this work should receive special attention. It will often be found economical to install a special machine for these parts and use it exclusively on this work. On some machines the driving box shell may be bored, the hub liner faced and the oil cellar bored to the radius of the axles at the rate of three an hour, or 24 in an eight-hour day, an output equal to the demands of many of the larger repair shops. This will be found to be a greater output than is generally obtained on what may be called universal machines. As the driving box job has come to stay, it certainly should pay to install the very latest machine tools for the purpose of handling the work. One special machine for this work will in many cases release two machines, such as vertical or horizontal boring mills, for other work.

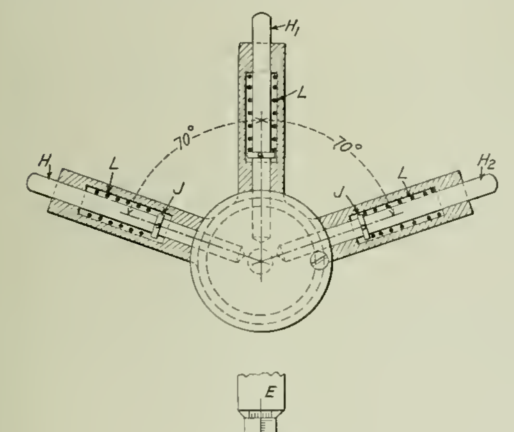


Fig. 1—Three Prong Micrometer Caliper for Measuring the Driving Box Bore

Accurate machining will also be found to be a paying proposition on these parts for the reason that when machined to proper sizes the work of assembling on the axle and locomotive will be reduced and an all-around saving will result. With a few special appliances, which will be described, the shells in the boxes may be bored, the sides faced and the cellar bored so accurately that individual fitting of the axle by filing or scraping may be entirely eliminated and better fits be obtained than with the general practice of scraping and filing. Several methods may be followed when performing this work. Those explained below have been taken from practices in several shops and will serve to illustrate various ways this work may be done.

First, it may be well to mention a few special appliances that may be used to good advantage in obtaining accuracy and reducing time.

Press for Applying Shell.—One of the first machine tools required is a press for removing and applying the shells. For this purpose the ordinary vertical hydraulic press answers very well and needs no explanation to railway shop men. In many respects it is advisable to equip this or any other form of press with a recording gage in order to produce a record of the pressure exerted when applying the shells. This, no doubt, may look like a refinement. However, a few points should be kept in mind. If the shell is forced in at too great a pressure the box will be spread apart and throw the shoe and wedge faces out of line. On the other hand, too low a pressure may result in the shells becoming loose. If a record of the pressure applied is kept it will soon be possible to determine a proper limit to be followed. The workman can also by observing the records, judge as to his work of fitting the shell and be governed accordingly when fitting future boxes. Records of this nature will be of interest to the shop manager and should be filed to be used in case of controversy. In many respects it will be found advisable to assign one press for applying shells, various side rod bearings and link motion bushings and equip it with a gage, using a second press for removing these parts. On account of the great pressure often necessary to start a shell, side rod brass or link motion bushing, a gage, if used on a press common to all work, will soon be in bad condition, due to the great pressure necessary to start a part loose.

MEASURING BORE OF SHELLS AND BOXES.

Measuring the bore of the brass or bronze shells and also the slotted half-round surface in the driver box for the shell bearing is very important, but difficult on boxes where these surfaces are less than a half circle and where the ordinary calipers cannot be used. A three-prong micrometer caliper has been used for this purpose, which answers very well, this being shown in Fig. 1. This is made up of an accurately ground steel cylinder *A*, having walls about ⅛ in. thick and the hole about 1 9/16 in. in diameter, a cap *B* at the lower end to resist the spring *S* and also to exclude dirt, and an upper cap *C* carefully threaded to fit the top of *A*. Adjustments of the caliper are made by this head and when it is properly set it is locked by the set screw *D*. A micrometer head *E*, such as may be obtained from several makers of these instruments is secured to the cap *C* by means of a nut *K*, fitting on a thread cut on the micrometer. This micrometer head is graduated for inside measurements or in opposition to the ordinary micrometer; that is, the readings are the smallest when the barrel is backed all the way up; as the barrel is screwed down, the readings become larger. The end of the micrometer screw bears on a hardened and ground plunger *G*, which fits very accurately into case *A*. The bottom of this plunger is accurately ground to a taper of six inches in twelve inches. The spring *S* forces the plunger *G* upwards against the micrometer head and takes up lost motion. Three rods, H, H_1, and H_2 fit into projections that are a part of case *A*. These rods are made of steel wire about ¼ in. in diameter, and are carefully hardened and ground, all three to exactly one length. The outer ends are slightly rounded, very similar to measuring rods used with micrometer calipers, the inner ends having points agreeing with the taper of the plunger. These rods are forced toward the center by springs, *L*, bearing against the frame and collars *J*. The three projections on the case are spaced at an angle of 70 deg. The rod H, H_1 and H_2 are of suitable lengths for shells and boxes to be measured. For measuring from seven to eight inches these are approximately 3¼ in. long. For each larger or smaller size the length will be increased or decreased by ½ in. Several sets of these rods may be used in one case where it will be necessary to change the rods when making measurements varying over one inch and will answer for small shops. Separate cases may be made for each size, which will avoid changing the rods.

For the purpose of setting this instrument, caliper rings carefully ground on the inside to even inch sizes are used. When setting the caliper the top cap *C* is adjusted up or down until the micrometer head registers zero, with all three rods in contact with the inner surface of the setting rings. After this the screw *D* is tightened to prevent the head cap *C* from turning.

In operation the plunger *G* is controlled by the micrometer head and opposed by spring *S*. The plunger *G* in turn controls the rods H, H_1 and H_2. It is obvious, on account of the angle on the plunger being six inches in twelve inches, that the rods will be forced out one-half the travel of plunger *G* and as the rods measure the radius, the reading on the

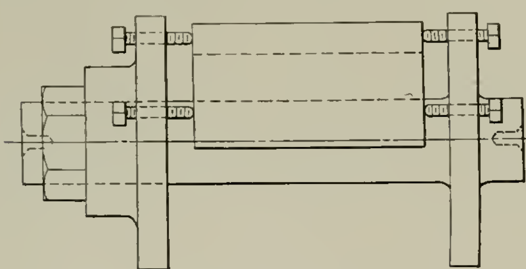

Fig. 2—Arbor for Turning Driving Box Brasses on a Lathe

micrometer head will show the actual diameter. When measuring the diameter of the bore of a shell or the slotted inner surface of the driving box, the micrometer head is screwed up or down until all three rods are in contact. No difficulty is experienced in determining this. If set too large the two outside rods H and H_2 only will be in contact, and by giving the caliper a slight rocking motion so that middle rod H_1 rises and falls, it will be noticed that the center rod is not in contact. Or if set too small the middle and only one side rod will touch, and by giving the caliper a slight right and left hand turn a very minute space may be detected. In practice a box or shell may be measured in a few seconds and to an accuracy of the thickness of a sheet of paper. This device is very valuable for measuring the bore of shells, and also to prove the accuracy of boring mills. With the best mills there is always the possibility of the boring head not being perpendicular to the mill table, causing the shell to be bored larger at one end.

Several different methods are followed for measuring the bore of boxes and shells. It is a question if any are more accurate or handy than using the three-pronged micrometer described. One of its greatest advantages is the fact that the machine operator can check his work and tell when it is correct, both for size and the straightness of boring. As the accuracy of boring is increased the labor of fitting the box

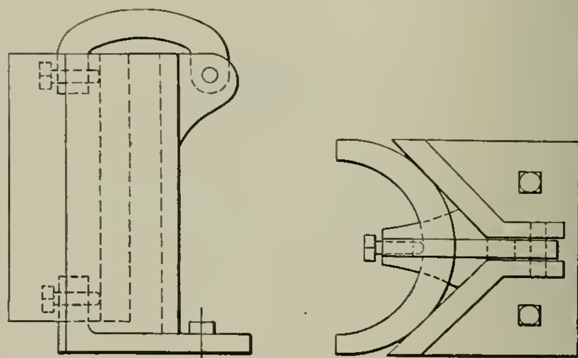

Fig. 3—Jig for Holding Driving Box Brasses When Machining the Ends on a Slotter

to the axle will be reduced. To properly make use of this device the axle should also be measured with micrometers.

MACHINING SHELLS.

For machining the outside surface of the brass shells several methods are employed, one being to clamp the shells to the table of a vertical slotter and revolve the table as the surface is being finished. This method is quite satisfactory. It, however, requires a somewhat expensive machine tool, compared with other methods. Another way is to hold the shell on a revolving arbor on a shaper table. In this case the arbor is revolved by a worm gear and wheel and generally operated by hand. This method works very well and does not require as expensive a machine as the slotter. In many respects the simplest and quickest method is to turn the shell on a lathe. For this purpose an arbor, as shown in Fig. 2, answers very well. This is made up of a heavy central bar about four inches in diameter, having a collar at one end forged solid with the arbor, as shown at *A*. On this arbor a loose collar *B* is fitted fairly snug. This is also keyed to a spline way cut in the arbor. The collar *B* is backed up by a large nut *C*, this nut being necessary to compensate for varying lengths of shells and may also be used for tightening the collar *B* on to the shell. The set screws *D-D* are used for tightening and holding the shells and are preferably made with cup points. In practice the shell is placed on the arbor and the set screws *D* drawn up enough to just hold the shell. The shell is then adjusted to the proper distance from the center of the arbor by a hammer. When properly set the three set screws in each collar are tightened. The method of setting the shells may be modified by placing a liner of wood or metal between the arbor and shell. This will locate the shell at once. It, however, requires a separate liner for each pattern of shell. In some cases these arbors are made double, so that two shells may be turned at one time on a lathe having two tool posts. This method increases the output of shells very materially and makes it possible to turn a pair of shells in less than 45 minutes, floor to floor. The diameter of the shells can generally be measured with calipers, as the castings in the rough are more than a half circle. In many respects a micrometer can be used to good advantage for this work, especially in conjunction with the three-prong caliper previously described.

For machining the ends of the shells several methods are employed, depending largely on the machine tool equipment available. One method is to hold the shells in a V-block set vertical on a slotter table, as shown in Fig. 3. This is made up of an iron casting *A*, which is bolted to the slotter table, and has a projection for a set screw *B* at the bottom and a hinged clamp *C* that may be thrown back when necessary to remove the shell. In practice the shell is placed with its machined surface against the *V* faces. The clamp *C* is brought over and the bolts *B* and *D* tightened.

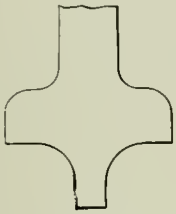

Fig. 4—A Shaper Tool for Machining the Ends of Driving Box Brasses

Another plan is to hold these shells by means of a similar clamp on the table of a shaper, in which event the fixture and the shell are in a horizontal position. This method is applicable to the ordinary or draw-cut shaper. A slotter or shaper tool, as shown in Fig. 4, can be used to good advantage for this operation. The end of the tool is used to remove the scale on the casting, the final forming being done with the formed part of the cutting tool.

Another method is to mill these ends on a plain knee type milling machine with a cutter formed to the contour of the desired end of shell. For new locomotives, where the shells are similar, two milling cutters may be used at one time.

For the average repair work the shaper will generally be found the most desirable, and is a less expensive machine tool than the others mentioned.

REPAIRS TO DRIVING BOX SHELL SURFACE

Machining the half-round surface in the driver box into which the shell fits is not necessary where the original work has been well done and the box has not been warped or sprained in service. On account of the enormous axle pressure of heavy locomotives it is very desirable that the shell have a perfect bearing in the driving box in order that the box may properly support the shell. It is, therefore, very desirable to check the shell bearing in the boxes after the shell is removed, and should there be a great variation in the radius of this surface the box should be reslotted. Just how much variation can be allowed is an open question. However, it is desirable to err on the side of safety, and it is a question if new shells should be applied where this surface varies over 1/32 in. or .032 in. from end to end. Should the variation be greater, reslotting is advisable. This variation may readily be measured with the three-prong micrometer. The actual machining of the boxes will naturally in most shops be done by the same methods prevailing for new work, of which the following may be mentioned.

Draw-cut Shaper.—This machine is provided with an arrangement in the ram for gradually revolving the cutting tool. In practice the box is held on the shaper table properly centered with the ram. After all is ready the cutting tool is set to the proper radius. As the machine makes a stroke the tool is rotated a small amount and so on until the work is completed.

Vertical Slotting.—This method is similar to the above except that the box is revolved instead of the tool. Either method admits of good workmanship when the machines are in a good state of repair. There is, however, always the possibility of the ram not being square with the work and machining one end of the box larger than the opposite end. To guard against trouble of this nature the boxes should be checked occasionally. This may be done with the three-prong calipers in Fig. 1. After the boxes are reslotted, or if it is not necessary to do this, the actual sizes of the box may be measured and a memorandum made of the actual sizes for the benefit of the workman turning the shell.

BOX FACE LINERS

For applying and machining the liners on the box faces several methods are followed both for brass and babbitt metal. When applying babbitt in some cases the practice is followed of pouring the babbitt the exact thickness desired.

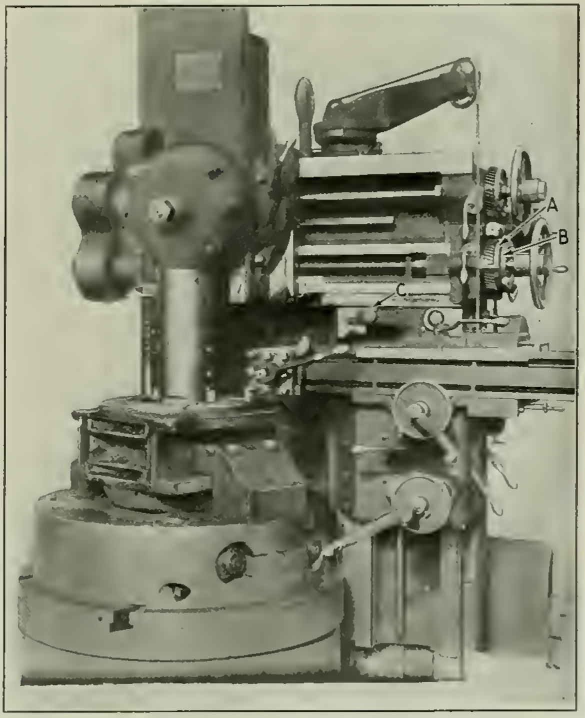

Fig. 5—Vertical Turret Lathe for Boring Driving Boxes

This is accomplished by locating a plate of boiler steel or cast iron the correct distance from the box and pouring the metal between the two. Where care is taken to locate the plate properly an excellent job may be made. A second method is to cast the babbitt somewhat thicker than necessary, which can be done by pouring from a ladle and without the use of a plate or other means of regulating the thickness of the babbitt. In this case it is necessary to machine the babbitt to the correct size. Where brass or bronze liners are used two methods may be followed, the use of either being governed largely by the design of the box on each particular road. In some cases the liners are faced on one side and secured to the box by flat-headed screws. In other cases the brass or bronze is cast onto the box. In either event, the liners are generally faced after applying.

In many respects the method of pouring these liners in the rough of either babbitt or bronze and facing them afterward will be found the more economical where proper machine tools are available for the purpose.

BORING AND FACING DRIVING BOXES.

For boring the shells and facing the liner several methods are followed, generally governed by the tool equipment available. The following methods are mentioned, which, however, do not cover the entire field.

Side Rod Boring Mills.—With this method the box is clamped on the machine table, the cutter for boring the shell being held in the revolving spindle and adjusted properly for the diameter required. A large sweep tool may also be used to face the babbitt liner. This method may be followed where better adapted machines are not available. It has the disadvantage that bronze liners cannot well be faced without a special facing tool and the bore and facing cannot be done at one time. Drill presses of heavy pattern are also used very similar to the method explained above.

Horizontal boring mills are also used for this purpose, the operation being very similar to that explained above, except that the box is set on its side instead of flat. This machine has the advantage that the table may be adjusted quickly to center the box.

Vertical boring mills of various forms are also made use of and are generally found more convenient than the other machines mentioned, having the advantage that the boring bar or tool may be readily adjusted for varying sizes of bore and either babbitt or bronze liners may be faced with an ordinary cutting tool. In the majority of cases the box is clamped on the mill table by the ordinary methods of clamping parts on these machines, which consumes considerable time in order to properly center the box.

Modifications of car wheel boring machines are also used for this purpose, in which event an adjustable tool is held

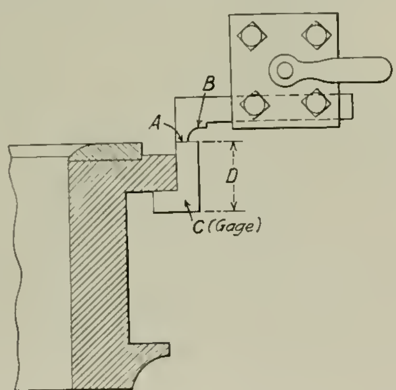

Fig. 6—Cutting Tool for Finishing Hub Liner Showing Use of Gages for Obtaining Proper Thickness

in the ram and the liner is faced by the facing attachments that are applied to these machines. Often special chucks are made to hold the box, with which it may be located and secured very quickly. This machine answers very well.

Vertical Turret Lathe.—For large and medium sized shops it will generally be found advisable to install a special vertical boring mill for boring and facing driving boxes and equip it with such chucks and special appliances as may be found desirable. At first glance this may appear extravagant. However, a careful review of the question will in many cases show that two or more machines are tied up on this work where one special machine will take care of the entire output. The so-called side head boring mill, or as sometimes called the vertical turret lathe, has been modified for this work. Fig. 5 shows a well known type of this machine fitted up specially for this work. As will be noticed on the illustration, the customary turret on the vertical ram has been replaced by a large single bar which is securely bolted to the seat for the turret. This bar, in order to secure rigidity, is made as large as possible, and on the machine illustrated it is seven inches in diameter and intended primarily for the larger driving boxes. For smaller boxes it would be necessary to reduce its diameter. At the lower end of this bar two cutting tools are held by set screws as shown. The tool at the right is used for roughing, and that at the left for the finishing cut. By always making use of one tool for the finishing cut the cutting edge will stand up for several

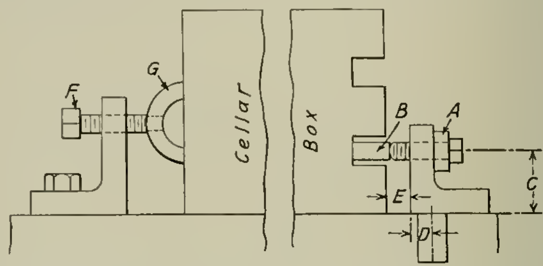

Fig. 7—Arrangement for Locating the Box with Respect to the Spring Saddle Pocket and for Holding the Cellar in Place While Boring

boxes and avoid too frequent settings of the tools. The hub liner is turned and the fillet formed by a specially formed cutting tool held in the side head, as shown in Fig. 5, and more in detail in Fig. 6. The facing of the liner is done with the cutting face *A* and the fillet by the concave cutting surface *B*.

In order to quickly locate the driving box a special two-jaw universal chuck, as shown quite clearly in Fig. 5, is used, the chuck jaws holding the box on the shoe and wedge surfaces, and as the two jaws tighten at a uniform rate, the box is located central with the center of the chuck. With this chuck it is unnecessary to measure the distances from the shoe faces to the center of the bore. The chuck is tightened by a square-headed screw clearly shown in the photograph. This screw operates two worm gears that are parts of the two right angle screws that close the jaws. The chuck is held on the table by T-bolts, the bottom surface of the chuck being keyed to fit the T-slots in the table. In practice these T-bolts are adjusted to allow free movement of the chuck on the table without lost motion. For readily adjusting the chuck to bore more or less from the crown of the brass an adjusting screw, not shown, is set in the mill table and works in a nut attached to the chuck, this screw being provided with a micrometer dial. By turning the screw, the chuck when holding the box may be set to run true or eccentric, as desired. This feature is valuable for reboring boxes having worn shells where only a small amount is to be removed to true up.

One feature incorporated on this machine that is worthy of mention is the method of setting the box with reference to the distance from the spring saddle pocket to the center of the bore of the shell. For boxes arranged for top saddle spring supports the boxes may all be set in the chuck the same distance from the saddle pocket to the center of bore, irrespective of the bore of the shell, without consuming any appreciable time in the set-up. A hole about two inches in diameter is bored in the chuck 13 in. from the center. A post, as shown in Fig. 7, fits into this hole. The post has a screw *A* with a large head, the point of which extends through the post a predetermined amount. The length of the screw and the distance *C* above the face of the chuck will vary with the different designs of boxes. The point of the screw *A* bears against the block *B*, which fits in the spring saddle pocket and which is of a definite thickness. The method of determining the use and size of each of these parts can best be explained by an example. Let it be assumed that the drawings call for a distance of 10 in. from the center of the bore of the driving box to the spring saddle pocket. As previously mentioned, the hole in the chuck is 13 in. from the center or three inches from the hole to the pocket. Suppose the dimension *D* is 1½ in. and dimension *E* is ½ in. In this case the block *B* must be one inch, giving a total of three inches. Other designs of boxes will call for modifications of these distances.

For the purpose of holding the cellar in the box while the boring operation is going on, a post, shown at the left in Fig. 7, is permanently bolted to the chuck face. This is provided with a bolt *F*, having a loose U-shaped shoe *G* attached to its point. After the driving box is clamped in the chuck the bolt *F* is screwed up to hold the cellar in place. The box will now be located so that the two shoe faces are an equal distance from the center of the chuck and from the center of the boring mill table. The cellar will be in place so that it may be bored with the shell, and the distance from the bore to the spring saddle pocket will be correct.

Very good use may be made of the micrometer dials on this form of machine, with which the time of calipering may be

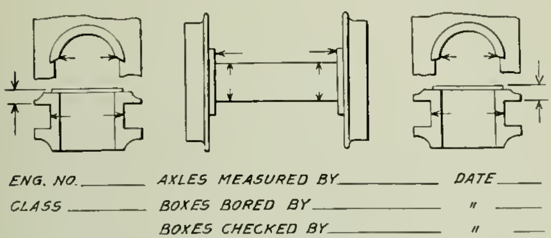

Fig. 8—Diagram for Recording Finished Dimensions for Driving Box Work

reduced to almost nothing. On the design in question two dials *A* and *B*, Fig. 5, are located on the cross screw. One of these dials is graduated right hand and the other left hand, each dial being independent of the other and arranged that they may be turned independently and clamped when properly set. The object of the two dials is to set one properly for the right hand or roughing tool in the boring bar, and the second for the left hand or finishing tool also set in the same bar, each dial being graduated to read to one-thousandth of an inch diameter. For the purpose of setting these dials a setting point *C* is arranged on the stationary part of the machine. In practice the boring bar is raised until the cutting tool is horizontal with the setting point and a pin bar of known length is set between the setting point and cutting tool. The cross screw is then turned until the pin bar just touches the setting point and cutting tool. The dial is then set with the zero mark to the pointer. The opposite cutting tool is then set in a similar manner with a *C*-gage. After setting the tools a trial cut is made on any box that may be on the machine, the bore measured and the dial given such slight corrections as may be necessary. With the dials once properly set any sized bore in the range of the machine may be made. That is, should it be necessary to bore a box 7, 7.5, 8, 8.070 or 9.120 in. the tools may be set by turning the cross screw until the dials read correctly and generally an accuracy of .005 in. will be obtained. It will readily be seen that a great amount of time may be saved by eliminating the calipering of each box as the boring operation is performed.

To insure facing the boxes correctly and to compensate for varying distances between the hub liners on the driving wheels and insure the correct amount of end play of the axles when assembled on the locomotive a very simple gage *C* may be used as shown in Fig. 6. This may be easily made from sheet steel about ⅛ in. thick. A separate gage is desirable for each class of driving box. The dimension *D* should be equal to the distance from the shoe space to the top of the liner on the driving box for a standard driving box made according to drawings and where proper allowances have been made for end play of axles.

This gage may be used in the following manner: Assuming that the distance between the hub liners is correct and the locomotive frame is also correct, the gage is held as shown in Fig. 6, and the cutting tool, held in the side head of the machine, is adjusted until it just touches the gage. The micrometer dial on the side head is then set to zero. This operation is repeated on the opposite side and should the two sides be nearly alike the average of the two may be taken. Should these two readings differ largely it may be necessary to plane the box in order that both shoe faces may bear equally on the shoes.

The liner may be faced by taking a roughing cut with the tool raised a small amount and the finishing cut with the micrometer dial back to zero. Should the distance between the hub liners on driving wheels be more or less than standard dimensions the tool is adjusted similar to that explained above, but when facing, the tool is raised or lowered the proper amount, which will be shown by the readings on the micrometer dial. For example, suppose the distance between the two hub liners is ⅛ in. above standard, owing to wear and refacing. This distance should be divided equally between the two driving box faces. In this event the facing tool would be raised one-half of ⅛ in. or .062 in. above the original setting. This amount may readily be ascertained by readings on the micrometer dial. Should the distance between the driving wheel liners be less the process would be reversed. This is a very simple operation and will be quickly understood by the machine operator.

MEASURING AND RECORDING SIZES.

For obtaining the correct size for boring the driving box shells the ordinary micrometer can be used to good advantage when measuring the axles. It will be found in practice that they are quicker to use than machinist's calipers and much more accurate, their great advantage being in the fact that the size measured may be recorded on a blank, as will be explained later. These micrometers are very useful for checking the axle for roundness and taper.

For measuring the distance between the hub liner faces on driving wheels the inside tubular micrometer may be used to good advantage. This measurement is essential in order to determine the correct amount the driving box liner should be faced to allow the proper amount of end play of driving wheels. It is advisable to bore the shell somewhat larger than the largest part of an axle worn taper or a new correctly turned axle. No well established rule appears to be followed for this amount. As a general proposition, if the box is bored from .015 to .025 in. larger than the axle the conditions of running will be found satisfactory.

Fig. 8 shows a form of card that may be used to good advantage for recording the desired finished dimensions for driving box work.

Rolling Stock for Danish Railways.—The Danish State Railways for a long time have been in need of more freight cars and recently ordered 750 from the "Scandia" factory in Randers, Denmark. This will give work to 500 people who have been unemployed. A set of wheels for a freight car before the war cost $40, while now they cost $348.—*Commerce Reports.*

SAFETY PRECAUTIONS FOR HANDLING OXY-ACETYLENE APPARATUS*

BY E. WANAMAKER
Electrical Engineer, Rock Island Lines

Unabsorbed acetylene, that is, in a gaseous state as generated, is highly explosive at a pressure of two atmospheres or more due to the chemical instability of the gas itself. Acetylene is more or less unstable and liable to sudden explosive decomposition under certain circumstances. Accidents sometimes occur when it is apparently impossible to guess what precipitated the decomposition which resulted in the explosion. Acetylene gas at ordinary atmospheric pressure and temperature does not fly apart spontaneously and explosively into its constituents, but does so when exposed to considerable pressure while in a wholly gaseous condition as previously stated.

It has been ascertained that acetone has the property of being able to absorb about 25 times its volume of acetylene for each atmosphere of pressure at 60 deg. F. When acetylene is dissolved in this way it ceases to be spontaneously explosive and may be stored with acetone at pressures up to 250 lb. with comparative safety. Persons not fully acquainted with the properties of acetylene gas should under no conditions be permitted to undertake the compression of it.

Acetylene gas is comparatively non-poisonous when inhaled in highly diluted form in small quantities such as might escape from small leaks: the only poisonous effects that have been observed in connection with it were due to the presence of impurities in the gas, such as phosphoretted hydrogen. Therefore acetylene should always be secured as free as possible from phosphorous and other contaminating substances.

It has been found that one pound of carbide will generate 46 cu. ft. of acetylene gas, which if permitted to leak into a room six by six by five feet, will mix with the air in such a proportion as to make it an inflammable explosive that may be set off by a spark as well as by a hot iron or flame. For this reason it is always well when using an acetylene torch in a small enclosed space to see that a sufficient quantity of air is obtained to prevent accidents from such a cause. A little air blowing from an air hose will prevent any such accident as this even though considerable acetylene were leaking into the space.

Oxygen is manufactured directly as a chemical product or electrolytically from water. Oxygen itself as a gas is non-explosive. However, it is generally stored in metal containers at a very high pressure, generally about 1,800 lb. per sq. in. It is therefore apparent that an explosion may take place due to the failure of the container itself permitting the gas to rush out at an enormous velocity.

It has been found at times when oxygen was made electrolytically, that due to the crowding of the pressure or careless handling a small percentage of hydrogen was permitted to mix with the product. Certain proportions of this mixture are highly explosive and may be set off by heat or jar. It is therefore necessary that oxygen be pure.

The following instructions for handling oxy-acetylene gas are strongly recommended:

In handling acetylene gas in tanks under pressure it should be remembered that at no time should the tank be allowed to remain near stoves, furnaces, steam radiators or any other sources of heat nor should they be exposed unnecessarily to the direct rays of the sun. Care should also be used in handling acetylene gas containers to avoid heavy jars. It must be remembered that any steel drum is liable to mechanical injuries if not reasonably handled. Acetylene cylinders should always be stored in an upright position with the valve end up.

*Abstract of a paper read before the Railway Fire Protection Association on December 4.

Leaking containers should never be used and should one be found, it should be set out in the open air as soon as possible away from all possibility of ignition of the gas or of the mixture of gas and air that surrounds the container.

Open flame lights should never be taken into confined spaces where there is any possibility of leakage of acetylene. In case it is found necessary to use an acetylene tank in a small enclosed space a little air should be blown into the space from an air hose in order to secure a good circulation of the atmosphere.

All acetylene containers should have fusible plugs.

Neither oxygen nor acetylene containers should ever be allowed to remain where they are exposed to sparks or flame.

Oxygen containers should not be dropped nor handled roughly in any way and should not be placed where they may be overturned by a collision with other objects or by reaction caused by the violent escape of their contents through the safety outlet with which containers should be provided.

The regulating devices, valves and other attachments on oxygen containers should never be lubricated with oil or grease. Whenever lubrication is required it should be secured by the use of pure graphite unmixed with either oil or grease. Furthermore the discharge valves of oxygen tanks should always be opened slowly and care should be taken to avoid twisting or straining them by the use of hammers or improper wrenches.

The hose and hose connections used between the gas manifolds or gas tanks and the welding torch must always be maintained free from leaks and all joints made mechanically tight and secure. The regulating valves and torches must be kept in a good state of mechanical repair to avoid leakage of the gases. No part of the equipment to which hose is attached should be used without securing the hose with the proper size hose clamp. Wire fastenings should not be used in any case.

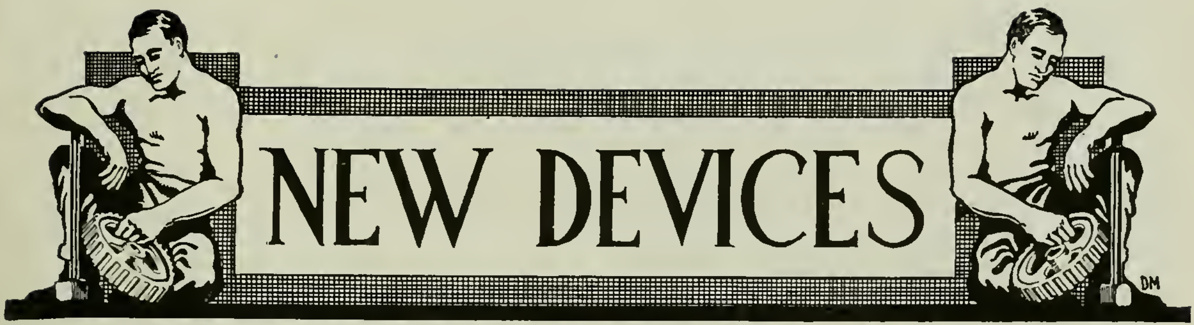
In case of any trouble with the torch the gas should be immediately shut off at the tanks or pipe line station.

Where generating stations are used the instruction cards sent with the parts must be carefully followed and no leaks must be permitted on any of the pipe lines.

No man should be permitted to use the gas welding torch until properly instructed by a welding supervisor or some experienced welder and if he is not the regular operator permission of the foreman in charge should be obtained before the machines are used.

Safety gages should be used on all regulators, that is, gages having loose or vented backs, so that in case the pressure on the gage builds up to a dangerous degree or builds up too rapidly, such as might cause a rupture of the Bourdon tube the force will spend itself without breaking the glass case, thereby causing possible injury to the operator.

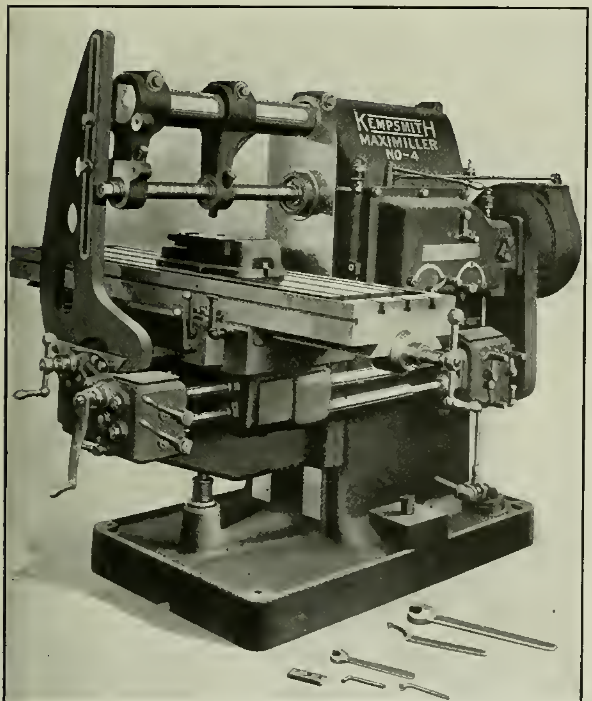
Some shops use portable welding outfits, purchasing tanked gas and tanked oxygen. Other shops install acetylene generating outfits, also oxygen generating outfits, piping the gas throughout the shops having manifold outlets to which the hose from the welding torches are connected. Still other shops generate acetylene gas and purchase tanked oxygen, connecting it to a manifold which in turn is connected with a system of piping in much the same manner as the oxygen generating plant. Each generating plant that is installed is equipped with a complete set of instructions for intelligently operating the generator, the most important of which are: "Remember to keep all light or fire of any kind away from the plant and never permit the generator to remain more than five minutes unless the generating chamber is filled with water, even when it is not in use." If the instructions that we have given in this paper and the detailed instructions which are given out with the generators are carefully followed out and leaks of all kinds prevented in the distribution piping system of the installed plants, there will be practically no danger from fire.



KEMPSMITH MAXIMILLER

The Kempsmith Manufacturing Company, Milwaukee, Wis., one of the first machine tool builders to make an all geared type of milling machine, has produced a new design of knee type milling machine called the "Maximiller." In designing the machine particular attention has been paid to insuring ease of operation and control with rapid production and accurate work.

Special material has been used in this machine in order to secure the adequate strength without excessive weight.

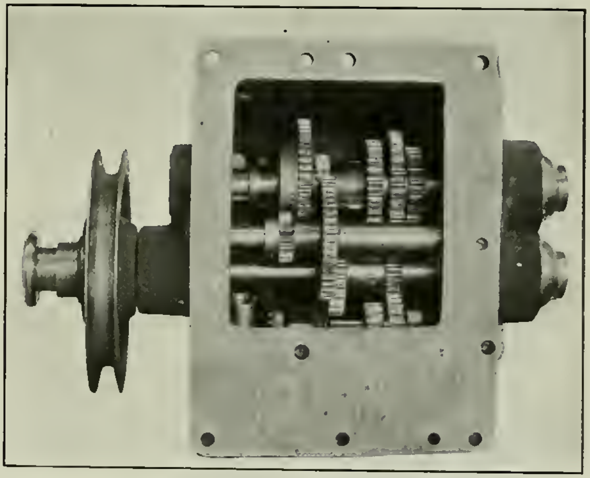


Heavy All-Geared Type Milling Machine

The spindle, gears and much of the shafting are made of heat-treated alloy steel. The column, knee, saddle and table are of semi-steel. The column is well ribbed and has few openings, and the knee is designed throughout to give the proper support to the saddle and table. The side walls are practically solid, having but two small openings, and the knee slide on the column is extended up beyond the top wall to provide extra resistance against strain. The top wall is solid, the cross feed screw being located in a shallow depression midway between the saddle Vees. The table is 18 in. wide with a working length of 72 in. The gibs in the saddle and table are of the adjustable taper type.

The over arm is a solid steel bar 5¼ in. in diameter, with a wedge lock which positively locates the pendants and alines the arbor, thus preventing any tendency to twist out of line under heavy cuts. The outboard support is of the open side type developed by this company, permitting free access to the table and the work at all times. It is reversible to bring the open space on either side as required.

The spindle is large in diameter and runs in adjustable phosphor bronze bearings. All other shafts in the speed transmission run on ball bearings. The driving force is applied to the spindle on a face gear which overhangs the front bearing, thus reducing the torsional strain in the spindle. As the face gear is the only slow speed member in



Feed Change Gears and Case, Showing Unit Construction

the driving train, chatter is practically eliminated and the drive is smooth under heavy cuts. The speed changes are secured through a train of gears giving 18 spindle speeds ranging from 14 to 350 r. p. m. All speed changes are secured by sliding gears and there are never more than three pairs of gears in mesh. The normal direction of spindle rotation is right hand which makes it correct for standard drills and boring tools. A spindle reverse has been incorporated in the machine, for, in order to get the cutting strains in the proper direction on the gibs and the tables, the face mills must run in the opposite direction from the spiral or slab millers.

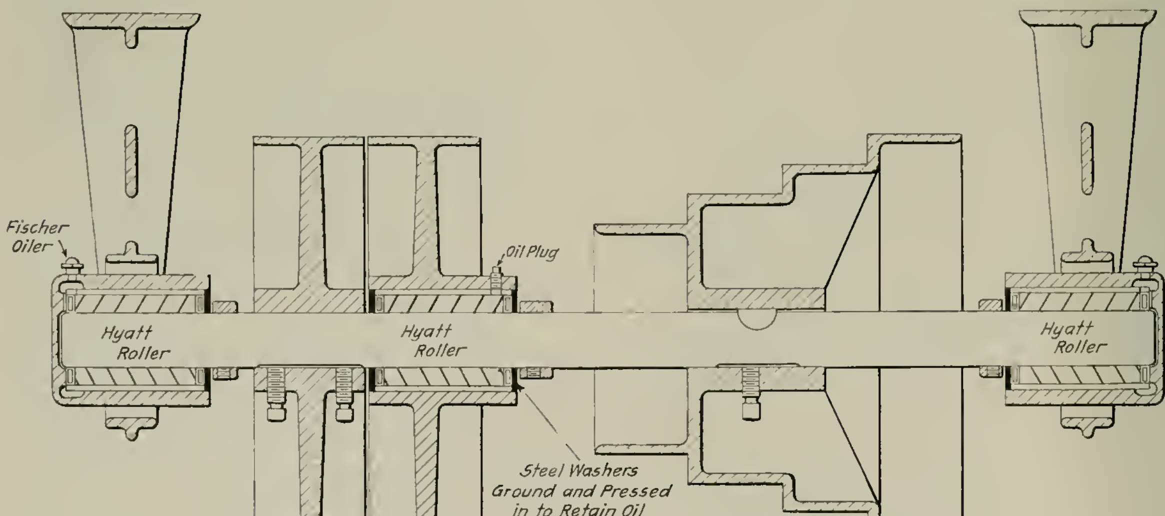
The principle of unit construction has been used to a considerable extent in the design, thus securing many advantages both in manufacturing and in repairing. The spindle speed change mechanism is an integral part mounted in a box secured to the column and the feed change mechanism is an independent unit mounted below the driving gear. There are 18 feeds available ranging from 5/8 in. to 25 in. per minute. Only one clutch is used and there are no tumblers or locking pins, all changes being obtained by sliding gears. All the speed changes are secured with only three levers and a direct reading feed plate makes it easy to obtain any combination desired. Incorporated in the feed mechanism is a safety coupling which slips before a breaking load comes on the feed drive but resumes the travel again as soon as the load drops to safe limits. The power rapid traverse can be used for all table movement without disturbing the set-up for whatever rate of feed may be in use.

A centrifugal type pump with a capacity of 15 gal. per minute is attached to an extension of the feed drive shaft to circulate cooling compound. The pump is driven through a clutch which can be disengaged if the nature of the work does not require a cooling fluid. The lubrication of the parts has been given special consideration in this machine. The gears and bearings in the speed and feed mechanisms are lubricated by splash from an oil bath in the case. Sight feed oilers are used to supply clean oil to the spindle bearings and drive pulley. The lubrication of the mechanism supported by the knee is centralized at two points which makes it certain that none will be overlooked when the machine is oiled.

The driving pulley is 16¾ in. in diameter and runs at 400 r. p. m., a six-inch belt being used. For general railroad shop work a 15-h.p. motor is recommended for driving this machine.

ROLLER BEARING COUNTERSHAFT

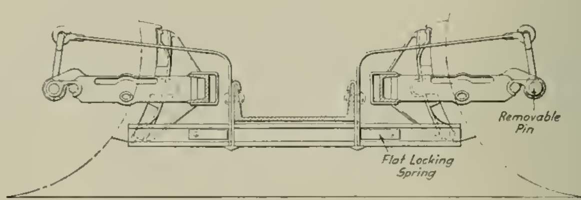
As a step in a program of refinement in its line of shapers, part of which has been carried into effect during the war, the Queen City Machine Tool Company, Cincinnati, Ohio, has designed a roller-bearing countershaft which will be included as part of the equipment of all shapers manufactured after March 1, 1919. As shown in the drawing, the countershaft hangers have been designed to include Hyatt roller bearings. The journal boxes are cast with the outer ends closed and the inner ends are closed with steel washers which are ground and pressed in to retain the lubricant. The loose pulley also runs on Hyatt rollers and both ends of this bearing are closed in the same manner as the inner ends of the journal boxes. The purpose of reducing the inefficiency with which power is transmitted from the line shaft to the machine has been carried out in a design the simplicity of which is intended to insure against any increase in the amount of inspection or attention required to keep it in satisfactory working order.



Roller Bearing Countershaft for Queen City Shapers

ATLAS SAFETY GUARD AND THIRD POINT SUPPORT

For some time past the American Steel Foundries, Chicago, has been manufacturing a safety device for brake beams known as the Atlas Safety Guard. This consists of a bar of I-Section fastened beneath the spring plank in such a position as it will support the brake beam in case the brake hanger should fail or the pins fall out. A further improvement has been made in this device by providing an additional support for the brake beam to insure even brake shoe wear. This is accomplished by extending arms upward and outward from the safety bar support on the spring plank and fastening the brake beams to these arms by short links. In cases where one safety bar is used on each truck, these links are attached to the end of the brake beam strut; when two safety bars are applied the links are fastened to the tension member. The safety bars, as in the previous design, are held in place by flat springs and can readily be slid through the supports under the spring plank when it is desired to remove the brake beam. The arm and links being above the beam, do not interfere with its removal in any way.



Atlas Safety Guard and Third Point Support

Railway Mechanical Engineer

Subscriptions payable in advance and postage free; United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 7,900 copies were printed; that of these 7,900 copies, 7,029 were mailed to regular paid subscribers, 57 were provided for counter and news company sales, 187 were mailed to advertisers, 25 were mailed to employees and correspondents, and 602 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 23,000, an average of 7,667 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

Exports of locomotives through the port of New York during December, 1918, amounted to $1,755,891, according to figures given in the monthly foreign trade records issued by the National City Bank. The report also shows rails exported to the value of $1,354,795 and car wheels and axles valued at $413,720. Freight cars are not separately shown in the tabulation.

The railways of India on March 31, 1914, had 170,444 freight cars. The number laid up for repairs at present is about 10,290, or about 6 per cent, of which 1,860, or about 1 per cent, of the total, were laid up for want of materials. The number is lower than in normal times, owing to the efforts the railways were making to keep every available freight car on the road. The number of cars sent overseas was 4,251, all of these except 56 were of metre or 2 ft. 6 in. gage.

The International Railway Congress has resumed its headquarters at Brussels with the return to that city of M. L. Weissenbruch, the general secretary. The Congress, before the war, held its meetings every five years, meeting in 1895 in London, 1900 in Paris, 1905 in Washington, 1910 in Berne, and the 1915 meeting was to have been held in Berlin. The Congress, before the war, also proved of service to railway men the world over by the publication at Brussels of a monthly bulletin.

The great scarcity of coal in Italy has made it necessary to use wood and lignites for fuel in locomotives. The boilers and fireboxes of the locomotives have had to be changed to suit the new fuel, and employees re-educated to a considerable extent. The use of substitutes for coal as fuel has been urged on all manufacturers, and prizes have been offered for noteworthy economies. In addition to that, two companies, with an initial capital of $1,200,000 each, have been formed for the development of lignite or brown-coal mines in Italy. One will operate mines in northern, the other in southern Italy.

The State Department at Washington has received through the American Legation at Brussels a request from the Belgium government asking the United States to lend it 400 locomotives and 2,000 cars in addition to returning all of the 359 locomotives which were placed at the disposal of the American Expeditionary forces. The communication from Minister of Railways Renkin, sets forth the urgent need for additional rolling stock in Belgium to replace that commandeered or destroyed by the Germans. The American army has returned 187 of the Belgian locomotives, but the remaining 172 still are in use by the Expeditionary forces.

Maximum prices on anthracite coal, together with all other coal and coke regulations except three, have been suspended by the Fuel Administration. The only restrictions not suspended, as to coke and all coal, are: Those requiring that contracts be made subject to maximum prices if reinstated, subject to cancellation by the Fuel Administration and subject to requisition or diversion of coal by the Fuel Administration. Those prohibiting reconsignments of coal. Those requiring shipments of coal to tidewater to go through the Tidewater Coal Exchange. The order includes the suspension of price and zone regulations on coke and bituminous coal which went into effect February 1. The administration's control of the oil industry already has been mostly suspended, so that the Fuel Administration's controls are now relaxed to the present limit of safety.

The Engineering Societies' Employment Bureau, New York City, desires that state and municipal authorities, corporations and individuals who need the services of professional engineers communicate their wants to the bureau, 33 West Thirty-ninth street. This bureau is maintained by the four national societies of civil, mining, mechanical and electrical engineers. In behalf of engineers who have been serving in the army or in government capacities during the war, it is the desire of the Engineering Societies to get in touch with contemplated engineering projects as early as practicable. By resolutions adopted unanimously (by the 650 members present at its annual meeting) the American Society of Civil Engineers has recorded "its profound conviction that public works should be carried forward to the fullest extent consistent with sound judgment, not only for fundamental economic reasons, but for humanitarian reasons."

Two new Safe Practices Bulletins of the National Safety Council have been published. No. 16 is a ten-page illustrated monograph on safe clothing for men and women in industry. These excellent brochures contain a large amount of useful information, gathered from varied sources and clothed in lucid and vigorous language. Some members of the Council, to encourage the wearing of suitable clothes, provide women employees with the first suit free of charge. Bulletin No. 18 is on Power Presses. The ingenious recent devices for preventing workmen from injuring their hands or feet in these ponderous machines are innumerable. One picture shows a large press, in a shop of the Ford Motor Company, where each of two men must press an electric push button with each hand before the machine can be operated. These pamphlets are provided at a cost of ten cents each by the National Safety Council. 208 South La Salle street, Chicago.

Future of Gas and Electric Welding

At a joint meeting of the American Institute of Electrical Engineers and American Institute of Mining Engineers, on February 19, five papers were presented on the subject of welding, as follows: "Microstructure of Iron Deposited by Electric Arc Welding," by G. F. Comstock; "Path of Rupture in Steel Fusion Welds," by S. W. Miller; "Welding Mild Steel," by H. M. Hobart; "Electric Welding in Shipbuilding," by S. V. Goodall, and "Fusion in Arc Welding" by O. H. Eschholz.

A lively discussion followed their presentation during which it was suggested that as so much had been done in the way of making repairs, particularly by the railroads during the past two years, the time was ripe for bringing the welding processes permanently into the field of construction. It was pointed out that there are many variables to be determined in order to secure a good weld and that successful welding is dependent upon uniformity of results. For this reason it was stated that the welding operator must be both skilled and conscientious, and a diversity of opinion was expressed in the discussion as to whether the operator should be a skilled engineer or whether the average worker could be taught to do good welding work.

The particular significance of the presentation of the papers and the discussion lies in the fact that welding is demanding so much of the attention of our best engineers. This in itself is sufficient indication that the constantly increasing use of welding is to be expected. Conclusions indicated by the discussion were that both gas and electric welding had come to stay and that we may prepare for the time when the average mechanic must learn the use of the welder, just as he has had to learn the use of the hammer and chisel.

The Disposition of Surplus Government Material

Announcement was made in Washington on January 29 giving the details of the plan of organization of the Office of Director of Sales of the War Department as follows:

Under the director of sales, C. W. Hare, is an assistant, E. C. Morse, chairman of the Board of Sales Review, comprising the following members besides Mr. Morse: Lt. Col. A. LaMar, Major W. M. Crunden, Col. Fred Glover, L. H. Hartman, G. F. Woods, Capt. A. L. Mercer, Capt. T. S. Schultz. Each of these members of the board is a division sales manager with the exception of Captain Schultz, who is legal member on the board.

The announcement gives the names of seven divisions, the first of which, headed by Colonel LaMar, will handle machine tools, including all metal and woodworking tools, railway equipment, steam shovels, locomotive cranes, gantry cranes, hand tools, forging equipment, iron and structural workers' power tools and machinery.

The following is the tentative agreement reached by the government and the machine tool builders.

"1. The inventory of all machine tools and equipment which is being made will be expedited to the greatest possible extent.

"2. As soon as it is known that a quantity of machine tools is available for disposal, the manufacturers of these tools will be given an opportunity to purchase them at a price and on terms of settlement which will be satisfactory to all parties concerned.

"3. In case it is impossible for the manufacturer to purchase his product outright, an effort will be made to arrange for the marketing of the product in an equitable manner, securing for the government and the manufacturer alike the best possible terms.

"4. In case both these methods of disposition fail, the material will be offered for sale to the general public in a manner prescribed by law.

"In the settlement of plant contracts which involve the sale of large groups of various kinds of tools and equipment, an effort will be made to prevent the sale of any equipment for resale, as it is realized that great injury could be done by indiscriminate sales of this character."

Railway Regiments' Tobacco Fund

The Railway Regiments' Tobacco Fund, to which 146 railway supply companies contributed, made seven shipments of tobacco, amounting to approximately eight tons, to railway regiments in service in France. Owing to the congestion in the transport service during the summer on account of the great number of troops going over, it was found that this tobacco was not being delivered to the regiments to which it was consigned, and shipments were therefore postponed until the transport service could be organized to the point where delivery was assured; but the movements of the various railway regiments were so uncertain that it was finally decided not to make any further shipments. The total amount subscribed to this fund was $16,129.94, of which $10,056.05 was spent for tobacco, leaving $6,073.89 still in the hands of the committee handling the fund. This sum is approximately 37.5 per cent of the amount subscribed, and the committee, in making arrangements for the closing of the fund, has decided to return to the contributors 37.5 per cent of each subscription received. This will amount to practically all the funds available, with the exception of a few dollars, which will be utilized to defray expenses. In requesting subscriptions it was specifically stated that they were only to be made up to the end of the year 1918, and accordingly, all checks received since December 31, 1918, are to be returned.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Mar. 11	Varnish	Norman Holland	James Powell	P. O. Box 7, St. Lambert, Que.
Central	Mar. 14	Unified Inspection and Maintenance of Car Equipment	J. J. Tatum	Harry D. Vought	95 Liberty St., New York.
Cincinnati	May 13	Fuel Conservation	D. E. Dick	H. Boutet	101 Carew Building, Cincinnati, Ohio.
New England	Mar. 11	Annual Meeting and Entertainment, Election of Officers and Reports		W. E. Cade	683 Atlantic Ave., Boston, Mass.
New York	Mar. 21	Railway Supply Men's Night		Harry D. Vought	95 Liberty St., New York.
Pittsburgh	Mar. 28			J. D. Conway	515 Grandview Ave., Pittsburgh, Pa.
St. Louis	Mar. 14	Unification of Telegraph and Telephone Facilities	F. E. Bentley	B. W. Frauenthal	Union Station, St. Louis, Mo.
Western	Mar. 17	Mechanical Stoking of Locomotives, by W. S. Bartholomew. Address by Lt. Comm. D. C. Buell on U. S. Naval Railway Batteries in France		A. F. Stuebing	750 Transportation Bldg., Chicago.

The Railway Regiments' Tobacco Fund was initiated by F. A. Poor, president of the P. & M. Company, Chicago, and in order to raise the necessary funds, a committee was organized composed of Mr. Poor, as chairman; R. P. Lamont, president of the American Steel Foundries; George A. Post, president of the Standard Coupler Company; E. H. Bell, president of the Railway Supply Company; J. M. Hopkins, president of the Camel Company, Chicago, and A. C. Moore, vice-president, Safety Car Heating & Lighting Company. Samuel O. Dunn, editor of the Railway Age, was secretary of the committee, and John R. Washburn, vice-president of the Continental Commercial Bank, Chicago, acted as treasurer of the fund.

MEETINGS AND CONVENTIONS

Railroad Club of Washington.—One hundred and twenty employees of the Railroad Administration in the city of Washington have organized the Railroad Club of Washington. W. C Kendall, manager of the Car Service Section of the Railroad Administration, was elected president.

American Steel Treaters' Society.—This association was recently formed for the announced purpose of promoting the arts and sciences connected with the heat treatment of steel. The principal means for this purpose is to be the holding of meetings for the reading and discussion of papers bearing upon processes, instruments, equipment, apparatus, etc., employed in practical and research work connected with the art, collection, publication, and dissemination of technical and practical knowledge for the improvement of conditions in connection therewith, and to closely unite those engaged in its practical and technical branches.

A monthly journal which brings the papers and discussions had at various meetings directly to the hands of every member is published. Comprehensive and valuable service features are also a growing part of the journal and of the society's activities. Sample copies and other information may be had by addressing the general office of the society, 154 East Erie street, Chicago.

In addition to meetings in Chicago, a chapter has been organized in Cleveland, and movements of this kind are now under way in several other large cities.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

AIR BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention, May 6-8, 1919, Chicago.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—W. R. McMunn, New York Central, New York, N. Y.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.

MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York. Convention May 26-29, Hotel Sherman, Chicago.

MASTER CAR BUILDERS' ASSOCIATION.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 18-21, Atlantic City, N. J.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C. Collinwood, Ohio.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

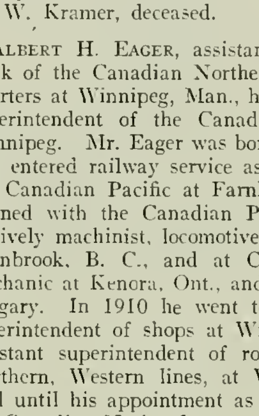
GENERAL

C. L. BUNCH, shop superintendent of the Southern Railroad, at Spencer (N. C.) shop, has been promoted to master mechanic of the Memphis division, with office at Sheffield, Ala., succeeding J. W. Gibbs, resigned.

J. L. CARVER has been appointed engineer of tests of the Illinois Central and the Yazoo & Mississippi Valley, with headquarters at the Burnside shops, Chicago, to succeed M. W. Kramer, deceased.

ALBERT H. EAGER, assistant superintendent of rolling stock of the Canadian Northern, Western lines, with headquarters at Winnipeg, Man., has been appointed mechanical superintendent of the Canadian National, with office at Winnipeg. Mr. Eager was born at Waterloo, Que., in 1868, and entered railway service as a machinist apprentice with the Canadian Pacific at Farnham, Que., in 1885. He remained with the Canadian Pacific until 1910, being successively machinist, locomotive foreman, general foreman at Cranbrook, B. C., and at Calgary, Alta, district master mechanic at Kenora, Ont., and again locomotive foreman at Calgary. In 1910 he went to the Canadian Northern as superintendent of shops at Winnipeg, and in 1915 became assistant superintendent of rolling stock of the Canadian Northern, Western lines, at Winnipeg, which position he held until his appointment as mechanical superintendent of the Canadian National.

WILLIAM F. KEISEL, JR., assistant mechanical engineer of the Pennsylvania Railroad, Eastern lines, has been appointed acting mechanical engineer, with office at Altoona, Pa., succeeding A. S. Vogt. Mr. Keisel was born on September 1, 1866, at Scranton, Pa., was educated in Lehigh Preparatory School, and in 1887 graduated from Lehigh University with the degree of mechanical engineer. He entered the service of the Pennsylvania Railroad as a draftsman, in the office of the mechanical engineer in April, 1888, and was promoted to chief draftsman in March, 1899. On July 1, 1900, he was appointed assistant engineer, and in September, 1902, he became assistant mechanical engineer, in which capacity he also had charge of the test department at Altoona until the separation of the two departments. Mr. Keisel's appointment as acting mechanical engineer of the Pennsylvania Railroad, Eastern lines, became effective on February 1.



W. F. Keisel, Jr.

T. J. LOWE, fuel agent of the Canadian Northern, Western lines, has been appointed fuel agent of the Canadian National, Western lines, with headquarters at Winnipeg, Man.

J. A. SUTTON, fuel and tie agent of the Transcontinental division of the Canadian Government Railways, has been appointed district fuel agent of divisions No. 1 and 2 of the Central district. Canadian National, Western lines, with headquarters at Cochrane, Ont.

H. Weitzel, master mechanic of the Arizona Eastern at Phoenix, Ariz., has been appointed trainmaster with office at Globe, Ariz., succeeding A. D. Rosecrans.

George W. Rink, mechanical engineer of the Central of New Jersey, has been appointed assistant superintendent of motive power, with office at Jersey City, N. J. Mr. Rink was born on September 4, 1875, at New York, and was graduated from Cooper Institute, New York City, with the degrees of B. S. and M. E. He began railway work on March 14, 1892, as a machinist apprentice on the Erie Railroad. From March, 1896, to March, 1899, he served as a machinist and shop draftsman, and then to September, 1900, as a draftsman on the Northern Pacific. He then entered the service of the Central of New Jersey, as a draftsman and from 1901 to 1902, was roundhouse foreman and inspector of new equipment. Later he was engaged in road testing of locomotives and as draftsman, until 1903, when he was promoted to chief draftsman. From April, 1904, to January, 1909, he was instructor of apprentices, and then was appointed mechanical engineer, which position he held until his recent appointment as assistant superintendent of motive power.

G. W. Rink

Axel S. Vogt, mechanical engineer of the Pennsylvania Railroad, Eastern lines, with office at Altoona, Pa., retired under the pension rules of the road on February 1. He was born on January 19, 1849, at Christianstad, Sweden, and was educated in the public schools. He began railway work in June, 1874, with the Pennsylvania Railroad at Altoona, and remained with that road until 1882, when he went with Schutte & Koehring, Philadelphia, Pa. In November, 1883, he returned to the service of the Pennsylvania Railroad as assistant engineer of tests. On March 1, 1887, he was promoted to mechanical engineer, and from that time until his retirement he served continuously in that capacity. The total length of his service with the Pennsylvania Railroad was a little more than 43 years, during which time freight and passenger cars passed through the transitory stage from wood to steel construction and locomotives increased in capacity fourfold and more, and the designs developed under Mr. Vogt's direction had considerable influence on their progress.

A. S. Vogt

Master Mechanics and Road Foremen of Engines

W. C. Barr has been appointed general roundhouse foreman of the Erie at Meadville, Pa., succeeding H. C. Eckardson, resigned.

W. E. Beck has been appointed road foreman of engines of the Erie Railroad with office at Meadville, Pa., succeeding Bert Hill, transferred.

James Carney has been appointed general foreman of the Erie Railroad at Newburgh, N. Y.

H. A. English, master mechanic of the Central district, Canadian Northern, has been appointed master mechanic of the Central district of the Canadian National, with headquarters at Winnipeg, Man.

R. E. Line has been appointed roundhouse foreman of the Erie Railroad at Kent, Ohio.

Andrew McCowan, supervisor of car works of the Canadian Northern system at Winnipeg, Man., was appointed master car builder of the Canadian National Railways, Western lines, with the same headquarters, at the time of the recent assimilation of the former road by the latter. Mr. McCowan was born at Perth, Scotland, on December 5, 1867, and was first employed by the Perthshire Carriage Works (Scotland), as an apprentice car builder, between 1881 and 1887. He began his railroad experience in May, 1888, as a carpenter on the Canadian Pacific at Montreal, Que. In March, 1890, he was promoted to car foreman, and seven years later he was appointed shop foreman at Farnham, Que. From September, 1903, to April, 1910, he was car foreman at Cranbrook, B. C., and on the latter date left the Canadian Pacific to become general car foreman of the Canadian Northern at Winnipeg, Man. He was promoted to supervisor of car works, Western lines, in September, 1915, and in May, 1916, had his jurisdiction extended over the entire system.

A. McCowan

H. G. Reid, assistant superintendent of rolling stock of the Canadian Government Railways at Transcona, Man., has been appointed general master mechanic of the Canadian National, Western lines, with offices at Winnipeg, Man.

L. G. Roblin, general master mechanic of the Canadian Government Railways, Western lines, with offices at Cochrane, Ont., has been appointed master mechanic of the Prairie district of the Canadian National, with offices at Saskatoon, Sask.

Purchasing and Storekeeping

A. E. Cox, general storekeeper of the Canadian Northern, Western lines, has been appointed general storekeeper of the Canadian National, Western lines, with headquarters at Winnipeg, Man.

W. D. Manchester, chief engineer of the Manistee & Northeastern, with office at Manistee, Mich., has been appointed purchasing agent to succeed E. H. O'Neil, who has resigned.

SUPPLY TRADE NOTES

J. H. Regan, assistant secretary of the Pressed Steel Car Company, has been transferred from the New York to the Chicago office of that company.

The eastern branch of the Independent Pneumatic Tool Company, Chicago, has been moved from 170 Broadway to larger quarters at 1463 Broadway, New York.

George N. VanSweringen, sales representative, has been appointed assistant to the vice-president of the Chicago Railway Equipment Company, with headquarters at Chicago.

On January 1 the Duntley-Dayton Company took over the entire output of the Dayton Pneumatic Tool Company, of Dayton, Ohio, and announced its entry into the pneumatic tool field. W. O. Duntley, former president of the Chicago Pneumatic Tool Company, is president of the new concern and his son, Capt. C. A. Duntley, is vice-president. Captain Duntley has not yet been relieved of his command in the 27th United States Field Artillery. The Dayton line of pneumatic tools has been on the market for many years. A new plant, equipped with modern machinery, has just been completed to take care of the business of the company.

W. O. Duntley

In addition to handling the output of the Dayton Pneumatic Tool Company, the Duntley organization is putting out a complete line of portable electric drills and grinders, as well as a full line of accessories, such as hose and hose couplings, rivet sets and chisel blanks. W. O. Duntley is one of the pioneers in the pneumatic tool business and has been closely connected with the industry for the past 25 years. He has a number of pneumatic and electric tool inventions to his credit, the Duntley electric drill being, perhaps, the most widely known. The offices of the Duntley-Dayton Company are located in the Westminster building, Chicago; the eastern offices are at 295 Fifth avenue, New York, and the Philadelphia branch in the Commercial Trust building.

Lieut.-Col. R. P. Lamont, division chief of ordnance department, with headquarters at Washington, resumed his duties as president of the American Steel Foundries at Chicago on February 1.

J. D. Corby has resigned as St. Louis district manager of sales for the Chicago Pneumatic Tool Company and has assumed the active management of the Corby Supply Company, of St. Louis.

W. R. Colklesser has been appointed purchasing agent of the Gadsden Car Works, Richmond, Va., succeeding W. F. H. Finke, resigned to accept service with the United States Railroad Administration.

Millard F. Cox, assistant superintendent of machinery of the Louisville & Nashville at Louisville, Ky., has become associated with the Louisville Fire Brick Works, Inc., of Louisville, as vice-president and consulting engineer.

William G. Denney, treasurer of the Standard Car Truck Company, Chicago, died on February 7, at his home in Millerton, N. Y., at the age of 65 years. Mr. Denney had been with the Standard Car Truck Company since its organization.

The Patterson Sargent Company, Cleveland, Ohio, is now represented by L. J. McComb as railroad paint and varnish salesman, with office at 201 Devonshire street, Boston, Mass. Mr. McComb succeeded F. Howard Childs, who died December 15, 1918.

W. W. Butler, vice-president of the Canadian Car & Foundry Company, Montreal, Que., has been appointed president. Mr. Butler is also president of the W. W. Butler Company, Ltd., and a director of the Page-Hersey Iron Tube & Lead Company.

Fred M. Egolf, who has been associated with the Acme Railway Supply Company and the Acme Steel Goods Company, has been appointed western railway and marine sales representative of the Glidden Company, Cleveland, Ohio, with headquarters in Chicago.

The Interstate Car Company, Indianapolis, Ind., is erecting a steel car and tank car repair shop and fabrication plant at Indianapolis, Ind. The building will be of structural steel, 83 ft. by 245 ft., and 40 ft. high, costing approximately $50,000. George J. Dive is in charge.

W. S. Quigley, president of the Quigley Furnace Specialties Company, Inc., New York, sailed for Liverpool on February 15, for the purpose of further developing European connections of his company. Mr. Quigley will spend several weeks in England, France and Italy, and visit the plants installing the Quigley system for preparing and burning pulverized coal and lignite.

Ezra S. Taylor, assistant to the vice-president of the Pullman Company, has been elected assistant to the president, with office in the Pullman building, Chicago. Mr. Taylor was born at Chicago in 1880. When 17 years old he entered the employ of the Atchison, Topeka & Santa Fe as a member of a surveying gang in Texas. After three years in this work, he came to the Chicago office of the Santa Fe as a clerk in the freight department, and in 1900 he entered the employ of the Pullman Company as a clerk in the auditing department. From 1902 to 1905 he was assistant to the storekeeper, and later to the operating superintendent of the Chicago Elevated Lines at Chicago. The following three years he was assistant purchasing agent for the Western Steel Car & Foundry Company, at Anniston, Ala., and later at the Hegewisch (Ill.) plant. To increase his knowledge of the steel business, Mr. Taylor subsequently entered the employ of the Illinois Steel Company at its open hearth plant in South Chicago, where he remained for one year. In 1909 he returned to the Pullman Company as chief clerk in the sales department, and was subsequently general eastern agent at New York and assistant to the vice-president, which position he held until his appointment as assistant to the president on February 6, 1919.

E. S. Taylor

W. W. Hayward, secretary and treasurer of the Butler Drawbar Attachment Company, Cleveland, Ohio, died of pneumonia on February 12. Mr. Hayward had served as secretary and treasurer of the company since its organization. He has been succeeded by W. B. Waggoner.

The Chicago Pneumatic Tool Company, Chicago, has established a branch office at St. Louis, Mo., under the management of H. W. Buker, who succeeds J. D. Corby as district manager of sales. A stock room and service station will be maintained at St. Louis, as well as the district office.

C. C. Farmer, until recently assistant western manager and resident engineer for the Westinghouse Air Brake Company, has been advanced to the position of director of engineering of the same company with which he has been connected for many years. He was born in California, where he received his education. After a number of years as machinist on the Southern Pacific, he began, in 1891, a study of brake action and train control in the Westinghouse Air Brake Company instruction car, on various roads throughout the country. In the same year, the Missouri, Kansas & Texas offered him the position of supervisor of air brake repairs, from which he was advanced in a few months to air brake inspector of the entire road. In 1896 he became general air brake instructor of the Central of New Jersey and soon after became an inspector for the Westinghouse Air Brake Company. Not long after his second association with the Westinghouse Air Brake Company he was transferred to the Chicago district as mechanical expert. Then he was appointed resident engineer, and later, with the understanding that he would still retain the title of resident engineer, he was made assistant western manager, from which dual position he has now been advanced to that of director of engineering.

C. C. Farmer

A. W. Preikschat, formerly assistant to the engineer of tests of the Pullman Company, and later special representative in the purchasing department of the Steel Tube Company of America, has been appointed sales representative of the Liberty Steel Products Company, Inc., with offices in the McCormick building, Chicago.

W. Jerry Stanton has resigned as sales manager of the Railway Improvement Company to become special representative of the National Railway Appliance Company, New York. Mr. Stanton was employed by the General Electric Company for a period covering 18 years in the testing, engineering and sales departments.

At the organization meeting of directors of the Air Reduction Company, Inc., New York, held on February 19, the following officers were elected: President, A. S. Blagden; vice-president, A. R. Ludlow; treasurer, C. E. Adams; secretary, M. W. Randall; assistant treasurer, C. L. Snow, and assistant secretary, C. C. Emerson.

The Rich Tool Company, Chicago, announces the appointment of J. L. Crowley as special railroad representative, with headquarters at the company's main offices, Railway Exchange building, Chicago. H. W. Ullman has been appointed sales representative in the St. Louis territory, with offices at 203 Security building, St. Louis, Mo.

Fred Mathews, sales representative of the Union Metal Products Company at Chicago, has been appointed southern manager of the Standard Railway Equipment Company, the Pressed Steel Manufacturing Company, the Imperial Appliance Company and the Union Metal Products Company, with headquarters in the Candler building, Atlanta, Ga.

The Quigley Furnace Specialties Company, New York, has opened a branch office in the Turks Head building, Providence, R. I., in charge of F. W. Reisman, who has been the company's eastern New England representative for Hytempite, a high-temperature, firebrick cement, and insulating brick, as well as the Quigley air transport system for distributing and burning powdered coal and other fuels.

Huntly H. Gilbert, who left the service of the Pressed Steel Car Company and Western Steel Car & Foundry Company at the start of the war to enter the army as captain in the Ordnance Department at Washington, and later was commissioned major and transferred to the Rock Island Arsenal, has re-entered the service of the above named companies, as assistant manager of sales for the western district, located at 425 Peoples Gas building, Chicago.

W. B. Gibson, manager of the mining machinery department of the Allis-Chalmers Company, of Milwaukee, Wis., has been appointed manager of the small tank department of the William Graver Tank Works, Chicago, and R. C. Huntington, manager of sales promotion of the Fuller Rubber Company, Hampton, Ohio, has been placed in charge of department of sales, promotion and advertising of the William Graver Tank Works at Chicago.

George Sherwood Hodgins, of the editorial staff of Railway and Locomotive Engineering, died at his home in New York on January 18, at the age of 59 years. A graduate of the Upper Canada College and the School of Applied Science, affiliated with the University of Toronto, he afterward served an apprenticeship in the Kingston Locomotive Works. After some experience in a division master mechanic's office on the Canadian Pacific, he was advanced to various positions on the road, and latterly was locomotive inspector on the entire system. He was recalled to the Kingston Locomotive Works as mechanical engineer. Later he entered the service of the Pressed Steel Car Company as general inspector of the output of that plant, and was also for some years inspector for the Richmond Locomotive Works. During these earlier years he had contributed to a number of railroad publications. In 1900 he entered the field of practical journalism as editor of the Railway Digest. In 1902 he joined the staff of Railway and Locomotive Engineering, as associate editor, and in 1908 became managing editor, which position he held till 1911, when he was called by the Canadian government to make a comprehensive report on the shops, appliances, tools and equipment necessary for the Trans-Continental Railway. On the completion of that work in 1915, Mr. Hodgins joined

G. S. Hodgins

the staff of the Railway Periodicals Company as managing editor of the Railway Master Mechanic and Railway Engineering and Maintenance of Way. In 1916 he returned to Railway and Locomotive Engineering and remained on the staff as editor until his death, besides contributing to popular science magazines.

P. C. Cady, office manager of the mechanical department of the New York Central at New York, has been appointed assistant secretary of the International Railway Supply Company, New York, which is the purchasing agent for the American Railroad Company of Porto Rico and the Trinidad Government Railways, and also the export department of the Pyle-National Company. Mr. Cady was in railroad service since 1893, when he entered the mechanical department of the Lake Shore & Michigan Southern at Cleveland, Ohio.

John S. Y. Fralich has been appointed resident engineer of the western district for the Westinghouse Air Brake Company, succeeding C. C. Farmer. Mr. Fralich has been with the Westinghouse Air Brake Company since 1904. He was born at Harrisburg, Pa., September 19, 1880, was educated in the grade and high schools of Philadelphia, and received his engineering training at Williamson School. He then served a regular three years' apprenticeship as a machinist and was employed for two years as a machinist in the Altoona shops of the Pennsylvania Railroad. He became connected with the Westinghouse Air Brake Company in June, 1904, having been hired as a machinist, and shortly thereafter assigned to the inspection force. He was then respectively shop inspector, special inspector with the experimental test department, supervisor of shop tests and acting assistant to the mechanical engineer. He did special engineering work in the Chicago office from March to December, 1913, was appointed assistant resident engineer in December, 1913, and resident engineer of the western district February 1, 1919, as above noted.

J. S. Y. Fralich

Randolph S. Reynolds, secretary of the Curtain Supply Company, Chicago, died of pneumonia on January 20. Mr. Reynolds was with the Curtain Supply Company since 1912. Prior to that time he was with the Western Steel Car & Foundry Company, at Anniston, Ala., and the Pressed Steel Car Company, at Pittsburgh, Pa., having been connected with their purchasing departments from 1905 to 1912. He left the Pressed Steel Car Company in 1912 to accept a position with the Curtain Supply Company, and later was made assistant to general manager, and on April 30, 1918, was elected secretary to succeed Holmes Forsyth, who on that date became president.

The American Arch Company, New York and Chicago, announces the appointment of the following as traveling engineers of the company: E. S. Nicholas, with headquarters at Detroit, Mich., formerly boilermaker foreman of the Missouri Pacific shop at Kansas City, Mo.; M. R. Smith, with headquarters at St. Louis, Mo., formerly master mechanic at Coxton, Pa., on the Lehigh Valley; H. Darby, with headquarters at St. Paul, Minn., formerly motive power inspector of the Grand Trunk Pacific at Transcona shop, Winnipeg, Man., and J. D. Brandon, with headquarters at Montreal, formerly general foreman at the Brightwood shops, Indianapolis, Ind., of the Big Four. E. T. Mulcahy has again assumed his duties as traveling engineer of the American Arch Company, having been honorably discharged from the United States Army. Mr. Mulcahy's headquarters will be at Denver, Colo. Before coming with the American Arch Company Mr. Mulcahy was connected with the Union Pacific at its Cheyenne, Wyo., shops.

Railroad Administration Takes Over Superheater Company

Director General Hines announced on February 18 that the United States Railroad Administration, at the instance of the alien property custodian, had purchased more than 51 per cent of the stock of the Locomotive Superheater Company. According to Mr. Hines' statement, this stock originally belonged to German interests. The alien property custodian suggested that the interests of this government could be best protected through some governmental agency acquiring the stock. The purchase by the Railroad Administration will prevent effectively the passing of the stock back to German control.

At the annual meeting of the Locomotive Superheater Company, held at the office of the company, 30 Church street, New York City, the following directors were elected: J. S. Coffin, chairman; S. G. Allen, George L. Bourne, H. B. Spencer, Sanford H. E. Freund, J. N. Wallace, F. W. Scott, T. C. Powell and Henry Morgenthau Five of these, Messrs. Spencer, Freund, Wallace, Scott and Powell, are representatives of the Railroad Administration.

It was announced that as the affairs of the company have been satisfactorily managed by its officers, no change was made in the management. George L. Bourne, R. M. Osterman, F. A. Schaff and S. G. Allen were re-elected, respectively, president, vice-presidents and secretary; Henry Morganthau was elected treasurer, and T. C. Powell, director of the Division of Capital Expenditures of the Railroad Administration, was elected an additional vice-president of the reorganized company.

The Pulverized Fuel Equipment Corporation

The Pulverized Fuel Equipment Corporation has recently been organized for the purpose of taking over the business of the Locomotive Pulverized Fuel Company, and to broaden the activities of the latter to cover the central power station, metallurgical and industrial fields. The head offices are at 30 Church street, New York, with Canadian office in the Transportation building, Montreal.

This corporation installs and delivers in operation complete plants of its "Lopulco" system for the preparation, distribution, storage, feeding and burning of pulverized fuel for any steam generating or heating purposes whatsoever. The development by the Locomotive Pulverized Fuel Company of its "Lopulco" system for the burning of anthracite and bituminous coals, lignite and peat in pulverized forms, has already commercially demonstrated its adaptability for not only steam locomotives and steamships, but for central power station and other direct and waste heat stationary boilers, and for metallurgical and chemical furnaces and cement and other kilns. Many such installations are now in use and in process of construction in connection with public utility properties and large industrial and manufacturing plants.

The officers of the Pulverized Fuel Equipment Corporation will be: J. S. Coffin, chairman; J. E. Muhlfeld, president; H. F. Ball, executive vice-president; H. D. Savage, vice-president in charge of sales; V. Z. Caracristi, vice-president in charge of engineering; Samuel G. Allen, secretary-treasurer.

Catalogues

Tanks.—Bulletin 259 of the Walter A. Zelnicker Supply Company, St. Louis, Mo., contains a revised list of new and used tanks of all kinds and sizes that are for sale by this company.

Threading Machines.—The complete line of threading machines for bolts, nuts and pipe, manufactured by the Greenfield Tap & Die Corporation, Greenfield, Mass., is described and illustrated in Catalogue 41, which also gives the specifications for the machines and detailed information regarding parts for threading machines.

Electric Drills.—A four-page folder descriptive of the Thor line of portable electric drills and grinders has been issued by the Independent Pneumatic Tool Company, Chicago. These drills can be operated on either direct or alternating current. The bulletin contains a table showing capacities, speeds, dimensions, etc., of the various sized tools.

Powdered Coal Transport System.—Bulletin 10, a four-page pamphlet issued by the Quigley Furnace Specialties Company, New York, describes the Quigley air transport system for transporting and burning powdered fuel and contains several illustrations showing the operation of the system and the difference in structural work between a screw conveyor installation and the air transport system.

Graphite Products.—A new pocket catalogue has been issued by the Joseph Dixon Crucible Company, Jersey City, N. J., entitled "Dixon's Graphite Products." While not a complete catalogue, it furnishes a good idea of the variety of products made by this company. Pages are devoted to lists of articles especially for mills, railroads, automobiles, etc., with brief descriptions. Pamphlets dealing in detail with any one product may be had upon request.

Wrenches.—The Coes Wrench Company, Worcester, Mass., has issued a 14-page catalogue dealing with the line of screw wrenches and accessories made by this company. These include steel, knife and hammer handle wrenches. Information is given regarding their construction, manufacture and strength compared with other wrenches, as shown by tests made at the Harvard University testing laboratory. The catalogue contains a number of illustrations.

Steam Engine.—A detailed description of a high speed, piston-valve steam engine manufactured by the Ingersoll-Rand Company, New York, is contained in Bulletin No 9026, issued by that company. This engine is of the horizontal center crank type and is known as class "F P." The details of the machine are fully described and are shown in a number of illustrations. Four sizes are specified, ranging from 6 in. by 6 in. cylinders to 14 in. by 12 in. cylinders, and brake horsepower from 12 to 81.

Oxy-Acetylene Welding.—The Air Reduction Sales Company, New York, has published an attractive booklet, containing an outline of a short course for colleges and technical schools in oxy-acetylene welding and cutting, prepared by Alfred S. Kinsey, professor of shop practice and head of the department of shop practice at Stevens Institute of Technology, Hoboken, N. J. This was prepared to meet requests from college instructors for suggestions as to the best course to follow in teaching this subject.

Flanging.—An attractive catalogue entitled, "A Solution of Your Flanging Problems," containing 30 pages, 9 in. by 12 in., has been issued by the McCabe Manufacturing Company, Lawrence, Mass., illustrating and describing the wide range of work that can be done on the McCabe flanging machine, and showing economies that may be effected by its use. The greater part of the book is given over to illustrations showing finished products, such as various kinds of tanks, locomotive firebox and boiler sheets, steel car parts, etc.

Boilers.—"Boiler Logic" is the title of an 86-page treatise on steam boilers prepared by the Heine Safety Boiler Company, St. Louis, Mo. Six topics are discussed as follows: Some fundamental considerations of boiler design; practical baffling of water tube boilers; Heine boilers for different fuels, firing and services; overloads; the boiler as a pressure vessel, and details of construction of Heine boilers. A number of illustrations accompany the text, including a supplement in color of a Heine boiler set over an underfeed stoker.

Belt Fasteners.—The Crescent Principle of Belt Joining is the title of a four-page bulletin issued by the Crescent Belt Fastener Company, New York, describing the fasteners made by this company for joining all kinds of belting. These are claimed to give a flush joint, allowing the belt to have continuous contact with the pulleys. Several illustrations show completed joints with the various kinds of fasteners. The method of making the joints is also explained and illustrated. A ready reference chart, by means of which a belt man or machinist can readily determine the correct type of belt fastener to use for any condition of service is included in the bulletin.

Railroad Water Softening.—The Wm. Graver Tank Works, Chicago, has issued a treatise on the subject of water softening which consists of a collection of 31 reprints of full-page advertisements which are unusual in that little or no reference is made to any particular make or type of water softener, the material being almost entirely in the nature of a comprehensive exposition of the entire subject. Of particular note are 12 sheets presented in the form of articles covering various phases of this subject, prepared by W. R. Toppan, manager of the railroad department of the Wm. Graver Tank Works. These appear with such titles as "Operating Efficiency Increased by Purifying Water," "Water Softening in Relation to Ton Mileage," "The Method of Water Treatment Determines the Uniformity of Results." In addition to these 31 pages there is an eight-page appendix on the chemistry and economics of water softening. This serves to combine in a very short space a large amount of information required by the water service engineer in solving the problems arising in his work.

Forge Shop Equipment.—The Erie Foundry Company, Erie, Pa., has issued Catalogue F, containing 43 pages 8½ in. by 11 in., describing the Erie steam forging hammers, steam drop hammers, trimming presses and sheet galvanizing and shearing machinery. This catalogue is attractively arranged and contains a large number of illustrations. Two pages are devoted to each machine, one containing a description of the construction and the other an illustration of the machine with a table of specifications. Other illustrations show forgings made under Erie steam drop hammers and installations of this equipment in industrial plants. Several special features of design are separately described and illustrated, including a safety device for the protection of the operator from injuries caused by the breakage of top cylinder heads, an improved construction of guides and guide bolts which makes it unnecessary to remove the guide from the frame, an improved sow block or anvil cap, which eliminates the possibility of its working loose, and a throttle control. There are also several pages of instructions for erecting, operating and adjusting the Erie hammers and sketches showing the proper construction of the foundations, as well as drawings of the machines with all the parts numbered and named.

Railway Mechanical Engineer

Volume 93 | April, 1919 | No. 4

CONTENTS

Don't Neglect Grinding Stands and Wheels

Observation of the conditions in a considerable number of railroad shops indicates that the grinding wheels and stands installed for free hand tool grinding are subjected to a great deal of abuse. These machines, although simple, are important and should be carefully selected and properly maintained. If either the stand or the wheel is not in the best of condition it will result in the workmen wasting time and spoiling tools. Grinding wheels cannot operate well unless they are firmly supported, and for that reason the stand should be rigid and equipped with a heavy spindle. A concrete foundation will give added stability and increase the life of the grinding wheels. Granting that the machine has been properly selected and installed, the next care should be to maintain the bearings in alignment without either end or side play.

One of the common mistakes in the use of grinding wheels is the selection of too hard a grade. This is often due to inadequate support for the wheel. If a soft wheel is allowed to vibrate it will wear down very quickly, and for that reason a hard wheel is some times chosen in an attempt to counteract the effects of a poor stand or a good stand improperly installed. On the other hand, hard wheels are sometimes chosen when the only argument in their favor is the increased life secured by their use. Harder wheels require more power to do the same amount of work, cut more slowly than soft wheels and are more apt to burn the tools. The development of grinding processes has undoubtedly been hindered in many railroad shops by the lack of knowledge of the properties of grinding wheels and failure to appreciate the advantages of and the wide field of application for grinding. Some few roads have done notable work in this direction; others should make better use of grinding processes. There is no better way to start than by putting the grinding stands in condition to give efficient service.

Tendencies in Boiler Design

The scientific design of locomotive boilers has developed rapidly in recent years. The tests conducted at Coatesville in 1912 demonstrated the relatively high evaporative value of firebox heating surface and these together with tests made at Altoona provide data which furnish a satisfactory basis for the rational design of boilers of moderate size. Large locomotive boilers, however, require further investigation.

A ratio of length to diameter of approximately one hundred to one is generally recognized as being the most desirable proportion for boiler tubes. If the tubes are lengthened beyond this limit, the heat absorption is increased very little, while the rate of evaporation is decreased and the vacuum required to maintain a given rate of combustion (and consequently the back pressure) is increased. The tubes can, of course, be shortened by making the combustion chamber longer. This sacrifices heating surface and while there is little evidence on which to base an opinion, many locomotive designers feel that it is not advisable to make a combustion chamber more than five feet long. If the length of the combustion chamber is limited to five feet, the tubes in the average Santa Fe or Mountain type locomotive will be about 20 or 21 ft. long. Assuming that 2¼-in. tubes are used, the ratio of length to diameter will be about one hundred and ten to one. Some roads are now using 2½ in. tubes and even larger sizes may prove desirable. As the flame area through the tubes is increased by the larger diameter, it may be advisable to shorten the combustion chamber.

There seems to be no good reason for retaining tubes of 2¼ in. diameter in large modern locomotives; nevertheless the practice is almost universally followed. It is probable that a ratio of length to diameter of approximately one hundred to one would prove the most economical and while the larger tubes needed to maintain this ratio would decrease the heating surface somewhat, they would very likely increase the boiler capacity. The problem is of great importance and steps should be taken to determine the best proportions for large locomotive boilers.

Eliminate Brake Beam Safety Chains

In glancing through a recent issue of one of the railroad employees' magazines, we were struck by three items telling of station agents who had been commended for noticing dragging brake beams on passing freight trains. These notices are compliments to the alertness of the men in station service, but are also a reflection on the mechanical department. Brake beams are recognized as frequent causes of derailments and thorough terminal inspection cannot prevent occasional failures of the hangers, yet few roads have equipped their cars with adequate safeguards to prevent danger from falling beams. This criticism does not apply to cars built in recent years, as improved safety guards have been used extensively on new equipment since their introduction; but little has been done toward replacing the safety chains which until a few years ago were practically standard equipment. The brake beam safety chain has so many defects that it should be replaced as rapidly as possible, and some standard device for supporting beams in case the hanger fails should be adopted by the Mechanical Section of the American Railroad Association. Such a device should, if possible, be made of materials commonly carried in stock; it should be of substantial construction and not subject to wear by reason of vibration. It would be desirable also to incorporate in it some means for insuring even brake shoe wear and for preventing the bottom brake rod from falling to the track in case the pin by which it is joined to the brake lever should work out.

Why Car Repairs are Behind

In his paper before the Central Railway Club on March 14, J. J. Tatum, general supervisor of car repairs of the Railroad Administration, gave an excellent presentation of the conditions required to bring about a satisfactory car repair situation. As is usually the case, however, the difficulty lies in the practical application of the principles enunciated. It is doubtful if anyone, even though he may have resorted to the practice himself, will attempt to defend the practice of clearing repair tracks by removing bad order cards, but a strict adherence during the war to principles of car maintenance which are generally recognized as correct, would probably have resulted in a complete tie-up of the transportation system within a week. The real crux of the whole situation is a falling behind on the purchase of new cars for renewals and a general lack of sufficient car repair facilities throughout the country.

The business of the railroads is to move traffic, and nothing can be allowed seriously to interfere with this, even temporarily. If traffic is waiting to be moved, cars must be furnished so long as there are any in sufficiently good condition to turn a wheel. There is little hope, therefore, of bringing about an improvement in conditions during a period of unusually heavy traffic movement. The inexcusable feature of the whole situation is the failure to take full advantage of such facilities as are available when conditions permit the release of the cars for heavy repairs.

The lack of facilities was hinted at in Mr. Tatum's paper. While it may be impossible for the Railroad Administration to carry out any extensive plans for increasing facilities, it has already rendered a real service in its campaign for unification of car inspection and repairs by drawing general attention of operating and administrative officers to the needs of the situation. To what extent this will be followed by action, particularly to increase facilities, will depend largely upon the final settlement of the whole railroad problem.

Wheel Arrangement and Boiler Proportions

One of the outstanding features of the Philadelphia & Reading Consolidation type locomotive, a description of which appears elsewhere in this issue, is the tractive effort which has been obtained in relation to the proportions of the boiler which it is possible to place on the 2-8-0 wheel arrangement. The tractive effort of 61,260 lb. has probably been exceeded only by that of the Delaware & Hudson pulverized fuel burning Consolidation type locomotive built three years ago, which is 61,400 lb. For heavy drag service, which the engines are designed to handle, it is apparent that tractive effort at slow speeds is relatively of greater importance than high sustained horsepower capacity at the speeds coincident with the maximum horsepower rating of the locomotive, and under such conditions the reduced first cost and maintenance which may be expected from the absence of a trailer are worthy of consideration. It is only on this basis that the sacrifices in boiler capacity with this wheel arrangement can be justified.

But considering the boiler of this locomotive alone, entirely aside from its relation to the cylinder capacity, the use of tubes 13 ft. 6 in. long appears to be shorter than is demanded for the highest efficiency. The best ratio of length to diameter of tubes, considering both capacity per unit weight and efficiency, is 100. With 2-in. tubes, which are in use on the Philadelphia & Reading locomotive, the ratio of length to diameter is 81, a considerable reduction from the generally accepted ratio. The sacrifice in tube length is partially accounted for by the inclusion of a combustion chamber, which is desirable for the best results in getting the heat out of the fuel, but it is evident that with the short tubes this will be partially offset by a loss of efficiency due to the higher front end temperatures. It is doubtful whether the best results, from the standpoint of efficiency, any more than from the standpoint of capacity, can be obtained with the 2-8-0 type, with tubes of the usual diameters.

Keep up Standards on New Work

The failure of Congress to pass the bill authorizing the appropriation which the Railroad Administration requested makes it necessary to curtail expenses until another revolving fund is provided. This unfortunate financial condition is already affecting the expenditures for improvements and has brought work on many partially completed projects to a standstill. Under these circumstances there is a powerful temptation to complete unfinished installations with the least possible additional outlay and it may not be out of place to sound a warning against the purchase of cheap equipment in order to stretch the appropriations.

There is often a noticeable tendency on railroads to give more consideration to first cost than to the cost of operation, due probably to the fact that requisitions are handled by purchasing officers who are interested in securing low prices but have little conception of the suitability of the equipment they purchase, or the great differences in the cost of operation that may exist between apparently similar types. Under present conditions, when it is difficult to secure authority for expenditures, railroad men are apt to figure their minimum requirements and accept facilities which their judgment tells them will prove wasteful in the end. There is every reason to believe that the traffic on railroads in this country will increase as rapidly in the future as it has in the past and that the motive power and rolling stock will continue to grow larger. Facilities which meet present requirements with little excess capacity for future demands are almost sure to prove inadequate in a few years. In the end it is more important that whatever is done be done right, than that a greater number of things be done in a half-hearted way.

There seems to be no question that the railroads will soon be given sufficient revenues to enable them to make the needed extensions to their properties. For that reason, it is advisable to make the best of present facilities for the time being with a view to making all improvements adequate to take care of future requirements. Whether it is a matter of adding to shop facilities or improving locomotives or cars, the mechanical department officers must realize the importance of choosing the course that will in the end prove the most economical and of standing firmly by the decision in spite of the obstacles with which they are confronted at the present time.

The Mechanical Associations

The convention season is fast approaching and railway mechanical department officers and foremen are giving much thought to the problem of the future welfare and development of the various railway mechanical department associations. The two major organizations, the American Railway Master Mechanics' Association and the Master Car Builders' Association, under the new order of things will be combined into the Mechanical Section of the American Railroad Association. Except that the names of the two organizations will be discarded and their efforts will be combined, it would appear that there is no reason why the good work that they have done in the past should not go steadily forward but at a faster pace. While these two associations have made many recommendations in the past, it has been impossible to make them generally effective, except insofar as the various roads subscribed to the Master Car Builders' rules of interchange. It has been suggested many times that the recommendations of the two associations should be passed on and approved by the American Railway Association but even that organization has had no way of generally enforcing its recommendations. The new organization provides that the various sections should report direct to the American Railroad Association and that its recommendations in turn should go to the Railroad Administration which has the power to make them effective throughout the roads under its control.

It is, of course, somewhat of a question as to just what will happen when the railroad properties are returned to the private managements, but it would seem that some steps should be taken to the end that the American Railroad Association should have authority to put into effect such recommendations as may be made to it by its various sections after full investigation, study and discussion, and which in turn receive the approval of the higher organization. If this can be done, then the amalgamation of the two major mechanical associations as a section of the American Railroad Association promises to add very greatly to the importance of such work as may be done by the Mechanical Section.

A careful study of the constitution and by-laws indicates that the different sections of the American Railroad Association will be left to work out their problems largely in their own way and there appears to be no good reason why any of their past methods or practices should be upset, provided they have been found effective. Regardless of what the future may hold, however, the mechanical department officers and foremen should make every possible use of the opportunity that lies before them in demonstrating their ability to meet the larger problems that now confront them. The past three years have brought vividly before the higher executive officers the importance of the equipment and maintenance situation. If a mechanical man proves that he is a master of those things which come within his province, he is bound to be listened to with attention. The great difficulty is that many of the mechanical department officers have allowed their lights to be hidden under a bushel and it is not strange that in some cases they have not inspired confidence on the part of their superiors. They have a great opportunity to overcome this deficiency at the present time.

Just what disposition is to be made of the minor mechanical department associations does not as yet appear. It would seem wise, however, that they should be allowed to preserve their individuality but that some channel be provided so that their findings will automatically go to the Mechanical Section of the American Railroad Association and either be approved and made standard or recommended practice, or be referred back to the minor organizations for further consideration. One great handicap to the minor mechanical organizations has been that they have lacked in official recognition and although their work has been a great help and inspiration to the members and to those who have followed their proceedings closely, their recommendations and findings have not had the force that they should have had. It may be well to more clearly define the exact field and limitations of each of the associations in order that the entire mechanical department be covered by these minor organizations and that there be no overlapping.

Thus far the Railroad Administration has asked the managements of the different roads to see that as many of the members of the various organizations as possible be sent to the conventions. Apparently, this practice is to be continued, at least in the case of all of the associations that receive the approval of the Administration. The result will be that the attendance in all cases will be larger and more representative than it has been in the past and this should do much to encourage the officers and committee chairmen in putting forth extra efforts to make the meetings of the very greatest possible value.

The reports and papers for the June mechanical conventions are being rapidly turned in to Secretary Hawthorne, and it is expected that all of them will be in the hands of the members at a much earlier date than usual. The conventions will be watched more closely and critically than ever before and every member should take a pride in going to Atlantic City prepared to discuss the reports intelligently and with the idea of going back to his home road prepared to advocate and make effective those things that are developed at the convention that seem to him to be of the greatest practical value. Officers at the head of the mechanical departments should encourage their subordinates in this respect and will do well to ask for a written report of recommendations from each one who attends the meetings. This will tend to encourage the men to crystallize their thoughts and findings and will add much to the returns that may be expected from the conventions.

NEW BOOKS

Mechanism of Combustion. By J. T. Anthony, vice-president, American Arch Company, New York. 24 pages, 8 in. by 10½ in., illustrated, bound in paper. Distributed by American Arch Company, 30 Church street, New York.

The American Arch Company is issuing a series of bulletins dealing with the subject of combustion and the transfer of heat, of which the bulletin on The Mechanism of Combustion is the second. This bulletin presents in a very clear manner the various processes that take place in the combustion of coal. It explains the molecular construction of fuel and shows just what transformations occur in its combustion and why they occur. In other words, a very well merited attempt is made to explain the "mechanism" of combustion. The illustrations included in the pamphlet serve as a tremendous aid to the reader in visualizing the chemical processes of combustion. The pamphlet also shows where and how the heat is generated from fuel by the process of combustion. It discusses first the structure of atoms and molecules and explains the hydrocarbon molecules which are found in fuel. It explains the action of these atoms and molecules in the coal in both the quiescent and active (when the coal is burning) state. It fully explains why and how the heat is obtained. The pamphlet is strongly recommended to those desiring to learn more of the secrets of the combustion of coal.

COMMUNICATIONS

INADEQUATE MAIN BOXES

Brooklyn, N. Y.

To the Editor:

The communication from J. H. Buck on the subject of "Inadequate Main Boxes," published in your issue of March, 1919, calls attention to a defect which has developed very rapidly in large modern locomotives. The writer does not agree with Mr. Buck that larger boxes and bearings would remedy the evil. An extension of bearing surface toward the neutral axis of the locomotive has not even proved palliative and an enlargement of journal diameter is open to the objection that the increased surface velocity of the journal might cause heating.

In order to call attention to some ratios which seem to have been neglected in modern locomotive design, the writer has prepared the table, embracing characteristics of four types of locomotives, namely, four-coupled, six-coupled, eight-coupled and ten-coupled. The writer has chosen a maximum static rail load of 30,000 lb. per wheel, and in order to make driving box conditions as nearly comparative as possible this load, the boiler pressure, the piston stroke and driving wheel diameter have been assumed as alike in each instance. The tractive effort is based on a factor of adhesion of four and appropriate cylinder diameters have been derived from the data.

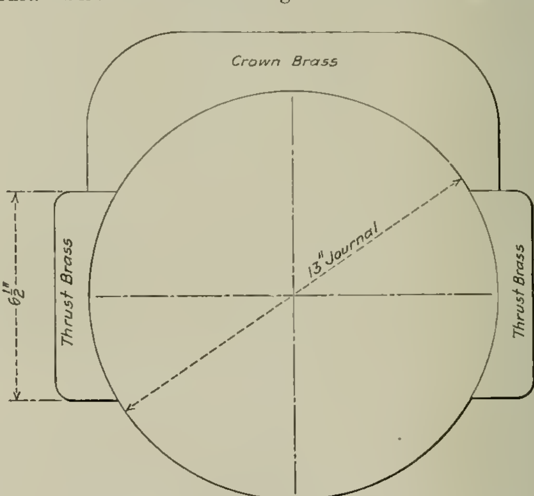
From the cylinder areas and boiler pressure, piston thrusts are derived. Journal sizes corresponding to current practice are given. In the table, line 4 has been derived from line 3 by subtracting the dead weight of one-half the axle, the wheel, the crank-pin and the attached rods. By reason oi the fact that these weights are somewhat greater in the ten-coupled than in the four-coupled engines the live loads carried by the journals are less in the ten-coupled engine than in the four-coupled. The vertical bearing pressures

1—Number of driving wheels	4	6	8	10
2—Total weight on driving wheels, lb.	120,000	180,000	240,000	300,000
3—Weight on each driving wheel, lb.	30,000	30,000	30,000	30,000
4—Live load on each main journal, lb.	27,500	27,235	26,950	26,650
5—Tractive effort (ratio of adhesion = 4), lb.	30,000	45,000	60,000	75,000
6—Boiler pressure, lb. per sq. in.	200	200	200	200
7—Piston stroke, in.	30	30	30	30
8—Diameter of driving wheels, in.	63	63	63	63
9—Cylinder diameter (derived), in.	19¼	23⅝	27⅛	30½
10—Piston thrust, lb.	57,454	87,672	115,574	146,124
11—Size of journals, dia. and length, in.	10x15	11x15	12x15	13x15
12—Vertically projected area of bearings, sq. in.	150	165	180	195
13—Horizontally projected area of bearings, sq. in.	75	82½	90	97½
14—Vertical bearing pressure, lb. per sq. in.	183	165	149	136
15—Horizontal bearing pressure, lb. per sq. in.	766	1,062	1,284	1,498
16—Line 10 divided by line 4	2.08	3.22	4.29	5.48

per square inch are obtained by dividing the figures in line 4 by those in line 12. Line 13 is based on the assumption that the bearing embraces only the upper half of the journal. The horizontal bearing pressures are obtained by dividing the figures in line 10 by those in line 13.

A perusal of the figures in line 14 (vertical bearing pressures) and line 15 (horizontal bearing pressures) reveals some interesting information. The vertical bearing pressures per square inch have decreased progressively as the size of the locomotive has increased, owing to the fact that the journal dimensions have increased, while the live load carried has slightly decreased. The horizontal bearing pressures due to piston thrusts have increased progressively with the increase of locomotive capacity. In other words, the bearings of the ten-coupled engine will wear in the vertical direction only 75 per cent as fast as will those of the four-coupled engine, while in the horizontal direction the bearings of the ten-coupled engine will wear 194 per cent as fast as those of the four-coupled engine. Thus, it will be seen that the tendency of the bearings to wear open at the points will be greater in the ten-coupled engine. That these are facts and that the effect is as described, no one can deny. The foregoing relates entirely to friction and wear.

In line 16 we find a ratio which, to the writer's knowledge, has never been used. This is the ratio between the piston thrust and the pressure downward which holds the bearing on the journal. During the writer's experience as a locomotive engineer he handled a class of heavy tandem compound ten-coupled engines. When working at full capacity these engines raised the main boxes from their journals. So pronounced was this tendency to rise that it caused an epidemic of broken oil cellars, which was cured only by increasing the clearance between the journal and the cellar. This would make it appear that the half-shell brass is, in effect, an inclined plane the angle of which depends upon and varies with the weight on the journal and the piston thrust. Somewhere in the range of the writer's table the



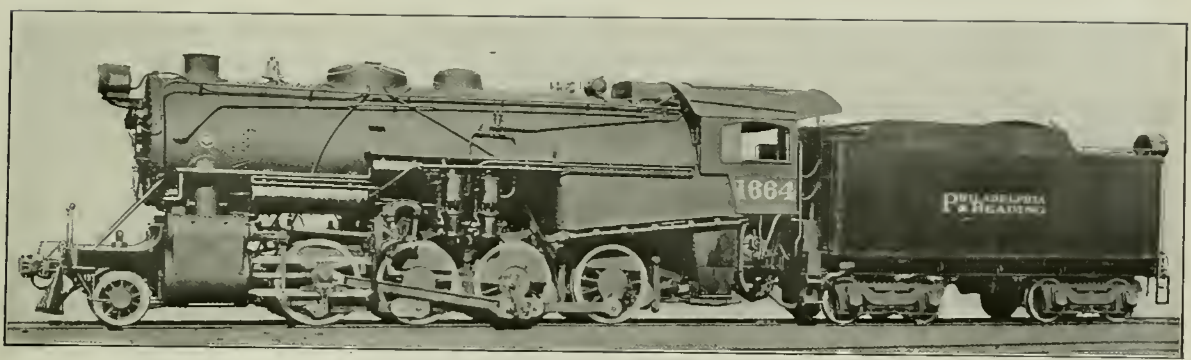
Proposed Arrangement of Driving Box Bearings

critical angle at which the box tends to rise from the journal could, no doubt, be found by experiment. It would probably be quite difficult to determine this angle mathematically, but the remedy is easily determined.

It is the writer's opinion that this tendency to rise is the principal reason for the rapid deterioration of main boxes in heavy power and that the only real remedy lies in providing bearing surface below the center line of the journal, as shown by the sketch submitted. By this means a horizontally projected bearing area 50 per cent greater than that ordinarily provided may be obtained. Such an increase would reduce the horizontal bearing pressure from piston thrust in the ten-coupled engine to 999 lb. per sq. in., which would probably vastly improve the wearing qualities. The tendency to rise from the journal would also be overcome.

Such a re-arrangement of the bearing surfaces would involve a radical departure from present practice, but it can be done, and there is no good reason for adherence to the antiquated half-shell bearing which has been long since outgrown. The heavy stationary engine has quarter boxes in which the bearing entirely encircles the journal and the brasses are adjustable in all directions for wear, while modern locomotives must get along with the half-shell non-adjustable boxes of seventy-five years ago. It would seem that a discussion of the points referred to in this letter might develop something of interest.

Charles F. Prescott.



Heavy Consolidation Type Locomotive Built for the Philadelphia & Reading

P. & R. LARGE 2-8-2 TYPE LOCOMOTIVE

Tractive Effort is 61,260 lb.; Boiler has a Combustion Chamber and 2-in. Tubes 13 ft. 6 in. Long

THE Philadelphia & Reading has recently received from The Baldwin Locomotive Works a number of Consolidation type locomotives which are notable for their weight and hauling capacity, and also because they are the only engines built to a railroad company's design to be included in the Railroad Administration orders last year.

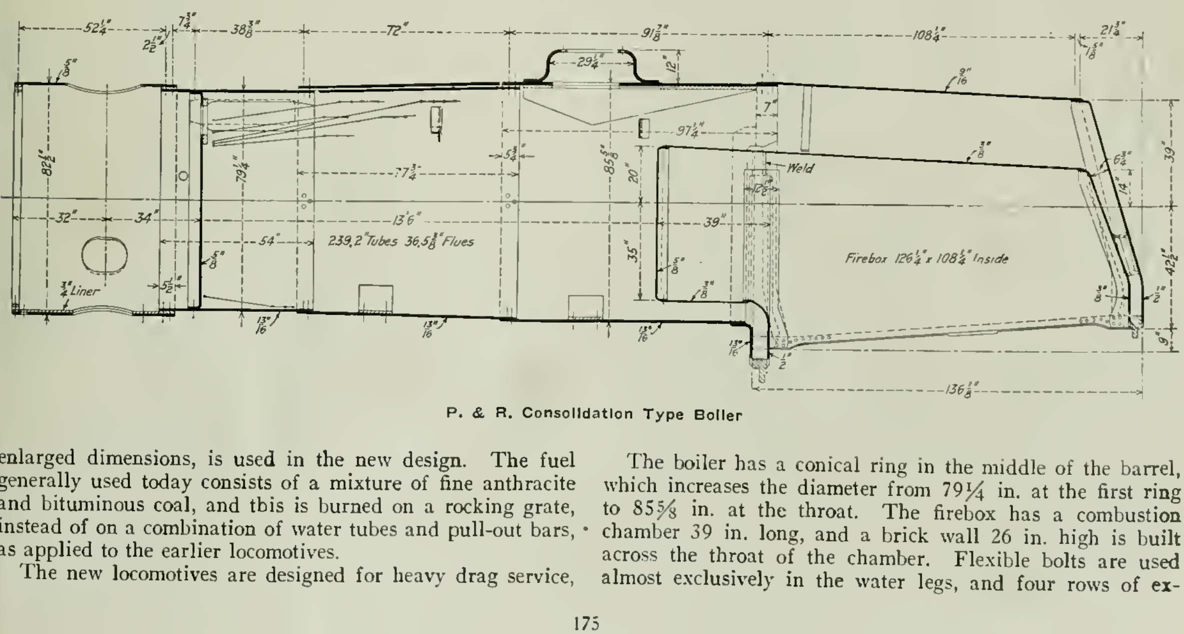
In the table will be found a comparison of the leading dimensions of these locomotives with the first Baldwin Consolidation type built for the Philadelphia & Reading:

Date built	Cylinders, in.	Drivers, diam., in.	Steam pressure lb. per sq. in.	Grate area, sq. ft.	Water heating surface, sq. ft.	Superheating surface, sq. ft.	Weight on drivers, lb.	Total weight, lb.	Tractive effort, lb.
1880.....	20 x 24	50	120	76	1,357	...	90,000	104,000	19,600
1918.....	25 x 32	55½	200	94.9	2,655	575	250,800	281,100	61,200

The locomotives built in 1880 had boilers of the Wootten type, equipped for burning fine anthracite, and this same type of boiler in a somewhat modified form and of greatly enlarged dimensions, is used in the new design. The fuel generally used today consists of a mixture of fine anthracite and bituminous coal, and tbis is burned on a rocking grate, instead of on a combination of water tubes and pull-out bars, as applied to the earlier locomotives.

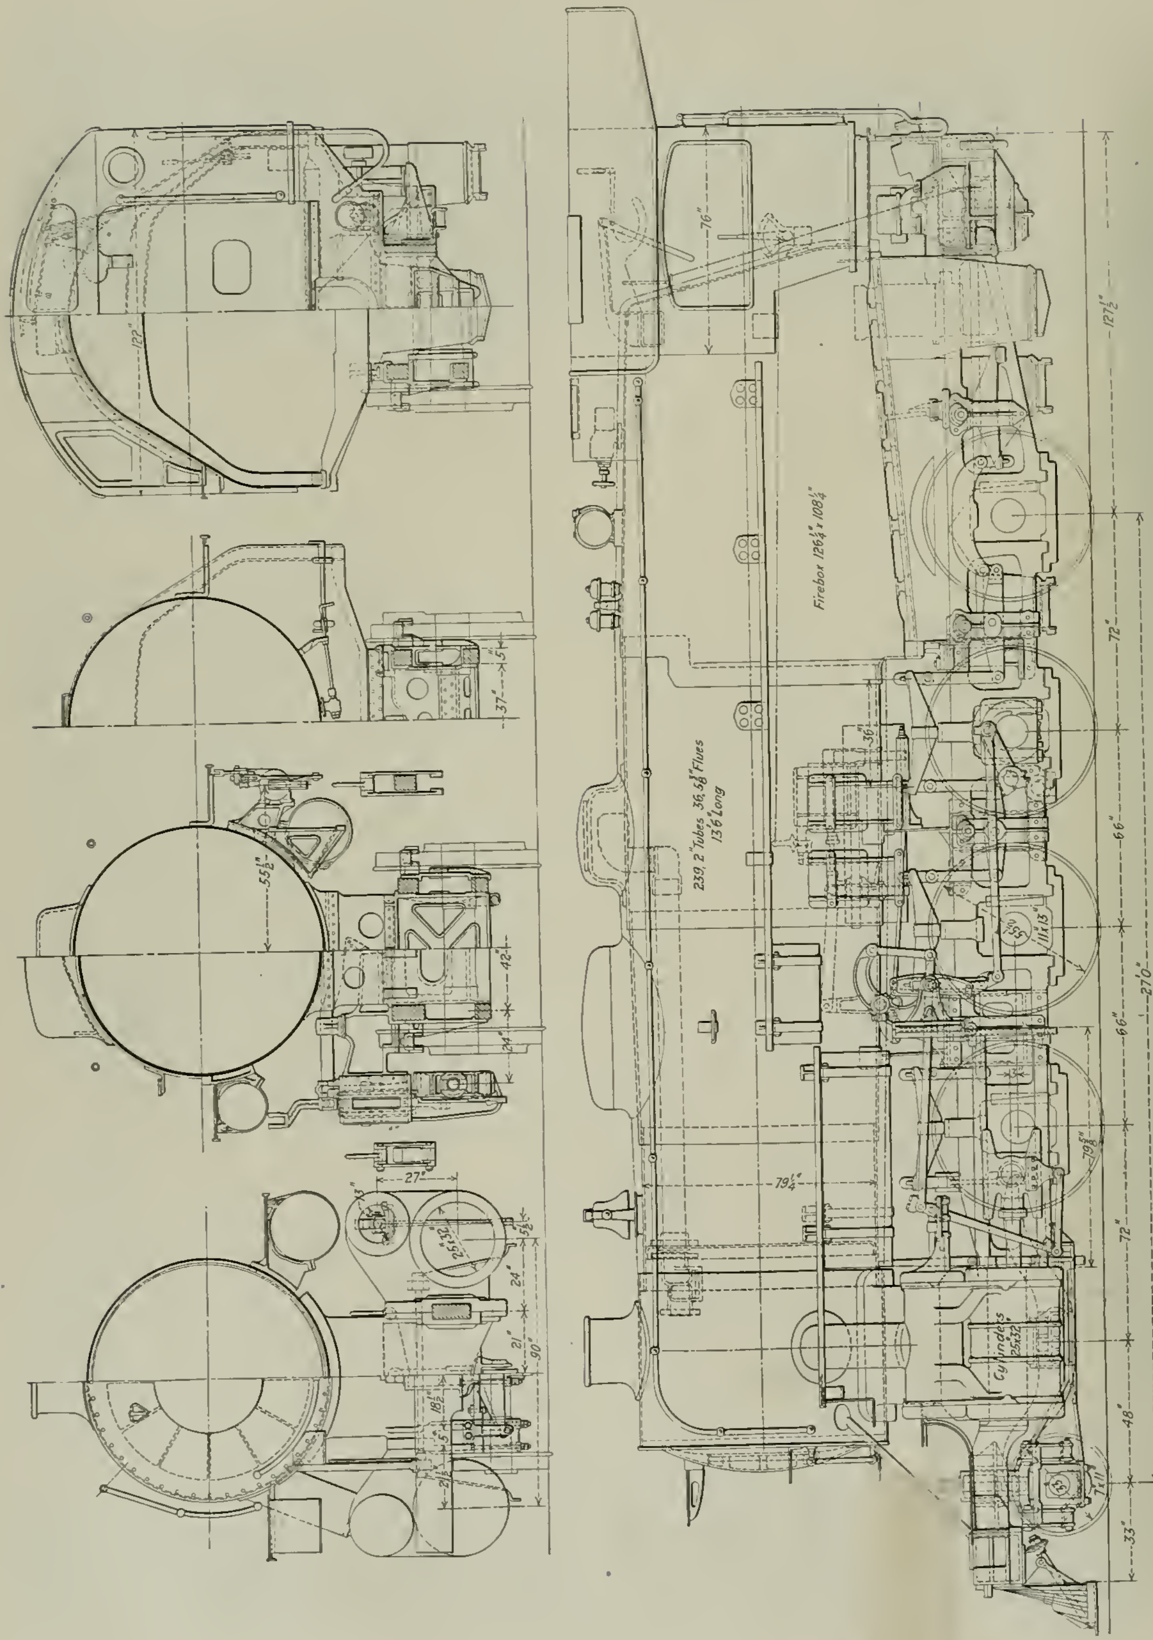
The new locomotives are designed for heavy drag service, and are in many respects similar to a group of Mikado type locomotives which preceded them. In consideration of the kind of fuel used, however, and the relatively small diameter of the wheels, a firebox of sufficient depth can be placed above the rear drivers without raising the boiler center to an excessive height. In the new Consolidations, the boiler center is placed 9 ft. 7½ in. above the rail.

In the following table will be found a comparison of the principal dimensions and ratios of the Consolidation and Mikado types. It will be seen that the new locomotives have smaller driving wheels and lower boiler pressure than the Mikados, but the cylinders are one inch larger in diameter and they have a starting tractive effort almost 4,000 lb. greater than the Mikados. It is evident that there is a considerable sacrifice in heating surface; there are eight less superheater units and 20 less tubes, and they are 4 ft. 2 in. shorter than those in the Mikado type boiler. The difference in grate area is less marked. For heavy drag service, however, high tractive effort at slow speeds is the controlling factor rather than a high sustained horsepower capacity.



P. & R. Consolidation Type Boiler

The boiler has a conical ring in the middle of the barrel, which increases the diameter from 79¼ in. at the first ring to 85⅝ in. at the throat. The firebox has a combustion chamber 39 in. long, and a brick wall 26 in. high is built across the throat of the chamber. Flexible bolts are used almost exclusively in the water legs, and four rows of ex-

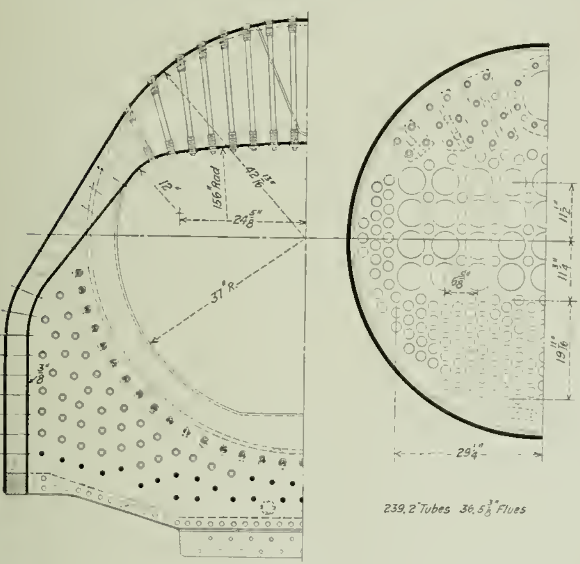


Elevation and Sections of the P. & R. Consolidation Type Freight Locomotive pansion stays support the front of the crown. The firebox has two oval fire-door openings, and the doors are power operated. A Standard stoker is applied. The mud ring is single riveted, except at the corners, where it is increased in depth to take two rows of rivets. A four-hopper ash-pan is applied with the two rear hoppers back of the wheels outside the frames. The equipment includes a power grate shaker.

The smokebox is comparatively short, and is equipped with the Economy front end arrangement,* and patented I. A. Seiders, superintendent of motive power and rolling equipment of the railroad. A special feature of this arrangement is a breaker plate, which consists of a slotted plate fitted with deflecting vanes. This plate is placed under the superheater damper and in front of the tubes, and is very effective in breaking up the large sparks before they strike the netting. The netting frames are most substantial in construction, and the device has proved effective in preventing the setting of fires due to escaping sparks.

Comparison of P. & R. Consolidation and Mikado Type Locomotives

Type	2-8-0	2-8-2
Tractive effort, lb.	61,260	57,320
Total weight, lb.	281,100	329,300
Weight on drivers, lb.	250,800	246,600
Diameter of drivers, in.	55½	61½
Cylinders, diameter and stroke, in.	25 by 32	24 by 32
Steam pressure, lb. per sq. in.	200	225
Heating surface, total evap., sq. ft.	2,655	4,224
Heating surface, equivalent, sq. ft.	3,518	5,264
Grate area, sq. ft.	94.9	108
Tractive effort x dia. drivers ÷ equiv. heating surface	966.5	669.7
Firebox heating surface ÷ equiv. heating surface, per cent	8.4	6.2
Grate area ÷ vol. cylinders	5.2	6.4



Half Section Through the Wootten Firebox and Half Tube Sheet Layout

The cylinders are cast separate from the saddle, the right and left hand cylinders being interchangeable. They are made without bushings, and have barrel walls 2¼ in. thick. The cylinder castings and central saddle are made with suitable recesses through which the frames pass. The frame at this point has a single section, 5 in. wide by 13 in. deep—and the cylinder, frame and saddle are held together on each side by a total of 59 horizontal bolts, 1⅛ in. in diameter. The saddle and cylinders are keyed to the frames at the front by vertical keys. The valve motions are of the Walschaert type, and are controlled by the Ragonnet power reverse gear.

The frames are of most substantial construction. They have a depth of 7½ in. above the pedestals, and the pedestal binders are held in place by three bolts in each end. The main pedestal wedges are self-adjusting. Strong transverse braces of cast steel are applied to the frames between adjacent pairs of driving-wheels. The brace back of the main drivers supports sliding bearings, which carry the front end of the mud ring. The rear end is supported by an expansion plate.

The cab, in accordance with the most recent practice for Wootten boiler locomotives on this road, is placed at the rear end instead of over the middle of the barrel. The sides of the cab are cut away in front in order to permit easy access to the stay-bolts.

Further particulars are presented in the following table of dimensions and data:

General Data

Gage	4 ft. 8½ in.
Service	Freight
Fuel	Hard and soft coal, mixed
Tractive effort	61,260 lb.
Weight in working order	281,100 lb.
Weight on drivers	250,800 lb.
Weight on leading truck	30,300 lb.
Weight of engine and tender in working order	462,000 lb.
Wheel base, driving	17 ft.
Wheel base, total	27 ft.
Wheel base, engine and tender	63 ft. 11 in.

Ratios.

Weight on drivers ÷ tractive effort	4.1
Total weight ÷ tractive effort	4.6
Tractive effort × diam. drivers ÷ equivalent heating surface*	966.5
Equivalent heating surface* ÷ grate area	37.1
Firebox heating surface ÷ equivalent heating surface,* per cent	8.4
Weight on drivers ÷ equivalent heating surface*	71.3
Total weight ÷ equivalent heating surface*	79.9
Volume both cylinders	18.2 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	193.5
Grate area ÷ vol. cylinders	5.2

Cylinders.

Kind	Simple
Diameter and stroke	25 in. by 32 in.

Valves

Kind	Piston
Diameter	13 in.

Wheels

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.
†Includes combustion chamber.

Railroad Administration News

Shop Crafts Present Demands for Further Wage Increases; Orders of the Regional Directors

Two representatives of each regional director and an equal number of representatives of the Brotherhood of Maintenance of Way Employees and Shop Men began a meeting at Washington on March 10 for the purpose of recommending to the Board of Wages and Working Conditions a set of uniform rules governing working conditions. A tentative draft was submitted to the board by the brotherhood some time ago.

DIVISION OF FINANCE AND PURCHASES REORGANIZED

John Skelton Williams has resigned as director of the Division of Finances and Purchases of the Railroad Administration, effective March 15, and the division has been divided into two new ones, the Division of Finance and the Divison of Purchases. Swagar Sherley, chairman of the House Committee on Appropriations in the Sixty-fifth Congress, who had charge of the railroad appropriation bill which passed the House, has been appointed director of the Division of Finance, effective about April 15, and Henry B. Spencer, formerly chairman of the Central Advisory Purchasing Committee, has been appointed director of the Division of Purchases. For the time being, Director General Hines will himself direct the work of the Division of Finance with the assistance of the associate director of the Division, Charles B. Eddy.

Mr. Williams is now chairman of an advisory finance committee, which will be expected to submit to the director general from time to time its advice on matters of financial policy and also to make to the director general preliminary reports on any proposed reorganizations which may require his approval. He is also chairman of an advisory committee on purchases, the other members of which are Robert S. Lovett, president of the Union Pacific, and Henry Walters, chairman of the Atlantic Coast Line. This committee will submit to the director general from time to time its advice regarding matters of policy with respect to purchases and for that purpose is authorized to make the necessary investigations.

Circular No. 1 of the Division of Purchases announces that Samuel Porcher and George G. Yeomans, heretofore members of the Central Advisory Purchasing Committee, are appointed assistant directors of the Division of Purchases, and William W. Morris, heretofore secretary of the Central Advisory Purchasing Committee, is appointed assistant to the director, Division of Purchases.

H. C. Pearce, manager, Procurement Section; M. E. Towner, manager, Forest Products Section; E. J. Roth, manager, Stores Section; and B. P. Phillippe, fuel distributor heretofore reporting to the chairman of the Central Advisory Purchasing Committee, will report to the director of the Division of Purchases.

WAGE DEMANDS FOR 1919

Now that most of the back pay for 1918 has been taken into the accounts, the processes which are expected to result in a new series of retroactive payments for 1919 are still being continued. The request of the train service brotherhoods for an upward revision of their wage scales and time and one-half for overtime is still pending, on a recommendation of the Board of Wages and Working Conditions which is before the director general for a decision. The award when issued is expected to be retroactive to January 1, and the shop employees have asked for a new increase to become effective as of the same date.

A letter addressed to the director general by B. M. Jewell, acting president of the railway employees' department of the American Federation of Labor, and the executives of the individual organizations, says that great dissatisfaction has been manifested by the machinists, blacksmiths, boilermakers, sheet metal workers, electricians and car men, regular and helper apprentices and helpers, "due to the present inadequate wage rates," as contained in the awards made in 1918, and they desire to present a request for further increase "to place them in a position to meet the ever-rising cost of living and maintain a more equal differential between classes of railroad employees and those engaged in a similar capacity in other industries." The letter states that these employees have been very insistent in their demands for some time, but the request has been withheld until they have become so persistent that it has been deemed advisable to comply with their wishes. The letter also urges upon the director general the necessity of arranging a conference with the representatives of the shop crafts for the purpose of arriving at a thorough understanding of the award to be issued covering this request, prior to the issuance of the general order.

The new scale of rates requested provides for a minimum hourly rate of 85 cents an hour, as compared with the present minimum of 68 cents, for machinists, blacksmiths, sheet metal workers, electrical workers, car men and boilermakers, a minimum hourly rate of 60 cents an hour for helpers, and differentials above the minimum hourly rate for certain classes of employees. Machinists working on valve motion work, tool room work, rod work, heavy machine operators, layers out, air men and federal inspection men ask an excess of 6 cents an hour above the machinists' rate. Certain classes of boilermakers ask an excess of 6 cents above the boilermakers' rate. Blacksmiths employed as hammersmiths and electricians employed as armature winders ask an excess of 25 cents above the rate for the respective crafts, making their rates $1.10 an hour.

The request provides that general foremen, foremen, assistant foremen, and leaders shall be paid on an hourly basis and receive overtime compensation for all services rendered in excess of eight hours per day, with a minimum hourly rate of $1 for general foremen, 95 cents for foremen, and 90 cents for assistant foremen, gang foremen and leaders; provided that all rates in excess of these shall be continued and monthly rates now in effect shall be the basis for establishing the hourly rates, the monthly rates to be divided by 200 to obtain the hourly rate.

The request also provides that operators of electric, acetylene thermit or other improved welding processes or machines shall receive an hourly rate of 91 cents, that all employees performing the recognized work of any craft who have had one year's experience or less shall receive 67 cents an hour, who have had one year or less than two years' experience shall receive 70 cents an hour, two years' and less than three years', 74 cents an hour, over three years' and less than four years', 79 cents an hour. This does not include regular and helper apprentices. It is provided that should any of the above leave the service, employees with not less than four years' experience shall be assigned to their positions and paid the minimum rate. Regular and helper apprentices assigned in connection with the work of their respective crafts are to receive as a starting rate 35 cents an hour, with an increase of 2½ cents an hour for each six months up to and including the first three years, and an increase of 5 cents an hour for the first six months of the fourth year and 7½ cents an hour for the last six months of the fourth year.

INVESTIGATION OF THE WILLIAM H. WOOD FIREBOX

The William H. Wood corrugated locomotive firebox is the subject of a report recently made by Frank McManamy, assistant director, Division of Operation, United States Railroad Administration, by a sub-committee of the Committee on Standards and published by the Railroad Administration. The committee made a thorough investigation of the service records of the five fireboxes of this construction actually applied to locomotives and examined the fireboxes, now all replaced by others of standard design. Its conclusions are "that the Railroad Administration should not apply any of these fireboxes for the following reasons:

"That the economy claims have not been proven.

"That the life to be expected, based on the best performances is very much less than that of the ordinary form of box.

"That the time out of service will be very much greater than with the ordinary box."

The committee does not believe that there is sufficient advantage in this form of construction to compensate for the added difficulty and expense involved in its repair and renewal.

Obligations of the Railroad Administration for Equipment Ordered in 1918* with Unit Prices of Cars and Locomotives

The Standard Locomotive Orders
Recapitulation

Number	Type	Price	Amount
150	Light switchers	$36,029.00	$5,404,350.00
50	Light switchers	38,416.33	1,920,816.50

POSTERS TO ILLUSTRATE FIRING METHODS

The Fuel Conservation Section has prepared two colored posters showing the interior of a locomotive firebox for the purpose of illustrating the effects of irregular firing methods, to be posted in roundhouses, foremen's offices, Y. M. C. A. buildings and other places where they may readily come to the attention of railroad enginemen. The method of illustration was employed in the presentation of a paper by D. C. Buell on "The Proper Method of Firing Locomotives" at the fourth annual convention of the International Railway Fuel Association and was amplified and enlarged upon by the University of Illinois engineering experiment station in a circular from which the illustrations now used were taken.

SAFE HANDLING OF OXY-ACETYLENE APPARATUS IN SHOPS

Form I F-12 has been issued under date of February 15, by The Fire Loss and Protection Section in which are reproduced the recommendations and instructions for the safe handling of oxy-acetylene apparatus in shops contained in a paper * by E. Wanamaker, electrical engineer of the Rock Island Lines at the last annual meeting of the Railway Fire Protection Association. These recommendations have been approved by the Association and authorized to be issued as its Bulletin No. 17.

RENTAL CHARGES FOR DINING CARS, LOCOMOTIVE AND WRECKING CRANES

The director general has approved a schedule of rental charges to be applied between railroads for dining cars, locomotive cranes and various classes of work equipment, effective as of March 1. The following were taken from the list:

	Rate per day
Dining Cars: Furnished (except provisions)	$40.00
Locomotive Cranes:	
Five tons capacity or less	15.00
Over 5 tons capacity and less than 20 tons capacity	20.00
Over 20 tons capacity	25.00
Wrecking Cranes:	
Steam wrecking cranes, 75 tons capacity and less	40.00
Steam wrecking cranes, capacity more than 75 tons	55.00

ORDERS OF REGIONAL DIRECTORS

International Railway Fuel Association.—The regional director, Eastern region, by file 1301-28A584, advises that the director of the division of operation desires a large attendance of railroad fuel men at the International Railway Fuel Association's annual meeting, at Hotel Sherman, Chicago, May 19, 20, 21 and 22. The convention will discuss the conservation of railroad fuel coal, and railroad fuel men ought to attend regardless of whether or not they hold membership in the association. Federal managers are asked to see that their lines are properly represented, more particularly by men connected with the transportation and mechanical departments; such delegates to go prepared, as far as possible, to take an active part in the work of the convention. The Southern regional director, file 520-6, and the Northwestern director make the same request.

Lettering of Locomotives.—The Eastern and the Southwestern Regional Directors have announced that on locomotives ordered by the director general for individual roads, and which are paid for by the roads, the letters "U. S." need not be shown on the engines or tenders.

Rental Rate for Locomotives.—The regional director, Eastern region, by file 500-1-3A555, prescribes the rental rate for locomotives as one mill per pound of tractive power per day, with a minimum of fifteen dollars a day. This cancels the circular, file 3000-42, of March 12, 1918. The Northwestern, Southwestern and Southern regional directors have issued similar orders.

Report of Classified Locomotive Repairs.—The Southwestern regional director in Order 172 announces the adoption of Form MD-34 for uniform reports of locomotives receiving classification repairs. This report is mailed monthly to Frank McManamy, Washington, and a copy is sent to the regional director.

Liberal Motion Devices and Removable Driving Box Brasses.—In order to secure current data for the Committee of Standards relative to the performance of these two devices, the Eastern regional director, file 500-71A608, has issued blank forms calling for the number of locomotives equipped, date equipped, and maintenance costs per mile in each case, compared with an equal number of locomotives of the same class and in the same service not so equipped. For the lateral motion drive a comparison of flange wear is also

*For an abstract of Mr. Wanamaker's paper, see the *Railway Mechanical Engineer* for March, 1919, page 160.

called for and for the removable brasses, mileage between shoppings and cost of upkeep for brasses are required.

Failures of Mechanical Stokers.—The Southern regional director calls the attention of federal managers to numerous delays and failures of locomotives equipped with mechanical stokers, due to iron bolts, and other metallic substances, as well as rock and other foreign material, left in bottoms of coal cars. Instructions should be issued through purchasing department and fuel inspection forces to insure that empty cars shall be thoroughly cleaned before loading, and every effort must be made to prevent any metal substance being loaded with coal. Supervisors and foremen in charge of coaling stations must be instructed that special effort be made to eliminate foreign matter, destructive to stoker equipment, when coal is loaded on locomotives. The Eastern regional director, by file 500-1-54A585 issues similar orders, and Order 170, Southwestern region, covers the same subject.

Locomotive Dictionary and Master Car Builders' Dictionary.—A. H. Smith, regional director. Eastern region by file 500-88A583, advises that the director general has authorized a continuance by the railroads of past practice with respect to the furnishing of the Locomotive Dictionary and the Master Car Builders' Dictionary to their mechanical and purchasing officers. The Southern regional director, file 1701-2-6, issues the same notice.

Journal Box Packing.—The regional director of the Eastern region, by circular No. 500-13-14A540, advises federal managers that journal box packing for locomotives and cars may be bought under the individual roads' specification, the Railroad Administration specification R-94-A not being compulsory.

Freight cars; Cost Limit of Repairs.—Supplement 1 to Circular 23 of the Northwestern regional director, in complying with paragraph 8 of Division of Operation Circular 20, includes a model for the report of inspection and estimated cost of repairs to freight cars recommended for retirement or application of betterments and states that after cars are inspected and reported on this form the federal manager of the using road will transmit the original and two copies, with his recommendation, to the federal manager of the owning road, who will transmit one copy to the corporation, securing its approval; retain one copy and return the original to the federal manager of the using road, notifying him of the action taken.

Sheds for Protection of Car Repairers.—The regional director, Eastern region, by Circular No. 1800-133A567 calls for information concerning laws requiring the construction of sheds for this purpose. The director general has been asked by the brotherhood to adopt a policy and is anxious to pass upon the matter with as little delay as possible. Federal directors are asked to advise what States now have car shed laws, and their provisions; what railroads have adopted the policy generally of providing car sheds at the more important car repair points, and to recommend what the practice should be.

Sleeping Cars for Japanese Railways.—The Imperial Government Railways of Japan have designed a type of sleeping cars for third-class passengers which, according to the Railway Times of Tokyo, is an ordinary day coach, the seats of which are convertible into lower berths while the upper berths are attachable at night. On the upper beds, which are located along the direction of the car, passengers can sleep in the usual Japanese manner, and on the lower, which are located crosswise, they can lie on their sides and can stretch their feet. The fare will be about 1 yen (50 cents) per day, including the extra fare for the high-speed train. and it is hoped that fairly good rest may be enjoyed by third-class passengers, which is the most important class in local passenger traffic.

FUSE SIZES FOR SHOP MOTORS

The proper size of fuse for a motor is only too often obtained by haphazard methods. The motor's normal operating current is given by the maker on the name-plate, but fuses are properly selected of a larger capacity to allow for starting and for momentary overloads. Hence it is rather more unusual for the maintenance man to select his fuses "be guess and be gosh," with a view to their permanence in service rather than the safety of the motor they are supposed to protect.

In order to give a practical working idea of what sizes to use, the Westinghouse Electric & Manufacturing Company has prepared the accompanying tables. These are based on the following assumptions as to size of fuse required to stand starting current without blowing:

Type	Times fuse load current at starting
Polyphase wound rotor	1¼
Squirrel cage (thrown on line)	3
Single-phase repulsion induction with rheostat	2
Single-phase repulsion induction without rheostat	4
Direct current	1¼

Since the fuses for squirrel-cage and repulsion motors without rheostats are, respectively, rated 3 and 4 times full-load current, they give practically no overload protection. Hence it is recommended that double-throw switches be installed connecting the motor through fuses of 1.25 times full-load rating (as under wound rotor sizes) for running and through the regular heavier fuses or direct to the line for starting.

The Resistance of Materials

The Effect of Sudden or Abrupt Changes In Section on the Distribution of the Unit Stresses

BY G. S. CHILES and R. G. KELLEY

II.

IN the common theory of beams we assume that the elongation or shortening per unit of length of any fibre is proportional to the distance of the fibre from the neutral axis of the cross-section, that is, that the stress distribution or intensity is linear.

Professor Croker found by experiment* (optical method) the distribution of stress in rectangular beams with holes cut through them. In the upper specimen of Fig. 7 the two-inch diameter hole is located at the center on the neutral axis, while in the lower specimen two one-inch holes were placed half-way between the upper and lower edges and the longitudinal center line.

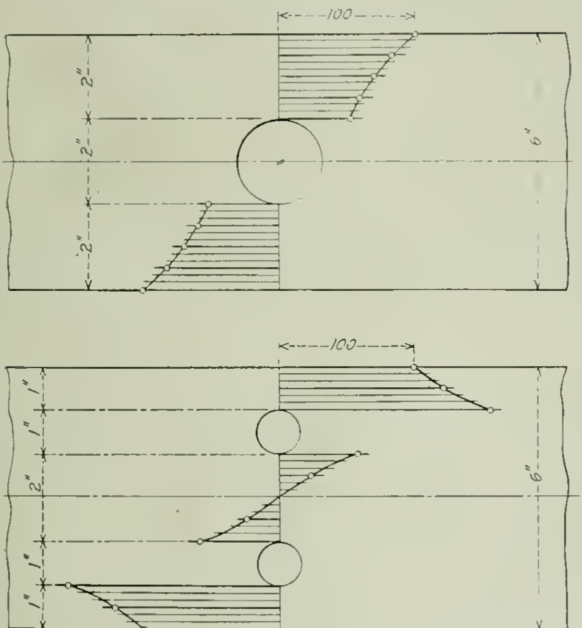

Fig. 7

The maximum stress in the beam having the central hole occurs at the outer edge of the beam but the stress intensity is not directly proportional to the distance from the neutral axis. At the outer edge of the hole, which is one-third the distance to the outer edge of the plate, the stress intensity if linear should equal one-third the value for the outer edge. Instead it is some 52 per cent of the value of the intensity at the outer edge, or some 57 per cent more than if it were linear.

The maximum stress in the beam having the two one-inch holes does not occur at the outer edge of the beam but at the outer edge of each hole. The intensity of the stress at the outer edge of the holes is 132 per cent more than it would be if directly proportional to the distance from the neutral axis and is some 55 per cent more than the stress at the outer edge of the beam. The stress at the inner edge of the holes is 74 per cent more than it would be if directly proportional to the distance out. The stress intensity at the outer edge was used in obtaining the proportional stress intensity in all cases.

It is evident that holes, especially those located near the outer edges of a beam, have a decided influence on the intensity of stress.

For additional information on the effect of holes in beams the reader is referred to a paper, "Some Important Points in the Design of a Box Bolster," delivered before the St. Louis Railway Club at the May, 1918, meeting, by Professor Louis E. Endsley, of the University of Pittsburgh.*

RESULTS FROM VIBRATORY TESTS AND ACTUAL SERVICE

For the purpose of determining the effect of abrupt changes of section in a few of the forms which are commonly used in machine design when subjected to the action of alternating stresses, Professor T. E. Stanton carried out a series of experiments† on the four forms whose contour and dimensions are illustrated in Fig. 8. The form *a* is that which offers the maximum resistance to the load and the values of its resistances will be considered to represent the maximum resistance of the material. The form *b* is a test piece of similar contour but having its center section threaded; the form *c* represents a piece having a moderately rapid change of section brought about by the use of fillets, while test piece *d* illustrates a form in which the change of section at the junction of the center section and shanks is abrupt due to the absence of fillets.

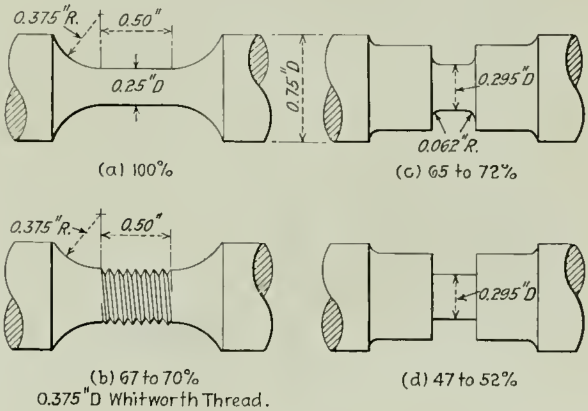

Fig. 8

The results of Professor Stanton's tests upon these four forms and four carbon percentages for each form are set forth graphically in the diagram, Fig. 9, the carbon content of the various test pieces being plotted as abscissae and the limiting range of stresses being plotted as ordinates. The curve *a* is the resistance curve of the section of maximum resistance designated by the corresponding letter in Fig. 8.

*See Engineering (London), March 3, 1912.

*See *Railway Mechanical Engineer* for June, 1918, page 343.

†See "A Factor in the Design of Machine Details," by T. E. Stanton, D. Sc., M. Inst. C. E., Engineering (London), April 19, 1907.

The curve *b* is the resistance curve of the threaded test specimen. It is evident that the resistance of a section which has been threaded has been reduced to a value ranging from 67 per cent to 70 per cent of the maximum resistance of the material.

Professor Stanton discusses the resistances of the screw threads as follows:

"The above resistances are, of course, estimated per unit of area, so that in calculating the strength of a screwed rod under alternating stress it will be further necessary to take into account the area at the bottom of the threads, so that the total reduction in resistance may well be more than 50 per cent of its maximum value.

"In the case of screw threads there is a further possible source of weakness due to faulty machining in the cutting of the screw. If the bottoms of the threads are not properly curved, (see Fig. 10 for enlarged section), but left with a sharp angle, there can be no doubt that risks of the development of a crack are very considerably increased. It seems quite probable that failures of steam-engine cross-head bolts, which have broken under very low range of stress, may be due to this cause. . . ."

The diameter at the root of the thread for the 3/8-in. screw

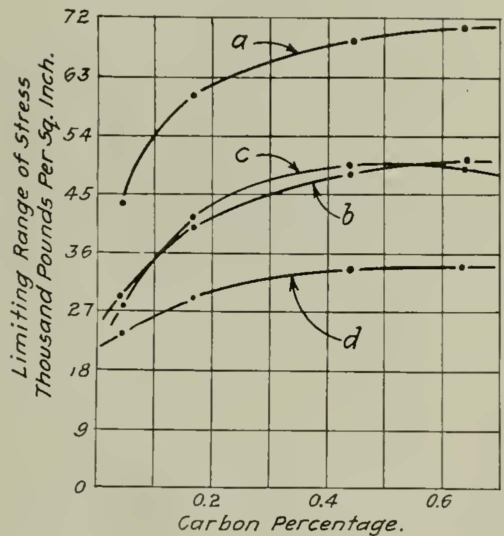

Fig. 9

is 0.2950 in. He obtained practically the same results for the resistance of the specimen having a gradual change of section when subjected to alternating stresses, as shown by the curve *c* which is the resistance curve of the section marked *c* in Fig 8. This curve indicates that the resistance of the section varies from 65 per cent to 72 per cent of the maximum resistance of the material as plotted in curve *a*. Finally, the resistance of section *d* was found to be from 47 per cent to 52 per cent of section *a*, Fig. 8. In regard to this curve, Professor Stanton directs especial attention to the fact that, while the maximum resistance of the test specimens of this form does not increase as the carbon content is increased in as great proportion as in the case of curves *a*, *b* and *c*, the resistance of the 0.4 and 0.6 carbon steels is about 40 per cent greater than that of the iron.

It is evident, therefore, that stress distribution is affected by any sudden change of section and the assumptions that the stress due to an axial load is uniformly distributed, or that a member subjected to bending has a linear distribution of stress from the neutral axis outward are not justified. For members not subjected to repeated or alternating stresses this would appear not to be especially serious. But in the case of members subject to dynamic action, the available information seems to indicate that extreme caution is necessary in members having abrupt sections, since any sudden change of section very greatly reduces the endurance of members subjected to a repetition of loading. Aside from service stress considerations the designer must give thought to the

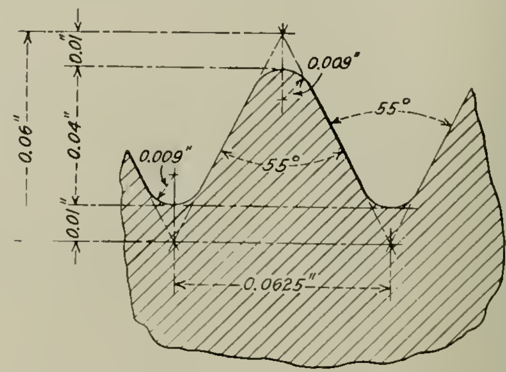

Fig. 10

manufacturing side, especially so in the case of heat treated parts.

EXPERIMENTS WITH RUBBER TEST SPECIMENS

In casting about, some time ago, for a suitable means to illustrate in a general way the results which might be expected from the effect of sudden or abrupt changes of section upon the distribution of stress the idea was hit upon to use models made of rubber. It was thought this would visualize

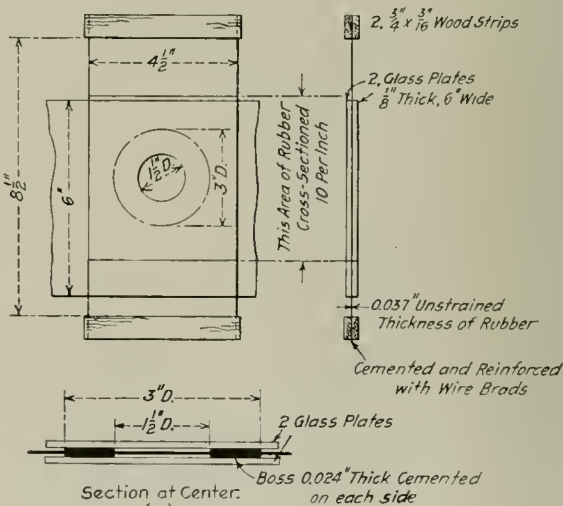

Fig. 11

the action and thus bring it more forcibly to the reader's attention.

The question may be raised as to whether or not there is any justification for comparing the action, under strain, of rubber with that of other materials more commonly used in engineering practice. In a recent investigation* for the purpose of determining Young's Modulus, which is the ratio of unit stress to unit strain or deformation, and Poisson's

*The Analysis of Finite Extensions and Elasticity of Rubber, Annalen der Physic, No. 21, 602, Nov., 1906.

Ratio, which is the ratio of lateral strain to longitudinal strain, (in the case of extension, the ratio of the elongation per unit of length to the contraction per unit of lateral dimension), O. Frank found it convenient to employ models consisting of a high grade of Para rubber. In this instance Mr. Frank used a test piece which was in the form of a strip 15.75 in. long, 3.94 in. wide and 0.016 in. thick and had fine lines about 3.15 in. apart ruled across it near its center when in a normal or unstrained condition. By measuring the distance between these ruled lines for each new extension of the strip up to a maximum extension of something less than 200 per cent, he obtained as the mean value of Poisson's ratio for rubber 0.46. Landolt and Börnstein (Physikalisch Tabellen) give, as the value of Poisson's ratio for rubber, 0.49.

For concrete, Poisson's ratio is from 0.1 to 0.13 and for the metals in general it ranges from 0.2 to 0.38, being from 0.25 to 0.33 for steel. As a preliminary to the experimental investigations which follow, tests were conducted upon a strip of rubber 1½ in. wide, ¼ in. thick and 14 in. long in order to determine the value of Poisson's ratio for the material. This was found to be approximately 0.33.

The rubber from which the models employed in the experiments covered by Figs. 12 to 15 inclusive were made was a high grade dental gum while that used for the experiments illustrated by Figs. 16 to 20 inclusive was a grade of ¼ in. rubber manufactured especially for the purpose.

A series of experiments was first conducted upon a number of rubber strips 4½ in. in width which were perforated with holes located as shown at *a*, *b* and *c* in Fig. 1. The diameter of the circular hole in the center of the strip indicated at *a* was 1½ in.; the diameter of each of the semicircular holes located on the outer edges at the midlength of the strip marked *b* was also 1½ in., while the square hole located at the center of the strip designated by *c* was 1½ in. square. The ends of the rubber bands were attached to small wooden strips (see Fig. 11) and while in an unstrained condition the rubber was ruled for a length of 5 inches with equally spaced horizontal and vertical lines of white show card ink, 10 lines to the inch, as shown in Fig. 12*a*. The dark ink lines which appear on the tracing cloth underneath the rubber, are for the purpose of comparison.

Fig. 12*b* shows the rubber strip when subjected to a pull of five pounds. In order to overcome the tendency of the rubber to buckle when in this condition, as is noticeable in the photograph, a glass plate was pressed lightly against either side of the rubber band as indicated in Fig. 12*c*, care being taken to apply to the plates an amount of pressure sufficient only to eliminate the tendency to buckle. The pressure was applied to the glass plates gradually while the pull was being applied thus allowing the rubber band freedom of movement and at the same time retarding the tendency toward buckling.

In Fig. 12*a* a part of the heavy black ink lines outlining the edge of the hole and the outer edge of the rubber strip are shown. In Fig. 12*b*, the hole in the rubber has decreased

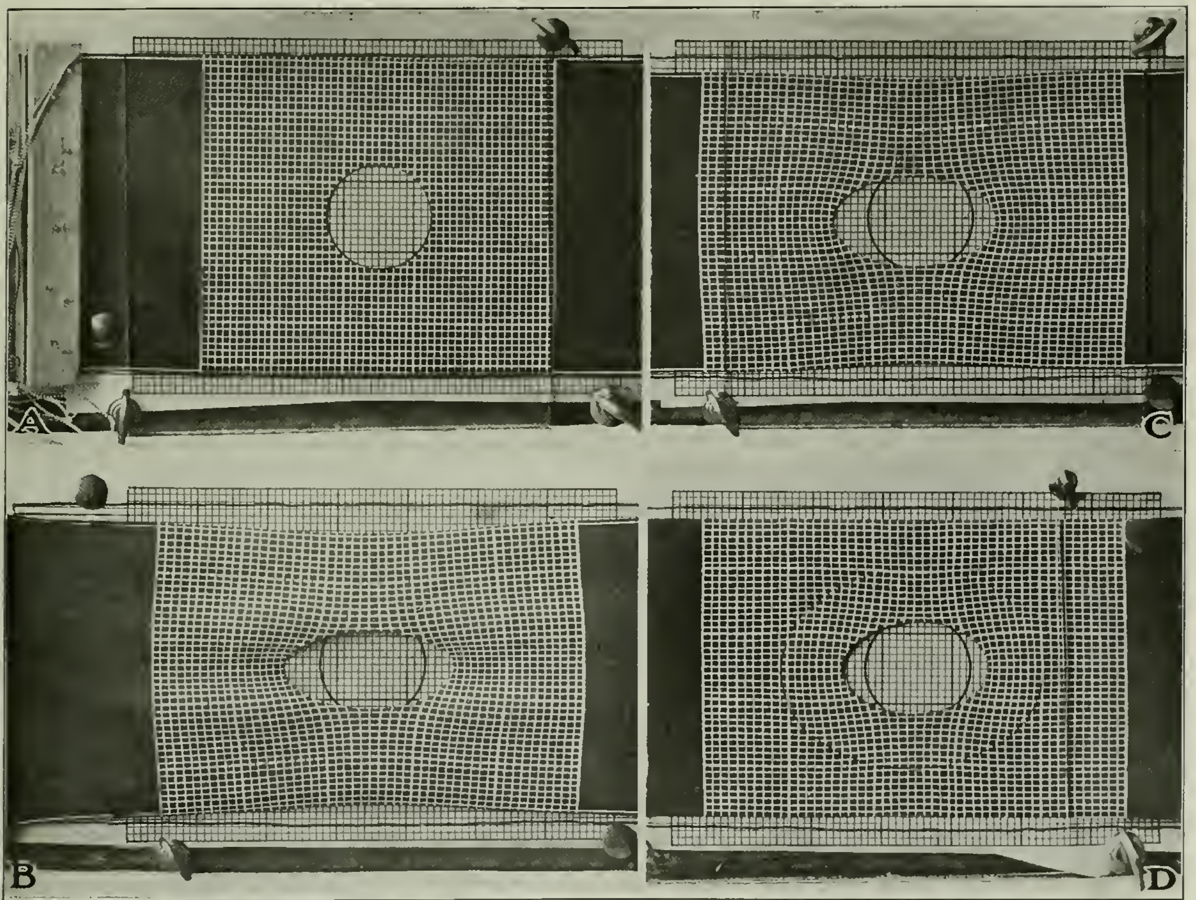

Fig. 12—The Effect of a Central Hole with and without Bosses, on the Stress Distribution in Sheet Rubber Under Tension

0.4 in. in width while the total width of the strip is about 0.7 in. less. After the glass pressure plates were applied the width of the hole decreased only about 0.2 while the total width of the strip was 0.5 in. less than in the unstrained condition. Thus the net width of the rubber through the center of the hole when given a five-pound pull was about 0.3 in. less when the glass plates were applied than it was in the unstrained condition.

That the rubber is strained relatively more near the inner edge of the hole is evident from the distance between the ruled white lines, at the side of the hole. At the ends of the hole the strained length is really less than the unstrained length, showing the rubber to be in compression at these points. The vertical and horizontal lines clearly visualize the action found and measured by the polarized light method as plotted in Fig. 3.

In discussing the stresses shown in Fig. 3, reference was made to the longitudinal stress f_t in the same direction as the pull and the radial stress f_{tr} of the stress at right angles to longitudinal stress. These stresses as well as those referred to in connection with Figs. 4, 5 and 6 are clearly illustrated by the action of the white ink lines on the rubber strips and by the eye bar of Fig. 16*b*.

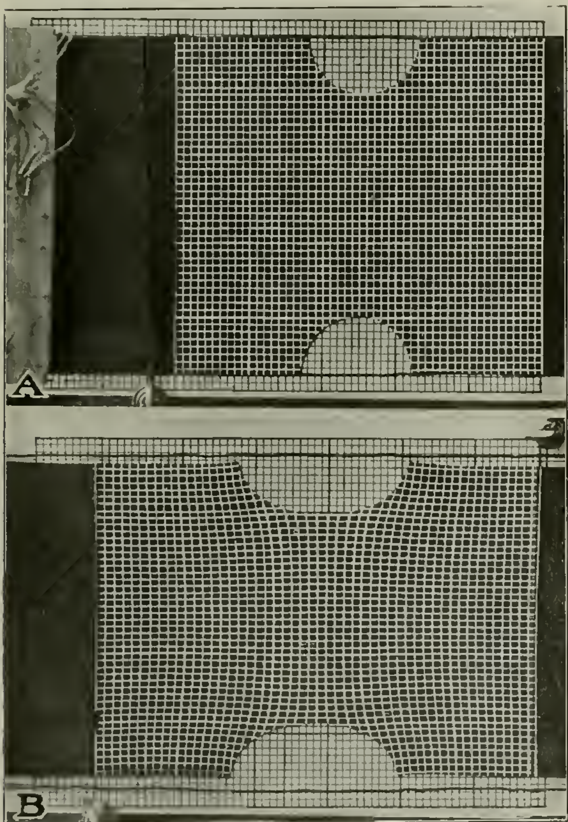

Fig. 13—Effect of Semi-circular Notches in Sides of Sheet Rubber Specimen Under Tension

The pictures of the rubber models in all the experiments showing the unstrained position were taken after the maximum strain position, the idea being to demonstrate that the models had not been given a permanent set, in other words, that the action was entirely elastic. The photograph shown in Fig. 12*a* was not taken until after the photographs of Fig. 12*b* and *c* had been taken.

Fig. 12*d* illustrates the strained condition of a strip of rubber subjected to a pull of five pounds which is alike in all respects to the strip of rubber shown in Fig. 11 except that a boss 0.024 in. thick was cemented on either side around the hole before the lines were ruled in. The location, size, etc., of the bosses are indicated by dotted lines in Fig. 11. The total cross-sectional area of the material immediately adjacent to the hole is now greater than that of the remaining portions, the total thickness of the bosses being 0.048 in. while the thickness of the rubber strip itself is 0.037 in. In this instance, the glass plates came in contact with the bosses only as indicated at *a* in Fig. 11. It is evident that the effect of the addition of the bosses has been to reduce the intensity of the stress, although the action is similar to that when no bosses were applied, the maximum stress near the edge of the hole is still greater than the average stress over the central section.

Fig. 13*a* represents a strip of rubber similar to that of Fig. 12 except that it is provided with semi-circular holes, each of which is equal in area to half of the hole in the original strip, located at either side of the strip on the same center line as shown at *b* in Fig. 1. The strip is shown in an unstrained position, ruled up in a similar manner, in contact (without pressure) with glass plates above and beneath, and resting, as in the preceding case, upon a strip of tracing cloth ruled with heavy black ink reference lines.

Fig. 13*b* illustrates the distribution of stress in this rubber strip, when subjected to a pull of five pounds and with the pressure plates in action as in the preceding cases. The resulting lines of distortion are very similar to the case illustrated in Fig. 12*c* where the hole was central.

(*To be concluded*)

One of the Engines Recently Surrendered to the French and Its Crew

The Atlantic City Conventions

Government and Program of June Meeting of Mechanical Section, American Railroad Association

THE American Railway Association has been reorganized as the American Railroad Association with five sections covering operating, engineering, mechanical, traffic and transportation. The mechanical section consists of the former American Railway Master Mechanics' Association and the Master Car Builders' Association, the work of which is now combined and co-ordinated with that of the similar organizations in other departments, through the parent organization.

Circular S-3, No. 1a has been issued by the American Railroad Association giving the personnel of the general committee which will be in charge of the convention at Atlantic City next June, together with the rules of order and a list of the committees which will report at the convention.

The general committee is made up as follows:

C. E. Chambers, mechanical assistant, Allegheny Region, chairman.
W. J. Tollerton, general mechanical superintedent, Rock Island Lines, vice-chairman.
Frank McManamy, assistant director, Division of Operation, U. S. R. A.
C. B. Young, manager, Inspection Test Section, Division of Operation, U. S. R. A.
F. F. Gaines, chairman, Board of Railway Wages and Working Conditions.
J. S. Downing, general master car builder, C. C. C. & St. L.
J. S. Lentz, master car builder, Lehigh Valley.
M. K. Barnum, assistant to general superintendent, maintenance of equipment, Baltimore & Ohio.
J. R. Gould, superintendent motive power, Chesapeake & Ohio.
A. Kearney, superintendent motive power, Norfolk & Western.
C. E. Fuller, superintendent motive power and machinery, Union Pacific.
T. H. Goodnow, superintendent car department, Chicago & North Western.
J. W. Small, mechanical assistant, Southern Region.
C. F. Giles, superintendent machinery, Louisville & Nashville.
J. E. O'Brien, mechanical superintendent, Missouri Pacific.
A. P. Prendergast, mechanical superintendent, International & Great Northern.
H. R. Warnock, general superintendent motive power, Chicago, Milwaukee & St. Paul.
James Coleman, superintendent car department, Grand Trunk.
W. H. Winterrowd, chief mechanical engineer, Canadian Pacific.

RULES OF ORDER

The following are the rules of order which will govern the conduct of the section:

1. (a) The membership of Section 3—Mechanical—shall consist of three classes: representative, affiliated and life.

(b) Representative members shall be those officials of railroads above the rank of general foreman having charge of the design, construction or repair of motive power or rolling stock, who shall be designated by the federal manager or executive official of the member of the association to serve in the section.

(c) Any person having such knowledge of science or practical experience in matters pertaining to the construction of motive power or rolling stock as would be of special value to the section may become an affiliated member on being recommended by three representative members. The name of such candidate shall then be referred to the general committee which shall report to the section on his fitness for such membership. He shall be elected by written or printed ballot at any regular meeting of the section held not less than six months after the candidate has been proposed and five dissenting votes shall reject. Affiliated members shall be entitled to all the privileges of representative members excepting that of voting and being elected to office in the section and may serve on committees on appointment by the general committee, in addition to the regularly elected members of such committee.

Such membership shall continue until written resignation is received by the secretary or the membership is terminated by the general committee or by the members becoming engaged in business which, in the judgment of the general committee would impair his usefulness to the section or discriminate against others, similarly engaged. Affiliated members shall not be subject to dues or assessments.

(d) Representative members who have been in good standing twenty years, or members who have served as chairman of the section may become candidates for life membership on the recommendation of the general committee. The names of such members shall be referred to the section in convention for election by written or printed ballot at any regular meeting of the section and five dissenting votes shall reject.

(e) Those persons, active or representative members, who have been in good standing in either the Master Car Builders' Association or the American Railway Master Mechanics' Association for twenty years, or members who have served as president of either association or as chairman of the section may also become candidates for life membership. Those now carried by the Master Car Builders' Association as life members or by the American Railway Master Mechanics' Association as honorary members will be continued as life members of Section Three—Mechanical.

2. (a) In addition to the chairman, vice-chairman and the general committee of the section, a nominating committee shall be elected.

(b) The general committee shall consist of sixteen elected members, including the chairman and the vice-chairman of the section, and, in addition, during the period of federal control, of three representatives of the United States Railroad Administration to be designated by the director of the Division of Operation. The elected members during federal control shall consist of two representatives from each region and two representing the Canadian railroads.

3. The duties of all officers shall be such as shall pertain to their offices or as may be delegated to them by the general committee of the section.

4. (a) The general committee shall exercise general supervision over the interests and affairs of the section, call, prepare for and conduct general conventions.

(b) The general committee shall exercise such supervision over the standards, recommended practice, or rules of this section as may be necessary to meet any emergency that may arise during the year in the conduct of the affairs of the section.

(c) It shall make a report at each convention which shall cover the action it has taken on such general or emergent supervision and make such recommendations as it may deem necessary on questions of importance to the section.

(d) The general committee shall select and appoint the members of the several standing committees and of such special committees as may be found necessary from time to time for conducting the business of the section and for investigating such matters as may be referred to the section or the committee may deem expedient to carry out the purpose of the section. It shall make appointments to the membership of any of the committees that may be necessary to fill any vacancies which may occur.

(e) The general committee shall receive, examine and approve before public reading all communications, papers and reports and it shall decide what portion of the reports, papers and drawings shall be submitted to each convention and what portion shall be printed in the annual report. It shall also determine which, if any, of the subjects presented at the convention or by members shall be referred to the executive committee of the association.

(f) The general committee shall offer to the convention the names of ten representative members not officers of the section as candidates for the committee on nominations.

(g) The general committee may call special meetings of the section to be held not less than thirty days after the notice thereof has been mailed to each member of the section.

(h) Nine members of the general committee shall constitute a quorum for the transaction of business.

5. (a) It shall be the duty of the committee on nominations to offer to the convention the name of one representative member as a candidate for chairman and one for vice-chairman, and the names of seven representative members as candidates for the general committee.

(b) When twenty or more members desire to propose the name of a member for any office, in addition to the names suggested by the committee on nominations, the secretary shall place the name or names of such persons for said office on the printed ballot, making a statement to the effect that such name or names has been proposed by a certain number of members.

6. (a) It shall be the duty of the secretary to issue a circular annually, intimating the date and place when and where candidates may be examined for the scholarships of the section.

(b) Acceptable candidates for the scholarship shall be first, sons of members or of deceased members of the section.

If there is not a sufficient number of such applicants for the June examination, then applications will be received from other railroad employees or the sons of other railroad employees for the fall examination. The secretary shall issue a proper circular in this case as before. In extending the privilege outside of the families of members, preference shall be given to employees or the sons of employees or the sons of deceased employees of the mechanical departments.

(c) Candidates for these scholarships shall apply to the secretary of this section and if found eligible shall be given a certificate to that effect for presentation to the school authorities. This will entitle the candidate to attend the preliminary examination. If more than one candidate passes the preliminary examination, the applicant passing the highest examination shall be entitled to the scholarship, the school authorities settling the question.

(d) The successful candidate shall be required to take a course prescribed by the general committee.

7. (a) The officers, excepting as otherwise herein provided, shall be elected at the regular meeting of the section held in June of each year and the election shall not be postponed except by unanimous consent.

(b) The chairman and the vice-chairman of the section shall be elected by written or printed ballots alternately every second year, the candidate receiving a majority of the votes cast shall be declared elected and shall hold office for two years or until his successor shall be elected.

(c) Members of the general committee and the committee on nominations shall be elected by written or printed ballots. Seven members of the general committee will be elected at each regular session to serve for two years. Five members of the committee on nominations will be elected annually.

(d) In the election of members of the general committee and the committee on nominations each representative member is entitled to one vote.

8. (a) At the first session of the annual meeting the report of the committee on nominations announcing the names of the nominees for officers and the general committee of the section shall be read. Elections shall not be held before the day after such announcement except by unanimous consent. Votes may be cast for any member eligible to serve as chairman, vice-chairman, members of general committee or members of committee on nominations by adding the name to the printed ballot.

(b) In all ballots for chairman, vice-chairman, members of general committee and committee on nominations or for affiliated or life members at the meetings of the section, the following form of voting shall be adhered to: An envelope shall be provided on which there shall be a blank space for the name of the railroad, and the name of the official voting; smaller envelopes shall be provided on which shall be printed the words "For Officers," "For Members General Committee," "For Members Committee on Nominations," "For Affiliated and Life Membership," and otherwise unmarked. In these envelopes the ballots shall be placed by those voting them and they shall then be placed within the larger envelope and presented to the general tellers. When a ballot is to be taken the chairman will announce the names of all required tellers. Three general tellers shall have charge of receiving and recording the ballots cast. When all ballots have been cast these tellers will announce that the polls are closed. They shall then remove the smaller envelopes, count and announce the vote for officers and shall deliver the envelopes marked "For General Committee" to two tellers, who shall count and announce to the general tellers the vote for general committee and those marked "For Committee on Nominations" to two tellers who shall count and announce to the general tellers the vote for the committee on nominations, and those marked "For Affiliated and Life Members" to two tellers who shall count and announce to the general tellers the vote for affiliated and life membership.

(c) The general tellers shall record and announce the total number of votes cast, the result of the vote, and shall be the judges of eligibility of any ballot presented.

(d) When a ballot for officers or membership on committees shall be announced as having eventuated in a tie vote, or be otherwise undecided, upon such announcement the final result shall be determined by the majority of the members present.

9. (a) Unless otherwise provided herein, a vote in the session of the section may be taken *viva voce*, by arising, or by written or printed ballot in any of which only representative members and representatives of the United States Railroad Administration shall participate. Letter ballots may be ordered to be taken in such manner and under such conditions as the section may by resolution from time to time or the general committee may direct.

(b) Printed ballots for use in the election of officers, members of the general committee and the committee on nominations, and for affiliated and life memberships to be of the form as prepared by the committee on nominations.

10. (a) At each annual meeting, the chairman shall appoint a committee on subjects whose duty it shall be to report at the next annual meeting subjects for investigation and discussion, and if the subjects are approved by the section, the general committee as hereinafter provided, shall appoint committees to report on them. It shall also be the duty of the committee on subjects to receive from members questions for discussion during the time set apart for that purpose. That commitee shall determine whether such questions are suitable ones for discussion, and if so, it shall report them to the section.

(b) When the committee on subjects has reported and the section approved of subjects for investigation, the general committee shall appoint individuals or special committees to investigate and report on any subject which a majority of the members present may approve; or individual papers may be presented to the section after approval by the general committee. Papers and reports shall be presented by abstracts, which shall not occupy more than ten minutes in the reading unless otherwise ordered by the section.

(c) Any proposition recommending the adoption of standard construction or practice shall be in writing and be accompanied by drawings, if the latter are necessary for a clear understanding of the subject. Such proposition shall then be submitted to the section for discussion, after which a vote shall be taken to decide whether the proposition shall be submitted for decision by letter ballot to all the members entitled to vote. If decided in the affirmative, the secretary within two months from the time the vote of the section is taken on such measure, shall send by mail to each member a blank ballot, and a copy of the proposed recommendation, with a report, to be approved by the general committee of the discussion thereon; such ballot to be returned to the secretary, who will count all the ballots received within thirty days from the date they were sent to the members, and he shall then announce the vote in such manner as the general committee may prescribe. Any recommendation securing two-thirds of the votes cast shall be adopted by the section.

(d) All reports, resolutions and recommendations involving the use, or proposed use, by railroads, of any device or process which forms the subject matter of any existing patent, shall first be submitted to the general committee, and shall be submitted to the section only by the general committee.

11. (a) The regular annual meeting of the section shall be held in June of each year. The dates of such meeting shall be fixed by the general committee.

(b) The regular hours of session shall be arranged by the general committee and published on the program for each meeting.

(c) The place for each annual meeting shall be fixed at least four months before the annual meeting by the general committee.

(d) At any regular meeting thirty or more members entitled to a vote shall constitute a quorum.

(e) The business of the meetings of the section shall, unless otherwise ordered by a vote, proceed in the following manner:

1. Address by the chairman.
2. Acting on the minutes of the last meeting.
3. Report of secretary.
4. Appointment of resolutions and other committees.
5. Unfinished business.
6. New business.
7. Reports of committees.
8. Reading and discussing questions propounded by members.
9. Routine and miscellaneous business.
10. Election of officers.
11. Adjournment.

12. The revision of the rules of interchange shall be the special order of business at 10:00 a. m. on the second day of each annual convention, unless otherwise ordered.

13. Unless otherwise ordered, the discussion of questions proposed by members shall be the special order at 12:00 noon of each day of the annual meeting.

14. The votes of a majority of the members present shall be required to decide any question, motion or resolution which shall come before the section, unless otherwise ordered. Matters upon which authoritative action is required after approval by the section shall be submitted to the executive committee of the association, through the general secretary.

15. (a) The reports of all committees must be in the office of the secretary not later than April 1 in order that the same can be printed and advance copies issued 30 days prior to the opening date of the convention.

(b) Committee reports which do not reach the secretary as provided for in paragraph (a) will be referred to the general committee to decide whether the report shall be submitted to the convention.

(c) An abstract of the report of each committee will be read to the convention, together with whatever additional data may have been accumulated after the publication of the reports.

(d) The members of committees who may individually or collectively submit a minority report must prepare the same so that it can be issued with the report of the majority to substitute for the majority report in the event the section shall so decide.

(e) Each member of a committee must approve either the majority or a minority report.

16. These rules of order may be amended at any regular meeting by a two-thirds vote of the members present provided that written notice of the proposed amendment has been given by the general committee at least four months before.

REPORTS OF COMMITTEES

Thirty-one committees will report at the convention. The first 20, ordinarily considered as Master Car Builders' committees, will report from June 18 to June 20, and 11 committees which would be considered strictly as committees of the Master Mechanics' Association will report from the period of June 23 to June 25. The election of officers will take place on Saturday, June 21. The list of committees is as follows:

June 18-20, 1919, Inclusive.

1. Arbitration, J. J. Hennessey (C. M. & St. P.), chairman.
2. Standards and Recommended Practice (M. C. B.), T. H. Goodnow (C. & N. W.), chairman.
3. Train Brake and Signal Equipment, T. L. Burton (N. Y. C.), chairman.
4. Brake Shoes and Brake Beam Equipment, B. B. Milner (N. Y. C.), chairman.
5. Couplers, R. L. Kleine (Pennsylvania), chairman.
6. Loading Rules, J. J. Burch (N. & W.), chairman.
7. Car Wheels, W. C. A. Henry (Pennsylvania Lines West), chairman.
8. Safety Appliances, C. E. Chambers (U. S. R. A.), chairman.
9. Car Construction, W. F. Keisel (Pennsylvania), chairman.
10. Specifications and Tests for Materials (M. C. B.), F. M. Waring (Pennsylvania), chairman.
11. Car Trucks, J. T. Wallis (Pennsylvania), chairman.
12. Prices for Labor and Material, P. F. Smith, Jr. (Pennsylvania Lines West), chairman.
13. Train Lighting and Equipment, J. R. Sloan (Pennsylvania), chairman.
14. Nominations, F. W. Brazier (N. Y. C.), chairman.
15. Tank Cars, A. W. Gibbs (Pennsylvania), chairman.
16. Draft Gears, R. L. Kleine (Pennsylvania), chairman.
17. Welding Truck Side Frames, Bolsters and Arch Bars, W. O. Thompson (N. Y. C.), chairman.
18. Standard Blocking for Cradles of Car Dumping Machines, James McMullen (Erie), chairman.
19. Revision of Passenger Car Rules of Interchange, H. H. Harvey (C. B. & Q.), chairman.
20. Depreciation for Freight Cars, M. K. Barnum (B. & O.), chairman.

June 23-25, 1919, Inclusive.

21. Standards and Recommended Practice (A. R. M. M.), W. E. Dunham (C. & N. W.), chairman.
22. Mechanical Stokers, A. Kearney (N. & W.), chairman.
23. Fuel Economy and Smoke Prevention, William Schlafge (Erie), chairman.

24. Powdered Coal, C. H. Hogan (N. Y. C.), chairman.
25. Specifications and Tests for Materials (A. R. M. M.), F. M. Waring (Pennsylvania), chairman.
26. Design and Maintenance of Locomotive Boilers, C. E. Fuller (Union Pacific), chairman.
27. Locomotive Headlights, H. T. Bentley (C. & N. W.), chairman.
28. Superheater Locomotives, W. J. Tollerton (C. R. I. & P.), chairman.
29. Design, Maintenance and Operation of Electric Rolling Stock, C. H. Quereau (N. Y. C.), chairman.
30. Train Resistance and Tonnage Rating, O. P. Reese (Pennsylvania Lines West), chairman.
31. Subjects, M. K. Barnum (B. & O.), chairman.

Standard 2-8-8-2 Type Locomotives

First of Government Order for Over 100 of These Engines Delivered to the Norfolk & Western

The first order of 1,025 locomotives placed by the United States Railroad Administration included an order of 20 heavy (2-8-8-2) standard Mallets. This was later increased to over 100, 65 to be built by the American Locomotive Company and 41 by the Baldwin Locomotive Works. The American Locomotive Company has within the past month made the first delivery of these locomotives. While they were scheduled and lettered for the Virginian Railway they have been assigned for duty on the Norfolk & Western. These engines are the largest of the standard locomotives built for the Railroad Administration and represent the limit to which a locomotive can be built to come within the maximum clearance limitations set by the Railroad Administration (15 ft. 9 in. high and 10 ft. 9 in. over cylinders). These locomotives are smaller than those which can be used on the Virginian Railway, as evidenced by the 2-10-10-2 type Mallet locomotives which were recently built for that road by the American Locomotive Company. These latter engines have a width clearance of 12 ft. and a height clearance of 16 ft. 7½ in. On the other hand, the clearance limitations of these standard engines compare very favorably with the 2-8-8-2 Mallets recently built by the Norfolk & Western to that company's own design. Being limited by these clearance restrictions a very careful design had to be made to provide a locomotive of the power required.

In the matter of power these standard engines may be compared with locomotives of similar wheel arrangement built by the Norfolk & Western in its own shops, and for the Western Maryland by the Lima Locomotive Company. A table comparing the principal dimensions of these two locomotives is included. A description of the Norfolk & Western locomotive was published in the *Railway Mechanical Engineer* of August, 1918, page 445. From this table of comparison it will be seen that the standard locomotive is 6,000 lb. heavier than that built by the Norfolk & Western, and 3,300 lb. heavier than that built for the Western Maryland. The working pressure on the standard locomotive is also 10 lb. greater than that of the Norfolk & Western locomotive and 30 lb. higher than that used on the Western Maryland locomotive. The boiler proportions of the standard locomotive and those of the Norfolk & Western compare very favorably. However, the Norfolk & Western design provides about 200 sq. ft. more heating surface and about 35 sq. ft. greater superheating surface. While these two engines are very nearly alike in proportions, they are of an entirely different class as far as the construction details are concerned, which will necessitate a different line of repair parts and illustrates one of chief objections to standardization.

Table of Comparison of 2-8-8-2 Type Locomotives

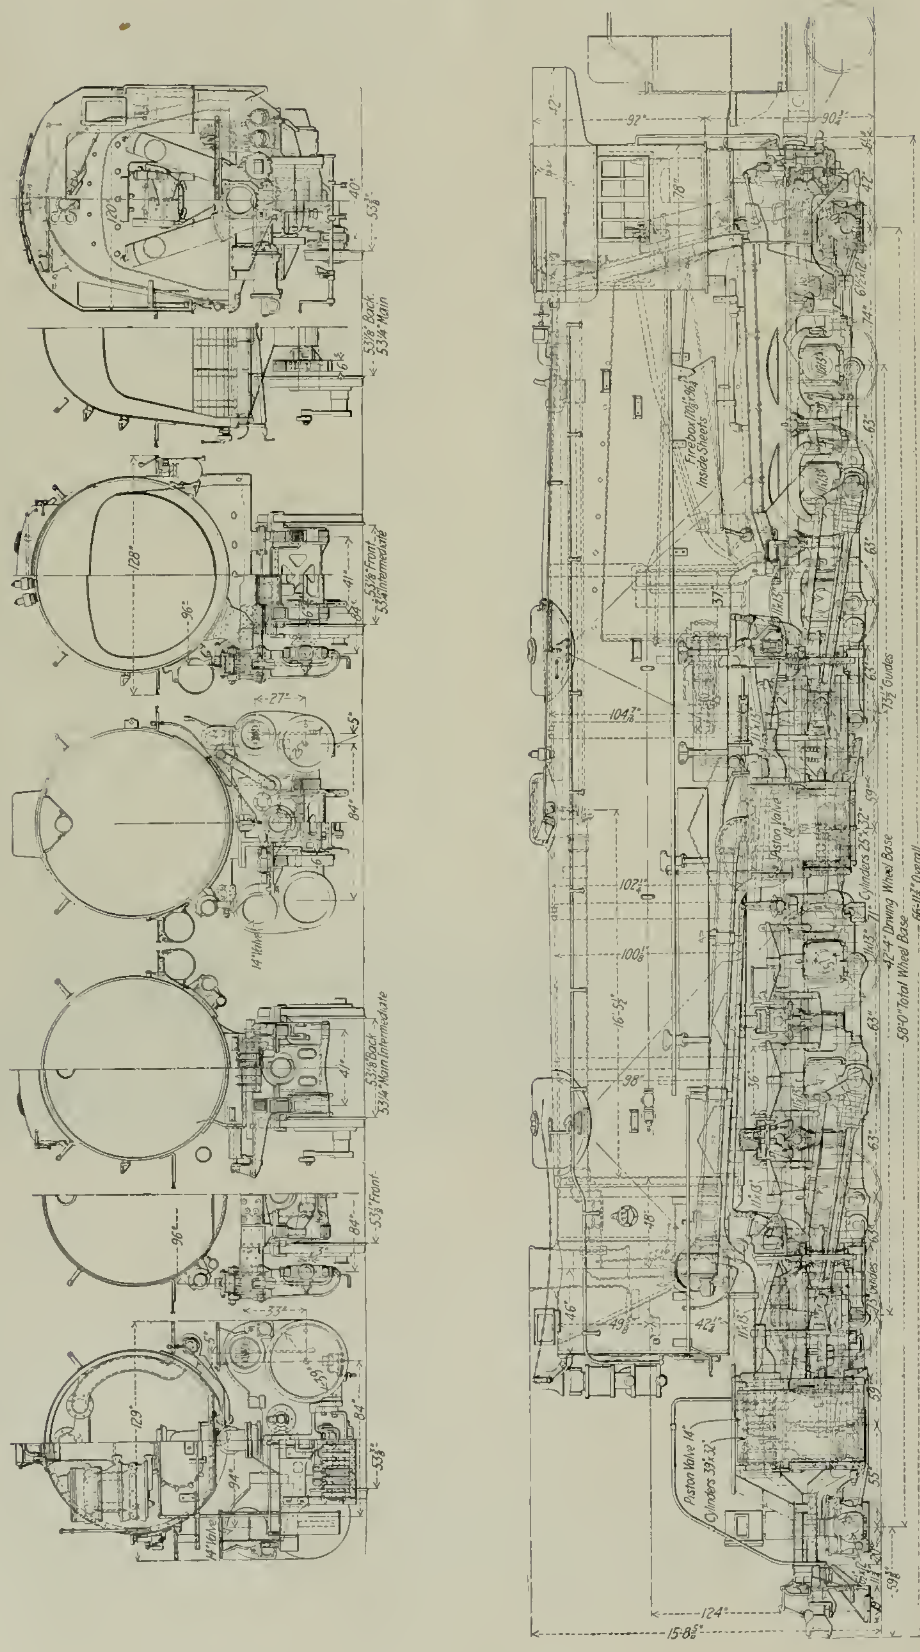
Name of road	U. S. Std.	Norfolk & Western	Western Maryland
When built	1919	1918	1915
Tractive effort, compound, lb.	106,000	104,300	106,000
Weight, total, lb.	531,000	535,000	495,000
Weight on drivers, lb.	57	56	52
Diameter of drivers, in.	478,000	472,000	445,000
Cylinders, diameter and stroke, in.	25 and 39 by 32	24½ and 38 by 32	26 and 40 by 30
Steam pressure, lb., per sq. in.	240	230	210
Total heating surface, sq. ft.	6,120	6,316	5,669
Superheater heating surface, sq. ft.	1,475	1,510	1,264
Grate area, sq. ft.	†96	96	80
Weight on drivers ÷ tractive effort (compound)	4.7	4.5	4.2
Tractive effort × diameter drivers ÷ equivalent heating surface*	695.	680.6	726.3
Equivalent heating surface* ÷ grate area	86.6	89.4	94.9

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.
†Gaines combustion chamber is used on this locomotive.

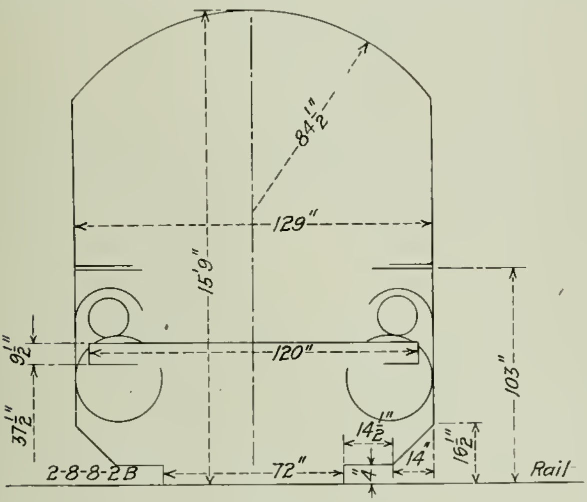
Standard 2-8-8-2 Type Locomotive for the U. S. Railroad Administration

The standard 2-8-8-2 Mallet locomotive has a total engine weight of 531,000 lb., of which 28,000 lb. is on the leading truck, 237,000 lb. on the front or low pressure unit, 241,000 lb. on the high pressure unit and 25,000 lb. on the trailing truck. It is built for a permissible axle load of 60,000 lb., which is the same limit prescribed for the standard 2-6-6-2 locomotive. The cylinders are 25 in. and 39 in. by 32 in., and a working pressure of 240 lb. is carried on the boiler. The distribution of the weights amongst the various drivers is shown in the weight diagram, which was prepared by F. P. Pfahler, chief mechanical engineer of the Mechanical Department, United States Railroad Administration. The clearance diagram, also prepared by Mr. Pfahler, is included in the illustrations.

The boiler of these locomotives has an outside diameter



Elevation and Sections of the Standard Heavy Mallet Type Locomotive at the first ring of 98 in. It is of the straight barrel type and has shell plates 1 1/16 in. thick. The dome is located on the third course and on account of the clearance limitation is only nine inches high. The boiler is equipped with a Gaines combustion chamber. The length of tubes is 24 ft. There are 274 2¼-in. tubes and 53 5½-in. flues, which are of No. 8 gage, being one gage heavier than the general standard practice in the construction of Mallet locomotives, due to the fact that a working pressure of 240 lb. is carried on the boiler. The firebox is 170⅛ in. by 96¼ in., having an effective grate area of 96.2 sq. ft. The firebox sheets are ⅜ in. thick and the back tube sheet is ½ in. thick. The tube



Clearance Diagram

spacing is similar to that used on the standard 2-6-6-2 type Mallets.

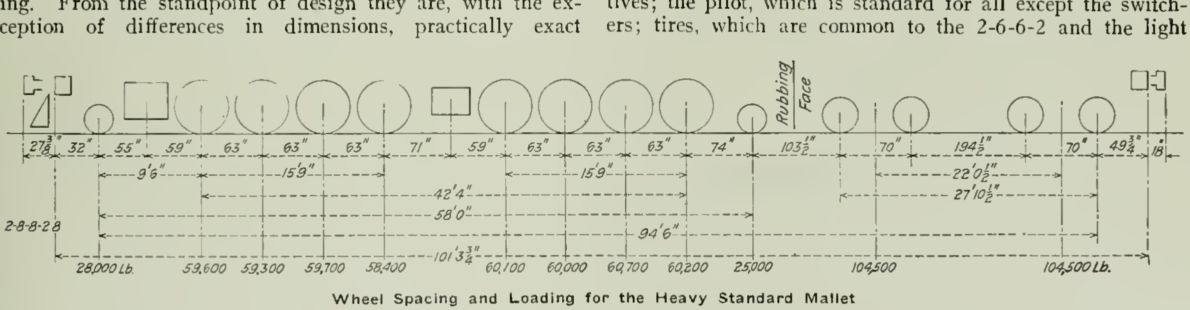
The frames for these locomotives are 6 in. in width, the same as for the 2-6-6-2 locomotives and are 6¾ in. deep over the pedestals, having a minimum thickness of 5½ in. The lower rails are 4½ in. deep, with a minimum thickness of 4 in. The frames for the high and low pressure engines are connected with the Baldwin type of frame hinged casting. From the standpoint of design they are, with the exception of differences in dimensions, practically exact

locomotives the valves and cylinders are bushed with Hunt-Spiller gun iron. Both cylinders are spaced 84 in. between centers, whereas in the lighter Mallets the spacing is 85 in. As in the case of the 2-6-6-2 Mallet the Mellin type of by-pass and intercepting valve is used to control the simpling and compounding of the locomotive.

In the matter of general design the crosshead for the 2-8-8-2 locomotive is the same as that of all standard locomotives. The dimensions are also practically the same, with the exception of the piston fit, the diameter of the boss in the body of the crosshead being made eight inches instead of seven, on account of the heavier piston rod, which is 4½ in. in diameter for the 2-8-8-2 locomotive and 3¾ in. in diameter for the 2-6-6-2 locomotive. The pistons have a dished section and those for the high pressure cylinders are interchangeable with those used on the light standard Pacific and the eight-wheel switchers. The specifications require that they be made of rolled steel or cast steel. They are provided with packing rings of Hunt-Spiller gun iron. The pistons for the low pressure cylinders are, of course, not interchangeable with any others used on the standard locomotives, although they are of the same general standard design. They are made of cast steel and are of dished section, having, as in the case of the high pressure cylinders, two packing rings of Hunt-Spiller gun iron. The piston rods for both the high and low pressure units of the heavy Mallet type locomotive are 4½ in. in diameter. Paxton-Mitchell piston and valve rod packing is used on these locomotives.

The main rods of both the high and low pressure cylinders are precisely the same. They are 118 in. long from center to center and are of I-section, being 3 in. wide and 6 in. deep, with 1½-in. flanges and a ½-in. web. They are of the same design as the main rods used on the 2-6-6-2 standard locomotive, the only difference being that they are one inch longer between centers and the flange is ½ in. deeper. Thus it will be seen that rods for both these locomotives can be manufactured from exactly the same size of stock material. The design of the strap end is exactly the same, the only difference being that the rods for the 2-8-8-2 type are a little heavier than for the 2-6-6-2 type locomotive.

Among the interchangeable details of these locomotives may be mentioned the dump grate rigging, which is the same as that used on the light and heavy Santa Fe locomotives; the pilot, which is standard for all except the switchers; tires, which are common to the 2-6-6-2 and the light



Wheel Spacing and Loading for the Heavy Standard Mallet

duplicates of the frames built for the standard 2-6-6-2 locomotive.

As in the case of the 2-6-6-2 standard locomotive, both the high and low pressure cylinders are provided with piston valves. A larger diameter of valve is used, however, it being 14 in. The travel of the valve for the high pressure cylinders is 6½ in. and it is given a lap of 1 in., a lead of ⅛ in. and an exhaust clearance of ¼ in. In the low pressure cylinders the valve is double ported and has a travel of 6 in. with a lap of 1⅛ in., a lead of 3/16 in. and an exhaust clearance of 7/16 in. As in the case of all the standard

Santa Fe; and engine truck and trailer axles, which are common to all of the standard locomotives. The engine truck box is the same as that used on both designs of Mikado and Santa Fe and the 2-6-6-2. The front bumper is the same as that used on all except the switchers and the frame pedestal shoe, wedge, and wedge bolt are the same on all locomotives except the switchers. In addition to this there are many other details which are interchangeable with the 2-6-6-2 type.

The specialties used on these locomotives as well as on the other standard engines were enumerated on page 137 of the March, 1919, issue of the *Railway Mechanical Engineer.*

The following is a list of the general dimensions of these locomotives with the principal data:

General Data

Gage	4 ft. 8½ in.
Service	Freight
Fuel	Bit. coal
Tractive effort (compound)	101,300 lb.
Tractive effort (simple)	121,600 lb.
Weight in working order	531,000 lb.
Weight on drivers	478,000 lb.
Weight on leading truck	28,000 lb.
Weight on trailing truck	25,000 lb.
Weight of engine and tender in working order	740,100 lb.
Wheel base, driving	42 ft. 1 in.
Wheel base, rigid	15 ft. 6 in.
Wheel base, total	57 ft. 4 in.
Wheel base, engine and tender	93 ft. 3 in.

Ratios

Weight on drivers ÷ tractive effort (simple)	3.93
Total weight ÷ tractive effort (simple)	4.37
Tractive effort (compound) × diam. drivers ÷ equivalent heating surface*	695.0
Equivalent heating surface* ÷ grate area	86.6
Firebox heating surface ÷ equivalent heating surface,* per cent	5.2
Weight on drivers ÷ equivalent heating surface*	57.5
Total weight ÷ equivalent heating surface*	63.8
Volume equivalent, simple cylinders, cu. ft	22.2
Equivalent heating surface* ÷ vol. cylinders	375.0
Grate area ÷ vol. cylinders	4.33

Cylinders

Kind	Compound
Diameter and stroke	25 in. and 39 in. by 32 in.

Valves

Kind	Piston
Diameter	14 in.

Wheels

Driving, diameter over tires	57 in.
Driving journals, diameter and length	11 in. by 13 in.
Engine truck wheels, diameter	30 in.
Engine truck, journals	6½ in. by 12 in.
Trailing truck wheels, diameter	30 in.
Trailing truck, journals	6½ in. by 12 in.

Boiler

Style	Straight top
Working pressure	240 lb. per sq. in.
Outside diameter of first ring	98 in.
Firebox, length and width	170⅛ in. by 96¼ in.
Firebox plates, thickness	⅜ in.
Firebox, water space	5 in.
Tubes, number and outside diameter	274—2¼ in.
Flues, number and outside diameter	53—5½ in.
Tubes and flues, length	24 ft.
Heating surface, tubes	3,860 sq. ft.
Heating surface, flues	1,825 sq. ft.
Heating surface, firebox	435 sq. ft.
Heating surface, total	6,120 sq. ft.
Superheater heating surface	1,475 sq. ft.
Equivalent heating surface*	8,333 sq. ft.
Grate area (with Gaines wall)	96 sq. ft.
Smokestack, height above rail	15 ft. 8⅝ in.
Center of boiler above rail	10 ft. 4 in.

Tender

Tank	Water bottom
Frame	Cast steel
Weight	209,100 lb.
Wheels, diameter	33 in.
Water capacity	12,000 gal.
Coal capacity	16 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

CO-OPERATION

BY FRANK McMANAMY
Assistant Director, Division of Operations, U. S. Railroad Administration

It has been generally understood that the government assumed control of the railroads because of the necessity of increasing their efficiency and operating them in such a manner that the necessary transportation would be provided to enable the country to successfully conduct the war against what had come to be recognized as the enemy of civilization.

It had been demonstrated that under individual control it was not possible to obtain the degree of co-operation necessary to bring about the increased efficiency which must be obtained and that only by operating the railroads as a single system under the direction of a strong central organization could the transportation needs of the country be met.

A survey of the situation showed that one of the principal, if not the principal, needs was to improve the condition of motive power and rolling stock.

Greater efficiency in this respect could only be secured by greater efforts and closer co-operation of the army of the railroad shop employees, because with the urgent demands for men for military service and for munition factories it was not possible to increase the forces in proportion to the increased work. The results of the past year show that increased efforts and better co-operation was secured to an extent hitherto unknown. Personal convenience and comfort on the part of railroad officials and employees were alike disregarded. Sundays, holidays and vacations were unknown to most of the railroad workers for the past year or more. Every loyal man was on the job 24 hours a day and seven days a week, or as near it as was physically possible. Employees' contracts were temporarily modified with respect to shop hours and to promotions and suggestions or requests of the Railroad Administration for changes that would increase efficiency and bring about closer co-operation have been cheerfully and promptly complied with. As a result of this it is not an exaggeration to say that a degree of efficiency in operating railroad shops was reached which has never before been attained. The railroad machine has been operated at high speed and with full tonnage and the shop employees have provided the necessary equipment.

In the matter of furnishing necessary equipment to conduct transportation during the war, the railroad shop employees have gone over the top and when the records of what they have accomplished is written they will have little to regret and much to be proud of.

The war is now over and the problems incident thereto are things of the past. We have, however, confronting us problems equally important if perhaps not so urgent.

The principal requirements necessary to go from a peace basis to a war basis were, unlimited energy and unceasing effort. To change the shop organization from a war basis to a peace basis, which is the task that confronts us now, will require unlimited patience, tact and judgment. A degree of co-operation equal to that which has been exercised during the war will be required. It will require the principle of the square deal to be recognized and observed on all sides and it will require absolute confidence that the necessary reorganization will be worked out with fairness.

The railroad shop employees with the co-operation of the officials, have performed a great service in their work during the past year, but it could not have been accomplished without complete co-operation and confidence in those who were directing the work. They have before them during the reconstruction or reorganization period an opportunity of performing an equally great service and if that is to be successfully performed it will require the co-operation of all and the work must be done in a way that will inspire confidence.

During war times two points in the operation of railroads predominated; namely, safety and efficiency, and others where they in any way adversely affected these could in a measure be disregarded. In times of peace safe and efficient service must be rendered to the public at a cost commensurate with the service performed. This, of course, means readjustments of hours and reorganization of forces, but this can and should be done along reasonable lines with proper consideration for the rights of the public and of the employees. If approached in the proper spirit and carried out with absolute fairness, necessary readjustments can be made without friction and without loss of efficiency.

The spirit of co-operation and the desire for performing constructive work which has been manifest during the past year is a sufficient guarantee that this will be done.

SWEEPINGS FROM SHOPS.—Attention has often been called to the importance of combing the sweepings which are hauled from the various shops, roundhouses, storehouses, etc., to the refuse car and taken out along the line and dumped. Yet there is reason to believe that there is much waste bound to accrue from lax methods in caring for the sweepings and an occasional inspection and renewal of instructions is worth while.—*Railway Storekeeper.*

MAINTENANCE OF FREIGHT EQUIPMENT*

BY H. L. SHIPMAN
Equipment Inspector, A. T. & S. F.

During the past year the maintenance of freight cars has been influenced by new conditions, due to the general pooling of equipment. This change is particularly noticeable in the box car. Formerly there was a normal percentage of from 35 per cent to 40 per cent of the box cars on the home lines. At the present time this percentage has fallen as low as 7 per cent to 12 per cent. Thus each road has less control over the maintenance standard of its own equipment. It would seem that some standard of maintenance should be established and all roads compelled to keep all freight cars on their lines up to that standard. This percentage should undoubtedly be higher than the standard now maintained by many of the smaller railroads, but some method should be devised to force all roads to come up to this standard. Unless this is done, under present conditions, the average standard of all cars will fall lower. and those roads, which under normal conditions would maintain this standard, will be helpless to keep it up.

There is a limit to the maintenance of equipment beyond which it is not practical or economical to go. If it were possible to maintain all freight equipment in 100 per cent condition, it would not be economical because there are many commodities that can be handled just as efficiently and satisfactorily in a car in fair condition as in one in 100 per cent condition. Since all cars in service are continually wearing out, or deteriorating, all that can be hoped for is to maintain in good condition a sufficient number of cars to handle the commodities that require a first-class car.

There are certain kinds of freight that require a box car, others a refrigerator, stock car, tank car or gondola and other freight may be handled just as well in several of the different kinds of freight cars. Some ladings require the cars to be in first-class condition and others only in fair condition. For example, a box car to handle grain, flour, sugar, or groceries, should be in the best condition possible. The siding must be tight, the roof non-leaking, and the floor and lining level and smooth, so as not to chafe or injure the contents. Wool, raw cotton, hay, brick, etc., may be handled in a car in fair condition without damage. A leaky roof or open siding will not injure these articles, and they cannot fall through cracks in the floor as would bulk grain. The only essential for cars handling the last mentioned articles is that the frame work of the car be strong enough to hold the load and that the trucks and draft gear be in good condition.

A refrigerator car must always be in good condition in order to protect its lading, due to the fact that the requirements of this service are very rigid. A stock car should be in good condition in order to handle live stock without damage, but the same car in fair condition will haul barreled goods, rough lumber, ties, lump coal, and many other articles, very satisfactorily. A gondola must be in very good condition to hold slack coal without loss, but will hold lump, coal, coke, scrap iron, etc., if in only fair condition.

On a typical western road there was a total of 1,240,324 car loads of revenue freight handled during the year 1917. This freight was subdivided under five general headings, namely, Products of Agriculture, Products of Animals, Products of Mines, Products of Forests, and Manufactured and Miscellaneous Articles. The number of car loads of each of these classes of freight was as follows:

Products of agriculture	298,717
Products of animals	172,836
Products of mines	385,836
Products of forests	99,301
Manufactured and miscellaneous articles	283,634

A close analysis of this freight as a whole shows that 72.6 per cent should be handled in cars of first-class condition in order to avoid possible loss or damage due to the condition of the cars; 27.4 per cent of the freight could be handled just as satisfactorily in cars of fair condition.

An extended investigation in the train yard and in a large repair shop of the causes of repairs to freight cars disclosed the fact that only a very small percentage of freight car repairs become necessary due to "time and the elements," or, in other words, rust and decay. To make this study, the repairs to freight cars were subdivided into four general headings representing the principal parts of the car, as body, draft gear, truck and air brake repairs. The investigation showed that most of the repairs required by the bodies of these cars became necessary due to time and the elements, and the next important cause of repairs in the body was starting, stopping and switching or load shift under shock. The draft gear and truck repairs became necessary chiefly due to the starting, stopping and switching of the car. Load shift causes the ends of the car to be pushed out, and posts broken and the siding and lining broken. A very small percentage of the repairs to draft gear or trucks was necessitated by time and the elements. Nearly all of the repairs to draft gear were caused by starting, stopping and switching. The draft gear is broken or weakened by shock in switching and the trucks need repairs because of stopping, as well as shock. The items of the greatest expense in truck repairs are brake shoes, brasses and wheels. It is very seldom a truck has a broken side frame or bolster. The air brakes need repairs because of running and stopping the car.

Combining the causes of repairs of the several parts of the car, the results showed that 47.2 per cent of the repairs to cars became necessary due to the running of the car, and time and the elements; 52.8 per cent of repairs to cars was necessitated by starting, stopping and switching, and the loading and unloading of the car. The 52.8 per cent in starting, stopping and switching and loading and unloading should be again subdivided to show the repairs due to the necessary wear of starting, stopping and switching and the unnecessary wear or abuse of the car. The subdivision shows that 33 per cent of the repairs would be eliminated if no draft gear, end sills, posts, siding or lining were broken by shock and no wheels slid flat or journal cut.

The next question to be considered is what percentage of

*From a paper presented before the Western Railway Club.

the freight equipment can economically be maintained in first-class condition. As mentioned above, 72.6 per cent of the freight equipment should be in first-class condition to carry the freight of this trunk line without damage or loss due to the condition of equipment. Is it feasible or practical to maintain this percentage as a standard of condition?

In a recent survey of bad order cars on several of our Western roads, it developed that the higher the percentage of revenue cars bad order on any line, the more men were employed per 1,000 revenue cars on the line, and the greater was the percentage of revenue cars that were repaired each month. Conversely, the lower the percentage of revenue cars bad order on the line, the smaller was the percentage of cars repaired each month. Comparing four of these roads, and averaging two of the higher and two of lower percentages, the results were as follows:

	Per cent of revenue cars, bad order	Per cent of cars repaired to revenue cars on line per month	Number car men employed per 1,000 rev. cars on line	Total number cars repaired per month	Number revenue cars on the line
Two higher ..	8.4 per cent	135.4 per cent	76.8	53,248	43,303
Two lower ...	3.0 per cent	59.4 per cent	37.7	25,909	37,443

Very few roads have a very high percentage of their own cars on their line. The freight car is common property today, therefore, it cannot be supposed that there is any very great difference in the physical condition of the cars on these four roads. These figures simply mean that different roads have different standards of maintenance, and that a road with a high standard will endeavor to keep the condition of freight equipment to a higher standard than the other road. In order to accomplish this end, the one road hires more men and consequently bad orders and repairs more cars than the other. These roads with the high standards of maintenance have found that the old saying "a stitch in time saves nine" is just as true when applied to a freight car as in its original application, and that the net results will show up on the credit side of the balance sheet.

A road with a high standard will cut down train delays and damage claims due to defective equipment, and as a result will pay a greater dividend than the road with the low standard of maintenance. A shipper prefers a road with a high standard of maintenance because he knows his products will receive better attention than on a road with low standards. There will not be the delays en route and the goods will arrive in better condition.

One step toward distributing repair work among all railroads so as to overcome the present practice of one road making only light repairs and another doing the substantial work, would be to have a standard classification of repairs. This would make it easier to judge work done and the output. I would recommend the following outline as a reasonable classification for the subdivision of repairs:

Classifications of Repairs to Freight and Work Cars

Heavy Repairs

One or two pair draft timbers.
Two or more sills renewed or spliced.
One or two end sills.
Two or more side or door posts.
One-half or more outside sheathing renewed.
Entire roof relaid or renewed.
Flooring renewed or repaired.
Door rehung or new doors applied.
Car trussed up and body tightened.
Two trucks given general overhauling.
Cars repainted and stenciled.
(Any seven or more of above items constitute heavy repairs.)

Medium Repairs

One or two pair draft timbers.
One end sill or new end and siding.
One pair draw sills spliced.
Roof relaid or new roof applied.
Door rehung or new door applied.
Trucks repaired.
Cars trussed.
All new work painted.
(Any five or more of above items constitute medium repairs.)

Running Repairs

Uncoupling attachments repaired.
Grab iron renewed or repaired.
Brasses applied.
Brake shoes renewed.
Running boards repaired.
Brake connection and lever.
Side door rehung.
(Any one or more of above items, or similar thereto, constitute running repairs.)

Light Repairs

One or more pair wheels renewed.
Draft timbers tightened and new bolts.
Side door rehung.
Couplers renewed.
Body tightened.
Deadwoods repaired or renewed.
Brake beams repaired or renewed.
(Any one or more of above items or similar thereto constitute light repairs.)

It is my opinion that such a classification will be more satisfactory than to have heavy, medium, light and running repairs subdivided on a money or hourly basis. The objection to the hourly or money basis of subdivision of repairs is that no record is kept of the cost of either labor or material on individual cars. To keep these records would entail a great addition to overhead expense. The proposed plan can be used without any addition to the present clerical force.

In conclusion, the question of freight car repairs may be summarized as follows: Freight equipment should be maintained in approximately 75 per cent condition in order to handle freight without danger of loss or damage due to the condition of the freight equipment; this percentage condition cannot be maintained without the co-operation of all roads, because the freight car today is common property so far as service is concerned.

Discussion

H. H. Harvey (C. B. & Q.): The statement is made in Mr. Shipman's paper that 72.6 per cent of all freight cars should be kept in first-class condition. I question whether it is necessary to have that figure quite so high. It would vary greatly on roads in different localities and will even vary on the different divisions of a single large road. There are many commodities that should never be loaded in a first-class car. One of the worst abuses prevalent on our railroads today is loading hides, fertilizer, immigrant outfits and similar material in first-class equipment. Car men in general are dilatory about calling attention to the abuse of cars. Since cars have been loaded up to the capacity of the axles there has been a great deal of overloading of light cars, and I think the sooner we get back to the 10 per cent overload, the better it will be for the equipment.

J. H. Milton (C. R. I. & P.): The only way that a car can be kept in service with the heavy tonnage handled at the present time is by reinforcing it. When we can get a system in force throughout the United States that will make all the roads reinforce their cars we will get good equipment. Until that is done we will simply repair the cars from time to time and get nothing from our labor. The majority of railroads are spending $50 to $75 to repair cars which only move off the repair track to become bad order again within a week or two. By spending $400 or $500 on these cars they could be put in first-class condition. The equipment is getting worse every day, particularly on the Eastern lines.

F. P. Schultz (Chicago Car Interchange Bureau): The designs of cars are so varied that it is practically impossible to keep a stock of the proper material for reinforcing these cars away from the home road. The Railroad Administration is now moving cars in bad order to the owning roads, and when they get home it is to be hoped that some rules will be formulated that will keep the car on the home road if it is not up to a certain standard. As far as the box car is concerned, I think as long as it is of a design that is kept in general service, it should be maintained in 100 per cent condition. A rough freight car may be given a load that it will carry, but when it is unloaded it may be in a district where there is nothing but grain loaded and the rough freight car will bring back the load of grain which it is not fit to handle. The proper way to handle the rough freight car is to mark it bad order if it is sent out under load.

W. G. Wallace (American Steel Foundries): We have heard a great deal about what has been accomplished by the united efforts of the men in the different regions in handling traffic. Would it not be a good idea to have the transportation men keep more closely in touch with the mechanical men and to prevent car repairs, instead of having so many cars bad ordered? There are a good many things that could be done by getting the transportation officers more interested in the mechanical department problems.

Mr. Milton: I believe the type of underframe required under cars depends largely on the type of draft gear. If a friction draft gear is used the entire shock is thrown on the draft sills. After a spring gear has traveled 1¾ in. the coupler strikes the dead wood and the shock is distributed on all the sills. This takes the load off the draft sills to a certain extent, and for that reason I think it is useless to have a heavy underframe under cars with spring gear.

G. S. Goodwin (C. R. I. & P.): I agree entirely with what Mr. Milton has said. Incidentally, it might be of interest to note that mechanical department circular No. 8 provides that draft sills must be constructed to accommodate friction draft gear, and also that the coupler shall be applied with 3 in. clearance between the coupler horn and the deadwood. The circular permits the application of two classs G draft springs which have a travel of about 1⅞ in. That means that the spring gear must take all the shock, since the horn of the coupler is 1⅛ in. away from the dead wood. It is easy to see what will happen under those conditions.

E. H. Hall (C. G. W.): I do not see how there can be much improvement in the condition of equipment as long as the present rules are enforced. Order No. 12 states that Interstate Commerce Commission Accounting rules must be observed. These rules provide that when the cost of repairs exceeds the major portion of the cost of the car to the carrier, the equipment must be retired. With the present high cost of labor and material the cost of repairs often exceeds 50 per cent of the book value, particularly when equipment has been acquired second hand or through receivership. To get such cars back into service requires additions and betterments which are chargeable to the corporation. It seems that the only thing to do in such cases is to put the cars on a side track until the Railroad Administration or the corporation can agree on the distribution of cost.

F. C. Kroff (Pennsylvania Lines): We have filed the inspection report on a considerable number of cars and have them set aside awaiting disposition. Up to the present time we have received no instructions from the Railroad Administration regarding this equipment.

C. J. Juneau (C. M. & St. P.): We are holding about 200 cars between Minneapolis and Milwaukee awaiting disposition and many more are coming in.

Reinforced Concrete Gondola Car

New Aggregate Used; Design Incorporates Steel Center Sills with Reinforced Concrete Body

An innovation in railway equipment is a reinforced concrete car of the gondola type, invented and designed by Joseph B. Strauss, C.E., president of the Strauss Bascule Bridge Company and recently built by the R. F. Conway Company, Chicago. The plans for the car were drawn up several years ago and patents were secured covering the important features of the design. The actual construction was started during the war when it was thought that it might be possible to relieve the car shortage materially by developing concrete construction.

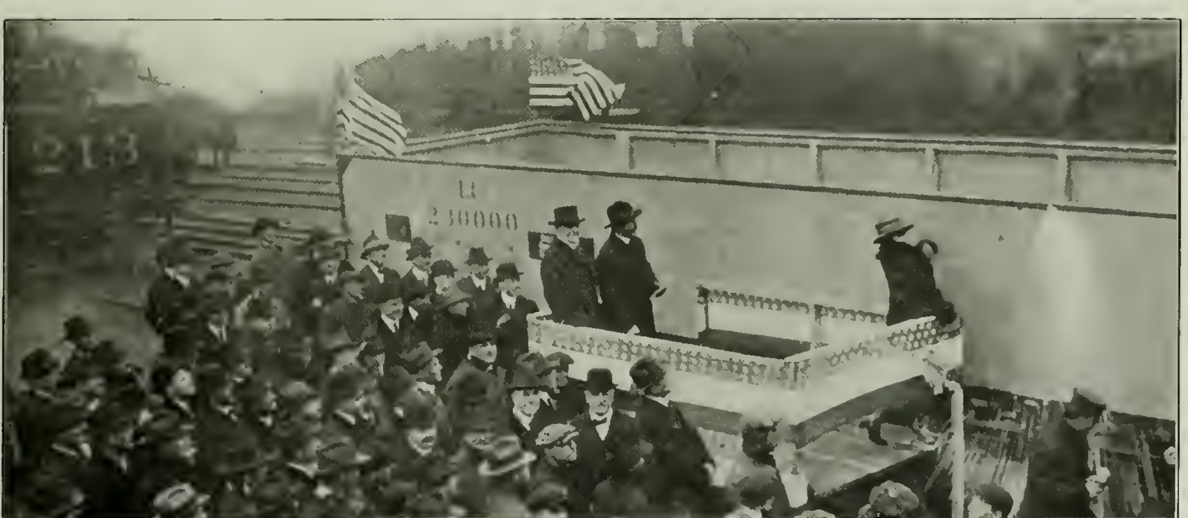


Photo. by International Film Service.

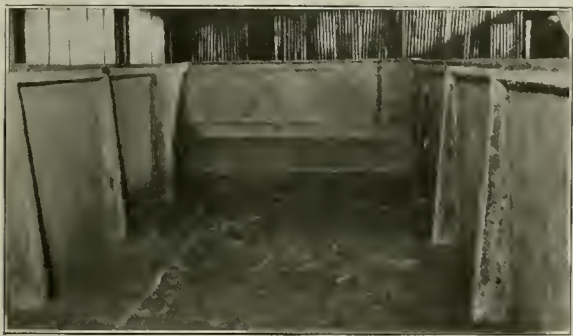
The Christening of the World's First Concrete Freight Car

The fundamental feature of the design is a steel skeleton body mounted upon the standard center sills and bolsters of the U. S. R. A. 40-ft., 50-ton gondola car. Concrete walls and floors are contained within the skeleton steel frame and together with the reinforcement in the floor are connected to the underframe in such a manner that the buffing and pulling stresses are distributed throughout the car body. The car was designed for a capacity of 100,000 lb. plus the usual 10 per cent overload. The end load was assumed at 200,000 lb. with an allowance of 25 per cent for impact, equivalent to an end load of 250,000 lb. The unit stresses in the steel were limited to 16,000 lb. per sq. in., and in the concrete to 1,000 lb. per sq. in. The gondola type was chosen for this experimental concrete car because equipment of this type is subjected to the severest handling. Dumping devices were omitted merely to simplify the construction, but this feature can be incorporated in such cars without any difficulty.

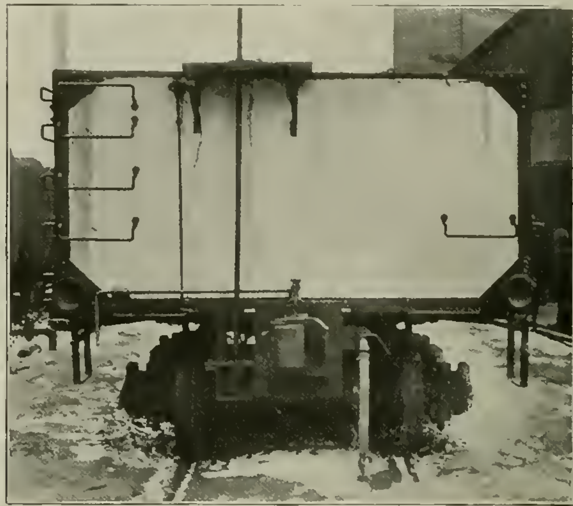
The car has an over-all length of 41 ft. 6½ in., and over-all width of 10 ft. 2⅞ in., with sides 4 ft. 10½ in. high. The steel members of the underframe consist only of the center sill, which is of two 12-in. 35-lb. ship channels, with a 1/4-in. by 20 1/2-in. cover plate, and the body bolsters and diagonal corner braces, which conform to the U. S. R. A. standard design. There are six reinforced concrete cross bearers in the car spaced approximately 4 ft. 6 1/2 in. apart. The size of the section varies from 4 in. by 12 in. at the sides to 4 in. by 1 ft. 4 1/8 in. at the center sill. The floor is 2 1/8 in. thick, reinforced with longitudinal and transverse



Interior of the Car Body

rods 1/4 in. in diameter. Along the outer edge of the floor is a 3 1/2-in. by 3 1/2-in. angle and at the top of the sides there is a 4-in. channel. This steel frame serves as the tension members of the truss and also furnishes a means of attachment for the reinforcing, the side reinforcing rods extending through holes drilled in the angles and channels. The sides are 1 3/4 in. thick and are strengthened at the bolsters and at the cross bearers by reinforced concrete posts.

weight of 104 lb. per cu. ft., and a compressive strength of 4,450 lb. per sq. in. in 28-day tests. It is the result of a manufacturing process developed by Stephen J. Hayde, of Kansas City, Mo. The concrete sections in this car are



Brake Staff End of the Reinforced Concrete Car

thinner than have ever before been attempted in similar work and for that reason it was decided to use the cement gun for the walls and floors. The cross bearers, however, were poured in the usual manner. The forms were placed

Skeleton Steel Frame and Reinforcing in Position in the Forms

Across the end of the car there is a reinforcing rib 6 in. by 1 1/4 in. located 1 ft. 11 3/4 in. from the floor. A diagonal rib extends up to the end from the lower end of the body bolster.

The concrete work on this car represents the first commercial application of a new light weight aggregate known as Haydite. This material produces a concrete having a

on the outside of the car and the skeleton frame and reinforcing were put in position as shown in the illustration. The concrete was then shot on from the interior. The resulting concrete was exceedingly dense and the finish remarkably smooth on the surface which was against the form. The interior was left practically as produced by the gun.

The use of the cement gun increased the specific gravity of the concrete above that computed. This fact, together with the necessity for using heavier steel sections than required in some cases brought the total weight of the car up to 53,600 lb., or 3,600 lb. more than the computed weight. It is evident, however, that with proper facilities for construction another car of this size and design can be made to weigh between 46,000 and 48,000 lb. The conditions under which the first car was built did not permit of certain refinement of design and details of construction, but the plans as now developed for commercial production of such cars have been so advanced that future cars will represent a reduction in weight, simplification of manufacture and lower cost.

This car was built with the sanction and co-operation of the United States Railroad Administration, and it was inspected during construction by J. J. Tatum, supervisor of car repairs. It was turned over to the Illinois Central Railroad on March 17, to be used on that line 30 days, after which it will be delivered to the United States Railroad Administration for such service as it may be desired to place it in. Meantime the further development of the concrete car will be handled by the Concrete Car Company of America, Chicago, which has plans completed for manufacturing concrete cars on a commercial scale.

One of the photographs was taken during the christening ceremonies with which the car was launched upon its career of railroad service, a consideration probably not accorded to any of the other more than two million existing freight cars.

The Automatic Straight Air Brake

I. C. C. Reports Successful Operation in Extensive Tests With and Without Other Types of Brakes

The Interstate Commerce Commission on March 4 submitted to Congress the report of a series of tests conducted by the Bureau of Safety of the air brake system of the Automatic Straight Air Brake Company of New York, as a result of which the bureau submitted the following conclusion: "In the tests of the automatic straight air brake system, both Westinghouse and automatic straight air locomotive apparatus was used with trains made up of various arrangements of Westinghouse and automatic straight air triple valve equipment, and the tests were made under varied operating conditions. Synchronous operation of the automatic straight air brake system with brake apparatus now in common use was secured in all of these tests. On trains equipped entirely with automatic straight air triple valves the reliability and flexibility of the automatic straight air brake system were sufficiently demonstrated." This conclusion, together with a report submitted to Congress June 29, 1916, is the result of a study and test of this system during a period of several years, beginning in 1910, when the triple valve was presented to the Block Signal and Train Control Board, and including experimental tests on the Atchison, Topeka & Santa Fe in 1915 and extensive rack tests and service tests on the Virginian Railway during the period from March to July, 1918.

The apparatus recently tested is a development of that formerly controlled by the California Valve & Air Brake Company of Los Angeles, Cal., tests of which were made by the bureau in November, 1915, which were the subject of the report to Congress in 1916. The tests which are the subject of the new report were made first with the apparatus installed on a 100-car test rack in New York City and later on the Virginian Railway with the same brake apparatus installed on cars used in coal service between the mines in West Virginia and the docks at Sewalls Point, Va.

As presented to the commission for test, the apparatus comprises a triple valve, a high volume feed valve and a compensating valve. The triple valve tested is of the 3-unit type,* the three units being a service section, an emergency section and a change-over section; the equipment also includes a quick action reservoir and a service reservoir in addition to the present auxiliary reservoir and brake cylinder.

This apparatus is designed to produce essentially the following operating results:

(1) Rapid serial action in service applications and in quick release.

(2) The maintenance of uniform and constant brake cylinder pressure, irrespective of piston travel or cylinder leakage. The cylinder is fed from the brake pipe, the pressure in which in turn is maintained by the compensating valve while the brake valve is in lap position.

(3) Graduated release, permitting a variation of brake cylinder pressure at the will of the engineman.

(4) Quick release when desired.

(5) Emergency applications of the brake available at any time during or after any service application, and an automatic emergency application on depletion of train pipe pressure to approximtely five pounds.

As is suggested by the name, the design of this system combines features of the automatic air brake and the straight air brake. Apart from its use to obtain quick release of brakes, auxiliary reservoir air is used only in emergency application. In service application brake cylinder air is obtained from the brake pipe and service reservoir, the auxiliary reservoir serving as a constant pressure chamber to regulate and govern brake cylinder pressure in proportion to brake pipe reduction. The design of the triple valve is such that in a service application the build-up of brake cylinder pressure as compared with the reduction of brake pipe pressure is in the ratio of two to one.

The high volume feed valve and the compensating valve of this system form a part of the brake equipment installed on the locomotive. The high volume feed valve performs the functions and takes the place of the feed valve commonly used, the purpose of this valve being to remove any restriction between brake valve and brake pipe when brake pipe pressure is below the pressure for which the feed valve is adjusted. The compensating valve is designed to compensate for brake pipe leakage during service application, as well as for depletion of brake pipe pressure by action of the triple valves in automatically compensating for brake cylinder leakage; its function is to maintain brake pipe pressure equal to the equalizing reservoir or chamber *D* pressure. It will also perform the equalizing discharge valve functions.

Tests on Virginian

The report includes a description and analysis of standing and running tests on the Virginian Railway from June 4 to July 9, 1918.* In the first tests, series A, the entire 100 cars were used and tests were made before the brake equipment was changed in any respect. When the A. S. A. equip-

*For a detail description of this equipment see the *Railway Mechanical Engineer* for November, 1917, page 633.

*For a description of the test equipment and an account of the final test runs from Princeton to Sewalls Point, see the *Railway Mechanical Engineer* for August, 1918, page 453.

ment had been installed on 10 cars, standing and running tests were made, series B, with a train of 50 cars, 40 equipped with the original Westinghouse equipment and 10 with A S. A. equipment in blocks of four Westinghouse and one A. S. A. In series C, standing tests only were made with 90 cars, 81 equipped with Westinghouse triple valves and 9 with A. S. A. equipment, in blocks of nine Westinghouse and one A. S. A. In series D, E and F a 50-car train was used, 25 cars having each type of triple valve equipment. In series D the cars were arranged in blocks of five Westinghouse and five A. S. A.; in series E and F, the cars of each kind were grouped together, in one case with the A. S. A. ahead and in the other with the Westinghouse ahead. For the standing tests, series G, a 100-car train was used, 81 cars equipped with A. S. A apparatus and 19 with Westinghouse, with the latter on every tenth car and on cars 20 to 30 inclusive. In series H all cars were equipped with A. S. A. triples, and standing tests were made with two trains consisting of 50 and 100 cars, respectively, and running tests were made with a 50-car train. In series I, 100 cars were equipped with A. S. A. apparatus; standing tests were made and the train was run from Princeton to Roanoke. At Roanoke the A. S. A. triples were removed from 50 cars and replaced by the original Westinghouse K-2 triples for the series K tests, which consisted of a test trip from Roanoke to Victoria with the first 49 cars and the rear car equipped with A. S. A. apparatus. Series L consisted of a trip from Victoria to Sewalls Point with the Westinghouse cars ahead. In all, the schedule included about 70 tests, standing, terminal and running.

In series A, brake cylinder leakage tests and retaining valve tests were made for the purpose of securing a record of the condition of the brake equipment. The purpose of the tests in series B, C, D, E, F and G was to demonstrate the operation of both types of triple valves in trains of mixed brakes with and without the A. S. A. engine equipment.

The purpose of the test run from Princeton to Roanoke was to demonstrate the ability of the A. S. A. brake equipment to control a long train on heavy grades, as well as the flexibility of the system for controlling a train on undulating and level grades.

Leaving Princeton, the A. S. A. locomotive apparatus was in service, and on all cars the brakes were operated in graduated release. In making the first brake application after starting down the grade, three brake pipe reductions were made, the total reduction being from 87 to 70 pounds, as indicated by gages on the locomotive; as a result brake cylinder pressures of 36, 29, 35 and 38 pounds were developed on the 1st, 29th, 60th and 95th cars. Following these reductions, the brake valve was not moved to release position in time to restore brake pipe pressure quickly enough and the train stopped before the brakes were released. As soon as pressure was restored the train was again started and a speed of 10 or 11 miles per hour had been attained when an emergency application occurred, due to an air hose being blown off from the 94th car. The train did not part, and was stopped without shock on either end. When the hose had been replaced and pressure restored, the train was started and a reduction of brake pipe pressure from 86 to 70 pounds was made for the purpose of controlling speed. Following this application, as the brakes were being graduated off when speed had been considerably reduced, the train parted, due to the coupler on the 85th car slipping over the top of the coupler on the 84th car, the carrier iron having fallen. This caused an emergency application, and although the speed was very low both portions of the train stopped without shock. Repairs were made and the train proceeded to Kelleysville without stop; the brakes were applied and graduated off and on as required to control the speed, which varied from 16 to 22 miles per hour. No difficulty was experienced in controlling the rate of speed, and the operation of the train was notably free from shock.

At Kelleysville the brakes on all cars were placed in quick release and the train was operated with brakes in that condition from Kelleysville to Whitethorne. Approaching the New River bridge as the brakes were being released following an application, the train parted between the 66th and 67th cars on account of a broken knuckle. The emergency brake application brought both portions of the train to a stop without damage or shock. Again, approaching Rich Creek the train parted between the 89th and 90th cars, due to a broken knuckle, while the brakes were being released, and the brakes on the head end back to about the 60th car had been released. Brake pipe pressure having been restored at the head end, higher brake cylinder pressure on the cars at the head end was built up in the emergency application than on the cars farther back. Notwithstanding this emergency application originated near the rear end, serial action of the brakes from that point to the head end was so rapid that the higher brake cylinder pressure developed on the head end stopped that end of the train first, causing a rather severe run-in of slack. However, the shock was not severe enough to cause any damage and when the coupler had been repaired the train proceeded.

At Whitethorne the brakes of all cars were again placed in graduated release. After passing Merrimac the first two applications of the brakes which were made on the grade east of that point were heavy, and each time the train was stopped before the brakes were released. Subsequently lighter brake applications were made and the speed of the train was controlled properly.

At Roanoke the A. S. A. triple valves were removed from 50 cars and the Westinghouse triples were replaced. On the trip from Roanoke to Victoria the train was made up with the first 49 test cars and the rear test car equipped with A. S. A. apparatus and cars 50 to 99, inclusive, were equipped with Westinghouse triple valves; from Victoria to Sewalls Point the first 50 test cars were equipped with Westinghouse triples and the last 50 with A. S. A. The purpose of these arrangements was primarily to determine what, if any, slack action there would be between cars with different types of brake apparatus grouped together in large numbers in different parts of the train and whether proper synchronous and serial action would be obtained under varied braking conditions encountered.

The trip from Roanoke to Victoria was made on July 8. Leaving Roanoke the brakes on 49 A. S. A. cars were operated in graduated release. On the grade between Goodview and Huddleston very light brake pipe reductions were made for the purpose of controlling speed, the reductions varying from two to four pounds each. At Stone Mountain approximately half-way down the grade, the train was brought to a stop to meet an opposing train. From that point it proceeded to the bottom of the grade without a stop, the operation being remarkably smooth and free from shock.

At Taber, 54 miles east of Roanoke, the brakes on the A. S. A. cars, except the first 25, were placed in quick release and the trip from Taber to Victoria was completed with the brake apparatus in that condition. Near mile post 129, about 9 miles west of Victoria, while running at a speed of about 20 miles per hour, the train parted between the 99th and 100th test car, due to a short knuckle pin and the top coupler lug being broken off. Before the break-in-two the brakes were not applied. The emergency brake application brought it to a stop without damage or shock.

The run from Victoria to Sewalls Point was made on July 9. A box car loaded with equipment and tools was hauled next to the locomotive, and there were four cabooses on the rear end; the brakes on the cabooses were not used. Approaching Purdy, approximately 40 miles east of Victoria, there is an ascending grade eastbound of .2 per cent followed by a descending grade of .21 per cent for a short distance and then by a descending grade of .5 per cent. Approaching Purdy an application of the brakes was made and before the rear end had reached the crest of the ascending grade, the head end being on the descending grade, the brake valve was placed in full release position for a period of nine seconds and then returned to running position. The train parted between the 82nd and 83rd cars, the knuckle on the rear end of the 82nd car being broken. Trainagraph charts indicated that prior to the break-in-two the brakes had been released back to about the 50th car, and it is apparent that the contour of the line, together with the short release period and a bad flaw in the knuckle caused the break-in-two. After the knuckle had been repaired the trip to Sewalls Point was completed without noteworthy incident.

DISCUSSION

In the discussion of the tests, the report says the A. S. A. brake equipment is considered, first, as used in mixed trains with other types of brake apparatus now in common use, and, second, when A. S. A. brake equipment exclusively was used in the test trains. In mixed trains, in both standing and running tests, synchronous operation with the Westinghouse apparatus was obtained, and the control of mixed trains having a large percentage of A. S. A. triple valve equipment under varied braking conditions, including heavy, undulating and level grades, was, with but one or two exceptions, notably free from shock.

The design and construction of the A. S. A. triple valves used in the Virginian tests provided for low brake cylinder pressure for a given brake pipe reduction, as compared with the Westinghouse triple valves, particularly in view of the short piston travel maintained on the Virginian Railway. In mixed trains better braking conditions would be provided and more harmonious operation with other types of brake apparatus if the A. S. A. brake provided higher brake cylinder pressure in proportion to brake pipe reduction. It is noted that this is merely a detail of construction and an increase in the present ratio can easily be obtained.

In mixed trains with the A. S. A. triple valve equipment on the head end the functions of graduated release were accomplished and tests demonstrated that the graduated release feature of the A. S. A. triple when used on the head end of mixed trains is very desirable under operating conditions similar to those encountered on the Virginian Railway, also emergency operation of the A. S. A. cars on the head end of mixed trains was obtained following a service application when the initial reduction was not too great. The use of A. S. A. triple valves in mixed trains on account of locally reducing and increasing brake pipe pressure results in some degree in more positive operation and an improvement in serial action both in applications and in releasing the brakes, the degree being dependent upon the number and location of the A. S. A. triple valves in the train.

On cars equipped with A. S. A. apparatus, the A. S. A. triple valves supplied comparatively uniform brake cylinder pressure which was not affected by piston travel, brake cylinder leakage or pressure retained in the brake cylinder at the beginning of an application; but under present practices of controlling trains the brakes ordinarily are not held applied long enough to obtain the full advantage in mixed trains of compensating for brake cylinder leakage.

In the standing tests with trains having all cars equipped with A. S. A. triple valves, practically all the intended functions were accomplished. In general, proper serial action in both application and release was obtained; when operating in graduated release the brakes were graduated on and off as desired, being fully released as intended when normal brake pipe pressure was restored. Comparatively uniform brake cylinder pressure was obtained regardless of piston travel or of pressure retained in the brake cylinders by the retaining valves, and it was maintained notwithstanding ordinary brake cylinder leakage. Emergency operation following a service application was not secured in every case when desired; after the installation of the special emergency valve on the locomotive, emergency operation was secured when the initial service reduction was 20 pounds or less. The emergency tests demonstrated that after a full service reduction followed by a full release period as short as 10 seconds emergency operation of the triples throughout the train can be secured. The automatic emergency feature of the triple valves tested, which becomes effective when the brake pipe pressure had been depleted to five pounds or less, was so much delayed as to be of little or no practical value; to make this feature of the brake system useful the period of time required before the automatic emergency operation occurs must be materially decreased, which can be accomplished by making this function operative at a higher brake pipe pressure. In the test providing for an angle cock on the rear end of the train to be opened with the brake valve in running position, the emergency operation carried to the head end of the 100-car train.

In the running tests on the grade between Princeton and Kelleysville with 50 and 100-car trains equipped exclusively with A. S. A. triple valves the operation of the brakes was precise and uniform and the control of the slack action during application and release of the brakes was practically ideal. The speed restriction for freight trains on this grade is 12 miles per hour, but was not observed in common practice. The test trains were in several cases permitted to attain speeds more than double the maximum authorized before the brakes were applied, necessitating a heavy brake application to control them. The pressure developed in the brake cylinder was comparatively uniform except on the head end, where high brake cylinder pressure resulted from an overcharge of the brake pipe while the brake valve was in full release position. The release of the brakes even at as low speed as two miles per hour resulted in no bad effects from slack action, but was very uniform.

In the two cases when the train parted between Kelleysville and Rich Creek the brakes had been released on the forward portion of the train and the break-in-twos occurred between cars farther back in the train on which the brakes were still applied. In neither case was there any noticeable shock or slack action at either end of the train prior to the break-in-two. At the time of these break-in-twos all of the triple valves were operated in quick release and no retaining valves were used. None of the emergency operations on the 100-car train on the trip from Princeton to Roanoke, originating at different points in the train, caused excessive shock and no damage to train or equipment resulted, notwithstanding the low rate of speed in the first two instances. After turning the summit of the grade at Merrimac, all cars being in graduated release, an excessive brake pipe reduction was made; in attempting to release the brakes the brake valve was held in full release position long enough to fully release the brakes on the head end, but the train was stopped before release on the rear end was secured. This resulted in slack running out, and a comparatively severe shock on the rear end, but this shock was not severe enough to cause any damage. When the break-in-two occurred at Purdy the brakes had been released on the first half of the train only and the rise in brake pipe pressure had barely reached the first A. S. A. car when the train parted; this break-in-two was also clearly due to improper manipulation of the brake valve rather than to any arrangement or feature of the triple valve equipment.

The A. S. A. feed valve and the compensating valve included in the A. S. A. locomotive equipment operated as designed and intended. The tests demonstrated that it was not necessary to use any special locomotive brake equipment in order to secure proper action of the A. S. A. triple valve, but the maintaining and compensating functions of the A. S. A. triple valves can be more fully accomplished and utilized when the compensating valve on the locomotive is used. Some alteration in the detail arrangement of the compensating valve on the locomotive as used in these tests is necessary in order not to interfere with emergency operation following a service application. When the compensating valve is in service in case of the train parting or a break in train line the brake valve must be placed in emergency position to prevent depletion of the main reservoir pressure.

In the tests of the A. S. A. brake system particular attention was devoted to principles of design and the functions accomplished. Some improvements, particularly in regard to the feature of securing emergency operation following a service application, can be effected and the construction of the A. S. A. triple valve can be materially simplified. An application of the principle of automatic straight air brake valves to meet the conditions of passenger train breaking was not considered in connection with these tests, which were entirely with freight equipment.

Treated Lumber for Freight Cars*

Possibility of Prolonging the Life of the Wooden Parts of Car Construction; Methods of Treating Used

Over two billion feet of lumber and timber are used annually for the maintenance of railway freight equipment and for the construction of new cars. This represents an annual outlay for material alone of approximately $60,000,000. To this must be added, of course, an even greater expenditure for labor, steel and other material. With a view of ascertaining the service which untreated wood has given in this character of construction and with the desire also to learn to what extent it has given added service in specific cases through wood preservation, and to what extent economy would be developed by the general adoption of the practice of wood preservation, and further, as the subject is of very pertinent interest at this time, the committee felt it advisable to make this study a subject of special investigation, both through the medium of a questionnaire to all car builders and by means of personal study.

The preliminary investigation developed that there was very little information available on this subject. As it was felt that it was a matter of great importance, and that it should be gone into thoroughly and fully, a questionnaire was prepared and sent to the members of the Master Car Builders' Association.

The questionnaire covered the following information, which, it was felt by the committee and collaborators, was necessary to a thorough fundamental study of the subject:

For Car Construction—(a) Availability, cost and quality of lumber and timber. (b) Suitability and economy of wood. (c) Factors affecting the physical and mechanical fitness of wood. (d) Importance of the assistance it may be possible to render the nation and railroads by augmenting the car building program by the extensive use of wood.

Eighty-eight questionnaires were returned representing about 75 per cent of the most important railroad systems of the country. Of these, 61 were analyzed and the replies summarized in tables published in the appendix, 21 were discarded for lack of information, and six were too late to be included in this report.

Table 1—Summary of Replies to Question No. 1

Percentage of Maintenance Due to Decay Grouped According to Expressions of Respondents (Number of Replies Given)

Type of cars	75 per cent and over	50 to 75 per cent	25 to 50 per cent	Less than 25 per cent	Indicating considerable loss due to decay	Refuting influence of decay	No reply	Total Questionnaires tab.
Ref. ...	11	7	8	3	18	5	9	61
Stock ...	4	11	9	9	14	2	12	61
Gond. ...	2	9	12	12	13	3	10	61
Flat.	1	14	7	17	8	4	10	61
Box	0	7	7	25	9	3	10	61

Note—Approximately 77½ per cent of those replying indicate that decay is decidedly an important contributing factor.

RESULTS OF INVESTIGATION

Question 1. To what extent, in general, does decay influence maintenance of all-wood and composite freight cars? (i. e., general observations from practical experience desired.) (a) Refrigerator cars? (b) Stock cars? (c) Gondolas? (d) Flat cars? (e) Box cars?

Over 75 per cent of the replies indicate that decay influences the maintenance of wooden freight equipment to a considerable extent, and only 9 per cent have given it as their opinion that decay is not a contributing factor. The indications are that conditions favorable to decay vary with the type of car, it being most predominant in refrigerator and stock cars, less in gondola and flat cars, and least in box cars.

Table 2.—Summary of Replies to Question No. 2 (a)

a—Underframe—Parts repaired or replaced due to decay previous to the expiration of the mechanical life. Number of replies referring to each part are given.

Points of contact are chiefly referred to, i. e., mortises, tenons and enclosed areas

Type of cars	Sills in general	End sills	Side sills	Intermediate sills	Center sills	Floors or decking	Nailing strips, composition cars	Draft timbers or sills	Body bolsters	Hoppers	Cross ties
All types. ..	24	10	9	4	5	11	1	3	2	..	1
Refrigerator.	13	3	9	1	..	11	..	2	3	..	..
Stock	8	4	8	1	..	12	..	..	..	..	..
Gondola ...	9	4	4	3	1	10	..	..	..	1	..
Flat	9	2	3	2	..	9	1	..	..	..	..
Box	2	3	10	..	..	..	..	..	..	..	..

Note—Sixty questionnaires analyzed. Two gave no reply to Q. 2-A.

Question 2. What portions of these various types of cars are most affected by decay? (i. e., where is decay the direct cause for replacements and repairs, or indirectly the cause of mechanical failure due to the weakening of certain parts resulting from attack by decay? (a) Underframe (name parts)? (b) Superstructure (name parts)?

(a) Over 95 per cent of the replies specify sills and about 90 per cent state that floors or decking of refrigerator, stock and open cars are replaced because of decay. The predominating opinion is that the points of contact are chiefly affected and weakened to such an extent as to cause mechanical failure of the entire parts. (b) Posts and braces, roof boards and siding at the points of contact, appear to be most affected. Other parts mentioned which are subject to failure due to decay are: Running boards, saddles, side and end plates, ridge poles and purlines.

Question 3. What species of wood do you employ for the following parts of refrigerator, stock, flat, gondola and box cars? (a) Draft timbers? (b) End sills? (c) Side sills? (d) Intermediate sills? (e) Flooring? (f) Posts? (g) Siding? (h) Lining? (i) Ridge poles? (j) Purlines? (k) Carlines? (l) Side and end plates? (m) Roof deck?

The prevailing practice is to require oak for draft timbers, end sills, posts and braces. Douglas fir and Southern yellow pine are generally used for all other purposes. The pine predominates owing to the nearness of the plants to the source of supply. In new construction, steel is very largely used in center sills, and to some extent for side sills and for draft rigging.

*From a report presented at the convention of the American Wood Preservers' Association held in St. Louis on January 28 and 29.

Question 4. What service records have you which are available for the study of this subject? (a) Natural life of untreated car material (name parts).

Ninety-three per cent of the answers stated "No record." The remainder reported as follows: Sills, five to eight years; roofs, four to six years; flooring (stock cars), four to six years; posts and braces, six to eight years.

TABLE 3. SUMMARY OF REPLIES TO QUESTION 2 (b)

b—Superstructure—Parts repaired or replaced due to decay. Number of replies mentioning each part given.

	Posts and braces	Roofs, decks or roof boards	Ridge pole and roof nailers	Hatches and ice boxes	Running boards and saddles	Side-plates	Siding	Sheathing inside and end	Stakes	Purlines	Top plates
All types...	31	14	4	..	5	7	9	2	..	1	3
Refrigerator.	8	7	..	6	..	2	1	3	..	..	1
Gondola ...	..	..	..	..	..	..	5	..	2	..	..
Stock	9	4	..	..	..	2	1	..	..	..	..
Flat	..	..	..	..	..	..	..	..	..	..	..
Box	8	9	..	..	..	..	2	1	..	..	1

Note—Sixty questionnaires analyzed. Three gave no reply.

Question 5. Have you used treated timber in car construction? If so, state kind and character, species and treatment.

Eighty-five per cent answer "No." Fifteen per cent reply "Yes," representing 10 railroads which have used coal tar preservatives, creosote oil, paint and other proprietary products.

Question 6. What has been the experience with treated car material, if any? Please state this in detail, by reference to part and character of service.

Eighty-five per cent of the answers stated "No experience." The balance report varying experience referred to in later questions.

Question 6-A. Does the handling of creosoted material in the shops present any labor problems?

Replies from the few firms having experience indicate that labor objects to handling freshly creosoted timber. (The committee feels that this is not a serious objection as it can be overcome by proper practices.)

Question 7. What service records can you give of treated car material?

Ninety-five per cent of the replies give no information, but 5 per cent of the replies give the following records: Reply No. 48. Treated refrigerator car sills in service from three to seven years. Reply No. 30. Treated log car sills in service eight years. Reply No. 26. Treated stock car sills and flooring in service six years. All of the above treated material is still in good condition.

Question 8. If creosoted sills are employed for refrigerator, box, stock and gondola cars, can all stenciling be applied to the body of the car?

Fifty per cent of the replies state "Yes" and 15 per cent state "No." The remainder do not reply.

Question 9. If creosoted sills are employed for flat cars, would it be practical and economical to use metal numerals and signs to replace stenciling?

Over 60 per cent state it is practical. Opinion is evenly divided as to whether it is economical.

Question 10. If stock cars are built of creosoted lumber throughout, would it be practical and economical to use sign boards on both sides for all stenciling?

Over 95 per cent agree that it is both practical and economical.

Question 11. Would it be satisfactory practice to use creosoted sills, sub-flooring and roofing for refrigerator cars? If not, why?

Opinion appears to be evenly divided as to whether creosoted material may be expected to contaminate lading, but one firm with several years' experience states that such practice is satisfactory.

Question 12. What is the mechanical life of the various types of cars, as follows: (1) Wood? (2) Composite (steel underframe)? (3) Composite (steel center sills only)? (a) Box? (b) Refrigerator? (c) Stock? (d) Flat? (e) Gondola?

It is evident from the character of replies to this question that the respondents had in mind the mechanical life of the car as meaning the full period of its usefulness, from the time of construction to the time the car is "wrecked" or dismantled, as being unprofitable, disregarding the outlay of repairs expended on it or the extent to which reconstruction was necessary at any time. In this case the committee feels a more reasonable definition of "mechanical life" would be the period required in which the expenditure for repairs, with interest, equaled the original cost of the car.

Question 13. Would the use of creosoted timber in underframe and superstructure materially increase the period of mechanical usefulness of all types of cars, or any particular type?

Eighty per cent of replies say "Yes," and 20 per cent say "No."

Question 14. To what extent would the use of creosoted sills, flooring, posts, roofing, etc., reduce repairs?

Over 80 per cent of the replies indicate that treatment would reduce repairs. The percentage of saving varies from less than 25 per cent to more than 50 per cent.

Question 15. Have you had experience with the brush treatment of sills (mortises, tenons, end, etc.) with coal tar or creosote?

About 65 per cent report having experience with brush treatment. Ten different products were used.

Question 16. Have you had experience with treating car material by the open tank system (hot and cold treatment) or by dipping (short immersion) using creosote oil? (a) If so, what procedure was followed in the treatment and what preservative was used? (b) What were the results obtained, and what is your opinion of the value of such treatment?

Less than 10 per cent report experience. Only one employs the standard open tank process and states that "Such treatment very greatly increases the life of the materials treated."

TABLE 4—SUMMARY OF REPLIES TO QUESTION NO. 3

Number of references to various species for different parts given

Species of wood used by

Part	White oak	Red oak	Oak general	So. Y. pine	Fir Douglas	Maple	Norway pine	White pine	Hemlock	Fir noble	Hickory	Red gum	Spruce	Cotton wood	Tamarack	Cypress	Mal iron or steel	Total ref's to parts

*End plates usually specified oak. Side plates, pine or fir.

Question 17. Have you employed car lumber creosoted by standard pressure processes? (a) If so, what species? (b) What specifications for treatment and preservative were followed? (c) What have been the results, and what is your opinion of the value of such treatments? (d) Have you used by any other method of treating for the purpose of retarding decay? (If so, mention material used, with results.)

But one firm reports experience with pressure treatment, having used with satisfactory results, both straight creosote and the Card process.

Question 18. To what extent would your shop practice be affected by the introduction of treating processes, and what method of preservative treatment would be the most practical, efficiency thereof considered?

The majority feel that shop practice would be affected to a greater or less degree by the adoption of wood preservation, indicating that the introduction of preservative treatment would necessitate at least some changes.

MISCELLANEOUS DATA

Question 1. What experience have you had with the use of "new" species of wood in car building? (e. g., have you used Sitka spruce, noble fir, Western white fir, or other species which are not common?)

The replies showed the new species used for various parts of cars were as follows: Roofing—Western hemlock, redwood, cypress, Sitka spruce, noble fir. Siding—cypress, Sitka spruce, noble fir. End sills—gum. Lining—noble fir. Decking—noble fir. Sheathing—Port O cedar. Posts and braces—Sitka spruce.

Question 2. To what extent have you used hardwoods such as oak, maple or birch, for flooring in cars subject to excessive mechanical wear? (a) Do you consider the extra life of hardwood parts justifies the expense?

Oak and maple are generally used in ore cars and to some extent in flat and gondola cars. A few firms report use of birch, hickory and beech for such purposes, and a few use pine or fir in these types of equipment. (a) More than 70 per cent of replies indicate that extra cost of hardwood parts is justified by greater life.

Question 3. What is the average amount of car stock kept on hand at your shops or yards? (a) Is this stock stored in sheds? (b) What is the percentage of loss from warping, weathering and decay? (c) What difficulties do you have in getting car stock true to grade and properly seasoned? With what species have you had this trouble?

Reports indicate that smaller shops carry from 60 to 90 days' stock whereas those which consume over 40,000,000 ft. per year carry a 12 months' supply of soft woods and an even longer supply of hardwoods. The practice of carrying a year's supply in order that the wood may become properly seasoned before use is to be commended very highly. It is essential that wood be thoroughly seasoned where it is to be given preservative treatment. (a) Replies indicate that the general practice is to store dressed lumber, kiln-dried stock and high-grade hardwoods in sheds. (b) Three-quarters of 1 per cent on the average is the loss from warping, weathering and decay. (c) Replies indicate that in recent years increasing difficulty has been experienced in securing satisfactory grades of oak and other hardwoods.

Note—Where the reply stated a term of years, i. e., "from 6 to 8 years," an average of the two figures was used in summary, i. e., 7 years.

Question 4. What efforts are made toward salvage of old car lumber at repair shops?

A general effort is apparent throughout the industry to salvage all material that can be worked over at a profit. The following instances of use for salvaged lumber are given: Old siding and lining cut into roof repairs, grain doors, coal doors, yard and snow fences. Old car sills cut into sill splices, cross-ties, engine wood, shims, car stakes, narrow gage ties, cripple posts, running board saddles, blocking, framing posts. Old roofing cut into yard fencing.

Question 5. What is the comparative life of single sheathed and double sheathed box cars of similar weight and capacity?

Three firms report the double sheathed box car has up to 25 per cent longer life than single sheathed. Four firms report single sheathed up to 50 per cent longer life than double sheathed. Four report that the life of the two classes of car is practically identical. The remainder report no figures available.

TABLE 17—SUMMARY OF REPLIES TO QUESTION 15

Tabulation of replies, number who used some sort of brush treatment—what product and whether satisfactory

Brush treatment used 37 — No treatment used 21 — No statement 3

Number of replies	Products used	Satisfactory	Unsatisfactory
8	Creosote	8	0
2	Coal tar	2	0
1	Carbolineum	1	0
18	Paints	13	5
5	Wood tar preservatives	4	1
2	Proprietary asphalt waterproofing products	2	0
1	Carglue	1	0

The report was signed by H. S. Sacket (C., M. & St. P.), chairman; K. C. Barth (Barrett Manufacturing Company), chairman sub-committee on Car Construction; Lowry Smith (N. P.), F. V. Dunham (Southern Pine Association), W. W. Lawson (T. & N. O.), V. R. Hawthorne, acting secretary Master Car Builders' Association, and S. W. Allen, United States Forest Products Laboratory.

DISCUSSION

J. H. Waterman, superintendent of timber construction, Chicago, Burlington & Quincy, reported that large quantities of timber had been treated and used in the construction of stock cars during the period from 1911 to 1914, inclusive. Recent investigation at all car repair yards on the system indicated that there was no record of any of these cars having been repaired to date, because of the decay of the treated timber. This treated timber was used for floorings and sills; the average life of untreated timber for these purposes is three or four years.

L. K. Sillcox, master car builder, Chicago, Milwaukee & St. Paul, at Milwaukee, urged the treatment of car roofing timbers and the material in stock cars.

J. H. Milton, superintendent of the car department, Rock Island Lines, favored the treating of longitudinal sills, posts and decking for gondola and stock cars, but opposed the creosoting of timber for box and refrigerator cars, because of danger of injury to the lading.

Car Inspection and Maintenance*

Unification Demands Capable Supervision and Inspection and the Backing of Operating Officers

BY J. J. TATUM
General Supervisor of Car Repairs, United States Railroad Administration

IT has generally been found by railroad managements that the inspection and maintenance of car equipment is not uniform and they have frequently urged unification of inspection and repairs, deeming it to be an important factor of safety, good performance and economical operation.

Unification of inspection and repairs to equipment was found by the United States Railroad Administration to be such an important requirement of good railroad performance that it soon began to lay plans and make instructions effective that would unify inspection and repairs, as well as to standardize equipment.

For this reason Circular No. 7 was issued, June 8, 1918, by C. R. Gray, former director of the division of operation, to insure that inspection and repairs would be properly made to car equipment. Mechanical Department Circular No. 7 was issued October 17, covering repairs to refrigerator cars for the purpose of standardizing the repairs to refrigerator cars to such extent that they would be suitable for the service they are intended to perform. Mechanical Department Circular No. 8 was issued November 1, 1918, for the purpose of standardizing materials for freight car repairs in order that repairs could be made promptly and uniformly.

Knowing that certain things must be done and issuing instructions to do them does not always mean they will be done, or that the instructions issued will be complied with. Something more is required. The men in charge should be capable not only of issuing instructions but capable of knowing when instructions are being complied with. They should also be capable of issuing workable instructions and selecting men who are capable of complying with their instructions.

If this statement is true then we should have thorough, capable and efficient men at the head of car departments, who know when a car is properly inspected and how to inspect it. They should know when a car is properly repaired and how to repair it. If they are capable of doing this, they should then be capable of selecting the right men to see that this work is properly performed. They should know that the foremen they have placed in charge of their repair shops are not only capable of repairing cars and knowing that they are properly repaired but that they are also capable of seeing that the men doing the work do it properly.

When selecting a man as foreman car inspector or leading inspector, it should be known that the man selected is not only capable of inspecting a car and knowing when it is properly inspected, but that he is capable of selecting men as inspectors who are able to inspect cars properly.

After these requirements are met, we may look with confidence for unified inspection and maintenance of equipment, but not until then.

Even after this is done there will still continue to be improper inspection and maintenance of equipment and a variance from the unification requirements if those in charge of these men do not respect their action. I mean by this statement that inspectors should be given all trains to inspect and they should be permitted to hold them a sufficient length of time to give each car the needed inspection and repairs, or to shop the defective car out for repairs. After a car inspector has shopped a car for defects which make it unsafe to be continued in service, no one should be permitted to cause such car to be placed back in service until the repairs for which the car was shopped have been made properly, or improper repairs corrected. One giving or assuming such authority, will by his act, become an enemy to safety and a promoter of disaster that may result in loss of life or limb and destruction of property.

It should be considered just as serious and dangerous for one to remove a shop card from a defective car and permit it to go into service without necessary repairs being made, or permit a car to go into service with a shop card on it without the repairs being made, as it would be for one to change a red signal to white before an approaching train, without knowing whether or not the block into which the train is to move is safe and clear. In my opinion, one act is just as serious and just as liable to cause disaster as the other.

Therefore, Mr. Railroad Manager, it is with you to see to it that your car inspectors are given your trains to inspect, with the time to make needed inspection and repairs. If this is not done you should be responsible for the failure of such cars and not the head of the car department or his inspector. It also lies with you to see that the car inspector's action, when shopping a car out for repairs, is given your full support, to the extent that, should anyone remove a shop card from a defective car and permit it to go into service before necessary repairs are made, or place a car in service with a shop card on it, such person should be relieved from the service for the good and safety of all concerned. If this is not done, then the motto we have established—"Safety First"—is only a mockery and you are deceiving yourself as well as the public, in your efforts to promote such a doctrine.

The protection of millions of passengers using the railroads of our country, as well as railroad employees, and the protection of billions of dollars' worth of railroad property and billions of dollars of freight hauled in cars operating over our railroads depends upon the thorough and careful inspection made to our cars. There also depends upon their careful inspection and the repairs to equipment the protection of foodstuffs needed to feed hundreds of millions of people. With this great responsibility upon the inspectors, their value cannot be discounted.

To bring about these desired conditions it is necessary that we first select for the heads of our car departments men who have been thoroughly trained and well experienced. They should see to it that inspectors selected are capable of making safe and proper inspection of car equipment. This can only be established by requiring inspectors to pass an examination that will insure that after once passing the examination they are capable of performing the work assigned to them.

They should also see that inspectors are given all trains to inspect and permitted to hold them until inspection is made. Cars once inspected and passed as being fit for service should be in such condition that, when inspected again at next inspection point, they will not be shopped out for defects that existed at the time of the previous inspection; neither should they fail while in movement due to such defects. In other words, should an inspector pass a car as being safe and fit for loading at St. Louis that car should be in condition to continue through to New York or any destination without being shopped out or breaking down in movement, due to

*Abstract of a paper read before the Central Railway Club at Buffalo, N. Y., March 14, 1919.

defects existing when the car was inspected at St. Louis. When a car repaired on shop tracks at Chicago is moved to New York for loading it should not be necessary to shop it for defects that existed when it was placed on the shop tracks, or for improper repairs made at Chicago, on or before its arrival at New York. No car should be placed for loading until first inspected and given needed repairs.

Unless we are able to obtain these desirable conditions our inspection or our repairs are not uniform, or our supervisors are not capable and efficient, or someone is removing shop cards or causing cars to leave inspection points or repair yards before they are in proper condition for service.

Unless such practices are corrected (if they exist) we cannot expect to establish the unified requirements which would result in safe and economical operation. Unified inspection and repairs will mean to our railroads less loss of life and limb of passengers and trainmen, greater car mileage, fewer accidents, less destruction of equipment and property, less repeated shopping of cars, greater car supply, less need for purchase of new equipment, decrease in cost of operation, less maintenance cost, prompt handling of business, greater satisfaction to shippers, better earnings for railroads and a more satisfactory dividend for the stockholders.

DISCUSSION

In presenting his paper Mr. Tatum referred to the fact that of the more than two and a half million freight cars in the country about 125,000 cars are being held for repairs and more than 100,000 cars are being repaired per day. There are on 80 railroads, or about 57.6 per cent of the railroads reporting to the Railroad Administration, less than four per cent bad order cars. On February 15 there were 141,000 men employed in car repairs on 139 Class I railroads, which were holding an average of slightly over five per cent of their cars in bad order.

F. W. Brazier, superintendent rolling stock, New York Central, questioned the significance of the figures given by Mr. Tatum as to the number of cars actually in bad order condition, owing to the fact that instead of giving cars thorough repairs too many of them had only received sufficient repairs to get them temporarily back into service. He endorsed the requirements for unification outlined by Mr. Tatum, stating that the instructions are clear enough, but that little attention is paid to some of them; when business is rushing there is a great demand for equipment and only such repairs are made as will keep the cars running, instead of giving them the thorough repairs they need, when they are empty and on the repair track. M. C. B. Circular 4-A, now in effect, was quoted to show that it is not so much instructions that are needed as some way of securing their full observance. This circular alone, if carried out, would greatly improve the condition of equipment not now suitable to meet modern service conditions. In this connection Mr. Brazier stated that the New York Central on August 1, 1918, had 7,000 cars yet to be equipped with safety appliances. Since that time only eight cars have been reported as being equipped with the safety appliances on foreign lines, as compared with 370 foreign cars which have had the appliances brought up to standard on the New York Central Lines. The need of adequate force behind instructions, if they are to be carried out, was further emphasized by Mr. Brazier, who cited the case of the safety appliance standards now adopted and enforced by the Interstate Commerce Commission. The Master Car Builders' recommendations for the ladder location were complied with by about 85 per cent of the railroads, but the other 15 per cent of the roads persisted in applying their ladders in exactly the opposite location. The Interstate Commerce Commission did not formulate new standards, but it required the force behind the Safety Appliance Acts to bring about 100 per cent compliance with the standards formulated by the association.

The need of the highest type of supervision in the car department was emphasized, its importance being indicated by the fact that in 1917 the New York Central spent $8,000,000 in the maintenance of locomotives, whereas the car department's expenditures totaled $17,000,000. But labor conditions have been such during the past year that it has been difficult to keep men in the service long enough to develop good inspectors.

Commenting on Mr. Tatum's remarks as to the need of holding trains for thorough inspection, Mr. Brazier advocated that no car be placed for loading until it has passed a thorough inspection. Such inspection should apply particularly to the running gear, brake rigging and draft gear, which must be in first-class condition on all cars, while some other parts of the car need not necessarily be in perfect condition to receive certain classes of lading.

Mr. Brazier called attention to the air brake situation, which is one of the most serious conditions affecting the proper operation of freight cars. He suggested as a subject for investigation how many railroads have proper yard facilities for testing the brake equipment and making necessary repairs to it. Referring to this matter, Mr. Tatum mentioned an instance in which a railroad was endeavoring to economize in the purchase of material by reclaiming old cylinder gaskets, no new ones being purchased. An inspection was made of some of the brakes thus overhauled after the work had been completed and the brakes stenciled ready to return to service; the fact was disclosed that the brakes leaked off so fast that it was impossible for the inspector to read the gage quick enough to say whether they had applied or not. A question as to the proper life of air hose in its relation to brake conditions was raised by H. C. Woodbridge, regional supervisor of the Fuel Conservation Section of the Railroad Administration, who stated that it costs as much to stop a train as to renew an air hose. This was cited as an indication of the false economy of attempting to retain air hose in service beyond the period during which they may reasonably be expected to remain tight. It was suggested that if road foremen and enginemen would report excessive train line leakage these reports might serve as a means of keeping the car department advised as to tendencies in the condition of air brake equipment. L. D. Gillette, inspector of the Canadian Dominion Railway Commission, also referred to the question of porous hose as being a source of great danger to the safe movement of traffic,—the proper place to locate the porous hose being in the yard and not on the road. In reply, Mr. Tatum stated that he considered the safe life of an air hose to be about one year, and referred to the fact that the Master Car Builders' Association is now considering the formulation of rules covering the question of air brake maintenance.

R. S. Miller, master car builder of the New York, Chicago & St. Louis, raised the question as to what constitutes a serviceable car. Various interpretations of this expression are being adhered to in different localities, which causes difficulty under present conditions in the free movement of equipment. If a uniform interpretation were available it would materially assist in securing unified inspection. Mr. Miller also advocated the universal use of the Master Car Builders' rules for the examination of car inspectors rather than the individual sets of such rules instituted by various car department heads. In answer to the question as to what constitutes a serviceable car, Mr. Tatum stated that he considered a car serviceable when it was in condition to carry the class of freight for which it was built, but that this did not preclude the use of box cars not in serviceable condition for first-class merchandise to carry rough freight.

W. H. Sitterly, general car inspector, Pennsylvania Railroad, emphasized the air brake situation, stating that the brakes contribute very largely to bad car conditions. The one difficulty is that time enough is not given to the car inspector to do his work properly, and it is also necessary that adequate time be given to making the needed repairs disclosed by the inspection. Cars should not be delivered in interchange with a clean bill of health merely to get rid of them. Facilities should be available for repairing the cars. There should be only about one and a half times the day's work ahead of the car repair forces and to keep within this figure adequate facilities and enough men must be provided. Great assistance in securing proper compliance with rules relating to car repairs in interchange has been rendered by the Railroad Administration in holding the individual responsible for failure to make needed repairs or for making improper repairs, instead of the matter being, as it formerly was, a subject for adjustment between the railroad companies involved. Mr. Sitterly referred to an analysis of 787 box cars which had been made at Buffalo to ascertain their suitability to be coopered for grain. Of these cars only 55 per cent were found fit to carry grain. He stated that this situation could be improved by using cars which were not suitable to be coopered for grain for loading such commodities as fertilizer, hides, oil, etc., which leave the car in a condition unsuitable for grain service.

In referring to Mr. Brazier's discussion Mr. Tatum called attention to Circular No. 20, which specified that when a car is repaired it should be put in service to give two years' service, barring accidents. In this connection he emphasized the need for more facilities. Operating officers and managers often complain about the condition of the equipment, but they seldom offer to furnish shop facilities adequate to carry out the amount of work which must be done to keep the cars from returning frequently to the repair tracks. It is not conducive to an ideal condition of rolling stock when a shop becomes somewhat congested with bad order cars to relieve the congestion by taking off the bad order cars without performing the work required.

T. J. O'Donnell, chief joint inspector, Niagara Frontier Car Inspection Association, referring to Mr. Tatum's statement that it should not be necessary to shop a car for defects that existed prior to the time of the last shopping, said that the Buffalo gateway had at least 1,000 loaded cars every morning, loaded from 24 to 48 hours earlier, which it was necessary to condemn, as high as 150 pairs of wheels having to be changed in one day. It is the endeavor at Buffalo to get cars through the terminal in three hours, but to do this the equipment must be in first-class condition.

A. R. Ayers, superintendent motive power, New York, Chicago & St. Louis, advocated the adoption of a regular periodical program of general overhauling of cars similar to that followed in the maintenance of locomotives. He also considered it best to allow the owning roads to handle the heavy repairs and betterments to their own equipment, as they are in a position to live up to the requirements of Circular No. 8. Furthermore, they are in a position to lay out the program for betterments to a whole class of their own equipment and then carry it out on a quantity basis rather than one car at a time. Mr. Ayers emphasized the need of carrying out such betterments by referring to a study which had indicated that steel cars or cars with steel frames came on the repair track on account of the draft gear less than once a year, whereas wood underframe cars appear on the repair track for the same class of repairs about two and a half times a year. In other words, it is a physical impossibility to repair a wood underframe car so that it will run two years, on account of draft timbers.

A question was raised if the Railroad Administration had any program in view for returning cars to the owner for such work. The difficulty of carrying out this work was indicated by the situation on the Delaware, Lackawanna & Western, which had less than six per cent of its own cars on its line, where formerly the average was 60 to 65 per cent. In answer to this Mr. Tatum called attention to the fact that cars can now be sent home at the owner's discretion when the cost of making repairs exceeds $200 and that cars on connecting lines can be sent to the home road for repairs. It is the policy of the Administration, however, that repairs be made wherever the cars are located when such repairs can be made in kind.

P. J. O'Dea, chief car inspector of the Erie Railroad, inquired as to what conditions had actually been found throughout the country and what might be expected in the future in the carrying out of betterment programs for equipment not now fully able to meet modern service conditions. In replying, Mr. Tatum called attention to the fact that the war had taxed the equipment as well as the other railroad facilities far beyond what has been considered its normal capacity. At the present time preparations are being made to carry out reinforcement programs on thousands of cars. It is, however, unreasonable to expect immediate results, as little of this work can actually be carried out within less than a year. Under present conditions it takes from three to six months to get together the material, such as center sills, bolsters, truck side frames, steel ends, etc., for a single lot of 1,000 cars. At the present time some 20 roads are preparing to reinforce about 20,000 to 25,000 cars, which will eventually result in an improvement in conditions.

INTERCHANGE OF FREIGHT EQUIPMENT*

BY J. C. O'DONNELL

The great volume of tonnage traveling through the country places upon us the responsibility as common carriers to handle that tonnage with despatch and due care. From the equipment point of view our first duty is to be absolutely certain that our mechanical inspection and upkeep are on a basis that will insure such service. This paper has been divided to cover points that are matters of daily observation with interchange inspectors, with the intention of creating discussion in order that we may take from it ideas that we feel will improve every day conditions.

THE HANDLING OF EMPTY FREIGHT EQUIPMENT

A car before it enters into interchange must first of all become a suitable vehicle for the load it is to carry, and upon this, barring unexpected conditions, depends its subsequent movement. To meet the requirements cars should be on the following basis:

A. Cars for grain or flour loading must be perfect as to roofing, flooring, sides and ends, clean and free from odors.

B. For merchandise, or similar loading, not susceptible to immediate damage, the roof in general must be free from leaks, but ordinarily not so close as an "A" car, and the body is acceptable for such loading if in fair condition.

C. For coarse freight loading, such as lime, ingots, spelter, pulpwood, and commodities not susceptible to damage by weather, the body should be in fair condition.

D. Open-top equipment in the ore loading districts and in season must have a special inspection to see that all sides and slope sheets are fit to withstand such commodity and that hoppers and attachments are in first-class condition and entirely free from defects. All other equipment of the hopper or gondola type for general utility loading may be inspected on the ordinary interchange basis with the conditions more or less perfect, but not with the special inspection required for ore loading.

The foregoing conditions from a mechanical standpoint will furnish the transportation department the equipment so that with little or no trouble it can be utilized for any purpose intended or desired. But let us not forget that the equipment must be carefully repaired after it has been thoroughly inspected for light truck repairs and work that seems to be overlooked as a general rule. I have in mind our vol-

*From a paper presented before the Car Foremen's Association of Chicago.

ume of empty refrigerator cars that should be specially handled before the load is placed in the car. This work should include not only the upkeep of air brakes, but also the arch bars, wheels, bolsters, draft rigging and all carrying parts of the car. To bring about such results there should be a systematic method of handling the empty equipment, preferably by the owners, when the owners are the loaders, or in immediate touch by the trunk lines, so that no car when the load is placed in it will necessitate repair track movement under ordinary conditions until reaching its final destination with the load in question. To illustrate the point I am trying to bring out for the benefit of interchange, for the month of December, 1918, in the Niagara Frontier district, the records indicate that our inspectors were obliged to condemn loaded cars to the repair track to the extent of having 1,200 pairs of wheels changed on eastbound interchange, and 20 per cent of this number were on high class freight carrying fresh meat, stock, poultry and similar commodities. This is one item alone out of our daily work that demonstrates the absolute necessity of doing all the necessary work on the crippled car before the load is placed in it for movement, and this must be done to get the service through on our high class special loading that invariably makes express time service.

NECESSARY ACTION ON LOADED EQUIPMENT BEFORE LEAVING THE INITIAL POINT OF LOADING

There must of necessity be close co-operation between the car department employees and the employees who are placing the loads in the car, both at freight houses, industrial plants and all other similar loading points, to see that the Master Car Builders' rules are strictly observed, both on open and closed cars, to protect the lading enroute from shifting and otherwise, and also on double and triple loads, to see that they are carefully built up to insure safe movement in line with the Master Car Builders' loading rules. These rules as in effect are revised from year to year and are perfect to cover the interchange throughout the country if strictly adhered to and carried out. The non-carrying out of these rules causes damage to lading, accidents enroute and serious delay, which could all have been avoided had proper care and supervision originally carried out the intent and purpose of the Master Car Builders' Association. I would especially call attention to the necessity of providing proper doorway protection and blocking on the closed car to overcome damage to the lading and injury at the doorway enroute.

The greatest responsibility of the mechanical department for protecting the lading is, first of all, to have a perfect car to put the lading in, and, secondly, to see when the lading is placed in the car by the consignor, that it reaches its destination and the consignee in the condition that it should, thereby overcoming, unnecessary expenditures to bring it back to its original condition.

INTERCHANGE INSPECTION FOR PROTECTION OF EQUIPMENT THROUGHOUT THE COUNTRY

Granting that we have complied with all of the previous requirements, the car is accepted for train service to its destination, and should proceed without serious difficulty. Primarily interchange inspection was intended for the purpose of a monetary protection on defects occurring through what we term unfair service that did not impair the strength or serviceability of the car, together with penalty provisions for not observing the requirements of selection as mentioned above. With the suspension of such service and the adoption of government control methods, there would naturally seem to be little use for interchange inspection, but when taken collectively the zones of our railroad centers are so distributed that when the equipment reaches these intermediate terminals it has covered, approximately, from 150 to 300 miles, and the service demands an examination of the running gear, a re-examination and repair of all air brakes and care and attention to lubrication and packing, which in the Niagara Frontier district, as a rule, is handled in about five minutes to a car.

The inspectors on the string as it reaches the receiving yard are two ground men, one roof man and two following-up men, and where the interchange demands it, the same number starting from each end of the string, except the roof man. At this time we inspect and condemn all handling line defects under government requirements, repair all yard defects, such as nuts on box bolts, carry irons, column bolts, draft pan attachments, also brake connection bolts and cotters, brake shoes and keys, brake hangers and parts, and all connections of the hand brake attachments. In many cases we apply brake beams in the train yard, in order to overcome switching any car to the shop track unless absolutely necessary. The finish of the string is then taken for switching and advanced to the receiving line yard as a rule, where the air brake test, repair and oiling is covered. The disposition of through business under such arrangements is based on the interchange of 8,000 loads and 3,000 empties every twenty-four hours, with an average of one car out of ten as a cripple to the repair track. This shows why we plead for better equipment at the initial point of loading, to overcome serious delays that must be faced enroute if such action is not taken, and which is kept constantly before us by our transportation department.

At this time I wish particularly to dwell upon the enormous losses through accidents that have occurred in our immediate district, where the old saying, "a stitch in time," is applicable. In going over some claims with the claim department of one of our trunk lines I was astonished to learn that during the year 1918 that particular line paid out, in the claim department, $5,619,000 to cover loss from accident, leakages, theft, improper stowing of lading and kindred causes. If each man takes pride in his position and is zealous to do his work without any sting of conscience, let us apply this principle to our trains enroute and not be charged with negligence that causes untold misery and loss of large amounts of money. In other words, if responsibility is ours, let us shoulder it and share it. This can only be done by every individual doing his full share both in the pit and in a supervising capacity.

I would strongly recommend that in order to have co-operation and a common bond of personal responsibility, frequent get-together meetings be held, bringing up points of self-interest for all concerned, which would bring about most excellent results.

We should not have any matters connected with the service that those associated with us are not thoroughly conversant with. The important duties the employees of our rolling stock departments are obliged to perform, should be an incentive for each and every one of us to give the very best that is in us to the railroads of our great country.

DISCUSSION

The discussion brought out many circumstances which hamper the repairing of freight cars at the present time. Mention was made of unsatisfactory labor conditions still existing and insufficient forces due to the reductions in the hours of service. Failure to authorize expenditures for betterments has resulted in the setting aside of cars requiring heavy repairs. The speakers agreed that there is much trouble due to the reloading of cars which are not fit for service but no method has been found by which this abuse can be controlled on industry tracks.

Some improvement has recently been noted in the condition of air brakes, but the tendency to neglect cars needing heavy repairs is causing a steady decline in the general condition of the equipment and cars are now accepted in general service that would have been carded bad order at the first interchange point under the standards in force a few years ago.

ENGINEHOUSE CRANES

BY E. A. M.

The following three types of cranes for use in enginehouses are in general use on one large road and have been found very serviceable and convenient.

POST CRANE

Fig. 1 shows a 2,000-lb. capacity post crane for roundhouses, which is generally located on the first post inside of outer wall of the house and is located on every post in that circle. In some cases possibly only a few located in some certain part of the house may be necessary, while in others it may seem most desirable on every other one. That is to be determined by local conditions and is, of course, optional with the user. The idea is to show a very good crane that has resulted in being a time saver for such work as lifting bumper castings, wooden bumper beams, front ends and doors, cylinder heads, steam chest lids, etc. By moving the smaller type engines forward in the house as much as possible, it is possible to lift air pumps by swinging the crane well back.

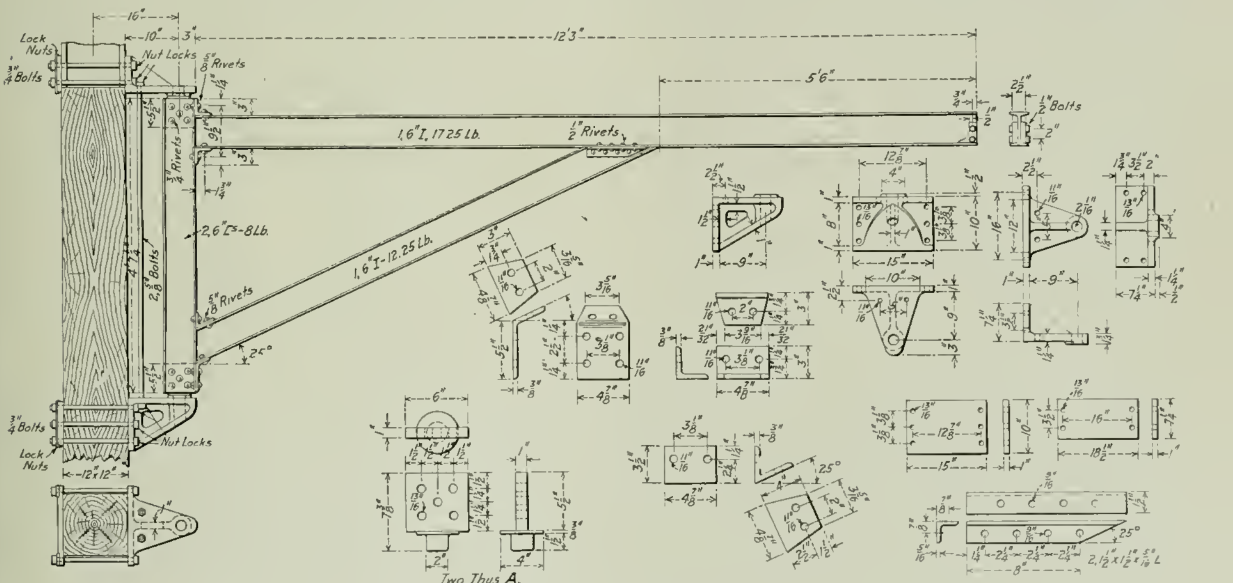

Fig. 1—Post Crane for Enginehouses

This is equipped with a 2-ton differential chain hoist on a trolley which has a movement of nearly 5 ft. The top I-beam is 6 in., weighing 17¼ lb. per foot and is 12 ft. 3 in. long; at the end there is a small casting on each side to prevent the trolley from running off. The brace is a 6-in. I-beam weighing 12¼ lb. per foot and the vertical pieces to which these are fastened by angle plates (riveted) are two 6-in. channels weighing 8 lb. per foot and 4 ft. 7¼ in. long. The castings (A) are placed between these upright channels at each end and have a circular base two inches in diameter, which extend into castings above and below, turning in them. These castings are bolted on the post with ¾-in. bolts, with plates on other side and nut locks are provided. Two ⅝-in. vertical bolts with lock nuts keep these castings a proper distance apart, or rather from spreading. Angles are used to secure the brace to the horizontal jib. The swinging axis is 10 in. in front of the post to give it greater range, in fact it has a range of about 284 deg.

In one of our roundhouses having 40 stalls, we have 39 of these, one on each post between the stalls, and nearly all are so provided, as a matter of fact all that are of any importance.

CRANE FOR LIFTING AIR PUMPS

A portable crane for lifting air pumps on or off engines is shown in Fig. 2. At times, when a locomotive comes into the roundhouse requiring repairs to the air compressor which require its being removed from the locomotive, this portable crane will be found very useful, and not only make a hard job easy but do the work with but a slight delay to the locomotive. The uprights are made of 2½-in. round iron pointed at the bottom for safety sake. These are amply braced by the ¼-in. by 1-in. pieces as shown. About 11 ft. 9 in. above the floor a weld is shown and the upper ends or pieces are welded to the 2½-in. uprights. These upper pieces are spaced ⅝ in. apart by the plate and washer, leaving a 5/8-in. space in center for the projecting or supporting arm which is shown as detail *A*. The piece *B* is bolted to this. The ends of this piece are about one foot apart and these rest on the handrail of the engine for support. You will note that there is plenty of space for lifting the pump as the connecting piece is 3 ft. 4 1/4 in. center to center. A suitable hoist is, of course, attached to the eye *C*, which has a trolley wheel. While this apparatus must be rather heavy in order to adequately support an air compressor, it can be easily handled by three or four men. The

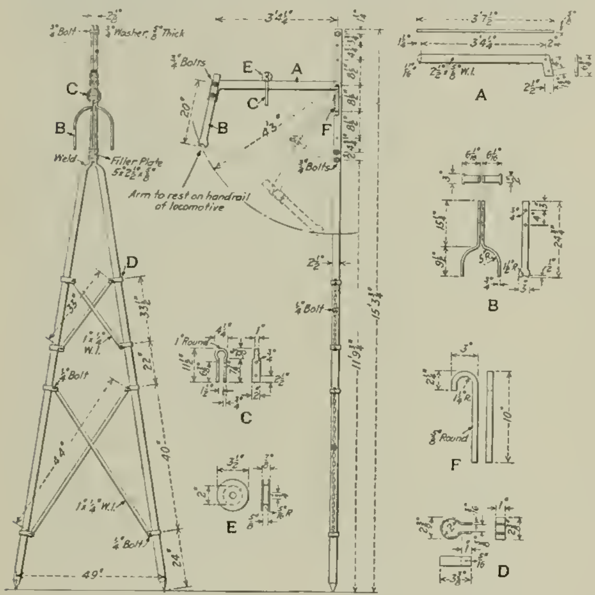

Fig. 2—Portable Crane for Mounting Air Compressors

swinging or supporting arm can be swung down to some extent, out of the road when not in use, as shown by the dotted lines.

STACK CRANE

Fig. 3 shows a locomotive stack crane which has been found very serviceable where other overhead or permanently

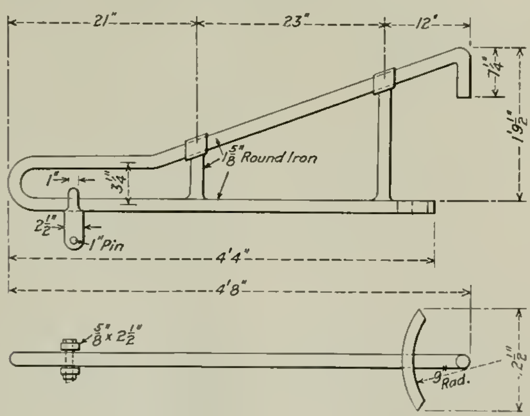

Fig. 3—Stack Crane for Locomotives

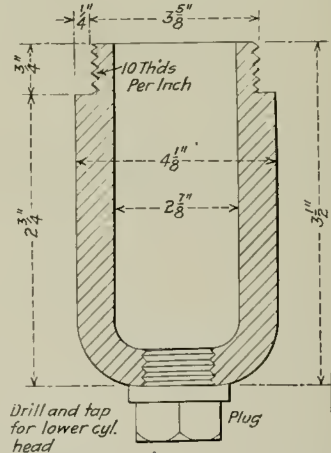
fixed cranes are not available. It is made up from 1 5/8-in. bar stock, as indicated in the illustration, the upper arm of which is bent over at the end to fit over the top of the stack. The horizontal arm has a curved rest, bent to a 9-in. radius, which fits against the side of the stack. The upper and lower arms are reinforced by two ties, also made from 1 5/8-in. iron, extended between them. The outer end of the frame supports an eye which carries a suitable chain hoist. This is free to move on the frame for a short distance, in order to get the proper location of the hoist. This is an excellent device for lifting heavy cylinder heads, steam chest lids, sections of cast iron bumper castings, wood bumpers, front ends, etc. Where other facilities are not provided it has been found very serviceable and will serve to materially shorten the length of time engines are kept in the roundhouse for repairs.

RECLAIMING LOWER HEAD OF CROSS-COMPOUND AIR COMPRESSORS

BY J. H. HAHN
Assistant Roundhouse Foreman, N. & W., Bluefield, W. Va.

One of the most common defects which develop in the 8 1/2-in. cross-compound air compressors is a broken piston rod. When the high pressure air piston rod breaks or the nuts work off the lower end, the result is generally that the pocket in the lower piston head in which the end of the rod works, is broken out. Ordinarily this starts the cylinder head on the road to the scrap pile.

The fitting shown in the drawing was designed for use in reclaiming cylinder heads broken in this manner and a large number of them have been applied with excellent results at Bluefield. The broken heads are placed in a large



Forged Fitting Used to Repair Broken Lower Cylinder Heads of Cross Compound Air Pumps

gap lathe and bored out and threaded to receive the fitting, which is forged from a piece of wrought iron and threaded as shown in the drawing. A large Stillson wrench is used to put the fitting in place, and it is set up reasonably tight. Heads thus reclaimed have been found to be as good as new ones.

Complete Locomotives Shipped to France.—The United States Army Transport Force has announced as one accomplishment under stress of war conditions the shipment to France of more than 400 American-built locomotives, weighing 73 tons each, completely assembled except for smokestack and tender and able to move under their own steam within a few hours after landing in France. The engines were shipped in special ships, each carrying 36 locomotives. About 1,200 other locomotives were shipped in sections easily assembled on the other side.

The Gas Welding of Thin Plates

Special Types of Joints Which May be Used, Some of Which Do Not Require Use of Welding Rods

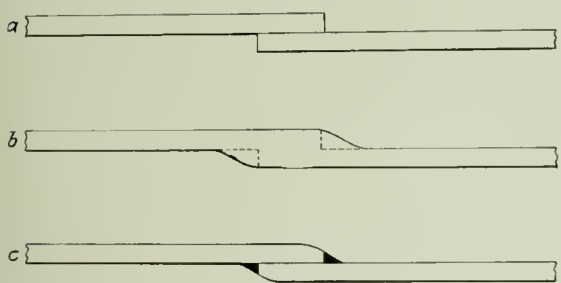
BY J. F. SPRINGER*

I.

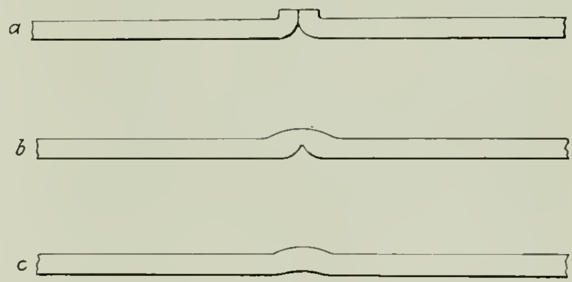
THE welding of plates not exceeding ¼ in. in thickness is an art in itself. Beveling, which is ordinarily so essential, is not always necessary or advantageous when welding thin plates, and with very thin sheets the highest temperatures are not desirable. But a shop using acetylene for general purposes may also find it advantageous to use the same equipment for thin work. The difficulty of uniting thin plates with an excessively hot flame lies largely in securing the necessary degree of rapidity and uniformity in the application of the heat. If the "hot spot" of the acetylene flame is advanced too slowly the edges of the work are apt to be melted away in places; if it is advanced too rapidly a good weld is not obtained. The operator must find the correct speed, taking into account the work in hand and the power of the torch. With thin work the necessary rate of advance will often be quite rapid, and it must be kept steadily at just the right rate. Furthermore, as the "hot spot" is not large, it becomes necessary that the torch be held at just the proper distance from the work.

It may seem that soldering and brazing would be preferable to gas welding as a means of joining thin sheets, and this is sometimes the case. However, soft solders are usually weak solders, and hard solders which possess high strength are not always convenient to use. An objection which applies to all solders is that they differ in character from the metal of the work, which means that the electro-potentials differ, and that under certain conditions electrolysis is to be expected. Thus, in the case of the thin steel sheets used in passenger car roofs electrolysis is to be feared if the joints are sealed with a metal differing from that of the work. With gas welding, it is usual practice to use the same or nearly the same metal for the joint as is to be found in the sheets to be joined.

The heat for soldering operations, especially where hard soldering is to be done, is not always conveniently applied. Thus, the case of the roof sheets for passenger coaches might present difficulty. This welding is done not for strength of joint, but for water-tightness. The edges of the sheets come together on the double flange of a T-bar and are riveted in place. Then the welding operation is carried out to seal the joint. The workman gets up on the roof and applies his torch. To do this job by brazing would probably be difficult, if not impossible. There are, in fact, so many cases where the oxy-acetylene and the oxy-hydrogen welding appliances may be taken to the job, that this alone gives the process a considerable advantage over brazing.



Plain Lap Joint



Modified Edison Joint

VARIETIES OF JOINTS

During the last 10 or 15 years, as gas welding has come more and more into commercial use, a variety of forms of joints suitable for thin plates have been developed. There are others which, although they have had no great test in actual practice, are worthy of consideration because of their conformity to requirements of the gas welding process. Some joints are good for one kind of service, but useless for another. Sometimes one joint is to be preferred to another not so much because it is a better joint, but because comparatively unskilled labor may be used in making it. Again, one style is preferable for certain jobs because it may be made accessible to the operator. In short, there are a variety of conditions surrounding individual jobs, all of which must be considered in the final choice of the type of joint to be used. But in all autogenous welding there is one rule which is quite generally applicable: Seek to locate joints away from corners. The object in removing the weld from a corner is to avoid the bending stresses to which corners are often subjected, but there may be exceptions even to this rule. In the case, for instance, of a tank with a bottom heavily dished inward, if the angle where the rim of the plate and the body of the cylindrical shell meet is sufficiently sharp, a weld where the edges come together may not be subject to appreciable bending stresses and such a joint may be permissible.

Plain Butt Joint.—The simplest joint is probably the one where the edges of the plates butt one against the other. The weld is made by melting the edges into each other and sometimes by the addition of new material. If the edges make a joint that is even and free from small cavities before heat is applied, there will be little use for a welding rod, unless it is proposed to pile up metal along the joint on one or both sides. However, where cavities exist, which will include the majority of cases, there will be more or less of a depression all along the line of the joint unless a welding rod is used to supply the extra metal needed. It may be added at the time the edges are melted together or put in place in a second operation.

The plain butt joint may be welded from both sides. This

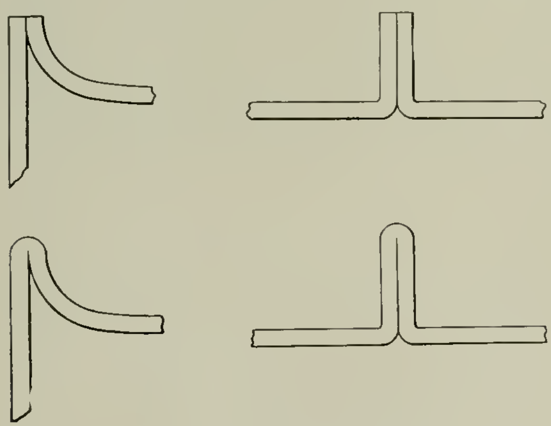
*Author of the handbook, "Oxy-Acetylene Torch Practice."

is often desirable and in some cases necessary. In welding from one side only it is necessary that the fusing temperature penetrate all the way through the full thickness of the plates to secure a perfect weld. Other things being equal, the difficulty of securing heat penetration will vary with the plate thickness.

It is possible to get welds without appreciable depressions, even though no rod is employed, by finishing the edges to make a close junction. The undesirability of a depression along the line of the weld depends on the service the work is to perform.

Beveled Lap Joint.—The edges of the two plates may be beveled and overlapped preparatory to the application of heat. The torch is to be operated preferably from both sides and the metal may be thickened by the use of a rod. If depressions are to be avoided when no rod is employed, the edges should fit closely to eliminate voids. If building up of the seam on both sides is carried out along the lines of the joint the two ridges of metal will not be directly opposite each other.

Beveled Edge Butt Joint.—In this joint the edges are brought up close together or even to contact. The rod is melted in to fill up the groove, and the groove is at the same time heated to the melting point. This particular joint is handled according to regulation methods used for general work, and the plates may be double beveled. The metal from the rod may be piled on one or both sides of the work. The groove, however, need not be as wide as in ordinary work.

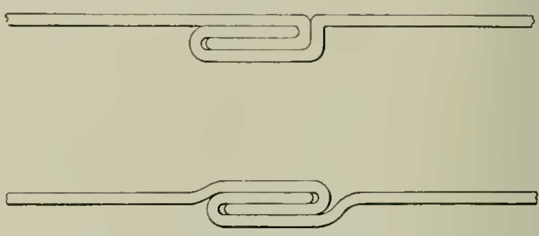


The Edison Joint

Plain Lap Joint, Without Rod.—With thin sheets one may simply be lapped over the other and heat applied to produce a molten condition over the entire area of contact. The question of thickness controls only to the extent that the torch may be limited in getting its heat through far enough. When working with metals which respond to old-time smith shop welding methods, light blows of the hammer may be employed to encourage union over the area of contact. Steel and nickel are such metals. The plain overlap may be especially useful where the two sheets are not of the same thickness.

There are cases where it is not necessary to secure the strength obtainable by melting the contacting surfaces into each other. In such cases the free corners of the overlapping plates may be welded on each side of the work. Where this style of weld is satisfactory from the standpoint of strength it may be carried out through a considerable range of thicknesses. In the diagram showing this modified plain lap joint, the darkened regions show metal that has been melted off the free corners and filled in the adjacent angles. Where rivets are depended on for strength and welding for the seal, this is a useful type. As no rod is required, the workman has his left hand free.

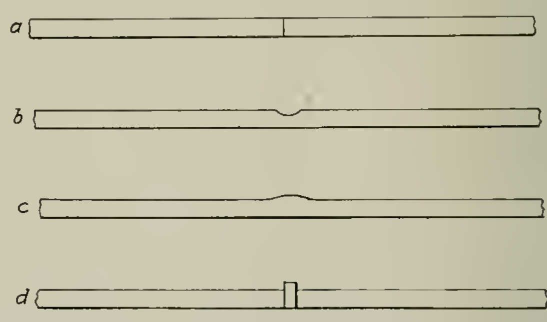
The Edison Joint.—In this type of joint the weld is made by melting together the edges of two plates lying alongside of each other. This joint secured its name from the fact that it was first used by the Edison Storage Battery Company in making storage battery cells. The metal in this case was thin nickel-plated steel, and the cell consisted of a rectangular shell with a single longitudinal seam and two heads of cup form let into the ends of the shell with their edges out.



Two Types of Folded Joints before Welding

The longitudinal seam was located on one side away from the corner.

This joint possesses a number of excellent features. It is easily prepared and easily welded, and as it requires no welding rod it permits the operator to have his left hand free. Considerable variation in the application of the heat is permissible, since there is a considerable margin in the amount of metal that may be brought into the weld. The effect of variations in the rate at which the torch is advanced and in the distance of the torch from the work will be evident only in irregularities in the profile of the finished joint which may be entirely satisfactory otherwise. The Edison joint is a good seam if the conditions of service do not produce stresses tending to open the joint on the unwelded side.



Plain Butt Joint, Showing the Effect of Welding Without or With Rod, and the Improved Butt Joint

Where such stresses are likely to occur the joint in its simplest form is not a suitable one.

Modifications of the Edison Joint.—Manifestly, it is not necessary that the bent-up portion of this joint be especially deep. In fact, the deeper it is the greater is the leverage tending to open the angle and break the weld. The bends may be reduced to a very slight depth, sufficient merely to supply metal easily reached by the torch. After the weld is completed it will, in such cases, show a protuberance on the operating side of the work and a groove or depression on the under side. The form of this depression depends on the sharpness of the bends and on the penetration of effective fusing heat. A groove in the shape of a narrow and deep indentation may for certain classes of service be objectionable as defining a line of breakage. The groove may be modified by applying a welding heat on this side of the work and totally eliminated by using a welding rod. Where the welding rod is not used, the form of the joint may be further modified by the use of the hammer. This provides a method of securing the full thickness of metal at the joint without using a welding rod.

The Improved Butt Joint.—Welding without rod is advantageous in working on thin plates, because it releases the operator's left hand to assist in steadying the torch, and because the new metal may be otherwise provided in a manner insuring a uniform amount all along the seam. This latter point is at times important where uniformity of appearance is desirable. Thus, with the Edison joint, where the bent-up portions are shallow, they provide the new material in a way to meet this requirement. The same result may be secured by another method which may be easier to carry out under some conditions. The edges of the sheets are left square as if for a plain butt joint. But instead of putting them in contact with each other, a thin strip of metal is set between them. This strip is wide enough to extend slightly above the surface of the sheets. When the weld is made the strip is melted into the edges of the sheets and the whole region consolidated. The amount of new metal added depends upon the extent to which the inserted strip projects above the surface of the sheets.

A modification of this type of joint requires the strip to be set so as to project on both sides of the joint. There are then two heating operations.

The Folded Joint.—Where the plates are very thin and it is not difficult to provide for the penetration of a fusing heat through several thicknesses of the metal, a folded joint may be used. There are two principal forms. In one both sides of the work disclose an increase in thickness; in the other this shows on one side only, the other side remaining flush with the general surface. The illustrations show clearly the manner of folding for each of the forms. It should be noted that where the former type is permissible, both sheets are folded alike, thus simplifying the preparatory work. This style of weld requires a considerable degree of skill. First, the thinness of the sheets requires prompt and uniform action on the part of the welder. Second, enough heat has to be supplied to secure intermingling. The skill required may be reduced somewhat by applying the heat in two operations, first from one side and then from the other, and by using the hammer to assist the union. In any case, however, it is not a job for a beginner.

(*To be concluded.*)

RECLAIMING BUSHINGS FOR 9 1-2-IN. AIR PUMP REVERSING VALVES

BY J. H. HAHN
Assistant Roundhouse Foreman, N. & W. Bluefield, W. Va.

A set of tools has been developed at the Bluefield shops of the Norfolk & Western, by which it is possible to reclaim successfully the reversing valve bushings for Westinghouse 9½-in. air pumps.

By referring to the drawings, which show the details of the various tools, the method of using them may very readily be explained. It is first necessary to remove the dowel in the reversing valve bush. After this has been done the arbor *A*, Fig. 1, is then placed in position in the bushing. The washer *B* and nut *C* are then placed on the end of the arbor and the nut securely tightened. Next the reamer *D* is placed on the arbor, followed by bushing *E*. This bushing has two lugs on each end, which fit in the slots in the end of the reamer. The split driving nut *F* is then placed in position, on the threads of the arbor, inside of sleeve *G*. The wrench *H* is placed over the sleeve, the projection on the side of the latter fitting in the slot in the wrench, which is finally secured in place with a ⅜-in. set screw.

With this device the bushing is then reamed out to fit the next larger size of reversing valve, which, as shown on the drawing, Fig. 1, is 1 13/32 in. After this reamer has been driven to the bottom of the bush a 1 7/16-in. reamer is placed on the arbor and driven down about 1/16 in. below the first port in the reversing valve chamber bushing. This gives the valve the proper clearance and prevents it from wearing a shoulder in the bushing, as is usually the case.

After the bushing has been reamed the dowel is replaced from the inside, using the tapered wedge shown in Fig. 2, or the special dowel replacing tool shown in Fig. 3.

The latter tool has a cylindrical body 1⅜ in. in diameter, which is made in two parts dovetailed together. Extending through the body longitudinally is a tapered hole in rectangular cross section, in the bottom of which is drilled a hole

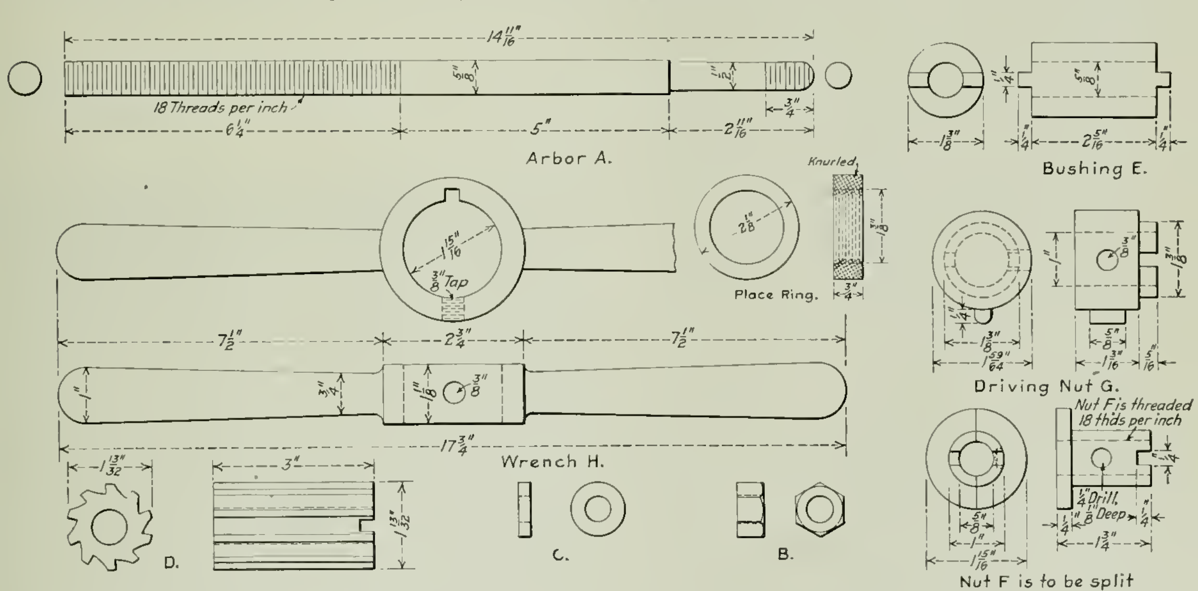


Fig. 1—Details of Special Tools for Reaming Out 9½-Inch Pump Reverse Valve Bushings

to fit the 5/16-in. dowel. A plunger of the same size is placed in this hole from the inside and a tapered wedge driven between the plunger and the tapered side of the hole in the body of the tool. With the device in place inside the bushing it is thus possible to drive the dowel into place. The

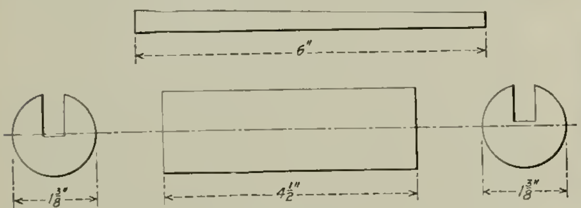

Fig. 2.—Simple Wedge for Replacing Dowel Pins in the Reamed Bushings

slot in the body of the tool permits it to be slid into place over the end of the dowel.

Special reamers of the shell type are used, which may be ordered from manufacturers or made in the shop. Aside from the reamers the tools shown in the drawing were all

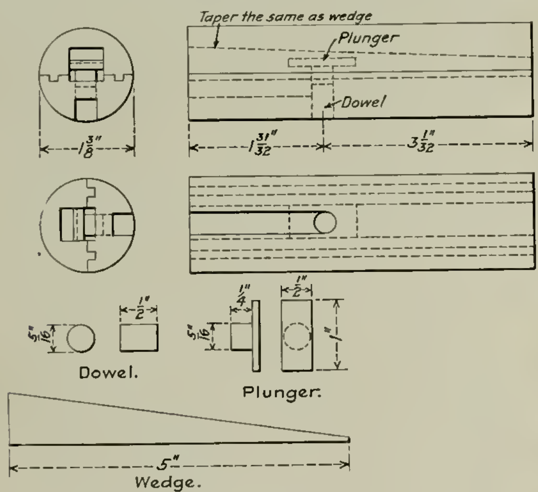

Fig. 3—Another Type of Dowel Pin Replacing Tool

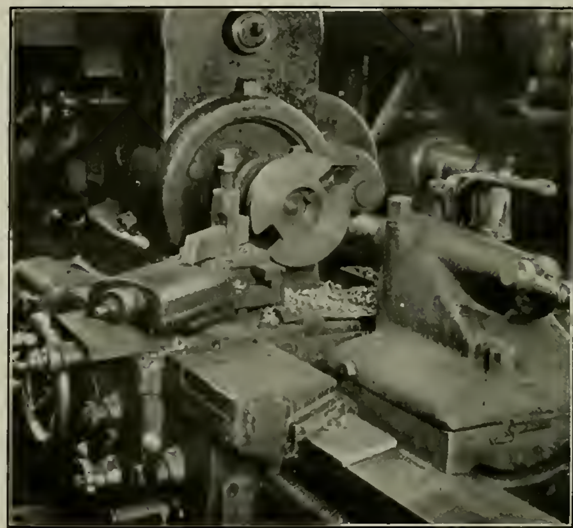
made by apprentice machinists from scrap material. A discarded piston rod from an 8½-in. cross-compound pump furnished a good grade of steel for this work.

INCREASING PRODUCTION ON BOLT LATHES

In the illustrations shown below are shown two devices applied to a portable lathe in the Beech Grove shops of the Chicago, Cleveland, Cincinnati & St. Louis which will save time on any lathe used for turning bolts. The chuck shown is simple but nevertheless very effective. It screws on to the spindle and projects beyond the center with a recess to receive the head of the bolt. Extending into this recess is a set screw which can be tightened to grip the head of the bolt. In practice the screw is run up so that it just clears the flat on the head when the bolt is on the center. The bolt can then be inserted but cannot turn in the chuck. The flange of the chuck extends beyond the head of the set screw in order to keep it from the possibility of catching the clothing of the operator.

The indicator shown in the illustration of the tail stock is a great convenience for setting the center where one standard taper is used. The arm is L-shaped and is pivoted at the angle on a stud in the top of the tail stock. The short vertical arm bears against a stud in the base, the point of contact being at a point that causes the pointer to move about 18 times as much as the tail stock. This lathe is used



A Safe and Convenient Chuck for Bolts

only for cutting the standard bolt taper of 1/16 in. to the foot. The indicator is adjusted to show when the lathe is turning straight; then it is set to give the proper taper for a bolt 12 in. long, and these points are marked on the brass

Indicator on Tail Stocks for Setting to Turn Standard Taper

plate at the end of the indicator. The distance between the marks is then graduated to show the setting for bolts of any intermediate length. This attachment saves a great deal of time in setting the lathe and it has been found to be very much more convenient to use than the standard taper attachment.

How Joe Harris Saved His Job

It Was "Up to Him;" He Learned That Courage Is an Essential Quality of the Successful Foreman

BY A. J. TEN CATE

It was Monday morning and although the 6:45 whistle had not yet sounded at McGregor shops, there was a gathering of unusual numbers around the shop bulletin board.

As each new-comer arrived he was instantly attracted by the crowd rapidly assuming large proportions in the center of the shop and naturally gravitated in that direction to ascertain the cause of the excitement. Sometime since Saturday afternoon a bulletin had been tacked on the board which read as follows:

TO ALL SHOP AND ROUND HOUSE EMPLOYEES

Mr. Joseph B. Harris is hereby appointed General Foreman at this point with jurisdiction over shops and round house.

Signed: H. L. BROWNLEE,
Master Mechanic.

Not that bulletins announcing the appointment of a new general foreman were of such rare occurrence as to cause wonder or even interest. The men in McGregor shops had long passed that stage. More general foremen had been appointed there during the past three years than at all other points on the road combined, and the new bulletin was the third notice of a similar nature in eighteen months. As each man who had held the job severed his connection with McGregor—invariably by request—the only comment heard around the shop was, "Who is the next victim?" and when that worthy put in an appearance it never caused even a ripple of excitement.

This morning, however, the usual order of things was reversed and an air of expectancy prevailed. Many and varied were the comments that came from the swelling crowd around the bulletin board. There were hoots and howls, cat calls, groans and much laughter. "Wait till old Hank sees it," said some one. "Hank'll explain what'll happen to him." This brought a yell of delight from the throng.

"Here's Hank now," shouted a man on the edge of the crowd, and all eyes were turned toward a tall, sinewy man possibly 55 years of age who, as he walked toward the crowd, wore an air of aggressiveness which indicated a determined and rather belligerent character.

Hank Hazard had been the rod shop foreman at McGregor for many years. A first-class mechanic and possessing marked executive ability, it was said of him by those who knew him best that had he been less aggressive in temperament he might easily have been a master mechanic many years ago. But Hank, while a good friend and with many traits of character that made for him a host of friends among the shop men, had the unfortunate habit of treating his superiors in a manner that always gained their dislike. Hank instinctively hated a new boss, and usually made it a point to let it be known. Yet he could be loyal, and when his support was once gained, as in the case of Mr. Brownlee, the master mechanic, who had been able to gain Hank's respect at the start, there was no task too big for him and his gang to undertake. It was claimed by many that when Mr. Brownlee was appointed master mechanic he owed his promotion from general foreman to Hank Hazard more than to his own efforts.

Hank wielded a powerful influence in the shop, and new general foremen usually tried to "get something on him" in order to fire him rather than to turn his influence to their own advantage. Perhaps it was natural that his regard for officials in general, and general foremen in particular, grew less and less as time went on, and his attitude toward a new foreman was always awaited with eagerness by the men.

So it was on this morning, and everybody expected some especially vitriolic remarks owing to the fact that the appointee was the last man any one in McGregor had expected to see in the position.

As Hank arrived the crowd made way for him so that he could read the bulletin. "What's up?" he asked, curtly, as he set down his dinner pail and adjusted a pair of steel-rimmed spectacles preparatory to reading the notice. A strange hush now pervaded the place where but a moment before so much excitement reigned. The crowd waited expectantly for an outburst.

"What's that?" said Hank, as he read the name, "Mr. Joseph B. Harris. Where did *he* blow in from?"

Not a man answered. They had expected Hank to catch on immediately, but apparently he had utterly failed to grasp the significance of the bulletin.

At last someone ventured, "Don't you know him, Hank?"

Realizing that somehow he had missed the import of the notice, which the boys seemed to understand, he read it again, this time more deliberately. Suddenly the truth flashed upon him and he turned abruptly to the men, with a flush on his face.

"Do you fellows mean to tell me that Mr. Joseph B. Harris is Joe Harris—our Joe?"

"Sure, Hank, that's who it is, all right."

"Well, if it is," said Hank, "it means another dead cock in the pit," and, picking up his pail, he started for the rod shop amid a roar of laughter as the 7 o'clock whistle blew and the men dispersed to begin work.

Old Ned Hanlon, the chief clerk, was busily engaged in sorting the night's accumulation of messages in the general foreman's office. As he finished his task he handed them over to a tall, broad-shouldered young man who was waiting for them. "There you are, Joe—I mean Mr. Harris," said Ned, half apologetically, as he handed over the last message.

Ned's attempt at being respectful was not lost on the new general foreman, who understood perfectly what was passing in his mind. Instinctively he knew what was passing in the minds of everybody in McGregor shops that morning, and as he turned to leave the office he felt his courage rapidly vanishing, and he began to wish he had refused the promotion Mr. Brownlee had persuaded him to take.

The ordeal was a hard one for Joe Harris. Born and brought up in McGregor, he was known by every kid in town as just a big, good-hearted, overgrown boy, bubbling over with good nature, always ready to help anybody, and everybody's good fellow. Not an enemy in the world, for who could dislike such a personality?

And Joe was a mechanic. There was no doubt of his ability in that line. When it came to understanding the locomotive and shop work, he outranked them all. He had served his time in McGregor shops, and long before he had completed his full apprenticeship he was regarded as a genius from a mechanical standpoint. His capacity for knowledge was extraordinary, and he easily led his classes in every department.

No sooner was he out of his time than he was placed in charge of the valve gang in the roundhouse, and his fame as a valve setter soon spread on the three divisions centering in McGregor. His unusual mechanical ability, together with his good nature, quickly made him the most popular man in the terminal. His knowledge of the work in every other department was remarkable, while he knew more about what was in the storehouse and the different classes of material than the division storekeeper himself.

But Joe was no man to handle men. Everybody's good fellow makes a poor boss, and he was no exception to the rule. There wasn't a day he didn't do twice the work of any of his men. Young, strong as an ox, he seldom asked a man to do what he could do himself and, as is usual in such cases, many imposed on his good nature.

However, it was not long before Joe was placed in charge of the valve work in the back shop, and he was holding this job when he was appointed general foreman. When he was first offered the place Joe promptly refused it. To take charge of McGregor shops, full of old men, many of whom he had served under, looked too big for him. Then, too, he knew to be successful as a general foreman at that point meant a man capable of using the iron hand frequently, for discipline was a thing long unknown in McGregor.

Time was, Joe remembered it, when every man took pride in his work. Gang vied with gang in good-natured rivalry in swelling the output. Those were the days when 25 to 30 engines per month was a normal output.

But those days were gone. The loyalty for which the shop was noted was a matter of history, now almost forgotten. Many general foremen had come and gone during those years. Some had "finished quick," as old Hank Hazard put it when speaking on the subject, which was always a bitter one for him. Most of them were unfitted for such a position, and the men were never long in finding it out. It all had a demoralizing effect on the personnel. Discipline, interest in the work and loyalty, the three great shop essentials, disappeared. Output dwindled and costs soared. Mr. Brownlee, long noted for his organizing ability, came in for much censure from the management, and the superintendent of motive power came to McGregor frequently because of the poor showing at that point.

Naturally, McGregor shops had long since gained an unenviable reputation. Things went from bad to worse and finally came to a climax when in desperation the superintendent of motive power sent a new man to McGregor as general foreman, who started in by firing some of the best men in the shop. This gained for him the enmity of every man in the organization, a feeling which was increased as it became known that his experience was limited to a year or two on special work after serving a special apprenticeship on another road. He had never even had charge of a shop gang prior to his advent at McGregor as general foreman, and had secured the position through the influence of a friend of the superintendent of motive power.

At the time this man came on the job the road was doing a very heavy business. Power was required as fast as it came in, and any slowing up in engine despatching promptly blocked McGregor yard. At such times co-operation must exist throughout all departments, and the lack of it soon developed a crisis at McGregor so acute that the general manager went there to investigate.

The new general foreman, unmoved by the fact that things were tied up, and not knowing the general manager was on his way to the shop, was sitting in his office smoking a cigarette and reading a newspaper. As the general manager entered the door the young man presented a picture of indolent ease. Not dreaming the identity of the general manager he simply bestowed a "well, what do you want" sort of stare on that official, who sized him up as a clerk and asked, "Where is the master mechanic?"

"I have no idea," replied the general foreman, as he flicked the ash from his cigarette.

"Well, you look it," said the exasperated official, and he turned to go out just as Ned Hanlon entered the door. Ned was recognized by the general manager, who asked him where the master mechanic or general foreman could be found.

"Why, this gentleman is the general foreman," Ned replied, pointing to that worthy.

The general manager immediately turned to him and said: "If you have been running the power here I don't wonder we are tied up. I think we can dispense with your services."

When this occurred it was generally understood that Mr. Brownlee had been given one more chance to straighten out McGregor, and it was at this time that he sent for Joe Harris.

At first Joe refused to consider the offer, but Mr. Brownlee was insistent. He told Joe what his refusal meant to him personally, for it was up to him to put a man in charge whom he could trust, and Joe was about the only man fitted for the position who answered that requirement. It meant a big future for Joe, too, if he made good, and there was no reason why he could not do so. He reminded Joe of his mother and family, who relied on him for support, and this helped to persuade Joe to accept, for his expenses had always been so great that he had been unable to save anything.

As Joe walked into the shop this Monday morning he recalled all this and keenly regretted his decision. He suddenly saw the colossal nature of the task before him. Scarcely a man was at work; his appearance was a signal for what few who were busy to stop their work and exchange views with each other. That the place was demoralized he had known for a long time, but somehow he had never thought it was as bad as he now saw it to be.

Some of the men that first day showed a desire to respect him, at least in his presence. Some were openly defiant, while others ignored him altogether. Joe Harris as a workman was all right, but as a general foreman—why, he was nothing but a joke. The idea of taking orders from him was, to most of the rank and file, ridiculous. Many of the old men resented his appointment, and did not take the pains to conceal their feelings. And so Joe started in with his former friends and associates for the most part arrayed against him.

As was usual with him Joe did not spare himself, and was soon a slave to the job. Mr. Brownlee frequently warned him of his mistakes in this line, but in spite of all the advice given him Joe plodded on. He knew instinctively he was losing headway, that things were getting worse every day. He had never dismissed a man, nor had he censured a foreman. In his good-natured, whole-hearted way he had reasoned that his former friends would rally around him when they found that he was just the same old Joe. But he erred sadly in this respect, as many men have done before him.

Mr. Brownlee finally lost patience with him and often criticised him bitterly.

It was the 20th of the month, and the prospects for shop output were dark. Engines on the road were constantly falling down, and so many men had to be sent to the roundhouse to keep power repaired temporarily, that output was lost sight of entirely in the shop. Never had so much overtime been paid, and conditions generally were the worst in the history of the shop.

About 3 o'clock Mr. Brownlee sent for Joe after a long-distance 'phone conversation with the superintendent of motive power. As Joe entered the office that afternoon Mr. Brownlee arose from his desk and said to him: "Mr. Harris, I have called you here to tell you that my resignation is expected the first of the month if things don't improve. It is safe to say they won't improve, and you are the cause of it all. You could hardly have done more to hurt me if you had tried. Mr. Harris, you are a coward."

Joe stood speechless before his accuser. The words burned into his soul.

"A coward," went on Mr. Brownlee, "is a man afraid to do his duty, and that is exactly what you have failed to do, because you were afraid of your men. Instead of making men respect you, and the position you hold, you have simply done the work, what little there has been done, and your men have stood around and had a good time. The best equipped man for the job on the system, you have proved to be the worst selection that has ever been made."

Joe knew he was hearing the truth; he realized he had failed, and for the first time he understood what it meant to the man who had tried to be his friend. As he rapidly called to mind the attitude of his men, their indifference, their utter disregard of instructions and their disloyalty, his blood boiled within him.

Suddenly turning to Mr. Brownlee, a new light shining in his eyes, he said huskily, "Is it too late? I want just one week more."

Mr. Brownlee noted with surprise his changed appearance. "All right," he said, "I'll give you one week more."

As Joe turned to leave the office he paused at the door, and then suddenly faced his chief. "Sir," he said, "one week is enough. If I don't get a move on things before that time, I, too, am ready to leave," and with this remark he left the office.

As he passed out to the shop he met one of his erecting foremen who asked Joe to accompany him to an engine in the roundhouse where he had some men making repairs which were giving them some trouble. Joe scarcely heard what the man said to him so deeply absorbed in thought was he, until he arrived at the engine. He then became aware of the presence of some men under the engine, whose conversation brought him to himself with a jolt.

"Well, Jack," said a voice, "we've been here now an hour and h'aint done anything but smoke cigarettes. Now they are all gone I am going home," were the first words Joe caught.

Laying his hand firmly on the arm of the foreman, who was about to call out to the men, Joe enjoined silence.

"All right," answered the second voice, "I'm with you, old-timer; gets tiresome hanging around in a pit waiting for the whistle. Some dump," went on the voice, "and always will be until they get a general who is one."

"Why, say, Jack," said the first speaker, "our gang h'aint done a day's work this month, and overtime! why, even I am ashamed to take the money, and you know I ain't no saint."

Joe fairly quivered. "Call them out," he said to the astonished foreman, who had never seen Joe Harris look like that before.

As the men crawled out from under the engine Joe recognized one of them as a man he had befriended only a short time before.

"A fair return you have made to me," he said, "but at least you have given me the opportunity I am looking for. Mr. Leslie," he said, turning to the foreman, "you heard what they said; you probably know it is true. You will not only dispense with their services, but you will see to it that their service record shows 'dismissed' and not 'resigned,' as has been done in the past; for they're fired." With this remark Joe started for his office.

A few moments later old Ned Hanlon, with an air of suppressed excitement, went through the shop and personally notified every foreman in McGregor to attend an important staff meeting at 5 o'clock that afternoon. No excuse would be accepted, Ned whispered he had been instructed to say, for failure on the part of any foreman to attend. The dismissal of the two men, quickly followed by a hurry-up call for a staff meeting, caused a sensation in the shop. The fact that Joe Harris had fired anybody, in itself was enough to start speculation.

"Something doing," was the unanimous verdict, and everybody was on edge.

Promptly at 5 o'clock the foremen filed into the large staff room over the office, where Joe, with cheeks flushed, was sitting at a table looking over some papers, while at his left was a stenographer from the master mechanic's office.

As he called the meeting to order, Joe noted that every foreman was present. "Gentlemen," he said, "I want you to listen to some letters." The stenographer then read some letters from the superintendent of motive power, two of which cited figures to show that McGregor shop was in worse condition than ever before. Joe waited impatiently, it seemed to the men, until the last letter was read, which concluded with "the conditions now obtaining at McGregor shops are a disgrace to this department and must not continue. Please advise at once what you purpose doing to effect improvement." Apparently this was what Joe had been waiting for.

"Gentlemen," he said as the letter was concluded, "I have advised Mr. Brownlee to answer that letter by saying that an immediate improvement may be looked for, and it is my intention to make good that promise. In the two months I have held this position I have tried to work with you all, hoping and believing that I might succeed in getting your co-operation. I reasoned that I had a right to expect it, but you failed to see it in that light. My attempts at bringing about an improvement have not only failed, but, as the records show, we have steadily grown worse, and at the present time we are far below the percentage we were making when I took the job. Every order I have issued has been a signal for even greater violations of the particular condition the order was designed to remedy. Overtime has doubled, although I have repeatedly called your attention to the necessity of reducing it. Repairs are made in a superficial manner, and men are allowed to do as they please. I have regarded you all as personal friends; you have treated me as an enemy. My predecessor was cordially hated by you all, and no effort was made to co-operate with him, yet his record is far ahead of mine. The last month he was here there were 15 general repairs turned out of the shop; if we get 13 this month it will be a surprise to me. Such, gentlemen, are the conditions which I have agreed to remedy."

As Joe faced his foremen there was an air of calm defiance about him no man had ever seen before. Joe Harris, the good-natured boy, had somehow disappeared. Joseph Harris, the man, a real general foreman who knew the game, stood before them.

"Gentlemen," he went on, "from this hour the slogan is 'Get Busy.' Each of you will have a copy of some instructions, on your arrival tomorrow morning, that mean business. I shall see that they are carried out. Engine failures and overtime will be reduced and output increased from now on. In conclusion, if there is a foreman present who does not want to start tomorrow morning with a firm and honest desire to work with that end in view and carry out instructions, I hereby ask him or them to resign here, tonight. Tomorrow will be too late."

Every eye in the room was fastened on Joe as he waited a moment before proceeding. "Very well," he said, "before we close, has anyone anything to say?"

Instantly Hank Hazard was on his feet. "Mr. Harris," he said, looking at Joe with an expression on his face no one ever remembered seeing before, "I want to take this opportunity to say that I for one am heartily ashamed of my record during your term of office, and I am likewise ashamed of the record of the shop and every man in it. We all needed just what you have handed to us, and I don't believe there is a man here who won't give you his hand and promise results from now on, and just to put it to the test I am going to take the lead," and Hank walked up to Joe and extended his hand. Every man in the room fell into line behind him, and each gave Joe a hand clasp that was genuine.

An air of unusual bustle and activity prevailed in the shop long before the whistle blew at 7 o'clock the following morning. Most of the foremen had congregated early in the rod shop where Hank was busily engaged figuring out some calculations on the back of a blue print. "It's got to be done, boys," said Hank when they separated as the whistle stopped blowing, "don't fail."

As Joe Harris passed through the shop next morning he was quick to note a great change that had already been made. Every man was at work, every foreman on the job. That afternoon he met Mr. Brownlee, who simply held out his hand and said, "At last, Joe, at last; I knew it was in you."

Never was the slogan, "Get Busy," so faithfully carried out. Partly finished engines lying in the shop and not included in the schedule for that month began to take definite shape and were added to the schedule. In the roundhouse when engines were held for boiler wash, the rods, motion work and wedges were thoroughly gone over, and engine failures soon began to decline. Overtime in all departments was cut in half the first week. When the last of the month arrived there had been 16 engines turned out of the shop with a general overhauling, but Hank Hazard kicked because it wasn't 18, the number he had figured on.

Joe held frequent staff meetings, and every foreman was asked for ideas. These meetings brought immediate and profitable results. Every man in the shop took a personal interest in production. From the worst managed and most expensive shop, McGregor was soon looked upon as the best handled point on the system. From 15 engines a month, the output grew to 20 general repairs turned out regularly. Engine failures had practically been eliminated. How it was all brought about was a mystery to the management.

One day the superintendent of motive power came to McGregor and, after a talk with Mr. Brownlee, sent for Joe.

"Mr. Harris," said he, "there is a vacancy for a master mechanic on the Eastern division, and I want you for the place. Your record here the past three months, which, I will say, is unparalleled in my experience, justifies me in offering you the position. Bad as you are needed here it is only simple justice to recognize what you have done. My only concern now is, who will be your successor. Can you suggest a man?"

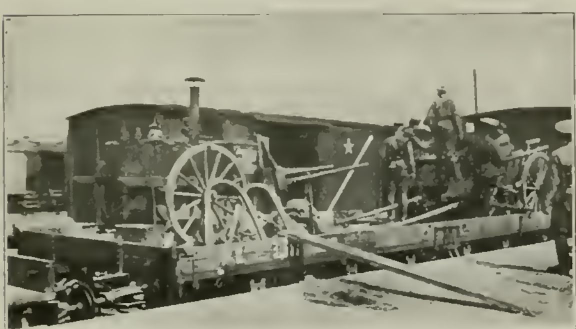
"I can," replied Joe, looking the superintendent of motive power squarely in the eye, "and a man who will continue getting the same results, if not better, than we are now getting."

"Does he work here, Mr. Harris? If he does, by all means, Mr. Brownlee," turning to the master mechanic, "let us give him the place. Do I know him?" he asked, again turning to Joe.

"Yes, sir," was the reply; "you have known him many years."

"Why, who can he be?"

"His name is Henry Hazard," said Joe.



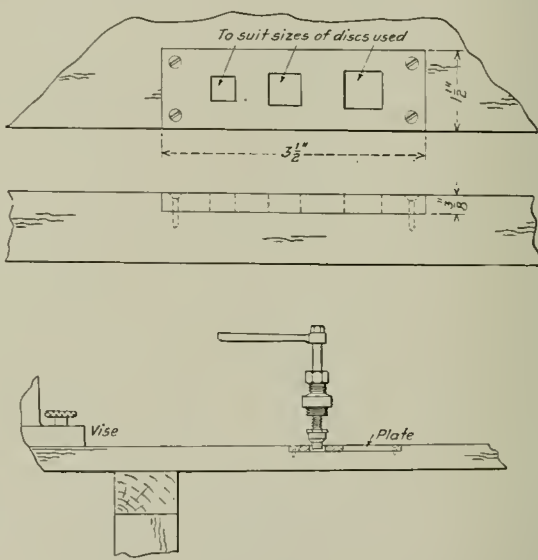
Railroading in Siberia

A CONVENIENT FITTING FOR THE INJECTOR REPAIR BENCH

BY F. W. B.

A very simple and convenient facility for the injector repair bench may be made by inserting a ⅜-in. steel plate, through which a number of square holes of suitable sizes have been cut, in the top surface at the edge of the bench. For the greatest convenience the plate should not be located far from the vise.

Where the injectors are fitted with valves of the disk type,



Bench Chuck for Removing Injector Disc Valve Nuts

the disks of which are held in place by nuts, it would ordinarily be necessary to place the nut in the vise when removing it, or when tightening it after the disk had been replaced. This is an awkward operation which in nearly every case can be dispensed with by the use of this simple device. All that is necessary to remove or tighten the nut is to drop it into the hole of the right size in the steel plate and the nut is thus held while the valve stem is unscrewed or tightened, as the case may be. Only occasionally will nuts be found so tight that the vise must be used.

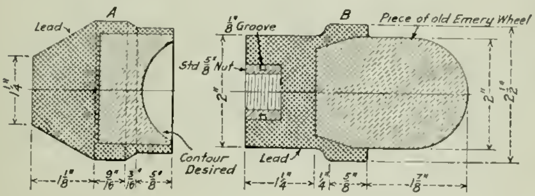
GRINDERS FOR SUPERHEATER UNIT JOINTS

BY H. P. MAUER

The drawing shows a set of shop-made grinders for superheater unit joints which are made from pieces of old emery wheel imbedded in lead or babbitt. The concave grinder is designed to fit the chuck which is in universal use for this work, while the convex grinder is provided with a ⅝-in. nut in which may be screwed shanks to fit any machine that may be used to drive the grinder. The grinders are made by placing suitable pieces of broken emery wheel in a suitable mold and then pouring the lead or babbitt around them.

In the case of the concave grinder the chuck fit is machined after the body has been cast, and after the grinder has been clamped in the chuck the contour of the grinding surface is finished with an ordinary emery wheel cutter. In casting the body of the convex grinder a standard ⅝-in. nut, around the body of which a groove has been cut, is placed in the mold to form the means of attachment for the driving shank. As in the case of the concave grinder, after the body has been cast the grinding contour of the emery stone is finished by the use of an ordinary emery wheel truing tool.

These tools were developed by A. Jiminez, roundhouse foreman of the Cuba Railroad at Camaguey, Cuba, and the tools have been in successful use at this point for five

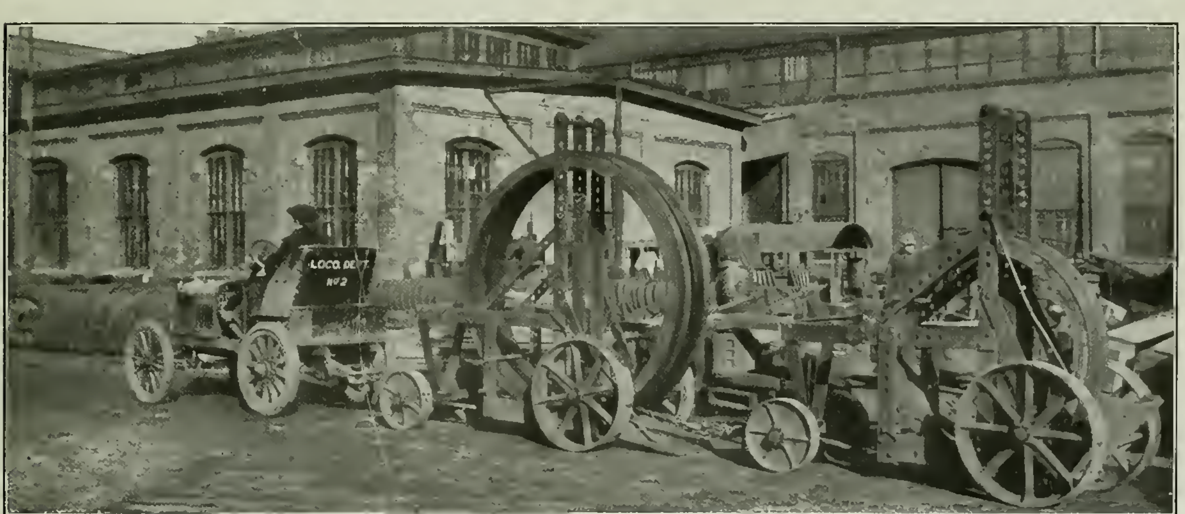


Shop Made Grinders for the Ball Joints of Superheater Units

months with excellent results. A set of superheater units can be ground with these tools in about one-third of the time ordinarily required with the regular grinders using oil and emery.

TRUCKS FOR HANDLING DRIVING WHEEL TIRES

Locomotive tires, particularly of the larger sizes, are difficult to handle unless an overhead crane or a large truck can be used. It is often necessary to transport tires from one shop to another where neither of the methods mentioned are practicable, and in such cases a considerable number of men are often used and a large amount of time consumed in the operation.



A Unique Truck for Transporting Tires

In the photograph which is reproduced above is shown a novel form of truck used in the shop of the Michigan Central at Jackson, Mich., to eliminate this waste of labor. The truck is constructed largely of second-hand material. The frame carries three uprights for holding the tires in position and the rear portion of the floor is hinged so that it can be dropped to form an incline up which the tires are run. When the tires are in place in the truck they are secured by bars placed through holes in the frame. The work of transporting a set of tires from one shop to another formerly required six hours with eight men on the work. With these trucks hauled by a remodeled Ford, the same job is handled by four men in one hour's time.

AN INSTRUCTION SCHOOL FOR ELECTRIC WELDERS

During the development of the extensive shipbuilding program of the Emergency Fleet Corporation the pressing

A Section of the School Equioment for Training Arc Welders

need for electric welders led the corporation to establish several schools for the training of electric arc weld operators. The purpose of the school was to enable men with no previous welding experience to learn the fundamentals of the art in the shortest possible time.

One of these schools was conducted under the supervision of the Lincoln Electric Company, Cleveland, Ohio. Now that the war is over this school has been released by the Emergency Fleet Corporation, and the Lincoln Electric Company is continuing it, putting its service at the disposal of any concern that desires to teach its men the art of arc welding. These men may come to the school and be instructed in any phase of the operation by thoroughly competent instructors. A general idea of the equipment employed for practical instruction work is conveyed by the photograph showing one section of the school with individual operating sets and switchboards for each operator's use.

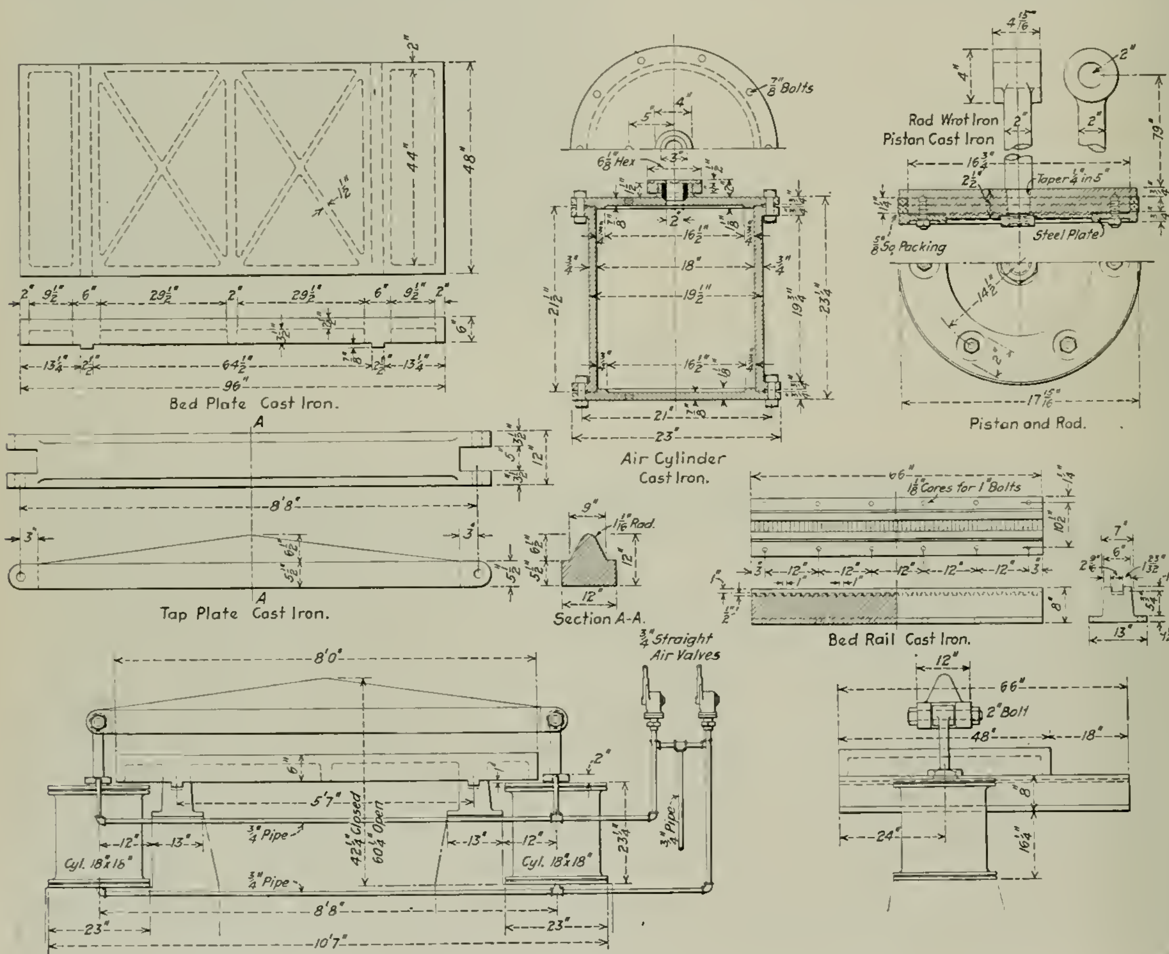
STRAIGHTENING AND FLANGING CLAMP

BY J. V. HENRY

The pneumatically operated clamp shown in the drawing is especially adapted to straightening and flanging work in connection with steel car repairs. The cast iron bed plate is 8 ft. long by 4 ft. wide, the length being sufficient to permit the straightening of the largest plates ordinarily used in steel car construction. By providing suitable blocks, larger sizes of various structural shapes may also be handled in the clamp.

The clamp is operated by two 18-in. by 18-in. air cylinders, one at either end. Two ¾-in. straight air valves are used to control the operation of the clamp, one for the admission and exhaust of air above the pistons and the other for the admission and exhaust of air below the pistons of both cylinders. The piston heads are of the solid type with a tapered fit on the rod. They are designed to take two rings of ⅝-in. square fibre packing, which are held in place by a steel follower ring.

It will be noticed that the tops of the bed rails are notched at the bottom of the grooves in which fit the tongues on the under side of the bed plate. This permits the bed plate to be moved backward or forward by means of crow bars, so that it may be used not only for straightening bent or distorted material, but also as a clamp for holding sheets in flanging operations.



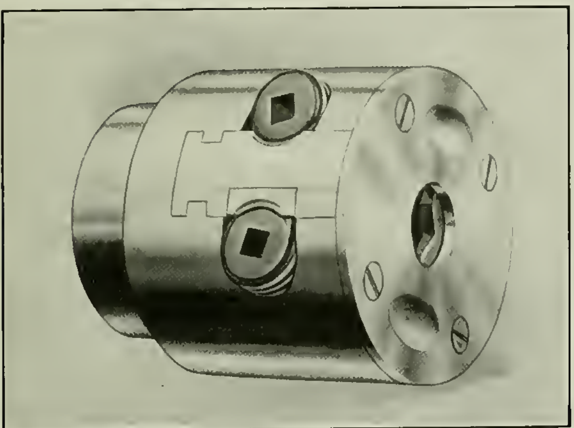
Pneumatically Operated Clamp with Movable Table, for Flanging or Straightening Steel Car Material

Stellite.—This is an alloy of semi-rare metals, but contains no iron and therefore cannot properly be termed steel. The binary alloy, consisting essentially of cobalt and chromium, can be forged with difficulty at a bright red heat, but when it becomes cool its hardness remains as great as before the first heating. According to an article in the Iron Age, by E. Haynes, Stellite does not get harder as it gets hotter, but it gets tougher and holds the cutting edge longer. Cobalt is not affected by heat up to about 1,900 deg. F., and the tungsten and chromium are not affected by any heat up to 2,600 or 2,800 deg. F. It is clear, therefore, that the cobalt becomes tougher up to the degree of softening, but at the same time the other two metals are not changed. This makes a closer and tougher bond, allays all chance of crumbling, and makes the tool last longer for the reason that it has the necessary strength to take off a heavy cut without breaking.

NEW DEVICES

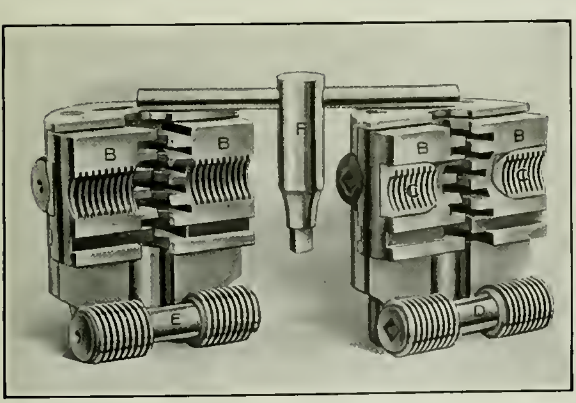
TWIN SCREW DRILL CHUCK

In the photographs are shown a twin screw drill chuck which has recently been placed on the market by the Marvin & Casler Company, Canastota, N. Y. The special features of this device are the twin screw clamping arrangement, and the rugged character of the construction throughout, the purpose being to provide for gripping the drill so firmly that it may be crowded to the limit of its strength.



The Casler Twin Screw Drill Chuck

Referring to the two views of the partially dissembled chuck it will be observed that the primary screw *E* is threaded directly in the chucking jaws *BB*, while the secondary screw *D* is threaded in floating nuts *CC*. When using the chuck the primary screw *E* is first operated to grip the drill shank between the jaws. After this screw has been set up, the secondary screw *D* is operated to bring the floating nuts *CC* against the ends of the pockets in the jaws, resulting in a grip equal to twice that obtainable by a single screw.

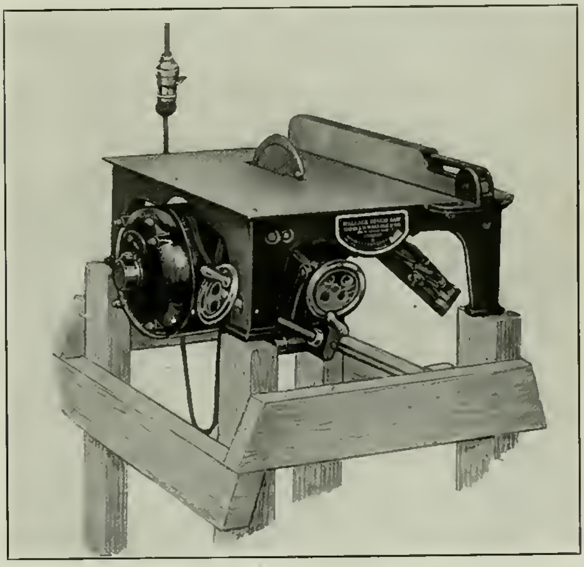


Details of the Drill Chuck

The body of the chuck is of close grained cast iron, while the jaws and screws are of high carbon steel, tempered. It is claimed that the combination of cast iron and steel tends to prolong the life of the wearing surfaces between the body, jaws and screws. The body is reinforced by a steel cap plate which prevents it from spreading when under strain, and the device has been designed to avoid any projections likely to catch the work or injure the workman.

BENCH SAW FOR WOODWORKING SHOPS

A recent addition to the line of bench machines manufactured by J. D. Wallace & Company, Chicago, is the saw shown in the illustration below. This machine is adapted for use in pattern, cabinet or carpenter shops, and is designed with a view to saving the time ordinarily wasted in taking material to a saw located at some distance from the bench. The machine can be operated on an ordinary electric light circuit, and therefore can be located at any convenient point with little difficulty. It has ample power to take a 2-in. cut through hard wood.



Bench Saw with Motor Drive

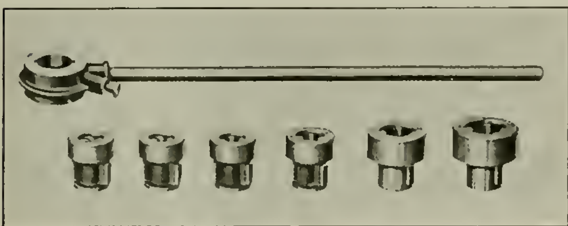
The saw has a table 17 in. by 20 in. equipped with a saw 7 in. in diameter, which can be raised and lowered and tilted to any angle up to 45 deg. The method used to adapt the saw for cutting at various angles is a departure from the usual practice. On this machine the table always remains horizontal, the motor and saw being tilted by means of a hand wheel and screw on the side of the machine. The advantage of this method over the usual tilting table is at once apparent. The saw can be raised or lowered so as to cut or groove any depth up to 2 in. The saw is driven through cut gears from a ½-hp. motor fitted with a ball bearing which also takes the thrust when the saw is tilted.

The cross-cut fence is adjustable to a 45 deg. angle. It is an integral part of the machine, but can be swung under the table when not in use. The rip fence is of the box type, and is clamped to the table by means of an eccentric lock. It is finished on both sides so that it can be used on either side of the saw. The saw is protected by a shutter guard which is held in place by a spring.

BEAVER SMALL PIPE THREADER

A pipe-threading tool has recently been brought out by the Borden Company, Warren, Ohio, for small pipe sizes. The dies are built on the unit plan to thread ⅛-in., ¼-in., ⅜-in., ½-in., ¾-in. and 1-in. pipe. The set may be secured complete or the units may be purchased seperately.

This tool, known as the No. 3 Beaver, Jr., consists of a



No. 3 Beaver, Jr., Pipe Threader

ratchet handle and separate die heads to thread each size of pipe. The whole outfit is packed in a convenient wooden case. The ratchet mechanism is entirely encased so that it is impossible for dirt or grease to accumulate and retard the action of the tool. The introduction of 1-in. size to the range adds greatly to the general usefulness of the tool.

NON-LIFTING INJECTOR INDICATOR

The usual form of tell-tale for non-lifting injectors warns the engineer by discharging a jet of steam into the cab when the injector blows back. An indicator has been developed by William Sellers & Company, Inc., Philadelphia, Pa., which not only performs the function of the tell-tale without discharge of steam into the cab, but in addition advises the engineer if the injector is wasting water at the overflow.

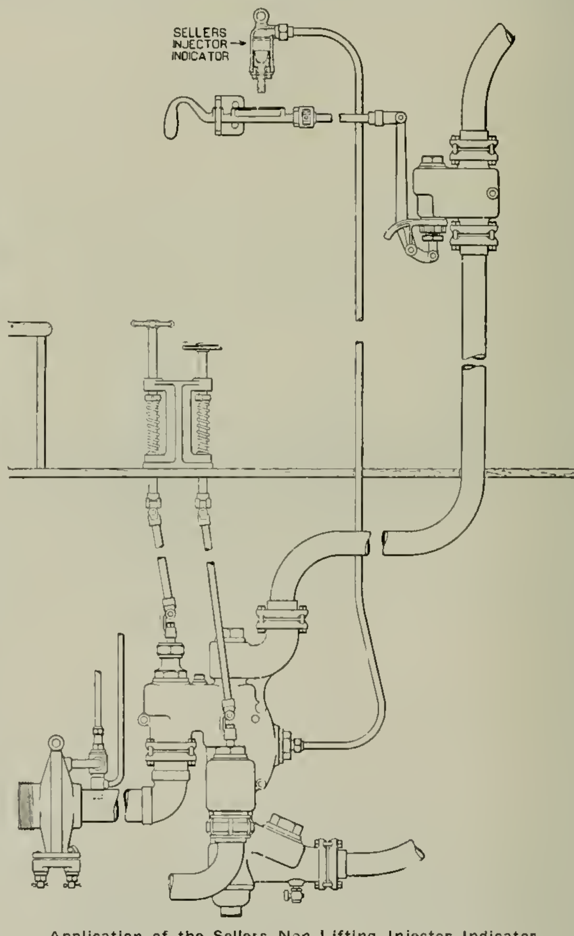
The device consists of a vertical cylinder 4 in. long, containing a loosely fitting piston, seating at each end of its stroke and provided with a projecting end, visible to the engineer when resting on its lower seat. The upper end of the cylinder is connected by a ½-in. copper wire with the overflow chamber of the injector.

Its action depends upon the well-known principle of the working of the injector, that when feeding without waste there is always a partial vacuum within the overflow chamber of an injector of the gravity overflow type. This vacuum is utilized to raise the loosely fitting piston to its upper seat, causing the projecting plug to disappear from view.

If for any cause the injector starts to waste, the vacuum within the overflow chamber is broken, the piston drops and seats at the lower end of its stroke, exposing the projecting plug. The operator is thus warned and will partially close the lazy cock, stopping the waste. If there is interruption of the water or steam supply, and the injector "flies off," the piston will instantly drop to its lower seat, preventing outflow of steam and warning the engineer of the danger.

When the injector operating valve is open, the end of the piston must always be invisible, unless heating the water in the tank. If steam is blown back into the tank in winter, the position of the projecting plug of the indicator is a continuous reminder that the injector is not operating and there may be danger of overheating the water.

A further advantage of this form of indicator is that it enables the engineer or fireman to obtain the actual minimum capacity. Most operators do not regulate the water supply closely, fearing that the injector may break off without warning or waste at the overflow. The indicator is so sensitive to conditions in the overflow chamber of the



Application of the Sellers Non-Lifting Injector Indicator

injector that the exact minimum can be obtained by regulating the lazy cock until the end of the piston appears, due to the loss of vacuum in the overflow chamber. It is claimed that a very slight opening of the lazy cock will cause the piston to rise and the exact minimum to be obtained.

The application of the indicator also will reduce the tendency of the engineer to close the heater valve, which prevents the injector from re-starting automatically. It is designed to make the non-lifting injector as safe and certain to operate as an open-overflow lifting injector.

The indicator is applicable to the Sellers, Nathan WF, Nathan Simplex, Chicago and other forms using an overflow chamber which contains the combining tube, and is closed against the atmosphere by a gravity overflow valve.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

The car repair shops of the Delaware & Hudson at Carbondale, Pa.—two buildings known as No. 18 and No. 20—were destroyed by fire on March 15. About 200 men are out of work temporarily. These buildings were of brick, 400 ft. long and 40 ft. wide.

In the large repair shops of the New York, New Haven & Hartford, the working time has been reduced to 40 hours a week. About 4,000 persons are affected. The Pennsylvania has reduced the working time at many shops. The Nashville, Chattanooga & St. Louis has made a reduction of 10 per cent in the forces of its large shops.

The French government, through the French High Commission, has bought from the Director General of Military Railways 485 standard gage, Pershing type locomotives now being built by the Baldwin Locomotive Works and 19,860 freight cars of various types that were under manufacture in the United States when the armistice was signed. There remains a comparatively small number of locomotives and cars yet to be disposed of and it is expected that they will be sold to some of the Allied governments.

Electric Furnace Association

At a meeting held on March 21 and 22 at Niagara Falls, N. Y., a permanent organization was formed to be known as the Electric Furnace Association, for the purpose of promoting the use of various electric furnace products. The meeting was called by Acheson Smith, vice-president and general manager of the Acheson Graphite Company, Niagara Falls. Resolutions were passed inviting all manufacturers of electric furnaces, electric apparatus, electric furnace supplies and accessories, public utility corporations, designers and inventors of electric furnace equipment and the users of electric furnaces to become members and to join in making an aggressive and thorough campaign to disseminate to engineers and the public accurate data as to the quality of electric furnace products of all kinds. The following are the officers of the association: President, Acheson Smith, Acheson Graphite Company, Niagara Falls, N. Y.; first vice-president, C. H. Booth, Booth-Hall Company, Chicago; second vice-president, W. E. Moore, Pittsburgh Electric Furnace Company, Pittsburgh, Pa.; secretary, C. G. Schluederberg, Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.; treasurer, F. J. Ryan, American Metallurgical Corporation, Philadelphia, Pa.

Iron and Steel Prices Reduced

Representatives of the steel industry and the Industrial Board of the Department of Commerce at a conference in Washington during March reached an agreement on a schedule of reduced prices for the principal articles of iron and steel which will apply to all purchases by the various government departments and below which the board says the public should not expect to buy during the current year. The price schedule is of especial interest to the railroads, which are the largest purchasers of steel, and as the government is operating most of the railroads the prices will apply to purchases for railroad use. The schedule agreed upon, which is effective at once, is as follows:

				Reductions	
	November 11 price	Present price	New price	From November 11	From present
Pig iron basic	33.00 G.T.	30.00	25.75	7.25	4.25
Billets 4-inch	47.50 G.T.	43.50	38.50	9.00	5.00
Billets 2-inch	51.00 G.T.	47.00	42.00	9.00	5.00
Sheet bars	51.00 G.T.	47.00	42.00	9.00	5.00
Slabs	50.00 G.T.	46.00	41.00	9.00	5.00
Skelp sheared	3.25 cwt.	3.00	2.65	12.00 N.T.	7.00 N.T.
Skelpt universal	3.15 cwt.	2.90	2.55	12.00 N.T.	7.00 N.T.
Skelp grooved	2.90 cwt.	2.70	2.45	9.00 N.T.	5.00 N.T.

Ore	No change				

Basing points and differentials unchanged. Prices effective at once.

In view of the higher costs developed throughout the world as a result of the war a return to anything like pre-war prices was regarded as out of the question.

Civil Service Examination for Locomotive Inspector

The United States Civil Service Commission announces an open competitive examination for inspector of locomotives, for men only, on May 21 and 22, 1919. Vacancies in the Interstate Commerce Commission, and in positions requiring similar qualifications, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. The salary of the position is $3,000 per annum and necessary expenses when absent from headquarters in the discharge of official duties. Applicants must have reached their twenty-fifth but not their fifty-fifth birthday on the date of the examination, and must have not less than three years' railroad experience in the capacity of master mechanic, road foreman of engines, locomotive boiler maker, locomotive boiler inspector, roundhouse foreman, shop foreman, locomotive machinist, or locomotive engineer; or not less than five years as locomotive inspector or locomotive fireman; and must have been within three years next preceding the date of application in active service in any such capacity or in the capacity of inspector of locomotive equipment under the government of the United States or of any state or territory. Applicants should at once apply for Form 1892, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

American Machinery in Australia

The Far Eastern Division of the Bureau of Foreign and Domestic Commerce has issued Circular No. 13 on American machinery in Australia. The report is of particular interest to readers of this paper because of the fact the railroad shops represent an important part of the market for American machine tools.

Australia, the circular says, is rapidly becoming a manufacturing country, and the demand for certain American machinery and machine tools is increasing. As a majority of the engineering establishments are also jobbing shops, the engineers in charge are averse to buying from catalogues, but desire actual demonstrations, especially of new machines, and the majority of sales are accordingly made after a sample machine has been received by the agent or importer.

The exclusive agency is accepted as the most satisfactory method of selling machinery and accessories in Australia. In a country like Australia, where vast distances must be traveled in seeking orders and where modern machinery is just being introduced, it is only fair to the agent who has stocked a machine, which may sometimes prove unsaleable, that he be protected by an exclusive contract.

Lathes are the most important essential in the machine shops which are springing up in Australia. As the majority of the work of these shops is jobbing, the machine tools should be universal. Gap lathes, for instance, permit one machine to cover a large range of work and are very popular in Australia. One American machine of this universal type has enjoyed a very large sale. Most of the American gap lathes before the introduction of this one were cheap, and light tools are not in demand.

The price of American planers as compared with that of English makes is disproportionately high. Though the American planers are very high grade with a number of automatic and convenient feeds, these conveniences have made the price too high for the Australian market, and at present there are not half a dozen of these machines in use in that country. A moderate-priced simple planer could be introduced to advantage. This is equally true of punches, shears, rolls, and other tools used in shipbuilding and structural work, our prices of which are much higher than the British.

Thirteenth Engineer (Railway) Regiment Sees Active Service

The 13th Engineers Regiment, composed of railway men on roads running west from Chicago, which has been operating military railroads back of Verdun was scheduled to leave Fleury-sur-Aire on March 7, on the way to an embarkation port preliminary to its return home. According to a cable published in the Chicago Daily News, on March 6, it has the distinction of being the first American Engineer Regiment to enter active service in the war, and has an excellent record for the handling of men and supplies, and for the assistance given in the preparation for the American drive on the Meuse-Argonne.

Although engineer regiments are generally classed as noncombatant units, the 13th has been classed as a combat unit in orders from the American and French headquarters, with the instructions that on the discharge papers of each officer and man the words, "Took part in the Champagne, St. Mihiel and Meuse-Argonne offensives," be inserted. Another distinction of the 13th is the insignia of a blue square cloth patch with a red engineer castle in the center, surrounded by a circle of 13 white stars, which indicates the beginning of the American nation and the start of the American expedition. Usually a division is the smallest unit that has its own shoulder insignia.

On October 18, 1917, the 13th took over the operation of the railroads in the French advanced zone and was relieved on February 28, 1919. At the end of 1918 it had moved 1,777 trains, carrying millions of men, including many who were wounded, and 9,230,080 tons of freight, as well as the private trains of President Poincare, General Pershing, Secretary Baker and others. The 13th was operating, on the day the armistice was signed, 229 kilometers (138 miles) of track supplying the Argonne, Verdun and St. Mihiel fronts.

As part of the railroad was within range of the German artillery and all of it within range of heavy explosives and machine guns of airplanes, the men were obliged to run the trains and repair the track under constant fire. Twenty-four immense railroad guns were firing along this line. One track was used for ammunition and the other for supplies.

Several members of this regiment received special recognition. In his letter forwarding the decorations, General Pershing said: "The cheerfulness, adaptability, loyalty and self-sacrificing devotion to duty uniformly displayed under trying circumstances by officers and men from the regimental commander to the most recently arrived private have added a new luster to the traditions of our railway service."

MEETINGS AND CONVENTIONS

International Railway Fuel Association.—The next annual convention of the International Railway Fuel Association will be held at the Hotel Sherman, Chicago, from May 19 to May 22.

American Foundrymen's Association.—The 1919 convention and exhibit of the American Foundrymen's Association will be held in Philadelphia, Pa., from September 29 to October 4. It is planned to make this convention an international one and invitations will be sent to foundrymen and industrial engineers all over the world. Details of the program will be announced later.

June Mechanical Convention Exhibits.—The Railway Supply Manufacturers' Association announces that at the assignment of space in Pittsburgh, February 14, there was sold and assigned over 80,000 sq. ft. The available space is a trifle less than 89,000 sq. ft., leaving less than 10 per cent for such exhibitors as will come in. This available space includes all of the space heretofore used in previous years together with a number of additions, which the committee found possible to use. The committee is looking over the pier with a view of providing additional space if possible, as indications are that it can be sold to exhibitors if provided. Edmund H. Walker, president of the association, in announcing the above, says that "the success of the June meeting from an exhibition standpoint is assured."

General Foremen's Association.—The annual convention of the International Railway General Foremen's Association will be held at the Hotel Sherman, Chicago, September 2, 3, 4 and 5. The topics to be discussed are as follows:

1. Welding of locomotive cylinders and other autogenous welding.

2. Safety first in shop and engine house service. The best method of application so that employees may be interested to practice same.

3. Draft gears.

The association has received permission from the Railroad Administration to hold this convention and due to the conditions on the railways at the present time a large attendance is to be desired from both the locomotive and car departments.

American Welding Society.—An association known as the American Welding Society was organized at the Engineering Societies building, New York, on March 28, 1919. This society is a merger of the welding committee of the Emergency Fleet Corporation and the National Welding Council, and its purpose is to provide a disinterested and dependable source of information on welding, not only for the benefit of the manufacturers of welding apparatus and supplies, but also to aid those who use welding in their production and those who purchase welded goods. The society will bring together in the manner usual for scientific societies persons from all branches of the industry who may be interested in any of the welding processes. It is proposed that the society will create and assist in maintaining a Bureau of Welding which will be a separate organization designed to take advantage of the principle of co-operation in research and standardization. The American Bureau of Welding will consist of a joint board of directors, 30 from the American Welding Society and one each from the various scientific and engineering societies, including the American Railway Association, and one each from the United States Commerce, Navy and War Departments and the United States Shipping Board.

Membership in the American Welding Society is divided into five classes: Class A, sustaining members, annual dues $100; open to one or more representatives from each corporation interested. Class B, annual dues $20; open to individuals who may or may not be employed by corporations, and to consulting engineers, college professors, etc. Class C, annual dues $10; open to members of existing societies which will become affiliated with the new society through the proposed Bureau of Welding. Class D, annual dues $5; open to welding artisans. Class E, open to trade associations, putting them in the same category as corporations. Class F, honorary members. Class C and D memberships do not carry the privilege of voting or holding office.

The activities of the society will include the promotion of research work on problems of common interest to all or groups of the membership, including the financing of such projects; the consideration of questions of standardization, which it is proposed shall be handled in co-operation with the American Engineering Standards Committee through the agency of the Welding Bureau; the exertion of a steadying and unifying influence on legislation affecting welding by supplying law makers with authentic information, and the study of proper methods of training autogenous welders.

It is reported that already a large number of corporations and engineers are interested in the project, including officers and members of many of the national technical and engineering societies, universities and engineering schools, government departments and bureaus, gas and electric welding companies, and shipbuilding, steel and automobile companies.

The following officers were elected:

President—C. A. Adams, President American Institute of Electrical Engineers, Cambridge, Mass.
Vice-President (for 1 year)—J. M. Moorehead, Union Carbide Company, New York.
Vice-President (for 2 years)—G. L. Brunner, Brunner Manufacturing Company, Utica, N. Y.

Directors for 1 year—
W. M. Beard, Linde Air Products Company, New York.
M. H. Roberts, Air Reduction Sales Company, New York.
M. M. Smith, Commercial Acetylene Company, New York.
L. D. Lovekin, American International Ship Building Corp., Philadelphia, Pa.
Alexander Churchward, Wilson Welder and Metals Company, New York.
W. H. Patterson, Westinghouse Electric & Mfg. Company, Pittsburgh, Pa.
Walter J. Jones, Chester Shipbuilding Company, Philadelphia, Pa.
C. A. McCune, Page Steel & Wire Company, New York.

Directors for 2 years—
R. R. Browning, Oxweld Acetylene Company, New York.
A. S. Kinsey, Professor of Experimental Mechanics, Stevens Institute, Jersey City, N. J.
Victor Mauck, John Wood Manufacturing Company, Conshohocken, Pa.
E. L. Hirt, Bethlehem Shipbuilding Corporation, South Bethlehem, Pa.
J. F. Lincoln, Lincoln Electric Company, Cleveland, Ohio.
H. M. Hobart, General Electric Company, Schenectady, N. Y.
D. C. Alexander, Quasi Arc Weldtrode Company, New York.
H. R. Swartley, Jr., Davis-Bournonville Company, Jersey City, N. J.

Directors for 3 years—
L. H. Davis, Linde Air Products Company, New York.
E. L. Mills, Air Reduction Sales Company, New York.
D. B. Rushmore, General Electric Company, Schenectady, N. Y.
James Burke, Burke Electric Company, Erie, Pa.
D. H. Wilson, Jr., Wilson Welder & Metals Company, New York.
Hermann Lemp, General Electrie Company, Erie, Pa.
C. J. Nyquist, Torchweld Company, Chicago, Ill.
Alexander Jenkins, Alexander Milburn Company, Baltimore, Md.

It was voted that the charter should be held open for ten days, and that those applying for membership in the society before April 8 should be considered charter members.

At a meeting of the directors in the afternoon, W. E. Symons, Galena Signal Oil Company, Franklin, Pa., was appointed treasurer, and H. C. Forbes, consulting engineer, New York City, was appointed secretary.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:.

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention, May 6-8, 1919, Chicago.

American Railroad Master Tinners' Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Master Mechanics' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. R. McMunn, New York Central, New York, N. Y.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago. Convention May 19-22, 1919, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention September 25, Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention May 26-29, Hotel Sherman, Chicago.

Master Car Builders' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 18-21, Atlantic City, N. J.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y.—Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Apr. 8	Car Trucks	W. J. Hyman	James Powell	P. O. Box 7, St. Lambert, Que.
Central	May 9	Railroad Power Plants	William Olsen	H. D. Vought	95 Liberty Street, New York.
Cincinnati	May 13	Fuel Conservation	D. E. Dick	H. Boutet	101 Carew Building, Cincinnati, O.
New England	Apr. 8	Track Maintenance		W. E. Cade, Jr.	683 Atlantic Ave., Boston, Mass.
New York	Apr. 18	Address by W. T. Tyler		H. D. Vought	95 Liberty Street, New York.
Pittsburgh	Apr. 24			J. D. Conway	515 Grandview Ave., Pittsburgh, Pa.
St. Louis	Apr. 11	Proper Loading and Handling of Live Stock.—Election of Officers	W. J. Embree	B. W. Frauenthal	Union Station, St. Louis, Mo.
Western	Apr. 21			A. F. Stuebing	750 Transportation Bldg., Chicago.

Personal Mention

GENERAL

H. P. Anderson, superintendent of motive power of the Missouri, Kansas & Texas, at Parsons, Kan., has been appointed mechanical superintendent of the Missouri, Kansas & Texas and affiliated lines, with office at Denison, Tex.

M. K. Barnum, assistant to general superintendent maintenance of equipment of the Baltimore & Ohio, with office at Baltimore, Md., has been appointed mechanical engineer for the corporation.

C. J. Bodemer, division master mechanic of the Louisville & Nashville, with office at Albany, Ala., has been appointed assistant superintendent of machinery, with headquarters at Louisville, Ky., succeeding Millard F. Cox, resigned to engage in other business.

E. W. Pratt, assistant superintendent of the motive power and car departments of the Chicago & North Western, with headquarters at Chicago, retired from active service on March 1, and was granted an extended leave of absence. Although only 50 years of age, Mr. Pratt has served the Chicago & North Western for nearly 30 years, starting as a message boy and telegraph student when 14 years old, then working in the engineering department and on construction work to earn money to enable him to complete a course of mechanical engineering at Lehigh University, where he also specialized in chemistry and metallurgy. Having had practical work in both civil and mechanical engineering, Mr. Pratt specialized in electrical engineering for one year with the Western Electric Company of Chicago, and again entered the employ of the Chicago & North Western as general air brake inspector and instructor, being promoted successively to enginehouse foreman, general foreman, master mechanic and assistant superintendent of the motive power and car departments, in which latter capacity he has remained ten years. Mr. Pratt has been active in railway association work, having been president of the Western Railway Club, Chicago, in 1914-15; president of the American Railway Master Mechanics' Association in 1915-16 and president of the International Railway Fuel Association in 1917-18.

E. W. Pratt

R. W. Burnett, superintendent motive power of the Missouri, Kansas & Texas of Texas at Denison, Texas, has been appointed assistant mechanical superintendent of the Missouri, Kansas & Texas and affiliated roads, with office at Denison.

E. B. Hall, assistant superintendent of the Wisconsin division of the Chicago & North Western, with headquarters at Milwaukee, has been appointed assistant superintendent of the motive power and car departments of the road, with headquarters at Chicago, to succeed E. W. Pratt, who is on leave of absence.

W. H. Maddocks has been appointed mechanical engineer of the Missouri, Kansas & Texas and affiliated roads, with office at Parsons, Kan.

T. O. Sechrist, general master mechanic of the Louisville & Nashville, with office at Louisville, Ky., has been appointed assistant superintendent of machinery and the position of general master mechanic has been abolished.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

G. H. Berry has been appointed master mechanic of the Knoxville and Atlanta divisions of the Louisville & Nashville, with headquarters at Etowah, Tenn., succeeding W. E. Hunter.

Clyde L. Bunch, whose appointment as master mechanic of the Southern Railway, with headquarters at Sheffield, Ala., was announced in these columns last month, was born in Wake county, N. C., on February 14, 1878, and received a high school education. In the summer of 1902 he entered the employ of the Richmond, Fredericksburg & Potomac as a machinist at Richmond, Va., resigning in the summer of 1904 to accept a similar position with the Chesapeake & Ohio. On March 1, 1905, he went to the Southern Railway as a machinist in the Spencer, N. C., shops, was promoted to gang foreman there in April, 1909, erecting shop foreman on October 1, 1909, and since January 1, 1913, until he was appointed master mechanic, acted as shop superintendent at Spencer.

C. L. Bunch

W. E. Hunter, master mechanic of the Knoxville and Atlanta divisions of the Louisville & Nashville, at Etowah, Tenn., has been transferred to the Cincinnati Terminals and Kentucky division, with office at Covington, Ky., succeeding C. W. Mathews.

C. W. Mathews, master mechanic of the Cincinnati Terminals and Kentucky division of the Louisville & Nashville, with office at Covington, Ky., has been transferred to the Albany (Ala.) shops, succeeding C. J. Bodemer, assigned to other duties.

CAR DEPARTMENT

Richard W. Moore, general car foreman on the Canadian National at Cochrane, Ont., has been promoted to district car foreman, with headquarters at Saskatoon, Sask. He was born at Listowel, Ont., on October 20, 1882, and received his education in the Brandon high school of that place. He entered railway service in July, 1906, as a car repairer on the Grand Trunk Pacific, which position he held for two years when he was promoted to car foreman, serving in that capacity for nine years at Melville, Sask., Rivers, Man., and Fort William, Ont. When the National Transcontinental was taken over by the Canadian government, Mr. Moore was transferred to that road as car foreman. In November, 1917, he was appointed general car foreman, with headquarters at Cochrane, Ont., which position he held until his recent appointment as district car foreman of the Canadian National, with headquarters at Saskatoon.

PURCHASING AND STOREKEEPING

J. M. Velasco, local purchasing agent of the National Railways of Mexico, at New York, has been appointed assistant to the general purchasing agent, with office at Mexico City, Mex., and F. P. de Hoyos, general agent of the traffic department, at New York, is now also local purchasing agent, with office at New York.

A. E. Cox, whose appointment as general steorkeeper of the Canadian National, Western Lines, with headquarters at Winnipeg, Man., was announced in the *Railway Mechanical Engineer* last month, was born at Huddersfield, Eng., in 1863, and received his education in private schools at Hamburg, Germany, and college at Huddersfield. Mr. Cox first entered railway service in 1883 as timekeeper on the Canadian Pacific Western division, with headquarters at Moose Jaw, Sask., which position he held for four years, when he was appointed chief clerk in the stores department of the Manitoba & Northwestern. In 1893 he was appointed storekeeper when the Manitoba & Northwestern was absorbed by the Canadian Pacific, and the following two years was assistant to the superintendent of construction of the Ontario and Rainy River section of the Canadian Northern. Since 1912 he was storekeeper of that road, until his recent appointment on the Canadian National.

A. E. Cox

George W. Snyder has been appointed general storekeeper of the Pennsylvania Railroad, eastern lines, with headquarters at Philadelphia, Pa. Mr. Snyder was born at Pottsville, Pa., on January 9, 1866, and was educated in the public schools of Pottsville and at Lehigh University. Mr. Snyder began railway work with the Pennsylvania Railroad on November 1, 1884, as rodman on the Renovo division. He was appointed assistant supervisor of the same division on January 1, 1886, and in August. 1890, was promoted to supervisor. On June 10, 1897, he was appointed supervisor on the Northern Central at Baltimore, and three years later was transferred to the Altoona yard. He was promoted to division engineer of the Monongahela division in January, 1901, and in June, 1903, was transferred to the Pittsburgh division. On April 1, 1907, he was appointed principal assistant engineer of the Western Pennsylvania division; in October, 1917, he was made assistant engineer, maintenance of way, in charge of bridges and structures, and served in that position until his recent appointment as general storekeeper.

G. W. Snyder

Supply Trade Notes

J. J. Haigh has been appointed assistant district manager of sales for the Chicago Pneumatic Tool Company, with headquarters at 175 First street, San Francisco, Cal.

Nelson B. Gadch has been appointed district manager of sales for the Chicago Pneumatic Tool Company, with headquarters in the Metropolitan Bank building, Minneapolis, Minn.

The A Gilbert & Sons Brass Foundry Company, St. Louis, Mo., recently installed a complete chemical laboratory at its plant and all products are now made under chemical supervision.

Fred H. Waldron, Minneapolis representative of the Chicago Pneumatic Tool Company, has been appointed manager of the pneumatic tool sales division, to succeed J. D. Osgood, who has resigned.

The Dearborn Chemical Company, Chicago, announces the opening of offices in the Commerce Trust building, Kansas City, Mo. E. M. Massen and W. H. Fairlamb will make their headquarters at that office.

John W. Foyle, vice-president of the Gustin-Bacon Manufacturing Company, Kansas City, Mo., who has been a major in the United States Army, has been released from service and has returned to his duties with his company.

Frank G. Wallace, vice-president of the Canadian Locomotive Company, has been elected president to succeed the late Dr. J. J. Harty, who died in London on February 23. J. L. Whiting succeeds Mr. Wallace as vice-president.

Clyde P. Benning, service manager of Mudge & Company, Chicago, has been appointed assistant general manager with headquarters at Chicago, in which position he will assist the railroad companies in developing motor car organizations.

J. E. Slimp, who has for many years been connected with the sales department of the Ohio Brass Company, Mansfield, Ohio, has resigned to become associated with H. C. Dodge, of Boston, who is at the head of several manufacturing companies in New England.

J. I. Edwards has been appointed manager of the rock drill sales division of the Chicago Pneumatic Tool Company, succeeding K. Eklund, who has been appointed special foreign representative, and who will leave shortly for Europe in the interest of that company.

J. A. Farris, who has been connected with the Whiting Foundry Equipment Company, at Chicago, as crane engineer in the engineering department for the past 10 years, has entered the employ of Scully-Jones & Co., at Chicago, as special sales engineer on cranes.

The controlling interest of the Carroll Foundry & Machine Company, Bucyrus, Ohio, manufacturers of locomotive cranes, has been purchased by Cleveland interests, and a temporary organization has been perfected which will be taken over later when the company is reorganized.

C. E. Hague, formerly production engineer of the Mid-West Engine Company, Indianapolis, Ind., has been appointed sales manager of the American Steam Conveyor Corporation, Chicago, manufacturers of the American steam ash conveyor and other ash handling equipment.

Lieutenant Sherman C. Amsden, formerly connected with Mudge & Co., Chicago, has been appointed assistant to the president, in which position he will have charge of publicity, special sales plans, and investigations. Upon his honorable release from the service he returned to Mudge & Co. to become assistant to the president.

The Chicago Pneumatic Tool Company announces the removal of its Boston, Mass., office to 182 High street. F. F. Eggleston, district manager of sales, will represent the company in that territory. The company also announces the opening of offices and warehouses at Tulsa, Okla.

Malcolm L. Maclean, formerly manager of sales, miscellaneous department, of the American Steel Foundries, with headquarters at Chicago, and until recently a major in the infantry, has been appointed manager of sales of the Duquesne Steel Foundry Company, at Pittsburgh, Pa.

Jean K. Vanatta, mechanical engineer of Mudge & Company at Chicago, has been appointed service manager, in which capacity he will have charge of the company's service engineers, who are working with the motor car men on the various railroads throughout the country, as well as the developing of the service idea.

The Bridgeford Machine Tool Works and the Betts Machine Company of Rochester, N. Y., announce the opening of joint branch offices in New York and Chicago. The New York office is located at 50 Church street, in charge of F. C. Severin, and the Chicago office is at 549 Washington boulevard, in charge of A. W. Van Buren.

General Guy E. Tripp, chairman of the board of directors of the Westinghouse Electric & Manufacturing Company, was recently decorated with the United States government distinguished war service medal, which was awarded him for his work in systematizing methods and practices in industries producing ordnance material for the army.

A. N. Willsie has resigned from the Chicago, Burlington & Quincy, with which company he has been connected for the past 29 years, to accept the position of district engineer of the Locomotive Stoker Company, with headquarters at Chicago. Mr. Willsie was born in Galesburg, Ill., where he received his primary school education. He entered the service of the Burlington on April 20, 1880, as an errand boy in the master mechanic's office, and later filled the position of chief clerk to the master mechanic in the same office. In 1890 he became a locomotive fireman, and then was engineman for six years when he became road foreman of engines, from which position he was promoted to division master mechanic at Brookfield, Mo., Aurora, Ill., and Omaha, Neb. Mr. Willsie left the mechanical department to take the position of division superintendent in the operating department, and for two years filled this position at St. Joseph, Mo., and three years at Hannibal, Mo. Since June, 1912, Mr. Willsie has been permanent chairman of the fuel economy committee and superintendent of fuel economy of the Burlington, with headquarters in Chicago, reporting direct to the general superintendent of motive power, and vice-president in charge of operation.

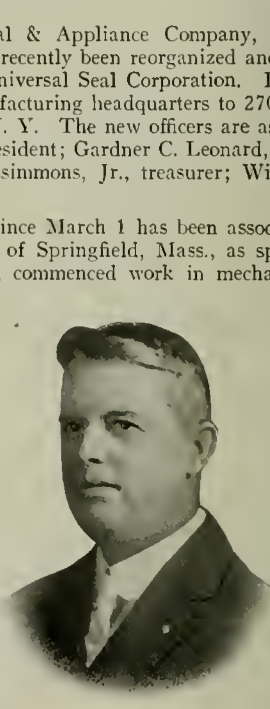
A. N. Willsie

Edwin Besuden has been appointed eastern district manager of the railway department of the Chicago Varnish Compeny, in charge of steam and electric railway sales. His headquarters are at 50 Church street, New York. Mr. Besuden was formerly sales manager of the Jewett Car Company and was connected with that company for 16 years.

The Pollak Steel Company announces that the G. F. Cotter Supply Company, Houston, Texas, will represent it as Southwestern sales representative. They will endeavor to sell the products, consisting of forgings of all kinds, axles, locomotive parts, as well as the Pollak special heat treated products. This covers the material produced both at the Cincinnati as well as the Chicago works.

The Universal Car Seal & Appliance Company, Lyon Block, Albany, N. Y., has recently been reorganized and has changed its name to the Universal Seal Corporation. It has moved its offices and manufacturing headquarters to 270-276 Hudson avenue, Albany, N. Y. The new officers are as follows: C. R. Martineau, president; Gardner C. Leonard, vice-president; Edward J. Fitzsimmons, Jr., treasurer; William C. Martineau, secretary.

John B. Canfield, who since March 1 has been associated with the Harley Company of Springfield, Mass., as special representative and counsel, commenced work in mechanical lines with the Boston & Albany, at Boston, Mass., in 1885, as machinist apprentice. He continued with the railroad as foreman machine shop, general foreman locomotive department and master mechanic of the Albany and Boston divisions, severing his connection with railroad work in 1916, after a continuous service of 30 years. In 1906, while in the railroad service as master mechanic at Boston, Mass., Mr. Canfield enrolled as a law student in the Boston Evening Institute, now the Northeastern College of Law, graduating in June, 1910, with the degree of LL.B., and was admitted to the Massachusetts bar September 23, 1910. At the time of his coming to the Harley Company, he was actively engaged in the practice of his profession at Springfield, Mass. During the war he served as major of engineers, and was commanding officer of the Sixth Battalion, 21st Engineers, being honorably discharged in January of this year.



J. B. Canfield

Arthur F. Braid has been appointed sales manager of the metal and alloy department of the Metal & Thermit Corporation, New York. Mr. Braid went to the company seven years ago as a traveling salesman, and after a few years of service in this capacity was appointed assistant superintendent of the Jersey City plant, in charge of the manufacture of carbonfree metals and alloys. When the United States entered the war, he assumed active charge of metal sales at the New York office of the company.

C. W. Johnson has been appointed assistant manager of works of the Westinghouse Electric & Manufacturing Company. After graduating from Ohio State University, Mr. Johnson entered the employ of the Steel Motor Company of Johnstown, Pa. A year later he became associated with the Bullock Electric Company, of Cincinnati, Ohio, and in 1904 was made superintendent of Allis-Chalmers-Bullock, Ltd., of Montreal, Can. In 1907 he entered the employ of the Westinghouse company, being appointed chief inspector of works, in which capacity he served until his recent appointment.

George K. Heyer is the new assistant telephone sales manager of the Western Electric Company, having been advanced from the position of railway sales engineer. He has been an employee of the company since 1902, and always has been in New York. He will remain there as his headquarters will be at 195 Broadway. E. V. Adams succeeds G. K. Heyer as railway sales engineer. He has been a Western Electric man since 1910, when he began in the railway sales department of the Chicago house. He was transferred to St. Louis in 1912, and the following year went to New York, where his headquarters will remain.

P. Harvey Middleton, executive assistant of the Railway Business Association, was invited by Señor M. Muñoz, general superintendent of the Mexican National Railway Administration, during his visit to New York recently, to make a trip with him over all the lines under the control of the Carranza government. Mr. Middleton has accepted the invitation and will leave for Mexico shortly. He will be met at Laredo, Texas, by Señor Muñoz and will visit all points of interest, including the steel mills and railway machine shops. Mr. Middleton speaks Spanish, which will aid him greatly in his investigations.

Wilson W. Butler, whose appointment as president of the Canadian Car & Foundry Company, Ltd., the Canadian Steel Foundries, Ltd., and the Pratt & Letchworth Company, Ltd., Canada, was announced in the *Railway Mechanical Engineer* last month, was born at Danville, Ohio, on December 9, 1862, and received his early education in the Danville Select School. Mr. Butler began his business career with the John Shillito Company, at Cincinnati, Ohio, and later was appointed western manager of the Sterlingworth Railroad Supply Company, at Chicago. Subsequent to his appointment as president of the Canadian Car & Foundry Company, Mr. Butler served as western sales agent of the American Car & Foundry Company, at Chicago; second vice-president and director of the Simplex Railway Appliance Company, at New York, and second vice-president and director of the American Steel Foundries, at New York. In 1901, as vice-president and director of the Simplex Railway Appliance Company, he established the manufacturing plant of that company in Montreal, Que. He was also vice-president and director of the Dominion Steel Car Company, near Montreal, where the first steel car manufactured in Canada was built. Mr. Butler was instrumental in the organization of the Canadian Car & Foundry Company, Ltd., composed of the Dominion Car & Foundry Company, the Canada Car Company and the Rhodes Curry Company. Since shortly after the beginning of the war, the plants of the companies of which Mr. Butler is president have been engaged in the production of steel, and the forging and machining of shells, for the American, British and Russian governments. Mr. Butler succeeds Senator N. Curry, who has retired from the presidency of the companies, and now holds the position of chairman of the board of directors.

W. W. Butler

Samuel T. Fulton, vice-president of the Railway Steel Spring Company, died in New York on March 29, at the age of 52 years. He was born in Topeka, Kan., and spent many years in railroad service in the west, becoming assistant to the president of the Chicago, Rock Island & Pacific in 1904. In 1909 he became associated with the spring corporation.

Lieut.-Colonel Merril G. Baker has been elected president of the American International Steel Corporation, effective April 1. Colonel Baker was formerly assistant manager of sales of the Cambria Steel Company and has been for many years one of J. Leonard Replogle's right hand men. He succeeds the late Edward M. Hagar, who died over a year ago. The American International Steel Corporation is the steel exporting subsidiary of the American International Corporation.

At the annual meeting of the stockholders of the Westinghouse Air Brake Company, held March 31 at the general office of the company in Wilmerding, Pa., A. L. Humphrey, who has been vice-president and general manager of the company since 1909, was elected president, succeeding John F. Miller. This action was taken at the solicitation of Mr. Miller, who after a service of 30 years, during which period he rose from the position of real estate agent for the company to its highest executive office, is desirous of being relieved of some of the active duties in the management of the air brake interests. He will remain, however, a member of the board of directors and hold the position of vice-chairman of the board, with H. H. Westinghouse as chairman.

The Onondaga Steel Company, Inc., Syracuse, N. Y., announces the addition to its board of directors of Morton D. Whitford, treasurer of the Semet-Solvay Company, and Charles H. Canfield, general auditor of the Onondaga Steel Company. The company is planning to remove its offices and remaining furnace and melting equipment this spring from its original plant in Syracuse to a large tract of land it recently acquired at Eastwood on the outskirts of Syracuse, and plans have been made for the immediate construction of a large temporary office building and an addition to the main building, 40 ft. by 40 ft., which will house the blacksmith shop and the small hammer shop.

W. J. Austin, general manager of The Austin Company, industrial engineers and builders, Cleveland, Ohio, has just returned from a three-months' trip to France, Belgium and England. Mr. Austin, in company with J. K. Gannett, export sales manager of the Austin Company, sailed from New York City on December 5. The party which included Alvin T. Fuller, member of Congress from New England, were for a time the guests of the British government and were taken on a thousand-mile trip over the battlefields. The 13 buildings which were erected by the American forces for the U. S. Army Transport Service, under the Austin Company's supervision, were inspected by the party. The first building was erected at St. Nazaire by the 17th Engineers in December, 1917, and the remaining buildings were erected at Verneuil.

H. A. Jackson, president of the Chicago Pneumatic Tool Company, Chicago, returned February 19 from England, where he has been inspecting the foreign plants of the corporation. The Consolidated Pneumatic Tool Company, Ltd., and the Pneumatic Tool Company (respectively the selling agency and the manufacturing corporation), subsidiaries of the Chicago Pneumatic Tool Company in England, were found to be in excellent condition. During the war the company made some profit manufacturing bayonets for the British government while carrying on its regular tool business to capacity. News of the disposition of the International Compressed Air & Electric Company of Berlin, Germany, which the Chicago Pneumatic Tool Company owns, has not yet been received, although Mr. Jackson has been striving for a year to get word of this property.

Catalogues

Time Zones.—A large calendar and wall map of the United States and the greater part of Canada, 28 in. by 40 in., is being issued by the Metal & Thermit Corporation, New York, the map showing the new railroad time zones in the United States, which went into effect on January 1, 1919.

Welding.—Two small folders have been issued by the Air Reduction Sales Company, New York, showing benefits derived from the use of their products and methods, one illustrating the results of repairing a badly damaged locomotive cylinder by Airco methods, and the other showing the Airco process of building up worn frogs.

Roller Bearings.—The distinctive features, together with price lists for the different sizes of its type "C" roller bearings, which are recommended for use under conditions of medium loads at medium speeds, such as inspection cars, baggage trucks, etc., are set forth in bulletin No. 1004, issued by the American Roller Bearing Company, Pittsburgh, Pa.

Overhead Carrying Systems.—Catalogue 50, issued by the Coburn Trolley Track Manufacturing Company, Holyoke, Mass., manufacturers of overhead carrying systems for both "round trough" and I-beam, shows price lists, illustrations, plans and dimension drawings of overhead carriers and their details. The catalogue contains 56 pages, 8½ in. by 11 in. and illustrates a number of actual installations.

Pipe Threading Machinery.—An illustrated catalogue of pipe threading and cutting machines and pipe and nipple threading machines has been issued by the Landis Machine Company, Inc., Waynesboro, Pa. The catalogue contains a detailed discussion of all the machines, but aims principally to set forth the distinctive features of the Landis die and chaser as compared with other types. This is known as catalogue No. 25 and copies may be had upon request.

Twist Drills, Reamers, Etc.—A machinists' supply catalogue, No. 91, listing carbon and high speed twist drills and reamers, screw and drop forged wrenches, spring cotters and keys, etc., has been issued by the Whitman & Barnes Manufacturing Company, Akron, Ohio. The catalogue contains 183 pages and a distinctive feature of it is a thumb index marked to show the products listed in the various sections, making it an easy matter to find desired information.

Pumping Machinery.—The National Transit Company, Oil City, Pa., manufacturers of special machinery to meet the requirements of pipe line companies, have begun the manufacture of other machinery for general service, including pumping machinery, gas and oil engines, which together with old lines are illustrated and described in various bulletins. These have been bound in heavy manila covers in such a way that others may be added from time to time as they are issued.

Drills and Reamers.—The Clark Equipment Company, Buchanan, Mich., lists and briefly describes all of the standard tools comprising the Celfor line in catalogue No. 16. These include drilling and reaming tools of various kinds, drill chucks, drill sockets, lathe tool holders, tool bits, flue cutters and drill gages. In the back of the book are several pages of tables showing feeds and speeds for Celfor drills and decimal equivalents in inches of millimeters and fractions of an inch.

Slotting Machines.—Latest information on three types of Newton slotting machines in a variety of sizes is given by the Newton Machine Tool Works, Inc., Philadelphia, Pa., in catalogue 49-A. This catalogue also contains photographs and brief specifications of upright generating planers, cold saw cutting off machines, locomotive link grinding machines, horizontal milling machines, vertical milling machines, rotary planers, keyseat milling machines and duplex locomotive rod boring machines.

Shop Production.—"The Missing Link" is the title of a 16-page booklet issued by the Gisholt Machine Company, Madison, Wis., explaining the principle of the Periodograph and the advantages to be secured from its installation. This machine was developed to make it possible to secure an accurate record of the time actually spent in producing, and the time lost by workmen waiting for materials, broken machines, lack of power, and other causes of delay. The booklet shows several cards which are used for registering the time lost, with the reasons, and a chart showing the record of a machine for an entire year.

Baldwin Locomotives.—In September, 1918, the Baldwin Locomotive Company completed the erection of its fifty-thousandth locomotive, which is the subject of Record No. 91. This locomotive is one of a group of 12 built for the Southern Railway Company and is of the Mallet articulated type with 2-8-8-2 wheel arrangement. The booklet gives some interesting facts regarding the Southern Railway System and a brief review and several illustrations of motive power built by the Baldwin Locomotive Works for this road, in addition to a description of the 12 Mallet locomotives represented by locomotive No. 50,000. It also contains interesting information regarding the growth of the locomotive industry and of the Baldwin Locomotive Company's plants, illustrations showing the shop in which the first Baldwin locomotives were constructed and the various plants in operation at the present time.

Perforated Metals.—The Hendrick Manufacturing Company, Carbondale, Pa., manufacturers of perforated metals, etc., has issued a catalogue of 127 pages which will be found useful for reference purposes to the user of perforated metals. Thirty-six pages are devoted to reproductions of standard perforated screen plates and 25 pages to illustrations of manufactured screens for various purposes in handling coal, cement, ore, etc., including strainers for locomotives and metal spark arresters for locomotive front ends. This company also manufactures elevator buckets, conveyor troughs and flights, stacks, tanks, hoppers, etc., which are also listed in this catalogue. Of special value should be found the tables showing the styles and sizes of perforations and the spaces between holes and maximum widths and gages in steel, according to the United States standard gage, and a number of tables of weights, measures, and gages for coal screens, decimal equivalents, metric conversion tables, etc.

Car Heating Devices.—The Gold Car Heating & Lighting Company, New York, has issued circulars describing the construction and operation of car heating apparatus which the company has recently developed. These are a vapor valve, No. 1112, designed for application on the inside of the car; packless end valve No. 1126, with automatic drip in the valve itself; packless quick opening single and twin supply valves, Nos. 1140 and 1145, respectively, which open and close on a quarter turn; and pop valve No. 1137, a train line safety valve designed to prevent the blowing off of the steam hose in case of excess pressure and also successfully used as a safety valve for hot water circulating systems. Circulars have also been issued describing other Gold devices, including a combination gasket tool No. 1077, for use in applying and removing coupler gaskets; a pressure regulator with a large steam capacity for long passenger trains, No. 1014; steam hose coupler, No. 804-S, with oscillating gasket; and steam hose coupler gasket G-4, for use in steam hose couplers using non-oscillating gaskets.

Railway Mechanical Engineer

Volume 93 May, 1919 No. 5

CONTENTS

OUR CINCINNATI OFFICE

The Simmons-Boardman Publishing Company, publisher of the *Railway Mechanical Engineer,* has opened an office in the First National Bank Building, Cincinnati, Ohio. It will be in charge of R. H. Smith, a member of the business staff formerly connected with our Chicago office, who will look after the interests of the Simmons-Boardman publications, including the *Railway Mechanical Engineer,* Railway Age, Railway Maintenance Engineer, Railway Signal Engineer, Railway Electrical Engineer and the Locomotive and Car Builders' Dictionaries.

Tender Tanks Need Stronger Bracing

One of the common results of collision is to cause the tender tank to slide forward off the underframe, demolishing the cab and in some cases injuring the enginemen. While such accidents are not of frequent occurrence, it is important that every precaution should be taken to prevent personal injuries in such circumstances and for that reason it would seem advisable to fasten tender tanks to the frame in a manner that would prevent the shifting of the tank, at least in so far as it can be avoided in minor collisions. The types of fastenings generally used on rectangular tanks have evidently not been designed with that end in view, but are intended rather to withstand only the pressure occasioned by the shifting of water resulting from brake applications. The weight of the contents of a large tender when fully loaded is more than 100,000 lb. yet this great mass is often secured to the underframe by six or eight bolts ⅞-in. in diameter. This criticism of the fastenings used on tenders does not apply with equal force to cylindrical tanks as they are usually set between headblocks which effectually prevent any shifting. On tenders with rectangular tanks, however, increased safety could no doubt be secured by the use of heavier braces to secure the tanks to the underframe or by forming a depression in the underframe into which the tank could be set.

Railroad Y. M. C. A. Extension

The Railroad Y. M. C. A. is about to enter a national extension movement that promises to double or triple its effectiveness within the next year. There are now about 300 Railroad Y. M. C. A.'s in this country and Canada. The greater part of their energies has been devoted to looking after the physical needs of the trainmen; and the practical results, in the way of increased safety and more efficient operation, are recognized by hard-headed railroad officers throughout the country. Some of the associations have given considerable attention to the needs of shopmen also, and not a few of them have been developed into community centers. The Railroad Y. M. C. A. believes, however, that it has a duty to perform for every individual on the railroads, although they may not be able to use the buildings in the same way as do the men in the train service. There is a big field, for instance, for educational work among certain classes of employees. There is real need in many places for an Americanization program. Many believe that the Railroad Y. M. C. A., with its physical experts, can be a strong factor in helping to develop system athletics and also to carry on a more extended program looking toward the physical needs of the individuals. There are many other phases of the work that might be extended to advantage.

The present extension movement includes a membership campaign this month and a series of campaigns during the fall in order thoroughly to organize the work in all departments for the next year. The extension movement is being very carefully planned, and one interesting development is that the railroad men, themselves, are taking the most aggressive part in promoting it; the secretarial staff is being used largely in an advisory capacity. The importance of this development in the success of the movement can be readily recognized by those who have given critical attention to the various aspects of the industrial problem, particularly so far as they relate to the so-called welfare work or the matter of relations between employers and employees.

Inspection and Test Sectioo Draft Gear Tests

At the invitation of the Inspection and Test Section of the Railroad Administration about 60 representatives of draft gear manufacturers, railroad men and others interested in the draft gear subject, witnessed a series of unofficial demonstrations at the draft gear testing plant of the T. H. Symington Company, Rochester, N. Y., in which was set forth a unique method of recording the action of draft gears under impact between two cars. The purpose of the demonstrations was to give all those interested an opportunity to study the recording apparatus and the methods used in advance of the official tests to be conducted by the Test Section on practically all the well-known types of draft gears. Aside from the unique method of graphically recording the action of the gears under impact, a description of which appears elsewhere in this issue, the outstanding feature of the demonstrations was the spirit of fairness and frankness with which constructive criticism and suggestions were requested and received by those in charge of the tests.

The series of tests under approximately service conditions, which are to follow the public demonstrations, are a part of a program in which complete comparative studies of the various draft gears are to be made. The work so far outlined is dealing with new gears. This, however, is but one phase of the whole draft gear problem. What is required in service is not only a gear possessing the nearest approach to ideal characteristics, but one which maintains throughout a reasonable service life the nearest approach to ideal characteristics. An investigation of this phase of the subject is one requiring a large amount of time and effort over a period of years. The draft gear committee of the Master Car Builders' Association, which is co-operating with the Inspection and Test Section, has been and is investigating this phase of the subject, and it seems reasonable to expect as the result of the efforts of the two co-operating agencies that results of great value eventually will be obtained.

The Mechanical Conventions

The Master Car Builders' Association and the American Railway Master Mechanics' Association will this year meet as the Mechanical Section of the American Railroad Association. The convention, which is to be held at Atlantic City the latter part of June, promises to be the largest and most successful one ever held. The reports will be out early so that the members can digest them before going to the meetings. The Railroad Administration is lending its full aid and support in order to have a representative attendance. The exhibit space, although it has been greatly increased over that required in the record-breaking year, 1913, promises to be inadequate.

The mechanical department officers and foremen should, of course, plan to take full advantage of this convention which has been discontinued since 1916 because of the war. On the other hand, they must recognize that they are on trial and that they will be closely watched not only by the Railroad Administration, but by the higher executive officers. They have a real opportunity to put the mechanical association on a much higher plane than was ever thought of in the past because it will now be possible to pass on its recommendations to the American Railroad Association and to have them made effective, if approved, by the Railroad Administration. Will the mechanical department officers grasp this opportunity and make full use of it?

Various suggestions have been made as to how each road may get the most from meetings of this sort. One of the best is that every man who is sent to the conventions be asked to report in writing those things that came to his attention that he thinks can be applied to good advantage on his own road. It may be that the suggestions will spring from some report presented to the convention or from the open discussion of it. It may be that the exhibits will suggest something or possibly the informal discussions, at the table, in the hotel, or on the train with officers of other roads, or with railway supply experts. If several men are sent from one road, it would seem wise to have each one instructed to investigate those problems which he is best fitted by experience and training to study. Is it not about time for the railroads to make scientific use of meetings of this kind and definitely to plan to get the utmost return from them?

Modernizing Stationary Power Plants

The intensive fuel conservation campaign that has been carried on during the past two years has caused the railroads to give more attention to the condition of stationary power plants. The result has been a remarkable increase in the efficiency of such plants, which many roads had formerly neglected. These economies were effected under the stress of war conditions, but the officers of the railroads should take effective measures to insure the continuance of the splendid performance now being secured. One of the reasons that the condition of stationary power plants was neglected in the past was that the roads had no special organization to supervise their operation but left it in the hands of the general foremen who were primarily shop executives and could hardly be expected to be authorities on the economical operation of power plants. It is evident that an organization charged with the responsibility for maintaining the condition of power plants at a high standard is needed to secure the best results and such a staff should be organized on every road, if it has not already been formed.

The mere fact that a power plant is operating at higher efficiency than ever before does not prove that the plant itself is efficient. During the war it was necessary to keep uneconomical equipment in service because new engines and boilers could not be secured. That difficulty has now been removed and it is advisable at this time to investigate the possibilities of saving by the redesign of existing installations. The question should be considered in the light of present conditions as conclusions based on data secured when lower wages and prices prevailed are sure to be misleading. Far larger expenditures to effect a given saving are justified now because of the great increase in the cost of fuel. There are many railroad power plants operating today with old boilers, perhaps taken from obsolete locomotives, and uneconomical reciprocating engines. In such cases it would almost invaribly prove advisable to install modern boilers and turbines. Aside from the reduction in fuel cost, there is often an opportunity for further saving by a reduction in the number of attendants required at the power house. This is especially true where large shops are supplied with power from several small plants. Such installations though not uncommon represent the extreme in the inefficient utilization of both fuel and labor and should be replaced as rapidly as possible.

Fuel Cooservation and the Movies

Moving pictures are not new in connection with educational work on the railroads. Possibly their most notable application in that field is in connection with the safety-first movement. The Pennsylvania Railroad has, however, gone outside of that field and has prepared some excellent films in connection with the maintenance of equipment, locomotive operation, etc. Moving pictures taken by the Northern Pacific in connection with its fuel conservation campaign were shown at the April meeting of the New York Railway Club. The western roads have always had more or less difficulty with their fuel supply and it has been necessary for them to study conservation methods to a greater extent than on roads in most of the other parts of the country.

A number of years ago the Northern Pacific equipped a fuel instruction car which has been sent back and forth over the system with excellent results. It is not an easy task to interest the average fireman or engineer in the theory of cumbustion and yet those in charge of this work on the Northern Pacific were able to develop a series of demonstrations that not only held the interest of the men, but inspired them to perform their work in such a way as to make the best use of the technical instruction that had been imparted to them. The management felt it necessary to intensify the fuel conservation educational work during the war because of the higher cost of fuel and the number of new men that it was necessary to employ on the locomotives. Careful consideration seemed to indicate that moving pictures could profitably be added to the equipment of the fuel instruction car in order to drive home and emphasize more forcefully the most important factors involved in an aggressive and successful fuel conservation campaign. Fortunately, those in charge recognized the necessity of having these pictures taken under the supervision of a moving picture expert and the results are really remarkable.

It is difficult at first thought to see how moving pictures could be used to demonstrate the advantages of single scoop firing, the abuses of popping, or the wastefulness in handling fuel. The moving picture expert and the fuel instruction expert working together have made it possible to tell the story simply and clearly and with the same effectiveness that is so characteristic of the high grade moving pictures. These pictures have been shown not only in the fuel instruction car on the Northern Pacific, but in various halls and meeting places at the more important cities and division points. When shown in the latter way, the townspeople are often invited to attend and are given suggestions as to the use of fuel in the home that have undoubtedly been productive of good results. An outline of how the work is carried out in detail on the Northern Pacific will be found elsewhere in this issue.

The Piece Work Question

Piece work is now a thing of the past on the railroads. There are those who believe that Director General McAdoo's order No. 8 was directly responsible for this because of the encouragement it gave to the extension of the union labor movement among railroad employees. The most important direct factor, however, was the increase in the hourly rate of the men without any corresponding increase in the piece work rates. It is contended by the Railroad Administration that there was so much dishonesty in the application of piece work that it was in the interests of the railroads to abolish it. Dishonesty, however, is something that cannot very well be instantly cured by rules or regulations. It is something that must be patiently dealt with through extended processes of education, in order to raise the moral standards of the individual or the group. It is doubtful, judging from various investigations that have been made, whether there is not an even greater amount of dishonesty under present conditions than could formerly have existed; this is indicated by the falling off in the productive output of the individual now that piece work has been abolished.

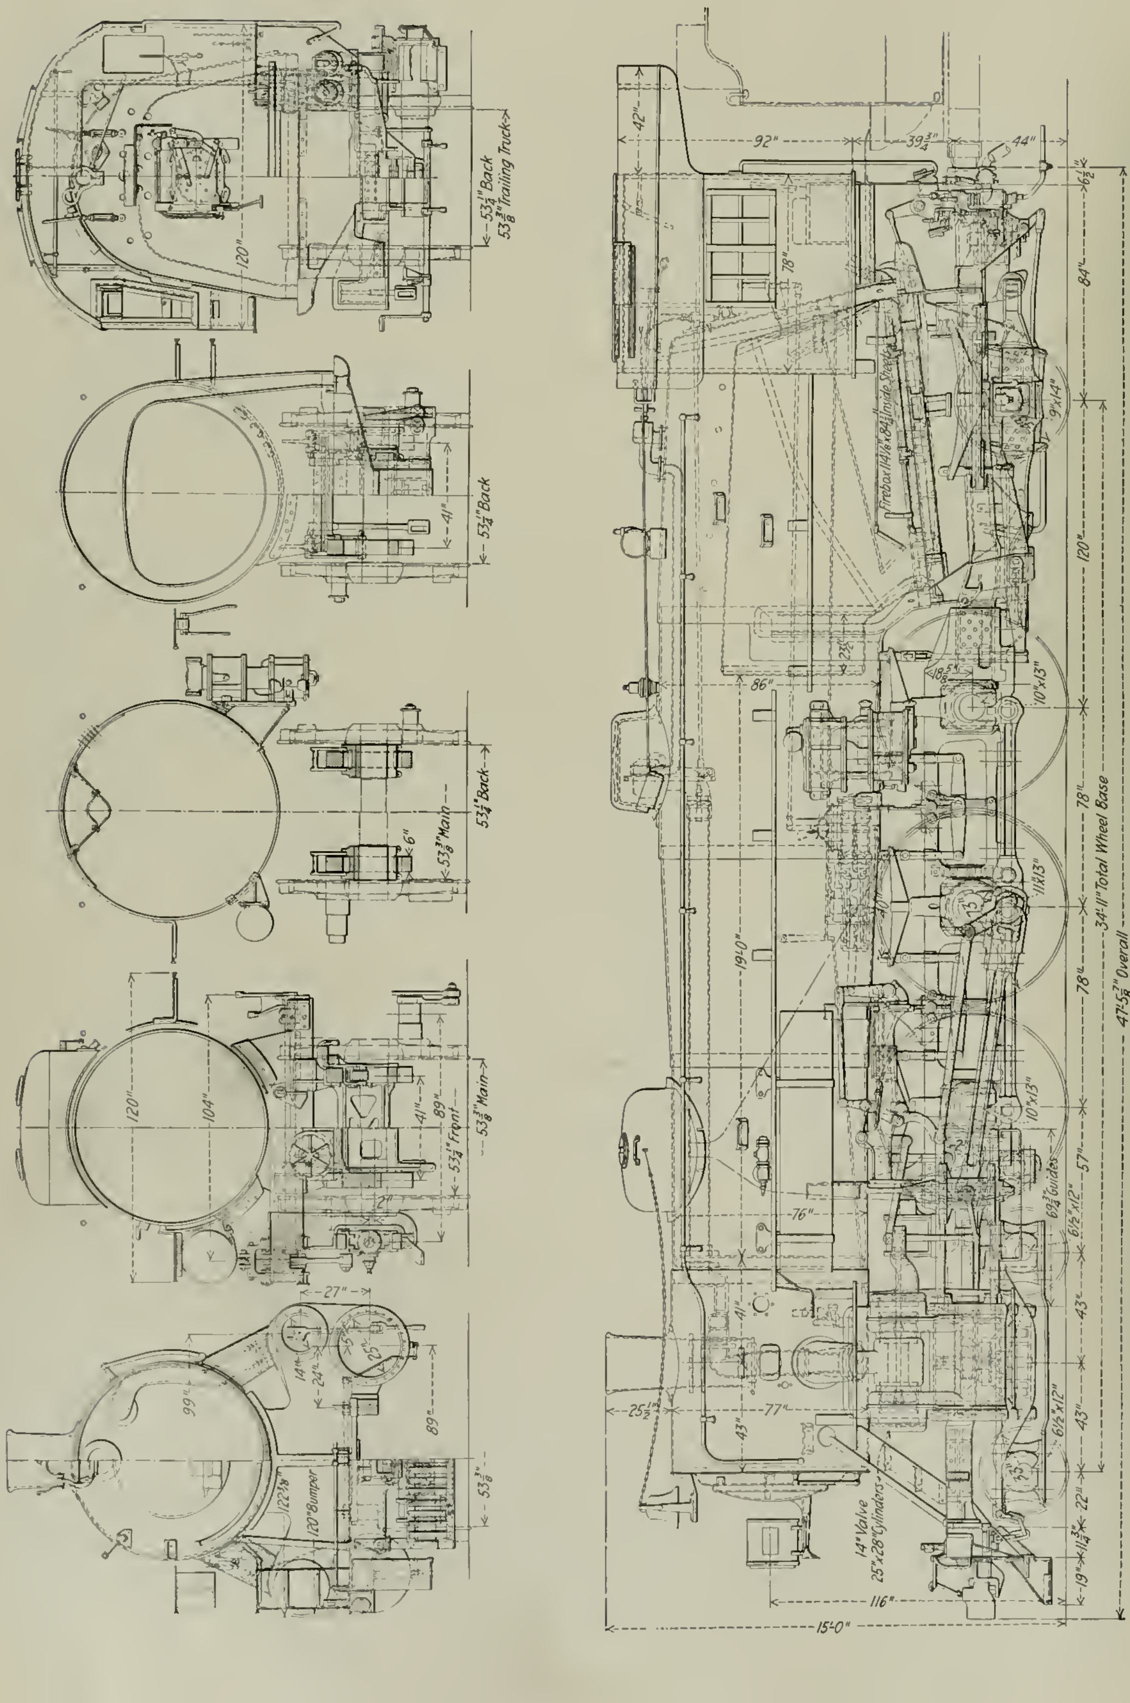
The important thing, however, at this time is not to lament the passing of piece work, but rather to study how to reorganize in such a way as to secure the best possible results under day work conditions. Manifestly, the supervision and practices and methods used formerly cannot give the best results under present conditions. Two things are absolutely vital to a successful solution of the problem. We almost hesitate to mention them, because, although the *Railway Mechanical Engineer* has advocated them for years, comparatively few railroad officers seem to have taken them seriously enough to make a real effort to promote them.

In the first place, a real, definite, aggressive effort must be made to educate not only the apprentices (and very few railroads have done this in the past), but also the men who have been in the service for long periods of time. Just because a man is classed as a mechanic, does not mean that he really understands how to do his job or knows the best way in which to do it. Very few things could be done with such telling results as to go at this matter in a serious way and utilize the best thought along these lines which has been developed in the industries and also in different branches of our army during the war. The next thing that should be done is to establish real schedules for doing the work, and this is particularly true in the locomotive repair shops. Not the least important result of the installation of such schedules is that weaknesses in the organization or defects in the methods and practices are automatically located and corrected. These suggestions are not theoretical. They are eminently practical and have been used with excellent results. It is unfortunate, however, that mechanical department officers as a whole have not had sufficient vision to recognize their value and to put them into effect.

NEW BOOKS

Proceedings of the International Railway Fuel Association. Edited by J. G. Crawford, secretary. 194 pages, 6 in. by 9 in., bound in leather. Published by the association, J. G. Crawford, secretary, 702 East 51st street, Chicago. Price, $1.50.

The tenth annual convention of the International Railway Fuel Association, which was held in Chicago last May, was an extremely important one, as it convened under the direct auspices of both the Railroad and Fuel Administrations. No better collection of railway fuel men was brought together at one gathering than at this convention. The papers read were not only inspiring, but full of great merit, and the prominence of the men that addressed the convention made these proceedings of great value. This book is a complete report of the convention and includes the following papers: Railroads and Their Relation to the Fuel Problem, by R. H. Aishton, regional director, U. S. R. A.; What the Canadian Railways Have Been Doing to Conserve Fuel, by Thomas Britt, general fuel agent, Canadian Pacific; Motive Power Men and Fuel Economy, by Robert Quayle, general superintendent motive power, Chicago & North Western; The Railroads' Industrial Army, by W. S. Carter, director, Division of Labor, U. S. R. A.; Relation of Locomotive Maintenance to Fuel Economy, by Frank McManamy, assistant director, Division of Operation, U. S. R. A.; Need for Fuel Conservation, by P. B. Noyes, director, Conservation Division, Fuel Administration; Fuel Oil and the War, by M. L. Requa, director, Oil Division, Fuel Administration; and Individual Effort Toward Fuel Saving, by Eugene McAuliffe of the Railroad Administration.



Elevation and Sections of the Standard Light Pacific Type Locomotive

Standard 4-6-2 Type Locomotives

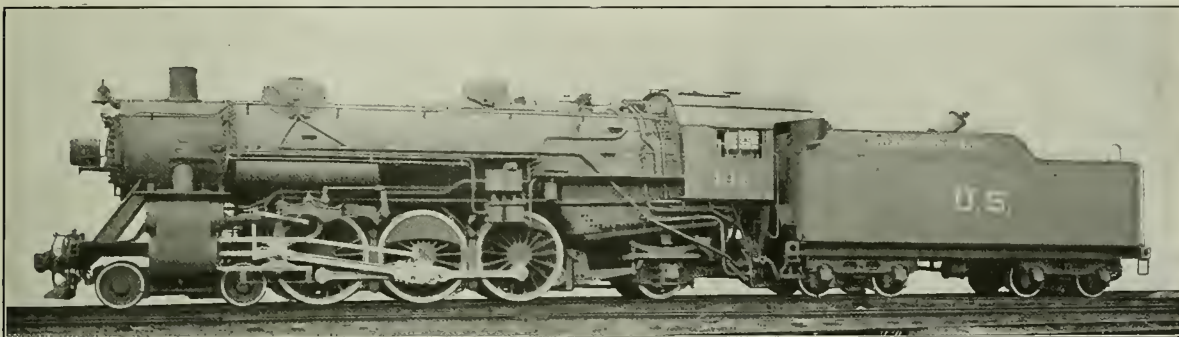
Both Light and Heavy Classes Have Many Details Interchangeable with the Other Standard Designs

The first of the two classes of Pacific type locomotives built to the United States Railroad Administration's standard designs have recently been turned out of the Richmond Works of the American Locomotive Company, the light locomotive for delivery to the Atlantic Coast Line and the heavy locomotive for delivery to the Erie. The light locomotive is one of a total of 59 of these locomotives which have been ordered by the Railroad Administration, 26 to be built by the American Locomotive Company and 33 by the Baldwin Locomotive Works. Orders have been placed for a total of 20 of the heavy locomotives, 10 with each of the above mentioned builders.

The light Pacific type was designed on the basis of driving wheel loads of 55,000 lb. per axle and has a total weight of 277,000 lb. in working order. The actual driving axle loads are 54,000 lb. each, and a tractive effort of 40,700 lb. is developed. In Table I will be found a comparison of this locomotive with a number of others of the same type designed on the basis of approximately the same axle loads. It will be seen that the standard locomotive is somewhat similar in its proportions to the Missouri, Kansas & Texas locomotive, which, however, has more heating surface, but a considerably smaller grate and a smaller ratio of firebox heating surface to total heating surface.

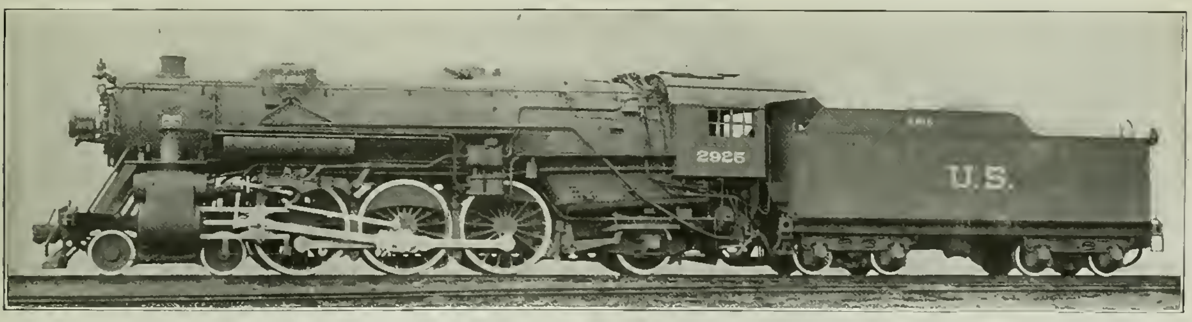
The design of the heavy Pacific locomotive was based on driving axle loads of 60,000 lb. The actual weight on drivers, however, is 197,000 lb., equivalent to slightly less than an average of 66,000 lb. on each axle. The total weight of this locomotive in working order is 306,000 lb. and it has a maximum tractive effort of 43,900 lb.

In Table II will be found a comparison of this locomotive with several other heavy Pacific type locomotives. The heavy standard locomotive compares more closely with the Pennsylvania K4s Pacific than with any of the others. It has about 4,000 lb. less weight on drivers than the Pennsylvania locomotive, with a total weight 3,000 lb. less, and on a comparative basis is rated at 600 lb. less starting tractive effort. A comparison of the heating surfaces of the two locomotives would indicate that the Pennsylvania locomotive had a considerably greater capacity for high sustained speed when handling similar loads.

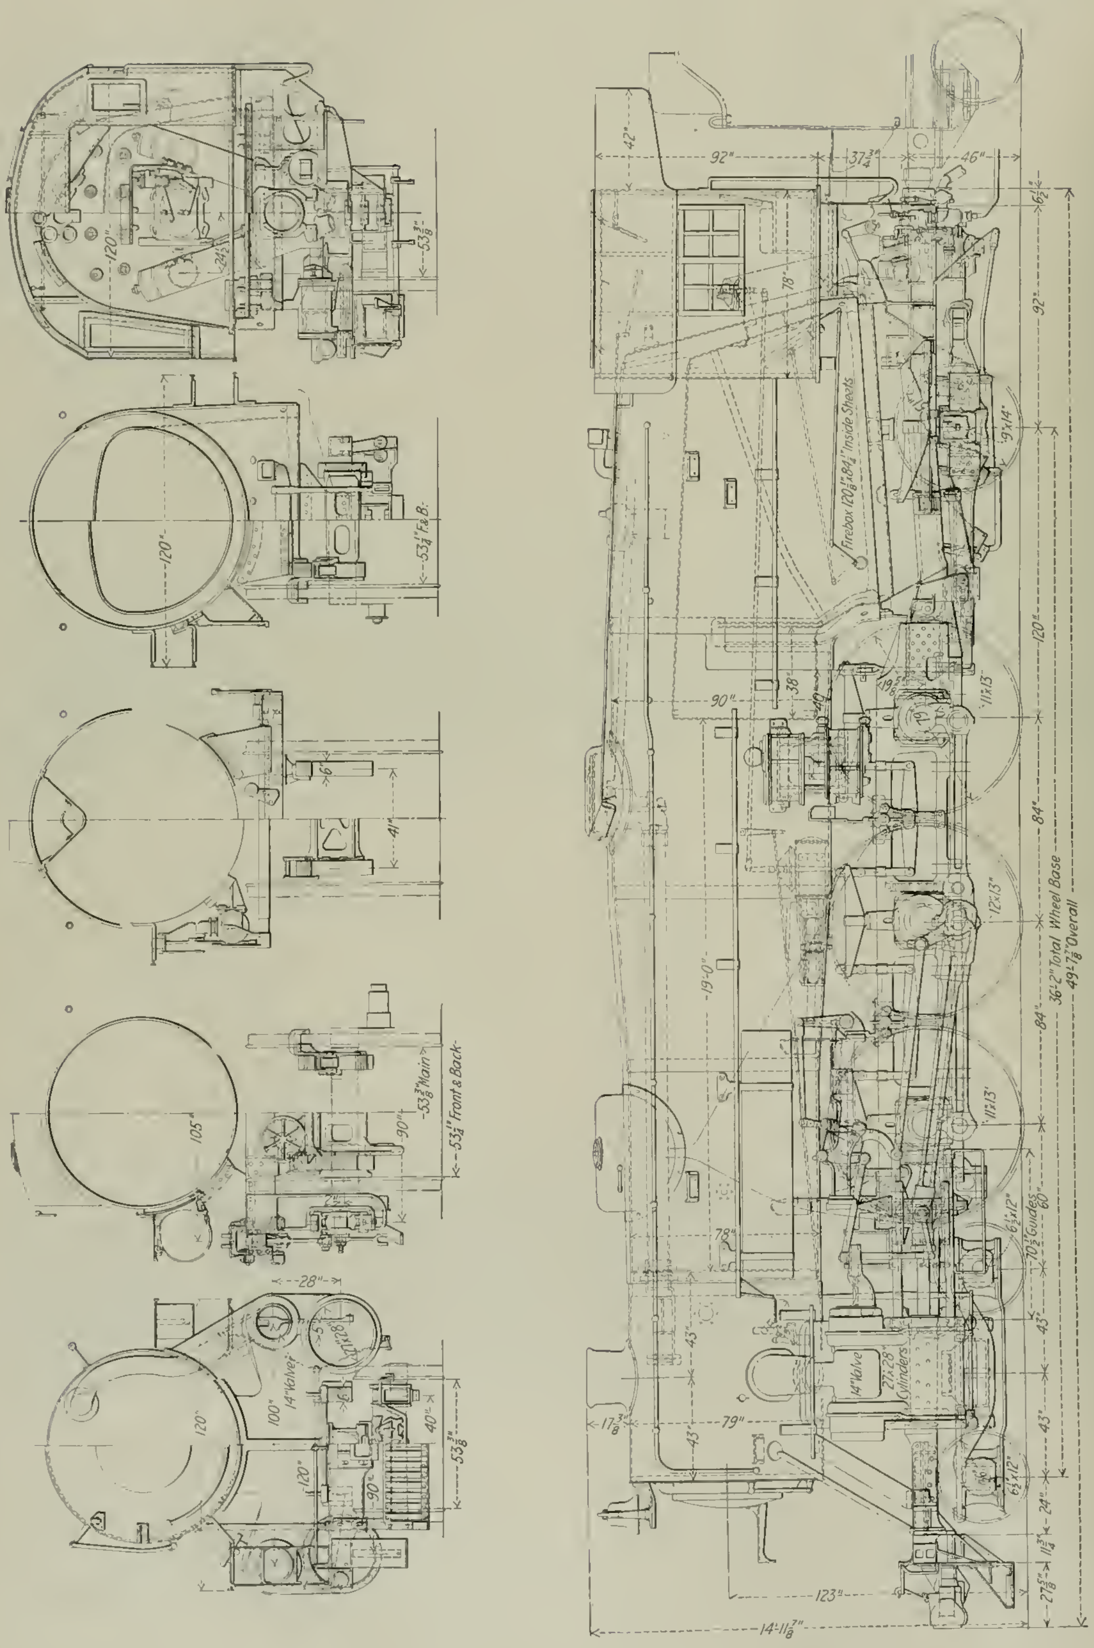


The Standard Light Pacific Type Locomotive

The boilers of the two standard Pacific type locomotives are generally similar in construction, both being of the conical wagon top type with combustion chamber fireboxes. The outside diameter at the first ring of the two boilers is 76 in. and 78 in., respectively, increasing to 86 in. and 90 in., respectively, at the dome course. The light locomotive has 188 2¼-in. tubes and 36 5½-in. flues, while the heavy locomotive has 216 tubes and 40 flues of the same diameters. The tubes of both locomotives are 19 ft. long, while the combustion chamber of the light locomotive is 23½ in. long and that of the heavy locomotive 38 in. long. The maximum diameter of the boilers at the dome course is 86 in. for the light locomotive and 90 in. for the heavy locomotive. The light locomotive is hand fired, while the heavy engine is equipped with a Duplex stoker.

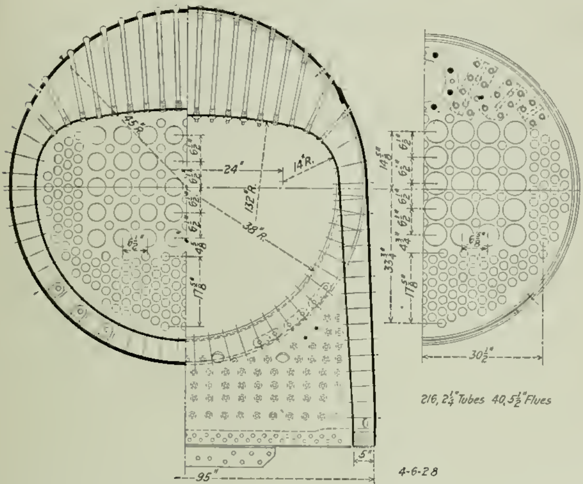


The Railroad Administration Standard Heavy Pacific Type Locomotive



Elevation and Sections of the Standard Heavy Pacific Type Locomotive

The design of the frames for both types is essentially the same. Both are of the single front rail type, each frame being cast in one piece with a splice back of the rear driving wheels for Commonwealth cradle castings. In both cases the frames are six inches wide. The lighter frames have a depth of top rail of 6⅛ in. over the driving boxes and a minimum depth of 5⅛ in. between the drivers. The maximum and minimum depths of the lower rail are 4¼ in. and 3¾ in.,



Half Sectional Views of the Firebox and Combustion Chamber and Half Tube Sheet Elevation

respectively. The frames for the heavy Pacific have a depth over the driving boxes of 7⅛ in. and a minimum depth of top rail of 6 in., while the maximum and minimum depths of the lower rail are 4¾ in. and 4¼ in., respectively.

The cylinders of both types are similar in design to those on all of the other single unit standard locomotives and both are designed for the use of 14-in. piston valves. Those of the light Pacific type are 25 in. in diameter, while the heavy locomotives have 27-in. cylinders, the stroke being 28 in. in both cases. The pistons are of the single plate dished type, used on all the other locomotives and that of the light Pacific interchanges with the crosshead of the eight-wheel switcher and the light Mikado type locomotive. While none of the cylinder designs are interchangeable, the front and back heads

Table I—Comparison of Light Pacific Type Locomotives

Road	U. S. R. A.	M. K. & T.	C. B. & Q.	N. Y. N. H. & H.

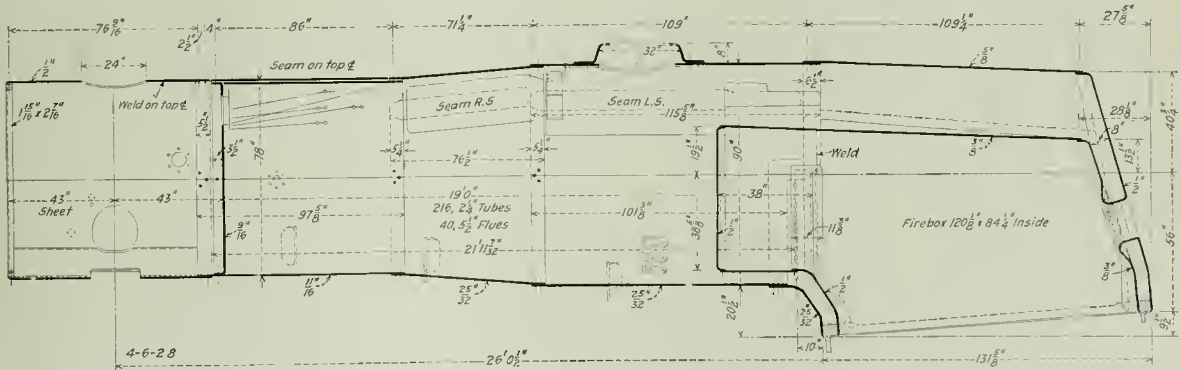
*For anthracite coal.

Pacific interchanging with the heavy Mikado and the light Santa Fe and Mountain type locomotives.

Both the main and side rods are of channel section, the rod design for all of the standard locomotives being the same

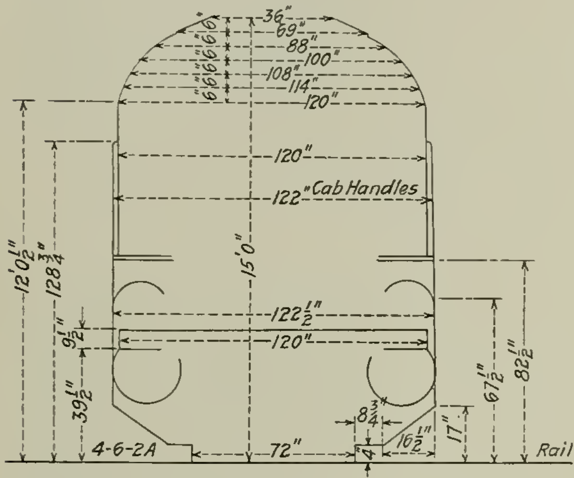


Boiler for the Heavy Pacific Type Locomotive

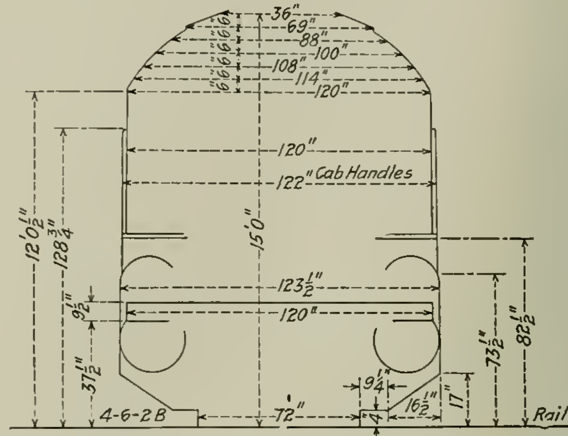
the specifications calling for either cast or rolled steel, with a cast iron bull ring and packing rings of Hunt-Spiller gun iron. In both cases the cylinders and valve chambers are fitted with the Hunt-Spiller gun iron bushings. The piston and rod of the light Pacific type are interchangeable with those of the eight-wheel switcher, while the piston on the heavy Pacific type interchanges with that used on the heavy Mikado and Mountain type locmotives and the light Santa Fe type. The crosshead is also essentially the same as that in details with the exception of the necessary variation in dimensions. The two Pacific type locomotives are the only ones having the channel section side rods, the others all being of slab section.

Wherever the journal sizes permit, the driving boxes have been made interchangeable on all of the locomotives. The light Pacific type locomotive has main journals 11 in. in diameter by 13 in. in length, while the front and back journals are one inch less in diameter. The front and back driving journals of the heavy Pacific are the same size as those of the main journals on the light Pacific, while the main journals of the heavier locomotive are 12 in. in diameter by 13 in. in length.

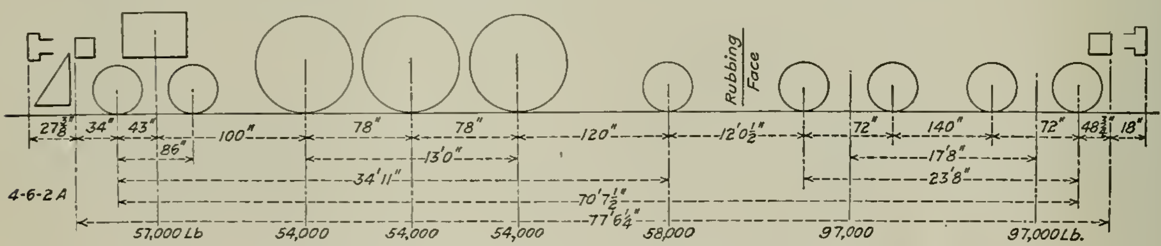
Both locomotives have the constant resistance type engine truck with 6½-in. by 12-in. journals and 33-in. wheels, while the trailer trucks are of the Cole-Scoville design with 43-in. wheels and 9-in. by 14-in. journals. A considerable degree of interchangeability exists between the details of this type of truck in use on the standard Mountain and Pacific type locomotives, although complete interchangeability of the trucks as a whole has not been maintained in every case.



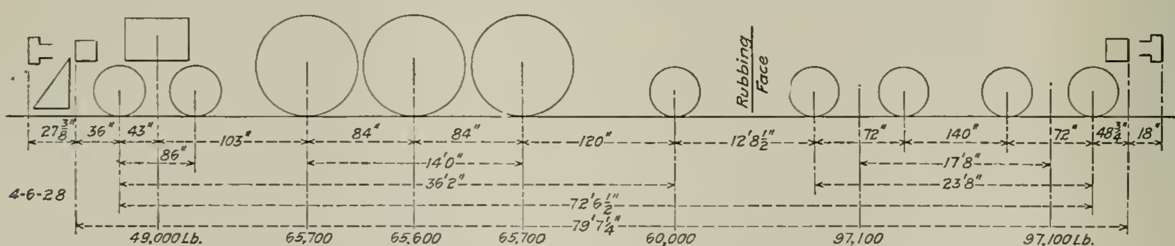
Clearance Diagram for the Light Pacific Type Locomotive



The Heavy Pacific Type Clearance Diagram



Distribution of the Weight of the Light Pacific Type Locomotive



Distribution of the Weight of the Heavy Pacific Type Locomotive

The tenders of both locomotives are built with Commonwealth cast steel frames and have tanks of 10,000-gal. capacity. The tender trucks for both are of the Commonwealth equalized type, differing from the trucks under the heavy Mountain type, which were equalized swing motion trucks of the locomotive builder's design.

Aside from the parts already mentioned a large measure of interchangeability has been carried throughout the various standard designs, including a large number of minor details, such as rod brasses, grate frames, bumper beams, many of the small castings, and in a number of cases, crank pins, axles and springs as well. A complete list of the specialties on all of the standard locomotives was published in the March, 1919, issue of the *Railway Mechanical Engineer,* on page 137.

Tonnage rating charts are shown, which were prepared by H. S. Vincent, and the clearance and wheel load diagrams were prepared by F. P. Pfabler, chief mechanical engineer, division of operation, of the Railroad Administration. The distribution of wheel loads as shown are actual weights of the completed locomotives.

The principal dimensions and data for the two Pacific type locomotives are as follows:

General Data

	Light 4-6-2	Heavy 4-6-2
Gage	4 ft. 8½ in.	4 ft. 8½ in.
Service	Passenger	Passenger
Fuel	Bit. coal	Bit. coal
Tractive effort	40,700 lb.	43,900 lb.
Weight in working order	277,000 lb.	306,000 lb.

I. C. C. REVISES LOCOMOTIVE INSPECTION RULES

On September 20, 1917, the Interstate Commerce Commission issued an order putting into effect a number of modifications and suspensions of the locomotive inspection rules. The changes were made at the request of the railroads because of the difficulty of meeting some of the requirements of the rules with a shortage of competent labor and a lack of sufficient material, without seriously curtailing the supply of motive power to handle the extraordinary traffic movement required to supply the war needs of the country. Since the signing of the armistice the readjustment of the industrial activities of the country and the demobilization of the army have changed the conditions which the modifications in the rules were intended to meet. An order reciting these facts, effective May 1, 1919, has been issued canceling the order of September 20, 1917, but making permanent such of the provisions of that order as experience has demonstrated may be made permanent without adversely affecting the safety of operation.

The new order modifies Rules 2, 10, 16, 23, 110, 112, 128, 142 and 150 to read as follows:

Rule 2—The lowest factor of safety for locomotive boilers, which were in service or under construction prior to January 1, 1912, shall be 3.25.

Effective October 1, 1919, the lowest factor shall be 3.5.

Effective January 1, 1921, the lowest factor shall be 3.75.

Effective January 1, 1923, the lowest factor shall be 4.

Rule 10. Flues to be Removed—All flues of locomotive boilers in service, except as otherwise provided, shall be removed at least once every four years for the purpose of making a thorough examination of the entire interior of the boiler and its bracing. After the flues are taken out, the inside of the boiler must have the scale removed and be thoroughly cleaned and inspected. The removal of flues will be due after 48 calendar months' service, provided such service is performed within five consecutive years. Portions of calendar months out of service will not be counted. Time out of service must be properly accounted for by out of service reports and notations of months claimed out of service made on the back of each subsequent inspection report and cab card. The period for removal of flues, upon formal application to the chief inspector, may be extended, if investigation shows that conditions warrant it.

Rule 16. Lagging to be Removed—The jacket and lagging shall be removed at least once every five years and a thorough inspection made of the entire exterior of the boiler while under hydrostatic pressure. The jacket and lagging shall also be removed whenever on account of indications of leaks the United States inspector or the railroad company's inspector considers it desirable or necessary.

The modification granted in Rule 16, in the Commission's Order of September 20, 1917, on account of the war, in which the date for removal of jacket and lagging was advanced for a period equivalent to the duration of the war, such advanced period shall be considered two years.

Rule 23. Method of Testing Flexible Staybolts with Caps—All flexible staybolts having caps over the outer ends shall have the caps removed at least once every two years, and also whenever the United States inspector or the railroad company's inspector considers the removal desirable in order to thoroughly inspect the staybolts.

The firebox sheets should be examined carefully at least once a month to detect any bulging or indications of broken staybolts. Each time a hydrostatic test is applied, the hammer test required by Rules 21 and 22, shall be made while the boiler is under hydrostatic pressure, not less than the allowed working pressure, and proper notation of such test made on Form No. 3.

Rule 110. Time of Cleaning—Distributing or control valves, reducing valves, triple valves, straight-air double-check valves and dirt collectors shall be cleaned as often as conditions require to maintain them in a safe and suitable condition for service, but not less frequently than once every six months.

Rule 112. (a). Piston Travel—The minimum piston travel shall be sufficient to provide proper brake shoe clearance when the brakes are released.

(*b*). The maximum piston travel when locomotive is standing shall be as follows:

Cam type of driving wheel brake	3½ in.
Other forms of driving wheel brake	6 in.
Engine truck brake	8 in.
Tender brake	9 in.

Rule 128 (a). Rods, Main and Side—Cracked or defective main or side rods shall not be continued in service.

(*b*) Autogenous welding of broken or cracked main and side rods not permitted.

(*c*) Bearings and bushings shall so fit the rods as to be in a safe and suitable condition for service, and means be provided to prevent bushings turning in rod. Straps shall fit and be securely bolted to rods.

(*d*) The total amount of side motion of rods on crank pins shall not exceed ¼ in.

(*e*) Oil and grease cups shall be securely attached to rods, and grease cup plugs shall be equipped with suitable fastenings.

(*f*) *Locomotives Used in Road Service*—The bore of main rod bearings shall not exceed pin diameters more than 3-32 in. at front or back end. The total lost motion at both ends shall not exceed 5-32 in.

(*g*) The bore of side rod bearings shall not exceed pin diameters more than 5-32 in. on main pin, nor more than 3-16 in. on other pins.

(*h*) *Locomotives Used in Yard Service*—The bore of main rod bearings shall not exceed pin diameters more than ⅛ in. at front end, or 5-32 in. at back end.

(*i*) The bore of side rod bearings shall not exceed pin diameter more than 3-16 in.

Rule 142 (a) Spring Rigging—Springs and equalizers shall be arranged to insure the proper distribution of weight to the various wheels of the locomotive, maintained approximately level, and in a safe and suitable condition for service.

(b) Springs or spring rigging with any of the following defects shall be renewed or properly repaired:

(*c*) Top leaf broken or two leaves in top half or any three leaves in spring broken. (The long side of spring to be considered the top.)

(*d*) Springs with leaves working in band.

(*e*) Broken coil springs.

(*f*) Broken driving box saddle, equalizer, hanger, bolt, or pin.

Rule 150 (a) Driving and Trailing Wheel Tires—The minimum height of flange for driving or trailing wheel tires, measured from tread, shall be one inch for locomotives used in road service, except that on locomotives where construction will not permit the full height of flange on all drivers, the minimum height of the flange on one pair of driving wheels may be ⅝ in.

(*b*) The minimum height of flange for driving wheel tires, measured from tread, shall be ⅞ in. for locomotives used in switching service.

(*c*) The maximum taper for tread of tires from throat of flange to outside of tire, for driving and trailing wheels for locomotives used in road service, shall be ¼ in., and for locomotives used in switching service, 5-16 in.

(*d*) The minimum width of tires for driving and trailing wheels of standard-gauge locomotives shall be 5½ in. for flanged tires, and 6 in. for plain tires.

(*e*) The minimum width of tires for driving and trailing wheels of narrow-gauge locomotives shall be 5 in. for flanged tires, and 5½ in. for plain tires.

(*f*) When all tires are turned or new tires applied to driving and trailing wheels, the diameter of the wheels on the same axle, or in the same driving wheel base, shall not vary more than 3-32 in. When a single tire is applied, the diameter must not vary more than 3-32 in. from that of the opposite wheel on the same axle. When a single pair of tires is applied, the diameter must be within 3-32 in. of the average diameter of the wheel in the driving wheel base to which they are applied.

(*g*) Driving and trailing wheel tires with any of the following defects shall not be continued in service:

(*h*) Slid flat spot 2½ in. or more in length; flange 15-16 in. or less in thickness, gaged at a point ⅜ in. above the tread, or having flat vertical surface 1 in. or more from tread; tread worn hollow 5-16 in. on locomotives used in road service, or ⅜ in. on locomotives used in switching service; flange more than 1½ in. from tread to top of flange. (See figs. 1, 2 and 3.)

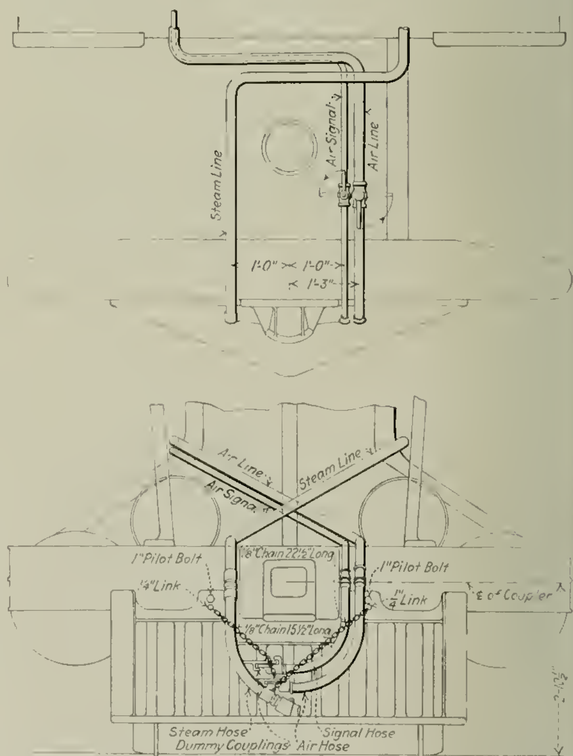
Note—The determination of flat spots and worn flanges shall be made by a gage as shown in fig. 8, and its application to defective tires, as shown in figs. 9, 10 and 11.

LOCATION OF TRAIN PIPES ON THE FRONT OF THE LOCOMOTIVE

BY H. SNECK
Supervisor of Air Brakes, Buffalo, Rochester & Pittsburgh

It is general practice to run the brake pipe and signal line on the front end of the locomotive out over the pilot beam on the right or engineman's side and the car heating steam line on the left side.

The front of a locomotive is the only piece of rolling stock that does not have the brake pipe on the right side when facing the front, according to the M. C. B. standard. Therefore, when coupling the hose on the front end of one locomotive to the rear of another locomotive or to a car both hose come together on the right side, causing the hose to buckle. This, to a great extent, reduces the opening through the hose and prevents quick action from running by this point.



Arrangement of Train Line Pipes on the Front of Buffalo, Rochester & Pittsburgh Locomotives to Comply with M. C. B. Standard on Cars

The new location in which the pipes are crossed is just the reverse of the old and was brought about as a remedy for the inability at times to get the emergency application of the brakes to run by the second engine in a two-engine train. It will be noted in the drawing that all the hose cross under the coupler when connected up, which prevents any possibility of buckling. The M. C. B. standard dimensions may be used for the location of each pipe.

The Buffalo, Rochester and Pittsburgh has used this method on all locomotives for more than 10 years and it has proved very satisfactory.

Fuel Saving Methods on the N. P.

Fuel Instruction Car Employs Laboratory Demonstrations and Moving Pictures, and Brings Results

BY M. A. DALY
Fuel Supervisor, Northern Pacific

THE Northern Pacific links together Wisconsin, Minnesota, North Dakota, Montana, Idaho, Washington, Oregon and Western Canada; yet, we don't feel that we are very far from the east. I suppose this is because every year we go to West Virginia and Pennsylvania to buy coal with which to supply a large percentage of our locomotives throughout the following year. Nevertheless, it is a long distance to haul coal. The average rail haul is about 200 miles from the eastern mines to the Lake Erie ports, where the coal is loaded into ships. It is a 900-mile boat haul from the Lake Erie ports to Duluth. At Duluth the coal is again loaded into cars and hauled by rail as far west as the Missouri River, a distance of 500 miles. By the time it reaches its destination the coal has become very expensive —and that is just the reason why our people have felt compelled to do everything they could to get the greatest possible amount of heat out of every ton of coal used.

The necessity developed a campaign of fuel economy, beginning about eight years ago, and we have kept right at it ever since. It has been largely an educational movement, designed to interest not only the men who handle coal, but the officers who supervise the operating performances.

FUEL INSTRUCTION CAR

To introduce the work a passenger coach was fitted up as a traveling lecture room.** Chemical and physical apparatus was installed to demonstrate the properties of coal and the chemistry of combustion. Stereopticon views and motion pictures were added from time to time, as needed.

In passing over the line, at suitable intervals, the instruction car was located at places convenient for the men at the various division points. Locomotive and power-plant engineers and firemen, interested roundhousemen, despatchers, yardmasters, superintendents, trainmasters, master mechanics, road foremen and other local officers presented themselves for the various lectures. The responsibilities of individuals were reviewed, proper methods of handling coal were emphasized and fascinating possibilities were pointed out.

With all who are directly or indirectly concerned with fuel the plan has been to realize a common understanding of its great value, develop an appreciation of the actual losses in known wasteful practices, and to anticipate the enormous savings to be accomplished by concerted efforts, systematically and persistently applied.

It was made clear from the start that fuel saving was a non-departmental matter, that instead of being the work of one department it was a matter of interest for all departments. And it was easily shown that there was enough available glory to be obtained so that all departments could take some of the credit.

Beginning with the preparation of coal at the mines attention is given to all phases of distribution, consumption and accounting. But, since approximately 95 per cent of all railroad fuel is consumed on locomotives, it naturally follows that special attention is given to its use on locomotives. Just as some engines through improper condition may burn more coal than others (of the same class), so, some enginemen through improper operation may burn more than other

*Abstract of an address before the New York Railroad Club, April 18, 1919.

**A description of the car and an outline of the lectures which are given was published in the *Railway Age Gazette* of May 1, 1914, page 976.

enginemen, and some firemen through improper handling may burn more than other firemen.

According to observations on various railroads, one fireman may burn as much as three tons per trip more than other firemen in the same service, using the same engine, on a similar train, over the same piece of track, under identical conditions. Now, men in general take a natural pride in doing good work. Once show a man that he can give better service with less labor and you have confronted him with a double argument which is seldom wholly lost. Once convince a fireman that when coal is properly placed in the firebox it will make more steam and less clinkers, that the required steam pressure will be more uniform and more certain, that the trip will require less shoveling and less shaking, and you have a fireman who is on his way to open-minded appreciation of instructions.

About all that is required for good firing is a little care and attention, with proper intention. Any instructed fireman can supply the necessary care and attention, and become a good fireman.

TALKS IN INSTRUCTION CAR

Of the lectures in the instruction car, perhaps the thing that most impressed our enginemen and firemen were the chemical experiments illustrating how combustion may take place. In one instance, a wide mouthed bottle was inverted over a lighted candle to prove that when the contained oxygen was consumed burning stopped. Hydrogen was prepared. With a proper supply of oxygen a lighted match could explode it. With no oxygen present, this highly inflammable gas would extinguish a lighted match. Thus, after a series of similar experiments, it was conclusively shown that to have burning, oxygen must touch the fuel. Accordingly, it became clear to enginemen and firemen why it was necessary to have a draft bringing air through the grates into the firebox, and why air must constantly supply new oxygen to the pieces of coal throughout the burning firebed.

Considering then that since oxygen of the air is necessary for burning, and, since air cannot well pass through clinkers or banks in a firebed, it follows that clinkers and banks are not desirable things to have in a firebox. Following this line of thought, it is but a step to consider that while gas is being driven from each piece of coal that lies in the firebox, this gas cannot be burned unless oxygen comes in contact with it. It then becomes obvious that the best firebox condition is possible only when air is coming through every square foot of grate surface.

In one of the demonstrations a pound of coal is put into a retort, heat is applied and the gases driven off. The coke remaining is weighed and computations made on a blackboard, bringing out the fact that approximately one-half of the heat value of coal is in the gas. The gases themselves, having been collected in transparent jars, are then burned in various ways to illustrate proper and improper combustion. They can be burned with a clear, white flame, giving off intense heat, or may be burned with a dull, yellow, smoky flame, developing very little heat. One smoky flame and one white flame are placed under separate test tubes containing equal amounts of water. The white flame evaporated completely the water above it, using much less gas than the smoky flame. We had the smoky flame when the supply of oxygen was not sufficient to burn the flow of gas; that is, the smoky, imperfect, low-heat, extravagant combustion took place when the supply of gas was greater than could be burned by the available oxygen.

Here again was a direct comparison with the locomotive firebed. A fire that is fed, at short intervals, with small quantities of coal, properly scattered over the surface of the firebed, will give a dazzling white fire to be compared with the dull red fire that comes when a large quantity of coal is thrown in at one time. To the enginemen and firemen this latter "slugging" method begins to take on a new aspect; the greater the quantity of coal thrown in at one time the greater the quantity of gas which may be rapidly driven off. And of course, when the quantity of gas exceeds the proportionate flow of oxygen through the grates, the excess gas cannot be burned and will pass off as smoke, through the stack—wasted. Then they correctly conclude that since 50 per cent of the heat value of the coal is in the gas, their aim must be to burn as much of the gas as possible, and thus they are intellectually persuaded to lean toward light and frequent firing, which is clearly the more economical method, and at the same time much the easier.

Firemen were encouraged to experiment for themselves, and it was not long before enginemen and firemen were boasting of the fact that they were making trips on one or more tons of coal less than formerly.

Competition is encouraged by comparing different crews on similar runs, between certain points. Road foremen use tally counters to ascertain the number of scoops, while a pocket scales will tell the weight of an average scoop, allowing the determination of the approximate number of pounds of coal used on the trip.

This all becomes very interesting when facing the fact that our Mikado locomotives often leave terminals with $125 worth of coal on their tenders, and each locomotive may take on an additional $50 or $60 worth of coal at some intermediate coal dock.

Our strong point with firemen has been that the more care exercised in placing the coal in a firebox the less coal will be required on the trip. This fact was taught not only verbally but by actual demonstration. So successfully has the plan worked out that we have men who actually fire our heaviest Mikados with one scoop to a fire. Now, single scoop firing is very particular work. Every fireman has not the patience to work it out, to master it. We do not advocate it, but we do point it out as an ideal to which firemen may aspire. Those who can approach it use less coal than formerly. Those who can master it use the least coal with the least labor. We do not ask our firemen to fire to a diagram.

THE MOVIES

The value of self-criticism has not been overlooked as a means of aiding enginemen and firemen to raise the character of their service. By the use of motion pictures they have been enabled to see themselves as others see them. The result has been very gratifying.

(Mr. Daly then showed several hundred feet of motion picture films which demonstrated in a most forceful way the advantages and disadvantages of proper and improper firing and the losses due to wastefulness and carelessness. For instance, with the moving picture camera mounted on the tender, pictures were shown of firing by the single scoop method as compared to the ordinary methods. Not only did the pictures clearly show the movements of the fireman but at intervals the camera was elevated so that a view was obtained over the top of the cab showing the results at the stack. Pictures were also taken from the roadside showing the trains in motion and the effect of the proper and improper methods of firing as reflected in the amount of smoke from the stack.

Moving pictures were also shown of the wastefulness of overloading tender tanks, of carelessness in unloading and cleaning out coal cars, and of the losses due to popping. In order to maintain interest on the part of the men, particularly during the period of the war, pictures were interposed showing the great need for fuel conservation in order to reduce to a minimum the number of cars required. Such pictures, for instance, might show the results of the freight congestion at the eastern seaboard, or the great trains of troops and munitions which it was necessary to transport, etc.

Typical individual pictures selected from the films are shown in the photographs, but, of course, they give no adequate idea of the forceful way in which poor or indifferent methods of firing can be contrasted by means of the movies.

RESULTS

Mr. Daly did not include in his paper any figures as to results secured on the Northern Pacific, but during the discussion he was questioned as to this and as to the size of the locomotives on the Northern Pacific. His reply showed that the average tractive power of the freight locomotives in service was high. He was also able to furnish the following figures as to fuel consumption which are taken from reports recently issued by the Fuel Conservation Section of the United States Railroad Administration:

EDITOR.)

DISCUSSION BY GEORGE M. BASFORD

Let's get our heads out of the sand. Our nation must get out of the wasteful class. It must get over thinking that its resources are limitless. It must conserve many things, first of all coal. Coal comes in train loads. There are other train loads waiting to be moved and all hands on a railroad naturally feel that anything so easy to get is somewhat like dirt and therefore is cheap.

With wages up, probably to stay, and with coal costs doubled, the locomotive must be looked at in a new light. The present generation is to be held accountable for its stewardship. In a large sense it is to be tried on the charge of wasting coal.

Let us acknowledge and appreciate everything that the government and the railroads are doing to improve the firing of coal and the management of the coal itself. Great improvements are being made in this direction. However, we must not overlook the fact that the best of coal and the best management of the fire may be nullified by the locomotive itself if the machine is not what it ought to be. This is being overlooked today in the case of thousands of old engines.

What is wanted is to put the locomotive in shape for its various parts to pull together to use the coal to best advantage. Boilers should not send wet steam to the cylinders. Fireboxes should not send unmixed and therefore unburned gases to the flues. Tender tanks should not send water to the boiler unheated by waste heat. There are a lot of other ways in which many old engines are working against themselves for lack of modern means for conserving their faculties and abilities. Even the best of firing of itself cannot insure the proper development of the heat of the coal or its use in producing power. The engine must have the means properly to make and use the power that is in the coal.

How about the 25,000 locomotives that as to power remain as they were built and are ten or more years old? Unless these engines are brought up to date they are antiquated, obsolete and an encumbrance as to power and as to the waste of fuel. Many of these engines were ten or more years old when they were built. This was because of bridge or other weight limitations. Today they are in the class of the old Rodman cast iron cannon, whereas we have Hindenburg lines to deal with today.

Think for a moment of the taking of the Hindenburg line. No small factor in the achievement was the confidence the men had in their equipment. They knew that this country had not sent them out without the best of everything to fight with. The inspiration of this confidence was necessary to success. Now think of the men who are handling these old engines we are talking about. What coal saving effort can you expect of men who know that the machine you give them wastes coal faster than they can save it?

In six years the coal consumption of locomotives has gone down from 3.6 lb. per draw bar horsepower to 2.25 lb., the figures being taken at the most efficient power of the engine. No parallel improvement has ever been made in six years in any other branch of engineering development.

This has been done by intelligent use of improved designs and by the employment of labor and fuel saving and capacity increasing factors which everybody knows about. These figures show what may be done and what is in everybody's mind to aim at with new engines, but why overlook the 25,000 old ones?

The fortunate feature of these improvements lies in the fact that they may be applied to all old engines that are in shape to run at all and they give these old engines increased power, making them, weight for weight, equal to the biggest, newest engines of the latest and best designs, and in many instances they will be better adapted for the work they are doing than new engines would be.

I mean that one big thing to do right now is to modernize those old engines—25,000 of them, applying to them the factors that make the modern locomotive take its place among the efficient power plants of the world. The way to do it is to make a survey of the old equipment in complete detail, to decide upon a modernizing program and determine the number of engines to be rejuvenated per month and then follow the program in spite of "hell and high water."

One of the roads that did this found that the improvements paid for themselves in seven months. Every $100 of cost earned $171.60 in the first year. This was 171 per cent investment. If the engines had but one year of life ahead of them it would have paid most handsomely. Did it pay? Is this one of the big economies? Does it not put in the shade all other locomotive economies that you can think of?

The steam locomotive of America is too big a factor in the success, stability and happiness of the nation to allow so large a proportion of antiquated equipment to be running hauling tons and hauling people at the high cost that these conditions entail. These old engines ought to be modernized or they ought to be scrapped, and that quickly.

The survey of the power on any railroad will reveal the merits of this question. It is my opinion that this survey is one of the most important immediate problems before the railroads. The best thing about it is that it can be done now, and that it will point out the best business policy of the roads—no matter who owns them.

A small engine need not be an uneconomical engine just because it is small. You need lots of small engines and always will need them. They should be put into the efficient class and their lives prolonged. By the way, this policy will overcome the extravagance of the past in the purchase of new power, much of which was necessary merely because there was so much unmodernized power on the road.

Some of you are thinking—"That's all right, but where is the money?" Let me tell you where the money is. It is blowing up the stack of every unmodernized engine. The entire first cost of modernizing is wasted in coal every seven to ten months on every one of these engines that is working. That's where the money is.

Did we back away from Germany because we didn't have the money for the war? We got the money!

You will find it easier to convince the hard-headed businessmen, the shippers, that you ought to have freight rate increases—after you have modernized these old engines. The shippers understand modernizing. That's why they succeed in business. That's why they have something to ship.

If you have had the inspiration of watching rival gun crews handling modern guns, you will appreciate the fact that, to do the work of today, which is greater work than that of yesterday, the guns must be *right*. It is not sufficient that the handling only should be right. The results are up to the right guns handled *right*. The more worthy the gun the better it will be served and the more it will do. This is exactly true of the locomotive. Every scoop of coal well fired does the more work when the engine is modernized. Modernizing augments every other means of saving. Let's get our heads out of the sand.

OTHER DISCUSSION

H. C. Woodbridge, fuel supervisor, Allegheny region, spoke particularly of the part transportation officers have in the conservation of fuel, mentioning a number of things not generally done now which they could do to reduce fuel consumption. When business is heavy it is now a common practice to start trains out from terminals whenever enough cars are available to make up a train, without regard to conditions at either the despatching or receiving terminals. He advocated the despatching of trains according to a predetermined plan, based on a careful study of the expected amount of business for any particular season, in which consideration has been given to conditions at terminals and important intermediate points on the division. In this way temporary congestion at terminal yards and engine terminals may be avoided and the power received only as fast as it can be handled. Such a plan has a marked influence on coal consumption through the elimination of delays en route and at the terminal.

The maximum allowable tonnage should be maintained, and tonnage should be reduced promptly to meet extraordinary conditions of weather, partial engine failures, etc. Tonnage trains should be given assistance out of the initial terminal to prevent delays in movement during the time in which the train is getting warmed up. Through loads should be segregated and pick-up work confined to certain trains rather than being handled hap-hazard by every train over the division. Train despatchers and tower men should be made to see clearly the effect on fuel consumption of slowing or stopping tonnage trains. Recommendations from trainmen as to the revision of schedules should be carefully considered; engines should be assigned and not pooled; the road foremen's time should not be taken up in conducting efficiency tests, etc., but devoted to supervising the operation of the locomotives on the road; the use of unnecessary lighting should be discouraged, and men should be disciplined for pulling apart air hose and allowing locomotives to waste steam at the pops. A close check should be kept on slow orders to eliminate their use or continuance except within absolutely necessary limits. The most efficient engines should be used and the inefficient ones scrapped or stored as opportunity permits.

Robert Collett, fuel supervisor of the Eastern region, laid stress upon the fact that nothing saves so much coal as an all-around good job of railroad operation. Any practice or plan which tends to improve general operating conditions is bound to reduce the consumption of fuel. Mr. Collett said that his conception of the function of the Fuel Conservation Section lay more in passing on the good things already being done from one road to another, than in initiating absolutely new practices. In dealing with the use of coal on the locomotive he suggested that more stress be placed on telling the men about their good performances than in continually criticising them for their failures. The business of a ralroad is to move trains and enginemen should not be critisised if they place more stress on keeping engines hot than upon the question of fuel economy, unless they have been thoroughly instructed in the best methods of firing and operating locomotives. As an evidence of the effect of operating conditions on fuel economy, he mentioned the fact that a 40 per cent difference in fuel used on the same passenger train on two succeeding days had been observed, where the principal difference in conditions lay in the necessity for stopping at block signals in one case, whereas a good run was made in the other.

Mr. Collett quoted from a comparative statement recently issued by the Fuel Conservation Section, which shows that the best results in reduction of fuel consumption on a gross ton-mile and passenger car mile basis have been obtained in the Central District of the Eastern region. Comparing the last six months of 1918 with the last six months of 1917, thus eliminating the effect of the extraordinary weather conditions prevailing during the early months of 1918, the average reduction in freight unit consumption for this district was 9.2 per cent and in passenger train-unit consumption 7.1 per cent. As shown by the available statistics, the total reduction in all regions was 5.5 per cent in freight service and 3.2 per cent in passenger service.

H. B. Brown, superintendent fuel department, Lehigh Valley, referred to the fact that, next to labor, fuel is the largest single item in railroad operating expenses and that the coal bill of the railroads was $150,000,000 greater in 1918 than in 1917, a fact which necessitates the redoubling of efforts to conserve coal from the standpoint of economy. He also referred to the necessity of fuel economy from the standpoint of the conservation of a natural resource which is not inexhaustible.

George L. Fowler called attention to the effect of proper firing methods on boiler repairs, stating that the opening and closing of the fire door produces a change in temperature of the firebox sheets reaching a maximum of 100 deg. F. in some parts of the firebox.

W. E. Symons referred to economies which could be effected in the 15 per cent of railroad fuel not burned in locomotives. By converting coal into producer gas for stationary power plant purposes, as high as $1.80 per ton may be realized from the sulphate ammonia, which is a by-product of the gas producer process.

The Resistance of Materials

The Effect of Sudden or Abrupt Changes in Section on the Distribution of the Unit Stress

BY G. S. CHILES AND R. G. KELLEY

III

FIGS 14a and 14b illustrate the unstrained and strained conditions of a strip of rubber perforated with a square hole as shown at *c*, Fig. 1, and in contact with glass plates as heretofore described. The pull which was exerted in this case was, as in the previous instances, five pounds. The stress action which is in evidence in this instance is somewhat similar to that which occurred in the case of the round hole with the exception that the maximum strain or deformation is found to take place at the corners of the hole. As in the case of the rounded openings, the compression at the upper and lower edges is again quite pronounced.

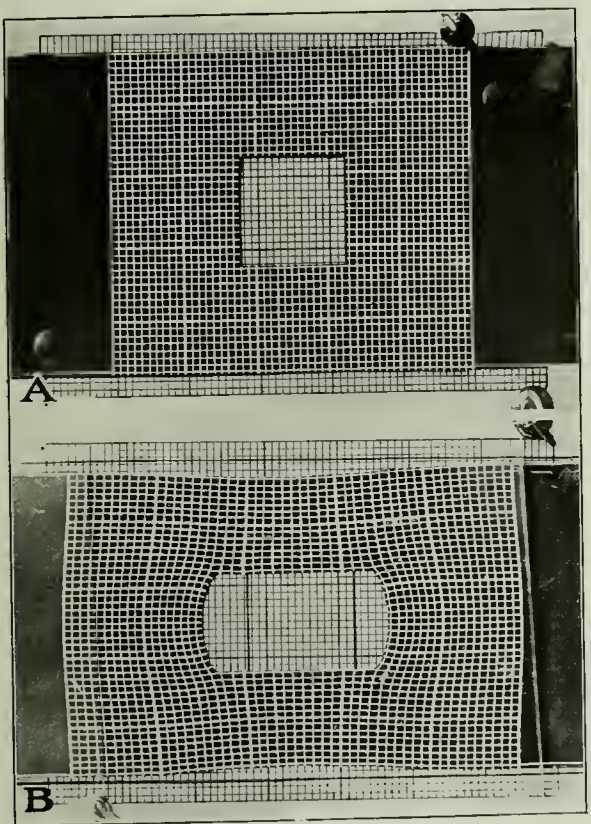

Fig. 14—Effect of a Square Hole on the Distribution of Stresses in a Rubber Sheet Under Tension

Table II summarizes briefly the data relative to the various rubber strips mentioned above.

TABLE II—DIMENSIONS, LOADS AND CALCULATED FIBER STRESSES OF SHEET RUBBER TEST SPECIMENS*

Line	Hole, 1½ in. diameter or square	Boss	Net sectional area, sq. in.	Total load, lb.	Calculated fiber stress lb. per sq. in.
1	Without	Without	0.1665	5	30
2	With	Without	0.111	5	45
3	Without	Without	0.1665	7	42
4	With	With	0.1836	7	38.2

*Specimens were 4½ in. wide by .037 in. thick; bosses were 3 in. in diameter and .048 in. thick.

Fig. 15 represents an eye bar designed in accordance with the standard practice of the American Bridge Company which calls for a maximum and minimum allowable thickness of one inch and one-half inch respectively.

Fig. 16*a* is a photographic reproduction of a model of the eye bar shown in Fig. 15 cut from rubber and having all of its dimensions exactly one-half of those of the standard eye bar of minimum thickness. The model was ruled up, as indicated in the photograph, in an unstrained condition

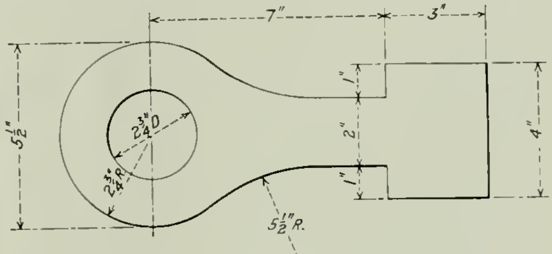

Fig. 15

with white ink lines spaced equally, ten to the inch, as heretofore described.

The lower end of the eye bar, the part having a width of four inches, was fastened to a soft pine board by means of a thin wooden strip as shown in Fig. 16*a*. The wood disk represents an eye bar pin. By exerting pressure on this disk the rubber was strained as shown in Fig. 16*b* and the

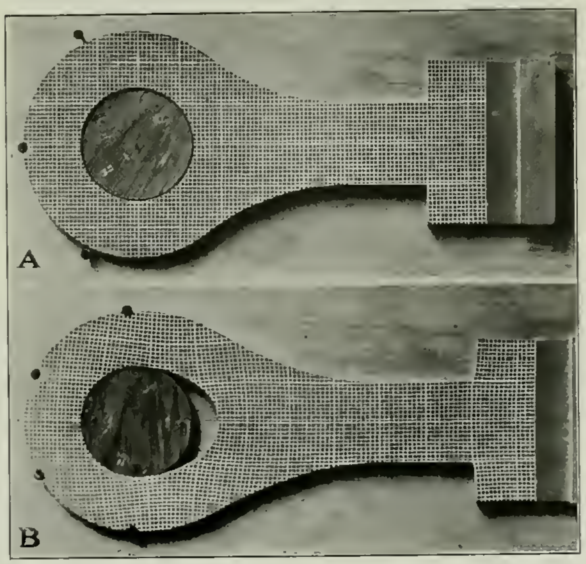

Fig. 16—Stresses Around the Pin in an Eye Bar

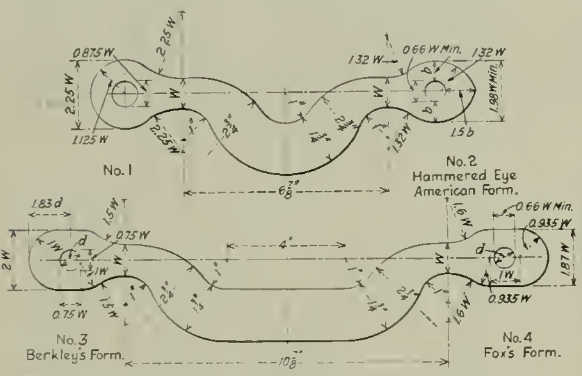
disk was then fastened with four small brads. It was found necessary to use tacks in order to keep the cutter rim of the circular end of the eye bar from buckling. The load was not measured in this experiment. The resulting deformation and stress distribution are plainly evident in the photograph and it will be noted that the stress action in the piece under strain in this photograph is quite similar to that illustrated in Fig. 12*c*, the similarity being quite marked along the edge of the hole which has been pulled away from the pin, and to a lesser degree along the edge in contact with the pin. The compression is again very noticeable at the lower edge of the hole. The lower white ink line, some ¾ in. above the upper edge of the wood strips, is not horizontal or parallel to the strip but is curved slightly near its center, a condition which becomes more pronounced near the offset portion. If



Note: Forms and proportions of eyes (in terms of W) No. 1—American Bridge Co. standard (2 inch width, 1½ inch maximum pin diameter) reduced one-half. Numbers 2, 3 and 4 see Machine Design, Construction and Drawing, by Spooner.

Fig. 17

a triangle is placed over Fig. 16*b* to coincide with the top four-inch line at the outer edges, this line, which was originally straight on the unstrained rubber, will be over 0.1 inch above the edge of the triangle near the vertical center line of the test piece. It is evident by comparing the horizontal lines near the projecting parts that these projections break up the uniform stress distribution so apparent an inch or so above.

Fig. 17 represents two different designs of offset tie bars each of which is provided with ends of different style. As stated in the legend beneath the drawings, the left end of the upper tie bar, marked No. 1, is designed in accordance with the American Bridge Company's standard practice, while the right end, No. 2, and ends No. 3 and No. 4 of the lower tie bar are designs abstracted from Spooner's "Machine Design, Drawing and Construction." It will be observed that the mid-section of the lower bar has a straight length of four inches and consequently is four inches longer than the mid-section of the upper bar, but that otherwise they have the same general dimensions up to the points where they meet the radii from the eye ends. The mid-section of the upper tie bar is a curved member, the inner and outer radius being purposely drawn from the same position. To this design a straight section was added, thus forming the lower design for the purpose of investigating the effect which this straight portion would have upon the deformation when the tie bars were subjected to the same load. The four designs of ends were used merely as a matter of interest and comparison, as it was considered that the difference in design would have no influence upon the stress action in the mid-section of the bars.

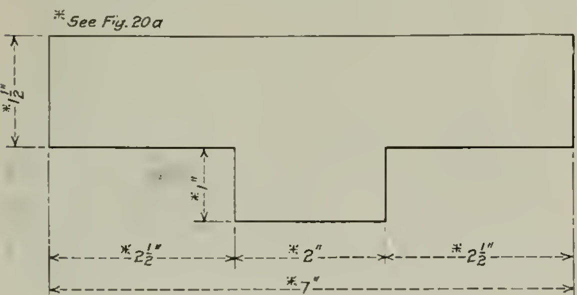


Fig. 18

Fig. 19*a* represents models of the tie bars cut to the dimensions shown on the drawings from rubber one-fourth-inch thick and ruled up, in an unstrained condition, with white lines spaced as previously described. For convenience in drawing comparisons between the unstrained and strained condition of the bars, the pine board upon which they were mounted was also ruled with corresponding lines, and the outline of the bars in their unstrained state drawn in. These

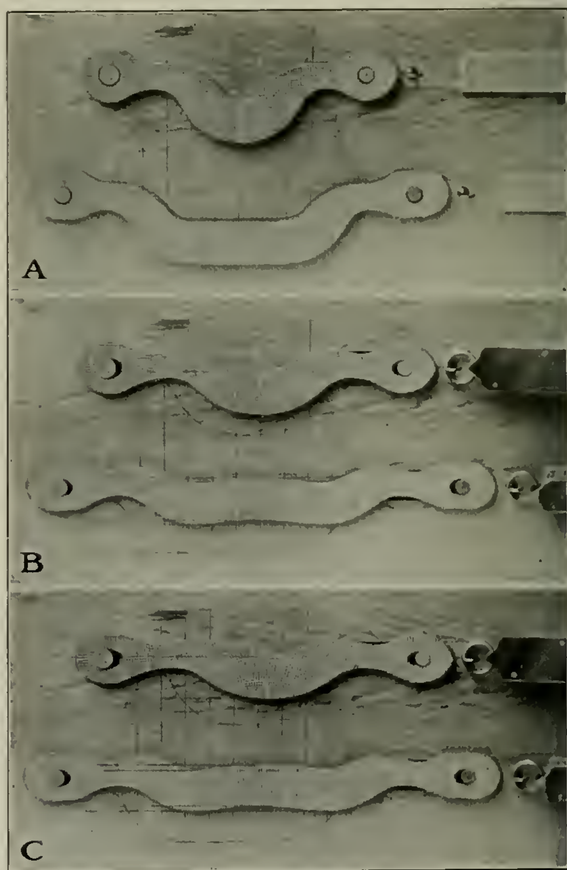

Fig. 19

pencil lines were drawn with the model in a horizontal (flat) position while the photographs were taken with it in a vertical (upright) position, as was true in all the experiments, and the weight of the test pieces together with slight pin clearances, accounts for the slight discrepancy between the actual and drawn contour of the eye bars in Fig. 19*a*. As in the case of Fig. 16*b* wooden disks were inserted in the eye ends to represent eye bar pins. In this experiment, however, the wooden disks on the right were fastened to a movable section of the stationary board.

Each of these tie bar models was subjected to two pulling loads of four pounds and seven pounds respectively and photographed in its distorted position under these loads as shown in Figs. 19*b* and 19*c*. From the reference lines on the board, it will be observed that the lower edge of the mid-section of the short bar is in compression and that the stress action, both as regards tension and compression, is more intense in the short bar than in the long bar.

The lower edge of the long bar for both loads measured very nearly the same as in the unstrained state showing that the tension due to the axial load is just sufficient to overcome or neutralize the compression due to the eccentricity of the load. There is very little tension along the upper edge of the neck of the short bar and practically no stress at the corresponding sections of the long bar. The most severe tension in the body of the short bar is along the curved part of the upper edge and a fairly high tension along the lower edge of the neck portions. In the long bar the most severe tension is in the curved parts on the upper

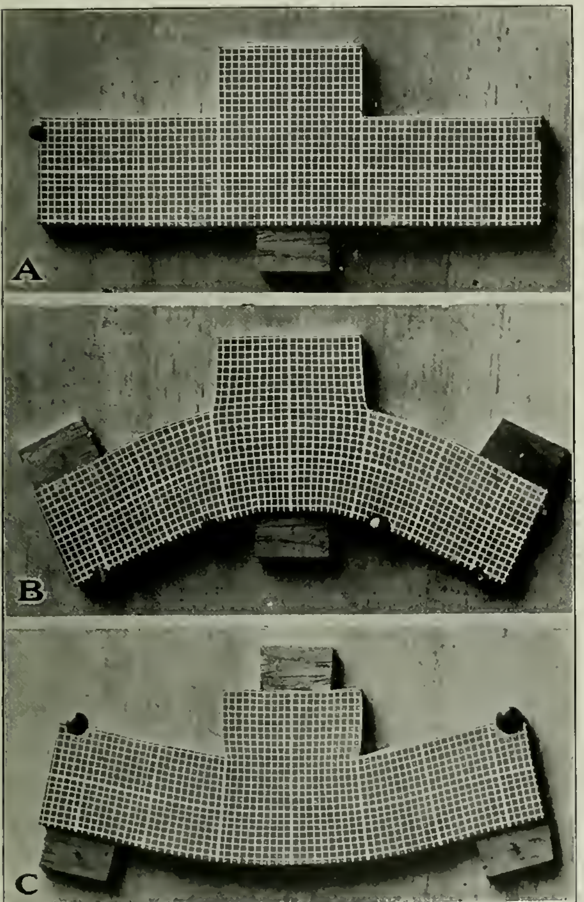

Fig. 20—The Effect of a Projecting Lug on Local Stresses in Rubber Specimen Subjected to Bending Loads

edge adjoining the straight portion. The tension along the lower edge of the neck of the long bar is greater than it is along the originally straight upper edge of the mid-section. The large deformation in these rubber tie-rods equalizes stress distribution to some extent.

In Fig. 19*b* it will be observed that, whereas Figs. 17 and 19*a* show one inch between the upper edge of the rubber models and a line joining the center of the pin centers, or an eccentricity of 1⅞ in., the upper edge of the short tie bar is approximately on the pin center line, equivalent to an eccentricity of ⅞ in., while the upper edge of the rubber at the center line of the long bar is 0.4 in. above a line joining the pin centers, an eccentricity slightly less than ½ in. With the greater load of Fig. 19*c* the rubber tie bars show a still greater deformation.

In order to investigate the effect upon the stress distribution in sections of irregular shape when subjected to a bending load, the irregular shaped section shown in Fig. 18 was cut from a special grade of rubber ¼ in. thick and ruled up in the unstrained condition as previously described. The ruled up section is shown, mounted upon a board, in Fig. 20*a*.

For the first experiment, the load was applied to the long straight edge so as to put the material along this edge under compression and the material in the opposite or irregular edge in tension. This arrangement is illustrated in Fig. 20*b*, the tacks being placed after the load was applied to prevent the rubber from buckling. The photograph clearly indicates that practically no deformation took place along the upper edge of the one-inch by two-inch projection, whereas the stress at the corners where this projection joined the main body was unduly severe.

For the second experiment, the load was applied at the upper edge of the projection. The stress action along this edge and at the corners was somewhat similar to that obtained above and is indicated in Fig. 20*c*.

It will be noticed that on a line through the projecting part, paralleling the uniform section, in the first test the rubber is in tension, and in the second test the ruled lines show a compression, the maximum stress in each case being on a continuous line, that is, on a line common to the upper and lower rectangles, and not at the outermost edge, as might be supposed. In fact if the width of the upper two-inch edge in Fig. 20*b* is calipered and compared with the corresponding edges of Figs. 20*b* and 20*c*, it will be found that very little change in length has taken place due to bending.

No doubt the reader in reviewing the elastic action of the rubber specimens, as illustrated, will question the validity of the test results, or their inconsistency with the usual theoretical formulae. It should be remembered that the usual formulae relative to the strength of materials apply only to such members as plain bars, etc., having a uniform and continuous cross-section and not to members having an irregular contour or whose cross-section increases or decreases suddenly.

In writing this article on the effect of abrupt changes of section on the resistance of materials it has been the aim of the writers to recapitulate available data and in addition thereto, by means of the rubber test specimens, assist the designer in visualizing its practical application.

TUBE SPACING TO SUIT BAD WATER CONDITIONS

BY C. E. BROOKS
Superintendent Motive Power, Grand Trunk Pacific

One of the greatest sources of trouble to railroad men operating in bad water territory without a doubt is tube leakage. By bad water conditions is meant waters which carry from 50 to 300 grains of impurities per one-thousand U. S. gallons. A typical analysis is as follows:

	Grains per U. S. gallon
Silica	.974
Oxide of iron	.128
Carbonate of lime	Trace
Sulphate of lime	56.391
Carbonate of magnesia	19.378
Sulphate of magnesia	7.007
Sodium and pot. sulphate	26.562
Sodium and pot. chloride	1.700
	112.140

It is a well known fact that often a locomotive does fairly well as far as steaming qualities are concerned, until shopped, with flues so badly scaled and mudded up that they have little if any conductance; in fact, many cases are found where the flues are simply smoke conveyors, and take but very little part in the action of the boiler. The remarkable feature is, that if firebox sheets are in good condition steaming qualities are much less affected than one would expect.

I believe this can be attributed almost entirely to the present systems of tube spacing, which I consider have these two general defects:

(1)—Impeding the circulation of water about the flues by forcing the globules of steam formed on the flues to work through a zig-zag course, thereby
  (a)—delaying steam generation, and
  (b)—forming a much greater insulating coat of steam over the tubes, resulting in loss of heating surface.

(2)—Facilitating the blocking up with scale due to the impossibility of loosened scale or mud working its way through to the belly of the boiler, the general result being blocking up of water spaces with mud and impeding circulation thereby.

The remedy for this appears to be: First, the use of a much larger diameter flue than present practice calls for below the superheater flues; second, spacing these tubes in vertical and horizontal rows, with the maximum reasonable spacing; third, eliminating all small tubes between the superheater flues.

The object of the use of larger tubes is to reduce the resistance of the gases and, combined with the vertical and horizontal spacing, to give the generated steam globules the shortest and easiest path to the surface of the water and permit loosened scale to drop to the belly of the boiler.

No doubt these recommendations will meet with criticisms from many sources, the chief of which will be loss of heating surface and poor staying of sheets. The answers to these objections are that the heating surface is of little value if not covered with water, and that in order to get a maximum so-called tube heating surface important principles of conductance and circulation have been sacrificed by designing the tube spacing to effect a maximum resistance to both.

As far as staying is concerned, it should be recalled that in bad water districts where a set of tubes, properly applied, may leak the first trip over the road, 90 per cent of the leakage occurs in a part of the sheet which is well stayed, namely, towards the center of the small tube area. This is due, not to the fact that too much stress is exerted on the bead of the flue, because in that case we would get the same results with good water. It is due to the fact that when certain combinations of impurities exist in the boiler steam pockets are formed where the circulation is poor, thereby resulting in overheating the beads, with the resultant expansion and contraction, which finally causes a leak. The only real remedy for this is circulation, which can be improved by a re-design of the vertical passages between the tubes.

Railroad Administration News

Status of Shop Crafts; Wage Case; Summary of Fuel Conservation Results; Report of Safety Section

Practically all of the locomotives that have been used during the past year on railroads other than those of their owners, in accordance with the Railroad Administration's plan of pooling facilities, are now being returned to their home roads or are in repair shops on their way home. Instructions were issued about March 1 that when leased locomotives could be returned to their owning roads without inconvenience and without serious interruption to traffic it should be done, as a large number of the roads at that time had locomotives of their own in storage. Nearly 800 locomotives at that time were being operated under lease by roads other than their owners. They have been repaired and put in good shape before returning at the shops where the work could be most conveniently done. In many cases, particularly where locomotives were returned from eastern or southern roads to the western lines, it was necessary to use very roundabout routes because of insufficient clearance.

Status of Shop Craft Wage Case

In reply to many inquiries from its members "relative to the delay in the settlement of wage increases" asked of the director general by the shop craft organizations on January 7, the Railway Employees' Department of the American Federation of Labor has explained that after having presented its arguments to the wage board on March 12, 13 and 14, its committee was notified that the representatives of the regional directors were not prepared to present their side of the matter, and the hearing was postponed by the board till April 14. The employees committee protested vigorously against this delay, but the board declined to alter its decision. This case is being presented by 14 representatives of the employees, with B. M. Jewell, acting president of the Railway Employees' Department, as chairman, and 14 representatives of the regional directors, with C. E. Chambers, mechanical assistant to the regional director for the Allegheny region, as chairman.

On April 15 Mr. Chambers testified before the Board of Wages and Working Conditions at Washington, and asked the board to deny the increases in wages and allowances asked by the federated shop crafts affiliated with the American Federation of Labor, on the ground that their wages are now higher than those paid generally by industrial concerns not under government control. The rates asked by the shop crafts include a basic rate of 85 cents an hour for experienced mechanics in place of the present rate of 68 cents, 60 cents for helpers, and also differentials for certain classes of employees, 30 days' holiday a year and other concessions in time. These increases, Mr. Chambers said, amount to 25 per cent in the basic rate, 46 per cent for second class electrical workers now paid 58 cents, 35 per cent for car men now paid 63 cents and 46 per cent for those now paid 58 cents.

He presented a set of exhibits comparing the rates of wages paid to railroad shop crafts with minimum, maximum, going and average hourly rates paid to employees performing similar work in 1,293 industrial plants. Ship yards and similar plants were not included, he said, because of the emergency character of the work. The information was received in reply to questionnaires, all of which have not yet been answered, so that the information is not entirely complete. The exhibits showed average hourly rates in the outside industries as follows: Machinists, 56.2 cents; boilermakers, 62.6 cents; blacksmiths, 58.4 cents; sheet metal workers, 54.7 cents; first class electrical workers, 55.8 cents; second class electrical workers, 46.3 cents; car men, 48.2 cents; molders, 60.6 cents, and helpers, 44.3 cents. The majority of the outside machinists receive rates of 50 cents and upward, while the prevailing rate for helpers is 45 cents. Mr. Chambers said that the pay rolls had also been increased by the classification of work made in Supplement No. 4 to General Order No. 27, because the first class rates are now paid in many instances for work formerly performed by helpers at a lower rate, as the craftsman rate is now paid for some of the work performed by men not fully qualified as craftsmen. Formerly a craftsman engaged in piece work made his helper do all he could, whereas now in the intervals between work assigned to the helpers, the helper frequently does nothing. Mr. Chambers also presented exhibits showing the labor turnover, which he said now is about 50 per cent less than it was during the first half of 1918; in other words, it has been reduced to about normal.

A. O. Wharton, vice-chairman of the board, questioned the completeness of the figures because they did not include many industries on the Pacific Coast where high rates have been established, or in the inter-mountain territory, where he said he knew that many mechanics were receiving a minimum of $1 an hour. He also commented on the absence of figures from the Ford Motor Company, which he said had recently established a minimum of $6 a day for mechanics. Mr. Chambers said that many of the questionnaires from the more remote points had not yet been received, and that the committee had been unable to obtain the figures from the Ford plant. He remarked that the $6 minimum was 75 cents an hour.

BACK PAY FOR SHORT LINE EMPLOYEES

Director General Hines has recently announced a decision that employees of the short line railroads which were not taken under federal control because of the general counsel of the Railroad Administration ruled that they were not "systems of transportation," are not entitled to back pay under General Order No. 27, and that employees of railroads relinquished and subsequently taken under federal control are not entitled to back pay for the period back of the date of the contracts subsequently executed. As to the employees who might have been induced to subscribe for Liberty bonds by the appeal sent to all railroad men early last year by Director General McAdoo, calling attention to the fact that they were about to receive increases in wages and back pay, Mr. Hines says that unfortunately these assurances were not restricted, as they ought to have been, to employees of railroads operated by the government, but that there was no intent to mislead any employees, and that those who bought Liberty bonds on the strength of such assurances have only done what every class of citizenship was urged to do; and have made a splendid investment unless they have lost because it became necessary to sell the bonds at a discount.

These conclusions, adhering to the position formerly taken by Mr. McAdoo, were expressed by Mr. Hines in a letter to the chief executives of the organizations representing railway employees, who had asked for back pay for the short line employees back to January 1, 1918.

ECONOMY IN CONSUMPTION OF COAL IN 1918

Good results attained in 1918 as a result of the campaign for fuel economy are shown in a compilation prepared by the Fuel Conservation Section of the Railroad Administration comparing some of the principal statistics relating to the consumption of coal for 1916, 1917 and 1918. The tons of coal consumed in freight service in 1918 amounted to 86,634,345 as compared with 79,454,966 in 1916 and 86,795,339 in 1917, but the pounds of coal per 1,000 gross ton miles show a decrease in 1918 as compared with 1917, although an increase compared with 1916. The amount was 199.7 in 1918, 200.9 in 1917 and 192.1 in 1916. In passenger service the tons of coal consumed in 1918 amounted to 30,570,030 as compared with 32,583,171 in 1817 and 30,494,233 in 1916. The pounds of coal per passenger train car mile used in 1918 averaged 19.3 as compared with 19.4 in 1917 and 18.5 in 1916. In the last six months of 1918 the pounds of coal per 1,000 gross ton miles were only 190.7 as compared with 201.8 in 1917, a decrease of 5.5 per cent, and the pounds per passenger car mile were 18.2 as compared with 18.8, a decrease of 3.2 per cent.

The report also compares the average cost of coal per ton in December, 1918, and December, 1917. The figures for some of the principal roads, which do not include the cost of the haul on the user's rails, are as follows:

Road	December, 1918	December, 1917
New York, New Haven & Hartford	5.78	5.25
Delaware & Hudson	3.99	3.61
Boston & Maine	6.21	5.44
Erie	3.49	3.77
Lehigh Valley	3.62	3.06
Michigan Central	3.78	3.63
New York Central	3.43	3.07
Baltimore & Ohio—Eastern Lines	2.66	2.30
Baltimore & Ohio—Western Lines	2.65	2.30
Pennsylvania Eastern Lines	2.88	2.48
Pennsylvania Western Lines	2.76	2.48
Philadelphia & Reading	3.75	3.51
Atlantic Coast Line	4.25	4.00
Louisville & Nashville	3.13	2.15
Southern	3.48	2.68

ARRANGEMENTS FOR EQUIPMENT FINANCING

Arrangements have been completed for temporarily financing the amounts now due the car and locomotive builders by the Railroad Administration, amounting to approximately $40,000,000, by the issuance of certificates of indebtedness, bearing interest at five per cent, which may be used as collateral for loans from the banks or possibly from the War Finance Corporation, but up to April 9 the certificates had not actually been issued. Some of the certificates, which are to be in convenient denominations for that purpose, will be passed by the equipment companies to the sub-contractors who furnished materials and specialties, but whose contracts are with the builders rather than with the government. For this reason the specialty people were not admitted to the conferences between the builders and the Railroad Administration representatives, but conferences between the sub-contractors and builders were held afterward. Some of the specialty men were inclined to insist on being paid in cash rather than certificates, but it is stated that if they insist on cash they will have to wait until it is available, as the companies to whom the certificates are issued will have to give their own notes to the banks and might thus be left "holding the bag" for a time in case of unexpected delay to the railroad appropriation.

Whatever interest above five per cent is charged by the banks will be reimbursed by the government.

A sub-committee was appointed to represent the equipment companies at Washington in connection with the issuance of the certificates, consisting of George Shaw, Standard Steel Car Company; H. W. Wolf, American Car & Foundry Company; L. O. Cameron, Pressed Steel Car Company, and F. O. Riener, Haskell & Barker Car Company. Companies having contracts with the builders were requested to telegraph their bills as of April 1 to J. M. Hansen, secretary of the car and locomotive manufacturing committee, at Washington.

REPORT OF SAFETY SECTION

The Railroad Administration has issued a notice regarding a report of the Safety Section, stating that since the government took control of the transportation facilities its record is one of which both employers and employees should have cause to feel proud. The statement indicates, however, that a similar pride is not felt in the activities of the railroad safety departments before that time. On January 1, 1919, there were 20,156 railroad men serving on railroad safety committees under the direct supervision of the Safety Section "actively working for safety on the railroads; whereas a year ago there were comparatively few men thus employed." It is also stated that on certain typical roads, where, in the month of January, 1918, there were in the aggregate 212 persons killed, and 3,118 were injured, the record for the same month in 1919 shows the number killed as 94, and of injured 363. Apparently it is not the province of the Safety Section to note any difference in operating conditions in the two months.

Concerning the campaign directed to cleaning up yards and rights of way, one of the big roads reports:

"One division has picked up between 675 and 700 carloads of scrap and debris; and 92 cars of scrap iron were gathered along rights of way in yards. On the divisions that were cleaned up through the efforts of the safety department a number of old link and pin couplers were picked up, a proof that no clean up had been made for a number of years." One of the circulars issued by the brotherhood lodges reads: "We feel the safety movement is of the utmost importance to all employees and your hearty co-operation and earnest support is requested, that accidents and personal injuries to our fellow employees may be reduced to the lowest minimum." The Safety Section is planning a "No Accident Month" for May in the Southwestern Region.

CONTINGENT FEE COVENANT MODIFIED

Director General Hines has announced that, with the approval of Attorney General A. Mitchell Palmer, he has consented to a modification of the covenant inserted in purchase contracts under the direction of the Department of Justice issued June 18, 1918, prohibiting the payment to agents of fees contingent upon the procuring of contracts with the government in so far as it relates to railroad contracts.

Since this order was promulgated by the attorney general, there has been a good deal of complaint from railway supply houses that its provisions were working a hardship upon them, and that the government itself was losing the benefits of a system which, previously, had proved both economical and satisfactory in every particular.

Hereafter, the attorney general's order will not affect contracts made between the Railroad Administration and supply houses which, previous to government control, carried on their business through bona fide selling agencies.

At the suggestion of John Barton Payne, general counsel for the Railroad Administration, the following clause will be inserted in appropriate cases in future railroad contracts:

"Provided, however, that this covenant shall not invalidate a contract obtained through a bona fide commercial representative employed under a general contract covering designated territory and shall not prohibit or penalize the employment of the same agencies, rates and methods of compensation in dealing with the United States heretofore customarily employed by the contractor in the regular course of his business in similar dealings with the railroad corporations."

ORDERS OF THE REGIONAL DIRECTORS

Payment of Employees on Hourly Basis Instead of Piece Work Basis.—The Southern regional director has issued the following:

"Referring to my telegram E-64, January 2, 1919, repeating message from the director general of railroads, dated Washington, December 31, regarding preference of shopmen throughout the country to be paid on hourly basis, as provided in Supplement No. 4 to General Order No. 27, rather than the piece work basis in effect on many railroads.

"Acting under the permission of the director general, granted by his message December 31, 1918, employees on many railroads have indicated their preference with respect to working upon an hourly instead of a piece work basis. Director Tyler, Division of Operation, Washington, writes me he is advised that at some shops, after a decision has been reached in this way, certain local officers or foremen are continuing to agitate the matter, urging upon the men that another vote be taken, with the result that in some cases two or three votes have already been taken upon the subject.

"This is taken as indicating a purpose on the part of those local officers to circumvent the wishes of the director general, so clearly expressed in his telegram of December 31. The effect is to keep the shop organizations at such points continually agitated with most certain detrimental effect upon the efficiency and morale of the organization.

"Will you please direct that on railroads under your jurisdiction where employees have once decided this matter by vote, it will be considered as definitely settled during the period of federal control."

Repairs of Short Line Cars.—The regional director, Eastern region, by circular 500-14-5A669, announces that beginning with April 1 bills for repairs to cars and engines belonging to non-federal roads—the "short lines"—are to be made on the basis of actual cost of labor and materials, plus 15 per cent, with 10 per cent added to the total to cover superintendence and accounting. Material furnished by the road owning the car or locomotive is to be billed to the road making the repairs, which, in turn, should re-bill it at the same rate plus 15 per cent for handling. Proper credit is to be allowed for scrap at current prices.

Reclamation of Scrap.—The regional director, Eastern region, by circular 2900-99A-670 calls attention to carelessness in the gathering and sale of scrap material. Scrap material has been sold without assortment, and new articles, available for immediate use, have been sold as scrap. Federal managers are called upon to review the instructions and regulations now existing in order to make sure that the greatest possible care is exercised, and to take any action that may be found necessary to insure that the sorting, reclamation and sale of the scrap is being properly and economically handled.

Use of Lock Nuts and Grip Unit Nuts on Boilers.—Order 186 of the Southwestern regional director calls attention to the fact that lock nuts and grip unit nuts are being used on studs which are screwed into boilers, and instructs that hereafter lock nuts and grip unit nuts must not be used in this manner, and that where a lock nut is required a jam nut is to be used.

Brakes on U. S. R. A. Hopper and Gondola Cars.—Order 194 of the Southwestern regional director requires inspectors to make a special inspection of all United States composite gondola standard and hopper cars, and that where these cars are found without sheave wheels on the brake shaft end of the hand brake rod to send these cars to shop, regardless of ownership, and have the brake arrangement changed to conform to the approved standard.

Use of Headlight Generators.—Circular 203 of the Southwestern regional director reminds enginemen that by keeping water gages and shields clean or by slightly relocating the lamps of these water gages, it will not be necessary to run headlight generators during daylight as is now being done in many cases.

Reports of Air Brakes Cleaned.—The Eastern regional director by Order 1801-131A691, calls for regular monthly reports, beginning with April, showing the number of freight car air brakes overhauled, with a statement showing the ratio of number cleaned to number of freight cars owned.

IRON THAT CAN BE WHITTLED.—It is well known that rapid cooling of hot metals hardens them. That the opposite is true has recently been demonstrated in striking fashion by the General Electric Company. One of their scientists annealed American ingot iron surrounded by hydrogen gas for three hours at a temperature above 1,600 deg. F. The product was very little harder than the softest copper, and can be whittled with a knife.

CAR DEPARTMENT

STORAGE BATTERY CARS FOR USE IN YUCATAN

The three cars shown in the illustrations have just been delivered to the United Railways of Yucatan by the Railway Storage Battery Car Company, New York. The cars are driven by motors geared to the axles and power is supplied to the motors by Edison storage batteries. The cars are designed to be operated either singly or in trains by multiple unit control.

The schedule as laid out for service to be performed covers the run from Merida to Progreso, a distance of 23.6 miles. There are six stops between terminals and the running time over the line is 45 minutes. The city of Merida has a population of 70,000, while that of Progreso is 8,000. The grade between the two cities is practically level and the total service per day is three round trips. The cars are fitted for passenger service and are able to draw a trailer carrying baggage and express matter.

Three Storage Battery Cars Recently Shipped to the United Railways of Yucatan

CONSTRUCTION

The car is constructed according to M. C. B. standards and the car body and its appliances are all steel with the exception of doors and inside fittings. The over-all length of car body is 56 ft., the extreme width is 8 ft. 6 in., and the extreme height is 12 ft. Reversible seats upholstered with rattan are used and the seating capacity of the car is 66 persons.

The underframe is built up of two 6-in., 10.5-lb. channel center sills spaced 13¼ in. back to back, with side and end sills of 10-in., 15-lb. channel sections. The transoms are built up of flat plate; the top or tension member is 9 in. wide by 7 in. in thickness, while the bottom member is 9 in. wide by 1 in. in thickness. In addition to the end sills the underframe includes a curved buffer beam of 5-in. by 5-in. by ½-in. angle section curved to a radius of 18 ft. ¾ in. The cross members of the underframe are 6-in., 8-lb. channels and are five in number.

The body frame is of light steel construction, the posts being 2-in. by 2-in. by ¼-in. T-sections, sheathed below the windows with 3/32-in. steel plate. The side plates are 2½-in. by 2½-in. by ¼-in. angles. The carlines are of sections similar to the posts and they extend across the car from side plate to side plate.

The cars are fitted with M. C. B. couplers and single spring draft gears.

Brill 69E trucks are used. These trucks have a 5-ft. 6-in. wheel base and are spaced 14 ft. between centers. They are of the arch bar type, are light, each weighing 6,220 lb. without motors, and are fitted with M. C. B. wheels and axles. Roller bearing journal boxes are used.

The total weight of car without load is 56,600 lb.; the batteries alone weigh 12,600 lb., and the total weight of the motors and control equipment is about 6,000 lb. This makes a total weight per passenger, on the basis of the seating capacity, of about 500 lb.

MOTOR AND CONTROL EQUIPMENT

Each car is equipped with four General Electric, No. 261, 250-volt, direct current motors. There is one motor for each axle and each motor is connected to the axle with a single reduction gear. These motors were supplied to meet the requirements of supplying a single car with 88 mechanical horse-power during acceleration and 28 mechanical horse-power when running free and to supply a car and trailer with 166 mechanical horse-power during acceleration and with 39 mechanical horse-power when running free. The motors are protected by Condit instantaneous, automatic, overload circuit breakers.

The electrical equipment includes double end multiple unit control and the cars are connected with a seven-point cable when they are used in multiple units. The cars are equipped with General Electric straight and automatic air brakes.

BATTERY

Each car is equipped with a battery of 248 Edison type A-12 cells; 240 of these cells are used for the power circuit and eight for the lighting circuit. While the battery is being charged all of the cells are connected in series. A Sangamo ampere hour meter is installed in the charging circuit to insure the batteries the proper amount of charge and to protect them from overcharge.

PERFORMANCE

These cars are capable of developing a speed of 45 miles an hour on level tangent track. It is possible for them to negotiate grades of from 8 to 10 per cent and to haul loads of from 30 to 35 tons at a fair maximum speed. They may also be used to spot and drill loads up to 150 tons. Under ordinary service conditions their range of operation on one charge of the battery is about 120 miles, although this range will seldom be required in branch line service.

The particular advantage of this type of car as presented by the maker lies principally in the characteristic of the alkaline storage battery. As the battery is comparatively light in weight, the total weight of the car is not excessive and as the battery is strongly built and not affected by ordinary vibration and shock it lends itself particularly to this class of service. The only attention required for this class of storage battery is to keep it charged and filled with water.

Interior of the Storage Battery Car for Yucatan Showing the Seating Arrangement

For branch line steam railroad service cars of this type have the advantage of requiring little attention which cannot be given by the regular passenger car maintenance forces. Aside from the batteries the only other special equipment are the motors and control apparatus, which need little attention except at general overhaul periods.

A storage battery, of course, represents a loss of efficiency, but it does away with line losses, as compared with a trolley system, and where 24-hour service is not required the cost of keeping power on the line with no cars running is eliminated. Furthermore, it is usually possible to charge batteries during an off-peak period and thereby obtain a lower charging rate.

Similar cars are in use on the Cambria & Indiana, the Lorain, Ashland & Southern, the Atlanta, Birmingham & Atlantic, the Chattahoochee Valley, the Long Island and the Pennsylvania. During the mechanical conventions to be held at Atlantic City next June a demonstration car of this type will be in operation between Atlantic City and Ocean City.

The Car Bodies and Their Appliances Are All Steel, Except for the Doors and Inside Finish

STANDARD FREIGHT CARS ARE HELD IN STORAGE

Since the signing of the armistice, in addition to the large number of idle cars which have been in service, several thousand of the new standard cars built on the orders placed by the Railroad Administration last year have been completed by the builders, but cannot be stencilled because the railroad companies, which are expected to take them and pay for them, have not yet accepted them. Over 26,000 of the 100,000 standard cars ordered had been accepted by the roads to March 31, according to a statement compiled by the Railroad Administration, but this does not account for at least 10,000 more than have been built, and are being held in storage until it can be ascertained whether the Railroad Administration can force the companies to take them at the high prices. The administration takes the position that it can, because they were ordered under war conditions and allocated to the various roads, but many of the companies are not in a position to finance them, and meanwhile the Railroad Administration is paying for them at the contract price minus an amount to cover the cost of stenciling. The standard locomotives, on the other hand, are being accepted as fast as they are turned out.

Draft Gear Test Plant of the T. H. Symington Company

Draft Gear Test Demonstrations

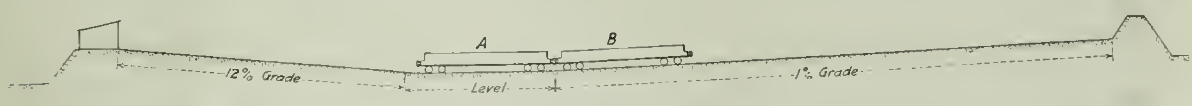
Method of Recording Action Under Impact Between Cars Devised by Inspection and Test Section

On April 10 and 11 a series of public demonstrations were conducted by the Inspection and Test Section of the Division of Operation, United States Railroad Administration, at the draft gear testing plant of the T. H. Symington Company, Rochester, N. Y. The manufacturers of draft gears, the draft gear committee of the mechanical section of the American Railroad Association, the mechanical committee of the Railroad Administration and a number of railroad officers were present. The purpose of the demonstration was to disclose in advance of a series of official draft gear tests to be conducted at this plant, the methods of testing which will be followed, and particularly to demonstrate the operation of the devices which have been developed to graphically record the action of the draft gear between two cars, one moving and the other standing at the instant of impact.

For a period of several months the Inspection and Test Section has been engaged in testing draft gears under the direction of B. W. Kadel, assistant engineer, the program including tests both with the static machine and under the drop, and the work to be performed on the Symington plant constitutes the next series of tests in the draft gear program, in all of which the draft gear committee of the Master Car Builders' Association is co-operating.

The test plant of the T. H. Symington Company was built to facilitate the testing of draft gears under as nearly as possible actual service conditions. It consists of a test track, one end of which is laid out on a 12 per cent grade for accelerating purposes, followed by a section of level track at the other end of which is a one per cent ascending grade. Two 50-ton steel frame gondola cars with wood floors and siding are used in the tests. The facilities for handling the cars consist of a motor driven drum hoist housed at the top of the 12 per cent grade, the cable from which is attached to a special puller car to which the test car is attached in such a way that the coupling may be tripped at any predetermined point on the grade; a motor driven capstan winch beside the track is used to spot the cars on the level track.

Both of the 50-ton gondola cars are loaded so that each has a gross weight of 143,000 lb. The adjoining ends are arranged so that they may be equipped with any draft gear of standard dimensions, or with solid buffers. The moving car, designated as the *A* car, is drawn up the inclined track and released at stations predetermined to produce whatever velocity of impact is desired. The stationary car, designated as the *B* car, is placed at a fixed point on the track so that the performance of the cars during the period of impact is comparable for all tests. This position is chosen so that the *B* car stands fully on the 1 per cent decelerating grade when struck by the *A* car, while the latter moves upon level track during the period of impact and for a distance of approximately six feet before the instant at which the buffing faces of the two drawheads come in contact. The cars are equipped with flat face buffing stems instead of standard couplers in order to produce a normal impact without coupling the cars.



Profile of the Test Track

The method of recording and comparing the action of various draft gears under impact between the two cars is a development recently worked out by the Inspection and Test Section and the engineers of the T. H. Symington Company, working together.

The outstanding feature of the new recording apparatus is that a direct and continuous record is made of the movement of both cars during a period beginning before the instant of impact and continuing after the final separation of the two cars. The records of the car movements are made by pencils traveling in a line parallel to the track and marking upon revolving drums, one for each car, both of which are mounted on a common shaft also parallel to the track. The drum shaft is worm driven by a 32-volt shunt-wound, direct-current motor, which receives its power from a storage battery. The paper speed of the drum is approximately 31 in. per second. The pencil holders for the two drums are mounted on guides parallel to the axis of the drums and are moved by bars which project out from the sides of the cars. Provision is made for horizontal movement of these bars at right angles to the longitudinal center line of the car. Guides attached to the instrument base engage a lever suitably attached to each bar to withdraw it from contact with the pencil holder before it can be moved beyond either end of the cylinder.

The line drawn upon the first or *A* drum shows the exact velocity of the *A* car at the moment of impact, denotes the exact point of impact, shows by the type of curve drawn the rate of retardation of this car and finally gives the velocity of the car after the two cars have parted. The line drawn upon the *B* drum shows the rate of acceleration of the *B* car and shows the final velocity of this car as the two cars part. Curves made in the same test upon the *A* and *B* drums are reproduced in Figs. 1 and 2, respectively.

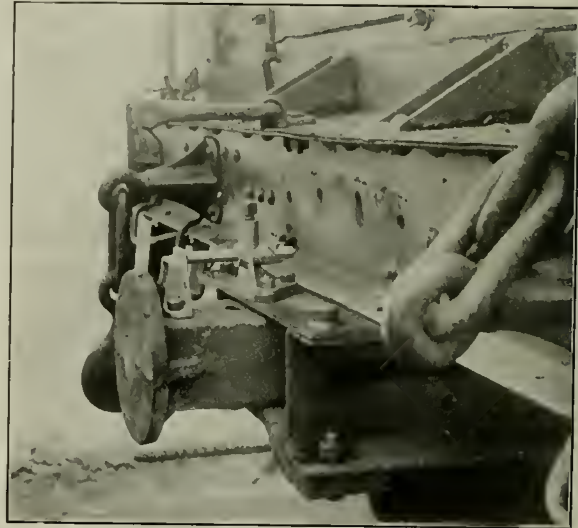
When a test is to be made the two cars are spotted with the buffing faces in contact and all slack eliminated from draft gears and attachments. With the drums standing, the pencil carriages are given a slight movement along the guides to draw common reference lines, 3-3, Fig. 1, and 4-4, Fig. 2, by means of which the two cards later may be synchronized as to time. The pencils are then set on both drums in the positions which they will occupy against the bars projecting out from the sides of the cars at the instant the buffing faces between the two cars come in contact.

With the pencil carriers thus located the drums are rotated to draw the common datum line, 1-1, Fig. 1, and 2-2, Fig. 2, upon these drums. Line 2-2 on the *B* drum indicates the standing position of the *B* car; line 1-1 on the *A* drum indicates the position of the *A* car at the first instant of contact with the *B* car. By means of these datum lines the cards for the two cars can be matched as to their positions along the track.

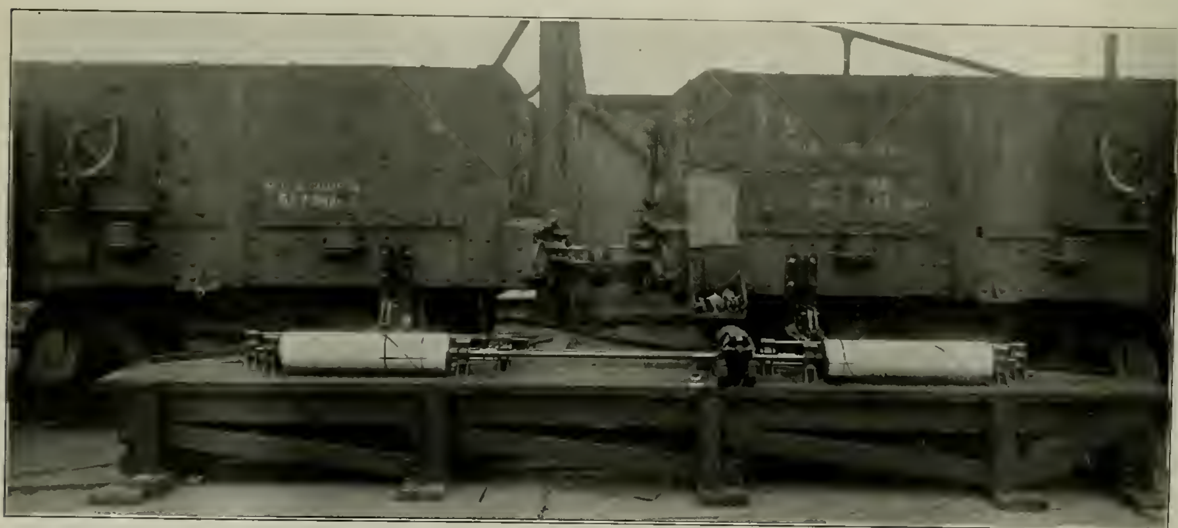
The test is then run by hauling the *A* car up the 12 per cent grade, releasing it at the point required to produce the desired velocity of impact, the pencil on the *A* drum being moved back from its impact position so that a record of the velocity of the car as it approaches the point of impact may be obtained.

From the curves a study can be made of the car movements throughout the cycle of draft gear movement and the velocity of the *A* car at the moment of impact can be accurately determined, as well as the velocities of both cars beyond the point of separation. Thus on the card for the *A* car, Fig. 1, the angularity of the line below the datum line denotes the exact velocity of the striking car, and the weight being known, its energy as a moving body can be accurately determined.

Referring again to Fig. 1, at point 5 it is known that the *A* car first met the *B* car, that the draft gears started to close



The Flat Face Buffer and Travel Gage



The Instrument on Which the Car Movements are Recorded on a Time-Distance Basis and consequently that its velocity began to decrease. Assuming that the draft gear action is entirely smooth and that the bombardments of static testing are not present in this service, it is possible to determine from the shape of the

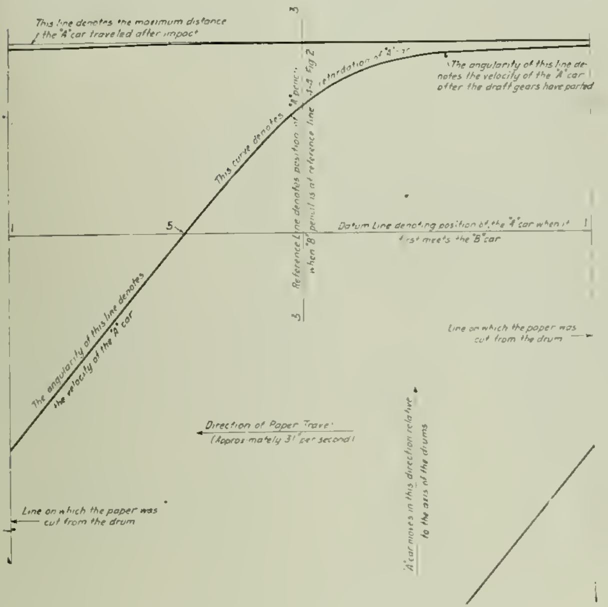


Fig. 1—Card Made by the A Car

curved line denoting the decrease in velocity of this car, the approximate forces which must have been at work to produce the retardation shown between any two points on the time

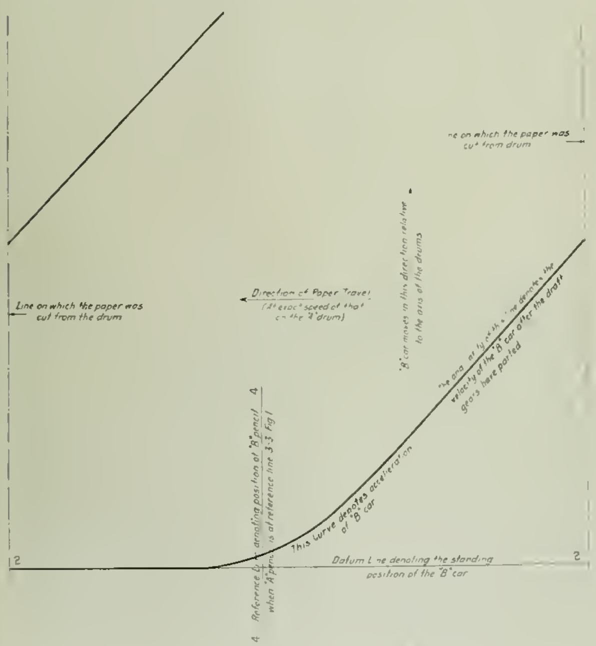

Fig. 2—Card Made by the B Car

axis. From the final angularity of the approximately straight line beyond the point of separation of the two cars can be determined the velocity of the *A* car after the draft gears have parted and the number of foot pounds of energy still stored in this car. On cards made from certain draft gears the *A* car comes to rest as denoted in Fig. 1 before it has traveled beyond the limit of the pencil movement along the *A* drum.

Referring to Fig. 2, from the curve drawn by the *B* car can be determined the rate of acceleration of this car and its final velocity when the cars part. Knowing this velocity and the weight of the car it is possible to calculate the energy transferred from the *A* car to the *B* car. From Figs. 1 and 2 it is thus possible to determine the actual energy absorption which has taken place during the draft-gear cycle.

The common datum and reference lines drawn on the two cards prior to the test run make it possible exactly to superimpose one curve upon the other, thus producing a graphic record of the relationship of the cars to each other throughout the significant range of movement. This has been done in Fig. 3.

From the superimposed cards it is possible to determine point 5 at which the draft gears begin to close, the point at which they closed to the maximum amount, point 6 at which they finally part, the distance the cars move along the track during any period of time within the range of the diagram, the time required for any phase of the gear movement cycle, and the amount of draft gear travel at any instant, this being

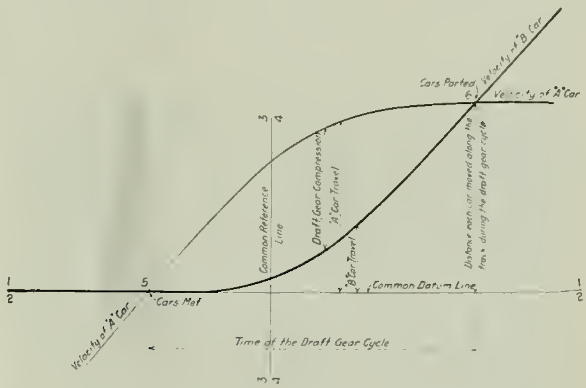

Fig. 3—Cards from A and B Cars Superimposed

indicated by the vertical distance between the two curves at that instant.

In addition to the instrument with which these diagrams are obtained, the *B* car is also equipped with a small constant-speed motor driven recording drum, the pencil movement of which records the movement of the buffer stem on that car with relation to the car body, by means of an equalized piano wire connection to the top and bottom of the rear end of the front follower. The card from this drum reflects the smoothness of action of the draft gear in closure and release on a time-closure basis and provides a measure of the maximum closure of the draft gear on the *B* car. In addition to the record thus obtained, which compensates for any tendency of the follower to tilt in a vertical plane, the buffers of both cars are fitted with the closure gage shown in one of the illustrations, from which the maximum gear movement may be measured. These gages are a part of the regular equipment of the test cars as they have previously been used.

To the side of each car are also attached two pendulum shift gages or seismographs. The pendulums of these instruments are arranged to swing freely in but one direction from the perpendicular, the two instruments on the same car being arranged so that the pendulums swing in the opposite directions. The swing of the pendulums under the action of inertia carries with it a small marker mounted on a graduated segment, a friction spring in the marker causing it to remain in the position to which it is moved by the swing of the pendulum. These instruments are a part of the regular test equipment of the cars and the records obtained from them provide a means of comparison of the load shifting tendencies of the impact with various draft gears.

The demonstrations were entirely unofficial in character, no records or detail comparisons of commercial gears being taken. The curves here reproduced were obtained with M.C.B. spring draft gears in both cars.

A SUPPLY TRUCK FOR EMERGENCY REPAIRS

BY A. J. KIPP
Shop Engineer, Chicago, Milwaukee, & St. Paul

A station supply truck fitted with all the material for emergency repairs which is usually carried in supply sheds, is a new device that has proved very useful since its introduction on the Chicago, Milwaukee & St. Paul. These trucks are designed to be used at passenger terminals and are a great help in making quick repairs. Formerly if a train came in with a hot box the inspector had to go to the shed for jacks, brasses and packing, but now the truck is brought up beside the car and the man has all the tools and supplies he requires within easy reach. For other minor repairs the truck has been found equally convenient.

The truck itself is 5 ft. 2 in. long, 3 ft. 8 in. high and 14 in. wide, with three horizontal doors on each side extending the full length of the truck. The arrangement was made as compact and narrow as possible so that the truck could readily be used between two trains standing on adjacent tracks. The interior is partitioned off for holding the standard supplies carried in the truck, which are listed below.

The Supply Truck Facilitates Making Quick Repairs

2—Journal box jacks.
2—Journal box jack boards.
2—Journal box jack levers (pinch bars).
2—Packing hooks.
2—Packing irons.
1—Pail prepared packing.
1—Empty packing pail.
6—Brake shoe keys.
3—Brake shoes.
Spring cotters (various sizes).
1—Brass 5½ in. by 10 in.
1—Brass 5 in. by 9 in.
1—Brass 4¼ in. by 8 in.
2—Brake connection pins 1⅛ in.
2—Brake connection pins 1¼ in.
2—Brake connection pins 1⅜ in.
1—Knuckle pin, cotter and washer.
1—Bearing wedge 5½ in. by 10 in.
1—Bearing wedge 5 in. by 9 in.
1—Bearing wedge 4¼ in. by 8 in.
12—Standard nuts each, ⅞ in., ¾ in., ⅝ in.
12—Lock nuts each, ⅞ in., ¾ in., ⅝ in.
1—Steam and air hose wrench.
1—12-in. pipe wrench.
2—1¼-in. train pipe nipples and couplings.
3—Each, ¾-in. and 1-in. train pipe nipples and couplings.
3—Combination air and signal hose couplings.
1—Small roll ⅛-in. wire.
6—Air brake defect cards.
1—Signal hose.
3—Air hose.
3—Steam hose.
1—1¼-in. angle cock complete.
6—Steam hose gaskets.
6—Air hose gaskets.
2—Signal hose gaskets.
1—Cold chisel.
1—Hammer.
1—Small drill.
1—Bracket for blue flag marker.
1—Bracket for blue lantern.
1—Screw driver.
1—Gallon can of car oil.
6—Wooden oil box lids (various sizes).
6—Pieces of second hand carpet to use as box covers.
4—Bolts ½ in. by 6 in.—3-in. thread with nut and washer and lock nut.
12—Tee head pedestal tie strap bolts with nuts and washers.
1—Coupler tail pin complete.
1—Ohio knuckle lock complete.
1—Uncoupling lever clevis complete.
1—Brake chain clevis complete.
1—Monkey wrench.
2—White pine reservoir drain plugs.

The car foremen in charge of the stations where the trucks are used are held responsible for keeping a full stock of material in the trucks at all times. Employees of the car department are the only ones authorized to have access to them, and this only in case of actual emergency. When any material is removed it must be accounted for and replaced by the employee using it. The truck is assigned to a definite location where it will be most convenient for the men who are using it, and care is taken to see that it is kept fully supplied and secured by a standard repair track lock at all times when not actually in service. These trucks have proved a great convenience and 50 are now in use on the C. M. & St. P. system.

Hospital Car Now Used in Evacuating Soldiers from Along the Line to the Base at Vladivostok

The Lubrication of Journal Boxes

Inspection and Care of Passenger and Freight Cars in Yards and Shops; Preparation of Packing

BY M. J. O'CONNOR
Special Inspector, New York Central

In view of the conditions that exist on practically all the railroads in the United States at the present time, the lubrication and care of rolling stock equipment is very important. The first and most important matter in connection with this feature of equipment maintenance is standard instructions, issued in book form, covering the preparation and maintenance of journal box packing, also the equipment necessary to handle the material as well as the tools, which is a very important matter in connection with the proper method of applying packing to journal boxes.

To handle the lubrication of equipment properly and to reduce hot boxes to a minimum, the following methods should be adopted: A suitable building should be fitted up with metal tanks equipped with ¼-in. mesh screens about three inches from the bottom of the tank and 1¼-in. faucets or molasses gates for drawing off the oil. The dimensions of these tanks should be in accordance with the requirements of the yard or shop, based on the number of cars handled per day. For example, at a large yard where from eight to twelve thousand cars per day are handled, in addition to a preparation tank, additional storage tanks should be maintained, in order to allow sufficient time for packing to become properly saturated in preparation tanks.

Preparation of Journal Box Packing

The waste must be carefully pulled apart and a known weight placed in the preparation vat, adding sufficient oil to completely submerge the waste (for 50 pounds of waste this will be 60 gallons of oil). Allow the packing to stand for 48 hours; draw off the excess oil (in above case this would be 35 gallons), leaving just sufficient oil to maintain the ratio of four pints of oil to each pound of dry waste. The work should be performed in a room at a temperature of about 70 deg. As the oil continues to drain, it should be drawn off from the bottom of the vat and poured back over the top of the waste, thus having the packing always ready for service. In tanks of two or more compartments, one can be used as storage for prepared packing, while the other is being used for the saturation of fresh packing.

It has been proved from experience that the waste used in the lubrication of passenger equipment cars, which is approximately 50 per cent cotton and 50 per cent wool, machine mixed, is superior to all wool, in that the fine cotton threads prevent excessive expansion and at the same time hold the material together, thus eliminating the lint which is produced by the revolution of the journal. The use of wool waste for the lubrication of freight cars is an unnecessary expense, as it has been found that as good results are not procured as from ordinary cotton waste. Cotton waste will retain the oil nearer the surface of the packing, which greatly assists the packer in knowing that the packing contains sufficient oil, whereas with all wool waste the oil precipitates to the cellar of the journal box with the result that it requires more than normal friction to convey the oil up to the surface of the journal.

The man in charge of the oil room should be thoroughly instructed to drain off the oil that settles in the bottom of storage tanks, and to pour it back over the packing several times daily. When the oil is poured over the packing it must be equally distributed to cover the entire surface of the packing contained in the storage tank. The oil rooms should be kept clean and free from dust and other foreign matter at all times, and no dry waste or wiping towels allowed to be carelessly thrown in or mixed with the packing.

In addition to these tanks, it is necessary to have a metal container to hold rolls that have been made up of dry waste, which have later been submerged in oil. These rolls are to be used without carrying much oil, or in other words, moderately dry, in order to have them ready to apply to boxes at all times. The standard dimensions of these rolls is 2½ in. in diameter by about 11 in. in length. These rolls assist in better excluding the dirt in the back of boxes as well as holding the oil in the box.

A standard dope bucket should be used for handling prepared packing and nothing else. After a train of cars has been gone over by the yard or shop doper, all packing remaining in the bucket should be placed back in the storage tank until necessary to go over the next train of cars.

Method of Packing Journal Boxes

First place the prepared roll in the mouth of the box, using care to center the roll, then it should be shoved back evenly under the journal with the packing iron so that it is in the proper position when it reaches the extreme back of the box. The packing should be picked up by hand and placed across the entire mouth of the box. This is absolutely necessary in order to keep the packing evenly distributed in the operation of placing it in the box. This method insures even distribution while being placed in the box due to feeding the packing in a continual strand under the journal (not on the sides) until the box is completely packed to the center line of the journal, straight down from the inside face of the collar. No packing should extend beyond the end of the journal. It has been proved that the elimination of the so-called front waste plug affords the inspector a better opportunity to examine the contained parts of the journal box, as well as assisting the doper to know that when packing extends beyond the journal collar, there is either surplus packing in the box or else the packing has worked outward. In either case, the remedy is immediately applied.

When wheels are applied, the journals should be thoroughly cleaned, and the bearing surface of the brasses coated with oil. No waste either dry or saturated should be used in oiling the journal bearing, to avoid any particle of waste or foreign substance remaining on the journal bearing when it is applied. Tight fitting dust guards should be applied in all cases when wheels or journal boxes are applied. Where new journal boxes or integral truck sides are applied, the interior of the boxes should be free from scale and sand or any other foreign substance.

Care of Packing in Journal Boxes

All passenger equipment cars are to have the packing removed, bearings examined and the boxes repacked in accordance with the foregoing instructions, as the cars go through the shops for general overhauling or where terminal facilities will permit. Passenger equipment cars operated in through and important service must have the packing re-

[1]From a paper presented before the Car Foremen's Association of Chicago, April 14, 1919.

moved, bearings inspected and boxes repacked once every six months thereafter; letters "NP," together with the date and initials of the place to be stenciled on the right-hand corner of the outside of the truck when so repacked.

Journal boxes of freight equipment cars must have the packing removed, bearings examined and boxes repacked as the cars go through the shop or on repair tracks, if the stenciling indicates that they have not been repacked within nine months. When newly packed or repacked, they must be stenciled as to the date and place of repacking.

When the movement of cars is reversed while en route, the proper adjustment of packing is very important, as it is found that the packing works to the rising side of the journal in a great many instances and will remain in that position in the reverse movement if not readjusted, causing the journals to heat, as packing in this position will not feed oil to the journal. Special instructions should be issued to the packers that where box lids are found difficult to open, they should obtain assistance from the running repairer or inspector. In no case should a box be jacked up in the yards or shops without first removing all the packing.

The most important part of the work for the successful lubrication of equipment is intelligent attention to the condition of the packing in the journal boxes, which, briefly, consists in loosening up the packing to avoid the hardened and glazed condition resulting from too long a contact with the journal, then loosening the packing by pulling it forward from the sides and working it back under the journal at the center. If new packing is needed, it should be worked back under the journal from the center by this method, thus raising the portion on the sides, care being taken that it is not lifted above the center line of the journal on either side.

When a car is found with a hot box or a mark indicating a hot box, a careful inspection must be made to ascertain the cause of heating. If the journal is smooth, a new brass should be applied and the box repacked with fresh packing. If the journal is rough, a new pair of wheels must be applied. Under no circumstances must a journal which has been heated be reapplied to a car unless it is in a perfectly smooth condition. A journal which has been heated sufficiently to discolor it, must never be reapplied to a passenger equipment car regardless of its condition in other respects.

The inspection and application of journal bearing wedges is a very important matter. In not more than one-half of one per cent of the cases where journal bearings are applied are the wedges renewed, and this is done only where the wedge lugs are badly bent or broken. This condition would indicate that the proper inspection is not made to ascertain whether or not the wedge has any crown. All new journal bearing wedges have a crown of about one-sixteenth of an inch and this crown should be maintained to obtain good results.

RECLAMATION OF JOURNAL BOX PACKING

All packing when removed from journal boxes should be pulled into a bucket, avoiding contact with the ground or any other place where it may pick up dirt, and taken to points designated on the several divisions for reclamation. In reclaiming packing, it should first be picked over carefully, the heavy dirt, metal, etc., shaken out, the knotted strands of waste pulled apart and then placed in the hot oil compartment of the "reclaiming tank." Not more than six to eight inches in depth of packing should be carried in the hot oil tank at any one time, as this insures thorough cleansing. Ten to fifteen minutes in the hot oil is sufficient. The temperatures of the oil must not exceed 180 deg. nor be less than 150 deg. The height of the oil in the hot oil compartment should be maintained to within about six inches of the top so that the waste may be washed in a pool of hot oil as it is removed.

After removal from the hot oil bath, the waste should be placed on the drainage rack on the hot oil side of the reclaiming tank and allowed to drain until the oil and water are well out of it. Only a small amount of packing should be carried on the drain rack at one time in order to facilitate drainage. After proper drainage has been effected, the waste should be transferred to the cold oil compartment for resaturation, this requiring about twenty or thirty minutes. When removed from the cold oil compartment, the packing should be placed on the drainage rack in the cold oil side of the reclaiming tank and allowed to drain until it has reached the proportion of four pints of oil per pound of waste (this condition being determined by the flow of oil under light pressure between thumb and finger), when it must be placed in a storage tank to prevent further drainage.

The hot oil compartment should be cleaned at intervals of two weeks or oftener where the volume of material handled warrants it. Oil should be extracted from all sediment removed, by pressure or drainage, and the oil thus extracted should be run through the separator and then returned to the hot oil compartment of the reclaiming tank.

The reclamation of journal box packing answers two very important purposes. First, it insures the material removed from boxes being placed back in them in a very much improved condition, so much so that the results obtained from its use where new journal bearings are applied has been very gratifying. These results are due in a measure to the reclaimed material being more thoroughly saturated than new, also forming a more compact body, thereby conveying the oil to the journal more readily. Second, it is a check against the shop doing this work; for example, a certain shop receives 10,000 lb. of prepared packing in a given period; nearly the same amount should be removed from boxes as compared with that applied. If a reasonable amount is not sent back investigation will develop that the boxes repacked have not been handled in accordance with instructions; in other words, the boxes have been overpacked or else the material removed has been carelessly thrown on the ground.

Truck conditions contribute very materially to the cause of journals heating on freight cars, as for example, the absence of nuts from column bolts and box bolts. Where the nut is missing from the column bolt, invariably the arch bar springs up, throwing the weight on the journal box and putting the box out of line. Where box bolt nuts are missing on trucks passing over low joints and crossovers, it has a tendency to allow journal bearing to become unseated from time to time with the result that packing becomes wedged between the journal and the bearing, also causing journal bearings to become broken. Cars with the arch bars worn at the column and box bolt holes, allow the box to cant inward causing the journal bearing to ride partially on the side of the journal. This defect of worn bolt holes is due primarily to nuts missing from bolts or nuts not drawn home, which allows the bolts to keep working upward and downward and also to turn when the car is in motion.

Another matter that contributes to journals heating is the absence of grease on center plates and friction side bearings. It has been found that body side bearings wearing into the truck side bearings causes the truck to bind, thereby throwing the weight to one side. This condition is due principally to center plates and side bearings not being greased. All empty cars making shop track movement should have the center plates and side bearings greased, also loaded cars where trucks have been removed. The proper time to correct these conditions, particularly on private owned cars, is when cars are home.

In order to maintain standard instructions and practices at all points on any one railroad, an experienced man with authority should be assigned to follow up this work exclusively, and where this is done, a performance of approximately 150,000 miles per car per hot box on passenger equipment cars and 30,000 miles per car per hot box on freight cars has been obtained. The basis upon which this performance is compiled includes cars arriving at terminals which have caused no delay as well as those which have caused delay to the transportation department.

DISCUSSION

There was considerable discussion of the advantages and disadvantages of packing boxes without the front waste plug. The majority of members considered that better results were obtained when the plug was omitted. In connection with the reclamation of waste, attention was called to a mechanical reclamation process in which no washing oil is used. Three machines are employed, a combination oil extractor and filter, a mechanical cleaner and an impregnator which saturates the waste with oil. With this equipment it was stated that one man can reclaim 100 lb. of waste per hour.

Creosote Treatment of Car Timbers

Methods Used by Marsh Refrigerator Service Co., Cost of the Work and Estimates of Increased Life

THE preservative treatment of lumber for use in car construction is a matter which has received considerable attention from railroads during the past few years. The possibilities for increasing the life of timber and thus reducing the cost of maintenance by such methods are now generally realized although treated lumber has not been used in the construction of cars for a sufficient length of time to determine the life which can be secured from treated sills, flooring or roofing. The method of treating cross ties and piling is different from the process used in applying preservatives to car timbers, and for that reason the life secured from structural timber when treated with preservatives does not indicate the length of service that may reasonably be expected from treated lumber used in car construction.

The Marsh Refrigerator Service Company, Milwaukee, Wis., has used the creosote treatment for sills and roofing applied to refrigerator cars for some time past. In order to determine the amount of impregnation being secured by the method of treatment used on these parts and to estimate the probable average life of the treated lumber, this company recently conducted a series of tests of the process of creosoting sills and roofing. The material creosoted consisted of standard refrigerator car sills 5 in. by 8 in. by 35 ft. and roof boards and sub-flooring 1 in. by 4 in. by 5 ft. All the lumber was southern yellow pine, the average grade being No. 1 common. The average density was approximately 8 annular rings per inch and about 30 per cent was summer wood. The lumber was all kiln-dry stock and was well seasoned, the average dry weight being 25.6 lb. per cu. ft.

TREATMENT OF SILLS

Seven sills fully framed, with mortises and tenons cut and bolt holes drilled, were taken from stock at random for the test. The individual sills were numbered and were weighed both before and after treatment. The preservatives used in the treatment of all the lumber was Carbosota, a liquid creosote oil, conforming to United States Railroad Administration specifications R 828-A. Sills numbers one to seven inclusive were subjected to a hot treatment for six hours, being completely submerged in the creosote oil, which was held at an average temperature of 150 deg. F. The steam was then shut off, and the timbers were permitted to cool for 11 hours, after which they were removed from the treating tanks and placed on a dripping rack, where they were permitted to drain for six hours. The temperature of the oil when the sills were removed was 120 deg. F.

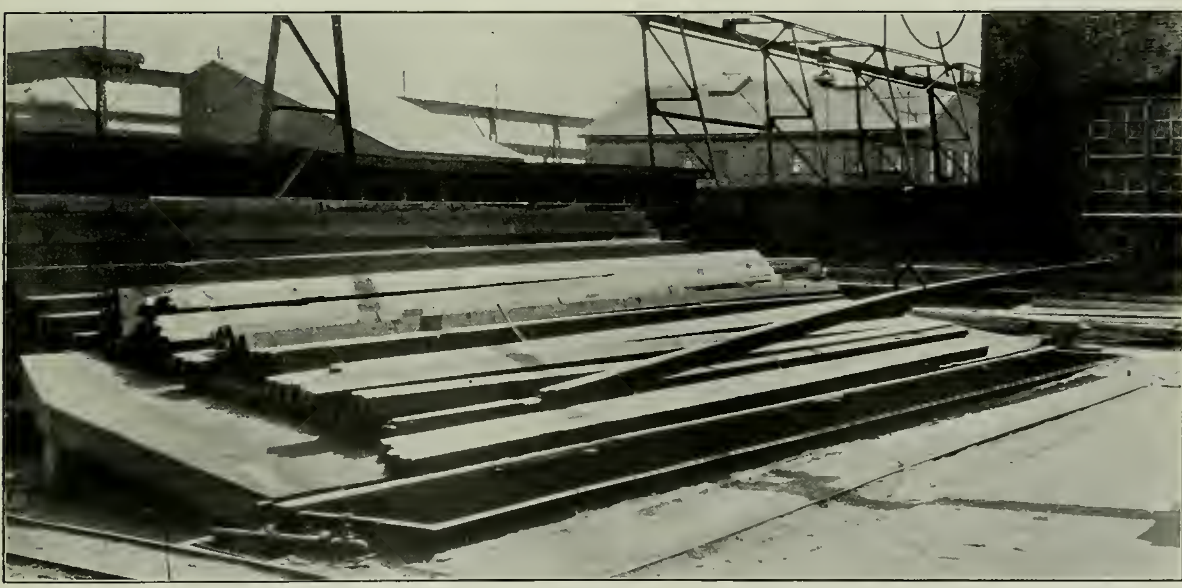

Fig. 1—Tank in Which Sills Are Treated with Creosote Oil

Sills numbers eight to ten inclusive were given a shorter treatment in the hot oil, the preservative being heated for only one hour during which the average temperature was 125 deg. F. The cooling treatment was continued for 11 hours, and upon the completion of the treatment the creosote oil was about 100 deg. F.

After draining the sills were weighed to determine the amount of creosote absorbed. The result of the treatments are shown in Table 1 below.

3	335.0	425.0	34.5	43.8	7.07	.9	3.34	10.7
4	350.0	449.0	36.0	46.2	7.90	1.0	4.88	15.6
5	350.0	524.0	36.0	54.0	15.24	1.9	4.88	15.6
6	352.0	483.0	36.3	49.8	11.0	1.4	5.1	16.4
7	332.0	471.0	34.2	48.5	11.90	1.5	3.03	9.7
Averages	355.6	473.7	35.85	48.24	9.97	..	4.65	15

As will be noted there was a considerable variation in the amount of creosote oil absorbed. Piece No. 2-B was impregnated throughout, the estimated absorption being 28 lb. per cu. ft. This exceptionally heavy impregnation was no doubt due to the slightly dotey condition. On the other hand, specimen 4-D absorbed only 1.9 lb. of creosote oil per cu. ft., due to the practically green condition of the timber which was also fairly dense and contained a large percentage of summer wood. Specimen 1-A is representative of the average grade of timber. This piece absorbed about 10 lb. per cu. ft., the penetration obtained being shown in Fig. 2, which represents sections cut about 4 inches from the end and from the center of the stick. As will be noted, the portions of the timber exposed to decay have been thoroughly treated.

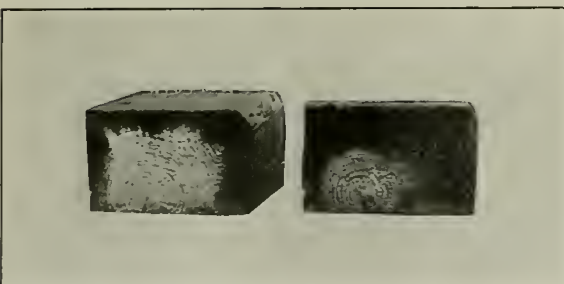

Fig. 2—Sections Through Treated Sill Showing Penetration of Creosote

The average absorption of 10 lb. per cu. ft. which was obtained with sills No. 1 to 7 inclusive indicates the possibilities of the open tank method of treatment with refined coal tar creosote oil under proper conditions. The lack of penetration in the case of piece 4-D shows the need for thorough seasoning of wood to be treated by the non-pressure process. Unless the wood is thoroughly dried satisfactory results are in most cases not obtained.

The results obtained on sills No. 8 to 10 are shown in Table 11.

Table II

Weight of Sills and Absorption of Creosote with Short Treatment in Hot Oil

Pc. No.	Estimated absorption: Total wt. before treatment, lb.	Total wt. after treatment, lb.	Wt. per cu. ft. before treatment, lb.	Wt. per cu. ft. after treatment, lb.	Increase in wt. per cu. ft., lb.	Lb. per surf. sq. ft.	Gals. per 100 sq. ft. surf.	Moisture: Lb. per cu. ft.	Per cent
8	312.5	340.5	32.23	35.10	2.87	.368	4.1	1.03	3.3
9	365.0	381.0	37.63	39.28	1.65	.210	2.3	6.43	20.6
10	342.5	370.0	35.31	38.14	2.83	.361	4.0	4.11	13.2
Averages	...	...	35.06	37.51	2.45	.313	3.5	3.86	12.37

The small absorption in these specimens proves the necessity for a long hot treatment. As an approximate rule it may be stated that wood naturally resistant to the injection of creosote oil should be immersed one hour for each inch of the largest cross section in both the hot and cold bath. When treating woods not difficult to impregnate this time may be reduced one half. This applies to treatments where separate hot and cold baths are used, but where the timbers are left in the hot creosote oil until it cools, the cooling treatment should be carried on for 10 to 12 hours.

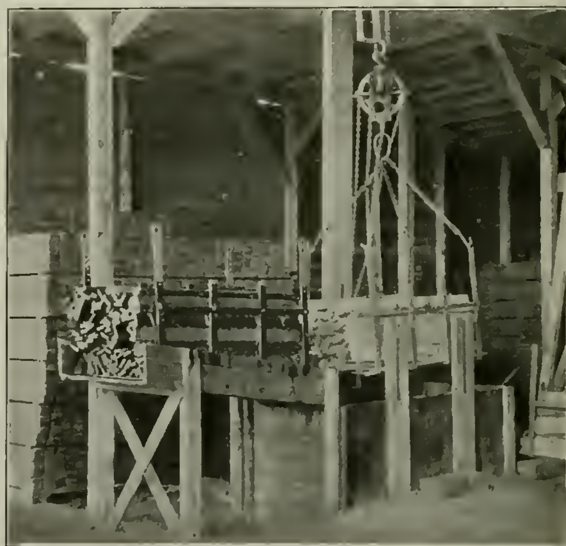

Fig. 3—Devices for Handling Roof Boards During Treatment

The theory of the process described above is that during the hot treatment the heat of the preservative expands and expels a portion of the air and water contained in the wood cells. Then upon immersion in the cold bath or upon the gradual cooling there is a partial contraction and the condensation of the air and water remaining in the wood results in a slight vacuum being formed. This, aided by atmospheric pressure and capillary action between the wood cells and the preservative, causes the actual impregnation with oil.

TREATMENT OF ROOF BOARDS AND SUBFLOORING

Ten pieces of roofing material 1 in. by 4 in. by 5 ft., taken at random from stock, were numbered and weighed. These pieces were then bundled together and were creosoted by immersion in the heated creosote oil only. Because of the small cross section of this lumber the standard open tank process used in treating the sills was not required. Pieces No. 0 to 9 inclusive were submerged for a period of 45 min. at an average temperature of 160 deg. F. They were then removed from the tank and allowed to drain, after which they were weighed to determine the absorption of creosote oil. The impregnation was somewhat greater than is necessary under the conditions of service for which this material is used. The average absorption secured by this method, as shown in Table III, was approximately 6.55 lb. per cu. ft. The expense of such treatment would probably not be warranted for this material.

TABLE III

Absorption of Creosote by Roof Boards Immersed for 45 Minutes

1 Pc. No.	2 Total wt. before treatment, lb.	3 Total wt. after treatment, lb.	4 Total increase in wt., lb.	5 Wt. per cu. ft. before treatment, lb.	6 Wt. per cu. ft. after treatment, lb.	7 Est. absorpt'n increase in wt. per cu. ft., lb.

CARING FOR TIMBER BEFORE TREATING

The proper drying of lumber before treating is of great importance, but satisfactory results can be secured with stock that has been thoroughly air dried. Timber should be piled in such a manner as to permit a constant circulation of air around each individual piece, and care should be taken to avoid contact with wood that has started to decay. If creosoted sills are available they should be used as the foundation for the pile. In no case should timber be piled on cinder fillings or where vegetation can come in direct contact with it. Sills before being placed in the creosote oil should be fully framed and all mortises and tenons should be cut and all bolt holes drilled.

EQUIPMENT USED FOR CREOSOTING

The equipment required for treating lumber with creosote oil is extremely simple, and both the initial cost and the cost of operation are low. The tank in which sills are treated at the plant of the Marsh Refrigerator Service Company is shown in Fig. 1. It is about 50 ft. long, 4 ft. wide and 4 ft. deep, with steam coils in the bottom for heating the oil, and is located in a portion of the yard served by a crane, which greatly facilitates handling the timber. It has been found that some lumber will float in the creosote, and to correct this the tank is to be fitted with a device for holding down the sills during treatment.

For treating the roof boards and the subflooring a smaller tank is used, shown in Fig. 3. This tank is made of wood lined with tin, and is 3 ft. wide, 6 ft. long and 2 ft. 6 in. deep. The boards to be creosoted are piled loosely in frames made of iron bars. About 150 to 200 pieces are placed in the frame which is raised by a chain hoist and lowered into the creosote. Levers attached to the frame above the tank are used to insure complete immersion of the lumber. After being treated about 30 min. the frame is placed on the drying rack to allow the surplus oil to drain off, after which the material is ready to be placed in storage.

The timber which has been creosoted, particularly the subflooring and roofing, is given an opportunity to dry thoroughly before it is placed in the cars. With the refined coal tar creosote oil the material dries readily in from two to three days during fair weather. In order to permit of keeping on hand a stock of dry creosoted material sufficient to meet the requirements, storage space is provided for an extra stock in excess of that required to permit the material to dry. Roofing and flooring is treated during the summer months in sufficient quantities to provide a supply to last through the winter, as this work can be more readily handled during the warm weather.

COST OF PRESERVATIVE TREATMENT

The average cost of treating sills 5 in. by 8 in. by 35 ft. has been estimated as follows:

Creosote oil, 10 lb. per cu. ft. for 9.7 cu. ft. (10.8 gal.)	$4.00
Labor and overhead	.50
Total cost per sill	4.50
Cost per thousand feet, board measure	38.54

In treating the subflooring and roofing two men handle approximately 400 pieces per hour, making the labor cost per piece $.0005. Overhead is estimated at $.0005 and the cost of creosote oil at 8 lb. per sq. ft. of surface makes a total cost per piece of about $.018 or $10.65 per thousand feet board measure.

ECONOMY OF TREATED MATERIAL

It is estimated that the treatment of lumber for refrigerator cars will result in a large saving. The average life of untreated roofing boards has been found to be approximately six years. Creosoted material in the same location, unless destroyed by abrasion, should last from 12 to 15 years. The life of the sills should be correspondingly increased. The savings effected will be much greater than would be indicated by the reduction in cost of the material over a given period of years, especially in the case of the sills, as the replacement of these parts entails not only a loss equal to the value of the sill and the labor of applying it, but also the value of such other material as may be destroyed or made unfit for further use in replacing the decayed sills.

TRACK CURVATURE IN CAR DESIGN

BY ALBERT H. LAKE, JR.

In the design of the modern railroad car having pivoted trucks, it is necessary to know the radius of track curvature over which the car will pass without interference of the wheels with the car body, the brake rods or the brake pipe, and also to ascertain if the striking plate is of sufficient depth to avoid interference at the corner of the car or push pole pocket.

With the following formulae and table, used in connection with Figs. 1 and 2, these clearances may easily be calculated. The angle A and the distance H may be found by the use of Fig. 1 and the formulae. Referring to Fig. 1:

A = The angle formed by lines drawn from the truck center and the center of the car to the radius point O and is also the angle formed by the center lines of the car and of the truck, as these angles are always equal.

B = The angle formed by lines drawn from the pulling face of the coupler, with the horn against the striking plates, and the center of the car to the radius point O.

C = Distance from center to center of trucks.

$D = \frac{1}{2} C$.

E = Distance from the center of the truck to the face of the end sill or interference point at the corner of the car.

F = Distance from the center line of the car to the face of the side sill or interference point at the corner of the car.

G = Distance from center of car to the radius point O.

H = Distance from the face of the end sill or interference point at the corner of the car to the pulling face of the coupler with the horn against the striking plate.

$K = G - F$.

R = Radius of track curvature.

With the foregoing values the formulae are:

(1) $\text{Sine } A = D \div R$

(2) $G = R \times \cos. A$.

(3) $K = G - F\ (R \times \cos. A) - F$.

(4) $\text{Cot. } B = \dfrac{K}{D + E} = \dfrac{(R \times \cos. A) - F}{D + E}$

(5) $H = (G \times \tan. B) - (D + E) = [(R \times \cos A) \times \tan. B] - (D + E)$

The following example will illustrate the use of the formulae for Fig. 1. Let R = 100 ft. 0 in., C = 30 ft. 0 in.,

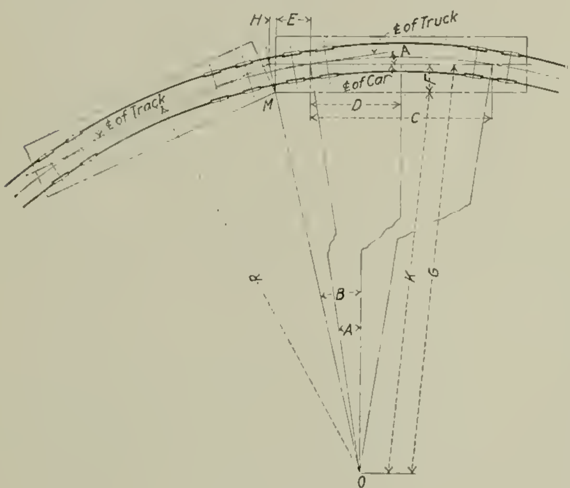

Fig. 1

D = 15 ft. 0 in., E = 5 ft. 6 in. and F = 4 ft. 9 in. From the table the angle A = 8 deg., 38 min. and cosine A = 0.9886.

Using formula (4)

$$\text{Cot. } B = \frac{(100 \times 0.9886) - 4.75}{15 + 5.5} = \frac{94.11}{20.5} = 4.59073$$

B = 12 deg., 17 min.; tan. B = 0.2177

Using formula (5)

$H = [(100 \times 0.9886) \times 0.2177] - (15 + 5.5) = 21.52 - 20.5 = 1.02$ ft.

It should be noted that formula (5) for the distance H does not consider the swing of the coupler sidewise, which varies to suit the detail of the striking plate.

Fig. 2 is used to find the distance of the highest point of the wheel flange from the center line of the car and also the travel of the truck side bearing. Referring now to Fig. 2:

A = The angle between the center line of the car and the center line of the truck, also between the center lines of the body and truck bolsters, and the axles.

B = The distance from the center line of the car to the center line of the side bearing.

C = Travel of the truck side bearing.

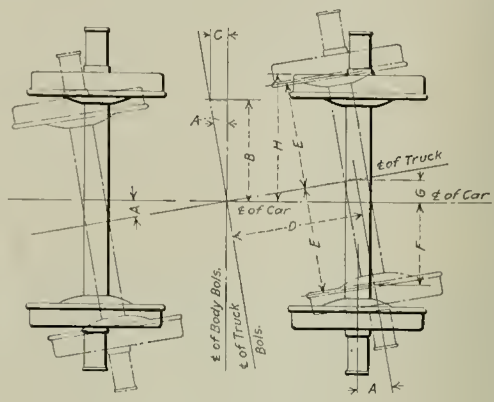

Fig. 2

D = The distance from the center line of the truck to the center line of the axle.

E = The distance from the center line of the truck to the highest point on the wheel flange.

F and H = The distance from the highest point on the wheel flange to the center line of the car.

G = The distance from the center line of the car to the center line of the truck at the axle.

The angle A is the same as in Fig. 1 and is found by formula (1) or from the table.

With these values the formulae for Fig. 2 are:

(6) $C = B \times \text{sine } A$

(7) $G = D \times \text{sine } A$

(8) $F = (E \times \cos. A) - G = (E \times \cos. A) - D \times \text{sine } A)$

(9) $H = (E \times \cos. A) + G = (E \times \cos. A) + (D \times \text{sine } A)$

The following example will illustrate the use of the formulae for Fig 2. Let A = 8 deg., 38 min.; B = 2 ft. 1 in.; D = 2 ft. 9 in., and E = 2 ft. $3\frac{1}{4}$ in. From the table, sine A = 0.1500; cos. A = 0.9886.

Using formula (6)

C = 2 ft. 1 in. × 0.1500 = 3.75 in.

Using formula (8)

F = (2 ft. $3\frac{1}{4}$ in. × 0.9886) — (2 ft. 9 in. × 0.1500) = 21.99 in.

Using formula (9)

H = (2 ft. $3\frac{1}{4}$ in. × 0.9886) + (2 ft. 9 in. × 0.1500) = 31.89 in.

For convenient reference the data may be calculated and tabulated as shown in the table.

Table Giving the Angle A and the Corresponding Sine and Cosine for for the Radii of Curvature and Truck Centers

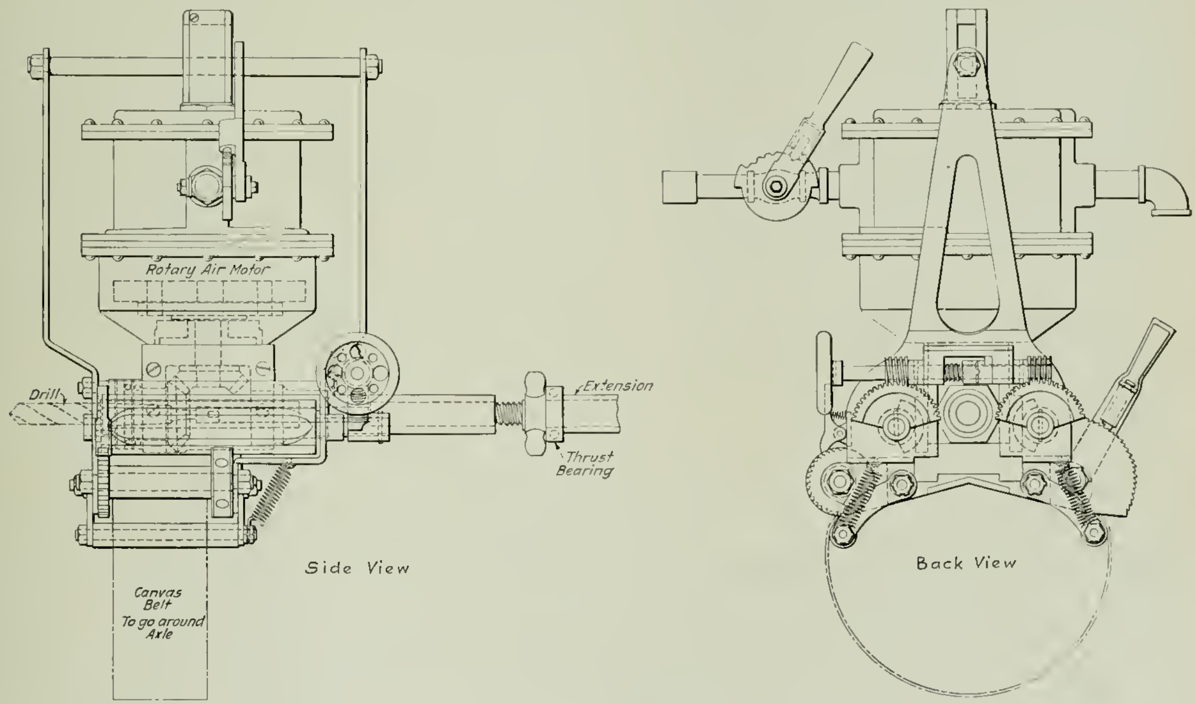
DRILLING HOLES FOR HUB PLATE STUDS

The work of drilling holes in driving wheel centers for holding hub plate studs is not easily performed with the ordinary air motor mainly on account of the difficulty of applying an "old man" on the axle. Furthermore, it is often difficult to get the proper alinement of the drill and air motor.

An ingenious device which saves considerable time in doing this work has been devised in the West Burlington shops of the Chicago, Burlington & Quincy, where it has been used with great success for some time.

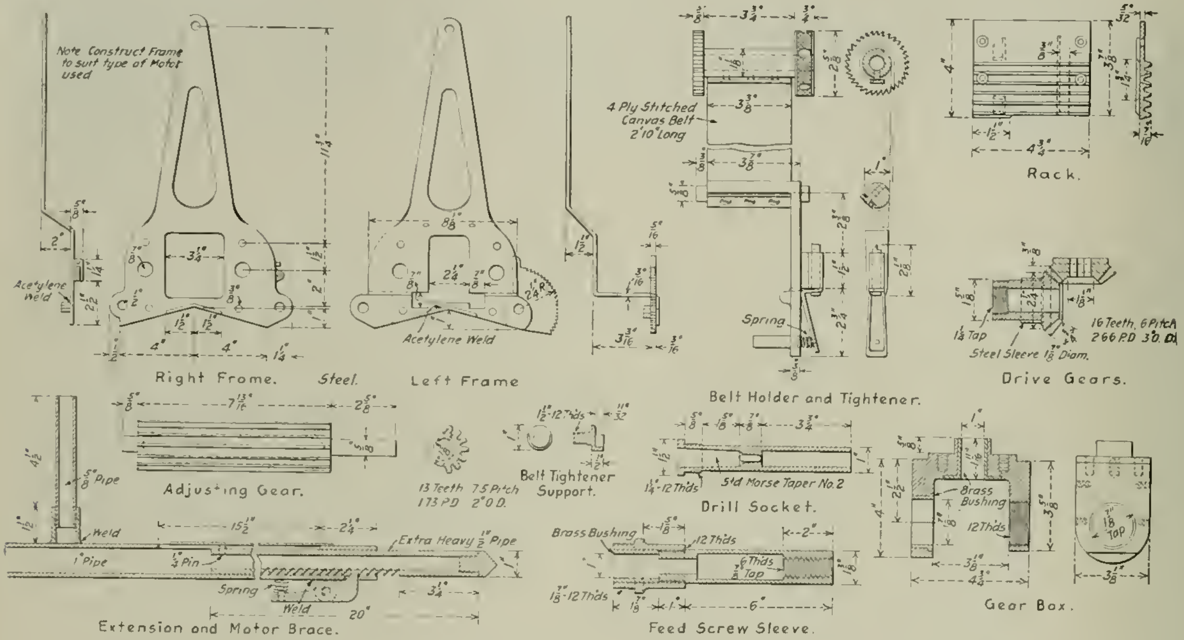
This machine, drawings of which are shown herewith, is arranged to clamp on the axle. It supports an air motor which drives a drill spindle, these parts being adjustable to bring the drill to any desired distance from the axle. The frame, *A* and *B*, is of 3/16 in. sheet steel with heavier sections welded on where necessary for bearings or other parts. On the lower end of this frame at one side is a spool which holds one end of a canvas belt 3⅜ in. wide and 2 ft. 10 in. long. The spool is fitted with a ratchet on one end and a wheel arranged with sockets for a short bar on the other end. The opposite end of the belt is attached to a tightener which is arranged to slip into the socket bearings *L*. To apply the machine it is set in place, the belt is slipped around the axle and the tightener is set in the sockets. The belt can then be adjusted by turning the spindle and tightened by pressing down the handle *K*.

The distance of the spindle from the axle is controlled by a hand wheel on the shaft *X*. This shaft carries right hand and left hand worms, and these engage worm wheels keyed to the shaft of two segmental adjusting gears. The adjusting gears in turn engage racks on the sides of the gear box which carries the drill spindle and driving gear. Thus by turning the hand wheel on the shaft *X* the spindle is moved radially toward or away from the axle. The width of the rack on the side of the gear box is 3 in. less than the length of the adjusting gears so the drill can be moved that distance parallel to the axle without resetting, this amount of adjustment being ample for the work on which the machine is used. The drill is fed by a hand wheel *R* which turns a feed screw *Q* in the sleeve *P* attached to the gear box, the extension *S* on the feed screw extending to the hub of the opposite wheel.



End and Side Elevation of Device for Drilling Driving Wheel Hubs

The drive is simple and is clearly shown in the illustration. The air motor is attached directly to the gear box, the end opposite the spindle being held by a guide which spans a rod across the frame. The bevel gear on the motor spindle engages another bevel gear which carries a socket for a No. 2 Morse taper shank, the inner end of which extends into a bearing in the feed screw sleeve. The gear which carries the drill socket has a ball thrust bearing and lock nuts on the end of the hubs which hold it in place in the gear box.



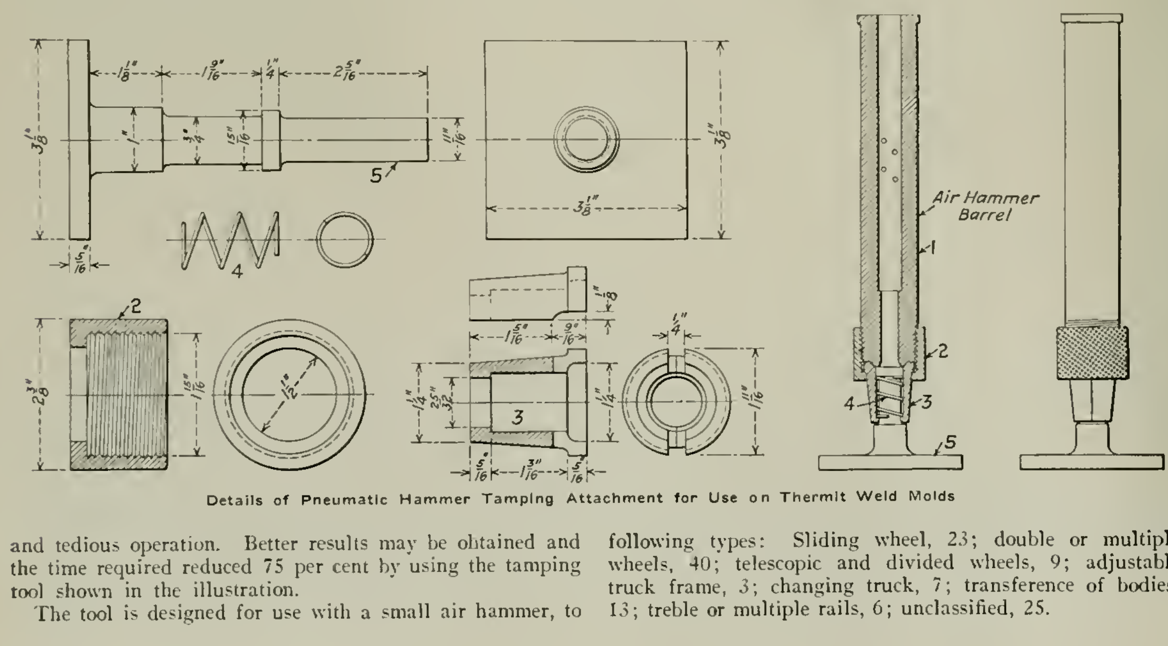
Details of the Hub Drilling Device

PNEUMATIC TAMP FOR THERMIT WELD MOLDS

BY J. F. D.

The practice on most railroads in making Thermit welds is to tamp up the mold box by hand. This is a rather long and tedious operation. Better results may be obtained and the time required reduced 75 per cent by using the tamping tool shown in the illustration.

The tool is designed for use with a small air hammer, to the end of the barrel of which is secured the special split fitting shown at *3* in the drawing. This is held in place by means of the nut *2*. The shank of the tamper works inside the fitting *3*; a coiled spring shown at *4* on the drawing is arranged within the fitting to effect the return stroke of the tamper after the blow of the hammer has driven it out.



Details of Pneumatic Hammer Tamping Attachment for Use on Thermit Weld Molds

Gage Difficulties in Australia.—The Federal railway authorities in Australia have had offered for their consideration no fewer than 126 different devices to meet the break of gage difficulty, but none has found favor. They are of the following types: Sliding wheel, 23; double or multiple wheels, 40; telescopic and divided wheels, 9; adjustable truck frame, 3; changing truck, 7; transference of bodies, 13; treble or multiple rails, 6; unclassified, 25.

E. J. & E. Has Efficient Flue Shop

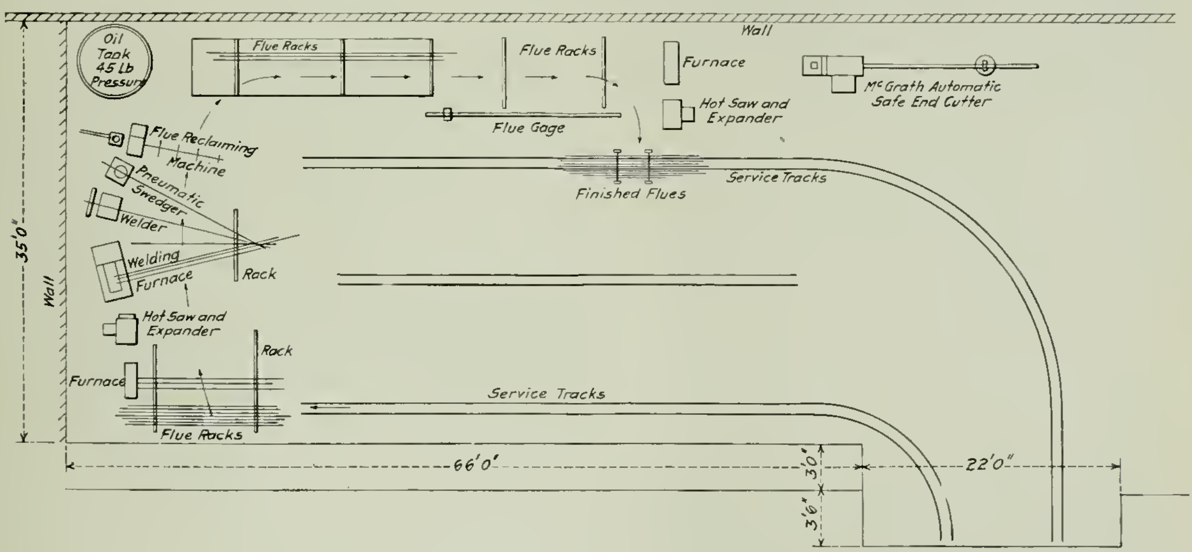
Rapid Production Secured with Small Force and Few Machines; Data on the Cost of Operation

THE locomotive repair shop of the Elgin, Joliet & Eastern at Joliet, Ill., has a flue shop which has made splendid records for high output and low unit cost. The plant includes a number of novel features which facilitate rapid production. One of the unusual points in connection with this layout is the fact that all the flue work excepting the removal of scale is handled on a balcony in the boiler department. In designing the shop it was thought desirable to provide ample room for the flue shop, and since the plan of the main floor did not present a favorable opportunity for securing the required space, the question of locating the department on the balcony was considered. The objection to this plan was the increased difficulty of handling the material. On the other hand, there were numerous advantages. The location on the balcony would keep the smoke and heat from the furnaces out of other parts of the shop, it would remove the tendency to encroach on the space devoted to flue work, and by reducing the space required on the ground floor would make a more compact layout possible.

The locomotive repair shop at Joliet is of the longitudinal type, approximately 400 ft. by 150 ft. The erecting bay extends along one side of the building. On the other side is a heavy machine bay served by a traveling crane and a light machine bay 35 ft. wide with a balcony. It was finally decided to locate the flue cleaner in the heavy machine bay with the remainder of the flue shop equipment on the balcony. A passageway 3 ft. wide extends along the balcony outside the columns on which the overhead crane runs, and by adding 3 ft. 6 in. to the width of the extension for a space of 22 ft. a landing stage was provided on which a set of flues can readily be handled. The flue shop was assigned a space about 35 ft. by 80 ft., which has proved ample for the work; in fact, a part is regularly used for storage purposes.

The layout of the machines in the shop is shown in the drawing reproduced herewith. Service tracks lead from the balcony to the first and last machines used in repairing the tubes, and in addition there is a storage track along the center. The tool equipment comprises two McGrath tube furnaces, two hot saws and pneumatic expanders (one equipped with a safe end magazine), a McGrath flue welding furnace, a Hartz flue welder, a Draper pneumatic flue swedger, a gaging stand, roller flue racks, a Ryerson boiler tube reclaiming machine and a McGrath safe end machine.

The operation of cutting the small tubes out of the boiler is performed in the usual manner by means of an air motor connected through a flexible joint to an expanding cutter. The large superheater flues are cut out of the boiler by the use of an oxy-acetylene cutting torch. The back ends of the tubes are cut out with an air hammer, after which the tubes are passed out through the front tube sheet and stacked on substantial standards built up of channels and flat bars, as shown in Fig. 1. The set of tubes or flues after being removed from the locomotive is picked up with chains attached to a yoke and set on stands, as shown in Fig. 2, until they are taken to the flue cleaning machine. The standards are of simple construction and provide ample space for passing chains around the tubes. The sets of tubes can be stacked one above another, and the space required is reduced to a minimum.



Layout of Flue Machinery on the Balcony

When the tubes are ready for cleaning they are taken to the flue cleaner or rattler, which is of the Ryerson pit type, and is shown in Fig. 3. An entire set of flues can be hoisted in chain slings and lowered into the pit onto the rolling chains of the rattler. The ends of the sling chains are fastened to hooks on the sides of the pit and left in position during the cleaning operation, as the flues rest on the rolling chains, and there is sufficient clearance between the tubes and the walls of the pit to keep the tubes from coming in contact with the chains. The tubes or flues are left in the rattler for from two to six hours, depending on the thickness and character of the scale. After the cleaning operation is completed, the sling chains are again hooked to the crane and the flues are raised out of the rattler and washed off with a hose, after which they are carried up to the balcony and deposited on the service track in the flue department, as indicated in the layout drawing.

The force employed in repairing tubes consists regularly of four men. The first man operates the hot saw, cutting off the rear end of the tubes, the second welds the safe end on the tube and swedges it, while the third cuts the front end of the tube and expands it. The fourth man is a helper, who assists in handling the tubes. When working on tubes more

Fig. 1.—Tubes Removed from the Locomotive Are Piled on Special Standards

than 18 ft. long an additional helper is required on account of the difficulty of manipulating the longer tubes.

The tubes undergoing repairs follow a predetermined course through the flue shop, as indicated on the floor plan by the series of arrows. From the car on the service track the flues are deposited on the roller flue rack adjacent to the first oil furnace. The front end of the tube is plugged with waste and the rear end is put into the furnace. Three or four flues are kept heating at one time to provide heated tubes as fast as they can be handled through the hot saw and

Fig. 2.—Tubes and Flues Stacked to Occupy Minimum Space

expander. The tube is heated just above the cherry red, and is then cut off in the hot saw shown in Fig. 4. The end is then inserted in the pneumatically operated expander. The movement of the expander is controlled by a hand-operated lever, which is arranged so that the movement of the latch operates the dies which hold the tube. Moving the lever forward opens a second valve, which forces the expander into the tubes and also releases a safe end from the safe end magazine at the side. The tube is next released from the expander, the safe end is forced into the end and the operator lifts the end of the tube over his head and inserts it in the welding furnace. The series of operations performed between

Fig. 3.—A Set of Flues About to Be Lowered Into the Pit Type Rattler

the first heating furnace and the welding furnace requires only five to seven seconds.

The welding furnace is especially designed for flue work

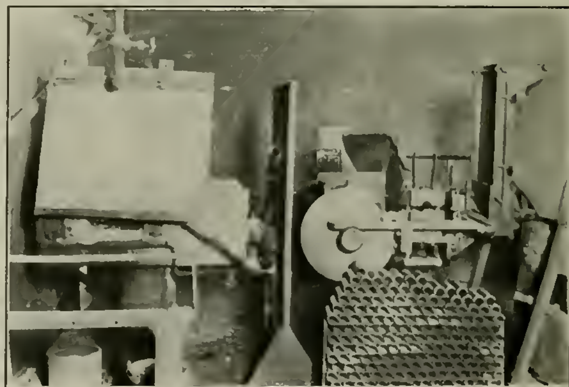


Fig. 4.—Furnace With Water Shield and Hot Saw and Expander With Safe End Magazine

and has three openings. The two openings farthest from the combustion chamber bring the metal up to a white heat, after

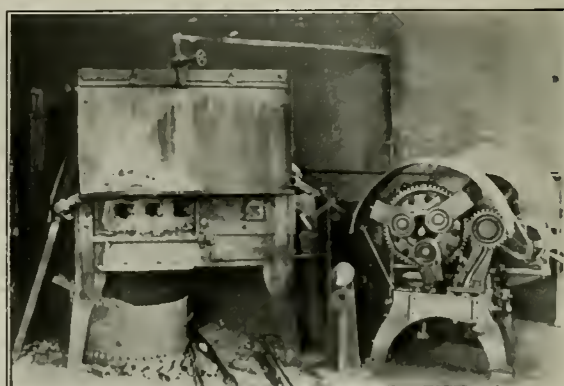

Fig. 5.—Welding Furnace and Roller Flue Welder

which it is placed in the opening nearest the combustion chamber for a few seconds, where the oxidizing flame brings it to a welding heat. The operator then removes the tube from the furnace and places it on the mandrel of the Hartz flue welder. By pressing down a treadle on the machine the revolving rollers are brought against the joints, welding the safe end to the tube. The operator then inserts the end of the safe end into the pneumatic swedger, reducing the size at the end and thus finishing the operation on the firebox end of the tube. The waste is then removed from the forward end of the tube and it is carried over to the roller flue rack and is pushed up within reach of the operator on the second hot saw.

The operation on the front end of the tubes consists in

Fig. 6.—Roller Flue Racks Serving Second Hot Saw and Gaging Stand

cutting to length and expanding slightly. The tube is inserted in the furnace until it is brought to the proper temperature for cutting. It is then removed and the back end is placed in the channel on the stop shown in Fig. 6, which has been set at the proper distance from the hot saw to make the tube precisely the length required. The tube is then placed in the expander with the back end resting against the angle stop, which brings it forward the proper distance to secure the required amount of expansion in the end of the tube. The finished tube after being removed from the ex-

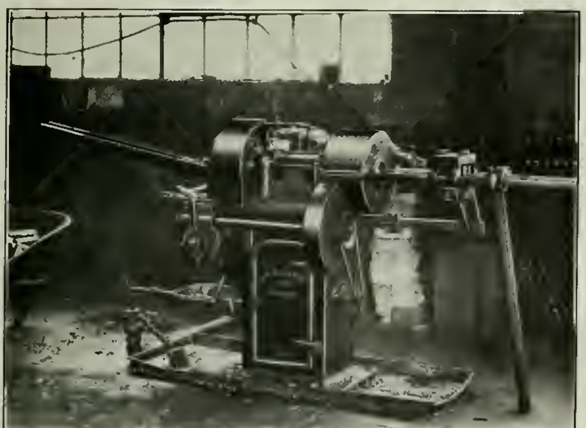

Fig. 7.—Automatic Machine for Cutting Safe Ends Reduces Labor in the Flue Shop

pander is placed on a car on the outgoing service track. The operator who works on the front end of the tubes marks them to indicate the various lengths and also attends to the automatic safe end machine, which is located just beyond the hot saw and expander. It will be noted that the tubes are not tested after being welded until they are subjected to pressure in the boiler. This policy was adopted because it was found that the proportion of defective welds was so small as to make testing of the individual tubes unnecessary.

The standard practice on the E. J. & E. is to apply not more than four safe ends on tubes or flues. When tubes are removed from the boiler which have been pieced four times they are cut and either used on smaller engines or have a single long tube welded on the end in the flue reclaiming machine. Superheater flues are handled with the same equipment used on the small tubes, the only alteration necessary being changes in the minor parts of some of the machines.

Records have been taken in the flue shop to determine the time required to finish a complete set of tubes. On one occasion, when the operators were working under favorable conditions, eight two-inch tubes 18 ft. long were completed in 2 min. and 40 sec., which is at the rate of a tube every 20 sec. or 108 tubes an hour. Another test was made with 47 two-inch tubes 22 ft. long, which were completed in 24 min. or at a rate of 117 tubes an hour. A third test on 22 two-inch tubes 18 ft. long required 8 min. 18 sec., or a rate of 158 tubes an hour.

The cost of applying safe ends to the tubes depends somewhat on the length of the tubes, the longer tubes requiring an extra helper. Including the cost of power for the rattler, oil and air for the furnaces, and labor for safe ending and cutting, the total cost for 18-ft. tubes will vary from 1.91 cents per tube at the rate of 180 per hour, to 3.18 cents at the rate of 100 an hour. For 22-ft. tubes the cost will be 2.16 cents per tube at 180 an hour, and 3.3 cents at 100 tubes an hour.

UNIFIED SHOP RECORD AND MANAGEMENT CONDITIONS

A committee was recently appointed from several roads in the Eastern Region, assisted by a representative from the mechanical department of the United States Railroad Administration, to visit a number of representative shops, collect data, and make a report as to the various methods of shop operation, supervision and shop records. Copies of the recommendations of the committee have been sent out to the federal and general managers of the Eastern Region by the regional director with Circular 1801-129A674, which states that while not mandatory, the recommendations if gradually adopted will secure uniformity in shop records and simplify many of the methods of procedure. The circular also suggests that, where no system is in use, the proposed plan may well be adopted. Reports are asked for as to what action is taken on the committee's recommendations.

The recommendations of the committee include the following:

SUPERVISION

The committee has paid particular attention to that supervision which comes in direct contact with the men, and invariably where the number of men assigned to one supervisor exceeded 30, a lack of activity was noticed.

It is generally conceded that shops on a day-work basis require more supervision than those on piece work, and after careful consideration it is recommended that the plan of assigning not more than 30 men to one foreman be adhered to as closely as practicable. The committee further recommends that this supervision be relieved of office clerical work during the work period; that shop staff and other meetings be held at other than the working period and that these supervisors be given the title of foremen rather than leaders.

CHECKING IN AND OUT

Your committee recommends a time clock system for checking men in and out; clock card should show employee's name, occupation and key number. Space should be provided on card for overtime as well as regular time. The same card should never be used beyond a payroll period and the one week card is preferable.

Clocks should be located convenient to the men's work and no clock should serve more than 125 employees. Unless existing agreements prohibit, clocks should be opened 15 minutes before starting time and closed promptly on whistle; opened promptly at quitting time and closed after all employees have checked out, with an attendant in charge of each clock during checking periods. This clock card should be used as a basis for payroll and checked against workmen's daily time cards.

Routing of Locomotive Work

Experience shows that any system of despatching or scheduling of work through the shop must be predicated upon: (1) A predetermined route; (2) a predetermined time limit.

With the above in view the general outline of a routing system is hereby made. In order to properly carry out the following routing it is necessary to have a competent schedule man, with authority, to follow up the system. The locomotive should be thoroughly inspected prior to entering the shop and the schedule man furnished with a copy of the inspection report from which the shopping schedule is prepared.

Separate forms should be made out by the schedule man covering parts to be repaired in various departments and furnished each foreman. These forms should show the locomotive number, class, date in and date scheduled out of shop and under the heading "Class of Work" the various units of the locomotive, condensed into not exceeding 30 items, to be listed in consecutive order in which the parts of the locomotive are dismantled and erected. Space should be provided opposite each of these items for the date the particular item is to be dismantled or repairs started, and the date the repairs are to be completed and erected. Space also should be provided opposite each of these items, for parts of the locomotive that it is necessary to send to the machine, smith or boiler shops, for the dates these parts should be received in the various shops and the dates they are to be completed. Space should also be provided opposite each item under the heading of "Remarks," for "Cause of delay," if any.

A "Daily Schedule Delay Report" should be furnished by the schedule man to the officers in charge, this form to cover all locomotives in shop on which any part is behind schedule. Opposite the individual engine numbers, space should be provided for the various units of repair, condensed into not exceeding 12 units of repair. Under the heading covering the units of repair space is to be provided for a check mark to show just what items are behind the schedule and are delaying the work, together with the causes of the delays.

A blackboard should be provided in each department, located in a conspicuous place, for the observation of the workmen as well as the foremen. All locomotives in shop requiring work in this department are to be listed on this board. At the top of the board should be shown the units of repair with which the particular department is concerned.

As the various parts of the locomotive reach the department a check mark opposite the locomotive number and under the parts is made. When repairs to these parts are completed and ready for delivery to the erecting shop, another check mark is made. When they are moved from the department, the check marks are erased.

By the use of this board it is possible for any one concerned to readily ascertain in just what department the repairs to the locomotive are being delayed.

Shop Order System

Shop or work orders should be issued to obtain the cost of manufacturing parts, repairing machines, cranes, etc., or, when desired, to determine the cost of a specific unit of locomotive repair.

After ascertaining that the necessary raw material is on hand, a shop order number should be assigned and a form issued giving the shop order number, requisition number, date issued, description, drawing number, pattern number and storehouse section. The accounting office should be notified so they may open the account.

The shop order clerk should then issue a card showing departments in which the work is to be performed and then enter in a book with duplicate stubs, kept for the purpose in the foreman's office, the work necessary in that department. After the department completes the work, the foreman will detach and return to the shop order clerk the duplicate slip. By this method it can readily be seen just what department has completed its share of the work.

When all slips have been returned, signifying the completion of the work, the accounting office is notified so it can close the account and compute the cost.

Where there is a sufficient amount of shop order work, it is recommended that a competent man be appointed, with authority, whose duty shall be to see that the work is promptly handled through to completion.

Accounting

Of the 10 shops visited, eight have in use daily time slips (paper) and two, daily time cards (light cardboard). In all cases except one the daily time cards are made out by the workmen and approved by the foremen. In the one case, the daily time card was also the clock card and the cards were filled out as to hours and distribution by time-keepers.

In all cases, locomotive numbers were shown and the number of hours spent on each, and distribution was drawn off to individual locomotives; arriving at a cost per locomotive as a unit.

The daily time cards in all but two cases provided space for description of work. In three of these cases some description was being shown and in the other seven none; but in no case were descriptions as shown considered specific and complete enough to form a basis of cost. Other than distribution to individual locomotives the only other information shown and the only other distributions made are those necessary to satisfy the requirements of the Interstate Commerce Commission classification of accounts.

Recommendations

It is recommended that one daily time card—size preferably 4 in. x 9¼ in.—of light cardboard paper be used. The card should show name, place, date, key number, occupation, department of shop and rate and should provide sufficient space for locomotive or shop order numbers, etc., description of work and hours worked. Total hours as shown by the daily time card of each workman should be checked with total hours indicated by registerings on his clock card.

After a careful consideration of this subject it is the opinion of the committee that it would be impracticable to endeavor to arrive at the cost of a smaller unit of locomotive repair, from description of work on daily time card, than the locomotive as a whole, except by timing each individual workman, which practice the committee does not believe would be countenanced by the workmen. Therefore, it is suggested that when it becomes necessary or desirable to determine the cost of any specific unit of locomotive repair a shop order or work order be issued, to which all labor performed in connection with this specific unit of repair be charged and in this way determine its actual cost.

Reducing The Labor Turnover

Discussion of the Advantages of the Employment Department Idea Applied to the Railroad Shop

BY W. C. NISBET

THE widespread movement toward placing employment matters in the hands of a special department has made less headway among railway shops than in industrial concerns perhaps because the latter by reason of their more centralized authority find it easier to get permission to follow courses of action that are new or unusual. There are, however, so many advantages in a centralized employment department that it is worth the while of mechanical department officers to study the possibilities of the scheme as applied to the railroad shop.

The symptom of trouble which has resulted in so many industrial concerns taking the radical step of turning the whole question of personnel over to a special department, is an abnormally high labor turnover and the attendant loss of production, disorganization and resulting increase of costs. Since Magnus Alexander of the General Electric Company made his extensive and careful investigation into the cost of training a new employee there has been a growing recognition that to lose and replace men on skilled or semi-skilled jobs is an exceedingly heavy and to some extent a preventable expense. Mr. Alexander's estimate was that it cost from $50 to $100 to fill the job of one quitting mechanic with another, due to the loss of production during the interim between men and during the breaking in period. The clerical expense of paying off the leaving man and putting on the new employee was also included. The secretary of Fayette R. Plumb, Inc., machine tool manufacturers, stated in an address, that his company had investigated this expense for machinists and found it to be not less than $100 per change.

Such figures are, of course, merely estimates, and the cost will vary within wide limits, depending on many circumstances. A yard laborer who quits may perhaps be replaced with another who at once completely fills the job of his predecessor, but the loss due to changing will vary from this instance to another extreme where the quitting of a valve setter, an air brake man or other skilled hand may slow up the entire shop production before a competent substitute is found and broken in to maintain the pace of the first man.

It is perfectly evident that whether the average cost be $10 or $200 per man quitting, it would be decidedly advantageous from every standpoint to reduce the labor turnover. The question is, how can this turnover be reduced?

One way of attacking any difficult problem is to assign a man to give it constant attention and supervision and thus escape the common fault that what's every one's business is nobody's business.

WHY AN EMPLOYMENT SUPERVISOR?

Assuming that an employment supervisor has been selected, to expect results from such an individual it will be necessary not only to make him responsible for reducing the turnover but also to give him authority to control at least a part of the causes which affect the coming and going of employees. To do this it has been customary to place what is known as hiring and firing in the hands of the employment supervisor, with the belief that better results will thus be gained than by leaving these important functions subject to the personal inclinations of 40 or 50 different foremen. The reasons for taking these duties from the foremen and giving them to the employment supervisor are many. Some of them are as follows:

(1)—Foremen lose much valuable time interviewing applicants for work. It is not infrequent for a foreman with such important responsibilities as supervision of an erecting gang or a rod and motion gang to be called to the office three or four times a day to see different individuals who apply for jobs. It is easy for a foreman thus to lose from a half hour to two hours daily, interviewing applicants, and hence impairing the effectiveness of his supervision.

(2)—All too frequently foremen hire or fire from prejudice, favoritism or on account of religious, lodge or other affiliations. Injustice in such cases is expensive, because the resentment aroused may be passed from one individual to another, until the shop acquires a bad reputation. Furthermore, it is unfortunately not uncommon that when a man desires to quit and applies to the shop office for his time, he is kept hanging around for hours before the foreman appears to give him his clearance. He may have the best reason in the world for leaving; in any case, what kind of a word is he likely to pass around as to the character of that particular shop? A centralized employment department handles such cases promptly and with a settled policy to remain friends if at all possible.

The good will of a business is recognized as a valuable asset. Is not the good will that some shops enjoy through friendly and just dealing an equally valuable asset?

(3)—Foremen often "give a man his time" because there is no more work for him in that particular department, when in another department the man might be needed and fit in exactly. The employment department offers an agency for conveniently effecting such transfers.

(4)—Most foremen have not the aptitude, time or opportunity for hunting up likely candidates, filling out their applications and maintaining records of workmen. As to the latter it is often found that comprehensive records showing the education, training and experience of those at work is a prolific source of information leading to transfers of laborers and other non-skilled men to better paid positions.

(5)—It is important to know why men quit, what departments they leave in largest numbers, what types or trades are most affected, etc. From such figures intelligent conclusions may replace guesses and proper steps be taken to cure or remedy such evils as become evident.

(6)—As we come to recognize that a competent workman is potentially of far greater value than one who is incompetent, it becomes increasingly important to take every means to select the more competent individuals. It is far easier to appoint one person as an employment supervisor and train him to make intelligent selection of applicants than to trust this most important function to scores of foremen each of varying capacity, all of whom are engrossed with a multitude of other duties.

RELATION OF EMPLOYMENT SUPERVISOR TO FOREMEN

In some plants using an employment supervisor the foremen have been notified that they might on cause dismiss a workman from their department but not from the plant. A man thus dismissed is turned back to the employment department for disposition. He may be discharged, but if let off for lack of work or dismissed by the foreman for trifling cause he may be transferred to another department with the proper kind of plain talk as to the conduct which will be expected of him in the future. Other plants allow the foremen to fire men, but require a written notice to the employment department three or more days before the dismissal is effected. This prevents hasty action and discourages the foreman from acting without good cause.

In hiring men the employment supervisor usually receives a form from the foreman stating that he is in need of a certain number of men, as radial drill hands, erecting gang men, laborers, etc., as the case may be. The supervisor selects from applicants, in person, on file or by advertising for the number required, but they are not actually hired until the foreman accepts them. He may reject them if he wishes, though in practice the employment supervisor should and generally does work in such close touch with the foremen that he will know the type the latter desires and will not refer men to the foremen unless they are likely to be acceptable.

If it is conceded that the man problem is in a way the largest single problem in industry, it appears only reasonable to spend considerable time and money in studying it and endeavoring to improve the present situation. For practically every machine there is a man who controls or at least affects the quality and quantity of output. His aptitude, training, experience, energy, regularity of attendance, even his frame of mind, are all variables which in some degree might be improved or corrected if proper provision were made to that end.

For a long time rigid specifications and careful inspections have been common in buying materials and machines. On the other hand, many of our workmen have been hired almost at a glance, without even the most elementary scrutinizing of credentials, experience or fitness. Does this not have a bearing on the fearful procession of incompetents and misplaced individuals who are today passing through our shops?

Of course, the answer will be made that labor shortage, high wages in munition plants, army drafts and similar causes have been the reason for high labor turnover and the placing of incompetents. Naturally these causes have had a great effect, but in many plants it had been recognized even before the war that the former methods of hiring and firing and handling workmen might be improved upon.

DUTIES OF THE EMPLOYMENT DEPARTMENT

Aside from hiring and firing there are many other duties that can be performed by an employment department to better advantage than by the already overburdened foremen. Some of these are to arrange for the physical examination, maintain proper individual records, investigate references and look into absenteeism and tardiness. The timekeeper's department no doubt has a record of the latter, but they are occupied with their regular duties and do not usually go into causes or act to prevent recurrence. The foreman generally knows of the cases, and is sorely tried by the absence of important workers, but his common remedy of angrily "bawling out" the offenders, or perhaps merely a sour look when men are scarce, seldom goes to the root of the matter. Besides, a foreman might well be freed from this task to have more time for others of more importance, such as planning his work, arranging for material, noting quantity and quality of production, instructing the beginners and in general keeping things in motion.

The employment department can listen to complaints. Some men satisfy themselves simply by airing their troubles. This may keep them away from the grievance committee.

Modern business is a cold proposition at best, and it is too frequently forgotten that the workman has human problems of his own and often has a natural inclination to ask advice at the shop where he earns his living and spends most of his waking hours. The foreman of today is forced by press of business to discourage this, and even if he does not there is little opportunity to tell domestic troubles beside a steam hammer, a forging machine or an air riveter.

The person selected for the position of employment supervisor should have rather more of the milk of human kindness in his makeup than is common, and should also be able to speak some of the more common foreign languages used by the workers. In a case where many of the workers were Mexicans an employment supervisor was selected who had lived in Mexico and who had considerable sympathy as well as understanding for the workers. The improvement in turnover was immediate, due as far as could be seen to the substitution of a little humanity for the former cold business dealing with difficulties unexplained and misunderstood.

We all know the foreigner who smiles and says "Yes, yes," but understands nothing and quits next week on account of some imaginary trouble. Doubtless the ultimate remedy is to teach these foreigners English, but meanwhile to do business with them this month, and today it is worth while to have one who can speak their language provided they are employed in considerable numbers.

The employment department can arrange for special training. In some shops to the employment supervisor has been delegated the duty of establishing schools to teach the inexperienced how to operate certain machines. In munition plants barbers, waiters, etc., have quickly been made into lathe hands who often became large producers. Railway shops seldom have such continuous production on any one machine, but the same method of intensive teaching could be followed on many kinds of work.

Some employment supervisors have been assigned the job of investigating the effect of hours of labor on fatigue for all the principal shop jobs. The subject of fatigue in industry is dismissed as "high brow" in most circles, but we cannot escape the fact that fixed rest periods have been found to have increased production in certain kinds of work; also that if we ourselves had to wheel pig iron all day we would soon discover that there was a decided relation between hours of labor and fatigue. We should probably declare in favor of the one-hour day. On the other hand, there are many shop jobs in which it would be no physical hardship to work 12 hours.

It is worth while to determine the facts as to the jobs between the very easy and the very hard and standardize rest periods accordingly. It is not sufficient to leave it to piece workers to rest as often as necessary. The lazy are inclined to rest all too frequently if their rate or the manner of checking production will allow it, and the ambitious but deluded will keep going even on heavy work when a five-minute-per-hour rest would produce a greater output.

DESIRABLE QUALITIES OF AN EMPLOYMENT SUPERVISOR

The element most essential in an employment supervisor is probably tact, as he must maintain co-operation between the men, the foremen and the management; next he should be of a friendly, sympathetic nature to develop similar feelings in the men toward the management and finally by natural aptitude, education and training he should develop the ability to judge men.

He should be a first-class man with a high conception of his work, for it is within the possibilities of his job to be of great value to his employers and also necessarily to help the men to improve themselves mentally, physically and financially.

It goes without saying that he should be a man with extensive mechanical and railroad experience in order to recognize the elements of the various jobs which he is called upon to fill so that when interviewing applicants he can instinctively recognize the fitness of the individual for some one of the half-dozen openings he may have at the moment.

SELECTION OF EMPLOYEES

The employment supervisor will develop a certain amount of ability to recognize competent workmen, he will even sooner develop ability to recognize and avoid types harmful in a shop, such as the belligerent ones, the agitators, the intemperate, the drug users, etc. Observation and conversation are very potent in discovering the traits and tendencies of applicants.

Letters of recommendation are seldom valuable but the occasional tip of value makes it worth while to utilize them. Investigation before hiring frequently develops that a man skilled in a certain trade may not be able to follow it in the particular assignment at hand. For example, a carpenter was hired for shipyard work and was assigned to putting up overhead timbers. It happened he was a skilled workman, but had a physical affection such that his back could not stand the overhead work. He asked for another assignment, but was told "that or nothing," and had to quit the yard, though his trade skill was needed in several places in that very yard. The loss of such a man might be avoided by preliminary investigation and proper assignment.

Psychologists like Walter Dill Scott and William Kemble have developed methods of testing applicants, some of which are extremely valuable, and can be applied to shop workers to good effect. Many successful concerns are adopting some part or adaptation of such methods.

There is a deep-seated feeling among many mechanical men that such methods are impractical and, in fact, they often may be. The term "psychological tests" is high sounding, no doubt, but at bottom what is meant is merely a test frequently using the tools of a given trade to allow the applicant to show he can do what is expected of him.

A test for a laborer would be chiefly as to his strength measured on a testing machine, and while strength isn't everything with a laborer, other things being equal, we desire the strong rather than the weak.

As to testing a lathe hand we know that if we led the applicant to a lathe, gave him the steel and a blue print of a knuckle pin and told him to turn it up we could readily tell whether or not he is the mechanic we want. This would be a practical test very desirable where feasible but probably not possible of application if we were selecting one lathe hand from several applicants. Almost the same results would be secured by handing the applicant a cut of a lathe and a print of the same knuckle pin and letting him tell the examiner how he would proceed with the job. The same idea can be developed indefinitely.

As to the selection of desirable employees in general it is worth remembering that while experience and ability are of prime importance, yet we may lose the advantage of his skill if a man is irregular in attendance, careless, lazy or belligerent. These traits can often be detected in advance by a skilful employment supervisor experienced in watching for just such traits. What we hope to avoid by the centralized employment department is by more careful scrutiny to avoid hiring the trouble makers, the incompetent and the otherwise undesirable who would soon quit or have to be let out. We wish to increase the number of steady workers, the men with constantly growing skill.

WHY SOME SHOPS HOLD THEIR MEN

The J. B. Stetson Company, according to an address by one of their officers, has the creditable record that over 69 per cent of their employees have been with the company over five years. Such records, while by no means common, are not the sole possession of this company.

Wages have probably the largest bearing of any one feature, but there are many other elements which hold men to the old job. Where wages are not a disturbing element perhaps the next most important feature is the treatment accorded the men by foremen and others in authority. Harsh, arbitrary or unjust treatment is very effective in driving men away, and, conversely, a friendly, human attitude and the occasional exhibition of sympathy helps to cement the workers to their jobs. Harsh treatment by those in high positions generally is reflected in the way the foremen treat the workmen.

The expectation of promotion or of periodical wage increase, provided such expectations are ultimately realized, are also helpful in holding workmen.

Good living accommodations for families within convenient access of the shop, allow the retention of married men living at home who naturally are more stable than boarders.

Lunch rooms in the shop or adjacent thereto are now common in industrial plants, for it is evident that whether the men go home, resulting in a hurried walk, or whether they bring their lunch and eat cold food, indigestion is encouraged. It has been found that where a committee of the men handles the lunch room there is less complaint than where the company manages it.

The management of certain plant activities by workmen's committees can be extended to good advantage. In some plants a loan society to beat the loan sharks is run by the men with the co-operation of the management. The itch to run something on the part of certain individuals among the men can thus be gratified and their activities on the grievance committee partly or wholly avoided.

Educational classes for the men appeal to those who are ambitious and help to make men more valuable. English classes in particular are helpful, as they at once make it easier for the foremen to communicate orders and instructions to their men. The intensive method of teaching English to the aliens in the draft army might be copied in this connection.

Parking space for bicycles, motorcycles and autos is appreciated by the considerable number using such vehicles.

As an indication of the extent to which some firms operating strictly for profit have gone to get the most from their employees by welfare methods, Montgomery Ward & Company is reported by the Department of Labor to have made tests and found that the low periods of production are at 10 o'clock in the morning and 3 o'clock in the afternoon, and to keep up the workers' energy, hot malted milk is passed around to all at these hours, free of cost. This may sound like a joke when we apply the idea to such husky workers as Polish riveters, forge hands, etc., yet almost any

ORGANIZATION OF A SHIPYARD SERVICE DEPARTMENT

Manager of the Service Department.

A—Employment division.
- Soliciting and advertising campaign for employees.
- Selection of employees.
- Records of employees.
- Adjusting grievances.
- Transfer to other work.
- Investigation of discharge and voluntary leaving.

B—Health and safety division.
- Physical examination of applicant for employment.
- Treatment of accident cases.
- Free medical advice to employees.
- First aid classes.
- Statistics of accidents and time lost.
- "Safety First" campaign.

C—Welfare work division.
- Restaurant.
- Bulletin boards and special reports.
- Employees' magazine.
- Clubhouse and reading room.
- Recreation and athletics.
- Naturalization assistance.

D—Educational division.
- Apprentices.
- Evening classes.
- Training new employees.
- Special training for certain important trades.
- Co-operation with state and federal agencies.

E—Housing division.
- Construction of new buildings.
- Finding and listing rooms and houses for rent.
- Information bureau.
- Co-operation with board of trade to prevent excessive charges.

such means of keeping up the production of day workers would pay far more than the cost.

The Curtis Publishing Company provides a farm home which employees call their country club and use as such.

The extensive labor department organizations of several of the shipyards is given in the table to show the scope of their activities in the selection and effort to hold employees.

RESULTS OBTAINED BY EMPLOYMENT DEPARTMENTS

Is the outcome of the effort and expense of developing an organization to work on the employment problem worth while?

To help answer this natural and reasonable question there are given below the comparative figures of several companies which have been working with an employment department to improve their turnover and using some or all of the methods mentioned herein, to secure and hold better employees.

The figures are taken from the Annals of the American Academy of Political and Social Science and may be considered as reasonably correct in most cases.

The Saxon Motor Car Company reduced labor turnover 140 per cent in one year. The Semet Solvay Company reduced labor turnover from 120 per cent to 29 per cent. In 1912 the labor turnover of the Plympton Press was 186 per cent; in 1916 it was 13 per cent. The Ford Motor Company has reduced labor turnover from 400 per cent to 23 per cent. The Dennison Manufacturing Company has reduced labor turnover from 68 per cent to 28 per cent.

The Gas Welding of Thin Plates

The Requirements of Thin Work With and Without Use of Rods; The Behavior of Various Metals

BY J. F. SPRINGER*

II.

One of the principal problems connected with the welding of thin plates with the oxy-actylene torch is the control of the temperature to which the plates are brought. There is frequently trouble in preventing overheating of the work, causing part of the weld to melt away and drop out.

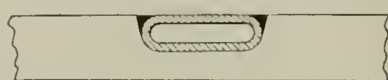
Control of temperature may at times be secured by modifying the angle that the axis of the jet makes with the surface of the seam. When the flame strikes perpendicularly it covers a smaller surface than when it strikes at a sharply acute angle. The same amount of heat is involved in both cases, but the higher temperature will be associated with the greater degree of concentration. For ordinary work, an angle of 45 deg. will be found about right, but in copper welding where there may be trouble in getting enough heat the torch may be used with a greater angle, even up to 90 deg. Aluminum sheets, on the other hand, may need a fairly sharp angle such as 20 or 30 deg. It should be remembered in using an acute angle, however, that the flame will tend to cover a greater part of the seam and will in consequence pre-heat the seam ahead of the zone in which the welding is being done. While the effective temperature will thus be reduced, the time required to secure the molten condition may not be reduced as much as one might expect.

Another method of reducing the effective temperature is to conduct a portion of the heat away from the work. This may be especially useful in welding very thin sheets in joints of the folded type where there may be four thicknesses of very thin metal through which the welding temperature must penetrate without melting the bottom sheet.

There are two ways of accomplishing this purpose. First, the work beneath the seam may be brought into close contact with comparatively cool metal. Thus, the work may be laid upon or even forced down upon a metal slab, which absorbs and conducts away a portion of the heat. The best ordinary metal for this purpose is copper, steel and iron being considerably less effective. The second method is to set a flat tube into the table top so that the work may be brought in contact with its upper surface. The ends of the tube should extend beyond the ends of the table and be of circular section for connection to water supply and discharge pipes. The metal in the tube alone may be sufficient for much of the work, but by turning on the water a further cooling effect is available. Flat under surfaces should be presented by the joints and effective contact with the cooling surface may require the use of clamps. The clamps may also be useful in holding the work against the deformation from expansion of the metal in the seam.

To intensify the heat presents exactly the reverse problem. Sometimes, the character of the metal is such that difficulty is experienced in getting the temperature up to the proper point. Such a condition might well arise with copper and even with metals whose heat conductivity is much less. The work may be steel plates of considerable thickness to be welded in a butt joint with no groove and without the use of a welding rod. The torch is thus called on to pour in heat rapidly enough to raise a considerable thickness of metal to the welding temperature. This situation may be more or less completely provided for (1) by the use of an air space beneath the seam, or (2) by the employment of a solid non-conductor of heat. The air space is provided by a groove or channel in the surface of the table. In the other case the groove may be filled with asbestos, mica or magnesia. If an open groove is used it should not be so wide that the edges of the work will be inadequately supported. The advantage of the solid conductor is that it provides complete support, although the air is probably the better non-conductor.

The greatest difficulties connected with the welding of thin plates are due to unsteadiness of the welder's hands, which results in irregularity in the speed at which the torch advances and in variations in the height of the torch above the work. To overcome these difficulties practice is invaluable, but the workman may find it of considerable assistance in keeping the torch at a uniform height to make use of a horizontal bar as a sliding rest. Or, if preferred, a bracket on wheels or runners may be used as a holder for the torch.



Cross Section of Cooling Tube in the Top of Welding Bed

In some cases it might be advantageous to extend this

*Author of the handbook, "Oxy-Acetylene Torch Practice."

idea a step further. The movement of the work beneath a stationary torch was a fundamental part of the design of the welding machines seen by the writer at the Edison Storage Battery Company's plant some years ago. The seam to be welded was held in a clamp so shaped as to provide access for the torch tip and the welding was done by moving the work along under a stationary torch. This method is especially adapted to cases where a welding rod is not used, the workman thus having both hands available for controlling the work.

WELDING WITHOUT ROD

Welding without the use of a rod is both practicable and advantageous. The object of using the rod is to provide new material to fill the groove and sometimes to increase the thickness of metal at the joint. Both results may be secured without the rod. The purpose of a groove is to make the full thickness of the joint accessible to the torch flame. Several types of joints have already been referred to in which heat penetration is secured by conduction and no groove is provided. Even if extra thickness at the joint is desired in order to offset the loss of strength through overheating, the welding rod may still be dispensed with as suitable ridges may be provided before the welding begins, the melting down of which supplies the extra metal. Where grooves are used, it is often quite possible to form the edges so as to furnish the extra metal required.

There are two principal advantages in omitting the rod and substituting formed edges. (1) The workman has his left hand free, and (2) a uniform amount of new material is supplied all along the joint. On the other hand, there is the disadvantage that the action of the high temperature makes ordinary steel rather brittle and wanting in ductility. By the use of a very pure iron rod, this condition may be remedied. There will, nevertheless, be many cases where the use of a rod will be, at best, of doubtful value and it may well be eliminated.

The edges may be prepared by bending and forming or by upsetting and forming. Where a groove is to be provided, it will, as a rule, hardly be necessary on thin work to bevel at so flat an angle as 45 deg., the standard for general work, the object being to insure a degree of heat penetration sufficient to insure a complete weld. A bevel of 60 deg. or even 80 deg. with the horizontal may be adequate.

MAKING THE WELDS

In welding the simple butt joint where edge is set against edge, particular attention is to be centered upon the necessity of making the high temperature penetrate all the way if the torch is to operate from the one side only, half way or more if the torch is to operate on the work after it has been turned over. If these directions as to penetration are not fully complied with, a defective weld will result. Where the plates are very thin, and too much heat comes from the tip of the torch, the axis of the flame may be directed at a sharp angle to the joint or some type of cooling surface may be used beneath the seam. If necessary, the torch tip may be made to oscillate from side to side across the line of the joint by rotating the tip as it is advanced.

The Edison joint is treated somewhat differently. No oscillation ordinarily will be necessary. The flame is steadily advanced along the line of the joint and is not diverted to one side or the other. The object is simply to melt the two edges and permit the metal to flow together. At times some adjustment of the pressures of the gases may be needed to avoid blowing the molten metal off the edges. The joint is a very simple one to weld, as is well proved by the fact that it has been found practicable to make it with power-driven machines.

In the modified Edison joint where the flanged edges are not deep, more care on the welder's part is needed. The welding may be done as in the original type of joint, or the method employed with the plain butt joint may be used.

In welding the modified plain lap joint where the edges are over lapped and the welding is done by melting off the corners on both sides of the work, and causing them to unite with the adjoining sheets, the torch may be held so that the force of the jet will carry the metal to position. In doing this, however, one must be careful to make sure that the sharp corner into which this metal goes has already been heated. There is probably no one fault more common among welders than that of putting molten metal onto metal not sufficiently heated.

In the type of butt joint where a strip is inserted between the two edges, the work may be handled after the manner used with the plain butt joint. If so, then make sure that the inner white flame is large enough to supply heat on both sides of the projecting strip at one moment. The strip and the edges of the plates are to be melted together.

The folded joint calls for an underlying cooling strip either of simple solid material or a flat tube through which water is kept circulating. With some work it may be necessary that the cooling strip be grooved out on top in order to hug the work along each side of the broad joint.

BEHAVIOR OF VARIOUS METALS

In welding metal plates, it is desirable that the welder be informed with some definiteness and completeness how various commercial metals behave when subjected to the oxy-acetylene torch. It is not only the heat of the flame that acts upon the metal sheets but the active chemical substances in the flame. The gases in the flame are distributed substantially as follows. The acetylene breaks up as it emerges from the torch into hydrogen and gaseous carbon. As far as the brilliant white flame extends there is incandescent carbon, which accounts for the brilliancy of this part of the flame. In short, all through the inner white flame, we have uncombined hydrogen, oxygen and carbon. At the end of the white flame, the carbon burns to carbon monoxide (CO), but the relative amounts of acetylene—the source of the carbon—and oxygen are regulated so that there is not enough oxygen for the conversion of the carbon to carbon dioxide (CO_2). There are two combustible gases beyond the white flame. These are hydrogen and carbon monoxide. Both require oxygen; this they get principally from the surrounding atmosphere with probably a small amount of excess oxygen from the torch.

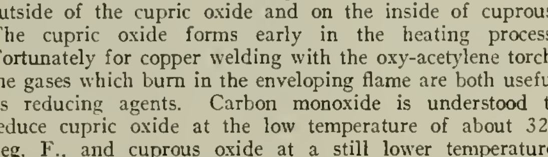
The excessive temperature of the oxy-acetylene flame, far beyond that of the oxy-hydrogen flame, seems to be due to two things: (1) the heat generated by the decomposition, or explosion, of the acetylene and (2) the burning of the gaseous carbon to carbon monoxide. The two sources of heat combined produce the "hot spot" just beyond the end of the small white flame.

A little consideration will show that the possibilities of chemical action are very considerable and in dealing with thin plates this may become a very important matter. If highly heated steel is brought within the white flame it encounters hydrogen, oxygen and gaseous carbon. The first will probably do no harm but both of the others have a damaging effect. Pure oxygen is, in fact, the cutting agent so successfully used in the cutting of hot steel, while carbon acts as a carbonizing—hardening—agent from, say, 1,500 deg. F. up. The lesson for the welder is that any carelessness in handling the torch that results in playing the white flame directly upon hot steel is very apt to damage the material.

The exterior enveloping flame, large in size and moderate in temperature, is beneficial in its action. Consisting as it does of gases avidly seeking oxygen, this flame acts as a protector against the activity of the oxygen of the air. The enveloping flame of the oxy-acetylene torch contains carbon monoxide and hydrogen, both actively uniting with oxygen, and consequently both protectors against it.

The lesson for the welder, especially when the condition and appearance of the work after welding is of importance, is to utilize this flame as far as possible as a protector of the work against oxidation. This lesson applies quite generally to commercial metals other than steel. When at a high temperature nickel is readily oxidized by the atmosphere and copper is probably the most dangerously affected of all. The prevention of the activity of oxygen is possibly the greatest difficulty in the commercial welding of copper.*

Two oxides—cuprous oxide (Cu_2O) and cupric oxide (CuO)—are formed by the oxidation of copper. Oxidation begins when copper is heated in the presence of air to only 365 deg. F. As the heating continues, so does the oxidation. The coloration of the metal varies from rose to brass, to blue green and then to a dark shade. A dark scale forms at a red heat, about 1,100 deg. F., which consists on the outside of the cupric oxide and on the inside of cuprous. The cupric oxide forms early in the heating process. Fortunately for copper welding with the oxy-acetylene torch, the gases which burn in the enveloping flame are both useful as reducing agents. Carbon monoxide is understood to reduce cupric oxide at the low temperature of about 320 deg. F., and cuprous oxide at a still lower temperature, probably about 260 deg. F. Hydrogen reduces both oxides, the cupric at a minimum of about 482 deg. F., and the cuprous at about 297 deg. F. It seems evident, therefore, that the oxy-acetylene torch is not only well fitted for copper welding, but that it is better than the oxy-hydrogen



Arrangement of Clamps on Edison Joint which Use the Outer Flame as a Protection against Oxidation

instrument, the minimum reduction temperatures with carbon monoxide being less than with hydrogen.

It is often possible to provide facilities by which a part of the outer flame may be utilized as a covering of the seam ahead of the point of welding and another part as a covering at the rear. This is what was done in the case of the machine welder used by the Edison Storage Battery Company in welding the longitudinal seam on nickel-plated steel containers. The clamping device which held the work was of such a character that it provided a deep canyon with the seam at the bottom, the canyon being large enough to admit the torch tip and the flame. With this arrangement, the enveloping flame naturally divided itself into two streamers, one lying on the joint ahead of the torch tip and the other on the joint behind the torch tip. The air was thus shut off from the metal all along the joint, until it had cooled down somewhat in the lower temperature of the enveloping flame of the torch. The forward streamre performed a good service by pre-heating the joint before it reached the welding flame, thus lessening the work which that flame had to do.

In all torches an excess of oxygen must be furnished beyond what is theoretically necessary. For one cubic foot of acetylene, only one cubic foot of oxygen is actually used in effecting the chemical combination of carbon monoxide. The excess may run up as high as 35 to 40 per cent, but this indicates a poor torch and oxygen is being wasted. Anything less than 25 per cent, however, may be regarded as reasonable. What becomes of this extra oxygen? Doubtless, some of it after passing through the white flame and past the "hot spot" combines with hydrogen and carbon monoxide in the outer flame. This should be the case when the torch is burning but is not in use. It would seem that this excess oxygen might make more or less trouble when the work is being operated upon. With steel and iron it is probable that the matter is not sufficiently serious to cause much trouble. But with copper and perhaps some other metals, it may be necessary to take measures to overcome the difficulty. One way of doing this is to convert the neutral welding flame into a carbonizing flame.

When the oxy-acetylene inner flame is a brilliant white, is sharply outlined, and consists of a single cone or pencil, it is said to be neutral—that is, there is a balanced condition, and the acetylene is being burnt with the least amount of oxygen possible with that torch. This is the proper condition for welding in general and especially for thin sheets likely to be harmed by either oxygen or carbon. If the oxygen cock is opened wider or the acetylene cock further closed, the neutral flame will be changed to an oxidizing flame. The brilliancy of the cone will be lost and the cone itself will shrink. If, on the contrary, the neutral condition be changed by partially closing the oxygen cock or opening the acetylene cock wider, then a carbonizing flame will result. This means that not enough oxygen is coming through the tip to burn the carbon of the acetylene to carbon monoxide. Consequently, there will be free carbon beyond the usual point. The carbonizing flame may be recognized by noting that the cone is double. For copper plates and for brass plates made from an alloy high in copper, the carbonizing inner flame may be used to make sure that there is no free oxygen in the outer flame.

The non-neutral conditions will occur accidentally, even after a torch has been adjusted to an exact neutral condition. This means that the welder must always be on the alert to correct the adjustment. The neutral flame is so distinct in its appearance that the condition of the flame is very readily determined. The welder operating on thin plates should be eternally on the watch for a change in his flame. Such a change may come about through variations in the pressure back of one of the gases.

Lead may be welded with the oxy-acetylene torch. In the shape of plates, however, the metal requires strict attention because of its low melting point, 621 deg. F. Not only is the melting point low, but the specific heat is also low. This combination means that it requires comparatively a very small amount of heat to attain the melting point. The workman needs to do his work steadily and quickly or else to provide for reduction in the amount or degree of heat. The amount of heat may be cut down by using less pressures or a smaller torch. The temperature may, in effect, be reduced by methods already described. That is, the angle at which the tip is directed onto the work may be flattened, or provisions for cooling may be used. Lead has the advantage of low heat conductivity which permits close localization of the heat in welding.

Nickel behaves a good deal like pure iron. When more than a plating of the metal has to be taken into account, the welding action does not take place so well by merely melting the edges, pressure being needed to assist the metal to unite. The union may then be effected at a temperature below the melting point without the use of a welding rod or a groove at the joint. The welding is, in fact, not a true autogenous process, but from a practical point of view the work may be done advantageously with the aid of the oxy-acetylene torch. The necessary pressure may be applied with a hammer or otherwise.

Tin has a low melting point (449 deg. F.) and a low specific heat. Accordingly, the welder of block tin plates

*For other information on copper welding, see an article by the same author in the *Railway Age Gazette, Mechanical Edition*, for July, 1915, page 367.

must act quickly and steadily. Similar remarks apply to zinc with its melting point at 796 deg. F., and a moderate specific heat. The readiness with which tin conducts heat is fairly slow, while the conductivity of zinc is quite slow. Consequently, with the former a fair localization should be possible and with the latter quite a good one.

The localization of heat may, as already indicated, be promoted by the use of a non-conductor of heat (such as air, asbestos or magnesia) in a groove on the work table underneath the seam. In addition to this, asbestos pasteboard or sheets may be laid on top of the work and brought up close to the seam on both sides of the joint.

Autogenous Welding at Albuquerque

Burned or Cracked Sheets and Tubes Repaired by Gas or Electric Welding; Welding of Flue Beads

BY H. LOUIS HAHN

The problem of efficiency and economically welding locomotive parts has resulted in the development of some interesting methods in the Albuquerque Shops of the Santa Fe System.

The method of applying two new side sheets and a three-quarter door sheet is shown in Fig. 1. The back end of the side sheet and each side of the door sheet are turned at an angle of 45 degrees. this slight turn being made cold in the clamps, thus eliminating the heating and flanging of the side flanges of the door sheet at the flange fire. The door hole opening is flanged at the fire and the flat sheet then sent to the fitting up floor, the sheets fitted and chipped to a 3/16-in. bevel opening as shown and the welding completed by using a gas torch. This makes a very neat job.

Fig. 2 shows a method of preparing side sheets along a

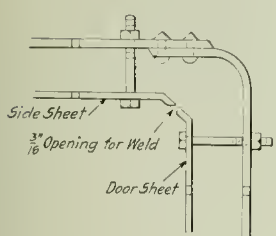


Fig. 1

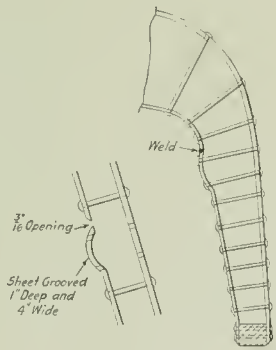

Fig. 2

horizontal seam to compensate for the contraction of cooling welds. The side sheets are laid out, sheared, punched and chipped in the usual manner and are then sent to the blacksmith shop, where a large steam hammer, fitted with a concave die and swedge to suit, is used to put the roll in the sheet as shown. The roll is put in the sheet for the entire length, except at the ends just below top edge to be welded. The ends at the door sheet and flue sheet are left flat for a distance of four inches.

In some cases staybolts are applied before welding the horizontal seam, in others the staybolts and rivets are applied before welding, but in most cases the sheets are applied with a temporary fitting using bolts. The welding is done with a gas torch. No difficulty is experienced from contraction of cooling welds as the roll in the sheet relieves the strains. The same method is also used for the horizontal seams of the three-quarter door sheet when the seam is a sufficient distance above the firedoor opening.

Fig. 3 shows the method of fitting a full or a three-quarter door sheet when old side sheets or the crown sheet are not removed. The portion of the old side sheet containing rivet holes is removed as shown at *B* and a 45-deg. bevel chipped on the sheet. The door sheet is fitted in the regular manner, allowing the surplus flange to lap over the side sheets. The flange is then scribed or marked even with the edge of the side sheet, the door sheet removed and the surplus flange chipped or punched off. The door sheet is then reapplied

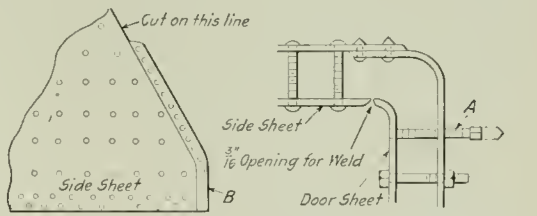

Fig. 3—Welding New Door Sheet to Old Side and Crown Sheets

and the edge of the flange set out 3/8 in. all around to make it flush with the side sheet. The edge of the flange of the door sheet is then chipped bevel for welding. Enough staybolts *A* are applied in holes in the outside sheet and screwed against the door sheet to push the latter into position to allow a 3/16-in. opening for welding. Bolts are applied between the staybolts, and loosened as welding progresses.

Fig. 4 shows the method of repairing cracks in side sheets

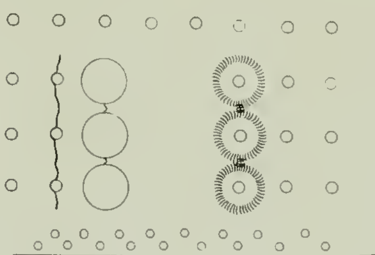

Fig. 4—Repairing Cracks in Door or Side Sheets

and door sheets where there are a small number of cracks and removal of the sheet is not justified.

The staybolts are removed and 3 1/8-in. sunflower plugs applied in the sheet as shown. The crack between the plugs is then chipped out to a 90-deg. opening and a space 1/2 in. wide, 1/4 in. on the plug and 1/4 in. on the sheet is thoroughly worked with a roughing tool in an air chipping hammer to remove all scale. The cracks and roughed edges of the plugs and sheet are then electric welded, using a metallic electrode.

After the patches, sheets and rivets are applied the calking edges of the side, door and flue sheets are welded to the mudring for a distance of eight inches each way from the corner, using an electric metal electrode process.

On old fireboxes, where it is desired to run a defective riveted seam until the regular shopping period, the seam is chipped clean, and the roughing tool used on rivet heads, the seam between the heads, the calking edge and on the sheet for a distance of ½ in. beyond the calking edge. The entire surface is cleaned and roughed and then covered with a layer of added metal about 2½ in. wide, using electric metal electrode process.

Cracks in door hole knuckles are V'd out and electric welded when they are less than two inches in length. For a door hole knuckle having a number of cracks which are over two inches in length a door collar is applied and gas welded. When welding cracks in fireboxes by the electric arc method a live steam line is always inserted in the water space at the mudring to bring the sheets to a good warm temperature before welding, thus prolonging the life of the weld in service.

All firebox door hole flanges are lapped over the backhead door hole flanges the regulation distance for applying rivets, the flanges fitted tight, and after the edges have been beveled as for calking the calking edge is welded to the backhead sheet, no rivets being applied. Should this weld leak at an outside division point where no welding facilities are available holes may be drilled, patchbolts applied and the door hole flange chipped and calked in the regular manner.

Flue beads are welded to the back flue sheet. The flues are applied in the regular manner and the engine taken out

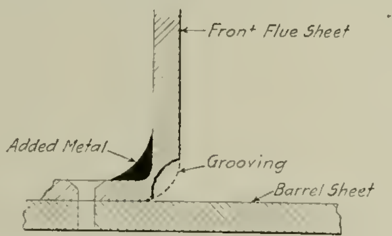

Fig. 5—Repairing Grooved Tube Sheet Knuckle

on its break-in trip in order to boil and burn off all oil and grease on and under the beads, after which the beads are sandblasted and welded to the back flue sheet.

In order to educate electric welders to become flue welders the writer prepares old tube sheets removed from fireboxes by rolling old tube ends about three inches or four inches long in all the holes, beading them in the usual manner. The sheet is then conveniently placed for the welder to practice on and after welding about one thousand of these experimental tube ends he is ready to go in a firebox and start welding regular tube beads.

No patches are applied to the firebox side or door sheets except slip patches at mudring corners, which are gas welded. Crown sheets are patched when they become defective under the T-bars. After the patch on the crown sheet is fitted up ready to weld it is stayed in position by the use of "strongbacks" made of two pieces of ¾-in. by 5-in. flat iron riveted together with a space between them to insert fitting up bolts. These are placed on the top of the crown sheet edgeways and are used to line up the new patch and the old sheet. They are kept in position until after the welding of the patch seam is completed. The gas torch is used on this job.

Grooving of the knuckles of front tube sheets adjacent to the barrel sheets is a common defect and is remedied as shown in Fig. 5. The flange rivets adjacent to the grooved portion of the tube sheet are removed and the fire side of the knuckle of the flange is built up until the thickness equals the original thickness of the sheet, using a gas torch. The flange is then heated, fitted tight and rivets reapplied. This method avoids the removal of tube sheets which otherwise would have to be renewed.

Fig. 6 at *A* shows a defective top tube sheet with the knuckles removed. The sheet is cut across in a straight line through the center of the horizontal bridges in the fourth row from the top. A new patch is flanged and fitted in

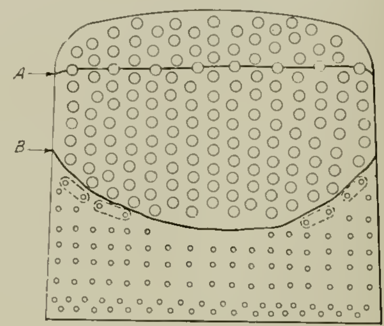

Fig. 6—Patching of Tube Sheets

position and a 3/16-in. opening is beveled and gas welded. After the welding is completed the tube holes adjacent to the weld are reamed to proper size.

The method of removing the tube area of the tube sheet when applying a superheater to a saturated engine is shown at *B*, Fig. 6. The tube sheet is cut across below the tube holes and the new top half flanged and fitted in place, leaving a 3/16-in. beveled opening across the bottom. Care is taken to have the ends of the old and new side flange butt tightly together so that the contraction of the cooling weld across the sheet will not pull the new sheet down from the top corners. After the cross weld is completed and cold, the ends of the side flanges are chipped bevel with a 3/16-in. opening and the welding completed.

In a firebox recently turned out for service by the writer there were two side sheets, one door sheet, one tube sheet patch on the top knuckle, one crown sheet patch under the T-bars and a door hole lap seam, all gas welded, making a total of 50 ft. 2 in. of welded seams in this one firebox.

In the tank department many economies are effected by autogenous welding. A method of building up worn faces of spring pocket castings is shown in Fig. 7, a new wearing face, formed of boiler plate, being electric welded as shown.

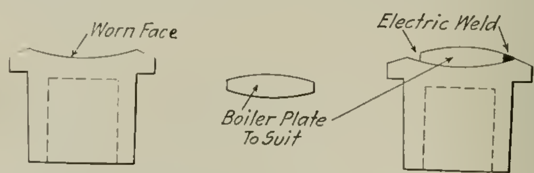

Fig. 7—Renewing Face of Spring Pocket

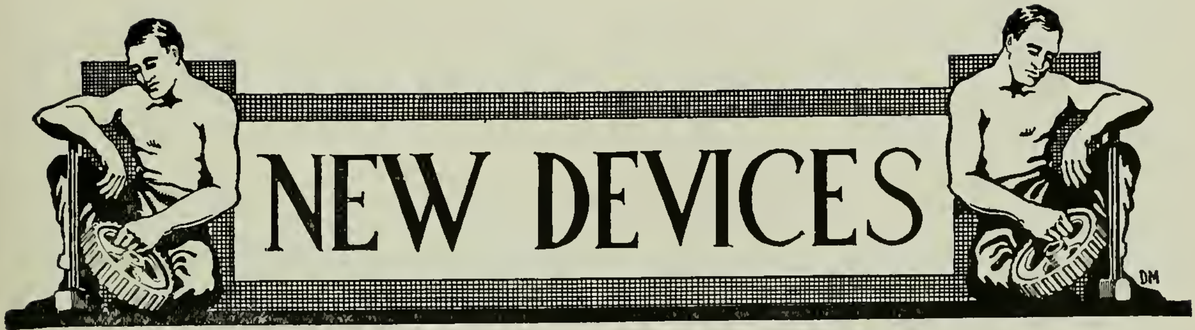
On castings where the wear is not enough to require the application of a plate the worn portion is built up by applying the metal electrode direct to casting. All castings are uniformly heated to a black heat before welding. This method is more expensive than machining off the face of the chafing casting to a new wearing surface, but constant machining soon causes scrapping of a casting, while the welding method saves it for further use.

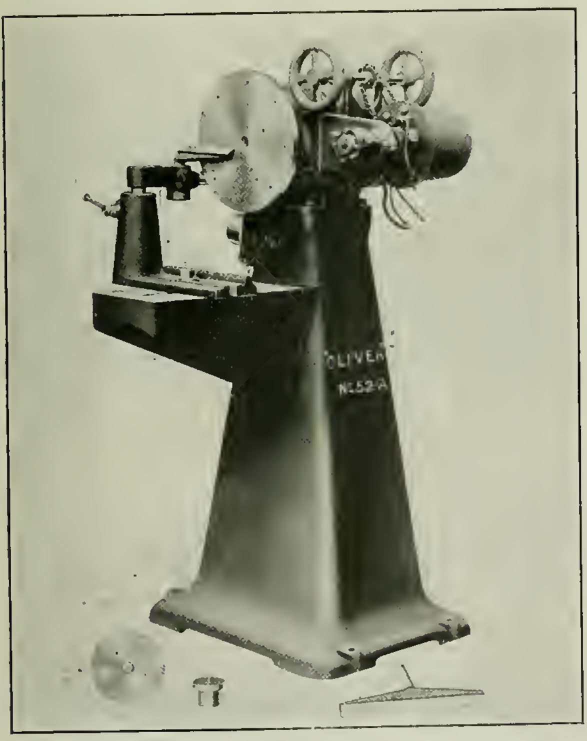
Drawbar pin holes in draw castings on tanks when worn out of round are built up where worn, using the metal electrode, and then rose reamed to the proper diameter. Coupler shanks and coupler carrier plates are reinforced where worn by using the electric arc welding process.



OLIVER MOTOR HEAD FACE LATHE

A face lathe in the head of which the driving motor is incorporated has been placed on the market by the Oliver Machinery Company, Grand Rapids, Mich. The machine has a swing of 24 in. over the bracket, and 20 in. over the rest socket. It will turn work up to 12 in. wide by 20 in. in diameter, or 6 in. wide by 24 in. in diameter, and is a particularly useful tool for pattern shop work.

The machine is entirely self-contained. The motor head, the controller or switch and the rests are mounted on the floor column, making the machine especially adaptable as a portable tool. All electric parts are totally enclosed and dust-proof. The equipment of the machine includes a 16-in. tool rest with an offset holder, one right-angle rest, one 6-in. and one 12-in. face plate and one 2¼-in. screw chuck.



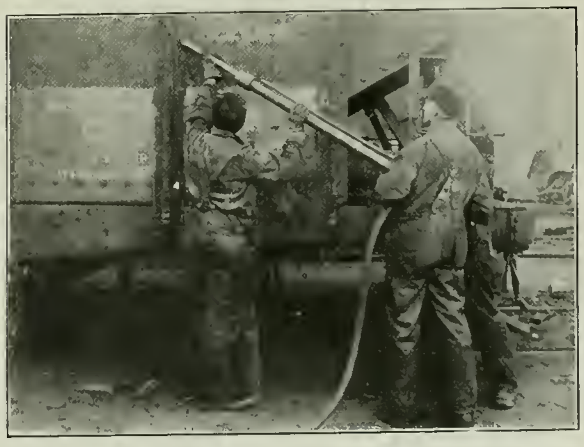
Motor Head Face Lathe Fitted With Alternating Current Motor

The machine is fitted with either an alternating current or direct current motor, the illustration showing the rear view of the alternating current machine with the speed controller attached to the head. The alternating current motor head will run at 800 to 3,500 r. p. m., the speed being controlled by handwheels governing a self-contained controller. The alternating current motor is of the single-phase series-compensated type and will operate on any single or polyphase circuit of proper voltage. It will operate satisfactorily on any frequency from 25 to 60 cycles. The direct current motor head operates from 600 to 3,000 r. p. m. the controller in this case being mounted on the side of the floor column.

The armature or rotor shaft of the motor constitutes the headstock spindle of the machine. This spindle is of steel tubing 1¼ in. in diameter and has a ½-in. hole throughout its entire length to facilitate the removal of centers. The inside end is threaded for face plates and bored out to receive No. 2 Morse taper shanks. The outside end carries a handwheel for holding the spindle while removing the face plates, for turning the spindle by hand when making adjustments, or for quickly stopping the motor. When rear end turning is desired the handwheel may be replaced by a face plate.

A PNEUMATIC RIVET CUTTER

The increase in the amount of steel car repairing has created a need for a tool that will cut rivets quickly and cheaply. Knocking the heads off with a sledge hammer and set is hard work and the pneumatic hammer cannot be used satisfactorily unless the rivets can be reached easily. A tool especially designed for rivet cutting is now being made by the Rice Manufacturing Company, Indianapolis, Ind., known as the Red Devil rivet cutter. By its use it is claimed that ⅞-in. or 1-in. rivets can be cut with from three to five blows and 1¼-in. rivets in 10 seconds.



Pneumatic Rivet Cutter Especially Adapted for Use on Steel Cars

The device consists of a cold drawn seamless tube about 5 ft. long with suitable fittings hydraulically pressed into each end. The rear end is fitted with a valve by means of which air is admitted into the tubes behind the plunger while it exhausts from the forward end into a rubber by-pass. By giving the valve a quarter turn air may be admitted into the by-pass at the forward end of the tube and exhausted from the rear. At the forward end there is a bushing designed to provide a fit for the end of the chisel bar. Inside the tube there is a plunger ground to fit with sufficient clearance to allow easy movement with a minimum amount of air leakage.

As shown in the photograph three men are required to operate the cutter. One stands at the forward end to guide the chisel while two carry the rear end by means of suitable handles, one of them manipulating the valve lever. After a little practice the workmen can operate the cutter either rapidly or slowly and can strike either heavy or light blows. Springs in each end of the tubes absorb the shock of the plunger so that it is not difficult to hold the device while in use. The best results are secured with an air pressure of 90 lb. per sq. in., although if desired the rivet cutter can be used with pressures as low as 40 lb. The total weight of the device in working order is 65 lb. and the total length is 58 in. Under average conditions three men operating this tool are said to cut from 25 to 33 times as many rivets as they could cut in the same time by hand. A smaller tool known as the Baby Devil is manufactured by the same company for use on rivets of 5/8 in. diameter and less. This machine is handled by two men instead of three.

SEMINOLE TOOL STEEL

Considerable thought has been given to the development of tool steels and great improvement has resulted from experiments with numerous alloys, but it has been characteristic of such steels that increased hardness resulted in an increased

Fig. 1—Seminole Steel Chisel Driven Through a 35 Per Cent Carbon Steel Block

brittleness and consequent loss of strength. This is a most important factor in chisel steel, which is subjected to sudden and severe stress from the blows of a hammer.

A tool steel having some unusual properties has been developed by the Ludlum Steel Company, Watervliet, N. Y., which has been given the trade name, "Seminole." It can be made so hard that it will cut glass, but will bend without fracture. Some of the possibilities of this steel are illustrated in Fig. 2, showing a piece 1/4 in. by 1/16 in. that is extremely hard but has been bent so that the loop is less than 1 1/2 in. in diameter. Fig. 3 shows a piece of the steel

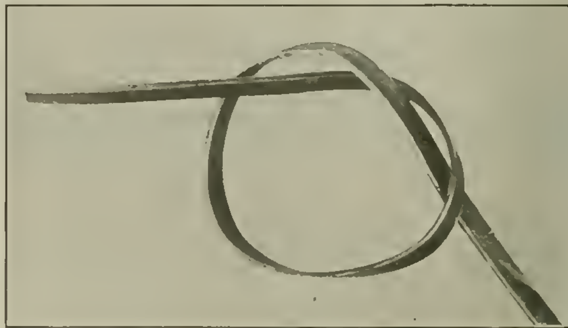


Fig. 2—A 1/4-in. X 1/16-in. Piece of Seminole Steel

drawn to a point and driven three times through a low carbon steel bar without breaking. Fig. 4 shows a chisel that was driven through a block of .35 per cent carbon steel, bent over and straightened several times without breaking, and was then found hard enough to scratch glass. Fig. 1 shows a chisel of this steel driven through a .35 per cent carbon steel

Fig. 3—Low Carbon Steel Bar Pierced by Chisel-Steel Spike

slab without bending the chisel or damage to its edge. All of these tests were made with tools and material cold.

This steel can be satisfactorily hardened in temperatures ranging from 1,650 to 1,950 deg. F., but the preferable range is considered to lie between 1,750 and 1,800 deg. After heating, the steel is quenched in oil and then slightly drawn. The drawing increases the toughness of the metal

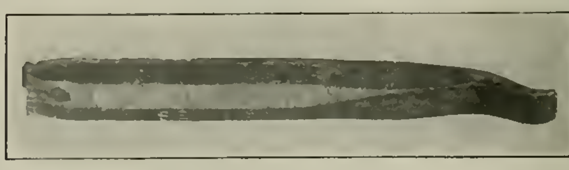

Fig. 4—Seminole Steel Chisel, Bent Several Times After Driving Through Steel Bar

without decreasing the hardness. Another desirable quality of this steel is that it does not sliver, thus eliminating a frequent cause of injury to users.

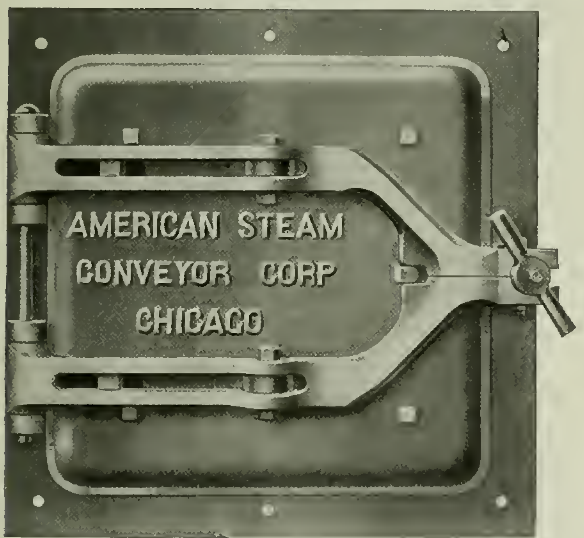
Photomicrographs taken at 400 magnifications show a very fine structure which tests have indicated is highly homogeneous.

AIRTIGHT ASH PIT DOOR FOR STATIONARY BOILERS

A perfectly tight ash pit door is essential to prevent combustion in the ash pit and also in preventing excess air from entering the firebox through some types of stokers. Plant economy and ease in handling ashes are features which should be carefully considered in choosing doors for the ash pits of power houses.

The American Steam Conveyor Corporation of Chicago and New York, specializing in all forms of ash disposal equipment is manufacturing the American ash pit door which has been produced as the result of careful tests and study, covering all points essential to successful operation and durability.

Experience has shown that an ash pit door should not be larger than is necessary to allow easy removal of ashes from the pit, as it is difficult to prevent a large door warping and thus leaking air and it is also too heavy to be handled easily. A 24-in. by 36-in. door is recommended as ample in size for the largest pit. Three other sizes, 18 in. by 18 in., 22 in.



American Airtight Ash Pit Door with Hinges Arranged to Produce Uniform Pressure on the Frame

by 26 in., and 24 in. by 24 in. are also built of the same general design.

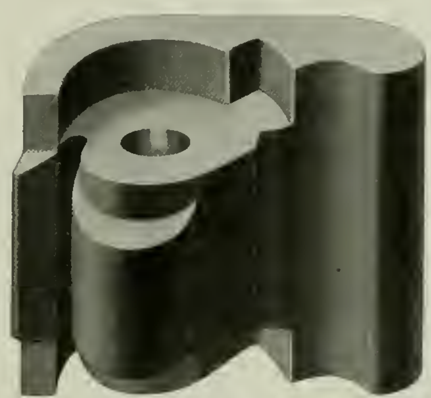
The door frame is of cast iron of ample strength for all conditions. It is of angle section, fits well back into the setting and is easily fastened into the pit wall by four bolts, one in each corner. The bearing surface is carefully machined. The hinge and locking lugs are cast on the frame and are of ample strength to meet the hard usage to which ash pit doors are subjected.

The door itself is of heavy cast iron and is provided with a heavy ventilated cast iron liner to prevent contact with the hot ashes and consequent warping. The bearing surface of the door is also carefully machined to make an airtight joint with the frame. Two hinges of the floating type with hinge bars pivoted to the frame carry the door at the center where it is pivoted to the bars. This gives a perfectly distributed pressure on the door and keeps a tight joint at all points with no possibility of a clinker in the corner of the frame opening, breaking or bending the door by a wedge action and also allows the door to be swung entirely out of the operator's way.

The door is easily, quickly and tightly locked by means of wing nuts at the end of the hinge bars, two locks being used for the 24-in. by 36-in. door and one lock for smaller sizes.

REX EMERGENCY KNUCKLE

It has become common practice on American railroads to carry in cabooses so-called emergency knuckles. These devices can be applied in place of any standard knuckle in case of breakage, and are stronger than chains and easier to apply. The National Car Equipment Company, Chicago, is now manufacturing a new device of this type which is known as the Rex emergency knuckle. When applied it is held in place by the knuckle pin and by a rib extending

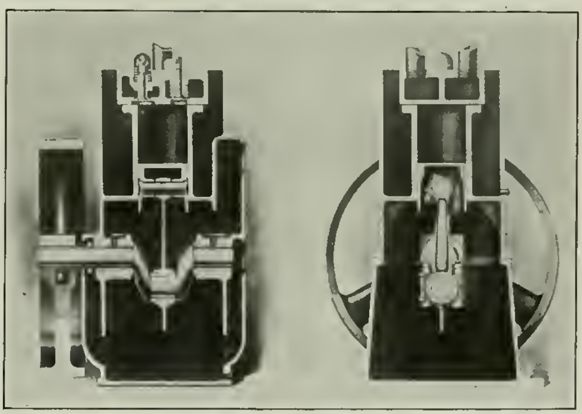


Emergency Knuckle That Can Be Applied Without Removing Knuckle Lock

over the side wall of the coupler. This makes it unnecessary to remove the locking device from the coupler before applying the emergency knuckle. The Rex emergency knuckle has the further advantages of being light and easy to apply, and its use does not increase the distance between cars. It has already been adopted by several important railroad systems.

SMALL AIR COMPRESSORS

To meet the need of a small air compressor the Ingersoll-Rand Company, New York, placed its "Imperial Fourteen Compressor" on the market. These compressors are of



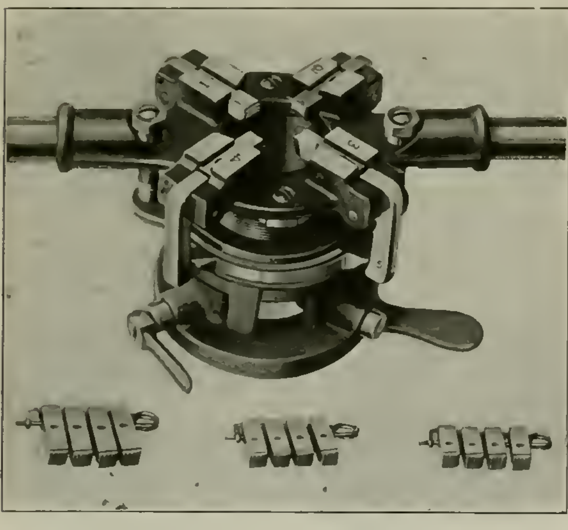
Sectional Views of Ingersoll-Rand Small Air Compressor

simple, rugged construction and the design is very similar to that of an automobile engine, having the same type of drop forged crank shaft and connecting rod, die cast, renewable bearings, and automatic splash lubrication system. They are made in four sizes, ranging in capacity from 3 to 45 cu. ft. per minute at pressures up to 100 lb. per sq. in. The small compressors may be used for pressure up to 200 lb. per sq. in. by using a slightly increased horsepower. The machines are of the single acting, belt driven, vertical type, and may be bolted to any solid flooring, but for permanent installation a concrete foundation is preferable. The smallest size is built with an air cooled cylinder for intermittent service, or with a water cooled cylinder of the reservoir type for continuous operation. The larger sizes are built only with water cooled cylinders employing the reservoir jacket system, except for the largest size, for which a closed jacket for connection to a pressure system is optional.

In the reservoir jacket system both the cylinder barrel and head are cooled, and the jacket is designed to hold sufficient water to operate for a period of 10 hours with a single filling.

RECEDING PIPE THREADERS

A new design of receding pipe threader has recently been developed and placed on the market by the Greenfield Tap and Die Corporation, Greenfield, Mass. This tool is turned on the pipe until the desired length of thread is cut and can then be pulled off without turning back. At the beginning of the operation the chasers cut a full depth thread, and as the work progresses the levers supporting them gradually change their position, permitting the chasers to recede until they have completely withdrawn from the pipe, thus allowing the threader to be pulled off without the loss of time that would be required to unwind from the threads. A single turn of any one of three lugs, conveniently placed, disengages the lead screw so that the head may be lifted and returned to its original position and the trigger reset to begin another cut.



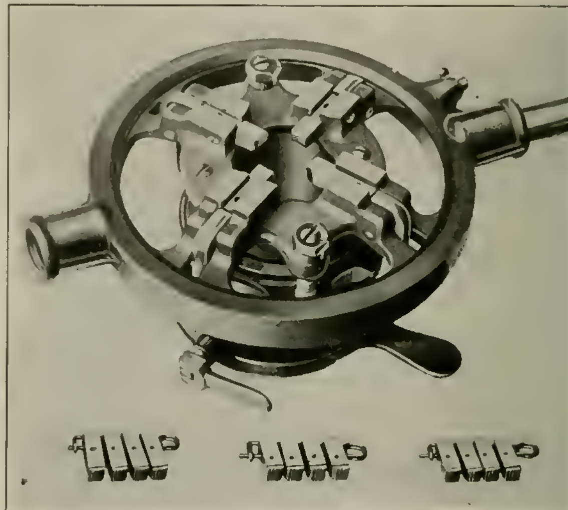
Pipe Threader the Dies of Which Automatically Recede to Permit Removal Without Unscrewing

The chasers are narrow and travel parallel to the thread they are cutting, thus reducing friction to a minimum. They are interchangeable and so made that in case of breakage a single chaser may be replaced and follow or "track" uniformly with the rest of the set. They are also made in sets for each pipe size and with either the Briggs or Whitworth thread.

The lead nut is in three segments, which are self-cleaning so that dirt or chips cannot gather on the lead screw, and both the lead screw and nut can be replaced without returning the tool to the factory. Adjustment for cutting shallow or deep threads is easily made by means of the lock nuts and adjusting rods that project through the head of the threaders.

A three-jawed universal chuck guide is provided, and after the jaws are tightened against the pipe one turn of a grip screw working inside the chuck, tightens it so it will not slip.

For threading pipe in trenches or other places where the space is limited, a threader of similar general design but provided with a ratchet receding mechanism has been developed. The ratchet mechanism is incorporated in the die stock and has two handles, one of which may be detached, thus permitting the tool to swing in a 14-in. circle. This tool can also be used in the same manner as the other receder by disengaging the ratchet.



Ratchet Receding Threader

SELLERS INJECTOR INDICATOR

In the description of the Sellers injector indicator, published on page 218 of the April, 1919, *Railway Mechanical Engineer*, an error was made in the last sentence of the second paragraph. One-half-inch copper pipe is used to connect the upper end of the cylinder with the overflow chamber of the injector instead of ½-in. copper wire as incorrectly stated in the article describing the device.

Exports from Britain.—The British railway supply export figures for the whole year 1918 are given in the Board of Trade returns for December. They are as follows, the corresponding figures for 1917 being given in parentheses. Locomotives, $5,377,435 ($8,147,270); rails, $2,421,000 ($3,452,375); carriages, $2,807,380 ($825,880); wagons, $1,644,055 ($2,215,120); wheels and axles, $1,722,340 ($783,165); tires and axles, $3,098,795 ($2,697,645); chairs and metal sleepers, $820,450 ($368,410); miscellaneous permanent way material, $2,785,165 ($2,472,210); total permanent way, $6,105,475 ($6,319,630). The weight of rails exported was 26,335 tons (38,900 tons), and of chairs and metal sleepers, 10,173 tons (5,650 tons). Of the locomotive exports $147,950 ($1,138,850) in value went to South Africa and $1,237,050 ($882,965) to British India.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.)

W. G. McAdoo, of New York City, former director general of railroads, has been appointed special counsel to the Railroad Administration on matters arising in the state of New York, to serve without pay.

Exports of locomotives in February, 1919, totaled 85 with a value of $2,584,269, as compared with 87 in January, 1919, valued at $3,076,543. Exports of car wheels and axles in the month of February, totaling $541,630, were double those of January, when exports of these commodities were made, which were valued at $278,393. Two hundred and twenty-five passenger cars were exported in February, valued at $130,768, and 583 freight and other cars, which were valued at $957,128.

For the purpose of meeting the emergency caused by the radical curtailment of the machinery of the United States Employment Service because of lack of funds, the Council of National Defense has announced the formation of an Emergency Committee on Employment for Soldiers and Sailors, including representatives of the various government departments. The chairman of the committee is Col. Arthur Woods, and the secretary will be E. H. Greenwood, who has been associated with the Department of Labor in its employment work. A representative of the Railroad Administration probably will be added to the membership of the committee.

The Pennsylvania Railroad is building an 11,000-volt power line from South Altoona to Altoona and is installing at that place the first unit in a centralized power station that will do away with the plants at Twelfth street, Fourth street and Juniata. These plants will be retained only to generate steam for heating and the operation of steam hammers. The installation of the new system, on which work is already well under way, will involve the placing of two 5,000-kw. generators and auxiliary machinery at the new South Altoona plant, the power line of all-steel construction, and sub-stations at South Altoona, Twelfth street, Fourth street and Juniata. At these places transformers will step down the current to the voltage needed to operate at that particular place. The change, which involves the expenditure of many thousands of dollars, will be completed in the early summer. Although the new system is being installed as a matter of economy, it will incidentally be a very material aid in lessening the smoke nuisance in Altoona.

Railroad Y. M. C. A. Campaign

Arrangements for the "Continental Extension Movement" of the Railroad Y. M. C. A., which is to be inaugurated on May 18, have been completed and the slogan "Couple Up" has been adopted. It is significant that the 300 associations in this country will act as a unit in this extension movement. Another important factor is that the railroad men themselves are taking the leadership in the movement, and the secretaries are being utilized largely in an advisory capacity. While efforts will be concentrated at the opening of the campaign to increase the membership, this is only a small part of the extension program. The summer months will be utilized for assimilating the new members and perfecting the general organization of the different branches and then early in the fall there will be a series of campaigns, each lasting one week, and each devoted to stirring up interest and developing plans for the year to cover the various phases of the work. For instance, there will be a religious week, a thrift week, a health and happiness week, educational week and Americanization week. It is expected that a very large number of new members will be drawn into the work and that active work will be carried on among employees who are not now served by the association.

Steel Price Situation

Little progress has been made in carrying into effect the schedule of steel prices announced in these columns last month as the outcome of a conference of the Industrial Board of the Department of Commerce with representatives of the steel industry. A controversy has arisen with Secretary Glass and the Railroad Administration on one side and the Department of Commerce and its Industrial Board on the other, which springs from a difference of understanding as to the function of the board, as well as over the price of steel. The Railroad Administration does not concede that the authority of the board goes so far as the arbitration of the question of prices, but that its function is merely that of a mediator to bring about agreement between the producers and government purchasing departments. The Railroad Administration takes the position that until a price was reached which would be satisfactory to it, the board had failed to accomplish its intended functions and it has never agreed to the schedule as announced. The result is that inasmuch as the Railroad Administration is the largest purchaser of any of the government agencies, the proposed prices have little prospect of becoming established, especially so far as steel rails are concerned.

Members of Thirteenth Engineers Receive French Decoration

On February 22, 1919, thirty-one officers and men of the Thirteenth Engineers were awarded the Croix-de-Guerre. The decorations were presented at Simmeilles-Nettencourt by Colonel Boquet, Director General of Military Transports of the French armies. In bestowing the decorations upon the engineers, Colonel Boquet said in part:

"I am very happy to have been directed to hand today the Croix-de-Guerre, which it has been Marshal Petain's goodwill to award some of you in accordance with the proposals made by Lieut.-Colonel Marchand, Military Commissaire of the Eastern Railroad, and myself.

"These rewards you fully deserve for the untiring zeal and devotion you have shown. * * * I have known the 13th Regiment of American Engineers ever since their arrival in France. I have constantly watched their work and efforts, and I have, better than anyone else, been in a position to appreciate their valor and good spirit."

Those to whom the decoration was presented were:

Colonel N. L. Howard, formerly division superintendent on the Chicago, Burlington & Quincy, at Hannibal, Mo.

Lt. Col. C. E. Whiting, formerly division superintendent on the Chicago, Milwaukee & St. Paul, at Lewistown, Mont.

Major E. Schultz, formerly division master mechanic on the Chicago & North Western, at Chicago.

Captain W. Haberlaw, formerly roadmaster on the Chicago, Rock Island & Pacific, at Rock Island, Ill.

Captain J. W. Kern, formerly supervisor on the Illinois Central at Mounds, Ill.

Lieut. Hugh MacKee.

Lieut. H. Halverson, formerly roadmaster on the Chicago & North Western at Eagle Grove, Iowa.

Lieut. E. E. Deyo, formerly yardmaster on the Chicago Great Western at Oelwein, Iowa.

Lieut. R. Harrisson.
Lieut. L. A. Weary.
Master Engr. F. Williams.
Master Engr. B. Berryhill.
Sergeant L. Face.
Sergeant O. Olsen.
Sergeant H. Lightner.
Sergeant Thomas J. Ross.
Sergeant J. E. Morrell.
Sergeant W. N. MacMahon.
Sergeant A. G. Crozier.
Sergeant W. Dreasher.
Corporal C. T. Barnes.
Corporal W. Lish.
Corporal W. T. Mott.
Corporal M. H. Bootjer.
Private D. C. Steinmeyer.
Private V. Nicholls.
Private G. Tichy.
Private F. Bitte.
Private E. Vondeveld.
Private W. B. Muller.

MEETINGS AND CONVENTIONS

Tool Foremen's Association.—It has been decided to hold the ninth annual convention of the American Railway Tool Foremen's Association at the Hotel Sherman, Chicago, on August 27 to 29, 1919.

Convention of Master Tinners', Coppersmiths' and Pipefitters' Association.—The American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association has announced that the next annual convention will be held on June 2, 3, 4 and 5, 1919, at the Marquette Hotel, St. Louis, Mo. The topics selected for discussion are as follows: Alloys of Soft Metal, George Hofford; Spot Welding in the Railroad Tinshop, A. Paulis; Light Gage Sheet Metals, Charles Borcherdt, chairman, and M. M. Byington; Pipe Threading, Cutting and Lubricating, F. J. Bucholtz, chairman, and J. G. Hunnicutt; Labor Saving Devices, C. E. Knight, chairman, and W. J. Moffatt; Commercial Iron and Steel Pipe and Copper Tubing, T. E. Holderby, chairman, W. E. Jones and J. F. Richards. The officers of the association are: President, W. J. Moffatt (N. Y. C.); first vice-president, G. B. Hofford (M. P.); second vice-president, W. W. Nash (I. C.); third vice-president, T. E. Holderby (C. & O.); secretary-treasurer, O. E. Schlink (C. & O. of Ind.)

Air Brake Association Convention.—The 26th annual convention of the Air Brake Association will open at 9:30 A. M., May 6, at the Hotel Sherman, Chicago, Ill. Frank McManamy, assistant director, division of operation, United States Railroad Administration, has issued a circular to the various regional directors, requesting them to send as many as possible of their air brake men to the convention, and from present indications the attendance this year will be greater than at any previous convention.

The complete list of subjects to be presented is as follows: (1) Air Consumption of Locomotive Auxiliary Devices, by C. H. Weaver and Committee; (2) Air Leakage and Money Wastage Through Failure to Keep Hose Couplings in Standard Gage, by the Manhattan Air Brake Club; (3) Recommended Practice; (4) M. C. B. Air Brake Defect Card; (5) Instructions on Freight Car Brake Maintenance; (6) Holding Standing Trains and Cars on Grades; (7) Damage to Air Brake Equipment by Thawing Plants, by the North West Air Brake Club; (8) Braking Ratio of About 40 Per Cent and Inside Release Valve for Caboose Car, by the North West Air Brake Club; (9) How Can Enginemen and Trainmen Assist in Air Brake Maintenance? (10) A Resumé of the Air Brake Supervisor's Responsibility to the Stores Department, by Montreal Air Brake Club.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City. Convention, May 6-8, 1919, Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind. Convention, June 2-5, 1919, Marquette Hotel, St. Louis, Mo.

American Railway Master Mechanics' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago. Convention, August 27-29, Hotel Sherman, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Chief Interchange Car Inspectors' and Car Foremen's Association.—W. R. McMunn, New York Central, New York, N. Y.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago. Convention May 19-22, 1919, Hotel Sherman, Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabash Ave., Winona, Minn. Convention September 2-5, 1919. Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention, May 26-29, Hotel Sherman, Chicago.

Master Car Builders' Association.—V. R. Hawthorne, 746 Transportation Bldg., Chicago. Convention, June 18-21, Atlantic City, N. J.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y.—Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Seretary	Address

Personal Mention

GENERAL

M. K. Barnum, assistant to general superintendent maintenance of equipment of the Baltimore & Ohio, with office at Baltimore, Md., has been appointed mechanical engineer for the corporation.

W. F. Connal has been appointed mechanical engineer of the Canadian National Railways, with office at Toronto, Ont., succeeding H. D. Cameron, resigned to enter other service.

J. E. McQuillen, mechanical superintendent of the Gulf, Colorado & Santa Fe, the Fort Worth & Rio Grande, the St. Louis-San Francisco & Texas, the Texas Midland, the International & Great Northern (from Spring to Fort Worth and the Madisonville branch), the Fort Worth Belt, the Fort Worth Union Passenger Station, and the Houston Belt and Terminal, has also been appointed mechanical superintendent of the Fort Worth & Denver, the Wichita Valley, the Missouri, Kansas & Texas (west of Whitesboro), the Wichita Falls & Northwestern, the Abilene & Southern and the Quanah, Acme & Pacific, with headquarters at Galveston, Texas.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

W. J. Ormsby, general foreman in the locomotive department of the Illinois Central, with headquarters at Chicago, has been promoted to master mechanic of the Wisconsin division of the same road, with headquarters at Freeport, Ill., to succeed E. Lawless, deceased.

CAR DEPARTMENT

C. A. Sasse has been appointed divisional car foreman on the Pennsylvania division of the Delaware & Hudson, with headquarters at Carbondale, Pa., succeeding F. S. Ganley, assigned to other duties. Mr. Sasse will report to the master car builder.

OBITUARY

Amos H. Watts, who was master mechanic of the Cincinnati Northern, with office at Van Wert, Ohio, previous to July, 1912, died on March 30, at his home in Walnut Hill, Ohio, at the age of 72.

David M. Perine, special agent on the personal staff of the general superintendent of the New Jersey division of the Pennsylvania Railroad, with headquarters at New York, died on April 22 at Baltimore, Md., while on a business trip in that city. He was born on February 13, 1869, at Baltimore, Md., and entered the service of the Pennsylvania System in May, 1889, as an apprentice at the Mt. Vernon shops of the Northern Central. He subsequently served consecutively as assistant road foreman of engines, assistant master mechanic, assistant engineer of motive power, and master mechanic until April, 1906, when he was promoted to superintendent of motive power of the Northern Central and the Philadelphia & Erie. The following year he was transferred to Pittsburgh on the Western Pennsylvania division, and in January, 1912, was again transferred to the New Jersey division and the West Jersey & Seashore, as superintendent of motive power, remaining in that position until his promotion in June, 1917, as special agent on the personal staff of the general superintendent of the New Jersey division, as above noted.

Supply Trade Notes

The Union Asbestos & Rubber Company of Chicago has moved its general offices from 112 West Adams street, Chicago, to 2834 South Loomis street.

The Standard Railway Equipment Company of New York, Chicago and St. Louis has moved its New York offices from the Singer building to the Equitable Trust building.

On April 1, 1919, the name of the Aspromet Company, Pittsburgh, Pa., manufacturers of asbestos protected metal, was changed to the H. H. Robertson Company.

The Pacific Car & Foundry Company, Seattle, Wash., has expended approximately $400,000 for new buildings, tools and equipment in refitting the car building plants situated at Renton, Wash., and Portland, Ore.

The Interstate Iron & Steel Company of Chicago has opened a branch office at Detroit, Mich., with R. B. Dutch in charge of sales in that territory. Mr. Dutch has been identified with the iron and steel industry for several years.

A. M. Mueller, manager of the St. Louis branch of Joseph T. Ryerson & Son of Chicago, has been promoted to general manager of sales, in which capacity he will have charge of all warehouse and mill products for all territory west of Pittsburgh. He was born at Plymouth, Ind., on July 30, 1874, and received his education in the public schools at that place. His business career dates back to 1899 when he first entered the employ of Joseph T. Ryerson & Son as a clerk in the credit and cashier department. During this period he served successively as traveling salesman, Texas representative for three years and manager of the New York and Minneapolis offices until 1911, when he was appointed assistant manager of sales. Later he went to St. Louis, Mo., as manager of the Ryerson-Hagar plant, being recalled at the end of three years to handle the sales at the main plant at Chicago.

A. M. Mueller

C. M. Schramm, chief clerk to the general mechanical superintendent of the Chicago, Rock Island & Pacific, with headquarters at Chicago, has been appointed assistant to the vice-president of the Vapor Car Heating Company at Chicago.

The Chicago Pneumatic Tool Company has discontinued its branch office at Wichita, Kan., and has transferred the stock from that place to Eldorado, Kan., where an office and warehouse have been established. A new office has also been opened by the company at Tulsa, Okla.

The Firth Sterling Steel Company, McKeesport, Pa., announces the removal of its New York and Boston warehouses to new quarters. The New York warehouse will henceforth be at 310 Hudson street and the Boston warehouse at 35

Oliver street. The latter was previously occupied by the company from 1873 to 1914.

The American Blower Company, Detroit, Mich., has purchased a plot of ground containing approximately 15 acres upon which it intends to build a new plant. Plans are now being prepared for the construction of a foundry on which work will be started in the near future.

F. J. Foley has been appointed general sales agent of the Railway Steel-Spring Company, with headquarters at New York. Mr. Foley's connection with the company dates from its organization in 1902. For the past eight years he has occupied the position of general superintendent.

The Chicago branch of the General Asbestos & Rubber Company, Charleston, S. C., has recently moved into new quarters at 14 North Franklin street, Chicago, the rapid growth of the business in Garco asbestos products having made the old quarters at 106 West Lake street inadequate.

Frederick G. Zimmerman, assistant secretary of Harry Vissering & Company and the Okadee Company of Chicago, has been appointed secretary, to succeed Marshall E. Keig, who has resigned to accept the office of assistant to the president of the Consumers Company at Chicago.

Frank Walsh Haskell, president of the Carborundum Company, Niagara Falls, N. Y., died April 2 at his winter home at Daytona, Fla. Mr. Haskell was born in Brooklyn, New York, in 1861, and was educated in the schools there and in Bloomfield, N. J. He was for a time in railroad service as a rodman in the engineer corps, which laid out the Chicago, St. Paul, Minneapolis & Omaha. In 1885 he moved to Pittsburgh and there affiliated himself with Henry C. Frick as secretary and treasurer of the Southwest Connelsville Coke Company, owned jointly by the Frick and Illinois Steel Companies. In 1897 he moved to Niagara Falls, representing the Mellon interests of Pittsburgh, and becoming president of the Carborundum Company, then in its infancy. This company under his leadership became the greatest abrasive manufacturing concern in the world. It is not generally known that at the request of H. C. Frick and E. H. Harriman in 1905 Mr. Haskell made the investigation of the Equitable Life Assurance Society, which later brought before the public the disclosure resulting in the entire change in the method of life insurance business in the United States. The Armstrong and Hughes Investigating Committees, so-called, were the subsequent results, their facts being largely based on Mr. Haskell's accomplishment.

F. W. Haskell

Ensign Donald Walker, U. S. Naval Aviation Corps, died in the Naval Hospital at Key West, Fla., April 7, as the result of a fall of an aeroplane, of which he was the pilot, at Miami, Fla., on April 1. He was the son of Edmund H. Walker, vice-president of the Standard Coupler Company and president of the Railway Supply Manufacturers' Association. Ensign Walker was a student at Yale University when he entered the aviation service last year. He was 21 years of age.

The Bailey Meter Company on May 1 moved its main office and factory from Boston, Mass., to Cleveland, Ohio. The Boston office, with H. D. Fisher as manager, is being retained to handle sales and engineering service work in the New England district. For the present, New York and Philadelphia districts will be covered from this office and all other districts will be covered from Cleveland.

The Liberty Steel Products Company, Inc., announces the appointment of J. M. Borrowdale as sales representative in the railroad department, with office at 1901 McCormick building, Chicago. Mr. Borrowdale was formerly superintendent of the car department of the Illinois Central and for the past two years was connected with the H. W. Johns-Manville Company, New York, as sales representative in their railroad department.

D. P. Lamoreux, general manager of the Pratt & Letchworth Company, Ltd., Brantford, Ont., has been elected vice-president of the Canadian Car & Foundry Company, Ltd. Mr. Lamoreux has been connected with the Pratt & Letchworth Company since October, 1916. He was born in Mayville, Wis., December 12, 1873. He received his education at the University of Wisconsin, where he took a course in civil engineering as a member of the class of 1895. After leaving college he spent two years in the maintenance department of the Milwaukee Northern Railway, and the California-Oregon Railway, and for the following three years was private secretary to the commissioner of the general land office at Washington, D. C. In 1900 he became associated with the Beaver Dam Malleable Iron Company and worked his way up through that organization until in 1913, when he left to take up another position, he was the company's general manager. During this period, also, he was on the executive and legislative committees of the Wisconsin Manufacturers' Association and for three years of this time, was also regent of the University of Wisconsin. In 1913 he entered the railway supply business in Chicago, and was connected with the Cleveland Steel Company and the Trumbull Steel Company. He became connected with the Pratt & Letchworth Company in November, 1916, as general manager.

D. P. Lamoreux

William H. Basse has been appointed manager of the Detroit, Mich., plant of the Joseph T. Ryerson & Son Company. Mr. Basse has been in the employ of this company since November, 1900, and for the past ten years has held various positions in the sales department at Chicago. In August, 1918, he was transferred to the Detroit office as acting manager of the Detroit plant, succeeding Ralph J. Stayman, who left the company temporarily to fill a war vacancy existing at the Chicago office and who later resigned.

The Oliver Machinery Company, Grand Rapids, Mich., in order to take care of increased business, has found it necessary to enlarge its Chicago office and has moved into new quarters at 810 Railway Exchange building, Chicago. G. C. Conklin, who for many years was connected with the factory at Grand Rapids, is in charge of the Chicago office as district manager, and George C. Ramer, who had formerly been connected with the St. Louis office of the company, has been added to the sales engineering force in connection with the new Chicago office.

A merger has been effected of the Hess-Bright Manufacturing Company, the S K F Ball Bearing Company, the Atlas Ball Company and the Hubbard Machine Company, the new company being known as the S K F Industries, Inc., which will handle a comprehensive line of ball bearings, including the Hess-Bright deep groove type, S K F self-alining radial and thrust bearings and ball bearing pillow-blocks and shafting hangers. The principal office will be at 165 Broadway, New York, with branches at Boston, Philadelphia, Atlanta, Buffalo, Cleveland, Detroit, Cincinnati, Chicago and San Francisco.

F. V. Sargent, has been appointed district manager of sales of the Chicago Pneumatic Tool Company, Chicago, with headquarters at Boston, Mass., to succeed F. S. Eggleston, who has resigned. Mr. Sargent was born in Belmont, Mass., on December 15, 1881. He began his business career in 1905 with the Bethlehem Shipbuilding Company as drafting clerk, and later was in charge of the heat treatment department and physical laboratories. In 1914 he entered the sales department of that company, in which capacity he remained until he accepted the position as district sales manager of the Chicago Pneumatic Tool Company.

Colonel Robert Andrews, one of the pioneers in American railroad construction and a former president of the Safety Car Heating & Lighting Company, died at his home in East Orange, N. J., on April 7, in his 85th year. Colonel Andrews was born August 2, 1834, at Andrewsia, near Wilmington, Del. His early schooling was at the Episcopal Academy of Cheshire, Conn., where he graduated in 1849. He then entered Trinity College, Hartford, Conn., graduating in 1853, and in 1854 completed a course at the Polytechnic College, Philadelphia. He adopted civil engineering as a profession, beginning his career as assistant engineer, Union Canal & State Canals of Pennsylvania. His long career of railroad engineering began in 1857 as principal engineer of surveys and construction on the Sunbury & Erie. In 1859 he went to the South Pennsylvania Railroad as principal engineer of surveys until the outbreak of the Civil War, when he was made a major of the 2nd Regiment, Delaware Volunteers. He was advanced to the rank of colonel in 1863. At the close of the Civil War he was made principal engineer of the Saratoga & Hudson River Railroad from 1863 to 1865; division superintendent of the Toledo, Wabash & Western from 1865 to 1873; chief engineer of the same road from 1873 to 1875, and general superintendent and consulting engineer of the Wabash System from 1875 to 1884. Then for one year he was consulting engineer of the Wabash, St. Louis & Pacific, and in 1885 was made general superintendent and engineer of the Virginia Midland. In 1889 he left railroad service to take the position of vice-president of the Safety Car Heating & Lighting Company. In December, 1901, he was elected president of this company, and from May, 1907 to 1915, he was chairman of the board of directors.

Col. Robert Andrews

Captain C. A. Duntley, who recently received his honorable discharge from the army after serving as captain in the 27th Field Artillery, has been elected vice-president of the Duntley-Dayton Company, with headquarters in the Westminster building, Chicago. He was born in Chicago on October 21, 1892, and received his education in Armour Institute, Chicago, and at Cornell University, from which latter school he was graduated in 1914. Captain Duntley will have charge of the sales work of the pneumatic and electric tool department of the company.

A. L. Humphrey, whose election as president of the Westinghouse Air Brake Company, succeeding John F. Miller, was announced in these columns last month, has been connected with the Westinghouse Air Brake Company since 1903 when he was appointed western manager with headquarters at Chicago. He was born in Buffalo, N. Y., and his family moved to Iowa when he was less than a year old. At the age of 14 after the usual amount of country schooling he struck out for himself and engaged in various occupations. At the age of 22 he organized a general machine shop and foundry in Seattle which afterwards became the present Moran Iron Works. He then entered railroad service and became constructing division foreman of the Mojave division of the Central Pacific, then master mechanic and later superintendent of motive power of the Colorado Midland. At about this time he took an active part in politics and was twice elected to the Colorado House of Representatives and during his second term served as speaker of the House. He then went back to railroad service on the Colorado & Southern in 1899 and went to the Chicago & Alton in 1903 as superintendent of motive power, soon after which he was appointed western manager of the Westinghouse Air Brake Company at Chicago. He went to Pittsburgh in 1905 as general manager of the air brake works, and was elected a director of the company in 1909 when he was also given the dual position of vice-president and general manager, which he held ever since. When the Union Switch & Signal Company was taken over by the air brake company in 1916, Mr. Humphrey was also elected president of that corporation. In addition he has been active in an executive capacity in all the other interests associated with the Westinghouse Air Brake Company, such as the Locomotive Stoker Company, Pittsburgh; the National Brake and Electric Company, Milwaukee; the American Brake Company, St. Louis, and the Westinghouse Pacific Coast Brake Company, San Francisco. During the war the companies of which Mr. Humphrey is in charge accepted from the British and Russian governments, contracts for the manufacture of shrapnel and explosive shells as well as time fuses numbering approximately four to six million units and component parts of war material, involving the expenditure of about $20,000,000 which contracts had to

A. L. Humphrey

be completed in a specified time. Mr. Humphrey not only put up factory buildings, installed special machinery and created an entirely new and separate organization for the construction of this work, but he also finished the job on time without having a single piece rejected. When the United States entered the war Mr. Humphrey received for the Union Switch & Signal Company a contract to produce 4,100 aeroplane engines of the Le Rhone type. Besides his activity as a manufacturer, Mr. Humphrey also acted in a consulting and advisory capacity to the government in Washington on many committees and boards. He was industrial "staff expert" for Brigadier General C. C. Williams, chief of the Ordnance Department, he was a member of the committee on Labor of the Council of National Defense, as well as a member of the War Industries Board and the War Resources Committee in Washington. He is president of the Employers' Association of Pittsburgh and a director of the Chamber of Commerce. Besides the election of a president, the stockholders at the annual meeting elected the following board of directors: Ben V. Becker, James D. Callery, E. M. Herr, A. L. Humphrey, John F. Miller, John R. McCune, John R. McGinley, Charles McKnight, M. S. Rosenwald, W. D. Uptegraff and H. H. Westinghouse.

E. I. du Pont de Nemours & Co., Inc., announces the organization on April 1, 1919, of E. I. du Pont de Nemours Export Company, a subsidiary corporation, created for the purpose of handling foreign business. The officers of the new company are as follows: F. W. Pickard, president; W. S. Gavan, vice-president and director of sales; F. D. Brown, treasurer; Alexis I. du Pont, secretary. The same staff which has previously been associated with the du Pont export business will be continued with some additions made necessary by the broader scope of the new corporation. The main offices will be located at 120 Broadway, New York, with branches in San Francisco, Mexico City, London and Rio de Janeiro.

Lieutenant Commander H. J. Elson, U. S. Naval Reserve Force, has been released to inactive status and has resumed his civilian work as secretary and treasurer of the Walter A. Zelnicker Supply Company, St. Louis, with which company he was in charge of internal management and manufacturing operations. Lieutenant Commander Elson was graduated from the U. S. Naval Academy in 1898, and after service in Cuba, the Philippines and China, resigned from the navy in 1902 to become interested in the Zelnicker company. He was chief engineer of the Missouri Naval Militia, with which organization he was mobilized into federal service upon the declaration of war, April 6, 1917. His assignment was as inspector of machinery, 9th, 10th and 11th Naval Districts, with headquarters at Chicago.

The American Steam Conveyor Corporation, Chicago, announces the appointment of Charles H. Florandin, formerly of the National Electric Welding Company, New York, as general manager of the eastern territory, with headquarters at the New York office, 110 West 40th street. Mr. Florandin was born in France and received his technical education at the famous Lycee de Marseilles. He is an engineer by profession, and upon coming to the United States did important work with the Brooklyn City Railway in the early days when the road was being electrified. After five years' service with this company, he joined the C. & C. Electric Company, New York, where he held a responsible position with them for many years. After a brief connection with the Western Electric Company, he returned to the C. & C. Electric Company, and later organized the National Electric Welding Company. During the war Mr. Florandin was a member of the welding committee of the Emergency Fleet Corporation.

Catalogues

Pneumatic Hammers.—Bulletin 101 has been issued by the Duntley-Dayton Company, Chicago, this being the first of a series of publications which this company has in preparation. It is devoted to the Duntley-Dayton line of riveting and chipping hammers, of which there are 20 sizes and styles, and features their low cost of maintenance. Pneumatic holders-on, pneumatic rammers, rivet sets, chisel blanks, hose, hose couplings, grease and oil, and lead hammers for use in repairing pneumatic tools, are also presented.

Motor Drive.—A universal motor drive for any kind of double spindle shaper has recently been developed by the Oliver Machinery Company, Grand Rapids, Mich., and this company has now printed a bulletin fully describing and illustrating the device and showing its advantages. It also includes a drawing showing the floor plan of the motor drive operating in connection with the Oliver No. 483 high speed double spindle shaper. A description of this device was published in the February, 1919, issue of the *Railway Mechanical Engineer*, page 107.

Air Transport System.—The Quigley Furnace Specialties Company, New York, has developed a system of carrying pulverized fuel which differs from screw conveyor and high pressure blast systems in that the fuel is transported in bulk from the pulverizing plant through small diameter standard wrought iron or steel pipe by compressed air to bins at the furnace, without the use of return piping. This system and the various apparatus used for the transport, distribution and burning of the fuel is described and shown in a diagrammatic drawing in Bulletin No. 11, containing 14 pages.

The Unit Car.—A steam propelled car, designed for railroad interurban and branch line service, known as the Unit car, is described in an attractive booklet containing 16 pages, issued by the manufacturer, the Unit Railway Car Company of Boston, Mass. As the name of the car indicates, its power plant, passenger and baggage space is combined in one car and it has been operated successfully and demonstrated its adaptability for satisfactorily handling short line traffic. The text is illustrated with photographs of the car and drawings showing the side elevation, floor plan and front end.

Cranes for Shops, Roundhouses and Yards.—The Whiting Foundry Equipment Company, Harvey, Ill., has recently issued catalogue No. 135 superseding catalogue No. 127. This catalogue describes electric, pneumatic and hand power traveling cranes, locomotive and coach hoists, gantry traveling cranes, jib cranes and pillar cranes. It gives a general description not only of the cranes but also of the details such as cabs, trucks, brakes and electric equipment, and discusses the field where the various types may be used to advantage. The illustrations show numerous typical installations on railroads.

Ash Disposal.—The American Steam Conveyor Corporation, New York, has issued a 160-page book on modern methods used in handling ashes in power plants. The first 32 pages are devoted to an exposition of the various methods in common use for the handling of ashes, including manual labor and the various mechanical and "current" methods. The remainder of the book is devoted to an explanation of the steam-jet conveyor method and its application to various types of boilers and furnaces together with a large number of descriptions and illustrations of actual installations of this equipment for office buildings, factories, railroads, etc.

Railway Mechanical Engineer

Volume 93 June, 1919 No. 6

CONTENTS

EDITORIALS

Why This Number?

TWO Shop Equipment Numbers of the *Railway Mechanical Engineer* have preceded this one. The first of these was published June, 1917, and the second June, 1918. This number is much more extensive and elaborate than either of the two preceding ones. There are two very good reasons for this.

As we have pointed out in these columns during recent months, it is necessary to do one of three things if the railroads of this country are to be maintained upon a satisfactory and efficient basis: either rates must be raised, wages reduced, or the efficiency of operation increased. Raising rates is a most difficult proposition and the director general of railroads is, apparently, not disposed to take any steps in this direction. It is desirable that the wages be maintained on the present basis. The only other alternative, therefore, is to increase the efficiency of operation by the introduction of the most efficient and economical methods and practices, by the improvement of facilities, and by bringing up the individual output of each employee. The elimination of piece work in many shops means that they must be entirely reorganized in various respects, in order to maintain their productive capacity even on the old basis. One purpose of this special number, therefore, has been to present constructive suggestions as to increased and more efficient shop production which will be helpful to those who are responsible for the maintenance of locomotive and cars.

The second thought that the editors had in mind in building up this special number has been to bring to the attention of railway mechanical department men all of the recent developments in machine tools and shop equipment that may be helpful to them. This is commented on in detail in the editorial following. Incidentally the editors would like to know to what extent this number proves helpful to you.

New Tool Section

DURING the war the builders of machine tools and shop equipment had little or no opportunity to improve their lines for general purposes, although some really remarkable improvements and developments were made in connection with the work of manufacturing munitions and war supplies. Now that the conditions are becoming more normal, the manufacturers are improving their lines so as to better meet the new conditions in the industrial field. The scarcity of skilled labor and the increased wage scales have created a heavy demand for labor and time saving tools and facilities. Possibly this, more than any other one thing, is the keynote of the large section in this number which is devoted to descriptions of new and improved machine tools and shop equipment.

Possibly something should be said as to the meaning of the expression, "new and improved machine tools and shop equipment." A large part of the material in this section covers entirely new designs. There are, however, a number of articles which cover products that have been improved in some of their parts only; in a few cases, tools or equipment have been described because of the addition of a new size to a line which has already been well established and is well known. Then there are several articles covering tools or equipment which cannot be classed as strictly new or improved because they have been manufactured for some time in practically the same form as they are at present. We decided, however, to describe some of these because recent changes in conditions have made their application to the railroad shops of very considerable importance, and a determined effort promises to be made on the part of their makers to bring them to the attention of the railroads.

Those who are planning on attending the June mechanical conventions will be particularly interested in a number of new or improved tools that are described in this issue which will be on exhibition at Atlantic City.

Our Advertising Pages

IT is rather unusual for the editorial department to make special reference to the advertising pages. We cannot, however, let this opportunity pass without commenting upon the really remarkable display in this special Shop Equipment Number. Great changes have taken place in the advertising pages of the technical and business papers during the past decade. The manufacturers were formerly content with using advertising space largely for display cards in order to keep their names before the public. Gradually they came to a realization that it would be far better to use this space for educational purposes by setting forth in an attractive manner the functions and advantages of their products. The difficulty in many cases was that the manufacturers did not have the facilities for getting together the necessary material or of putting it into attractive shape.

One of the greatest editors which the railway mechanical department has ever produced, used to say that the time would come when the advertising pages would be read in preference to the editorial pages because the advertiser, unhampered by those standards as to form which must necessarily be observed by the editor, would be able to make the material more attractive to the eye. The editors are not worrying, but so rapidly have conditions improved in preparing advertising copy that there is no question but what our readers will be forced to study the advertising pages critically and carefully. Unlike conditions 10 years ago, the copy is changed with each issue, thus helping to maintain the interest.

A large part of the data in the advertising pages in this and in our regular issues includes photographs which were actually taken in railroad shops and upon time studies which were made at the same time. While we have made no actual comparisons, it is quite probable that it costs more to prepare the average page in the advertising section than it does to prepare a similar amount of material for the editorial pages—and the publisher will tell you emphatically that the editorial department of this publication is an expensive institution.

Problems of the Air Brake Organization

THE Air Brake Association met this year under conditions that were more nearly normal than existed at the time of the convention last year. Problems bearing on war conditions occupied the attention of this body at the 1918 meeting; the discussion this year showed that the biggest problem which the air brake department has to face now is the improvement of the standard of maintenance. Last year brake equipment was not adequately maintained, and while some of the deterioration has been offset in the past few months there is still an abnormally large amount of equipment which is not up to the required standard. With the maintenance forces working shorter hours there is an increased necessity for getting the most effective work from the entire organization. Under the stress of war conditions some of the practices of former years were allowed to lapse. The question to be considered now is, which methods should be resumed and which abandoned.

The experience through which the railroads have passed has demonstrated the need for some organization on each system to supervise the air brake service. Some roads have been inclined to lean rather heavily on the service organization of the air brake companies. The staff of experts employed by the manufacturers should be called on to act only in a consulting capacity and they cannot be expected to handle routine matters such as the training of employees. This is properly a function of the railroad organizations and where the roads do not employ their own forces to handle this work, the service is almost sure to suffer.

The labor situation in the air brake department has undergone a radical change and will probably never revert to the old conditions. In past years there were plenty of competent air brake mechanics, but now the supply is inadequate and the roads must train men to do this work. The intricacies of the modern equipment cannot be mastered in a few days or weeks and in order to build up the shop organization with experienced men, special inducements should be offered to the employees on the more important jobs. In some instances wage differentials recently established have had the opposite effect, and as a result the shop organizations have been disrupted. It seems probable that there will be a large labor turnover for some time to come, as the shifting of workmen will continue until more stable industrial conditions are established. Instructions in the simplest form will be needed to enable the new men in the air brake department to become proficient in their special work as quickly as possible. The general distribution of the M. C. B. instructions on the maintenance of air brakes has had a good effect. The more detailed report of the Air Brake Association's committee on freight car brake maintenance should prove a great help in the difficult work of training the new employees.

Machinery Repairs on Heavy Locomotives

THE changes in the construction of locomotives during recent years have eliminated some of the defects that were most troublesome in earlier designs. Locomotives of moderate size now give large mileage between shoppings, but designs in which the maximum weight on drivers and tractive efforts are sought as a rule have certain weak points which add to the expense of maintenance and the proportion of time out of service. The development of designs for large locomotives in which no part will have an unduly short life demands the attention of those who design and maintain motive power.

It is interesting to note the general changes in locomotive repair work during the past decade. The mileage between flue renewals has probably increased somewhat while there is but little change in other boiler repairs. Frame failures, which formerly were a constant cause of annoyance, have been almost eliminated. General machinery repairs amount to about the same proportion of the total as before, but the work on rods and driving boxes has caused more and more trouble as the size of the locomotives has increased. The increase in rod work is a natural result of the use of larger cylinders, causing greater stresses, without a corresponding incease in the length of bearings. Long rigid wheelbases add further to the difficulty of maintaining rod bushings. The increased wear on driving boxes is due to greater stresses combined with a wider spacing of cylinder centers and a narrower spacing of frames. This is perhaps a more serious matter than the short life of rod bushings due to the greater difficulty of performing the work on the boxes.

The added difficulty of maintaining these important machinery parts will undoubtedly increase the time locomotives are held out of service and may even prove a limiting factor in the design of large motive power units. Comparatively few attempts have been made to improve on the types of bearings used or the material from which they are made and investigations along these lines may lead to the development of more serviceable designs. Another opportunity for eliminating the trouble lies in designing the parts so that they are more easily removed. The most promising alternative, however, seems to be the adoption of an articulated construction for extremely large locomotives. By dividing the power between two units the individual stresses are reduced and in spite of the added complication, the design would probably give less trouble than a locomotive with a long rigid wheelbase and might even in the end prove cheaper to maintain.

Machine Tool Situation Abroad

AMERICAN business men visiting England and the Continent since the signing of the armistice have learned somewhat to their displeasure that while there is a great need for material and manufactured products of all kinds, there is but little actual business being done. This applies particularly to the machine tool industry. The London agents are extremely busy answering inquiries but have received very few orders. The industrials, particularly those which manufactured munitions during the war, are seeking products that can be made without too great a change in the equipment of their plants. With every new product considered there are requirements for machines they do not happen to have and prompt inquiries are made to ascertain the price and deliveries of those machines. Thus the agents are kept busy, all to no seemingly definite purpose. It is this—the readjusting period—that is so trying. And further, but little actual business is expected for possibly two, six or nine months after peace is signed.

The railways, on the other hand, are in immediate need of machine tools, because there was but little replacement of "railway shop machinery" during the war, and because much of this machinery was given hard usage during the war on munition work in addition to railway work. Careful investigators of the market have picked the railroad field as offering the best possibilities for early sales.

The extent to which the American machine tool manufacturer will participate in this field depends on several things. That he will participate to some extent there is but little question in view of the urgent demand, but the extent to which he will participate hinges upon credits, deliveries and price. In the first place it must be remembered that foreign countries needing machines most have been at war, or, if they be neutrals, have felt the effects of war for over four years, and their financial condition is weakened. They need money and credit. Our government can help in this respect. It is rumored that England has made a loan to Roumania for railroad rehabilitation with the proviso that the money be spent in England. With judicious use of the War Finance Corporation's bond issue of $200,000,000, American exporters can likewise be assisted. In the matter of deliveries American manufacturers have the advantage although the shipping problem still remains serious. The price, however, is going to be the principal difficulty. It is not so much the cost of the tool at the point of manufacture as at the point of delivery. With the excessive and unregulated freight rates now existing on vessels sailing out of American ports, the American manufacturer is at a marked disadvantage all over the world. Some commodities can be shipped from England to

South American ports cheaper than from the United States. American shipping must be made to co-operate more closely with the American exporting industry.

At best American manufacturers of machine tools will be at a disadvantage with European manufacturers of like tools in European markets on account of distance. There are many tools, however, which the Europeans have left to American manufacture for the principal reason that, regardless of the additional ocst due to freight charges, they have not thought it profitable to make them. However, if prices remain too high for very long, it is going to pay the European to enlarge his line of tools, and England particularly is anxious to do this. At the present time purchasers, because of the excessive prices, are buying only those American tools they absolutely must have. Where by any chance purchases can be delayed, they are, with the hope that lower prices will come later. Some even suggest that purchasers are waiting for a low German market! It really is a serious question as to how long sentiment will stand up against a depleted pocketbook. It is very necessary for American machine tool manufacturers, and other manufacturers as well, who really want foreign business to do their utmost in getting into the market, in facilitating credits and extensions and in bringing freight rates down so that they may compete on a more even basis.

The Labor Situation

THE abolition of piece work is a matter of controversy on which there are probably almost as many shades of opinion as there are individuals interested in the subject. But whatever opinion may be held, the fact remains that piece work is out of consideration for the present and it is obviously the duty of everyone having to do with railroad shop administration to accept the situation and make the best of it. In an article on another page will be found a discussion of the fundamentals of wage payment which, while abstract in its treatment of the subject, is worthy of the most careful consideration. The principles therein set forth are, we believe, correct and the first step in the solution of any problem is an understanding of its fundamental principles.

The greatest difficulty in the application of these principles to any system of wage payment lies in the human problem of arriving at a common understanding of what constitutes the "reasonable measure of skill and effort" which the management has a right to expect, and the "commensurate rate" which should be paid for its exercise. It is precisely this problem that underlies the greater part of all our difficulties in securing a satisfactory man-hour output and in maintaining industrial peace. Neither the piece work system, the various bonus systems of wage payment, nor profit sharing schemes have been the solution of this problem. None of them has removed the real difficulty; i. e., the lack of a common understanding by the workmen and the management of what service should be rendered on the one hand and what should be expected in return for that service on the other.

Whatever scheme has been adopted, the basis on which it is administered has been fixed, more or less justly, by one or the other of the interested parties, but never to the satisfaction of both. This is true whether it be a bonus schedule fixed by the management in a non-union shop, or an hourly wage scale dictated by the workmen in a closed union shop. In the former case, whatever the general opinion as to the justice of the basis may be, the opportunity to increase earnings by increased effort has tended to satisfy the more skilled workmen only, the primary cause of general discontent not being removed. In the latter case both parties may agree on the "commensurate rate," but the management is seldom satisfied with the "measure of skill and effort" which is exercised in return. The two cases are fundamentally the same; in neither have both parties to the agreement had a voice in framing the platform on which they must work together.

In either case the principle is despotic, whether or not it results in injustice. Self-respecting human beings can not be contented when subjected to despotic control, even though its exercise may not result in tyranny. It is an inherent characteristic of human nature to desire a hand in the settlement of its own destiny.

A number of experiments in what has come to be designated as industrial democracy are now being conducted, notably in the steel industry, the outcome of which it would be unwise to predict. They are all based on the same fundamental principle, namely, that the management on one hand and the workmen on the other have equal rights to a voice in the determination of the conditions under which they must work together. Whatever the results of the detail plans which have been put in practice may be, the principle on which they are founded is sound and the experiments may well be watched with the keenest of interest.

There is nothing radical in this principle. It is the basis of all contracts and is the only way in which whole-hearted support of an agreement can be secured from both parties interested. Terms virtually dictated by either party, no matter how just in themselves, are not conducive to the best relations between the parties during their administration. This principle does not interfere with the right of the management to exercise its functions. It is still the duty of the management to conduct the industry, the difference between the new plan and time-honored methods being only that it is conducted according to law established by agreement to safeguard the interests of both the management and the workmen, rather than in accordance with the unregulated inclination of either one or the other of the two parties, which may or may not be tyrannous in effect, but which is despotic in principle.

How Railroad Administration Circulars Affect Car Repairs

ONE of the clauses in the contract of the railroad companies with the Railroad Administration provides that the equipment shall be returned at the end of federal control in substantially as good condition as when the roads were taken over. At the present time traffic is light and cars are available for repairs, yet apparently little effort is being made to improve the condition of equipment. The percentage of bad order cars is being reduced, to be sure, but a single heavy repair car requires as much work as several light repair cars and the increase in the number of heavy bad orders more than offsets the decrease in the number of lights, the net result being that there is a deterioration rather than an improvement in the average condition of equipment.

At the present time many of the heavy bad order cars are being set on sidings instead of being sent to the repair tracks. An accumulation of heavy bad order cars presents a serious problem for the shop forces and caring for light repairs to the exclusion of the heavies can only be justified as an expedient for making available the greatest possible number of cars when there is a shortage of equipment. No such condition exists at this time, nor can the policy be justified on other grounds. The Railroad Administration probably did not intend to restrict the repairing of heavy bad order cars; the present situation is rather an incidental result of the attempt to standardize repairs to freight equipment.

The most drastic regulations concerning car repairs are found in circular No. 7, which prescribes standards for repairs to refrigerator cars. The standards in themselves are excellent, but they specify types of construction radically different from those used in the majority of railroad owned refrigerator cars. To require cars to be changed to conform with the new standards would necessitate heavy expenditures.

The situation is further complicated by the provisions of circular No. 20, limiting the amount to be spent for repairs or additions and betterments to equipment. If both these circulars were rigidly enforced some roads would be obliged to retire every refrigerator car they own and the minimum thus affected would probably be 10 to 20 per cent.

A similar situation exists with regard to circular No. 8, which will require a large amount of work or the destruction of a great many cars. It has been estimated that circular No. 8 applied in connection with circular No. 20 would force the retirement of as high as 20 per cent of the cars on many roads. The rules governing minor repairs are also unreasonable in some cases. For instance, to apply a standard body bolster would often necessitate a change in the truck bolster, which in turn would call for new truck sides. It would seem advisable to permit existing standards to be maintained on the older cars to avoid the unreasonable heavy expense entailed under such circumstances.

It is not only in conjunction with the standards for repairs that objections are raised to circular No. 20. The provisions of this circular alone will require heavy expense for remodeling or will force the retirement of many cars. It does not fit in well with the reinforcing programs of the majority of the roads. For instance, some lines have equipped cars of 50,000 lb. capacity with steel center sills, thus making them fit for service in heavy trains and providing a type of equipment that fulfills the requirements in many classes of service, yet the limit of repairs on these cars is set at $75. The circular undoubtedly errs in not taking into account the condition of the individual car. The limit to the amount that can be expended for repairs drops sharply when the car reaches the age of 20 years, though there is no corresponding decrease in the actual value of the car. The circular might be justified if freight cars had a definite and uniform life. As a matter of fact, extended investigation has shown that in actual service the physical condition of cars does not deteriorate beyond a certain point. The condition of individual cars varies considerably, so the amount of expense that would be justified in repairing them would be subject to a corresponding variation.

Because of the operation of circulars 7, 8 and 20 the roads are setting aside many cars, or are making temporary repairs. Such practices will cause the equipment to deteriorate rapidly. Freight cars are now being returned to the owning roads, and as the standards of the individual systems can be followed, the necessity for uniform repair standards no longer exists. Under these circumstances circulars 7, 8 and 20 should be revised in order to facilitate the much needed improvement in the condition of freight cars.

The Mechanical Conventions

THE mechanical conventions will be held at Atlantic City this year, from June 18 to 25. The meetings last year were little more than a gathering together of representatives of the various committees so that the convention this year is really the first one since June, 1916. The three years since that time have been crowded with unusual experiences for the men in the mechanical department of our railroads; never has the necessity for maintaining the equipment in good condition at all times been so forcefully drawn to the attention of the chief executives and those in charge of the operation of the roads. Too often in the past the mechanical department has been tolerated as a necessary nuisance. This has rather tended to discourage the mechanical department officers and has hampered the development of the department.

The time is now ripe for the mechanical department to assert itself and to insist upon having adequate facilities and authority to keep the locomotives and rolling stock in such condition that they can be operated to the best advantage. The mechanical department must insist that locomotives be not allowed to run when in poor condition and that the cars be kept on the repair tracks if not in condition to be used. Will the mechanical department officers take advantage of the changed conditions or will they let the opportunity go by and allow the effect of the lesson to be lost? It will be interesting to watch the conventions from that viewpoint.

Of course, it is necessary to develop standards and recommended practices and to spend a lot of time in technical investigations and analyses. It is true that the mechanical department officers are confronted with the most intricate engineering problems and must give much attention to them; on the other hand, they must not forget that they are executives and that the large questions as to organization, personnel, production and things of that sort are far more important in the interests of efficient and economical operation than is the technical detail work of the department. It is strange, in studying the proceedings of the Master Car Builders' and Master Mechanics' Associations, to see how little real attention has been given to these larger problems.

Take the labor problem. There has been too much beating around the bush and too little straightforward talking in the open on this question. It is safe to say that there are a great many mechanical department men who, because of this, are at least a generation behind the times in the understanding of the labor situation and the best ways in which to secure real co-operation between the men and the management. What better place could there be to discuss this problem in a big way than at the Atlantic City conventions?

Piece work has been done away with and there is apparently a tendency to discourage discussing it in public. There is, however, no more important question demanding the solution by the mechanical department than as to the best ways in which to reorganize the departments which were working on a piece work basis in order to keep up their production capacity. The problem can be solved and if the men now in charge do not tackle it in earnest, it will be necessary to supplant them with other men of keener vision. There are many men who, because of experience, environment or nature, have failed to realize the significance of the change that has taken place in conditions in recent years. One big thing that can be done at Atlantic City is for the leaders to develop this situation clearly and to encourage their brothers to tackle the job with renewed energy and inspiration.

Frank McManamy, assistant director of the Division of Operation, has made a splendid move in suggesting that the superintendents of motive power instruct their representatives at the convention to make notes of those things that particularly appeal to them and report back in writing as to the practical things that were brought to their attention at the meetings, either at the formal or informal gatherings or in visiting the exhibits. Mr. McManamy's purpose must not be misunderstood. He is exceedingly desirous that the Railroad Administration should receive credit for helping to make the present conventions the best and most productive that have ever been held. The Administration will make a heavy investment in sending the men to the conventions and it is desirous of getting the biggest possible returns for this expenditure. This is good business and is to be commended. The fact that written reports are to be turned in does not mean, however, that Mr. McManamy or his assistants are going to check up the individuals and criticize their observations.

E. H. Walker, the president of the Railway Supply Manufacturers' Association, has been quick to take advantage of a real opportunity for co-operation with the Railroad Administration; arrangements have been made whereby each railroad man in attendance at the conventions will be furnished with a special and very conveniently arranged notebook, which promises to prove most helpful in noting down facts for future reference or for making the above mentioned reports.

The Northwest Corner of the B. & O. Shops at Glenwood, Showing the Heavy Castings Platform at the Right

The New B. & O. Shops At Glenwood

Longitudinal Type, 21 Pits; Crane Service in Erecting, Machine; Boiler, Blacksmith and Tank Shops

A NEW locomotive repair shop which, with the new equipment installed, represents an expenditure of more than $1,700,000, has recently been completed by the Westinghouse, Church, Kerr & Co., for the Baltimore & Ohio at Glenwood (Pittsburgh), Pa. The nature of the new shop layout was largely controlled by the rigid limitations of space imposed by the old shop site, most of which is included in the new shop, as no site for a general relocation was available.

The old shop was housed in a group of buildings starting with an old roundhouse which was used as an erecting shop, adjoining one end of which was the machine shop. The blacksmith shop, boiler shop and tank shop occupied three steel frame buildings with corrugated siding adjoining the end of the machine shop in the order named. Between the boiler shop and tank shop was located a transfer table. These latter three buildings were practically all included within the site of the new shop and continued to house their respective shops until the new structure was erected, after which they were torn down and the equipment rearranged in its proper location in the new building. The old machine shop and roundhouse structures remain and will be used to take care of some of the tank work, hose mounting for the car department, etc.

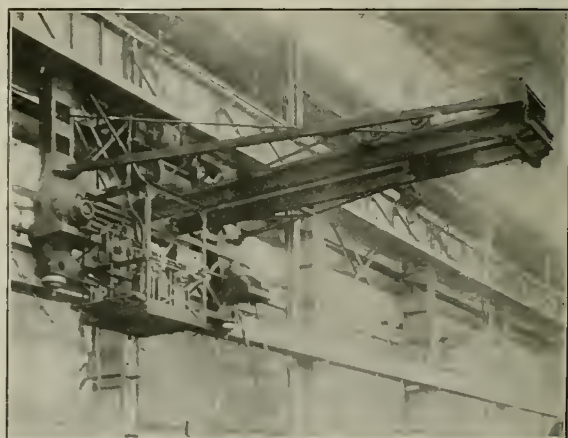
The new shop is of the longitudinal type, of steel frame, brick curtain wall construction and has a total length of 635 ft., with a width of 232 ft. 6 in. It is divided longitudinally into four bays. The monitor bay, 440 ft. of the north end of which is occupied by the erecting shop, is 90 ft. wide. On the east side of this is a single bay 42 ft. wide in which is located the tank shop, pipe shop, tin shop, cab shop and part of the blacksmith shop. West of the monitor bay are two bays, both of which are principally occupied by the machine shop. That adjoining the monitor bay is 62 ft. wide while the outside bay is 40 ft. 6 in. wide. With the exception of 120 ft. at the south end of the building, which is occupied by the storehouse, the outside bay contains a gallery floor, on which space is provided for a manufacturing tool room, facilities for electric repairs, a millwright shop, and the air pump, stoker and injector repair shop, the apprentice school room, offices for the assistant shop superintendent, the general foreman and the supervisor of shop schedules, and toilet facilities.

An unusual feature of the shop structure is the storehouse within the main shop building, which occupies 120 ft. of the west bay at the south end of the building. It is designed for six stories, five of which have been built, and is of reinforced concrete construction.

Along the entire length of the west side of the shop building is a platform 50 ft. wide, served by a 15-ton half gantry crane for about four-fifths of its length. Across the south end of the building is a space of the same width spanned by a 15-ton bridge crane, the surface of which is at ground level.

Equipment and Facilities

Operating over the entire length of the monitor bay there are one 100-ton Toledo bridge crane, one 100-ton Morgan bridge crane and four three-ton Toledo traveling jib cranes operating under the bridge cranes, two on either side of the bay. The east bay is equipped with a 30-ton Toledo bridge crane and in the inside west bay there is a 15-ton Toledo bridge crane. In the two west bays there are a number of one and two-ton electrically operated Yale hoists mounted on swinging jibs, about 15 of which eventually will be employed when the shop is fully equipped. There are two



One of the Three-Ton Traveling Jib Cranes, Serving the Erecting, Boiler and Blacksmith Shop

Otis freight elevators used for carrying material between the machine shop floor and the balcony, one of which also serves the storehouse, and an Otis automatic passenger elevator serves the four floors of the storehouse and the main office on the fifth floor.

In addition to the equipment moved from the old shops, the new plant contains 44 new machine tools, practically an entire new spring plant, a new 6,000-lb. steam hammer, two new forging machines, an additional power hammer and several furnaces in the blacksmith shop, and a new flue cleaner. Practically all of the new machine tools have individual motor drive and the greater part of the machines moved from the old shop are arranged for group drive. Many of the larger machines from the old shop were already individually motor driven.

There are two electric welding sets in the shop, one of which is illustrated. Both of the sets are Westinghouse constant voltage type welding machines; one has sufficient capacity for eight operators, while the other has capacity for five. Along each side of the monitor bay there are 12 welding outlet boxes, making a total of 24 welding outlets. Near the ends of the bay on each side there are transfer panels from which either welding machine may be connected to any welding outlet. Oxy-acetylene tank outfits mounted on trucks are used for cutting.

Good general lighting is provided for the entire shop and individual lights for separate machines have been dispensed with insofar as possible. The monitor bay is provided with four rows of 700-watt incandescent lights placed 22 ft. apart. The lights in the two center rows are fitted with deep bowl reflectors, while those in the outside rows are fitted with angle reflectors. All of the lights are placed above the cranes.

The north end of the east bay is provided with three rows of 400-watt incandescent lamps placed on 36-ft. centers. The two outside rows have angle reflectors and the center row has deep bowl reflectors. In the south end of the east bay the center row of lights is eliminated.

The inside west bay is lighted in the same manner as the north end of the east bay, except that the lights are placed on 22-ft. centers. Under the gallery there are four rows of 200-watt incandescent lamps in deep bowl reflectors 15 ft. apart, with the same lighting in the gallery.

New Tools Installed at Glenwood

2 30-in. vertical turret lathes.	1 26-in. by 12-ft. eng. lathe.
1 84-in. boring mill.	1 30-in. by 12-ft. eng. lathe.
1 44-in. boring mill.	2 27-in. by 14-ft. axle lathes.
1 D. H. rod boring machine.	1 D. H. center drive axle lathe.
1 slab miller.	1 3-ft. radial drill.
1 42-in. vertical miller.	1 4-ft. radial drill.
1 Keyseat miller.	4 5-ft. radial drills.
1 20-in. slotter.	3 20-in. drill presses.
1 24-in. slotter.	1 36-in. drill press.
2 28-in. crank shapers.	1 12-in. by 36-in. plain grinder.
2 24-in. crank planers.	6 emery wheels.
1 16-in. by 8-ft. eng. lathe.	1 100-ton hydraulic press.
2 18-in. by 10-ft. eng. lathes.	1 6,000-lb. steam hammer.
2 18-in. by 10-ft. portable lathes.	1 300-lb. power hammer.
1 20-in. by 10-ft. eng. lathe.	1 1½-in. forging machine.
1 24-in. by 10-ft. eng. lathe.	1 3-in. forging machine.
1 26-in. by 10-ft. eng. lathe.	1 6-in. pipe cut. and th'd machine.

The Erecting Shop, Looking Toward the South End of the Monitor Bay

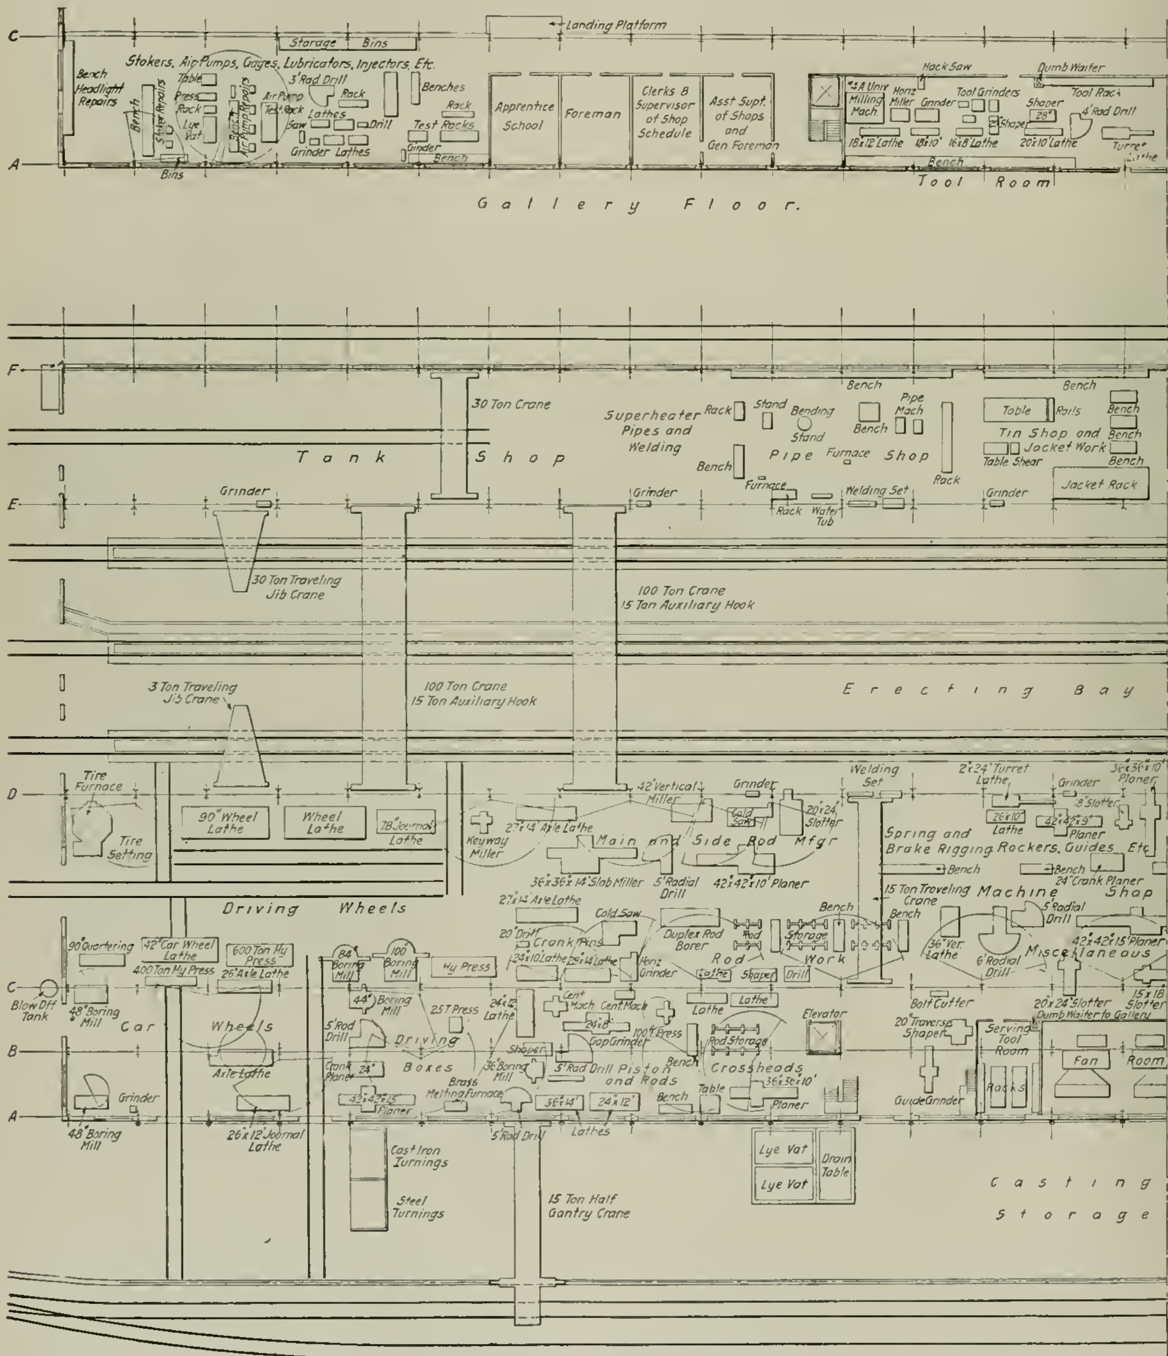
The existing power plant has insufficient capacity for the operation of the new shop and during the day power is brought from the Duquesne Power & Light Company. The night load is handled by the railroad power plant. This plant has been equipped with extra transformer capacity and rotary converters and during the day it is operated as a sub-station to transform the power to the various kinds needed in the shop. The lighting circuits use 110-volt single-phase alternating current, 440-volt three-phase alternating current is required for machine tool and elevator motors and 230-volt direct current power is used for crane motors and some of the machine tool motors.

All of the circuits are carried from the power plant to the shop by lead covered cables in fibre ducts under ground. The lighting feeders are brought up through the floor to the various lighting distributing panels, from which the lighting circuits are controlled. Each switch controls either three 700-watt, four 400-watt or six 200-watt lighting units.

The main power circuits rise from the floor through circuit breakers and cut-outs, just above the floor, to the power feeders, which are run open just under the roof of the east bay and the inside west bay for the entire length of the shop. Branches to individual motors or group motors are carried down the pillars from the feeders. Just before reaching the floor these branches enter a totally enclosed circuit breaker and cut-out, from which they go through a branch cut-out and thence under the floor to the motors. Each branch from the feeders is divided to supply from one to three motors. All wiring in the shop with the exception of the feeders is rubber covered and is all in rigid metal conduit.

Along with the rest of the electrical equipment, the shop is fitted with an electric time clock system. There are 16 branch clocks located at various points in the shop and one master clock located on the south wall of the balcony.

The building is heated by hot air, the system consisting of two 200-in., direct engine driven fans. The plant is a so-

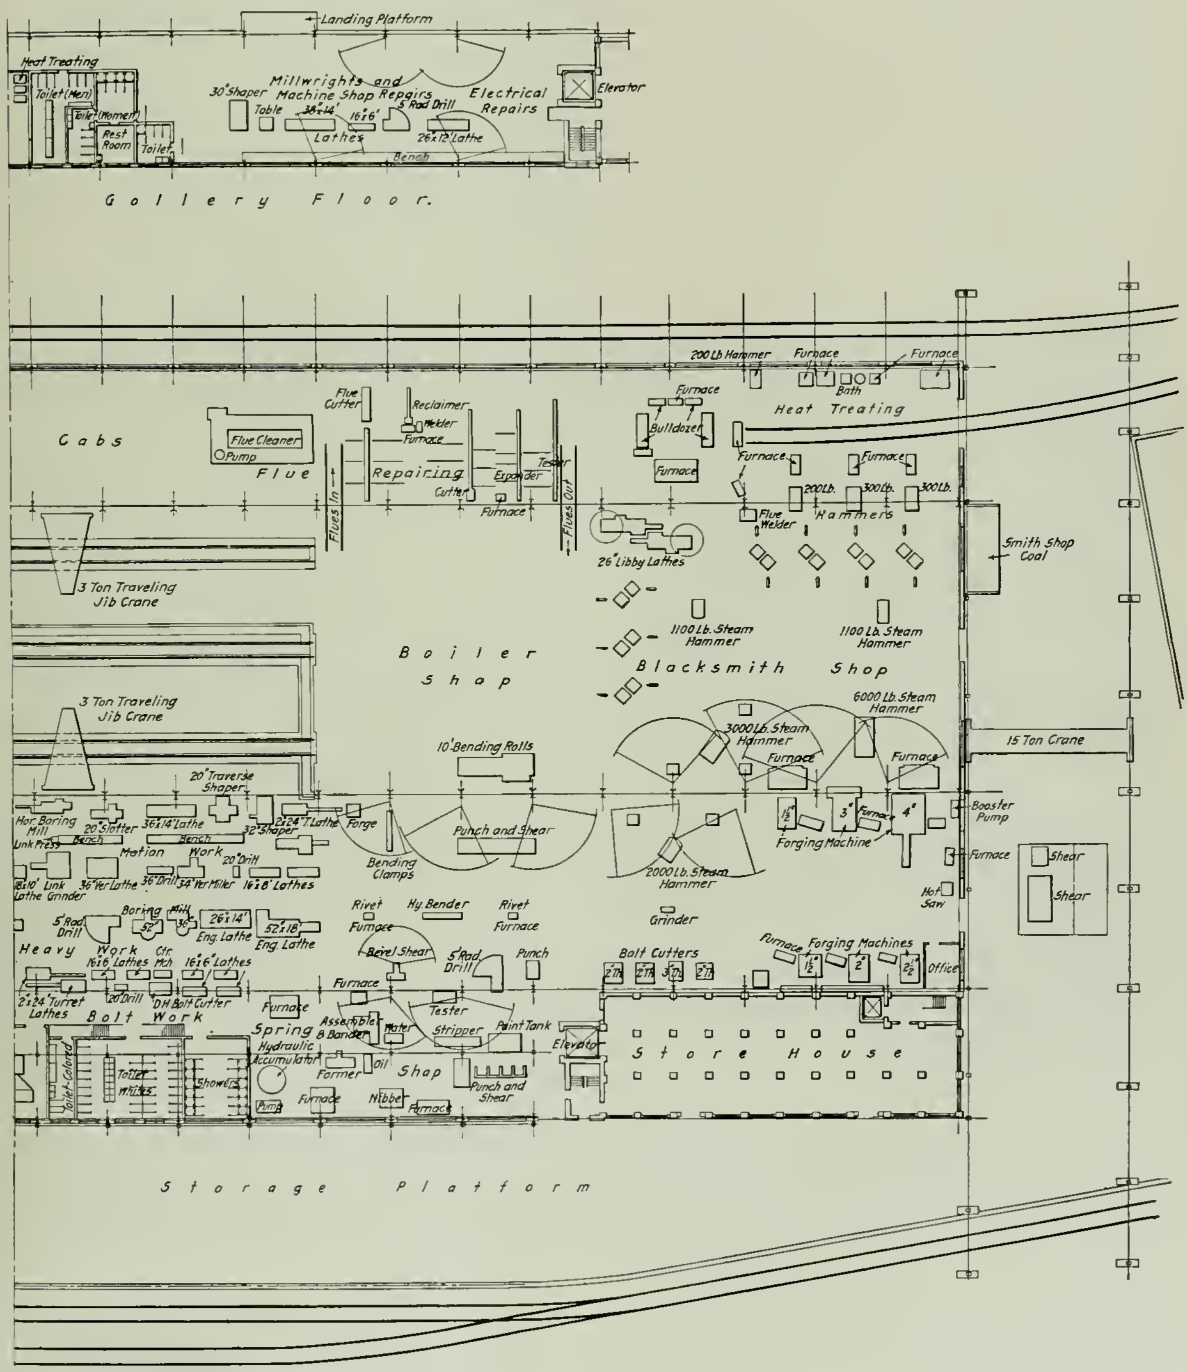


Plan of the North End of the Glenwood Shops called twin system with one fan for each end of the building. Before passing through the fan the air is heated by 71-in. Ventostacks, placed two tiers high and six stacks wide. The fans discharge into concrete heating ducts, forcing the air to outlet boxes at the columns and along the sides of the building. Each fan supplies heat for half of the building.

ERECTING SHOP

The erecting shop in the monitor bay, is 440 ft. long by 90 ft. wide from center to center of columns. It is provided with three longitudinal tracks, all of which are served by the two 100-ton cranes, while the outside tracks in addition have the service of two three-ton traveling jib cranes each. These cranes have a working range extending across the outside tracks to a line about eight feet inside of the inner rail in each case. The three tracks provide room for 21 working pits.

Space equivalent to about two pits on the east track is reserved for stripping as engines enter the shop. About the same amount of space on the middle track is reserved for



Plan of the South End of the Glenwood Shops wheeling and coupling up tenders on completed locomotives. At the present time approximately two working pits at the north end of the west track are used for wheel storage, but eventually one of these pits will be released by providing wheel storage outside the shop, only enough space being reserved on this track to take care of one set of wheels at a time.

As far as possible light repairs are taken care of on the east track, while the heavy repairs occupy the middle and west tracks.

As an engine enters the shop it is stripped and unwheeled on the north end of the east track, then being moved by the 100-ton cranes, one at each end, to a vacant pit on one of the three tracks. The locomotives as they are completed ready for wheeling are moved by the cranes to the north end of the middle track to be wheeled and when this operation is completed are replaced on their respective pits, where the erecting is finished, the valves set and the locomotive completed ready to leave the shop. It is then moved back to the north end of the middle track where the tank is coupled on and the engine then removed from the shop.

The three-ton jib cranes are used for handling light material and stripping and erecting the light parts of locomotives on the two outside tracks, thus greatly facilitating operations on these tracks and relieving the large cranes of a considerable amount of light work.

Another feature which facilitates the erecting shop work is the provision of two portable direct motor driven, 18-in. lathes, one in each erecting shop aisle. These are used on frame bolt work and may be moved to any engine in the shop where a heavy run of frame bolts is required.

All scrap material and refuse originating in the erecting shop is collected in open side steel boxes placed on the floor near the north end of the building. During the night scrap and dirt cars are moved into the building on the stripping track and the boxes dumped into them by one of the cranes, the cars being removed before morning.

MACHINE SHOP

The machine shop occupies both west bays, from the north end of the shop 440 ft. to the spring shop in the inside bay, and 260 ft. to the serving tool room in the outside bay. The heavier work is handled in the inside bay, which is served by a 15-ton traveling crane.

The wheel work is grouped in the north end of the building, driving wheels under the crane and car wheels under the gallery. The driving wheel and journal lathes are located so that the greater part of the work moves continuously in one direction. From the storage on the west track in the erecting shop the wheels are either moved by the crane to a cross track just north of the wheel lathe, or moved outside the building and brought in the machine shop on a track which is located in front of the machines and extends inside the shop to the cross track on which the finished wheels are moved over to the erecting shop. The equipment now includes one 90-in. wheel lathe and a 78-in. journal lathe. Eventually, however, another wheel lathe will be installed and a tire furnace will be placed just inside the north wall of the shop. New driving axles are handled just south of the wheel group, the equipment including an axle lathe and a keyway miller. New tires and wheel centers are bored and turned on two boring mills placed on the outside of the heavy machine bay just south of the driving wheel press.

The car wheel group in the northwest corner of the shop has access to the platform on the west side of the building by two tracks which enter the side of the building and extend entirely across the platform. The gantry crane is available for handling the wheels to and from the cars.

Looking North in the Heavy Machine Tool Bay Showing the Day Lighting and the Location of the Electric Lights

Axle and wheel storage occupy the platform adjoining these two tracks.

All driving box work is handled by one group of machines and facilities so arranged that the movement of the boxes from the time the first machine operation is started until they are refitted with the cellars complete, ready for the journals, is continuous with no back handling.

Driving Wheel Section of the Machine Shop Showing the Route of Wheels from and to the Erecting Shop

It is the practice of the Baltimore & Ohio to use brass hub plates and shoe and wedge faces, both of which are cast on the box. As the boxes come from the engines the hub plates are first stripped off on a vertical turret lathe, which also bores main rod brasses and rod bushings. The brasses are pressed out and then holes are drilled in the hub face of the box to hold the new liner on. These holes are drilled at different angles from the vertical in order to clinch the brass and this work is done on a radial drill, the box resting on a special jig which may be tilted from side to side to change the angles of the holes. New brasses are turned on a 36-in. boring mill and the corners fitted on a 28-in. shaper ready to press in the boxes. This shaper is also used to finish new axle keys, crank arm keys and eccentric keys.

The boxes and brasses are then moved to the press, from which they go to the brass furnace, which is placed under a hood opening through the side of the building, where the shoe and wedge faces and hub plate liners are cast on. The shoe and wedge faces are then surfaced on one of the two planers included in the driving box group. A 24-in. crank planer takes care of cellar work and some of the driving box work, while the other planer, which has a 15-ft. table, is also used on new shoes and wedges.

The boxes then go to a radial drill, where the holes for the crown bearing plugs are drilled, and the crown bearings are then bored on a 44-in. boring mill. The boxes are fitted up on the floor just in front of this machine, ready to be moved to the erecting shop.

This group of machines occupies a space less than 50 ft. square and the whole series of operations, including the fitting up on the floor, employs about ten men for from two to three sets of boxes a day.

The piston and crosshead work are grouped together in the outside bay just south of the driving box work and the tools and facilities are arranged so that all fitting of the two parts is handled with as little movement as possible.

Crank pins and rods occupy the space in the inside bay adjoining the piston and crosshead groups. New main and side rod work is handled by a group of machines on the side adjoining the erecting shop. These include a slab miller, a vertical miller, a five-foot radial drill, a slotter and a planer. The largest part of the machining on new rods is taken care of on the slab and vertical millers. The slab miller channels and finishes the sides throughout, and finishes the edges of the rod bodies, and the vertical miller is used to finish the edges of the stubs. The slotter is used partly on rod work, for main rod straps, and also finishes

Part of the Wheel Shop Group

the crown brass fit on new driving boxes. Not included in this group of machines, but located just across the longitudinal runway down the center of the bay, is a duplex boring machine. This machine is principally used on side rod work.

The spring and brake rigging work, rockers, guides, etc., and motion work groups adjoin the erecting shop south of the rod group, in the order named. Beyond these groups are the tools for handling miscellaneous heavy work and a number of machines, including two turret lathes, for handling bolt work. A portion of the outside bay opposite these groups is occupied by the serving tool room, which com-

The Heavy Forging Machines in the Blacksmith Shop; Looking Toward the Monitor Bay

municates with the manufacturing tool room in the gallery by means of a dumbwaiter. Adjoining the tool room are the fan rooms for the heating system and the toilet and wash room facilities, which include a group of 12 shower baths.

THE BOILER SHOP

The boiler shop adjoins the end of the erecting shop in the monitor bay and also occupies the space in the inside west bay adjoining the end of the machine shop. It extends from the south end of the erecting shop to the blacksmith shop, a distance of 88 ft. longitudinally of the building.

With the exception of the bending rolls, the tools are all located west of the monitor bay, leaving a practically clear floor space in the latter.

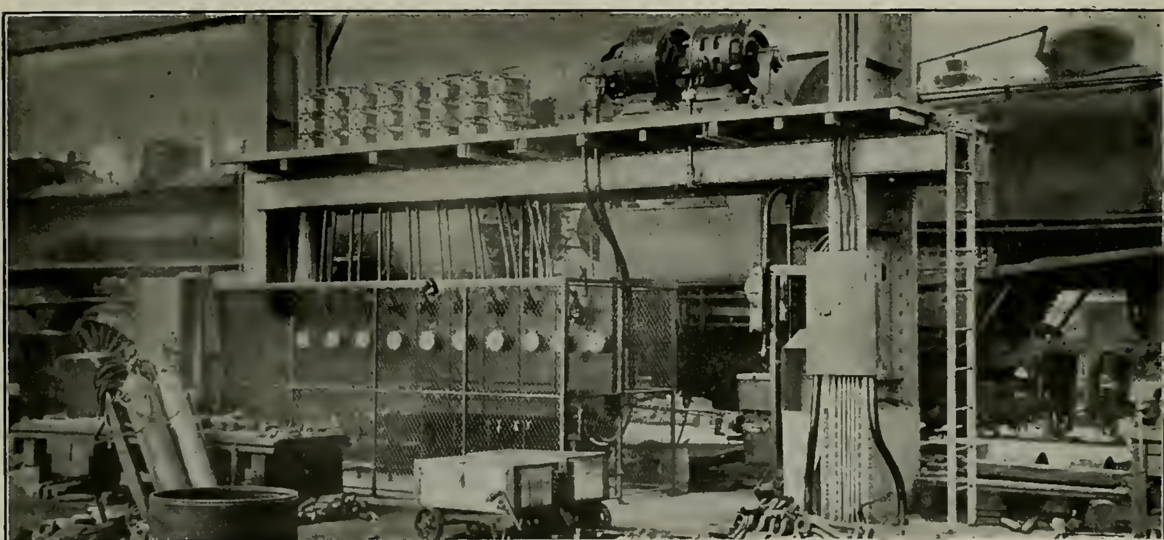
THE BLACKSMITH SHOP

The blacksmith shop is one of the most interesting departments in the plant. In addition to the usual run of light and heavy forgings, bolts, etc., this department includes a highly developed spring shop and also has jurisdiction over flue repairs. This shop handles all locomotive and car forgings for the Glenwood shops, as well as a number of forgings for other points on the system, and repairs four or five sets of flues per month for outside points in addition to those required for the engines in the local shop. It occupies the entire south end of the building with the exception of the corner occupied by the storehouse. Adjoining the boiler shop it is 110 ft. wide and it has additional space in the two side bays, the flue shop occupying 130 ft. of the east bay and the spring shop about 80 ft. under the gallery.

The equipment of the blacksmith shop consists of five steam hammers, three power hammers, four bolt threading machines, six forging machines and two bulldozers, and also includes a 26-in. turret lathe, with provision for the installation of another similar machine. This machine is used on crosshead pins, crank pin collars, knuckle pins, driver brake hanger posts, etc. These parts are rough turned for stock and are used for distribution to outside points, as well as at the Glenwood shops. The bulldozers, which are located on the east side of the shop, form a miscellaneous list of car forgings, which may be loaded directly into cars for removal from the shop on a track extending into the south end of the east bay.

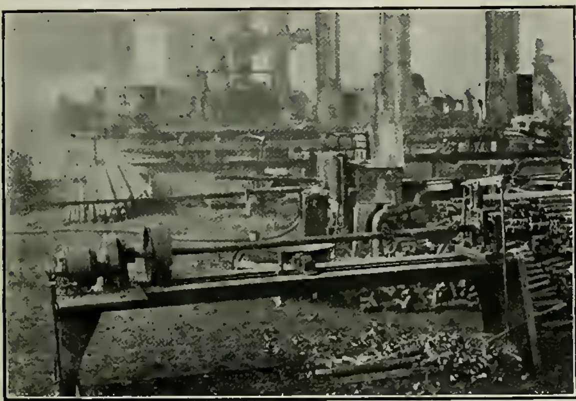
With the exception of the 2,000-lb. steam hammer, which is located in the adjoining west bay, the hammers are all placed in the monitor bay with ample floor space for handling large and heavy material. This part of the shop has the service of the 100-ton cranes and the traveling jib cranes. The lighter hammers are placed adjoining the fires while the 3,000-lb. and 6,000-lb. steam hammers are served by furnaces.

The flue shop is laid out with a view to continuous movement of the tubes from the time they leave the rattler until they are ready for reapplication. They are taken into the flue shop at the end of the erecting shop, where they



One of the Two Electric Welding Sets, Serving Outlets Conveniently Located at Various Points in the Building are placed in a pit type water cleaner. Adjoining the cleaner in the order named are located the flue cutter, the safe end furnace and welding machine, the cutter for trimming the tube sheet ends and the expander. From the expander the tubes go to the hydraulic tester, thence being removed from the shop. They are handled in and out of the flue shop by means of slings and the erecting shop cranes.

Superheater flues are handled separately. The furnace and welder which are provided for this work are located next to the power hammer group and are so arranged that there is room to handle the tubes between the bulldozer furnace and the turret lathe, longitudinally of the shop.



Looking South in the East Bay at the Flue Shop

The welder is used both for welding safe ends and cutting off the ends of the tubes. It is of the roller type and is converted from a welding machine to a flue cutter by removing the welding rolls and then replacing them with shear disks.

The spring shop equipment is practically all new and when fully installed will provide excellent facilities for this class of work. The equipment includes a hydraulic stripping machine, a hydraulic spring testing machine, a triple pressure assembling and banding machine, a forming table and a nibbing machine. A punch and shear adjoining a rack for storing spring stock, a paint tank for dipping the completed springs and a steam dryer complete the working equipment. The stripping machine, testing machine and banding machine are hydraulically operated and are served by a hydraulic pump and 10-in. by 10-ft. accumulator. The furnaces for the fitting machine and for drawing the temper on the plates each will be equipped with a pyrometer temperature recording set.

As springs are received from the erecting shop, they go to the tester. If the test indicates that the spring is in good condition it is returned to service. Should a broken plate show up, the spring is passed to the stripper where the band is removed and the broken plate and band replaced at the assembling and banding machine.

Where the spring needs renewing, it goes from the stripper to the punch and shear, where stock for new plates is cut. This goes to the nibbing furnace and nibbing machine. From the nibbing machine the plates go to the furnace adjoining the forming table to be heated for forming. Adjoining the forming machine is an oil bath in which the plates are cooled and hardened after being formed. They are then taken to the temper drawing furnace and thence pass to the assembling and banding machine. When completed each spring is tested and then painted.

The completed springs are placed in store stock, the engine from which they are removed is credited with scrap and new springs charged out to replace those removed. When only testing is required the work is charged directly to the engine and the springs replaced in service.

CAB, JACKET AND PIPE WORK

Just north of the flue shop, about 60 ft. of the east bay is provided for making cab repairs. The tin shop, which is largely devoted to jacket work occupies 50 ft. north of the cab work and the next 70 ft. is occupied by the pipe shop facilities. Floor space for taking care of superheater pipes and welding occupies 30 ft. north of the pipe shop.

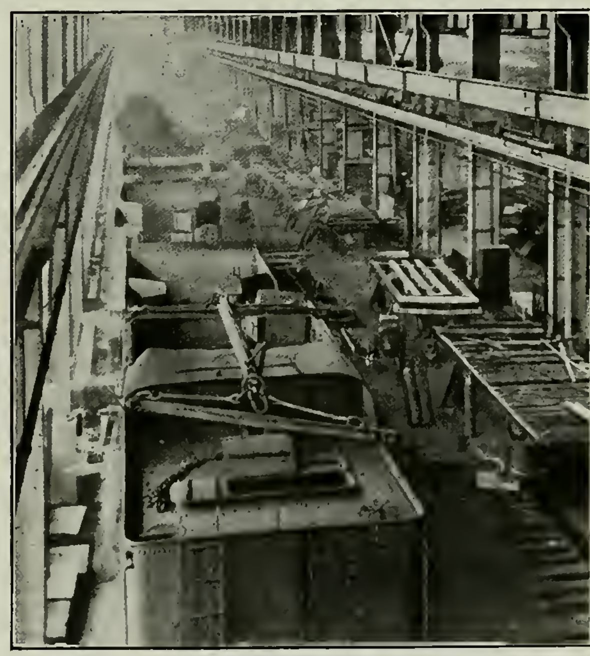
TANK SHOP

The tank shop is located at the north end of the east bay, of which it occupies about 175 ft. This shop is served by one track which enters the north end of the building and extends down the center of the bay about 130 ft. It is served by the 30-ton traveling crane which handles the tanks to and from the frames and removes the trucks from the track, placing them on the floor alongside the track.

The location of this shop at the north end of the building, where locomotives enter and leave the shop, reduces the amount of movement in placing and removing tenders in this shop. It places the shop entirely out of direct communication with the boiler shop. For the handling of such new material as is required, however, the two shops are connected by crane service.

THE GALLERY

On the gallery floor adjoining the storehouse is located the millwright and electrical repair shop, which occupies



A View of the Tender Shop

about 100 ft. Adjoining this shop are toilet facilities for men and women and a woman's rest room, the manufacturing tool room and offices for the assistant superintendent of shops and general foreman, the supervisor of shop schedules and other shop foremen. Room is also provided for the apprentice school. The air pump, lubricator, injector, stoker and gage repairs occupy about 130 ft. at the north end of the balcony.

Two landing platforms project out from the balcony over the heavy machine shop bay, where they are served by the 15-ton crane. One is opposite the millwright and electrical repair shop and the other near the specialty repair shop. Two elevators are also provided, one at the north end of the storehouse which it also serves, and the other at the north end of the manufacturing tool room.

STOREHOUSE

The storehouse, which occupies the southwest corner of the building is 120 ft. long and about 40 ft. wide. The fifth or top floor is occupied by the offices of the superintendent of shops and the local storekeeper. The four lower floors are devoted to storehouse stock. The fourth floor is given over to bulk storage while the third floor, which opens directly onto the gallery, contains the stock of material for air pumps, injectors, etc., which is disbursed directly on this floor. The second floor contains transportation department material while the ground floor is given over to mechanical department stock.

A storage platform extends along the entire west side of the shop building and is served by a half gantry crane of 15 tons capacity, for all but about 140 ft. of its length. Track clearance at the end of the building made it impossible to extend the crane service to the end of the building. This platform is used largely for storing castings and driving wheel tires, the bridge of the crane being arranged to extend over the adjoining track to permit of handling material to and from cars.

This platform contains two lye vats and a drain table. The parts to be cleaned are handled to and from the shop on trucks, it being the plan eventually to provide electric trucks for this service and for handling material into and about the shop.

Under the craneway at the south end of the building arrangements will be made for the storage of bar iron and steel stock.

NEW SHOP ORGANIZED WITHOUT LOSS OF OUTPUT

During the construction of the new shop the organization at Glenwood has been severely handicapped. Conditions demanded that locomotive repairs continue and an output consistent with the old shop facilities was aimed at during the transition period in which machine tools were being moved from their locations in the old shop to the positions which they now occupy in the new shop. This has substantially been accomplished, the work gradually being concentrated in the new shop as the completion of facilities and the placing of machines would permit.

The construction of the new shop at Glenwood is part of a general plan to relieve the serious shortage of back shop facilities on the Baltimore & Ohio, which also includes a similar but smaller shop at Cumberland, Md. Prior to the construction of these two shops the main shop at Mt. Clare, Baltimore, Md., was practically the only plant capable of taking care of heavy repairs on the road and for some time it has been the practice of the road to contract with the Baldwin Locomotive Works for the handling of some of its heavy repair work.

Each of the new shops has a monthly output capacity in excess of any of the old shops on the system. Prior to the erection of the new shop the output at Glenwood was about 27 engines per month. The new shop, with space for handling 20 or 21 locomotives at one time, is expected to have a monthly output, when all the facilities are completed and the organization fully developed, of about 60 locomotives per month. These will include some heavy running repairs as well as the classified repairs for which the shop is designed. The output of classified repairs will probably run from 45 to 50 locomotives per month and under maximum output conditions the shop will employ a force of approximately 1,200 men.

NEW SECTION OF AMERICAN RAILROAD ASSOCIATION

The Executive Committee of the American Railroad Association has created an additional section, to be known as Section VI, to consider and report upon all questions affecting the purchasing, selling, storing and distribution of materials and supplies, and kindred subjects; and the section will include the former activities of the Railway Storekeepers' Association. In this section the representatives of the railroads will be officers of the purchasing and stores department.

J. E. Fairbanks, general secretary of the association, in circular No. 1949, has issued a tentative code of rules of order for the section, as approved by the executive committee. These rules, in principle and very largely in detail, are like those which have been adopted for the other sections of the association. The membership is divided into three classes, representative, affiliated and life. The present honorary members of the Railway Storekeepers' Association are to be continued as life members of section VI of the American Railroad Association.

The section is to be managed by a general committee of 16 elected members, and, in addition, during the period of federal control, of three representatives of the United States Railroad Administration, to be designated by the director of the Division of Purchases. The elected members must be divided equally between the purchasing departments and the stores departments; and during the period of federal control there must be two from each federal region, and two from Canadian railroads. The regular meeting of the section is to be held in May of each year, and at that meeting officers are to be elected.

The first general committee, which has been appointed by the executive committee, will organize the section and will serve until a regular election is held. This committee consists of the following:

H. S. Burr (Chairman), superintendent of stores, Erie Railroad.
E. J. Roth, manager, Stores Section, Division of Purchases, United States Railroad Administration.
S. Porcher, assistant director, Division of Purchases, U. S. R. A.
G. G. Yeomans, assistant director, Division of Purchases, U. S. R. A.
A. W. Munster, purchasing agent, Boston & Maine.
W. G. Phelps, purchasing agent, Pennsylvania Lines West of Pittsburgh.
E. W. Thornley, supervisor stores, Allegheny Region, U. S. R. A.
E. T. Jellison, purchasing agent, Chesapeake & Ohio.
J. P. Murphy, general storekeeper, New York Central (West).
H. C. Pearce, general purchasing agent, Seaboard Air Line.
H. H. Laughton, staff officer, Materials and Supplies, Southern.
G. E. Scott, purchasing agent, Missouri, Kansas & Texas.
W. A. Hopkins, supervisor of stores, Southwestern Region, U. S. R. A.
F. D. Reed, purchasing agent, Chicago, Rock Island & Pacific.
H. E. Ray, general storekeeper, Atchison, Topeka & Santa Fe.
F. A. Bushnell, purchasing agent, Great Northern.
J. E. Mahaney, supervisor of stores, Northwestern Region, U. S. R. A.
E. N. Bender, general purchasing agent, Canadian Pacific.
E. J. McVeigh, general storekeeper, Grand Trunk.

A meeting of the general committee was held on May 16 for the purpose of electing officers. H. S. Burr, formerly president of the Railway Storekeepers' Association, was elected chairman of the Section. E. J. Roth, formerly vice-president of the Storekeepers' Association, was elected vice-chairman of the Section, and J. P. Murphy, former secretary of the old association, was elected secretary for Section VI. Sixteen committees were organized to carry out the work of this section.

Cars Built in Railroad Shops.—During the month of March, 1919, there were constructed in railroad shops one steel underframe baggage car, 59 steel freight cars, 44 steel underframe freight cars, 131 cars with steel center sills and 249 wood freight cars, making a total of 484 cars for the month.

Fundamentals of Wage Payment

Variations in Results More Due to Variations in Management Than to Methods of Compensation

THE general abolition of piece work in railroad shops has confronted the managements of these shops with the problem of securing satisfactory output under a new set of conditions. In approaching this problem a clear understanding of the fundamental relations of supervision, labor incentive and labor output are highly desirable if what constitutes a satisfactory output is to be correctly determined and the conditions affecting its attainment properly controlled.

In an article by B. B. Milner, published in the Railway Age Gazette for April 25, 1913, page 952, these relationships

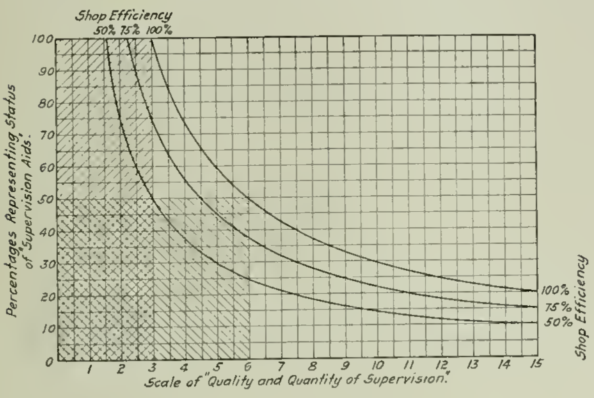


Fig. 1

were set forth in a discussion of the fundamentals of wage payment, the purpose of which was to indicate that all systems of labor compensation, including piece work and the various bonus systems, as well as the straight time basis, if properly administered, are more equally effective than generally supposed. What follows is based largely on the principles then set forth, to which the present situation has given added interest.

The real purpose of the piece-work system or of any of the other so-called reward systems of labor payment is to provide an incentive for the continued exercise of at least a satisfactory amount of skill and energy on the part of the workman. The prohibition now placed on all such systems of wage payment in railroad shops leaves to the workman only a portion of this incentive. It is evident, therefore, if satisfactory results are to be effected where piece work has been abolished, that their attainment becomes more largely a matter of administration, which involves the quality and quantity of supervision and assisting adjuncts provided by the management. Basicly, the problem does not involve the question of shop practice, or shop facilities, but is confined to the relative administration of the various systems of payment under the same physical conditions.

INCENTIVE VS. QUALITY AND QUANTITY OF SUPERVISION

To some it is difficult to appreciate how satisfactory output may be assured. To the incentive referred to—i. e., the ability to voluntarily increase the earning rate by increasing output—most workmen respond at least to the point of maintaining with a minimum amount of supervision their output, even under adverse conditions of shop service and facilities, if not always to the extent of actually increasing their output beyond that represented in a performance which workmen are morally bound to give and the employer has a right to expect under a day-work system. The loss of this incentive may be made up in quality and quantity of supervision and in the conditions and facilities which may be embraced under the general caption of supervision aids—those things outside of the supervising personnel making for the goal of highest efficiency represented by maximum output and minimum cost.

The efficiency obtainable varies with the adequacy of either or both the quality and quantity of supervision and the supervision aids, so that in order to maintain a selected or given efficiency, any loss in one of these items must be made up by an adequate increase in the other.

The principle of this relationship is clearly suggested by the chart in Fig. 1. In this chart note that the adequacy of supervision is relatively represented in the left-hand percentage scale from zero to 100, while the quality and quantity of supervision is represented relatively in the horizontal scale from zero to 15. Uniform efficiencies are represented by the efficiency curves marked respectively 100 per cent, 75 per cent and 50 per cent. These may be algebraically presented by the equation.

Shop efficiency = supervision aids × quality and quantity of supervision,

so that it will be seen that any loss in one of the latter terms must be accompanied by either (1) an increase in the other or (2) a loss in efficiency. For example, if with supervision aids at 100 per cent—that is, of such a character that no fault can be found with them—the resultant efficiency is 100 per cent, quality and quantity of supervision must be of a value arbitrarily denoted as 3 on the chart. If for any reason the value of supervision aids is disturbed by a reduction from 100 per cent to 50 per cent, the quality and

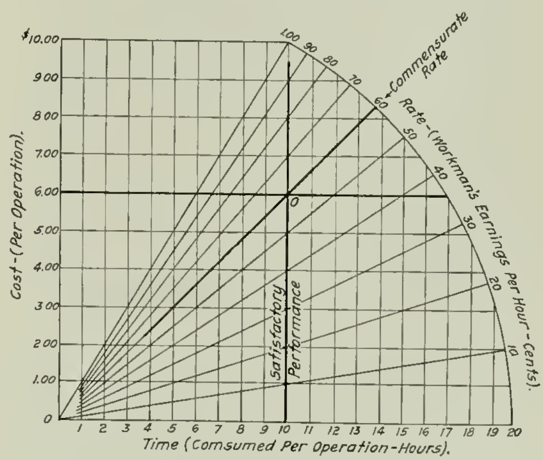

Fig. 2

quantity of supervision remaining constant at 3, the efficiency will also be reduced to 50 per cent, from which point, assuming the continuity of the lowered supervision aids, the efficiency can only be made to again approach 100 per cent by increasing the quality and quantity of supervision toward the value indicated on the chart as 6.

Careful consideration, therefore, of the two complementary factors entering into efficiency is important.

Quantity of supervision is a function of the number of workmen and the character of work to be supervised—i. e., whether unskilled or skilled, repetition or non-repetition work, operations standardized or unstandardized. The required quantity of supervision also depends on the quality of supervision available.

Quality of supervision involves the personal characteristics of foremen, their attitude toward men, their ability to plan and lay out their work, their genius as leaders of men, etc.

Supervision aids involve the general plan of shop operation, the variety of duties required of foremen, their clerical assistance, shop routing plans and their administration, records reflecting the individual performance of workmen; these should be susceptible of combinations reflecting the efficiency of groups of workmen, sub-departments and of an entire shop.

ELEMENTS OF ALL WAGE SYSTEMS

The concern occasioned by the alteration in the plan of labor payment seems to be based upon an erroneous idea of the differences in the relative efficiencies of the various labor payment schemes. All schemes or systems, properly administered, should bring approximately the same results. The fundamental and inter-dependent elements involved in any wage system are:

(1) The labor cost of production per operation (identical with the workman's earnings per operation).

(2) The rate of the workman's earnings per hour.

(3) The time consumed per operation.

These will hereafter be referred to as the cost, rate and time, respectively.

The time consumed per operation should be understood as that, not of the unusually skilful and rapid workman, nor the one lowest in the scale of skill and speed who is qualified satisfactorily to perform the work, but of the average work-

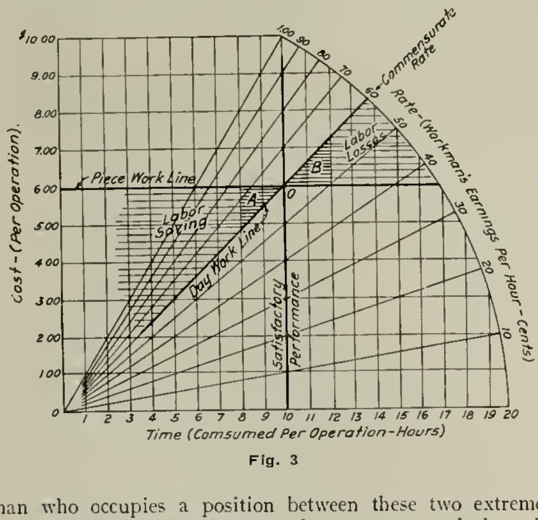

Fig. 3

man who occupies a position between these two extremes. The relations existing between the cost, rate and time elements are expressed by the following equation:

$$\text{Cost} = \text{Time} \times \text{Rate}$$

so simple in application that, having any two of these factors given, few workmen are unable to calculate the desired third. These same relations are presented advantageously by Fig. 2, which geometrically interprets the following equation:

$$\frac{\text{Cost}}{\text{Time}} = \text{Rate}$$

obtained from the previous equation by transposition. Within the range of values exhibited by the cost, time and rate scales, having given any two of these elements, the third may immediately be ascertained by inspection of the chart.

In order to be more specific, in the following development of the relatively small difference which exists in the efficacy of various wage payment systems when properly administered and the advantages which, though smaller than sometimes believed, obtains with the piece-work plan, an operation will be assumed, the satisfactory performance of which requires for ten hours of time the exercise of an amount of skill and effort for which the commensurate rate is 60 cents an hour, as shown by Fig. 2.

It should be understood that what constitutes "satisfactory performance" is prescribed by the management and varies with different managements. Once established for any operation it requires the exercise of a definite amount of "skill and effort" for a definite length of "time." The "skill and effort" required by the established standard of performance commands a commensurate "rate." The product of this "rate" and the "time" determines the equitable "earnings" of the workman and the equitable "cost" to the employer.

Fig. 3 is a duplication of Fig. 2, on which the characteristics of the piece work and the day work systems are represented. From this chart it will be seen that under the day-work system the employee does not participate in the value of labor savings accruing from increased output, as evidenced by the uniformity of his rate of earnings. On the other hand, he does not participate in any of the labor losses resulting from lower output, whereas, under piece work the employee enjoys the whole of the value of labor savings accruing from increased output, and sustains all of the losses which result from a decrease in output. Under the day-work system all labor savings or labor losses, as the case may be, resulting from increased or decreased output, revert to or are sustained by the employer, whereas under the piece-work plan these savings or losses are enjoyed or sustained by the employee, as the case may be. Furthermore, for the time corresponding to satisfactory performance under either system of wage payment, the cost and rate are identical. This situation cannot be disturbed without throwing out of balance the relations which must exist between the "time corresponding to satisfactory performance" and the workman's earnings expressed either as (1) a certain rate per hour, or (2) a certain fixed sum for the completed operation.

EFFECT OF VARIATIONS IN WAGE SYSTEMS SMALL

Between the two extremes represented by the day and piece-work plans there are many systems,—premium, bonus, profit-sharing, etc.,—which may be generally classed as divisional, because they are compromises under which the labor savings and losses resulting from increased or decreased output are divided between the employer and employee. The equity of compensation to the employee and of cost to the employer, in the case of all of them, is dependent on proper determination of the "time corresponding to satisfactory performance," since it will readily be realized that when such time is properly determined, along with the employee's hourly rate, the workman is not concerned in the plan under which he may be paid his compensation, so long as it is equitable and in correspondence with the skill and effort which he exercises. The employee complains justly when, under any system of payment, after having adequately fulfilled his obligation to exercise during a specified time the proper amounts of skill and effort, he fails to obtain his "commensurate rate."

All except unusual workmen, when honestly exercising that amount of skill and effort which they are bound or have agreed to deliver, will not vary much in their output from that represented by satisfactory performance and the time corresponding thereto. In other words, the honest performance of all except unusual workmen will fall within the range of the small triangles of Fig. 3, identified as *A* and *B*, for workmen exceeding and failing respectively to keep pace exactly with satisfactory performance. Since the workman must be paid the commensurate rate for satisfactory performance, regardless of the system of wage payment under which he may happen to work, the wage lines of all systems must pass through the point *O* and lie wholly within the triangles referred to.

It becomes apparent, therefore, that under uniform degrees of management efficiency the actual differences due to variation in wage systems are relatively small, and that any large variation in the efficiencies of operation under them must be due to variations in the efficiency of the methods and the management under which they are administered.

So far as the workman is concerned, the most vital factor in administration is the equitable determination of the time corresponding to satisfactory performance. Whether this time be used in the determination of a piece-work price, a bonus or premium system schedule, or the judgment of the supervising officer upon the matter of whether the workman has succeeded or failed to deliver satisfactory performance under day work, the determination of this time is all important. If it is low under the piece-work system, the resulting piece work price will inadequately compensate the workman. So also in the case of the bonus or premium plan, while under the day-work system, the workman may be unfairly criticized by the supervisor. If too liberal, an unfairly large piece-work price will result, which, according to experience under the piece-work system, is subsequently adjusted, i. e., lowered. These adjustments have caused discontent. The same is also true with regard to the bonus or premium schedules, while under the day-work system of operation, it results in a loosely operated, low efficiency shop.

The time consumed in the satisfactory performance of any operation under given conditions can only be determined from some sort of a time study. This is a very elastic term covering a wide range of precision and exactitude from that involved in, say, the gathering of information upon which to base a rough estimate of the time required for a day workman to mow a lawn, to that referred to by some as of the "blood-drawing type," involving the most minute stop watch data which has, in some places, been applied to the determination of working schedules. Workmen rightfully object to the latter, especially until all conditions and adjuncts of shop operation have been reduced to a degree of precision somewhat nearly consistent with the character of the time studies made.

PROBLEM WHOLLY ONE OF ADMINISTRATION

The fact that a reward system of payment is not used does not obviate the necessity of giving the time element any attention. Although not used directly in the determination of wages, the keeping of accurate output records must be of very significant value in connection with the day-work system; in fact, such records are essential to the maintenance of high shop labor efficiency. Such records form an essential part of the "supervision aids" previously referred to, which result in either (1) increasing the capacity of a given "quality and quantity of supervision," with respect to the number of workmen covered, or of (2) making it possible for the same "quality and quantity of supervision" to enhance the shop's efficiency.

The problem, therefore, is wholly one of administration, involving the provision of adequate supervision and of aids thereto, including shop records which may serve as a basis for measuring labor performance under the conditions and practices obtaining, for application to the individual workman, groups of workmen, whole departments, entire shops or to a number of shops collectively considered. To say that satisfactory outputs cannot be maintained under the day-work plan of labor payment apparently is to disregard the fundamental elements of the problem and their mutual relations.

It is, however, unreasonable with the day-work system, at a rate of, say, 68 cents per hour, to expect the exercise and delivery of the same amount of skill and effort within that hour, as under the piece work or any other reward system of payment, in which the workman actually earns a higher rate of compensation, say the equivalent of 90 cents or 95 cents for that hour.

IMPORTANT REVISION OF M. C. B. RULES

Circular No. 37 has been issued by the Mechanical Section of the American Railroad Association for the purpose of reestablishing delivering line responsibility and the practice of defect carding of car in interchange. The text of the circular is as follows: "This circular re-establishes delivering line responsibility and the practice of defect carding as between roads under U. S. Federal Control, and all circulars and interpretations to the contrary are hereby abrogated.

"In view of United States Railroad Administration Accounting Division Circular No. 86, issued April 15, 1919, effective the date of that circular, Articles 1, 2, 3 and 4 of the 1918 Code of M. C. B. rules for freight cars and modifications A to C, inclusive, of the 1918 Code of Rules for Passenger Cars are hereby abrogated and the following will apply to railroads under U. S. Federal Control:

"To the end that interchange inspection work may not be duplicated under U. S. Federal operation of railroads, so that more repair work and less unnecessary inspection will result, it is ordered—

"(1.) That joint arrangements shall be made to prevent such duplication in inspection by arranging all inspection forces at interchange points with a lead or chief joint inspector as conditions require, to supervise the forces and see that inspection and repairs are properly made to car equipment.

"(2.) M. C. B. Rule 2 is modified as follows: (a) Loaded cars offered in interchange (except those having defective safety appliances) must be accepted by the receiving line which may either run, repair or transfer lading from car; (b) the repairs to car or transfer of lading is to be done by the railroad having facilities nearest available. If facilities are equally available by both railroads, the car will be moved to facilities located in the direction car is moving.

"(3.) If car is shopped for repairs due to: (a) old defects that existed before car was loaded; (b) lading requiring transfer or readjustment, account of not being in accordance with M. C. B. loading rules; (c) overload requiring transfer of lading; (d) not being within clearance dimensions over route it is to pass; (e) not meeting A. R. A. third rail clearance. In each case above mentioned, the facilities nearest to car will be used in making repairs to car or transfer of lading.

"(4.) Should the location of facilities require a receiving line to make transfer or readjustment of lading, the cost of such transfer or readjustment of lading will be billed against the delivering line as per Rule 2 of the 1918 Code. The chief joint or lead inspector will make report and forward to the head of the mechanical department of both railroads, showing all cars transferred or shopped for old defects, whose duty it will be to impose discipline for willful and inexcusable violation of the M. C. B. rules of interchange and loading rules, the same as instructed in Director General's Order No. 8 for the violation of the safety appliance law.

"(5.) Cars, whether loaded or empty, having safety appliance defects will have such defects repaired immediately upon discovery and will not be offered in interchange. If necessary to move car to shops for repairs of safety appliance defects, it must be moved to shops of the company upon whose line it became defective.

"(6.) Empty cars offered in interchange, if in safe and serviceable condition, must be accepted.

"(7.) Bad order cars which previously had been delivered in bad order under load must be repaired by the road making transfer, if they have facilities and material; if not, the nearest repair point on any line, having material and facilities, should make the repairs.

"(8.) Owners must receive their own cars when offered home for repairs at any point on their line.

"Rule No. 92 is amended to read as follows: 'In rendering bills cars shall be treated as belonging to companies or individuals whose name or initials they bear, except that bills for repairs to leased cars or cars of other ownership shall be rendered direct if so directed in the billing instructions in the Official Railway Equipment Register.' "

ELECTRIC TOOL TEMPERING FURNACE

An electric tool-tempering furnace, which uses the barium-chloride and salt principle, is proving highly successful in the South Philadelphia works of the Westinghouse Electric & Manufacturing Company. The chief advantages of this type of furnace over those using gas, coke, oil or wood are constancy and ease of control of heat, cleanliness, equal heating of each atom of the specific part of the tool to be

Electric Tool Tempering Furnace Used by the Westinghouse Electric & Manufacturing Company

tempered, low cost of operation, and excellence of the finished work.

One of the photographs illustrates the simple construction of the furnace. The outer shell, a cast iron cylinder, is about 3 ft. high and 3½ ft. in diameter. This is packed with fire brick and an occasional layer of asbestos. The circular reservoir in the center which forms the operating part of the furnace is 12 in. in diameter and 14 in. deep.

The heat is supplied by two pairs of electrodes built in on opposite sides of the walls of the reservoir. The electrodes operate on a 16 to 30-volt alternating current circuit which is controlled by the switchboard and transformer shown in one of the illustrations. Carbon sticks are placed between the electrodes in the reservoir to complete the circuit.

The current is started on the 30-volt circuit. Salt is fed into the reservoir and when it is melted it acts as a conductor and completes the circuit. The carbon sticks are then taken out. A mixture of barium chloride and salt is then fed into the reservoir, the final proportion being about 60 per cent barium chloride.

When the temperature of the liquid reaches 1,425 deg. F. the voltage is lowered. The current regulation at the switchboard gives a quick and easy method of control so that the temperature of the liquid can be held at any predetermined degree of heat required for each specific tool.

The liquid, kept at one temperature, heats the tool uniformly from surface to center and eliminates soft spots in

Switchboard and Transformer for Controlling Alternating Current Supply to the Tool Tempering Furnace

the finished tool, which is seldom possible when a tool is exposed to a direct or indirect flame.

The furnace throws off very little heat, a feature which meets with the approval of the workmen.

Concrete Cars in the Netherlands.—The construction of concrete rolling stock for railroads is under way in Holland. Only the wheels, axles, buffers and couplings are made of steel. The weight of cars of the new type is said to be no greater than that of steel cars, the construction is simpler and cheaper and the upkeep light.

Electrification of Swedish Railways.—The Swedish State Railway Administration has published a statement to the effect that after investigations regarding the electrification of the entire Swedish railway system, it has come to the conclusion that the plan can be carried out in 30 years at a cost of 192,000,000 kr. The advantages of electrification are that the whole of the power needed can be obtained from eight Swedish electric power stations, the traffic capacity will be considerably increased, and a great saving in staff costs will be effected. Sweden's enormous water power will, in the first place, be made available for this purpose.

Air Brake Association Meeting

Record Attendance at the Twenty-Sixth Annual Convention; Brief Account of the Proceedings

The largest delegation of air brake men in the history of the organization gathered at the Hotel Sherman, Chicago, for the twenty-sixth annual convention of the Air Brake Association, which met May 6 to 9 inclusive. The first session was devoted to addresses by Frank McManamy, assistant director division of operation, United States Railroad Administration; W. J. Bierd, federal manager, Chicago & Alton; W. J. Patterson, bureau of safety, Interstate Commerce Commission, and F. J. Barry, president of the associtiion.

PRESIDENT'S ADDRESS

President Barry in his address spoke of the past work of the association and mentioned its recognition by the Railroad Administration as showing the general recognition of the progress that had been achieved through the leadership of the organization. He urged that the association should continue its efforts to improve air brake service and to extend its sphere of activity, particularly by more active co-operation with the local air brake clubs, which offer an excellent opportunity for keeping in close touch with the problems arising in the maintenance and operation of air brakes. In closing he paid a glowing tribute to the genius of Walter V. Turner, whose work has been largely responsible for many of the most important advances in the art of train control.

F. J. Barry (N. Y. O. & W.)
President

T. F. Lyons (L. S. & M. S.)
First Vice-President

L. P. Streeter (Ill. Cent.)
Second Vice-President

ADDRESS OF FRANK McMANAMY

Mr. McManamy emphasized the necessity for promoting safety, efficiency and economy in the operation of the railroads under present conditions and pointed out how the Air Brake Association can help to secure these aims. He spoke of the need for a realization of the fact that the air brake is not merely a safety device, but is essential for proper operation with the heavy motive power and long trains now in use. He mentioned also the part that could be taken in reducing damage claims by the proper maintenance of the air brake equipment.

Mr. McManamy stated that in his opinion the neglect of brake equipment was too common on roads with low grades and that steps should be taken to remedy the condition. He recommended increasing the forces employed on air brake work and installing proper facilities at repair points where the equipment is overhauled. As the first essential for proper operation he suggested that more attention should be given to stopping leakage in the air brake system and especially in brake cylinders and retainer valves. He spoke also of the co-ordination of the mechanical associations under the American Railroad Association and the benefit that the Air Brake Association could derive by having its recommendation referred to the Mechanical Section and issued as mandatory instructions.

ADDRESS OF W. J. PATTERSON

Mr. Patterson outlined the work of the Division of Safety as it affects air brake matters and spoke of the importance of improving general air brake conditions throughout the country. He advocated the universal use of the incoming brake test as a means of securing better conditions. He also referred to the fact that hand brakes are used to control freight trains when descending heavy grades and said that it was the intention of the Division of Safety to require such practices to be discontinued.

INSTRUCTIONS ON FREIGHT CAR BRAKE MAINTENANCE

A paper giving detailed instructions for the maintenance of freight brake equipment was presented by Mark Purcell (Northern Pacific). The need for clear and definite instructions in printed form was shown by the tests of cars shortly after cleaning, which demonstrated that 21.3 per cent of the brakes cleaned were ineffective within one month. Two years of special inspection and instruction work reduced the percentage to 8.8 which still left a big opportunity for improvement. The need for detailed instruction is particularly urgent at the present time because of the large number of inexperienced men employed in the air brake department.

To avoid unnecessary switching and loss of car service, work should be done well when the cars are sent to the repair track and every opportunity taken to ascertain the condition of the brakes when on the repair track, house track and transfer track. The installation of air lines at such points was advocated as a means of reducing the cost of brake maintenance, increasing car efficiency and expediting train movement.

DISCUSSION

The convention discussed at length the instructions for the testing and repair of certain parts of the air brake equipment, particularly with regard to brake cylinder leakage, retainer valve leakage and the lubrication of the brake cylinder wall. A special committee was appointed to pass on these questions and to prepare the instructions for publication as recommended practice of the association.

AIR LEAKAGE DUE TO DEFECTIVE HOSE COUPLINGS

A paper on Air Leakage and Money Wasted Through Failure to Keep Hose Couplings in Standard Gage, submitted by the Manhattan Air Brake Club, was presented at the Wednesday session of the convention. The paper emphasized the fuel waste due to brake pipe leakage and stated that examination of 1,600 freight cars showed that 35 per cent of the leakage existed in the hose couplings. Further investigation developed that it was difficult to find couplings in service that would pass the M. C. B. standard coupling gage test. Employees often use makeshifts to secure tight joints and at least one road has adopted a special gasket to eliminate hose coupling leakage. Some special types of gaskets submitted to railroads for approval when tested have required from 1,000 to 1,300 lb. to pull the hose apart. Such excessive strains fracture the hose and cause the brake pipe to shift, resulting in leakage. The paper recommended that the universal practice of gaging air brake hose couplings be included when periodic attention to air brake equipment is being given freight cars in shops or on repair tracks.

FUEL SUPERVISORS ADDRESSED THE CONVENTION

At the Thursday session L. R. Pyle and F. P. Roesch, fuel supervisors of the Central Western and Northwestern Regional Districts, respectively, delivered addresses in which they pointed out the way in which the air brake men could assist the Fuel Conservation Section. Mr. Pyle stated there has been a marked improvement in air brake conditions during the past few months, especially as regards brake pipe leakage. He urged the association to continue its support of the Fuel Conservation Section particularly by giving publicity to the magnitude of the waste of fuel caused by train line leaks. Mr. Roesch spoke of the necessity for reducing the cost of operation on the railroads now that normal conditions are being restored. As it appeared impossible to reduce wages or cut the cost of material, more efficient service was the only means of effecting economies that was left. He urged all the employees to justify the large increases in wages by greater efficiency in their work.

ADDRESS OF F. W. BRAZIER

At the Wednesday session F. W. Brazier, superintendent of rolling stock, New York Central Lines East, gave an inspiring address in which he counseled the younger members to devote their energies whole-heartedly to their work. He condemned the lax enforcement of the rules governing the maintenance of brake equipment to which he attributed in large measure the present unsatisfactory conditions. As an indication of the efforts the New York Central has made to maintain cars in good condition he cited the fact that as many as 800 men had been employed on air brake work alone and in 1917 the expenditure for freight car repairs had been over twice as much as for locomotive repairs.

OTHER BUSINESS

On Thursday morning a report was presented on damage to car brake equipment by thawing plants. The practice of thawing loads of coal and ore in buildings heated to a high temperature destroys the packing leathers, gaskets and air hose. The removal of the triple valves, hose and brake cylinder piston, before thawing, was recommended. No objection was raised to thawing by inserting steam pipes in the lading.

A paper was also submitted by the Northwest Air Brake Club advocating a braking ratio of 40 per cent and an inside release valve for caboose cars; the Central Air Brake Club also presented a report advocating large radiating surface between the compressor and the main reservoir.

The secretary reported a membership of 1,050 with a registration at the convention of 650.

The following officers were elected: President, T. F. Lyons, New York Central; first vice-president, L. P. Streeter, Illinois Central; second vice-president, Mark Purcell, Northern Pacific; third vice-president, G. H. Wood, Atchison, Topeka & Santa Fe; secretary, F. M. Nellis, Westinghouse Air Brake Company; and treasurer, Otto Best, Nathan Manufacturing Company. Newly elected members to the Executive Committee are C. M. Kidd, Norfolk & Western; R. C. Burns, Pennsylvania; H. A. Clark, Soo Line; and H. A. Sandhas, Central of New Jersey.

M. Purcell (Nor. Pac.) Third Vice-President

F. M. Nellis (Westinghouse Air Brake Co.) Secretary

Otto Best (Nathan Mfg. Co.) Treasurer

Eight-Hour Day in Italy.—Italian railway employees, according to a Havas press dispatch, have been granted by ministerial decree an eight-hour day with one day off in seven.

Automatics in Railroad Shops

Description of Typical Machines of the Three Primary Types; Set-Ups for a Variety of Jobs

BY M. H. WILLIAMS

On many railways it is found advantageous to blank out articles to a finished or semi-finished state in one central shop and ship them to other shops, a practice which results in economy when compared with manufacturing in each shop. The good results obtained with the automatic screw machine put it in a class that should be carefully considered when additional machine tool equipment is contemplated. This class of machine is being introduced into railway shops and is generally meeting with favor. Its field lies in the manufacture of smaller articles used in locomotive and car construction and repairs, such as are required in larger quantities than would be economical to make on turret lathes.

Contrary to general expectations, no serious difficulty has been encountered in operating these machines and it has not been found more difficult to secure operators for them than for the average run of machines generally used. While it is true that a certain amount of special talent is necessary for successful operation, in most shops there will be found one or more universal geniuses who will take naturally to machines of this nature and who with encouragement and a few visits to plants where similar machines are in operation will become experts and capable of camming, setting up or arranging for any work required. Where one expert is employed the machines may be run by operators who have not had extended experience. The operators rapidly acquire the knowledge necessary to set up and run these machines, one of the principal requirements being the grinding and setting of cutting tools, which is about the same as grinding and setting tools used on turret lathes.

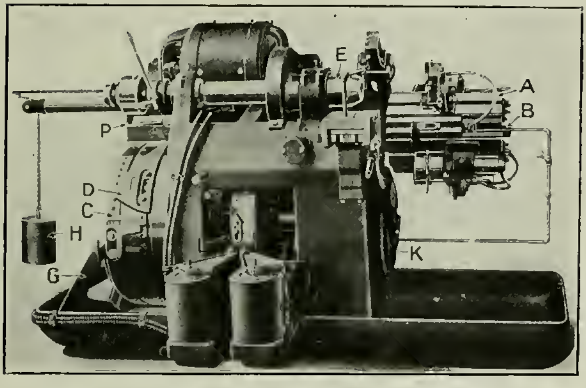

Fig. 1—Typical Single Spindle Automatic Turret Lathe

The economy of the automatic screw machine as compared with the turret or center lathe is due to the fact that one operator can run from two to four machines, each of which will turn out work as rapidly as a turret lathe and much more rapidly than a center lathe. The automatic screw machine is quite similar to the turret lathe, with the difference that on the automatic machine the various operations are controlled by cams and on the turret lathe by hand.

The machines best suited for the first installation in railway shops may be divided into three classes: the single spindle machine suitable for bar work, in which one bar is worked on at a time, Fig. 1; the multiple spindle machine, on which four or more bars are worked on at one time, Fig. 2; and the automatic chucking machine, Fig. 3, having one spindle and used mostly for machining castings and forgings.

The machines illustrated have been selected as representative of their class and for the purpose of explaining the general principle of operation. There are several makes and designs that are extensively used, all of which, together with those illustrated are very popular. Selection must necessarily be governed by the volume of work a particular shop is called on to turn out, cost and other considerations. The kind of work suitable for each class of machine and the general principles of operation and set-up will be considered separately.

THE SINGLE SPINDLE MACHINE

This class of machine, shown in one form in Fig. 1, is very useful for railway work on account of the ease with which it may be cammed and tooled, or as it is generally termed "set up." For the small batches of articles, such as valve motion pins and bushings, set screws, bolts or cap screws having finished surfaces, boiler patch bolts, turned air brake pins and similar articles, this machine will be found very desirable for work made in too large quantities for economy on turret lathes and in too small quantities to justify setting up a multiple spindle automatic.

The machine which is shown in Fig. 1 is motor driven,

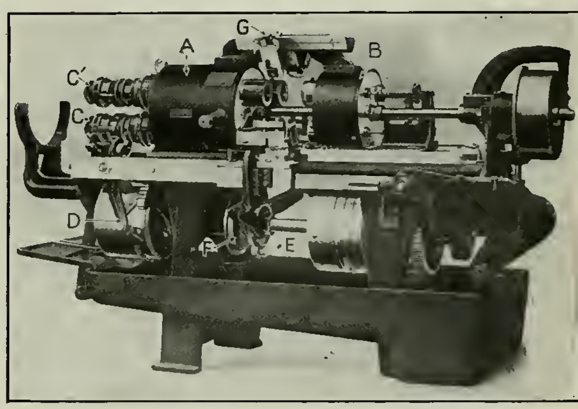

Fig. 2—Multiple Spindle Automatic Screw Machine

and practically all classes of automatic machines may be driven by motor, which is generally considered an advantage. There are several designs of single spindle machines on the market, all of which work on one general principle, therefore, a description of the machine shown will be for the purpose of explaining the various operations. This description will apply in a general way to any single spindle machine.

This type of machine generally has a four hole or face turret to which the various cutting tools, dies or tap holders, shaving tools, etc., are secured. To those accustomed to turret lathe practice four tool holders may not appear enough. In practice it is found ample on account of combining several cutting operations in one tool holder, as will be brought out later. On the machine shown the tools are held on a four sided horizontal turret that is indexed from one position to the next in succession as each tool is required, the active tool being at the top. Each tool is mounted on a slide that is moved to the left by cam *D*. Fig. 1, secured to the cam drum at the left of the machine. This cam works on a roller attached to a rod which connects with whatever slide is at the top, the slide being moved back to the right by cam *C*, also acting on the roller.

Other forms of machines have a round turret revolving around a vertical shaft similar to turret lathe construction, while others have round turrets revolving around a horizontal shaft. On all of these machines the turret and slide are moved to the right and left by cams acting on a roll secured to the turret slide. When the turret is moved to the right it is indexed to the next position.

The cam shaft shown in the lower frame on this machine, and the corresponding cam shaft on practically all single spindle automatic machines, makes one complete revolution for each piece manufactured. To the cam drum or cam disks secured on this shaft the various cams for controlling the operations of the machine are secured. This cam shaft is driven on the belted machines by a separate belt, the pulleys or gears being changed to obtain different speeds. On motor driven machines the speed is often changed by rheostatic control. An explanation of the uses for the various cams will be made in order to give an idea of the work involved when changing from one job to another and not for the purpose of explaining the design of the cams.

With the machine shown in Fig. 1 the slide on the turret face is made to travel in a horizontal direction by cams *C* and *D*, mounted on the left hand drum, working on a roll secured to bar *B*. The cam *D* is for feeding the turret slide up to and over the work and cam *C* for the reverse direction, the length from the right to the left hand side of these cams being sufficient to cause the turret to travel the maximum length the machine is designed for. With the machine in question the turret is indexed by separate mechanism. On other forms the indexing is done when the turret is at its extreme right hand travel, similar to hand screw machines. Cams *F*, F^1 (at the right, but not shown in the illustration) on the same drum are for tightening and loosening the chuck or collet, forcing the spring collet into the inclined spindle head or nose *E*. This does not differ to any great extent from turret lathe practice. The cam *G* on the same drum is for feeding the bar, and in this case the cam draws the feed tube backwards over the bar, the weight shown drawing on the chain which forces the feed tube to the right and feeds the bar as soon as the pin *P* passes over the peak of the cam. The cam disk *K* at the right of the machine is cammed to operate the front and rear cut-off tool holders. The middle drum has cams *N* and *O* (one of which is not shown) for controlling the direction of the rotation spindle. The pins *L* on this drum are for controlling the speed of rotation of the cam drum shaft and perform the following operation.

The speed of rotation of the cam drum must of necessity be slow while the tools are cutting. In order to increase output a speeding-up arrangement is applied to the cam drum driving mechanism, by which the speed of drum rotation is very much increased, often 70 to 1, and which causes the machine to go through the non-cutting operations, such as the travel over the surface of cutting cam *D* previous to the tools in the turret coming into operation, backing off and indexing the turret, feeding stock, etc., at a rapid rate. When tools are cutting the speeding-up device is non-operative and the cam shaft travels at a slow rate. This device performs practically the same operation as the operator on a hand screw machine, who after a cut is completed quickly backs off the turret to the rear position for indexing and bringing it up to the work. The speeding-up device is controlled by pins *L* bolted into a groove cut in the side of the cam and may be readily altered by simply loosening and tightening a nut. This makes it possible to eliminate lost time between cutting operations and to do practically the same as the operator does on the hand screw machine.

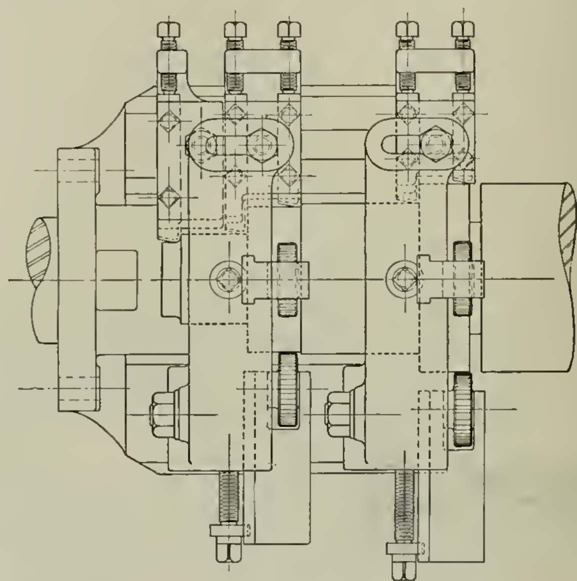

Fig. 4—A Box Tool

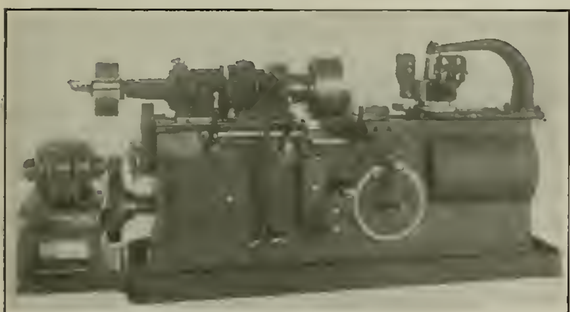

Fig. 3—An Automatic Chucking Turret Lathe

SETTING UP A NEW JOB

The cams for the two cut-off rests bolted to the right cam disk *K* do not require much changing for different jobs, as cutting off is generally the last operation. For some work it is necessary to form with one of these cut-off rests before the piece is ready to cut off, which will make a change of cam necessary.

The cams for feeding the stock and chucking on the drum at the left are generally permanently located and are rarely altered. The reversing cams *N* and *O* for rotation of the spindle must be altered when tapping operations are performed or a solid die is used. This operation is readily performed by removing the bolts and setting to new location. The cams or pins for the hurry operation *L* must be changed for each job. This requires only the loosening and tightening of a nut. The cams for feeding the turret will be considered later.

The tools used on the single spindle machines are comparatively simple, not differing greatly from tools used on hand screw machines or turret lathes. The principal tool for average work is the box tool in some of its forms, one form being shown in Fig. 4. These tools are well understood by those familiar with hand screw machines or turret lathes. On the automatic it is customary to make use of a number of cutting tools in one box in order to turn to various sizes and shoulders in one operation. These tools are found convenient of adjustment for various sizes and shapes of work. The cut-off tool, drill and reamer holders and forming tools are very similar to those used on turret lathes. The die holder may be similar to that used on turret lathes, but the self-opening and closing die is generally preferred, the machine and die being arranged to open and close at the right moment. All these tools are regularly supplied by the makers of the machines.

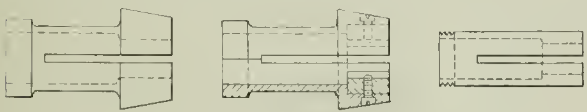

Fig. 5 Fig. 6 Fig. 7
Spring Collets and Feed Finger

For each size of stock it is necessary to use the correct size of spring collet, as shown in Fig. 5. Those for the smaller machines are made from one piece of tool steel very accurately machined and split as shown. They are then hardened and ground to the correct size in the bore where the stock is clamped and also on the outside where they fit the chuck nose. This is a somewhat difficult operation, requiring experience and proper appliances, and can best be done by the makers of the machines. For the larger machines a spring collet or holder is used into which pads may be held by screws, as shown in Fig. 6. With this arrangement one or two holders will answer for any size of bars within their range. It is necessary, however, to obtain pads for each size and shape of bar.

The feed fingers shown in Fig. 7 are made similar to the spring collets. For the smaller machines they are solid and for the larger machines are used with pads. These, like the two forms of spring collets, can best be purchased from the makers. The collets and feed fingers will last a long time and are not an item of great expense. It is necessary to use collets made correctly for each size of round, square or hexagon stock, as their range for satisfactorily holding bars is rarely 1/32 in. and unless properly made it is not possible to obtain satisfactory work or output.

CAMMING FOR AVERAGE JOBS

Before going into the question of the laying out of cams it may be well to consider the conditions of camming and set-up generally found in railway shops, having in mind such work as may come within the range of the class of machines in question.

When purchasing a machine it is customary to have the maker cam it for one or more jobs and also supply an entire equipment of tools for the more common pieces to be made, the result being that the machine is received set up in the most approved method and will be an object lesson in the art of camming. After obtaining a few machines properly cammed it is surprising how many jobs may be done without changing cams, and how quickly changes may be made from one job to another. As previously pointed out, the cams for feeding and chucking the stock rarely require changing; the speeding up cams are set by altering their position with a wrench; the cut-off cams do not require frequent changes. It then comes down to the feed cams for the turret, which will have to be changed when a radical change is made in the class of work.

Assume that a machine has been purchased set up to make cup pointed set screws, say 3 in. long and ¾ in. in diameter, made from ¾-in. square stock, as shown in Fig. 8. A possible set-up would be as follows: The tools used in the turrets could be made up of a stop for limiting the length of bar fed out, a box tool to turn the threaded portion of the screw and at the same time reduce the pointed end, a drill to cup the point, and a die for threading. A tool would be placed in the front cross slide to break off the corners of the head and neck under the head and the cut-off tool in the rear or top cross slide. For holding the stock a collet having a ¾-in. square hole would be used and also a feed finger having a similar hole.

The cycle of operations is as follows: The feed finger is pushed forward to the right by the weight and carries the bar until the end of it strikes the stop set on the turret, which arrests its travel. For this operation the feeding and cams controlling the left hand travel of the turret must be set so that the stop meets the bar at the right moment, it being customary to design the stop cam with a short straight surface, which will allow the turret to remain stationary while the bar is feeding and the chuck is closing. The cam for the collet chuck now forces the collet tube forward, which causes the collet to close on the bar and lock. The turret is now forced to the right and is indexed to the next position by one of the backing off cams *C*, Fig. 1. It is then caused to travel to the left by work cam *D*. All of these operations are performed with the cam drum revolving at a rapid rate by the adjustment of the speeding-up device. When the box tool is within about ⅛ in. of the end of the bar the speeding up device is thrown out of operation by the speeding pins *L*. The turret then travels at a speed suitable for taking a cut with the box tool, which then machines the threaded body of the screw and also reduces the end and points. After this operation is completed the speeding up device is set in operation and about this time one of the reversing cams backs off the turret and causes it to go through the same operation as has been explained until the drill is about ⅛ in. from the point of the screw. The cam drum then again slows up until this operation is completed.

Threading is done in identically the same way. If a solid die is used the spindle of the machine would be reversed at the proper moment by the cams for that purpose. The cut-off cams then cause the tool for breaking off corners of the head to feed in and do its work, and also at the same time the cut-off tool is cutting off the bar. When the set screw is completed it falls into the base of the machine or onto a chute and drops into a box. The cam drum now goes to fast speed, the chucking cam loosens the collets, the bar feeds, and the various operations are gone through again.

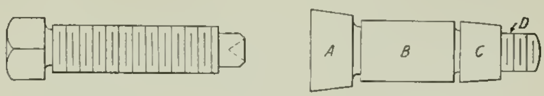

Fig. 8 Fig. 9
Cup-Pointed Set Screw Valve Motion Pin

The set-up just described could be modified to save time by holding the drill for cup pointing in the box tool, in this event the turning and cup pointing would all have been done at one time and the separate operation of cup pointing done away with; the third position of the turret could thus be passed over while the cam drum is revolving at a rapid rate.

Set screws are required of various lengths and diameters for locomotive repairs. If necessary to make to lengths differing from that mentioned above the operations of altering the machine would not differ greatly from those of changing a turret lathe. To change from the 3-in. screw above mentioned to a 2-in. screw will require the following changes. The stop for gaging the length of stock must be set out one inch, the cutting tool in the box tool for reducing the point adjusted, the drill for cup pointing moved out one inch and the speeding-up cams or pins relocated to throw the same out of operation at a later period, all of which may be done in a few moments. If it is necessary to make a longer screw the cutting tools would be reset in the opposite direction from that mentioned and the speed-up pins reset. For manufacturing bolts from hexagon or square stock it would be necessary to change the collets and feed fingers and alter the tools on the turret faces. The cams used for

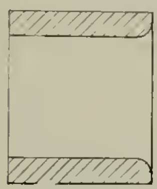

Fig.10
Rod Bushing

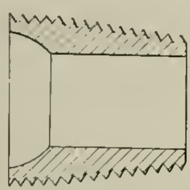

Fig. 11
Staybolt Sleeve

set screws would answer without changing. Shifting from set screws to bolts will involve about the same work as changing on a turret lathe.

A NUMBER OF TYPICAL SET-UPS.

Next it may be well to consider work such as valve motion pins or bolts, as shown in Fig. 9. This pin may be made from cold or hot rolled mild steel of the nearest diameter kept in stock. The cycle of operation of manufacture would be as follows: The stock would be fed out against a stop and the collets tightened. Next a box tool would rough turn the diameters *A*, *B*, *C* and *D* as shown in Fig. 9, except that the tapers would not be made in this operation. For roughing these four diameters four cutting tools would be placed in the box tool, each set to cut to the proper diameter and correctly spaced to allow for the correct distances. The next tool may be a finishing box tool in which are held two broad faced shaving tools for shaving the taper portions, a plain tool to turn the body *B* to correct diameter and also a center drill for centering the end of the pin. The remaining turret face would be taken up by the threading die. In the front cut-off rest would be placed two tools for necking, as shown, should this be desired, the cutting off being done by the rear cut off.

The stop, chucking and feeding cams would be identical with those used for the set screw. Under most conditions the same work cam *D* would be used. However, on account of heavier work and more tools cutting it may be desirable to alter this cam to provide a slower rate of feed, which would involve removing the two bolts shown, removing the cam and applying a new one. A reasonable amount of care must be taken to locate the new cam similar to the one removed. The same operation would possibly also be necessary for the next cam, on account of the center drilling, which is a delicate operation; it may be desirable to reduce the angle of the cam near the end of the cut in order not to crowd the drill. The operation of threading would be similar to that on the set screw. The cut-off cams would be the same. The speeding up cams would be set to speed up at completion of each cut and slow down at the start of each cut, as has been explained.

As another example let it be assumed that it is desirable to make bushings such as are used in valve motion levers or rods, shown in Fig. 10, from solid bar stock. The operations of feeding the bar would be similar to the above. In the second position of the turret the operations would be those of drilling and rough turning the outside, both of which may be done at one time by a drill and turning tool held in the box tool. If accuracy is desired, an inside and outside turning tool may be used on the next turret face, inside turning of the hole being for the purpose of insuring that the hole is concentric with the outside and to correct trouble from the drill not running true. If accuracy is not necessary, as would be the case where these bushings are to be finished later to fit worn levers, this operation may be omitted. The next operation would be that of reaming the hole and cutting off. On account of the drilling which may be for a comparatively large hole, it will be necessary to employ a slow feed work cam *D*, Fig. 1, the changes of which would be similar to those previously explained.

For making flexible staybolt sleeves, Fig. 11, the operations may be those of drilling and forming the outside at one time, threading the taper end and, in the last position of the turret head, threading the straight portion and cutting off. This would require a slow feed cam for the drilling and require relocating the cut-off cam for the outside forming, which should be done at the same time as the drilling. This will involve in most machines the drilling of additional holes in the cut-off cam disk. The threading could be done with the regular work cams. On account of two dies it would be necessary to add a pair of cams to take care of the second reversal of the spindle, and the speeding-up cams would also have to be properly set. This describes only one of the many methods of setting up for this much used article. In the larger shops it is customary to make these sleeves on multi-spindle automatic machines, where the output will be greater. The countersinking for the head of the staybolt must be a second operation.

Much space could be used in dealing with the proper angle and design of cams in order that the greatest output may be obtained. On this class of machine it is the custom of the makers to supply cams known as slow, medium and fast, which will generally meet all requirements for railway work. To go too deep into this phase of the subject would only complicate matters and it is a question if anything would be gained in the long run.

When purchasing a machine it is customary for the maker to cam for certain jobs. From the original set-up a study of cams and tools may be made that will serve as a guide for future jobs of a similar nature. That is, suppose a machine is set up for the set screw, Fig. 8, where the cam for feeding the box tool is what is known as medium, or in the case of the bushing, Fig. 10, a slow cam is used for drilling the bushing. If these work satisfactorily a record may be made of the set-up and similar cams used for jobs of a similar nature. By obtaining a supply of cams of various degrees of speed about any job encountered in railway shops may quickly be set up. The cams used on most single spindle machines are made of iron or steel castings and are comparatively cheap. While the speed of output may not be all that an expert may desire the results for the month will be found satisfactory if attention is given to reducing the lost time by proper setting of the speeding up device for the cam drum.

Making use of as many cutting tools in one operation as possible results in time saving. Never make use of two faces of the turret if by combining the tools the operations may be done on one face. This is a question of judgment on the part of the employee having charge of the machine.

The single spindle machines are made in various forms and designs, having rod capacities of from ¼ in. to 5 in.

For railway work, except in the largest shops, there is not enough work to keep the smaller machines fully employed. As a general proposition machines smaller than 1½-in. rod capacity will not meet with favor. However, the general run of work must govern the size of machines selected.

THE MULTIPLE SPINDLE AUTOMATIC MACHINE

The multiple spindle automatic machine, shown in Fig. 2, differs from the single spindle machine in that four or more bars are operated on at one time and as a result a greater output is obtained. Its principal use is for making articles in large numbers at one time; it begins where the field of the single spindle automatic machine leaves off.

The machine shown has four live or work spindles and will serve as an illustration for describing any class of multi-spindle machine, some forms having five or six spindles. However, they all work on one general principle.

With the machine shown, each of the four bars when being worked on is chucked and revolved in one of the work spindles C, C^1, C^2 and C^3, only two of which are clearly shown. These spindles have their bearings in a drum that is indexed on the quarters. That is, the spindle shown at C next indexes to position at C^1 then to C^2 and so on. The stock is always fed and chucked in the spindle while in position C, the operation of feeding stock and chucking being controlled by cams on the cam drum D. These operations are similar to those of the single spindle machine.

The turret, or more properly speaking, the fixture for holding the cutting tools, dies, taps, etc., is shown at B. This is mounted on a slide that works longitudinally in a horizontal plane and is controlled in its movements by a roll attached to it, which is operated on by the cams on cam drum E, the number of tools in this tool holder corresponding to the number of spindles of the machine. The cut-off and cross forming tools are controlled by cams on cam disk F. There are also special shaving tools at the top of the machine shown at G.

HOW THESE MACHINES OPERATE

When setting up this machine a bar is passed through the spindle shown at C and the chuck and feed finger properly set. The machine is then indexed by hand to the next position, so that this spindle is rotated to position C^1. The second bar is then placed in the spindle now at C and the chuck and feed finger for this spindle properly set. The same operation is gone through with for the remaining two spindles. The machine may then be started, when all spindles and bars will revolve.

When machining, the four tools in the turret each performs a certain operation very similar to the single spindle machine, except that with this form of machine the first tool performs a certain operation, which for the set screw may be to turn the threaded portion for a part of its length. The live head then indexes and this bar is passed on to the next tool, which may finish the turning and pointing. In the meantime the bar just fed is having the first operation performed on it. The head then indexes and the first bar is threaded and the second and first bars are turned. In the last position the bar is cut off. It will be noted from the above that each time the tool holding turret advances a complete piece is made, the time to make a piece being that of the longest single operation. The method of setting the tools is very similar to the single spindle machine.

The operation of indexing the live spindle drum, threading and revolving the live spindles would require a lengthy description and will therefore be omitted; suffice it to say that these operations have been carefully worked out and give very little trouble.

The cam drum shaft makes one revolution for each piece manufactured, that is, the cam drum makes four revolutions to one complete revolution of the live spindle drum. The cams are very simple, consisting of the customary cams to open and close the chuck and the bar feeding cams, which are mounted on cam drum D. Like those on the single spindle machine, they are rarely changed. The tool turret is controlled by cams mounted on cam drum E, which are generally changed when a job is set up, which varies to any great extent from the previous job, this being done to obtain greater output. The cut-off cams on disk F do not require frequent changing. In addition, the machine has the customary speeding up device for rapidly revolving the cam drum during the non-cutting operations.

As a whole this class of machine is not difficult to set up and is readily understood by persons having a knowledge of automatic screw machines in general. It is naturally more difficult and more time is required to set it up than the single spindle machine on account of the greater number of chucks and feed fingers that are used, each of which must be adjusted to the correct tension. The cutting tools do not differ greatly from those used in the single spindle machine and require about the same time to set up. With the multi-spindle machine it is necessary to employ one set of chuck and feed fingers for each spindle, amounting to four or more sets compared with only one for the single spindle machine. On this, as on the single spindle machine it is often possible to change from one job to another without changing the cams or, possibly only a change of the cam that controls the tool holding head.

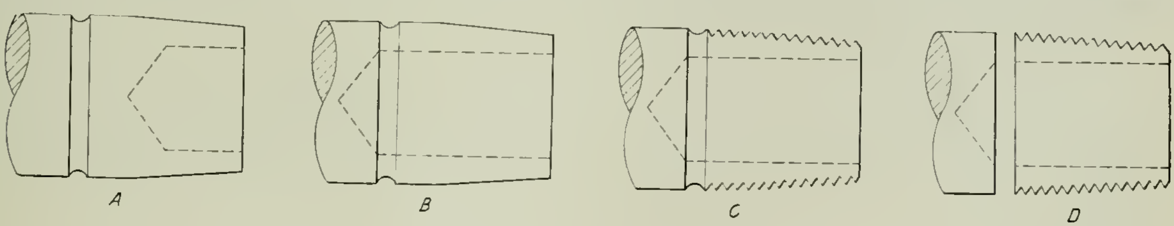

Fig. 12—Successive Operations in Making Sleeves for Flexible Staybolts

SOME MULTIPLE SPINDLE RAILROAD SHOP JOBS

In railway shops there are a number of articles that can be made to good advantage on these machines. Their selection should be confined to articles made in large quantities where frequent changes or set-ups will not be necessary. One job these machines are often used on is the making of sleeves for flexible staybolts, as shown in Fig. 12. A description of the different operations when making this piece may be of interest and will serve as an illustration for any similar job. Assume that the four bars are in the machine and ready to start. The bar in position C is fed against a stop that is moved up in front of the bar at the time of its feeding. After the bar has been tightened in the chuck the stop lowers out of the way. The cutting tools then advance to the left and drill a hole for a part of the distance and at the same time a front forming tool is cutting the outside of the bar to the form shown at *A*. When this operation is completed the tools back away and the spindles are indexed a quarter turn. The second bar is now fed in the spindle in position *C*. The bar previously mentioned has now advanced to the next position, where the hole is drilled the full depth by a second drill, as shown at *B*, and at the same time the bar just fed is drilled and formed on the outside. The tools now back off and the third bar is fed and chucked. In this position the first bar is threaded, which for this particular piece is done by two dies held in one holder, one being for the straight thread and the other for the taper thread, as shown at *C*. While the threading

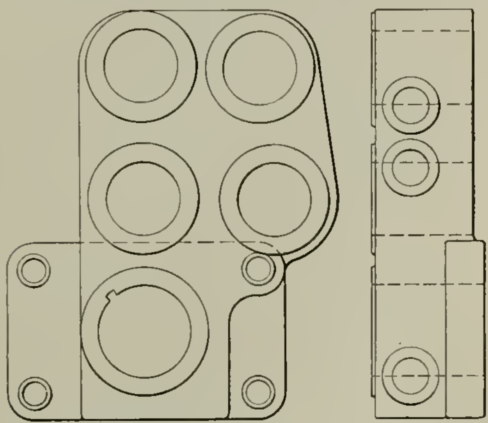

Fig. 13—Turning Tool Holder

is going on the two operations explained are also going on on the bars following. The tools now back off and the first bar indexes to the fourth position, where the sleeve is cut off, as shown at *D*, and at the same time the operations that have been explained are being performed on the succeeding bars. As a result, each time the tools advance a complete piece is made. If it is necessary to make a longer or shorter sleeve the cutting tools and speeding dogs should be changed. A change to a larger or smaller sleeve will also involve changing collets and feed fingers, but for the average length

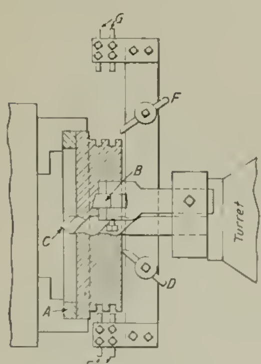

Fig. 14

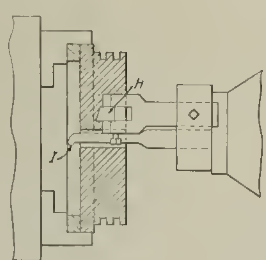

Fig. 15

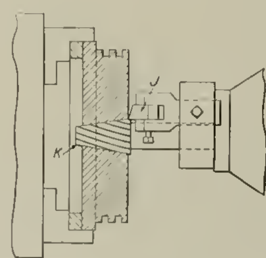

Fig. 16

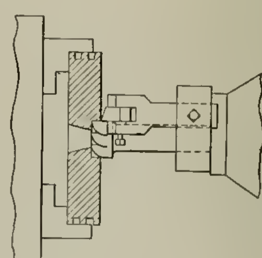

Fig. 17

Operations in Turning an Air Pump Piston Head

of these sleeves it would not be necessary to change the cams. To make set screws or similar articles would probably require a complete change of collets, feed fingers and cams on the drum for feeding the tool slide.

THE AUTOMATIC CHUCKING MACHINE

The automatic chucking machine, shown in Fig. 3, is used mostly for machining castings and forgings. It differs from the automatic screw machine principally in the omission of automatic chucking and feeding of the stock, the turret travel and indexing, the cut-off, forming and speeding-up of the cam shaft being operated by cams. The articles to be machined are chucked in regular lathe chucks or special chucks or holders and follow practices very similar to holding castings or forgings in center lathes.

In operation the piece to be machined is chucked and a starting lever is shifted which throws the cam shaft revolving mechanism into operation. The machine then goes through the various operations necessary to complete the piece, being controlled entirely by the cams. When the piece is completed the mechanism for revolving the cam shaft is thrown out of operation and remains inactive until the operator adds a new piece and starts it again.

The method of camming and setting up this form of machine is very similar to that used on the single spindle automatic screw machine and a description would be largely a repetition of what has already been said; therefore this will not be considered except where it is necessary to note differences.

CAPACITY RANGE OF CHUCKING MACHINES

These machines are made in various sizes and forms, the largest being capable of machining work up to about 16 in. in diameter by about 12 in. long. Their principal use in railway work is the manufacture of special cocks and valves used on locomotives, air pump piston heads and packing rings, nuts for side and main rods, oil or grease cups made from forgings or castings, parts for metallic packing, water gage parts, boiler fittings, piston rod and other nuts, piston packing rings and parts, nuts for flexible staybolts, knuckle pins and bushings, or generally speaking, any article finished from castings or forgings within the size capacity of the machine, which are made in quantities of 50 or more at a time.

The tools used on these machines differ materially from those used on automatic screw machines, principally because the work is larger and made from castings or forgings. These tools in many respects resemble those used on the larger turret lathes for similar work. When the machines are purchased they may be equipped with various forms of tool holders, turning tools and devices, which make it possible successfully to machine a large variety of work without designing special tools. The cutting tools are generally made from square high speed steel, similar to the bits used in lathe tool holders.

One form of turning tool holder, shown in Fig. 13, is used quite extensively. This, as shown, may be secured to the face of the turret by four bolts, the outer face being drilled and reamed to take tool holding bars such as those shown in Fig. 18, which in turn hold the high speed cutting tools. The holes for the tool holding bars are spaced to varying distances from the center line of the lathe spindle, which makes it possible to select a hole suitable for practically any article to be made. It is customary to make use of one, two, three, or more of these holes and tool holding bars at one time, in order that a corresponding number of cutting tools may be in operation at one time, each machining a separate diameter or face. A good illustration of this is the valve bonnet shown in Fig. 21, where the shoulder, threaded portion and end are all machined at one pass of the turret. Drills and reamers are held about the same as in turret lathes. It is customary to use the self-

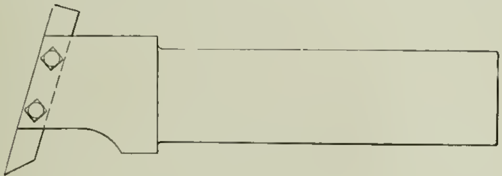

Fig. 18—Outside Turning Tool

opening die, as these machines are not usually arranged for reversing the direction of the spindle, and collapsing taps are also used for the same reason. These dies and taps give very good results. The cross facing is done with ordinary tools held in tool posts similar to lathe practice. Special tool holders and appliances are designed for various jobs, making it possible to machine almost any article required that comes within the range of the machine. It is a question of having a large enough run of one kind of article to warrant the designing and making of these special appliances.

TYPICAL CHUCKING MACHINE WORK

A few illustrations will be given showing jobs suitable for the machine in question. A fair sample of larger work is the 9½-in. air pump piston head, Fig. 14. There are numerous ways this job could be set up. For the comparatively small number called for at a time the set-up as outlined below may be followed and is advocated because it will involve only a few tools in addition to those which would be required to make the same piece on center lathes. The casting would be chucked for the first operation, as shown in Fig. 14, having it supported as far away from the chuck face as possible while assuring a satisfactory hold and permitting the entire outside face to be machined at this one chucking. It is backed up by ring *A* to prevent shifting and admit of quick chucking. The tool *B*, for turning the periphery of the head, and the drill *C* are held in a tool holder secured to one face of the turret. As the turret advances the drill bores the hole for the piston rod and the outside is rough turned. As soon as these operations are completed far enough for the tool holders and turret to get out of the way the front facing tool *D*, held in the cross slide, starts to rough face. Generally the cams may be set so that these two operations are going on at one time. In the front cross slide are also held two tools, *E, E* for roughing out the grooves for packing rings and which come into operation about the time the facing is completed. The front cross slide now backs off and the rear slide, in which are set a finish facing tool *F* and two finishing tools *G, G* for packing ring grooves, comes into play and completes these operations. These latter tools are held with the cutting edge downward. These now back off and come to rest to clear the casting. The cam shaft now goes into high speed and causes the turret to index and advance until the tools are about ¼ in. from the work when the cam shaft goes to slow speed and the finishing tool *H*, Fig. 15, finishes the outside diameter of the casting to correct size and at the same time a boring tool *I* bores the hole true for the purpose of correcting any inaccuracies that may have developed on account of blow holes or the drill not running true. The cam shaft now goes to fast speed and indexes the high speed continuing until the tools shown in Fig. 16 are ready to cut, when it slows down and tool *J* in the tool holder breaks off the corner while at the same time the hole is reamed by reamer *K*, held in a floating holder. When this is completed the cam shaft goes to fast speed and indexes around to the starting position, where it automatically stops, until the finished piece is removed and replaced.

The second side is finished in a very similar manner, as shown in Fig. 17, the front facing tool, in the cross slide shown in Fig. 14, the rear facing tool rough facing the piston, while the rear tool does the finish facing. A tool in the tool holder on the turret breaks off the corner. If necessary to counterbore for a piston rod nut, a counterbore is also held in the turret and operates at the same time. The second side of these pieces only takes up one face of the turret, the remaining faces being indexed and passed over at fast speed until the machine comes to starting position.

This set-up, while not ideal for great output, is one that may quickly be made without much in the way of tools not supplied with the machine. The two front and back tools to cut the packing ring grooves require a special holder which is not expensive. The facing tools are held in regular toolposts on the cross slides which may be supplied as part of the machine.

The cutting tools are similar to lathe tools used for similar purposes. The drill is held in a holder in one of the turret holes, the inside turning tool being held in a similar manner. The outside turning tool is shown in Fig. 18, the nature of which has already been referred to. For accurate reaming it is advisable to hold the reamer in a floating holder. If necessary to tap the head the inside turning and reaming may be omitted and a tap substituted.

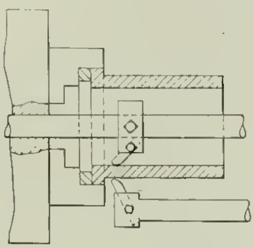

Fig. 19

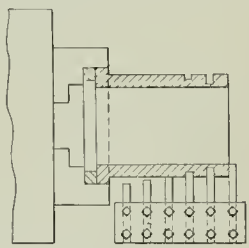

Fig. 20

Turning Air Pump Piston Packing Rings

The regular cams supplied with the machine may be used for the turret. The cams for the cross slide would have to be set to insure that the cross facing does not interfere with the turret tools, which is a comparatively simple operation. The time for making this piece would be less than is required to make it on a center lathe on account of the tools being set to size on this machine and requiring considerable resetting and adjusting when made on a center lathe. Considering the fact that one operator may attend to three or four of these machines, their economy is self-evident.

Air pump piston packing rings may readily be made on these machines. The general custom is to make the castings in pots which are held in the three-jaw or a special chuck and about the same practice is followed as in chucking cylinder packing. When machining, the outside and inside of the pot is turned at one time by tools held in a fixture secured to the turret face and provided with a pilot bar passing through a bushing in the chuck for the purpose of steadying the fixture. The outside is then finished with a second similar tool, also guided with the pilot bar as shown in Fig. 19. The rings are then cut apart by a number of cutting off tools, as shown in Fig. 20. This method is followed very largely by automobile manufacturers.

Globe valve parts may also readily be finished on this class of machine, the tooling operations not differing materially from turret lathe practice, except that the self-opening die,—generally hand-closed,—should be used. A valve bonnet will be used as an illustration, shown in Fig. 21. This piece may be held in a three jaw chuck if such device is suitable, or if of a special shape, special jaws that conform to the shape of the bonnet may be necessary. The first operation would be to turn at one time the outside of the shoulder, the threaded portion and the end, with the tool held in the tool holder supported from the turret. At the same time the hole would be drilled and countersunk by a combination drill and countersink held in the same tool holder. After this operation is completed the piece would be necked and the shoulder rounded over by tools held in the front cross slide. The hole would then be finish reamed by a reamer held in the floating tool holder and the countersunk seat may be finished by combining the reamer and countersink. After this the piece would be threaded. Should this piece require

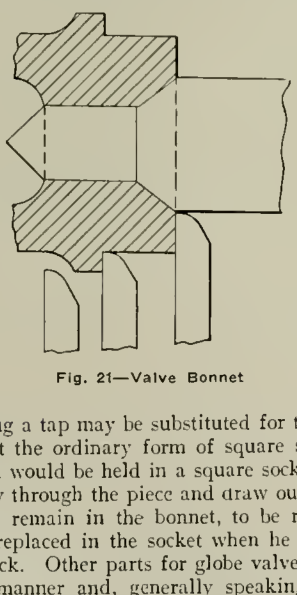

Fig. 21—Valve Bonnet

inside threading a tap may be substituted for the last reamer, in which event the ordinary form of square shank tap may be used, which would be held in a square socket and allowed to feed entirely through the piece and draw out of the socket; the tap would remain in the bonnet, to be removed by the operator and replaced in the socket when he takes the piece out of the chuck. Other parts for globe valves may be made in a similar manner and, generally speaking, require only such special tools as would be needed on a turret lathe.

MANAGEMENT OF AUTOMATIC MACHINES

There is some diffeience of opinion as to the speeds and feeds at which automatic screw machines should be operated. Fast cutting speeds and feeds naturally turn out more work per minute. To offset this the cutting tools dull more rapidly which makes it necessary to stop the machines for the purpose of sharpening the tools. Slower speed results in smaller output per minute, but also in less delay. Generally speaking, for soft steel where good, high speed steel cutting tools are used and also a good grade of cutting oil, a cutting speed of 100 ft. per minute and a feed of 1/200 to 1/50 in. per revolution can be maintained without too frequent sharpening of cutting tools. By observing the speeds on a few jobs made from various grades of material, a fair estimate may be made as to speeds for new jobs and data secured for selecting cams and setting spindle speeds. These machines are equipped with oil pumps for flooding the tools with cutting oil, and may therefore be used at top cutting speeds.

SUPERVISION

In most shops where automatics are installed it is the custom to assign one man to these machines, whose duty is to see that they are properly set up, and in case there are only a few machines, to do the actual setting up and also to make a study of various contemplated jobs to ascertain if they can be made on these classes of machines to advantage. Such a man will soon find a number of jobs that may be made cheaper on the automatics than by other methods, resulting in reduced shop costs. This supervisor should make sketches of the first set-up of various jobs on the various machines. These will be of assistance for future jobs. Preferably a draftsman should make drawings of the set-ups, which will be valuable as shop records and also in the absence of the supervisor. This will work two ways. If the machines are not run up to the original speed some one is at fault. If the supervisor is ambitious he will soon find ways to turn out work quicker than the original set-up.

The nature of the work will govern the number of machines per man. Generally speaking, one operator is necessary for four machines.

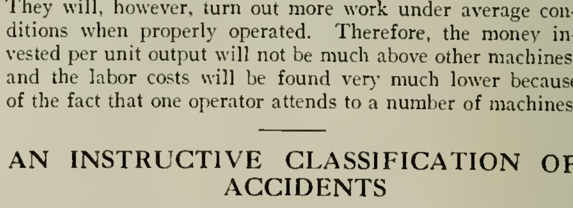
WHEN SHOULD AUTOMATICS BE INSTALLED?

There is not much to be gained by installing less than four automatics. This number would require one man to supervise and set up and one man to operate. The machines need not all be the same, but should be selected with reference to the work that is in sight. Under most conditions for railway work one multi-spindle machine for staybolt sleeves, having bar capacity of about 2¼ in., two single spindle machines of about 2¼-in. bar capacity and an automatic chucking machine will be found suitable. These will demonstrate the possibilities of this class of machine.

Considering these machines from an investment standpoint, they generally cost more than plain machines of equal capacity, such as lathes, turret lathes or hand screw machines. They will, however, turn out more work under average conditions when properly operated. Therefore, the money invested per unit output will not be much above other machines, and the labor costs will be found very much lower because of the fact that one operator attends to a number of machines.

AN INSTRUCTIVE CLASSIFICATION OF ACCIDENTS

The Pullman Car Works recently analyzed the accidents occurring in the company's shops during the year 1918 to determine the relative extent to which the various parts of the body were involved. The result of this analysis is shown



Anatomical Distribution of Accidents

in the chart below, which is taken from the Pullman Car Works Standard. It is interesting to note the large percentage of optical accidents, many of which were due solely to the carelessness of employees, as they could have been prevented by the wearing of goggles, which are furnished free of charge.

Who Are the Real "Live Wires?"

"J. W." Discovered One of Them Just in Time; Read the Story and Then Formulate Your Own Answer

BY A. J. TEN CATE

THINGS were not breaking right at Hadley. Everybody knew that from the office boy who shot craps in the filing room with Rastus Johnson, the colored janitor, to the president of the road 500 miles away, it was known that something was amiss, that something was radically wrong in the big shops at Hadley. Not that there was friction of any kind to mar the harmony of the organization; there was no factional strife—no pulling against one another, nor was there any lack of loyalty on the part of the organization to the shop superintendent, John Williams, commonly known among the men as J. W., whom the men all respected, and who in turn swore by his men.

True he swore at them as well. In fact he hadn't done much of anything else lately but express his feelings in profanity of the sulphuric sort, for to tell the truth, J. W. had seen matters go so rapidly from bad to worse during the past few months that he was beginning to feel that he had a "Jinx" of some kind hovering over his head that was destined to "get him" if things didn't change mighty soon at

Even the Office Boy, Who Shot Craps in the Filing Room with the Colored Janitor, Knew that Something was Amiss

Hadley. But deep down in his heart he had always believed in his "boys" as he called them—had faith in their ability and loyalty and, up to the time our story opens, he had felt that they would be able to overcome the difficulties looming up so formidably and soon have things going right.

With but few exceptions, the personnel was the same as it was six years before when J. W. took charge. He had come to Hadley at a particularly opportune time, succeeding a man who had been very unpopular with the organization and, having had a large experience in handling men he had shrewdly "cashed in" on his predecessor's unpopularity by showing an immediate disposition to treat the men fairly. By quickly gaining their confidence and good will, he had soon secured a spirit of co-operation heretofore unknown. Of course, this had a decidedly beneficial effect on shop output and better results than ever before were soon obtained at Hadley and J. W. was given the credit for being a genius in shop management, without having really effected a single change in the organization or methods. The output prior to his advent had been 12 to 14 engines a month, which soon increased to 16, a figure never before reached in those shops.

Naturally, the management was highly pleased at the showing and the superintendent of motive power never lost an opportunity of telling how they did things at Hadley.

The shops at Hadley had always taken care of the general repairs on all power operating on three principal divisions. This had been done satisfactorily for many years, but gradually, as traffic grew, and new and heavier power was made necessary, it became increasingly evident that Hadley shops were entirely inadequate to handle the repairs required to keep power in shape. In fact, scores of engines had been put in service that could not be gotten into the shop at all. For a while these engines were given only light repairs in the various round houses where they were assigned, but this of course, could not continue, and with a greater volume of business than ever confronting the road, the company had finally decided to enlarge Hadley shops to suitable size and capacity for the overhauling of 30 engines per month. The work had been started a year and a half before the commencement of our story.

BUILD NEW SHOPS AT HADLEY

Unlike many roads where large shops are reconstructed, there had been no controversy of any kind over proposed design or construction. When it had finally been decided to make the improvements, "Get together" meetings were held, often in the president's office and everybody who had an idea was given an opportunity to express it. When the final plans had been approved it was found that the cost would approximate a million dollars, but this was not considered too great an expenditure for the results expected.

When it came to shop equipment, machine tools and appliances, the management had used a lavish hand, installing many of the new and expensive tools which, to J. W., seemed unnecessary and ill advised. In his estimation, the majority of the later types, which were unknown in his day, were only useful on special work, and he would much rather have had more lathes, planers and boring mills than the grinders, millers of various types and other machines which were not familiar to him. He seriously doubted their ability to make good on general utility work.

When the shops were completed and everything in readiness for operation, it was conceded by those who were in a position to compare them with other shops of similar capacity, that the new shops were far superior in many ways and capable of greater output than many shops of a more pretentious character employing a greater number of men.

"J. W." COULDN'T GET 30 ENGINES A MONTH

The first month or two after completion nothing was said to J. W. about output. That it would take some little time to get organized on the new basis was to be expected, and as he enjoyed the confidence of the management to an exceptional degree, nothing was said when at the end of two months the output had only been increased to 19 engines per month. But now after six months, and with 20 engines, the largest number overhauled so far for one month since the shops had been completed, the management had begun to take serious notice of the unfortunate situation. At first, only inquiries of the most friendly character had been made. These failing to bring satisfactory explanation for past failures, and to convey information as to when an improvement could be expected, soon became demands for explanations.

The situation was greatly aggravated by the division superintendents, who were constantly wiring the general superintendent about congestion in their respective territories due to shortage of power on account of inability to get engines through Hadley shops. The president, who had been extremely lenient the first few months, was now aroused over the situation and demanded results without delay.

Of course the superintendent of motive power was after J. W. and J. W. was after everybody at Hadley.

A mechanic of the old school and still clinging to many old fashioned ideas, he made no effort to solve the problem by applying new methods. In fact it was known that J. W. had but little time for some of the new fangled notions advocated in other shops. He had held staff meeting after staff meeting during this period and given everybody a chance to make suggestions for improvement. But no one came forward with anything tangible in the way of a solution. None of them had ever been employed in a supervising capacity elsewhere and only knew one way to handle their work, and that way was not getting results now.

At these meetings it was invariably brought out that the machine shop was inadequate to turn out the finished parts for an output of thirty engines per month. To do the machine work for this number of engines, and at the same time fill the many shop orders to keep six round houses supplied with finished material ready to use, was altogether too much for the machines they had. Fred Shipley, the machine shop foreman, whose ability was unquestioned, said it could not be done. George Wheeler, the general forman, was equally sure that Fred was right.

The erecting foreman agreed to put the work up and get the 30 engines, if he could only get the finished parts as fast as he called for them. J. W. got acrimonious as time went on and the demand of the management for output became more insistent.

"SOMEBODY HAS GOT TO DO SOME HEAVY BATTING"

One day he received a message from the president to meet him at the station on arrival of Number Seven. He was under no illusions whatever as to the character of his forthcoming interview with the big boss, and as he climbed on board the president's car that afternoon, and noted the expression on the face of the president who had always before had a smile of welcome for him, what little hope he had failed him. He realized that something *would* have to be done if he remained at Hadley in his present position.

"Mr. Williams," said the president, when J. W. was seated, "if I had lost that million the company gave me for improvements here in a good clean cut, fast game of poker, I would not have felt so bad about it as I do under the present circumstances. As the game now stands"—the president was an old baseball fan—"the company has put up their good money for a fluke—not a hit made so far. I wanted to say to you first hand, so there wouldn't be any misunderstanding about the matter, *somebody in Hadley has got to do some heavy batting from now on.*"

When he got back to the office, J. W. sat down and thought the matter over. It was plainly apparent that he was getting all he could out of his organization under present methods. While he seriously questioned if the results expected by the management could ever be obtained, he began for the first time to consider a change in foremen.

As this idea became fixed in his mind, he left his office and started down through the shop. At every machine he passed he noticed the inevitable pile of work waiting its turn to be finished, all marked "rush." He noted that every operator was pushing his machine, both feed and speed.

"I doubt if it can be done," he said to himself as he reached the lower end of the shop. As he turned round he was attracted to a big boring mill over at his right which was being operated by a tall, broad shouldered young man of perhaps 25 years of age. J. W. instantly noticed piles of finished cylinder packing rings close at hand, and a little further away some pistons which were completed. It was the only machine he had seen so far that did not have a lot of unfinished work piled all around. He remembered too, that this was always the case with Tom Wilson's machine, and he wondered why he had never looked into it before.

"J. W." HEARS THE TRUTH

With this thought in mind he walked over near the machine and watched its operation awhile. Suddenly it struck

"If I had lost that million the company gave me for improvements here, in a good, fast game of poker, I would not have felt so bad about it as I do now."

him that for a boring mill, running as that one was, it was unusually silent. Most mills he had ever run were about the noisiest machines in the shop, especially when going at the rate this one was running. The next thing that attracted his attention was a tool the operator was using that was doing business very effectively. J. W. was interested.

"Tom," he finally said, "you certainly have the edge on the rest of the gang when it comes to turning out work. You're the only man in the shop who is not snowed under; how do you account for it? "Why, I guess there ain't any secret about it, Mr. Williams," replied Tom, as he looked around with a smile, "I simply try to use my head and spare my heels; anybody can do the same if they try."

"Some tool you have there, Tom," went on J. W. eyeing it, "where did you get hold of that? I never saw one like it before."

"Why, I got the idea from something I read, got the blacksmith foreman to make it for me and you see the result; she sure does the business;" replied Tom proudly. "Saves tool steel too," he went on, "don't use half so much as I used to since I got hold of this tool."

"How do you keep that mill so quiet?" J. W. asked, as he again noticed how still the boring mill was running.

Tom laughed. "Well sir, I thought you'd notice it after awhile. I just experimented on a little compound of my own. I read awhile ago of something that was done like that somewhere else and I just thought if I could produce a little silence instead of listening to the constant noise this machine always made, it would be a welcome change, so I went at it and you see what it does. I only use it twice a week; costs less than the old way of oiling and the comfort I have had since I began to use it can hardly be described.

Tom's replies set J. W. to thinking. He knew Tom Wilson was an energetic, observing fellow. He knew too, that he had never heard a complaint from any one about pistons or cylinder packing since Tom had been put on the job, and before that, it was nothing but complaints. Tom's evident resourcefulness prompted J. W. to sound him a little on the subject nearest his heart.

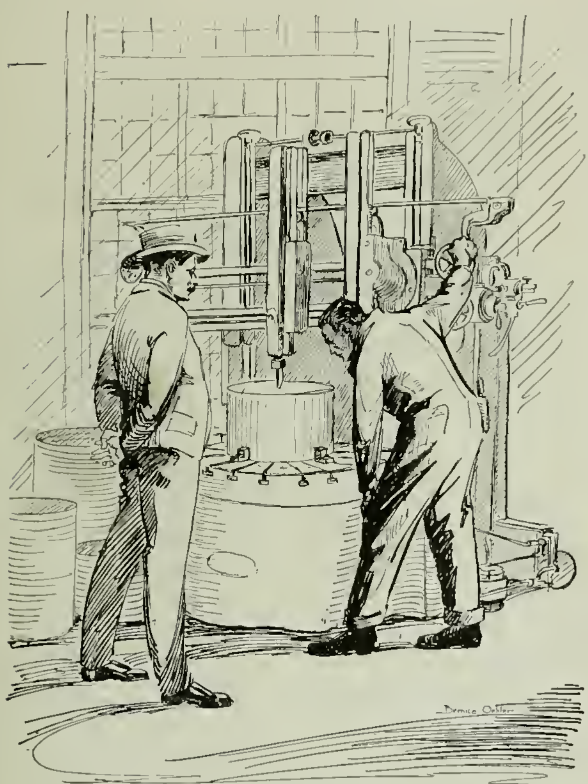
"I wish I could get the same results from other machines that I get from yours, Tom," he said. "You know we are trying to get 30 engines a month; what do you think of it?"

"Well sir," replied Tom, "I can't see why we shouldn't."

"You can't!" gasped J. W., scarcely believing he had heard Tom correctly.

"No sir," asserted Tom, "I can't see why."

"You're crazy," said J. W. when he had regained his speech. "Do you see anybody idle up through there?" pointing at the long lines of machines and their operators, all hard at work.



J. W. Walked Over Near the Machine and Watched Its Operation

Tom merely glanced in the direction indicated and said quietly, "It is not a question of anyone being idle, Mr. Williams, it is only a matter of method."

"What do you mean by that?" demanded J. W., his gorge rising at the cock-sure manner of treating a matter which had caused him more sleepless nights than anything else he could remember ever having been up against. "Do you know any better methods?"

He never did relish criticism and when it came from a man like this, only out of his time about three years—well, it didn't listen good.

"I know this," said Tom, noting his chief's rising anger, "there are many machines in this shop not operating half the time, that are considered big producers in other shops. Those grinding machines, for instance, only do certain work here, while in other shops where they've got them, they work night and day on work never attempted on them here.

"They are grinding driving and trailer axles, engine truck journals and packing rings in many shops now-a-days, and doing it quicker, more accurate and with a better finish than by the old way. There are other machines here too," went on Tom, "that are handled to better advantage elsewhere, which could help relieve the congestion here."

In spite of his anger, J. W. felt he was hearing something worth while from a man he knew to be no fool. Determined to get all he could out of Tom, he went on.

"How do you happen to know so much about what they do elsewhere, that's what I would like to know?"

"Well, sir," replied Tom, "for one thing I read. I like to keep posted on my line of business. You probably see more of the mechanical papers than I do."

"Oh yes," replied J. W., "I see enough of them, but you don't suppose I spend my time reading all the stuff they print, do you? Theory is one thing, my boy—practice is another." J. W. prided himself on being practical.

"But they are not all theory, Mr. Williams," said Tom. "For instance, a few months back I read an article on how they did their driving boxes at Sawyer on the R. L. & N. Jack Raymond is working in Sawyer. You remember Jack—worked here while I was serving my time. Well, I wrote and asked him if they were actually doing it the way the article said? He replied that they sure was."

J. W. was silent. He felt he had heard the truth, but it had come in painful doses for ready assimilation. He turned without a word and started away.

Suddenly he wheeled around to Tom again and said, "Why the devil didn't you speak to Shipley about all of this long ago?"

Tom tried to evade the question but J. W., his suspicions now aroused, insisted on a reply.

"Why, I did a couple of times, Mr. Williams," he said, "but he didn't take very kindly to it."

"What did he say?" demanded J. W. "I want to know."

"He told me I was hired to run a boring mill, that he could do all the theorizing that was necessary around here."

"He did, eh?" said the irate shop superintendent, now fully understanding Shipley's attitude at a time when he ought to have welcomed a suggestion from anybody interested enough to make one. "You shut down your machine and come to the office with me."

A NEW MACHINE SHOP FOREMAN AT HADLEY

On the way J. W. met the call boy and sent him for the general foreman and Shipley, who soon appeared at the office.

"Gentlemen," began J. W. as they were all seated, "it has come to a point where things have got to be done different around here. We've got to get out more machine work if we increase our output to thirty engines. What are you going to do about it, Shipley?"

"I have done my best," replied Fred, "and I am ready to take my hat off to the man who can get out any more work than I have already done. I can't get blood out of a stone and neither can anyone else, but I'd much rather go back on a machine and let someone else have the job for awhile, than to stand the gaff for not being able to meet somebody's unreasonable expectations; I've had all of that I want."

"Well, Fred," said J. W. after a pause, "I am going to take you at your word. Take any machine you want in the shop, and Mr. Wilson here," looking at Tom, "will take your place tomorrow morning. What do you say, Tom?"

"I'll do the best I can, Mr. Williams," said Tom, "but I would like to have you make it clear to these gentlemen that this is entirely unsolicited on my part, and something I never dreamed of."

"What he says is exactly right," said J. W., turning to Shipley and the general foreman, "I never thought of this change myself up to twenty minutes ago. I want it understood that Tom had no knowledge of this move or reason to believe he would ever be considered for the place. Further, if he don't make good he will come off the job just as suddenly as he goes on," and with this parting comment the meeting closed.

The next morning Tom took charge. The first thing he did was to get some men on the machines not regularly run, with instructions to clean them up, inspect and oil them ready for business. He then began a thorough check on work most needed by the erecting side and gave this immediate attention. Inside of a week he had re-distributed the work that was piled around the machines with the result, that in an incredibly short time machine production of required work began to increase. The grinders were kept going constantly on work formerly done on lathes, and the milling machines began to make a little money for the company, as Tom put it. In short, every machine was allotted only the work best suited to it, and each was worked to capacity.

THE SHOE BEGINS TO PINCH THE OTHER FOOT

Along with the new order of things there came a better spirit of co-operation on the machine side. Long blamed for holding up output, constantly rushed from one job to another, weeks of work always ahead of them, and never permitted a day off, no matter how hard they worked—many of the men had long since lost interest in their work and some of them had sought more congenial conditions elsewhere. After Tom Wilson had been in charge but a few days all that was changed. The big piles of waiting work had somehow disappeared. The men soon noticed too, that they were not being nagged by erecting foremen after this or that piece of work. Those gentlemen, formerly on the machine side half the time finding fault about delayed parts, suddenly seemed to have more business on the erecting side to engross their attention. The erecting gangs were having all they could do to put up the work Tom was sending over to them.

J. W. was not slow to notice the welcome change. The way he went after those foremen and the general foreman "was good for sore eyes," as old Sam Mason said. Sam, one of Tom's lathe hands, had overheard some scorching comments J. W. had made to the general foreman about "the shoe pinching the other foot now."

Tom kept after the machine work and his men were with him, for they liked the results of his new methods. They hugely enjoyed the turn affairs had taken; it was a satisfaction to see some one else the goat.

In the meantime it had become apparent that, while output for the month would reach 25 engines, the erecting side could handle no more than that. Much of the machine work for other engines laying in the shop had been done but no effort had been made to start putting it up.

"Tom," said J. W. one day, "we've got 'em going; we are going to get 25 this month. I only wish I could get another one or two."

"Why I guess we can do it, Mr. Williams," said Tom after thinking a moment.

"How can we do it, Tom?" demanded J. W.

"Why I am way ahead of the game and happen just now to have a man who says he is an old erecting foreman and I can spare him for awhile. He told me this morning that he would like to show them how to put one together, and I could give him another good man, a couple of apprentices and some helpers. I'll gamble they would get a couple more; the work is all ready for hanging, you know."

"All right," said J. W., "get those fellows lined up and see whether you can get the engines out."

That afternoon the new gang went to work. Whenever Tom could send them any more help he did it and two more locomotives were added to the month's output. The general foreman was not at all pleased with this arrangement and frequently let Tom know it.

When the end of the month arrived 27 engines had been overhauled. J. W. was jubilant. He openly gave Tom credit for all that had been accomplished and this was more than the general foreman could stand. He went to J. W. and requested a leave of absence, he was "all in" he said and needed a rest.

TOM'S METHODS GET RESULTS

J. W. told him to take as long a vacation as he wanted, secretly delighted at the turn events had taken, for he knew

"I Like to Keep Posted on My Line of Business"

Tom could do better with the general foreman's influence out of the shop. He gave Tom full charge temporarily.

Tom's first official act was to mark up 30 engines for the next month's output. His next was to divide up the erecting gangs so that more engines were covered at one time. With the general foreman gone, Tom had no difficulty in securing the best of support from everybody. By the middle of the month it was clear the 30 engines would come easy and the entire organization was as proud of the showing as J. W., who was beginning to enjoy life again.

One day toward the end of that month he sent for Tom and showed him a letter of resignation he had just received from the general foreman, who had secured another position.

"Tom," said J. W. after he had read the letter, "I'm going to appoint you to the position. The superintendent of motive power is mighty well pleased with what we are doing here now, and I want to see the same results continue."

"Thanks, Mr. Williams," Tom said, "I'll do my best."

A day or two later J. W. was down at the depot just as Number Seven pulled out. As he glanced down the long train he noticed the private car of the president on the end.

"Wonder what he thinks of our batting average now?" he mused.

With his eye following the rapidly moving car, he paused at the end of the station platform. As the car was passing him, the president, who was seated at a window, saw J. W. and started for the door.

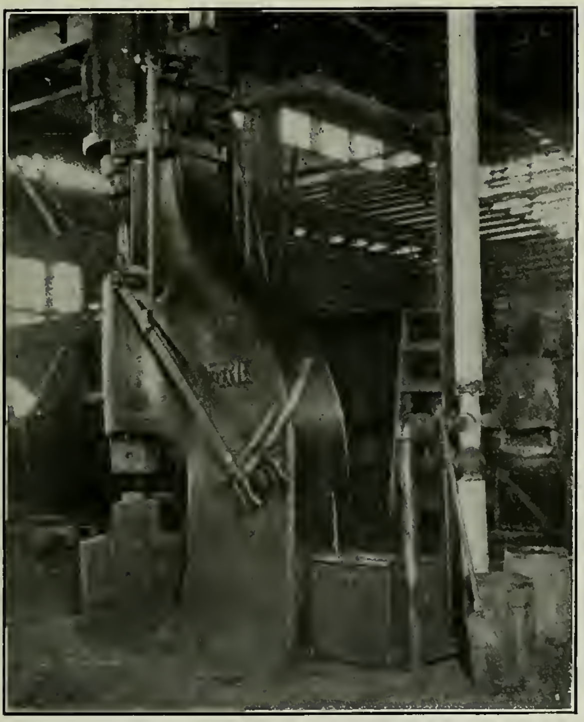
From the rear platform he called out "How's the game?"

Putting his hands to his mouth, megaphone fashion, J. W. roared back, "*Everybody batting over 300.*"

New York Central Steel Car Shop

Well-Equipped Plant at Ashtabula, Which Employs Some Unusual Methods of Forming Parts

THE INCREASE in the amount of steel car work at Ashtabula, Ohio, several years ago overtaxed the capacity of the existing facilities. To take care of this class of work a special shop was erected in 1914 on a site about one mile west of the old shops. This building is of brick, concrete and steel construction, 431 ft. 3 in. long and 243 ft. 6 in. wide. It is divided into three bays of approximately equal width. The roof has six square double monitors, 10 ft. high extending across the building, the extreme height at the gables being 51 ft. and at the sides 42 ft. Each of the two side bays has four tracks with a capacity of eight cars each, on which the repair work is done, and two standard gage material tracks. The repair tracks are spaced 18 ft. apart, except where the supply tracks run between them, in which case the distance is increased to 22 ft.



Steam Hammer Operated by Either Steam or Air

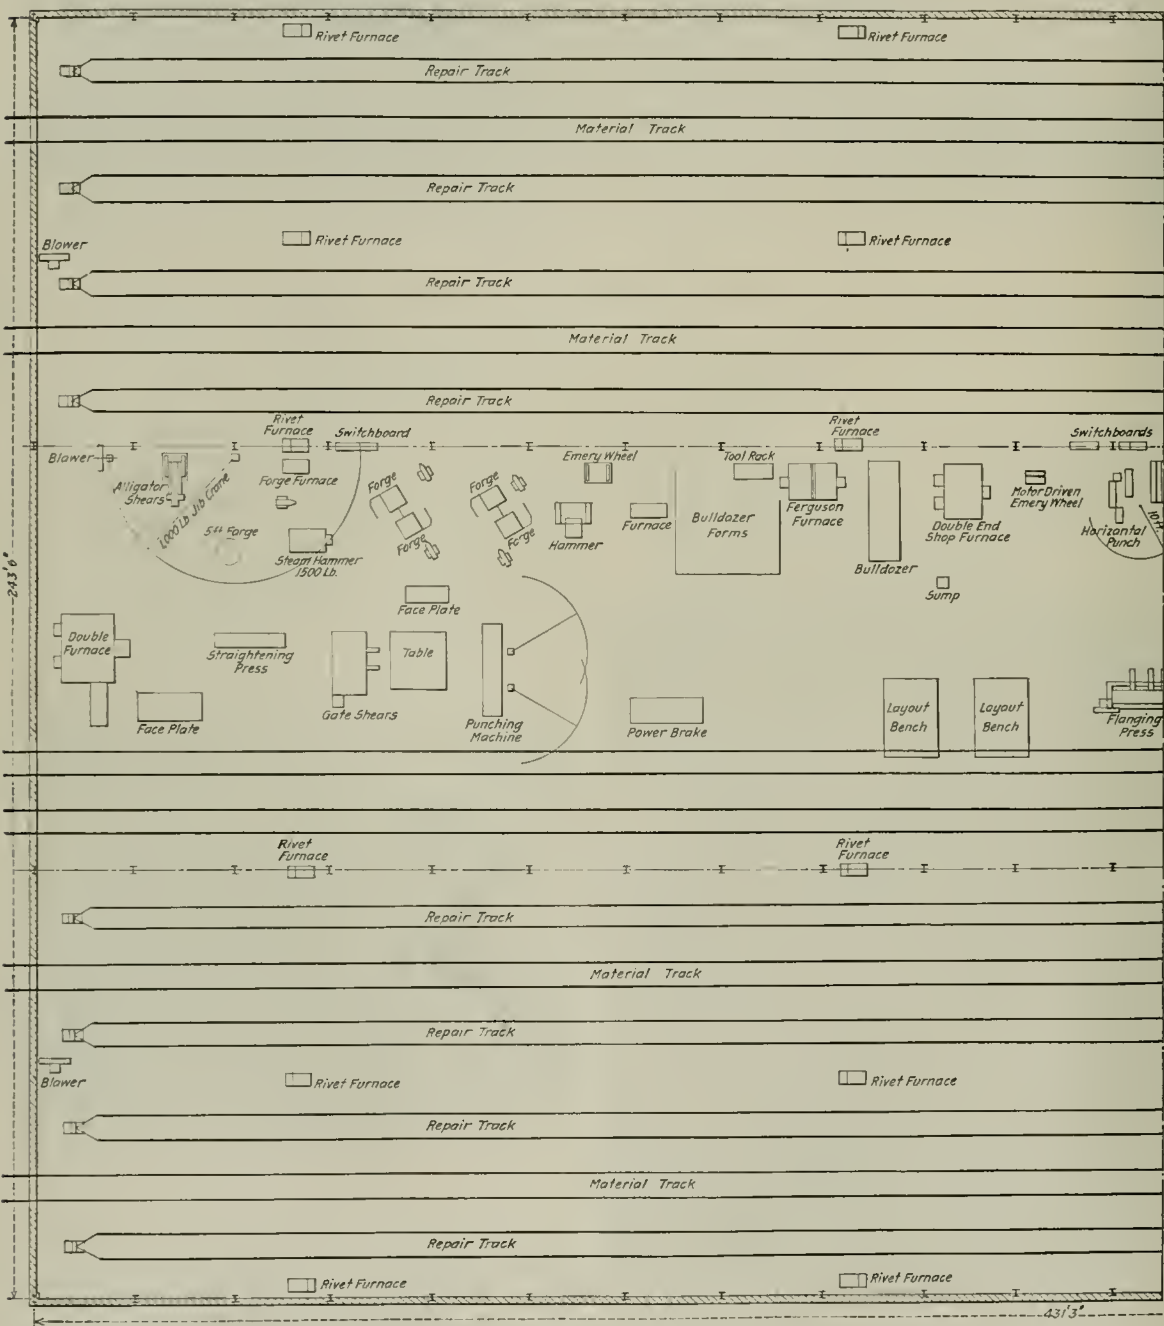
The center bay is used for straightening, fabricating and machining, all the machine tools being located in this section. A supply track extends along the east side of this bay for its entire length and a short stub track runs in at the north end. East of the main shop building are the office, store room, power house and transformer building and the air brake building.

Power for the shops is secured from a high tension power line at 13,000 volts and is transformed to 440 volts for power and 110 volts for lighting. The shops are heated from a battery of three locomotive boilers, two of 150-hp. and one of 100-hp. capacity. A vacuum return system is used, the radiating pipes being placed directly on the walls and columns. The compressed air is furnished by two Ingersoll-Rand electrically driven compressors, each having a capacity of 1,500 cu. ft. per minute. Air lines are installed along both sides and also between the center tracks in each working bay. Fuel oil is piped from the storage tanks, located adjacent to the store-house, to the plate furnaces in the center bay and to the stationary rivet furnaces located in the side bays. All the furnaces are also supplied with natural gas, which can be used in case of a shortage of fuel oil. Air for the blast is furnished by electrically driven blowers, one located in

Parts Formed on the Bulldozer

each bay. The lighting system consists of incandescent lamps in enameled steel reflectors set along the bottom of the roof trusses with connection for extension cords along the walls.

The main shop building has traveling cranes covering



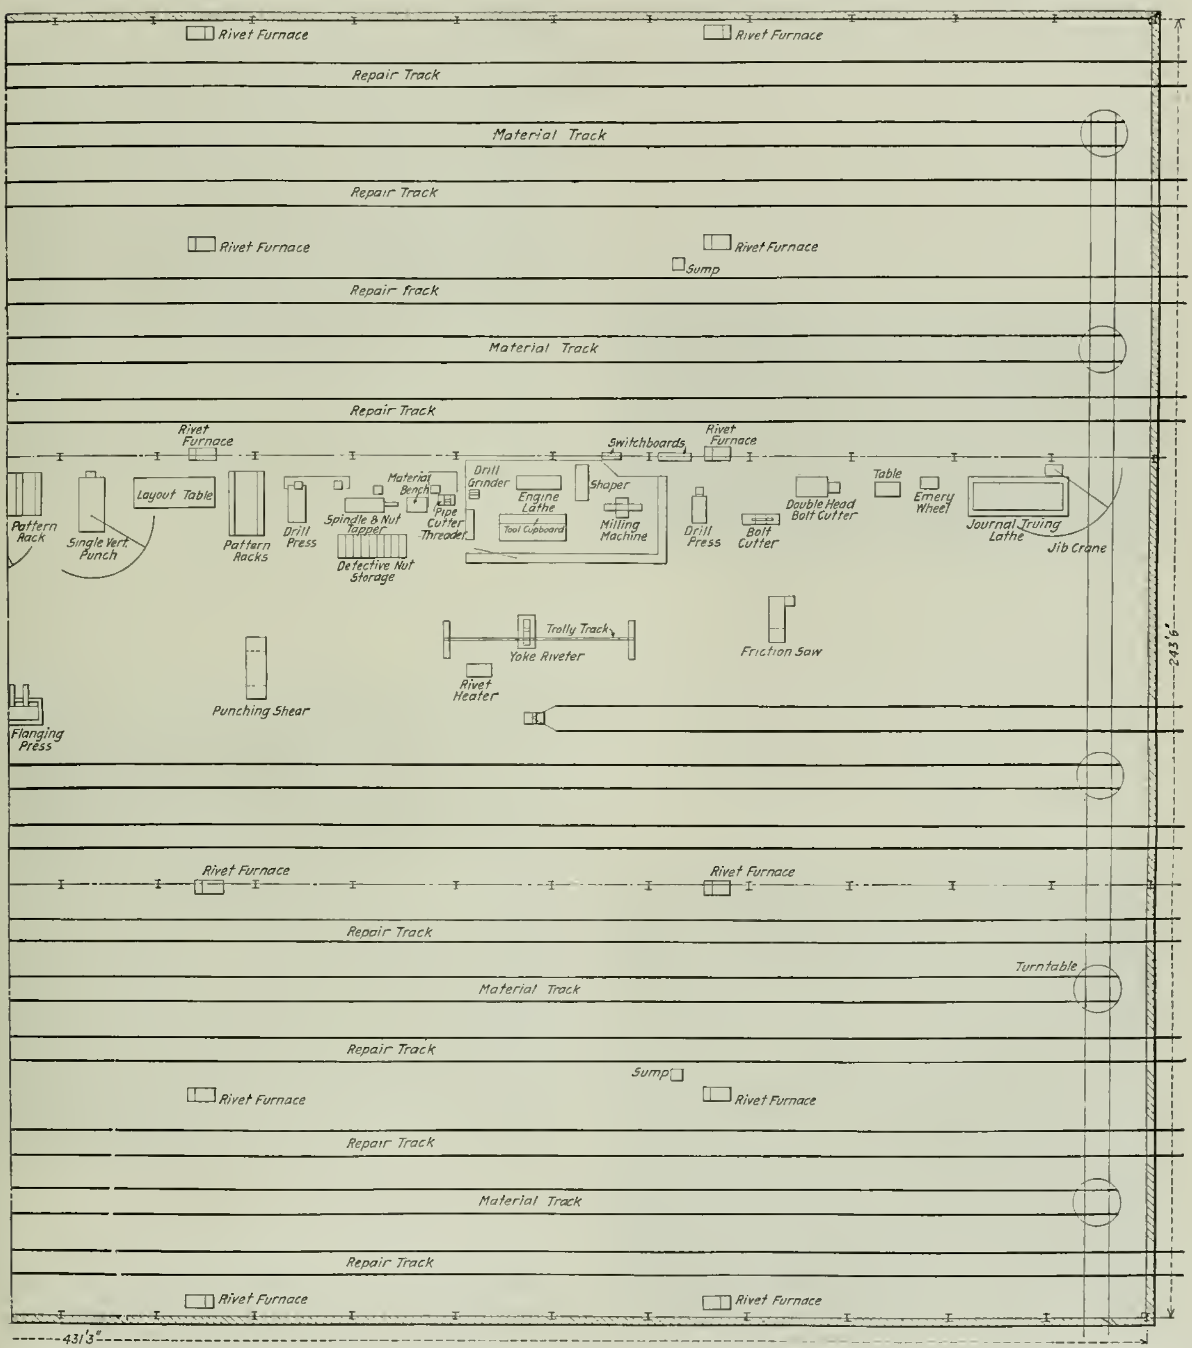
South Half of the Ashtabula Steel Car Shop

the entire floor area of all three bays. The cranes are of 20 tons capacity and run on rails 24 ft. above the floor. Further facilities for transporting material are furnished by the supply tracks which run between the repair tracks and extend on to the material platform at the south end of the shop. There are two traverse tracks crossing all the supply tracks, one on the material platform, and the other just inside the north end of the shop. Turntables are provided at the intersections of the tracks.

The track layout is such that cars enter and leave the repair tracks from the north end of the shop only. When the cars are set in the shop they are lifted by the crane while the trucks are removed and horses set under the body. The trucks ordinarily remain on the track at the end of the car while it is being overhauled, except that when wheels are to be changed or other similar work is to be done, the trucks are often set in the supply track. The forces working on dismantling and assembling are divided into gangs of six men each, three usually working on each end of a car.

The majority of the work of straightening sheet metal parts is handled at the extreme south end of the shop, where there is a double furnace 10 ft. by 12 ft. 8 in. Adjacent to this is a large face plate and a pneumatic straightening press. A large jacking stall is now being erected outside the shop to care for cars on which the parts can be straightened without being removed. Next in order along the center bay is the blacksmith department, which has five forges and anvils and two power hammers.

The heavier work in the blacksmith shop is handled on a 1,500-lb. Erie steam hammer, while for lighter operations a Bradley impact hammer is provided. A notable feature in connection with the steam hammer is the fact that it has both steam and air connections. This hammer is the only steam driven tool in the plant and it would have been necessary to keep one boiler in service at all times in order to operate it,



North Half of the Ashtabula Steel Car Shop had it not been possible to use air pressure in the summer.

A large amount of the forming work done at this shop is pressed out in a No. 8 Ajax bulldozer driven by a 20-hp. motor. Dies have been made at this shop for many of the standard sheets used in all types of steel cars owned by the New York Central Lines. These dies are of unusual construction, being built up of plates and bars riveted to the plates which form the base. While this type of die was adopted largely because it could be more readily made with the facilities available, it has numerous advantages over cast iron dies. It can be made without a pattern, it will not break and errors in machining can usually be corrected at slight expense by changing a few parts. Two of the illustrations show a typical pair of dies, together with the part which is

Built Up Dies Used on the Bulldozer

formed on them. Another illustration shows the wide range of work that is handled on the bulldozer. The parts include hopper side sheets, hopper doors, side stakes, carrier irons, striking plates and end sill corner braces. The bulldozer is also used for the class of work generally performed on these machines, such as forming coupler yokes, etc.

Alongside the blacksmith department are located some of the machines for the cold working of plates. These include a Hilles & Jones gate shear 124 in. between the housings with a 20-in. throat, having a capacity for cutting 5/8-in.

Power Brake With Capacity for Bending Half-Inch Plates, Twelve Feet Long

material, and a Cleveland vertical, double ended punch and shear with a 48-in. throat. Cold flanging is handled on a Chicago power brake with a 12-ft. by 6-ft. table. This machine is driven by a 25-hp. motor and will bend a 1/2-in. plate 12 ft. 1 in. long. When working on parts made in quantities it can be set to bend any desired angle, which will be automatically duplicated until the machine is reset. For other flanging work there is a 200-ton hydraulic press built in the railroad company's shops.

Two large layout benches are provided near the flanging

Built Up Bulldozer Dies and Hopper Side Sheet Formed by Them

press. The laying out on the majority of plates for system cars is done with templets made of sheet metal. Wooden templets are often used on work of this nature because of the ease with which they can be made. The use of wooden templets was not considered advisable at this shop because of the excessive amount of space required for the storage of a large number of templets and also on account of the possibility of inaccuracies due to warping and shrinking. The metal templets are cut away wherever possible in order to decrease the weight. In this form they are easy to handle and experience indicates that, due to their longer life, they are

Sheet Metal Templets for Laying Out Parts of Steel Cars

more economical than templets made of wood, even though the first cost is higher.

For punching partly or wholly completed sheets a horizontal and a vertical punch are provided near the center of the shop. Large plates and angles are handled on an Oeking combination punch and shear, which will split plates of any length and width and will shear angles up to 3/4 in. by 6 in. by 6 in. and bars up to 2 1/8 in. square. Large structural steel shapes are cut on a Ryerson No. 2 friction saw with a capacity for cutting 15-in. I-beams, up to 60 lb. per ft.

Parts which can be assembled before erection are handled with a Hanna pneumatic riveter especially arranged for this work. The machine which has a 20-in. gap and a 24-in.

throat is mounted upright on a stake. A chain hoist runs on a trolley track directly above the riveter so that parts after being assembled can be slung from the hoist to facilitate the riveting operation.

The tool room is located in the north end of the shop. It provides a supply of pneumatic and hand tools and makes the special appliances used around the shops. The machine tool equipment consists of a 24-in. heavy duty shaper, a Lodge & Shipley 8-in. engine lathe and a Kearney & Trecker No. 2-B Universal milling machine. Beside the tool is located equipment for reclaiming miscellaneous small material. The small scrap collected around the shop amounts to about 20 tons a month. From this material the bolts that

Machine Used for Truing Journals by Grinding

are fit for rethreading and nuts that can be retapped are sorted out and returned to the shop where they are reclaimed and again placed in stock.

The truing of cut journals is handled at this shop on a special machine built in the railroad company's shops, on which the journals are ground instead of turned. The illustration shows the general arrangement of this machine. The wheels and axles are swung on centers and are driven by a dog attached to one journal. At the other end of the machine there is a tool post which carries a grinding wheel driven by a belt from an overhead countershaft. The wheel can be traversed back and forth along the journal until it is ground truly cylindrical. Because of the fact that no water is used while grinding the journal is polished by the use of emery paper. This device makes it possible to true journals with the minimum reduction in diameter. It is being installed at all the principal car repair shops on the New York Central Lines.

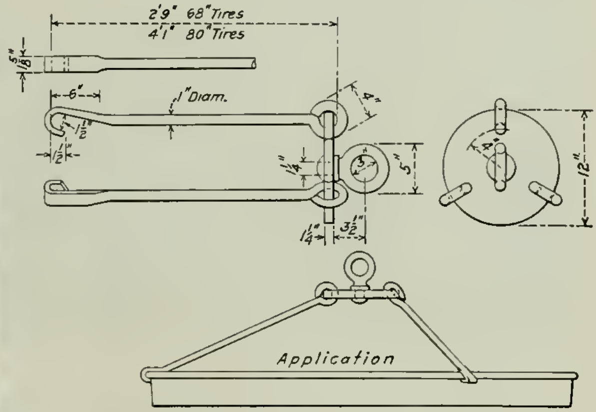
TIRE LIFTING DEVICES

BY E. A. M.

Crane attachments for lifting plain and flanged locomotive tires as illustrated in the drawings have proved very useful.

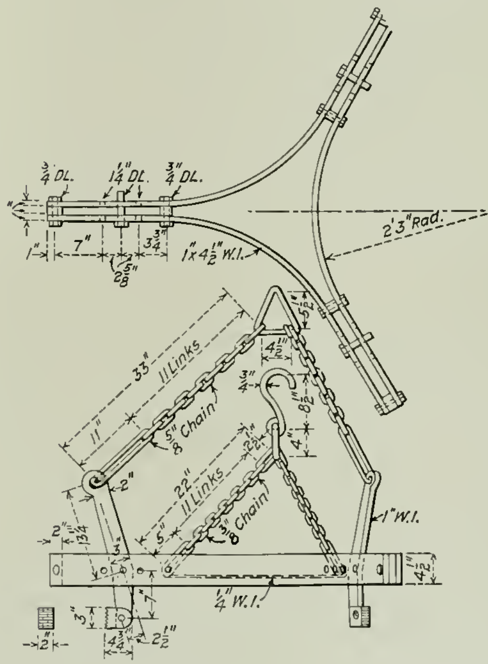
The device for lifting plain tires is made of three pieces of 1-in. by 4½-in. wrought iron bar bent to a radius of 2 ft. 3-in. and bolted together by ¾-in. bolts, as shown in the drawing, with a spacing block between the bars to provide space for a lever near each of the three ends. These levers are of 1-in. wrought iron, three inches wide at the center, where the pin is inserted, and two inches wide at the ends. On the lower end of each level a steel jaw with teeth cut in it engages the tire while lifting it, the weight of the tire tending to tighten the grip of the jaws. On the upper end of each lever is a link and a ⅝-in. chain connecting the levers to a triangular link in which the crane hook is inserted. Three holes in each arm of the device, where the levers can be placed and the pins inserted, provide a means of adjustment to accommodate tires of different diameters. The small ⅜-in. chain is only for the purpose of carrying the device from place to place as it may be needed, the ⅝-in. chain being used for lifting.

The other device for lifting flanged tires consists of a plate 1¼ in. thick and 12 in. in diameter with three 1 1/16-



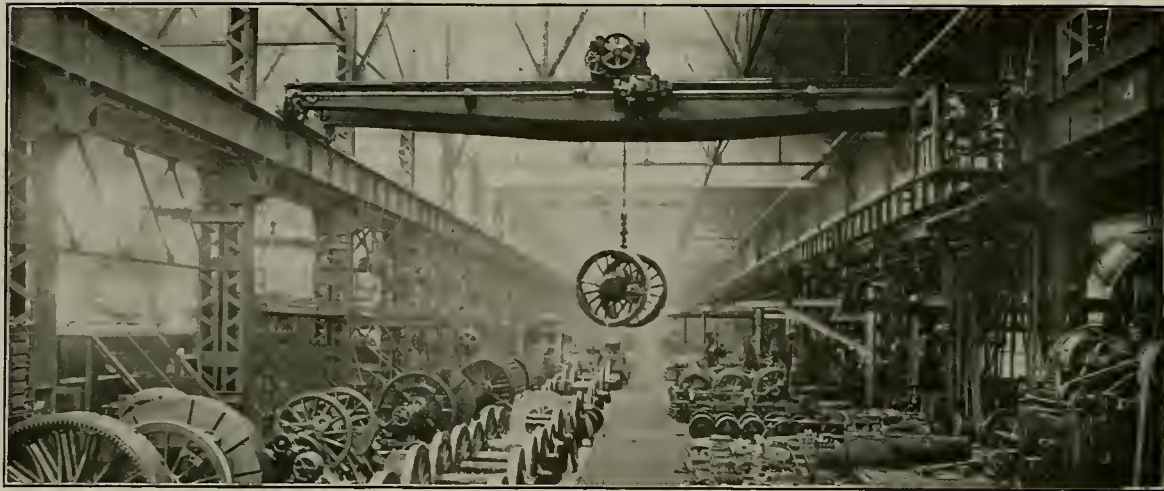
Lifting Device for Flanged Tires

in. holes drilled in a 8-in. circle and a 1-in. diameter rod with a hook on the lower end placed through each of the three holes with the eye bent over as shown in the drawing. An eyebolt of 1-in. round material is inserted through a hole in the center of the plate and riveted over on the under side, thus providing an attachment to the crane hook. The



Lifting Device for Plain Tires

three rods which engage the flange of the tire may be made in any desired length to accommodate a number of different sizes. By making the various parts to a close and accurate fit the hooks cannot slide and provide a safe method of handling locomotive tires.



C. P. R. Machine Shop, Angus (Montreal).

C. P. R. Shop Production Methods

Schedule and Follow-Up System which Is Part of, Not Separate From, the Producing Organization

BY E. T. SPIDY
Production Engineer, Canadian Pacific, Montreal, Quebec

PRODUCTION methods are the ways and means by which we get output whether it be locomotive repairs or new locomotives, coach repairs or new coaches, freight cars or anything else that constitutes a manufactured product.

Two methods which have generally been used with more or less success, according to the manner in which they have been employed, may be enumerated as controlling factors in getting a satisfactory output. The first and oldest is to have a piecework or other system that provides an incentive to the operator by making his earnings dependent on the amount of work done. The second, which may be said to be of latei origin, is to lay out for each plant, shop, department and, if necessary, each workman, its day's work and to make possible the accomplishment of the task assigned by routing the work, tooling the shop machinery and taking measures to overcome all the factors that militate against the desired end.

The developments of the last few months with regard to piecework have created in most railway shops a condition which throws the onus of production entirely upon the management. If the managements do not have any other means or aid to maintain output than the regular supervision, then undoubtedly they are going to be hard put to it to maintain anything like their previous records.

Leaving the dead alone, however, the writer will confine himself in this article to the second class of aids to production, i. e., the setting of the day's work for each department and the means whereby each item may be followed up and completed on time, at the same time not interfering with the foreman's authority in each section.

The fact that the foreman's authority need not be interfered with is mentioned purposely. There are shop managers who will say that "we found it impracticable to run a schedule and have thrown it out long ago." No doubt this has been done and the reason is obvious enough when looked for. With these shops, the writer will willingly agree that it is impracticable to put into the hands of a set of clerks the running of an absolute schedule and to expect them to get results. *It is absolutely impracticable to get any results from any system unless all the foremen are convinced that the principle behind it is right and that they themselves, each in his own department, are the men who are running it and backing it.*

This all may be summarized by saying that co-operative

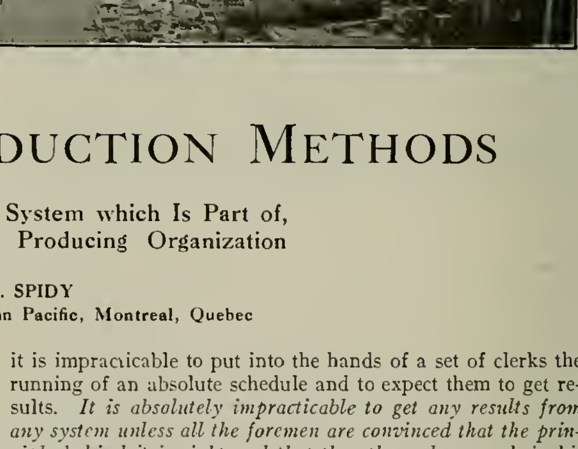


Fig. 1—How the Production Department Ties Into the Shop Organization

effort is necessary. Now the principle that actuates a successful production, planning or schedule department is just this: The production department is simply a specialized group of men who, at the direction of the management, spread over the month at as regular intervals as practicable the output as required by road conditions so that each departmental foreman receives each week or day one sheet which tells him exactly *what* he is required to deliver finished and *when* the delivery is required. It is obvious that such a group under proper direction must have more information regarding delivery of materials from the supply sources, more information as to whether drawings are available, as to patterns, as to delays in other shops, etc., than any one foreman possibly can have, and that it can advise the management intelligently regarding the causes of delays far better than the individual boss who is only in touch with his own immediate situation. Shown diagrammatically, the plant with a production department operates as shown in Fig. 1.

There may be 40 departments, all of which require information from the supply side of the diagram. Without a production department how is this information secured? We all know what happens. Each foreman or sub-foreman or workman simply hikes to the other department and gets whatever information he can, personally. When he gets it, he tells the boss and the boss most likely verifies it in some other way and then does something.

Comparing this with the production department method, what do we find? The production department knows what is wanted by each department and has a date when raw material should be in stock by the stores. They check this, in many cases weeks before the material is due in the shops and consequently are able to report to the management future delays they see that look to be unavoidable unless immediate action is taken. In other words, they report delays in time for them to be prevented, or when they cannot be prevented, in time for a change in program to be effected without loss of output.

It is not to be presumed that delays do not occur under this arrangement, but they certainly are very much reduced. The very nature of engine repairs is such that much information is not available just when it is needed, especially regarding defects which are revealed after stripping down. Such situations must be handled as they come.

The principle having been outlined, a word is necessary to show how the production department is synchronized as a living part of the organization and not an outside unit, as the diagram makes it look.

The man who sets the master schedule, who designates the actual engine numbers of all engines that are to constitute the shop output, must be the general shop foreman. In practice the superintendent, perhaps in conference with others, actually sets the schedule, but it is essential that the shop foreman be in on the layout so that he feels that it is his schedule and not that of a clerk on whom the blame for failure may carelessly be thrown.

In a shop where the planning department had been dropped, the following observation was once made to me: "It's all very well to have a schedule, but the schedule does not get the work." No schedule gets the work out if the foreman does not co-operate with those controlling it by making known the reasons for delays or failures to comply with the requirements of the schedule. A co-operative schedule does not advise the superior officer of delays in order to bring censure on a department, but with the idea of helping out by supplying more men, more machines or by redistributing work that is accumulating in one place so that the final completion dates may be met. When a schedule department tries to run independently of the shop, then it fails because it "does not get the work." When it operates in conjunction with the shop or when it is run, as advocated by the writer, "by the shop," then it succeeds because it is simply a concerted effort to attain a single aim.

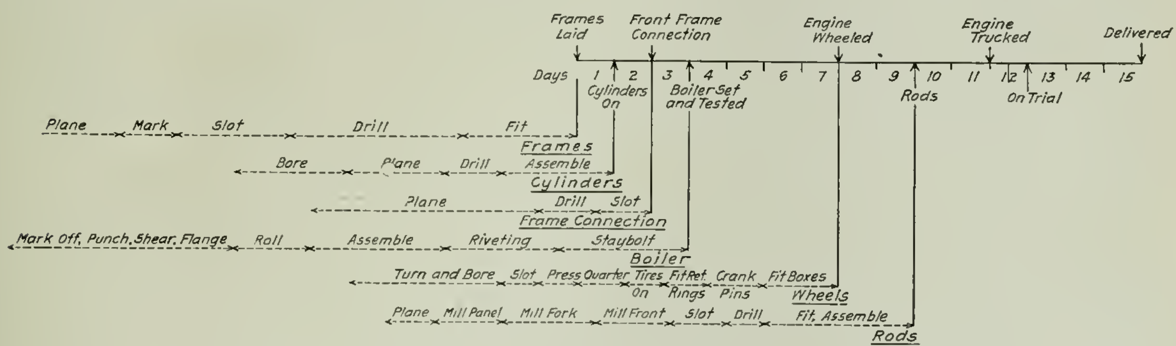
The following is a description of the Canadian Pacific production department methods as they are at present applied at the Angus Shops, Montreal. The methods of taking care of new work will first be followed, after which the same principle as applied to the repair work will be taken up.

For the purpose of this description the Locomotive Department only will be considered, the output being new and repaired locomotives, although it should be understood that the principles apply to all classes of output in all shops.

ROUTING AN ORDER OF NEW ENGINES

We will assume an order is placed to build a number of engines of a certain class and the management desire them completed by a certain date determined from past experience, a general survey of conditions and the known capacity of the shop. After the first one is delivered the balance is required, say, at the rate of four engines per month.

In all cases the first engine is desired as early as possible. In order to determine the best possible date of delivery of this first engine it must be found out which parts will take the longest time to deliver to the erecting floor and which parts have the most machining on them, since the delivery date can only be accurately computed when these larger items are scheduled. A list must be made up of all the large items: frames, boiler, cylinders, etc. Opposite each item on this list all the operations that have to be done on it are entered. Next the time each operation will take must be estimated. Adding up the time required by all the operations gives us the total machining or operation hours for each piece. To this time must be added an allowance of about five hours for each succeeding operation to take care of delays due to movement of material and awaiting attention at the next operation. It is evident that there must be some overlap at each machine to avoid constant delays while waiting for work. These times all totalled and divided by the number of available



This illustrates the method only and is not to correct scale

Completed Work by Extending the Heavy Lines

working hours per day give the number of days required for machining. In the case of castings the line-up must begin with the delivery of drawings to the patternmaker, time to make the patterns, time to cast, time to deliver and then all shop operations up to the delivery on the erecting shop floor. In cases where material, such, for instance, as plates for

boilers, is not in stock an allowance of the time required to secure delivery must also be included; obviously it is futile to set a scheduled date and expect to live up to it unless this provision is made. Purchased finished material must also be taken into account because the engine cannot be delivered minus any part.

Having determined the date of delivery of the frames,

boiler and other large parts, eight days are added for erection up to the wheeling date and, say seven days more, which gives a final delivery date. Thus a final delivery date is arrived at on the basis of which a complete schedule for everyone to work to is built up, onto which all the various de-

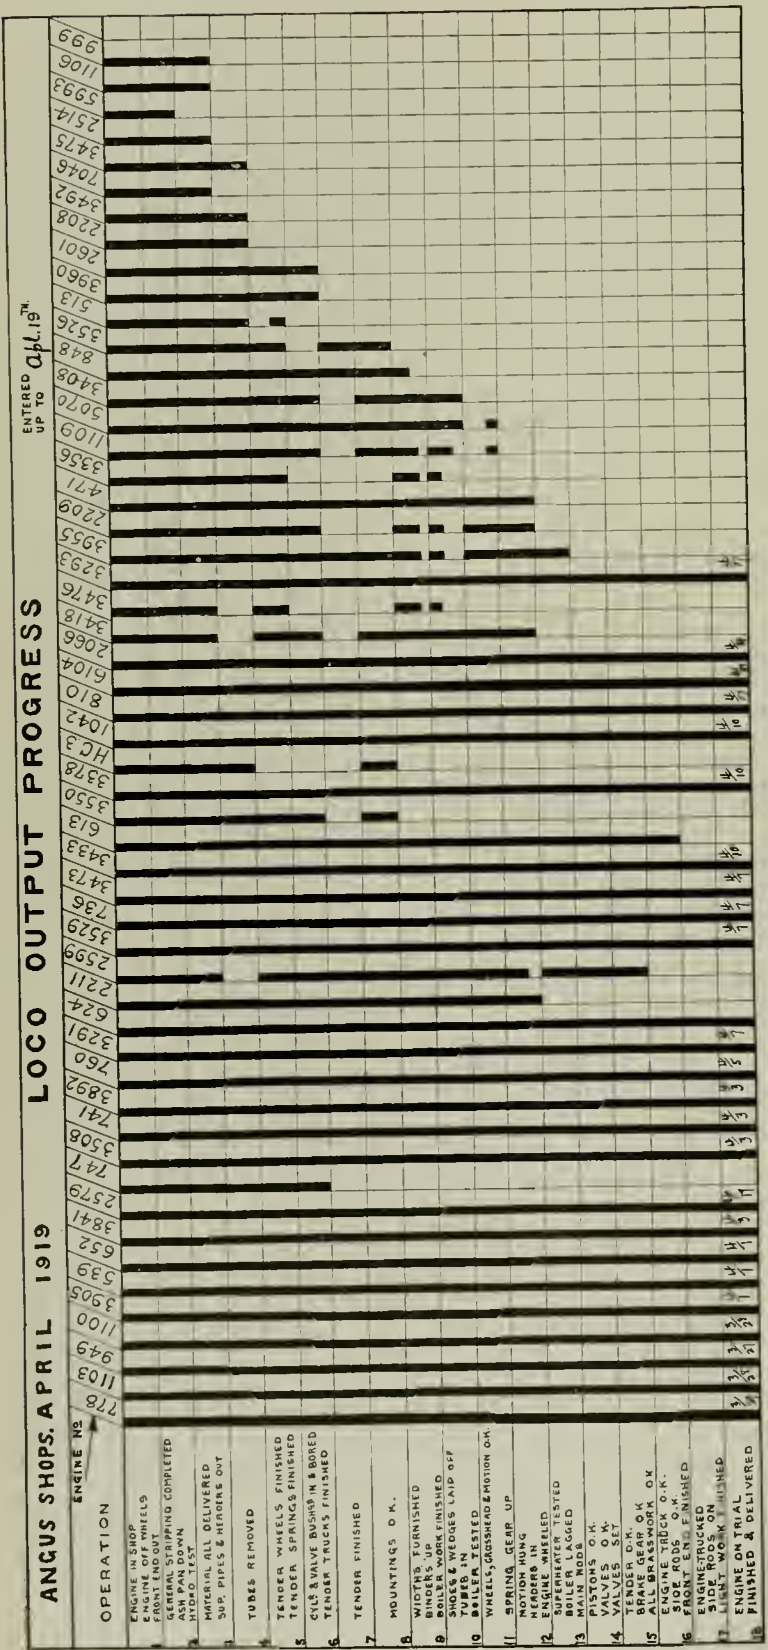

Fig. 6—A Graphical Presentation of the Progress of Engines Through the Shop

tails can be added showing the required delivery dates from all departments.

To determine the dates to be marked on the master schedule, the writer uses a graphic method which is simple and less liable to error than plain tabulation. Fig. 2 is a sample of such a computation, which is made on section paper, hours being shown on the horizontal scale. Starting with the last operation in each group, at the point when it is required to be delivered to the erecting floor and working backwards, all items are entered to scale. The final result in hours is easily converted to days, and actual dates entered on the master schedule. From this all the different shop foremen and chargehands are given details of finishing dates for the different operations and parts.

Our practice is then to take one of our standard schedule forms, Fig. 3, which are 24 in. by 22 in., and list all parts down the left-hand side. Along the top are inserted the dates of all working days and in the squares corresponding to the correct delivery dates for each part the engine numbers are entered. Having determined the proper date for the first engine, as illustrated in Fig. 2, it is a simple matter to insert the numbers for successive engines at regular intervals of six days or whatever is necessary to show their respective delivery date.

We thus build up a master schedule which is the foundation of the system and is also of much value to the shop managers to show them just how each engine stands. As each part is delivered a production department man crosses out the items by extending the thick black lines in each case, thus giving a graphic and plain representation of the situation and incidentally emphasizing items not on time for his personal investigation.

At the Angus Shops engine repairs as well as new engines are being handled and in order to condense the instructions both new and repair engine dates are included on the same sheet. The object is to give each shop foreman but one order-of-work sheet covering the work of his department.

According to the nature of the work in each department, either weekly or daily order-of-work sheets are issued, samples of which are shown in Figs. 4, 5 and 7. These sheets go to the foreman actually directing the workmen, and are copies of that part of the master schedule which concerns each particular foreman for the day or week, as the case may be. It is the duty of the production department men to check over every shop every day with the foreman to determine whether all work scheduled is completed or whether and why it is delayed. On his return to the office the production department man marks up the master schedule and then issues the next day's sheets. These are always issued before quitting time in the evening so that foremen can lay out their work ready for the next day.

The first line of each order-of-work sheet is labelled "Still due" and represents work that was due but not delivered on time. A summary from all sheets of the work which is late is given every day to general shop foremen and the shop superintendent for their personal attention. It is thus seen that the whole work is covered by a checking system that releases the foremen and management generally, from a chore which previously occupied a considerable portion of everybody's time, giving more time for taking care of shop difficulties, of which there are always plenty.

Routing Repair Engines

For routing engine repairs a master schedule form slightly different from that for new engines is used. The difference

Fig. 7—Daily Order-of-Work Sheet for Stripping Operations

is, however, only in the form, because of the number of engines to be carried. A line is provided for each part or section of the work scheduled and working dates are carried across the tops, as in Fig. 3. One month only is carried on the repair schedule, whereas over two months are represented on the new engine schedule, each form having been found to be the convenient size to cover the conditions to be taken into account in each case.

As each engine arrives at the shop an inspection is made for missing and broken parts, report of which is checked up with the road report of repairs to be made. From these the general foreman with the chief scheduleman of the production department, decide how many days in the shop are to be allotted to the repairs. The scheduleman then proceeds to apply a ten, fifteen, eighteen, etc., day standard schedule to the engine, adding in where necessary an allowance for such specific repairs as broken frames, new cylinders or heavy boiler work. After this the engine number is entered on the master schedule under the correct date for each operation and then included on the daily order-of-work sheet as they come due.

All acquainted with engine repair work know that there are delays due to unforeseen boiler work or unreported defects that are not discovered until after stripping, which necessitate setting back some dates and advancing others as the work progresses. This condition is taken care of by the production department by issuing the form shown in Fig. 8, to those concerned. It is not issued to such departments as are able to get ahead on their work without interfering with the general program. It is good policy not to change any schedule unless absolutely necessary. If a department can handle its work on the original layout, it is better to let them do so, even if the work is not needed on the date scheduled. This policy reduces shop costs because foremen do not have to break in on work that may be started to give preference to something else.

Since the primary object of the production department is to reduce the time and cost of the work, delays and their causes are of great interest to us. The direct effect of routing work is to reduce the time between jobs, and this is especially important in that it increases the capacity of the shop without additional pit space.

A production system of this kind is very much comparable to the recording gages in a power plant. The sheets show clear all the time the work comes through on time, but if a department for any reason gets out of order, just as the gages

in the power house show trouble, so will the record of "lates" show it in the shop and continue to do so until the trouble is rectified. This, of course, is exactly what is aimed at.

A weekly progress sheet is shown in Fig. 9. This is issued to all general foremen and piece-work foremen as a means of general information to those not getting detail order-of-work sheets. It gives the engine number, class of repair, date in shop and date scheduled out, of every engine being worked on in shop. This information thoroughly posts all concerned on the general shop standing. One file of these sheets, with all engine reports, is kept in the general foreman's office, where the master schedule board is also located, so that all can see them and watch the shop progress insofar as it concerns them. By making all production department information and data available in this way, every foreman becomes conversant with how it all is developed and consequently has confidence in it. This confidence begets results.

The method of making up and checking the order-of-work sheets has been described, but a little further information may be of interest. Fig. 4 shows a machine shop sheet covering deliveries of guide bars, motions, valves, bell stands, main rods and side rods. In this department, as on other work of similar character, is shown all principal work due for a week. In this case the work of more than one chargehand is shown on the sheet; this is simply to economize on the typing which comes in a rush at the end of each day. On Fig. 5 it will be noted that four engines show on the "Still due" line, and naturally get first attention. Fig. 7 is one of the daily operation sheets which is issued to the stripping gang bosses. Here it is seen that the exact operations to be performed are enumerated, and it can readily be appreciated that when a department which is falling down gets a sheet of this kind the information is of the real helping-hand nature because the planning is already done. In our case the stripping of engines now takes just 50 per cent of the time it did three months ago, a result which has been accomplished simply by distributing the gang according to the daily order-of-work sheets.

Another chart of interest to the shop management is the graphical representation of engine progress. Fig. 6 contains along the top all the engines in the shop in the order in which they came in. On the left is listed in 54 items the principal work in the order in which it is to be done on a general repair. As each item is completed the black line is extended downward towards the bottom horizontal line, which represents completion of the engine. This chart is also used as a check on output, but principally as a check on costs. It instantly gives a line-up on the engine progress, which is compared with a corresponding line on another chart which represents the cost to date.

It is equally as important to keep a check on engine costs as on output. As soon as practicable after the receipt of complete information as to what has to be done on an engine, an estimate of the cost is prepared. This estimate is based on the average cost of the individual class for the past year plus additions for all specific repairs that are known. This total cost is apportioned to the different shops according to the amount of work each has to do, and the whole is graphically plotted daily on a c[illegible] similar to Fig. 3, except that the allowance is indicate[illegible] l mark to which the heavy black line of actual cost [illegible] proaches. From this chart, together with Fig. 9, en[illegible] which the cost is running high quickly can be pick[illegible] d the reason learned before it is too late. Often it is [illegible] at high costs are due to poor distribution of labor in some particular department, which is brought to the notice of the proper party for rectification.

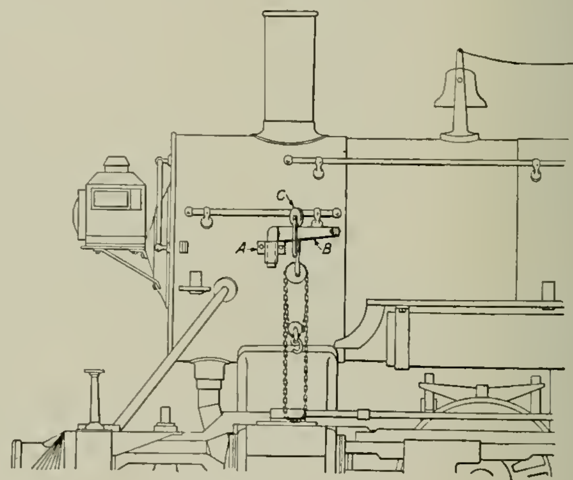
Fig. 9—Weekly Progress Sheet Issued to General Foremen, Who Do Not Receive Detail Order-of-Work Sheets

In common with all other roads, war-time conditions took away a lot of skilled men who knew the back shop practices and brought into our shops a lot of unskilled railway mechanics. But the management is still responsible for getting the output at the right cost. The methods here outlined are in principle the same as laid down at Angus shops by H. L. Gantt several years ago, simply modified to give desired results with minimum expense as present conditions and common sense dictate.

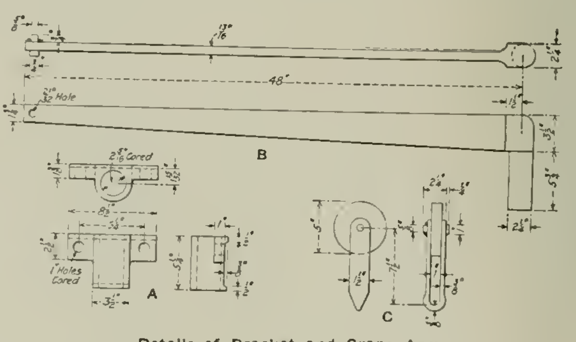
A LIGHT CRANE FOR FRONT END WORK

To facilitate the handling of valves, steam chests, guides and other parts at the front end of locomotives a light capacity crane has been devised in the Duluth & Iron Range shops which is giving very satisfactory service.



Crane Attached to a Locomotive

A cast steel bracket *A* is fastened permanently on each side of the smokebox of all engines. This bracket has a socket to receive one end of a forged steel crane arm *B* fitted with a trolley *C* to which a chain hoist is attached. Two



Details of Bracket and Crane Arm

of these cranes are kept in the main roundhouse and one at each outside point where repairing is done.

This crane may also be used for any other light work in the roundhouse or shop by placing the brackets *A* in convenient places such as at presses, for handling crank pins and driving box brasses.

Meeting of the Fuel Association

Fuel Conservation Problem Discussed by a Large Attendance at the Eleventh Annual Convention

The International Railway Fuel Association held its eleventh annual meeting May 18 to 22 at the Hotel Sherman, Chicago.

ADDRESS OF PRESIDENT PYLE

Mr. Pyle in his opening address made a plea for economy in fuel, speaking in part as follows: Those who have not had a practical working knowledge of the conditions under which the railroads labored during the past year have no conception of the task which has confronted all connected with the movement of transportation. The railroads have

L. R. Pyle (M. St. P. & S. S. M.)

H. B. MacFarland (A. T. & S. F.)
Vice-President

J. G. Crawford (C. B. & Q.)
Secretary-Treasurer

been the backbone of our war preparation and without them we would have failed miserably.

They will also be the backbone of our country during the reconstruction period, and it behooves every man connected with the American railroads seriously to consider just what part he is to perform. We will be called upon to do things which at first glance appear almost impossible of accomplishment, not because what we will be asked to do is impracticable but because of the difficulty of getting others to put these things into practice. If we are the men for the job we must get results and this will be the measure of our ability as railroad men. Regardless of who operates the railroads during the coming year this fact is clear and unequivocal. It will be necessary to produce better transportation facilities, both freight and passenger, at a lower cost than ever before. Wages and cost of supplies entering into the operation and construction of a railroad are higher than ever before. To offset this we must eliminate waste.

There is a wide field for discussion as to how economy can be realized on the locomotive, in the roundhouse or stationary plant, by the transportation man in more efficient methods of train handling, by the mechanical man through better maintenance of locomotives and cars, by the maintenance-of-way man through better track conditions and fewer slow orders, or by the car and air brake man in maintaining the air brake system and so taking care of lubrication to eliminate hot boxes, or by the yardmaster in making up trains efficiently.

The results obtained through effecting economies in fuel are far-reaching and assist in speeding up the movement of transportation, which, in turn, effects other economies. Everything done to save coal has a beneficial effect on all other angles of railroad operation. Even now operating officials do not fully realize the tremendous opportunity for a material reduction in the cost of transportation by specializing on the second largest item of expense on a railroad, namely, that of fuel.

Although some roads have and are eliminating fuel waste through systematic efforts, we have as yet barely scratched the surface. To get the real reduction in cost that is possible and absolutely necessary a more practical interest has to be shown by general operating officials and a closer co-operation must exist between the heads of the different departments. This does not mean that there is no co-operation between the heads of the different departments, but to continue fuel conservation in a haphazard manner the maximum economy can never be attained.

A fundamental principle of fuel conservation is co-operation, as even the slightest error in one department often disturbs the entire organization. A chain is no stronger than its weakest link, and a federal manager can have ever so good a fuel organization, but if a superintendent fails to co-operate fully there is a break in the chain and the railroad suffers. It is not so much individual effort that is needed as a practical give-and-take co-operation from the chief operating official to the smallest individual on a road.

Hale Holden, regional director of the Central Western region, was to have delivered an address, but was unable to attend. W. B. Storey, federal manager of the Atchison, Topeka & Santa Fe, spoke, in part, as follows:

We who are handling the railroads are vitally interested in saving fuel. We must save fuel in order to get back to normal conditions. On the Atchison, Topeka & Santa Fe the fuel bill for engines alone was one-third of the total transportation expenses and one-seventh of the total operating expenses during 1918.

There are many difficult phases to the problem. If we could make fuel economy the prime consideration, the matter would be greatly simplified, but service to the public must receive the first attention. Another serious phase is the labor situation which we must handle differently from what we did in the past. We must get these problems before the men as matters that concern them and the railroads with which they are connected.

ADDRESS OF FRANK McMANAMY

The position of the Railroad Administration is in many ways analogous to that of a tenant, the landlord being represented by the corporate interests. The landlord whose rental is fixed hesitates to make improvements which do not have the effect of increasing his revenue regardless of the saving they may effect for the tenant; for that reason it is necessary for us to do our best to make savings with the equipment, facilities and the organization we have.

It is comparatively easy to make a substantial saving in the cost of locomotive fuel by wholesale application of recognized fuel saving devices. However, the application of these devices involves charges to capital which must be borne by the railroad corporations and the acceptance of these charges by the corporation is not always easily obtained. But if we can not install those improvements which will effect fuel economy, there is no reason why we should not maintain in thoroughly good condition those devices with which locomotives are equipped, nor any reason why we should not make every effort to save fuel by eliminating waste of steam and water.

Conservation of fuel from the Railroad Administration standpoint requires careful supervision by the Fuel Conservation Section and close co-operation on the part of practically every department in the Railroad Administration, and in this the International Railway Fuel Association can be especially helpful. Fuel economy is not, as a rule, accomplished by saving one huge sum, but the huge sum which it is possible to save is made up of the accumulated results of many small items. We gain nothing from conventions unless we make use of the knowledge obtained. It is easy to attend a convention of this kind, and by discussion bring out some most valuable points in connection with conservation of fuel, but it requires real courage and perseverance to go back home and consistently practice what we preach.

Conservation of fuel is one of the important matters before the Railroad Administration during the period of government control, and will be no less important when that period has passed. It is the desire of the administration to have the sympathetic co-operation of the International Railway Fuel Association and all of its members as individuals in effecting the conservation of fuel. The administration desires to co-operate with the members of the Fuel Association in the purchase, inspection, weighing, distribution, handling and accounting for fuel, as well as in its economical use to bring about the greatest possible saving.

The administration will aid in every possible way and will be helpful in every way that a central organization can be under the present method of operation, but if we are to be successful we must have teamwork in getting the very best we can out of what we have.

OTHER BUSINESS

A report on Front Ends, Grates and Ash Pans was signed by H. B. MacFarland (A., T. & S. F.), chairman; W. J. Bohan (N. P.), E. B. DeVilbiss (Penn. Lines), J. P. Neff (Am. Arch. Co.), and Frank Zeleny (C., B. & Q.).

A report on Pulverized Fuel was signed by W. J. Bohan (N. P.), chairman; H. T. Bentley (C. & N. W.), H. B. Brown (L. V.), R. R. Hibben (M., K. & T.), D. R. MacBain (N. Y. C.), J. H. Manning (D. & H.), H. C. Oviatt (N. Y., N. H. & H.), John Purcell (A. T. & S. F.) and L. R. Pyle (U. S. R. A.).

Other papers submitted were: Teamwork of Enginemen and Firemen; Locomotive Fuel Losses at Terminals; What Can a General Operating Officer Do to Promote Fuel Economy? Certain Essentials; Dirt in Coal; Equated Tonnage and Its Relation to Fuel Consumption; Lame Engines and Their Effect on Fuel Consumption; Storage of Coal by Railroads During 1918; Fuel Department Organization; Co-operative Research and the Railway Fuel Problem; The Effect of Reducing Exhaust Nozzles to Overcome Front End Air Leaks; Internal Combustion Versus Steam Engine for Small Stationary Plants. Abstracts of these reports and papers will appear in subsequent issues.

THE NEW OFFICERS

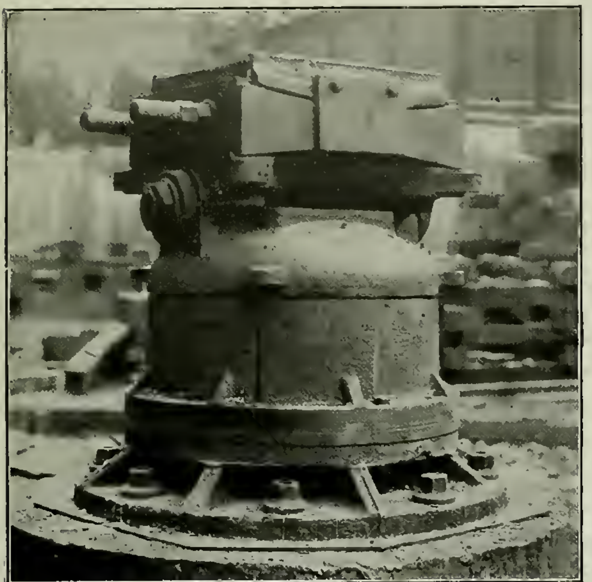
The following officers were elected: President, H. B. MacFarland (Atchison, Topeka & Santa Fe); vice-presidents, W. J. Bohan (Northern Pacific), J. B. Hurley (Wabash), and W. L. Robinson (Baltimore & Ohio Western Lines); executive committee, J. W. Hardy (U. S. R. A.), M. A. Daly (Northern Pacific), C. M. Butler (Atlantic Coast Line), L. J. Joffray (Illinois Central), C. C. Higgins (St. L.-S. F.), and J. M. Nicholson (A. T. & S. F.).

Railroad Employees' Subscriptions to Victory Loan.—Officers and employees on railroads under government control throughout the United States subscribed a total of $138,637,250 to the Victory Liberty Loan. The returns from the seven regional directors show that out of a total of 1,841,267 employees, 1,417,042, or 77 per cent, subscribed to the loan. Employees on 13 roads showed subscriptions of 100 per cent. Railroad officials and employees subscribed a total of $184,868,300 to the Fourth Liberty Loan. General offices of regional directors of Southern, Pocahontas, Allegheny, Southwestern and Northwestern regions subscribed 100 per cent, the general office of the Central Western region 99 per cent, and the general office of the Eastern region 96.8 per cent.

A Turntable of Unique Design

P. R. R. Develops Adjustable Center, Supports Table at Three Points and Puts Tractor at Each End

A CENTER bearing, adjustable vertically over a range of 1 in. by means of screw operated wedges, is one of the main features in the 110-ft. turntable recently designed by the Pennsylvania Railroad and now being installed at several of its more important engine terminals. This vertical adjustment has permitted the development of



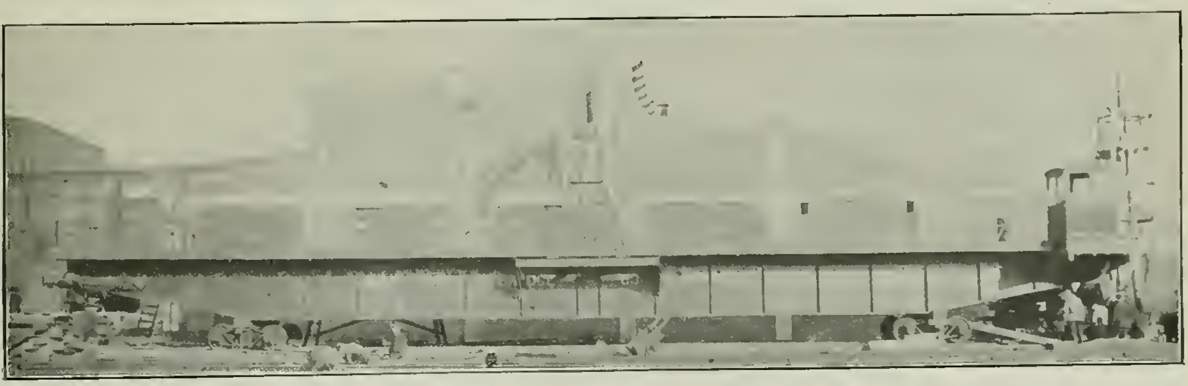
The Center Is Adjustable By Means of Screw Operated Wedges

plans for tables of the three-point supported type, the design of which includes many other novel and interesting features and avoids the use of the usual balanced type with its objectionable features, particularly in tables of such extreme length.

The 110-ft. tables were designed in anticipation of the increased requirements at engine terminals incident to the impending introduction into service of the new Mallet engines of the HC1s type, several of which are now under construction in the company shops. These locomotives have a wheel base of 97 ft. 3¾ in., an over-all length of 105 ft. 9¼ in., and an estimated weight of 555,000 lb., exclusive of the tanks, which weigh 219,000 lb., or a total weight complete of 774,000 lb. Owing to the extreme depth of girder required for a balanced table of such great length and further because of the conditions under which a turntable must operate, in which it is difficult to spot a locomotive of this size and weight with any degree of accuracy, it seemed inadvisable to build a table of the usual balanced type. Furthermore, the tendency of all balanced type tables to teeter has an undesirable effect on the approach rails and outside trucks, due to pounding, which is augmented as the length increases. It was therefore decided that the new tables should be of the continuous girder three-point supported type, in which the weight of the table and its load is distributed over the center and the four end trucks. Exclusive of the tractors and center the table, ocmplete with the end trucks, has a weight of 75 tons.

Reliability of service and low maintenance costs were the main objectives of the design and in the preliminary studies particular attention was given to the requirements of traction. Time studies were made of the various table operations at existing tables and the information secured was utilized in the design of the tractors to insure that the operating cycles of the new table, with its greater loads, would not exceed those of the smaller tables and that the new tables would easily turn an engine end for end in 45 sec. Special attention was given to starting, accelerating and stopping the table to avoid excessive whip action, with the result that the maximum acceleration does not exceed 0.35 ft. per sec. and the maximum circumferential speed of the table is 240 ft. per min. Reliability of service has further been provided for by the utilization of two tractors, either one of which is capable of moving the table under emergency conditions. The two tractors provide sufficient traction to eliminate the necessity for the use of sand and a separate circle rail for the tractors.

Low maintenance costs are further insured by the permanent type of construction employed throughout the entire structure, including the foundation, the circle wall and rail, the bridge, the deck, and the electrical apparatus. In the design of parts simplicity, accessibility and interchangeability were the objectives. Sheet metal was avoided in the selection of materials and cast iron was used wherever possible



Pennsylvania 110-Ft. Turntable Designed for Three-Point Support because of its resistance to corrosive action. For the same reason galvanized iron is used for hand rails.

To eliminate the pounding out of the approach rails and approach rail supports at the table ends and at the approach rails, cast steel end ties were installed at the ends of the turntable bridge and iron coping castings were used on the coping walls, the cast steel end ties being aligned accurately to the center line of the table and brought to alignment level by means of stereotype metal between the end tie and the girder flange and secured to the bridge with eight 1-in. bolts. Opposite tracks are also perfectly aligned. The same permanent character of construction is employed in the pit, where the circle rail of Cambria No. 539, 150-lb. section, bent cold, is held in place on 33 iron support castings firmly secured to the concrete.

The adoption of the three-point supported type table permitted the use of girders only 6 ft. ½ in. deep, reducing materially the depth of pit required. These pits are drained from the center to a sump from which the discharge is by gravity or syphon, according to local conditions.

THE ADJUSTABLE CENTER

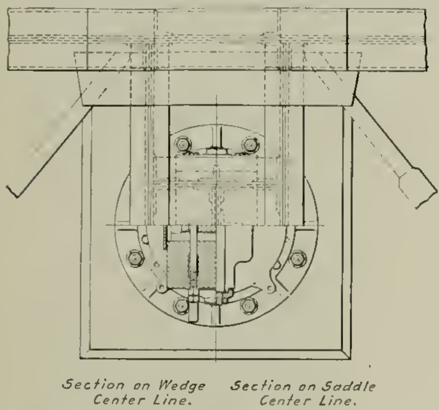
In order that the table function properly on three points of support it was necessary that one of the supports be adjustable so far as vertical alignment is concerned. This adjustment is accomplished in the center by means of screw operated wedges, the total range of adjustment being 1 in. As the load of the table comes down on the sole plate it bears on wedges which in turn bear, through the lower wedge casting, on the equalizing hinge pin, the center of which is at right angles to the longitudinal center line of the table, thence on the thrust bearing proper. This thrust bearing is of the roller type with a babbit liner between the lower roller race and the center casting to insure uniformity of bearing pressure. The load from turntable center is transmitted to the concrete center pier through a ¼ in. linotile liner, which insures a uniform, resilient bearing for the steel casting.

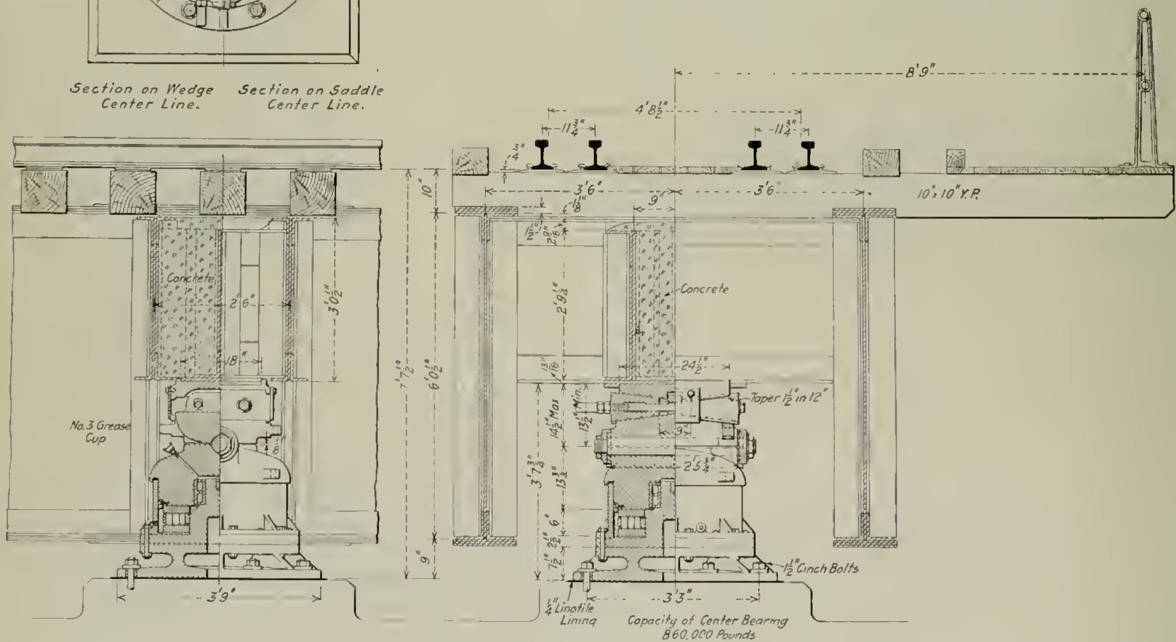
The capacity of the center bearing is 865,000 lb., and it is fully grease lubricated. It has been designed and built with a view of making it accessible for inspection or repairs. The upper half of the center proper can be removed from the base casting and the entire center slid out of position and passed up through the deck of the table. To perform this operation it is only necessary to jack up the table approximately 3 in. All the adjustment wedges and the wedge screws are thoroughly protected against corrosion and grit. The center is all of steel with the exception of the housing shell, which is of cast iron.

TRUCKS

Each end of the table is supported on two, two-wheel end trucks with cast steel frames and hinge connection centers. The hinge casting is provided with a compound angle in order to give proper angularity in all directions. The center line of each hinge pin is in a radial plane passing through the common center of rotation, in which it has vertical angularity sufficient to take care of the circular travel of the truck. The truck wheels are all 30 in. in diameter, coned, with steel tired treads and cast iron centers. They are provided with roller bearing centers with the bearings enclosed in labyrinth casings, the details of which will be made clear by an inspection of the truck drawing, and are fully grease lubricated.

The truck hinge castings as well as the steel end ties on top of the girder are lined to the girder flanges by means of





General Arrangement of the Turntable Center stereotype metal. The trucks each have a capacity of 186,000 lb. and travel on the same circle rail as the tractors. They may be removed by taking out the hinge pins without removing the hinge castings from the girder.

TRACTORS AND TRACTOR CONTROL

Two tractors are used on each table to give uniform torque action on each end of the table in starting and stopping, as well as to afford reserve power to meet emergency demands. They are operated in multiple from one controller located in a cab on one end of the table.

There are three points of particular interest in connection with the tractors and their control. The first is that two motors are used, one on each tractor, of approximately 30 h. p. each. Considerably more power is required than to operate a type of table in which the locomotive is balanced on the center bearing, but with the two tractors the operation is fast, is always dependable, and in an emergency one of the tractors working alone is capable of operating the table.

The second point of interest is the controller. A type of controller has been developed which is used to control one or both motors, and which may be used on any table of this type, irrespective of the kind of electric power that may be available. The same controller may be used for direct current, single phase alternating current, three phase alternating current and three-wire or four-wire two phase current.

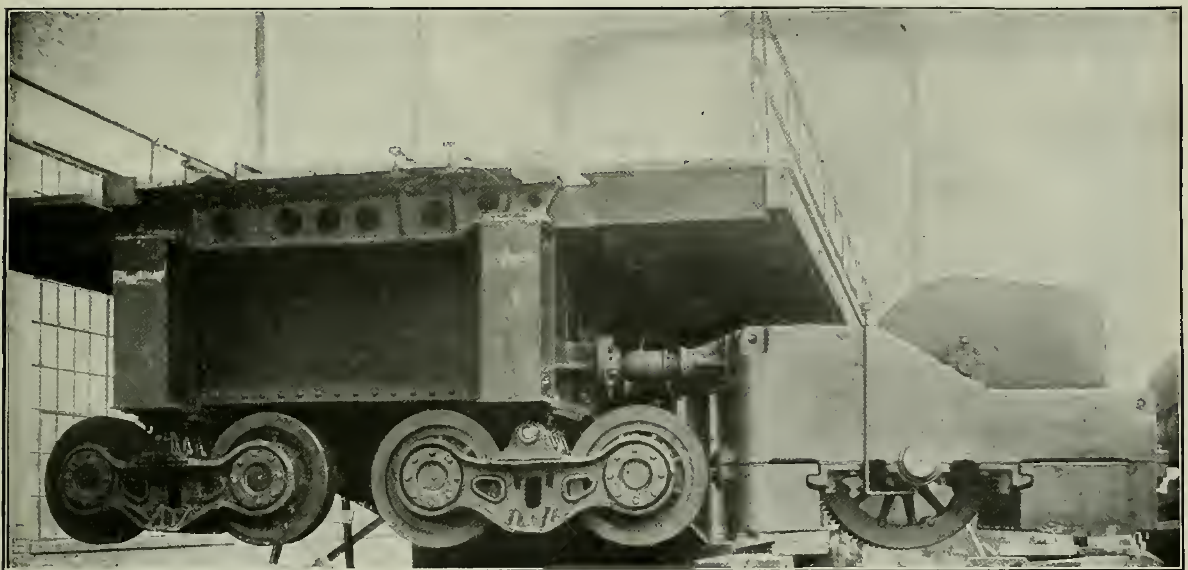
The third point of interest lies in the fact that the motors are equipped with solenoid brakes. The brakes are applied instantly when the controller is moved to the "off" position and are released automatically when power is applied. The brakes are adjusted so that the braking effort corresponds to the maximum torque of the motor. The solenoid brakes make it possible to operate this type of table without any of the so-called locking devices to hold the table in alinement with the approach tracks.

For direct current, 27½ hp. motors are used and 30 hp. motors have been adopted for alternating current. Power is transmitted from the motor to the driving wheels through two sets of gears and an intermediate shaft, with a total gear reduction of 25 to 1. As the tractor is provided with plain cylindrical tires, it was necessary to include in the design a suitable thrust bearing to care for the lateral thrust of the drive wheels. This thrust bearing is located on the inner side of the tractor frame.

In case of accident to either motor or to any part of the driving mechanism, electrical cut-outs are provided for taking the damaged motor out of service without affecting the operation of the other motor, while the solenoid brakes can be blocked in the "off" position. A motor may be disconnected mechanically by removing the split main gear or by removing the motor.

The two tractors engage the table through ball and socket connections located at the end of the stabilizing arms. The relation of the joint locations to the plane of the driving wheel precluded the use of hinge joints. All bearings of the tractors are grease lubricated. Each tractor weighs approximately 23,000 lb. in working order, giving a total tractive effort of 12,000 lb. per table.

The tractor frames on account of the weight required are made of solid cast iron with suitable ballast weights suspended from the lower surfaces. Special attention is given to the machining of all mechanical parts to insure absolute interchangeability for repairs. All gears are fully enclosed against the weather. The tractor wheels have cast iron centers, steel tires and are provided with cast steel cut driving gears. The bearings are all of brass.



The Trucks and Tractor in Place

When operating at night the table is lighted by floodlights on each end which illuminate the approach rail ends. The operator's cab is electrically heated and is lighted only with a small, well shaded lamp to keep down the reflection at night.

CURRENT COLLECTOR

Overhead current collectors for the usual type of turntables must be suspended from the overhead wires, as the portal over the center of the table must move back and forth over a considerable distance when the locomotive is moved on or off the table. Since the three points of support prevent the table from rocking on the center bearing, the collector in this case is bolted securely to the center of the portal.

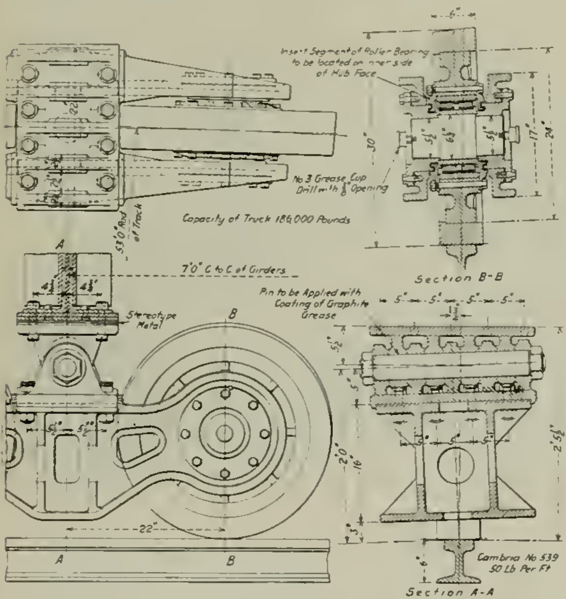
The collector in itself is of particular interest as it is made up of standard parts, bolted together, and may be used for direct current, or one, two or three phase alternating current by simply bolting together the required number of parts. It is weather, gas and steam proof.

Structual steel poles placed on opposite sides of the enginehouse circle support the overhead wire. One messenger wire is provided instead of the usual two, and it is not required to support the current collector. The only function of the messenger is to support the current carrying wires and to prevent rotation of the stationary part of the collector. The messenger is supported rigidly on one tower and on the other is fastended to one end of a weighted bell crank which insures uniformity of tension on the messenger wire at all temperatures.

PIT AND BRIDGE CONSTRUCTION

In order to insure no settlement at the coping wall on account of the pounding received in service. iron coping castings with 1-in. walls were employed instead of wooden sills. These castings are arranged one for each approach track and are thoroughly embedded in and bolted to the concrete. They are accurately aligned to the approach tracks and weigh about 9,000 lb. each, are 5 ft. 6 in. long, 12 in. deep and 30 in. high.

The circle rail on which the trucks and tractors run is 106 ft. in diameter and is supported on 33 castings each



General Arrangement of the Trucks

9 ft. 4 in. long, 10 in. high and 12 in. wide, with 7/8-in. walls. No sand is used in connection with the operation of the tractors because of the ample capacity of the tractors themselves. This feature eliminates the resistance of the sand to rolling of the trucks.

The cast steel end ties on the bridge have a maximum depth of 12 in. a flange width of 5 in. and a minimum width of 8 3/8 in. The sections are 1 in. thick. They support both the traction rails and the guard rails and are lined to the bridge girders by means of 3/8 in. of stereotype metal.

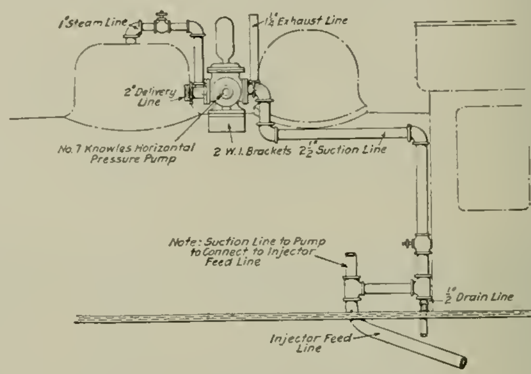
The design of this table was developed under the direction of A. S. Vogt, formerly mechanical engineer, who has now retired.

Tables of this type have been installed at Pitcairn, South Philadelphia, Erie, Kane and Renovo, Pa., and at Gardenville, N. Y. Others will be installed in the near future at Wilmington, Del., Youngwood, Pa., Pitcairn (Pa.) (emergency table) and at East Altoona.

FIRE PUMPS ON SWITCH ENGINES

BY J. H. B.

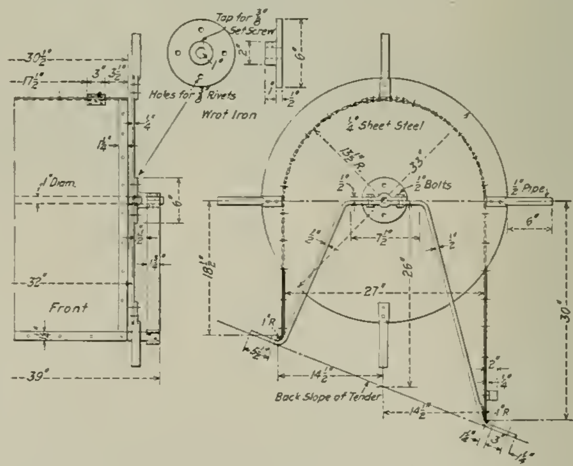
An arrangement for fire pumps on switch engines, in which the pump is mounted on top of the boiler, is shown in the illustrations. A horizontal pressure pump of the capacity required is placed between the sand box and the steam dome with a 1 in. steam line leads from the dome



Fire Pump Installed on the Locomotive

to the pump, which delivers the water through a 2 in. delivery line provided with a hose connection. Water is drawn from the tank to the pump by means of a 2½ in. suction line which connects to the injector feed line just above the running board.

The hose reel is mounted on the sloping top sheet of the tank where it is easily accessible so that in case of fire the



Hose Reel as Applied to Tender

hose can be unreeled readily and connected to the delivery line. Details of the construction and mounting of the reel are clearly shown in one of the drawings.

The protection thus given the various shop buildings and cars in the yard warrants the expenditure necessary to apply the pumps as a switch engine so equipped can quickly reach a fire and becomes a very effective means of reducing fire losses.

Master Boiler Makers' Convention

Over 700 Members Were Present; Report on Drilling Staybolts, Addresses and Other Business

THE Master Boiler Makers' Association held its eleventh convention at the Olympic Theater, Chicago, May 26 to 29, with over 700 members in attendance. An address was made by Frank McManamy, assistant director, Division of Operation, U. S. R. A. Mr. McManamy spoke of the benefit to be derived from a full discussion of new methods and practices at conventions and mentioned particularly the importance of some of the topics which had been made the subject of reports to be presented at this meeting. In closing he dwelt on the necessity for thorough workmanship in locomotive repairs.

D. A. Lucas (Prince Mfg. Co.)
President

J. B. Tate (Penn. R. R.)
First Vice-President

C. P. Patrick (Erie)
Second Vice-President

T. Lewis (L. V.)
Third Vice-President

T. P. Madden (Mo. Pac.)
Fourth Vice-President

Following Mr. McManamy's talk, D. A. Lucas, president of the association, delivered the presidential address. Addresses were made by A. G. Pack, chief inspector of locomotive boilers; R. H. Aishton, regional director of the Northwestern Region, and H. T. Bentley, superintendent motive power and machinery, Chicago & North Western.

ADDRESS OF H. T. BENTLEY

Under present conditions a first-class boilermaker is a specialist and no hit-and-miss methods will do; with steam pressure from 150 to 240 lb. per sq. in., the boiler must be maintained in good condition to do its work safely and efficiently, and with the labor-saving devices now in use at all up-to-date shops there is no excuse for not having it in that condition. With the good wages now paid there should be a corresponding increase in output, so that the government we are all working for will feel that the increase given the employees is appreciated and the results obtained justify the action taken.

The railroads before the war had a number of plans to improve the service, and probably nothing in the motive power department would give greater returns for the money expended than the providing of water purifying and hot water washout plants. All of these plans were temporarily side-tracked during the strenuous times just past. Now that the war is over, these plans should again be given early and favorable consideration and plants installed where it is known that the expense is justified. With good water and freedom from boiler troubles, failures on the road and maintenance costs are low; with poor water the conditions are changed, resulting in high maintenance costs, inferior service on the road, delays at the roundhouse and a disgruntled superintendent. Money must be spent either to purify the water and keep the engine in service or to make frequent repairs and have occasional failures. In my judgment it is far better to furnish good water and obtain good service instead of poor water and poor service.

One important thing that foremen should get together on is the balancing of work so that necessary boiler and machinery repairs will be made while the engine is out of service to enable a locomotive to go out of the shops and perform a proper period of service without trouble from boiler or machinery. On several occasions it has come to my attention that an engine will be out of service, having the wheels dropped and quite heavy machinery repairs and a few weeks afterwards the same engine will come back to shop for new flues or side sheets and, of course, nothing will be necessary on other parts of the locomotive. In this case the engine is out of service for two periods close together, whereas all of the work could and should have been done at the same time.

The electric welding of two-inch boiler flues in back flue sheet is something that interests me. We have tried it and find that with good water the flues don't leak or bridges crack and therefore welding is unnecessary; with poor water it is very desirable to do this if you do not run into other troubles. We bought 26 new boilers some time ago and specified that the two-inch flues should be welded, and after three or four months service the flue bridges cracked and new flue sheets had to be applied. The welding of superheater flues appears justifiable by reducing troubles on account of leakage and overcoming engine failures, and if this is so successful, I cannot see why the welding of small flues would not be a good thing.

The federal locomotive inspection department has been responsible for a great improvement in the condition of locomotive boilers, etc., and a closer co-operation on the part of the mechanical officers with the inspectors will bring about a still greater improvement.

APPLICATION AND DRILLING OF TELL TALE HOLES

The best method in all cases to apply tell tale holes is before the staybolt is applied. This may be done on an automatic drilling machine or a small drill press rigged up for this in the shop. The most economical and best method to cut the bolts off is with the oxy-acetylene torch, in this way not disturbing the bolt in the sheet as is done with a hammer or a chisel bar, or staybolt nippers.

It is the practice in one shop to punch the tell tale hole in the staybolt on a forging machine in the blacksmith shop. This is done in one heat in two operations; first a rather blunt tool is used which punches a hole about 3/8 in. in diameter to about 5/16 in. depth, which acts as a countersink on the end of the bolt; the bolt is then raised in the die and a 7/32 in. hole 1½ in. deep is punched. It is our opinion that this is the best method known of applying tell tale holes in staybolts. If the dies are properly made the result will be a bolt of proper size with the tell tale hole in the center.

For drilling tell tale holes we use a 7/32 in. high speed twist drill both in new bolts and in opening up old tell tale holes. However, where holes are forged as above mentioned, we do not find it necessary on new bolts to use a drill as the holes can be very easily opened with a taper pin. The lubricant used is composed of soft soap and water, both for drilling and for opening up new bolts.

The report was signed by Louis R. Porter (Soo Line), chairman, A. N. Lucas (C. M. & St. P.) and Barnard Wulle (Big Four).

OTHER BUSINESS

Reports on Application of Brick Arches to Fireboxes: Design of Ash Pan and Draft Appliances and Bracing of Locomotive Tenders were submitted by committees and will appear in a later issue.

The products of 47 different companies were exhibited at the convention.

There was an attendance of 745 members at the convention, and during the convention 198 applications for membership were received.

The following officers were elected for the ensuing year: President, John B. Tate, foreman boilermaker, Pennsylvania Railroad, Altoona, Pa.; first vice-president, Charles P. Patrick, general boiler inspector, Erie Railroad, Cleveland, O.; second vice-president, Thomas Lewis, general boiler inspector, Lehigh Valley, Sayre, Pa.; third vice-president, Thomas P. Madden, general boiler inspector, Missouri Pacific, St. Louis, Mo.; fourth vice-president, Edward W. Young, general boiler inspector, Chicago, Milwaukee & St. Paul, Dubuque, Iowa; fifth vice-president, Frank Gray, foreman boilermaker, Chicago & Alton, Bloomington, Ill.; treasurer, William H. Laughridge, foreman boilermaker, Hocking Valley, Columbus, O.; secretary, Harry D. Vought, New York City. The following were elected members of the executive board to serve for three years: E. J. Reardon, district inspector, Interstate Commerce Commission, Chicago; Thomas F. Powers, foreman boilermaker, Chicago & North Western, Oak Park, Ill.; Harry F. Weldin, foreman boilermaker, Pennsylvania Railroad, Philadelphia. Henry F. Wandberg, foreman boilermaker, Chicago, Milwaukee & St. Paul, Minneapolis, Minn., was elected to the executive board for one year.

Treasurer

Locomotive Repair Shop Output

A Proposed Formula for Measuring and Comparing the Cost of Repairs in Relation to the Output

BY HENRY GARDNER

There have been a great many formulae proposed for measuring the output of a locomotive repair shop or for the purpose of comparing the output of two or more shops. All are more or less in error and no one of them will give figures which can be relied upon to state positively which one of two shops delivered the largest output per man or indicated the most able and successful management.

The old method of equating or listing repairs by classes is very unreliable. A Class 3 repair in one shop may cost twice as much as in another, and the amount of work done will vary in proportion. When you compare two shops on this basis, the superintendent having the smaller output will at once start to tell you of the superheaters, stokers, valve gears, etc., that he put on and the other man did not. He will also show you a list of flue sheets, side sheets, etc., greatly in excess of similar work done by the competing shop. The size of the power, weight, and wheel arrangement and cost of repairs will then be brought into the argument as factors rightly having a decided bearing upon the exact quantity of work performed in the shop. Finally the argument is dropped just where it started; no definite and satisfactory conclusion could be made.

It has been generally conceded that the cost of repairs to a locomotive varied almost in direct proportion to its weight. Ernest Cordeal in an article describing a method for determining shop output by means of cost units (Engineering Magazine, May, 1915), states that "The cost of identical repairs will usually vary in direct proportion to the total weight." This may be correct if parts of engines or jobs are considered. For example, the cost of repairs to main rods might run higher on a large engine than a small one, but if the entire repair is considered the cost per ton weight of engine will be found to vary, in most shops, in some inverse proportion to the weight. Assuming that costs of repairs vary directly as total weight of engine, the tonnage repaired was added up and this figure divided into the total cost to get the cost per ton. The result was arbitrarily called a "work unit," and the lower the unit the better the showing for the shop considered.

Another method consisted of adding up these units to indicate quantity of output delivered and then comparing the totals. It amounts to the same thing whether we add up the costs per ton of all engines delivered or call the average cost per ton a "unit" and multiply this unit by all the tonnage delivered. The final result simply reduces itself to a cost per ton comparison of output.

The simple output formula described above was found to be closer to facts than the older methods and might in some cases fairly measure the shop rating. Weight is an important element in output and total labor and material costs vary almost directly as the quantity of work performed. A large engine, as a whole, would usually cost more to repair than a small one, provided exactly similar work was performed on each, but the cost per ton for the large engine (Mallets and engines under 50 tons total weight excepted) is found to be less than for the small one.

Pursuing this course further the writer has developed an arbitrary formula which closely represents the quantity of shop output. This formula gives no rational figures that can be used for statistical or accounting purposes, but it has a legitimate and proper value when used exclusively for making comparisons. Bearing in mind that the cost per ton of the majority of repairs varies inversely as the total weight, it is apparent that we must compensate in some manner for this variation. In other words we must devise a formula which will give proper credit for the Mallets and small power. Such a formula would read as follows:

$$\text{Total cost per equivalent work unit} = \frac{\text{Total labor and material cost}}{\text{Total work units} \times \text{a constant}}$$

Referring now to Fig. 1, a curve is shown which approximates a parabola. Plotting this curve for a large number of repairs developed the fact, for the repair shop considered, that the cost of repairs per ton varied in inverse ratio to the total weight for engines weighing between 50 and 180 tons. The total labor and material cost to repair an engine weighing 100 tons will average $34 a ton (four classes of repairs averaged together), but an engine weighing 50 tons will average $60 a ton. This unexpected result may be due partly to the tendency on most roads to run up the mileage between shoppings on small branch line engines and switching power.

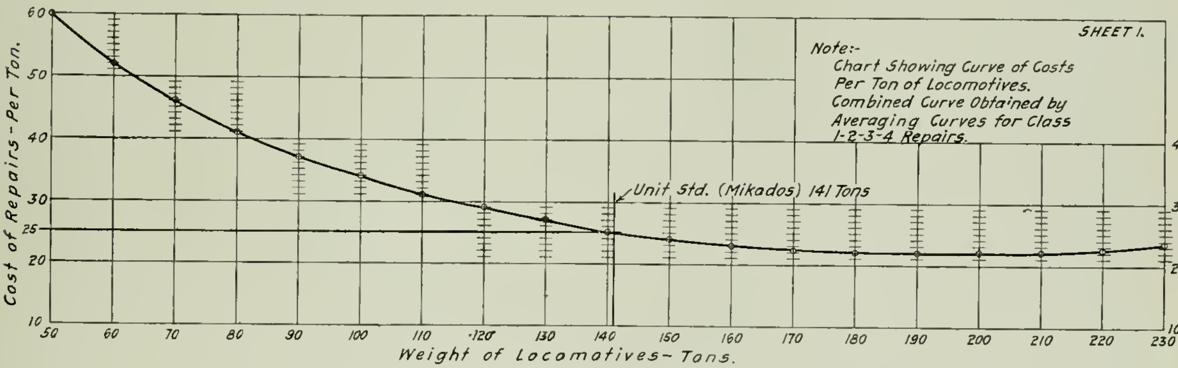

Fig. 1—Cost of Repairs Per Locomotive-Ton Curve

It is also the case that patterns, castings and blue prints for small, out-of-date engines are not as easily located as for the larger modern power. There is also considerable work to be done on small boilers and fireboxes in order to meet present government regulations.

In the formula given above the total cost per equivalent work unit is our output measure. This is derived by dividing the actual labor and material cost of the repairs (for one month or any period desired) by the work (cost) units multiplied by a constant. As the total cost of the repairs increases in the numerator of the fraction the total work units, to a degree, will correspondingly increase in the denominator, since the work units result primarily from the money expended. One work unit is arbitrarily taken as $20 labor and material cost in order to make the quotient come out in easily comparable whole numbers.

It is evident that this formula is fair and logical for all cases. When the numerator gets credit the denominator will also get a varying amount of credit. But since the work units are fixed and based upon averages, and the total cost is an actual quantity, any extraordinary increase in expenses due to overtime or improper management will be reflected in the actual total cost figures. This increase will correspondingly raise the quotient and indicate the abnormal conditions present. The converse of this is of course equally true.

The constant used in the formula needs some explanation. Referring again to the curve (Fig. 1) we find that an engine weighing 100 tons will cost $34 per ton, and an engine weighing 141 tons will cost $25 per ton. It is now evident that to give the lighter 100-ton engine the proper credit for its greater cost per ton we must multiply the work units for that engine by 34÷25, or 1.4. It is through this constant that the tonnage of output becomes a factor.

By using the formula we are now able to give shops turning out a large proportion of Mallets or small old-fashioned power due credit for the quantity of work performed.

Substituting concrete values in this formula we will have, for a 100-ton engine, Class 3 repairs:

$$\frac{\$4,000}{(120 + 60)\ 1.4} = \$16\ (\$15.87\ \text{actual})\ \text{cost per equivalent work unit.}$$

Where 4,000 = actual labor and material cost from shop accounts
120 = standard work units allowed for straight Class 3 repairs
60 = work units allowed for betterments as per list (Fig. 3)
1.4 = constant from the curve (Fig. 1)

It may be explained that the standard Mikado locomotive and some heavy Pacifics weighing about 141 tons were taken as unity for the constant scale. The work units for 141-ton engines will then be multiplied by constant 1.0 and the equivalent will not differ from the actual. This weight was chosen for starting the scale for the reason that engines of these types represent a large percentage of the power repaired and cost figures covering repairs to such engines were found to be most uniform and reliable. The work units are now compensated for the variation of cost of repairs with weight of engine in exactly the same manner as steam tables show the equivalent evaporation from and at 212 degrees, the boiling point of water.

An examination of Fig. 3 shows how the extraordinary work and betterments applied to the regular repairs are listed under 36 items. It was thought best to include small flues and radial stays in this list since credit could then be adjusted for full or partial sets if desired. Each item is given a current cost unit figure based upon actual average costs, including overhead, covering all classes of power for a considerable period. Dividing these costs by 20 gives in each case the number of straight cost units expended for each item. The units here shown were adopted in 1917

Fig. 4—As Classified from Sheet 3

when applied to the 36 items shown on Fig. 3, is of interest but has no particular value for applying the formula.

This procedure involves a considerable amount of work and a familiarity with shop repair records, but there is no known short and easy way to accurately compare shop output if a reliable decision is required.

It may be well to state that repair costs vary with different shops, and if a nicer comparison is desired, separate cost units can be worked up for each shop. This should of course be done if the above methods are employed to compare the relative efficiency of shops on different roads, as different operating methods and facilities will vary the costs considerably. Another refinement could be made by constructing separate cost per ton curves for each class of repairs instead of using the composite curve shown in this article. The repairs should then be separated by classes and the constants obtained from the corresponding curve for that class. Separate curves indicate that Class 1 repairs cost more for light tonnage than other classes, Class 2 and 3 repairs follow the composite curve closely and the

Fig. 5—Monthly Summary Sheet

Class 4 repair curve shows a more nearly uniform cost for all tonnage, as would be expected. These repair classes should conform to the standards adopted by the United States Railroad Administration.

The formula and principles described in this article have been used for checking the relative output of several shops and the results have substantiated the opinions of those competent to judge by other methods combined with experience. This work could be drawn much finer, and instead of using only 36 betterment items, 100 could be taken,

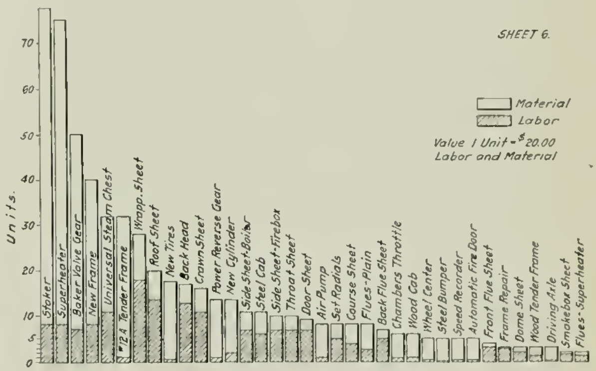

Fig. 6—Comparative Cost

or all the work performed on the engine could be itemized directly from service and material cards, but it is felt that the method shown is simple and inexpensive and serves the purpose. Moreover it is questionable whether service and material cards as made out in the majority of railroad shops are as accurate a guide as the averages here obtained. Using this same relative cost unit data for all shops puts all on the same basis and no one shop could claim that service and material cards or clerical compilations were in error.

This subject is important and one which has never yet been satisfactorily settled. What is needed is a measure that will equal the foot rule when applied to the output of locomotive repair shops, and until such a measure is accurately constructed no one is in a position to state positively that one shop is well or poorly managed or that the output is greater or less when making comparisons with other shops.

Railroad Administration News

About 19,000 Standard Cars Stored Awaiting Acceptance by the Roads to Which They Are Assigned

APPROVAL has been given to issuance of Pullman annual passes to general chairmen of shop crafts, to be made good on railroad or railroads over which such general chairmen have jurisdiction, and also on such foreign lines as they may hold railroad transportation over, which has been furnished to them for the purpose of enabling them to make short cuts between points on the lines over which they have jurisdiction.

Application for these passes should be made by the federal managers to the director, Division of Operation, at Washington.

385,000 surplus freight cars

The net surplus of freight cars on May 1 was 385,447, including nearly 20,000 on Canadian roads, according to reports compiled by the Car Service Section. This represents a larger number of idle cars than has been recorded at any time since April, 1908, except on March 1 and April 1 of this year. On March 1 the net surplus stood at 473,080 and on April 1 it was 446,685, so there was a reduction during April of 61,000.

Punitive overtime up to director general

The question as to whether the train service employees are to be allowed a punitive rate for overtime is again up to Director General Hines for decision. The brotherhoods have reiterated since the Railroad Administration has been in control their demands for time and a half for overtime which was waived during the negotiations which preceded the enactment of the Adamson law. When Supplements 15 and 16 to General Order No. 27 were issued by Director General Hines in April the matter was referred to Board of Adjustment No. 1 for a report. The board, however, was not able to agree, and has submitted two separate reports, one of which presumably represents the views of the brotherhood representatives on the board, while the other represents the views of the managers of the roads. Before deciding, Director General Hines has ordered an investigation as to the cost of paying punitive overtime in road service.

Mechanical officers instructed to report on June conventions

Frank McManamy, assistant director of the Division of Operation, has addressed the following to the regional directors, asking that mechanical officers be instructed to make written reports regarding their observations at the June conventions:

"The convention of Section 3, Mechanical, American Railroad Association, which is composed of the Master Car Builders' Association and American Railway Master Mechanics' Association, will be held at Atlantic City, June 18 to 25.

"It is desired that the representative members from the different railroads attend, as far as possible, and that other mechanical department officials who are members be permitted to attend for at least a portion of the time, where they can be spared from their regular duties without adversely affecting the service. It is anticipated that there will be on exhibition the most complete collection of mechanical appliances that has ever been exhibited at one of these conventions, and a study of it will be of substantial value to the mechanical department officers who are in attendance.

"In order to obtain the greatest possible amount of benefit from this convention, it is desired that each member present below the rank of superintendent of motive power shall, on his return from the convention, make a written report to the superintendent of motive power, relative to the new devices which he inspected at the convention, or ideas which he obtained from the discussions which can be applied with profit to the work under his direction.

"The superintendent of motive power will make a digest of the various subjects presented in this way, so that those which can be profitably adopted may be given consideration, sending a copy of it to the assistant director, Division of Operation, in charge of the mechanical department, for the use of the Committee on Standards for locomotives and cars.

"Will you please issue the necessary instructions?"

Comparison of car and locomotive repairs in 1917 and 1918

The following table showing comparisons regarding car and locomotive repairs in 1918 and 1917 was included in a general statement filed by Director General Hines with the Senate Committee on Interstate Commerce, showing the expenses of the Railroad Administration:

Repairs to Locomotives and Cars Combined, 12 Months, January to December, 1917-1918

	1918	1917
Average number of serviceable freight locomotives	30,824	30,378
Average number freight locomotives in or awaiting shop	4,624	4,286
Per cent freight locomotives in or awaiting shop	15.0	14.8
Average number freight cars in service	2,430,786	2,363,309
Average number freight cars in or awaiting shop	138,989	133,252
Per cent of freight cars in or awaiting shop	5.7	5.6
Total number of locomotives receiving repairs requiring more than 24 hours	235,522	193,924

Comparison of Freight Cars Repaired by Railroads Under Federal Control, 1917 and 1918

	Light	Heavy	Total
(1) Number of freight cars repaired by 133 Class I railroads and 22 Class II railroads, showing separation between light and heavy repairs:			
1917	29,207,081	1,941,380	31,148,461
1918	27,650,214	2,005,926	29,656,140
Increase, 1918 over 1917	....	64,546	....
Decrease, 1918 over 1917	1,556,867	....	1,492,321
(2) Number of freight cars repaired by 6 Class I railroads that were unable to give complete separation between light and heavy repairs:			
1917			1,112,966
1918			1,154,085
Increase, 1918 over 1917			41,119
(3) Total number of freight cars repaired by 161 railroads, representing ownership of 2,357,208 cars:			
1917			32,261,427
1918			30,810,225
Total decrease, 1918 over 1917			1,451,202

(*a*) Referring to item (1), showing decrease of 1,556,867 light repairs, 1918 over 1917, with an increase of 64,546 heavy repairs: The reduction in light repairs is due to reporting light running repairs, requiring less than one 1-man hour to repair, in 1917, which were not permitted reported in 1918.

(*b*) Item (2) shows substantial increase, 1918 over 1917.

(*c*) Item (3). Explanation for total decrease, 1918 over 1917, is given in paragraph (*a*).

Allocation of equipment

Of the 100,000 freight cars ordered by the Railroad Administration in 1918, 44,542 had been built up to April 30 and 92,750 had been assigned to various companies, but only 25,570 had been accepted, while 18,972 of the cars already built were in storage at the car-building plants. The numbers of the various types are shown in the table.

Numbers and Types of Cars Built by the Railroad Administration Not Yet Accepted by the Railroads

Type of cars	Number of cars
40 ton double sheath box cars	3,702
50 ton single sheath box cars	1,169
50 ton composite gondolas	6,043
55 ton steel hopper	8,057
70 ton low side gondolas	1
Total	18,972

Of the 1,930 locomotives ordered, all but 41 had been assigned, but all the assignments had not been accepted. The locomotives have been accepted as fast as they have been built, but various companies have objected to the assignments just as they have to the cars. Some of the objections are based on the inability to finance the equipment, some on the statement that the cars or engines are not needed, and some are based on the types, although the Railroad Administration has allowed the roads to exchange one type for another where it can be done before the builders have progressed too far with the building or the ordering of materials to make the change.

The circulars sent out by the regional directors asking for information as to the number and types of locomotives that will be required and whether the corporations will be willing to purchase locomotives of their own standards represent an effort to place some of the unaccepted locomotives, but it will not be possible to substitute individual or "made-to-order" designs for the standard types in many instances because the work on the parts for the standard types has been so far advanced.

Plans for the creation of an equipment trust to finance both the cars and locomotives by a single issue of equipment trust obligations amounting to approximately $400,000,000, instead of having individual securities issued by each of the roads, are under consideration by the Association of Railway Executives and the Railroad Administration.

COSTS OF TRAIN AND LOCOMOTIVE SERVICE

A monthly report is being compiled by the Operating Statistics Section of the Railroad Administration which shows the itemized costs of locomotive service per locomotive mile, and train service per train and 1,000 gross ton miles. The figures for February and March, 1919, compared with the same months a year ago are shown in the table. No comparisons are made with last year on the gross ton mile basis.

The comparisons with last year are disturbed to some extent by the factor of back pay being included in this year's figures, while last year's figures do not include the increases in wages which became effective later in the year. Most of the figures for March, however, show decreases as compared with February.

NUMBER AND COMPENSATION OF EMPLOYEES

The January, 1919, pay roll of the Class I railroads under federal control was $230,800,589 for 1,848,774 employees, as compared with $153,039,988 for 1,703,748 employees in December, 1917, according to a statement compiled by the Operating Statistics Section, which shows the effect of the wage increases during 1918 as between the different classes of railway employees, together with the numbers, the days and hours worked, the compensation per day and per hour, and the percentage of change in the unit compensation for each of the 68 classes prescribed by the Interstate Commerce Commission. The average increase in unit compensation was 48 per cent, the range being from a 20 per cent reduction for general officers receiving $3,000 per annum and upwards, up to 98 per cent increase for structural iron workers and 99 per cent for "other yard employees."

The increase in the number of employees was 145,026 or 8.5 per cent and the average compensation per employee in January was about $125, as compared with about $90 in December, 1917. This would amount to an average of $1,500 per year, as compared with an average for the year 1917 of $1,004.

COSTS OF TRAIN AND LOCOMOTIVE SERVICE

	February, 1919	February, 1918	March, 1919	March, 1918
Cost of locomotive service per locomotive mile	120.7	106.3	119.2	100.1
Locomotive repairs	40.2	31.5	40.1	30.7
Enginehouse expenses	10.4	7.4	10.2	6.7
Train enginemen	18.8	20.3	18.8	18.8
Locomotive fuel	47.3	43.9	46.3	41.0
Other locomotive supplies	4.0	3.2	3.8	2.9
Cost of train service per train mile	169.3	155.0	167.5	145.1
Locomotive repairs / Enginehouse expenses	57.7	45.2	57.1	43.4
Locomotive fuel	54 0	51.1	52.6	47.6
Other locomotive supplies	4.6	3.7	4.4	3.3
Train enginemen	21.5	23.6	21.3	21.8
Trainmen	25.1	26.6	25.6	24.4
Train supplies and expenses	6.5	4.8	6.5	4.6
Cost of train service per 1,000 gross ton miles	126.5	....	119.5	....
Locomotive repairs / Enginehouse expenses	43.1	....	40.8	....
Locomotive fuel	40.3	....	37.5	....
Other locomotive supplies	3.4	....	3.1	....
Enginemen and trainmen	34.8	....	33.5	....
Train supplies and expenses	4.8	....	4.6	....

The largest increases in the number of employees are shown in the mechanical department. A considerable reduction is shown in the number of train employees, attributable to the decreased volume of traffic.

A comparison of the number of employees and their compensation in December, 1917, and January, 1918, is presented in the table for the various classes of mechanical department employees and the men in the engine service.

ORDERS OF REGIONAL DIRECTORS

Superheaters.—The Eastern regional director, by circular 500-1-97A728, authorizes the application of superheaters to locomotives where all of the needed material is already on hand. The corporations must be consulted, but if material is on hand such consultation need not cause delay.

Record of Work at Enginehouses.—The Eastern regional director, by circular 1801-127A748, sends to federal mana-

NUMBER AND COMPENSATION OF EMPLOYEES IN OR ASSOCIATED WITH THE MECHANICAL DEPARTMENT (MONTH OF JANUARY, 1919, COMPARED WITH MONTH OF DECEMBER, 1917—CLASS I ROADS UNDER FEDERAL CONTROL)

Road passenger firemen and helpers	11,622	12,433	....	....	.694	.559	24

gers revised instructions for reporting, monthly, the number of man hours worked at enginehouses. This report goes to Frank McManamy, Washington.

Report on Reclamation of Materials.—The Northwestern Regional Purchasing Committee, in supplement 7 to circular 10, gives a list of items of material being reclaimed by various roads in this region. The list is long and detailed, containing about 800 items.

Preparation of Box Cars for Grain.—The Central Western regional director in a letter dated April 17 calls for immediate attention to the preparation of box cars for grain, and the providing of well-adapted temporary grain doors where needed.

Annual Passes for Employees.—The Eastern regional director, by circular 2100-9A750, advises federal managers that where an employee requires an annual pass over other than his home road, that pass should include also his transportation over the home road, so that he will carry only one pass for all.

Sanitary Maintenance of Cars, Shops, Etc.—The regional director, Eastern region, by circular 500-97A705 advises federal managers that a committee is at work standardizing the rules for practice in the maintenance of sanitary conditions in cars, shops, offices, etc. The committee wants copies of all such regulations now in effect.

Blacksmiths' Convention.—The regional director, Eastern region, by circular 102-37A745, approves the annual convention of the International Master Blacksmiths' Association, to be held at Chicago, August 19, 20 and 21. Each road will follow its usual practice in regard to allowing blacksmiths to attend.

Tinners' Convention.—The regional director, Eastern region, by circular 102-36A738, and the Northwestern director, by circular 77-1-93, announce approval of the convention which is to be held by the American Railroad Master Tinners', Coppersmiths', and Pipefitters' Association in June. Federal managers exercise their own judgment as to granting leave of absence and giving passes.

Employees' Passes for Conventions.—A. H. Smith, regional director, Eastern region, by circular 2100-37A716, advises federal managers that employees regularly elected as delegates to conventions of their brotherhoods are to be granted free transportation both ways; and ordinarily these passes will be issued at Washington. Trip passes for side trips should be requested and secured through the usual channels.

Violations of Inspection and Safety Appliance Laws.—The Central Western regional director in a letter dated April 19, states that, from the large number of reports which are being made by Interstate Commerce Commission Inspectors to the assistant director of the Division of Operation covering violations of federal inspection and safety appliance laws, it is evident that either the railroad inspectors are not adequately educated or they are careless. A systematic method of handling this matter is advised. Division master mechanics should keep a check upon whether or not the work reported by engineers is being done, and see that reports of violations of rules are followed by suitable discipline. Records should be kept of the violations at each terminal and of the employees responsible for them in each case.

ELECTRIC WELDED PATCHES

BY JOSEPH SMITH

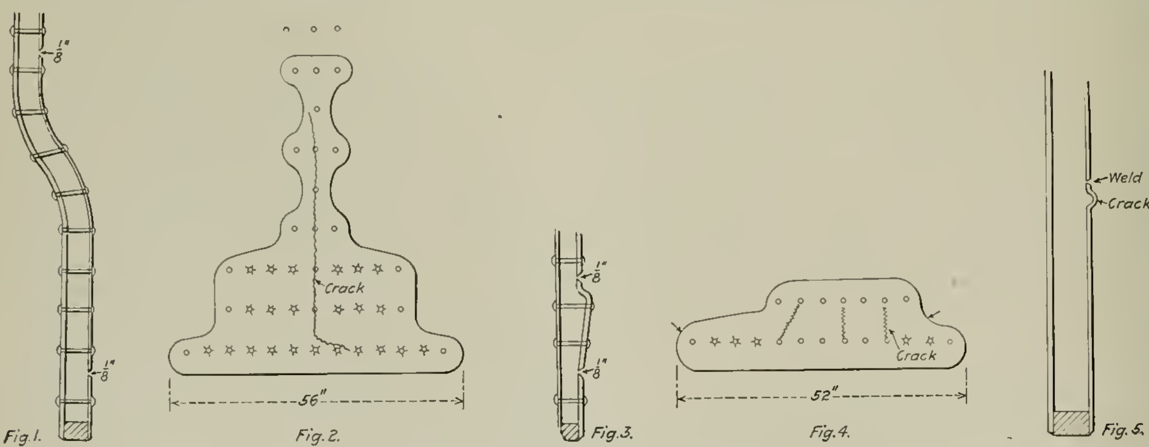
The subject of welding locomotive boilers is one of great importance and various methods of welding patches have been used with success. When patching side sheets the writer has used the electric weld and applied the patches as illustrated.

In the drawing, Fig. 1 shows a patch applied to the right side sheet of a heavy switch engine. The shape of the patch is as shown in Fig. 2 which also shows the crack that had developed in the side sheet.

Figs. 3 and 4 show the shape and application of a patch on the left side sheet of the same engine. This patch was offset 1¼ in. at the top and tapered down to the points indicated by the arrows in Fig. 4. This offset has been found preferable to that shown in Fig. 5, which not only gives trouble at the weld, but frequently cracks in the offset.

The stars in Figs. 2 and 4 indicate staybolt holes which were so badly fire cracked that it was necessary to remove that portion of the side sheet.

Both of these patches were fitted in place with the edges of the patches and side sheets beveled to about 30 deg. with ⅛ in. clearance all around as shown in Figs. 1 and 3. The staybolts were then applied, and the patches electric welded to the side sheets.



Two Electrically Welded Side Sheet Patches

The welding was done by an operator who had had only a few hours' instruction from an experienced welder, and considerable doubt was expressed that this method of patching would prove to be satisfactory. After three months of service, however, there has been no sign of failure or even sweat at the weld.

New And Improved Machine Tools And Shop Equipment

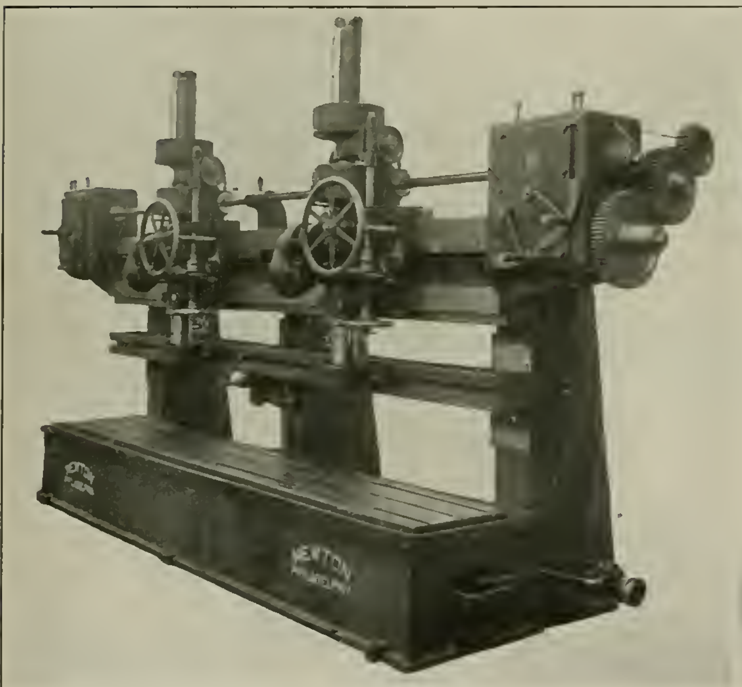
DUPLEX LOCOMOTIVE ROD BORING MACHINE

A DUPLEX locomotive rod boring machine, which was primarily designed for the boring of locomotive rods, but which may be used for the rapid production of parts which require heavy drilling, such as the reaming of cross-heads, etc., has recently been built by the Newton Machine Tool Works, Inc., Philadelphia, Pa. For work of this kind it is, of course, necessary to provide for a strong and rigid support of the spindles and this is particularly true where full advantage is to be taken of the maximum output with high-speed steel tools. The photographs convey some idea of the massiveness of construction which has been necessary to accomplish this.

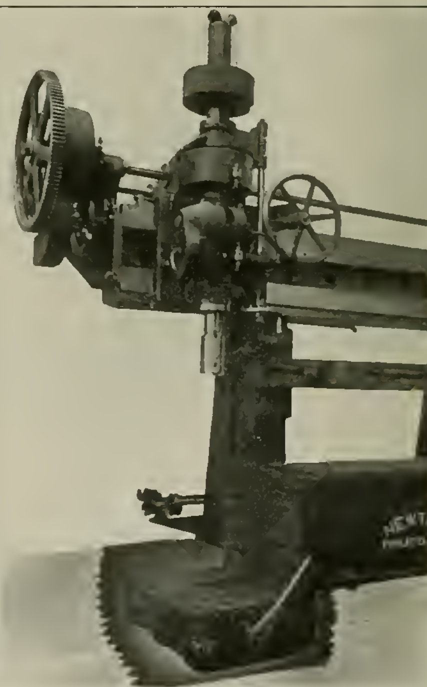
The most novel feature of the new design is the incorporation of the auxiliary side table. This is specially valuable for the reaming of cross-heads. The in-an-out adjustment of this table, supplemented by the longitudinal adjustment of necessity for drilling pilot holes for the boring bars. The kerf made by the cup cutters in no case exceeds $\frac{5}{8}$ in., and the cores are removable solid. The saving in time and power and of wear on the drills is, therefore, an important item. The twin spindles allow a duplication of center distances for similar rods. Two ends of one rod or one end of two rods may be bored at the same time, as may prove most desirable.

One of the photographs shows quite clearly the arrangement of the side table, while the other one shows the machine without the side table but with speed boxes applied for use with constant speed motors, or for single pulley drives. The changes in speed are made by means of sliding sleeves without the removal of the gears; each spindle is under the control of its own speed box, thus making it possible to suit the speed of each tool to the size of the work.

The top of the massive base is finished and slotted to form



Duplex Locomotive Rod Boring Machine With Speed Boxes in Place, But Without Side Table



Showing Application of the Auxiliary or Side Table

the spindle over the table, permits of clamping the work without having to locate it to the actual center. These adjustments also permit of drilling or boring a series of holes at one setting of the work. The T-slots on the vertical face of the adjustable table permit clamping the work in either a horizontal or vertical position, according to the convenience of the operator. The rail is extended to carry the spindle center 18 in. beyond the vertical face of the auxiliary table, thus giving a maximum distance between the spindles of 14 ft. 5 in. The side table is low to allow work of extra height to be placed under the spindle. For instance, the distance from the top of the side table to the spindle end is 50 in. maximum and 34 in. minimum. This corresponds to a maximum distance from the top of the main table to the end of the spindle of 25½ in.

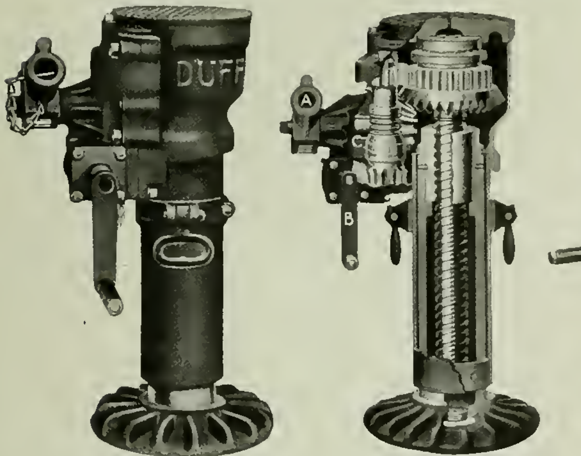
The machine utilizes cup cutters which dispense with the a working surface or table. It is surrounded by an oil pan, cast integral with the base. The rail is supported by the three uprights and is of heavy construction, of box type, braced internally by ribs. The spindle saddle has an angular bearing on the bottom section of the rail, insuring close contact under heavy pressure. The top bearing is square, the adjustment being made by a bronze taper shoe on the top and a gib bolted to the saddle on the rear. The saddle may be securely held in any predetermined position on the rail and is adjustable crosswise by means of a pinion. the end of which is squared to fit the removable ratchet.

The spindle revolves in bushed bearings in the sleeve and has a Morse taper, and drift and retaining key slots. The spindles are 4 in. in diameter with a diameter of spindle nose, outside of 5½ in. The minimum distance between spindle centers is 30½ in. The distance from the center of the spindles to the uprights is 17½ in. Each spindle is driven by a worm and worm wheel, the worm wheel having a bronze ring with teeth of steep lead; the driving worm is of hardened steel with roller thrust bearings. Both the worm and the worm wheel are encased for continual lubrication. The sections of the spindle fitting in the rack sleeve revolve in bronze bushings. The upper end of the spindle and the rack sleeve are encased and protected from dust and dirt by covers which also serve as a support for the counterweight. Thrust of the worm is taken by a bearing cast solid with the saddle.

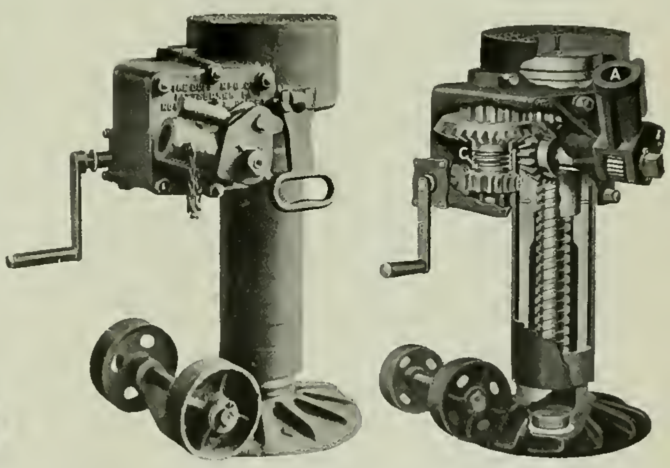
Motion for the feed is provided through spiral gears, one of which is mounted on the spindle sleeve; the other is keyed to the horizontal pull pin shank on which are also mounted four pull pin gears, giving four changes of feed which are transmitted to the rack sleeve by means of a worm and worm wheel. A cone friction clutch permits either power or hand elevation. The saddles have hand adjustment on the rail. The auxiliary or lower support for the spindles has a bearing on each upright; it securely supports the spindles at the lowest possible point when cutting, and is raised and lowered by means of a worm and worm wheel. The work table is 24 in. wide and 13 ft. 6 in. long.

HIGH SPEED BALL BEARING SCREW JACKS

An improved type of high speed ball bearing screw jack has recently been designed by the Duff Manufacturing Company, Pittsburgh, Pa. These jacks are specially adapted for the handling of railway equipment and are made in several sizes of three capacities: 35-ton, 50-ton and 75-ton. The high speed feature is obtained through the use of a large pitch, double-thread screw, and safety is insured by a patented automatic, positive safety clutch. The load is raised by placing a long solid steel bar in the lever socket *A* and operating it up and down, the load being raised on each down stroke. The positive clutch *C* holds the load at all times and prevents the possibility of sinking or dropping under the load. A few easy turns of the handle *B* allows the load to be lowered quickly. Regardless of the speed at which the jack may be descending, the lowering handle may be stopped with absolute safety to within a thousandth of an inch of any desired point. So little effort is required to lower the load that a boy can operate the 75-ton jack with ease. By turning the lowering handle in a reverse direction, it is possible quickly to raise the jack up to the load.



External and Sectional Views of 35-Ton and 50-Ton High Speed Jacks



External and Sectional Views of the 75-Ton High Speed Jacks

The thread of the large double screw is so steep that the jack would run down under its own weight were it not for the positive safety clutch. It is, of course, the combination of the steep thread screw and the positive clutch that provides for speed and safety. The screw is made of special steel and turns in a hard bronze nut, having a tensile strength of 90,000 lb. per inch. The combination of bronze and hard steel materially reduces the friction. The base, consisting of the foot and the stem, is made in one piece of cast steel; the shell is of steel tubing; the bonnet and hood of cast steel, and the gears, clutch, shafts, etc., of open hearth machinery steel with the more important parts heat-treated. The pinion shaft is fitted with a heavy phosphor bronze bearing bushing. The ball bearing in the head consists of two chrome nickel steel discs, hardened and containing large hardened alloy steel balls tested to a crushing strain of 110,000 lb. each.

The design and workmanship are such as to reduce the friction to a minimum. To provide for lubrication the inside of each jack is packed with a semi-fluid grease, in which all of the moving parts revolve. The composition of the grease is such that it is not affected by heat or cold and will not leak. Oiling places are provided for the lubrication of every part which requires lubrication and is not reached by the grease.

These jacks may be fitted with foot lifts for the convenient handling of low loads; the toe lift is cast integral with the shell. The 75-ton jacks, which are specially adapted for heavy locomotive work, may be equipped with wheels, as shown in the illustration, to facilitate handling.

The 75-ton jack is made in three sizes as follows:

26 in. high	12 in. lift	weight 360 lb.
24 in. high	10 in. lift	weight 345 lb.
20 in. high	6 in. lift	weight 315 lb.

The 50-ton capacity jack is made in three sizes as follows:

36 in. high	24 in. lift	weight 270 lb.
26 in. high	14 in. lift	weight 235 lb.
24 in. high	12 in. lift	weight 228 lb.

The 35-ton jack is made in two sizes; one 30 in. high, 17 in. lift, weighing 175 lb.; and the other 26 in. high, 13 in. lift, weighing 163 lb.

TWENTY-ONE INCH VERTICAL DRILLING MACHINE

THE vertical drill shown in the illustration is a modification of the standard machine made by the Weigel Machine Tool Company, Peru, Ind. The regular quick return and power feed with back gears have been replaced by a plain quick return operated by four extra levers mounted in the form of a pilot wheel which provides a powerful hand feed. The control lever operating the friction clutch for starting, and acting as a brake for stopping the drill, is conveniently placed for the operator.

The spindle is driven through a friction type back gear device enclosed in the oil-tight box which is cast as an integral part of the top of the frame. An improved tapping attachment may also be furnished and is placed directly on the spindle.

The standard machine, which is furnished with the friction type back gear contained in a box casting similar to that shown on the top of the frame of the drill illustrated, provides eight feeds for each spindle speed, as indicated by the feed plate attached to the machine, and the same type of lever which is used for starting and stopping the plain hand feed machine is employed on the standard type. A special back gear lever provides means for throwing the gears in and out of mesh. Feeds per revolution of the spindle run from .004 in. to .0432 in., and an automatic stop is provided which can be set to throw out the feed at any predetermined depth.

The plain hand feed machine, as well as the standard power feed machines, are made in 21-in. and 25-in. sizes, and may be arranged for either direct gear motor drive by a 3-hp., 1,500 r.p.m. motor, or for drive by belt. The lower cone pulley is covered by a cast housing and the tight and loose pulleys in the belt drive type have an adjustable cast guard. The mechanical belt shifter, a detail small in itself, contributes to a saving of time.

The base of these machines is heavy and well ribbed underneath. A slot is provided at the front and rear to accommodate a bar for moving and placing the machine when setting it up on a solid floor. The spindle has a 9-in. vertical travel and a No. 4 Morse taper. The column is tubular in section and has an extra large bearing for the table arm, as well as for the sliding head.

The table is 19-in. in diameter and has a traverse of

Vertical Drill With Powerful Hand Feed

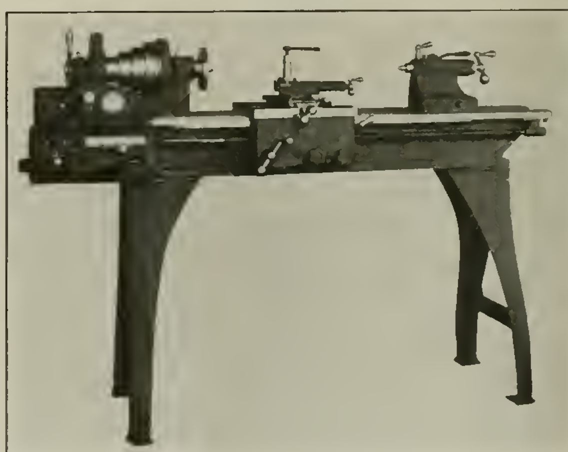
13½ in. on the column. A square table with an oil pan can be furnished instead of the round table. The table is raised and lowered by rack and pinion through a worm gear.

QUICK CHANGE ENGINE LATHE FOR SMALL WORK

THE new 11-in. Star quick change engine lathe in 4, 5, 6 and 7-ft. lengths of beds, has been recently added to the line of tools manufactured by the Seneca Falls Manufacturing Company, Inc., Seneca Falls, N. Y. Because of their wide range for exacting service on light and accurate work they should commend themselves generally to railroad shop tool rooms and testing laboratories.

The smaller size (4 ft.) occupies a space of 27 in. by 64 in.; the largest (7 ft.) requires 27 in. by 100 in. floor space; distances between centers range from 24 in. to 60 in. The actual swing over beds is 12⅛ in. Threads from 6 to 40 per inch may be obtained with a simple, quick change mechanism. By the shifting of a gear on the stud, the range may be increased from 3 to 92 threads per inch, including 11½ per inch, all of which are plainly listed on the index plate on the face of the machine. A special countershaft with three friction pulleys may be furnished to give higher speeds for wood turning.

Details of the construction of these new tool room lathes include a web pattern headstock and a hollow spindle made from carbon crucible steel, accurately ground to size, revolving in ample hand-scraped ring oiling bearings; the nose is threaded part way only to facilitate changing chucks and face plates without damaging the threads and to insure perfect fit. The spindle has a large hole suitable for a draw-in chuck. The cone is locked to the head-gear by an improved



11-Inch Quick Change Engine Lathe

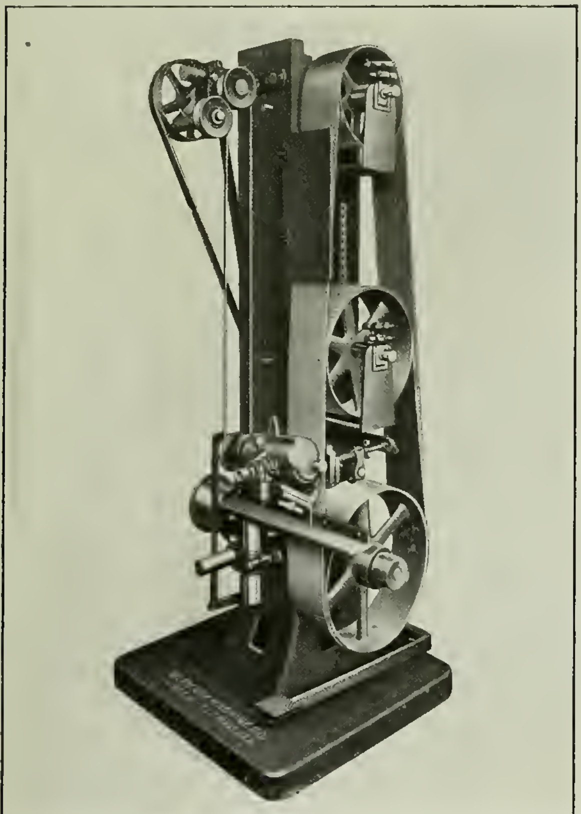
push pin and may be secured or released instantly without using a wrench; all gears are fully guarded. The tailstock has a large spindle with a self-discharging center.

The cross-feed screw on the carriage is supplied with a micrometer collar graduated to read in thousandths of an inch, secured by friction spring and readily set to any position. An adjustable stop for the cross-slide is provided for screw cutting, etc. Feeds may be thrown in or out by turning a hand knob on the apron, which operates a friction clutch. The automatic power cross feed is indispensable for good work; it insures accurate results and smooth surfaces when facing and other similar work. A new safety device is provided in the apron, so that the opposing feeds cannot be engaged at the same time.

The countershaft has two improved clutch pulleys with a large friction surface on the rim of the pulley. Wear on friction parts when the pulley is running idle is eliminated. The net weight of these machines varies from 720 lb. in the 4-ft. model to 985 lb. in the 7-ft. model, complete with countershaft.

AN ADAPTABLE FINISHING AND BUFFING MACHINE

FOR rapidly polishing and finishing round, flat or curved shapes, grinding flue and tube ends, buffing nickel plated parts, such as car fittings and fixtures, the vertical abrasive finishing machine, embodying a patented two-belt system of finishing, with an abrasive cloth belt running at high speed over a heavy corrugated leather cushion belt, is a most important development in the art of abrasive finishing. Without mechanical holding device or power feed attachment, the work is held by hand and produces a finished product of a superior nature, whereas with a mechanical holding device and the power feed attachment, the machine becomes automatic in operation and its production is limited only by the ability of the operator to handle the work, which can be performed by unskilled labor.



Vertical Abrasive Finishing Machine

The Blevney Machine Company, Greenfield, Mass., will exhibit one of its type A-6-14 machines illustrated herewith, as well as one of its type *F* horizontal finishing machines and a type *A* automatic polishing and finishing machine with power feed attachment, at Atlantic City.

The machine has a heavy cast iron column, providing the necessary rigidity for high speed operation. Steel ways are attached to the column, and the sliding frames in which the idler pulleys operate travel on these ways. The cushion belt is run over the main pulley and the idler next above, traveling at a speed of 7,000 ft. per minute. The cloth abrasive finishing belt is placed over the cushion belt but extends to an idler pulley at the top of the machine. The idler pulley frames in both cases are governed by weighted levers having a fulcrum journaled wheel and steel pinion, forming connection with a steel rack attached to the frame. These weighted levers stand in a horizontal position when the machine is in operation and are governed by a spring which holds the pinions in engagement with the rack. By pulling the fulcrum against the action of this spring the pinion becomes disengaged and the lever may be moved to any desired position, the spring restoring the engagement between the pinion and the rack.

The alinement of the two belts may be controlled by means of the handwheels on the idler pulley boxes, these wheels serving to tilt the pulleys so that the position of the belts may be changed as desired.

A suitable holder or stock rest is provided for holding the stock and for the application of fixtures and attachments. A spring platen or pressure bar is applied back of the cushion and finishing belts, the action of which is controlled by a foot treadle; stops are furnished to limit the forward and return movement of the platen. The face of the platen is made to suit the work to be finished. For plain flat work, the platen has a plain face, whereas, for finishing tubes or round pieces, parallel strips are placed at the top and bottom of the platen, causing the belt to curve around the circumference of the stock being finished. Where desired the platen may be made sectional, or special rotating platens may be furnished with yielding centers.

The productive powers of this machine are made possible through the use of the two-belt system. The corrugated leather cushion belt runs at 7,000 ft. per minute; the cloth abrasive finishing belt which runs over it operates at a slightly increased rate of speed, due to the larger driving member, which is increased in size by twice the thickness of the cushion belt. The increase in speed is slightly more than one inch on each revolution of the main pulley. This creeping is neutralized in operation when the pressure is applied behind the belts, with the result that the travel of the abrasive belt is somewhat retarded at the point of work, so that it must curve into the high and low sections. In this manner high points are obtained for cutting and low points for chip recesses. The corrugations in the leather cushion belt assist in providing chip recesses. After the belt has passed the point where the work is held, it, of course, resumes its normal position and this action throws off or expels.

the chips. A joining machine is used in making the abrasive belts endless; the method employed is such that the thickness is practically no greater at the joint than at any other part of the belt. By this process, not only is a strong belt possible, but one which runs smoothly and evenly and does not jump over the work at the point of joint.

Coarse belts after being first used for roughing, are later dressed down for finishing in various stages until they are finally used as greased belts for the finest finishing.

The cloth abrasive belts do away with centrifugal action upon the finishing grains when they are under strain and provide a uniform speed for each cutting grain. It is claimed that there is practically no loss in abrasive material through the use of the cloth finishing belts.

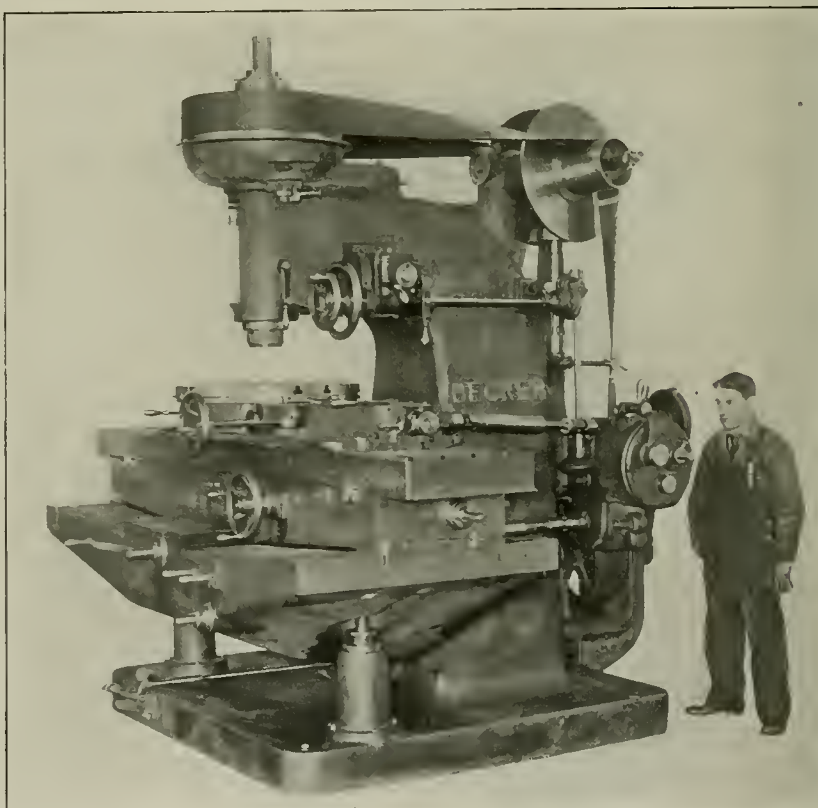
A MONSTER VERTICAL MILLING MACHINE

The model D-1 vertical milling machine, shown in the illustration, is perhaps the largest machine of this type ever built, and was developed primarily by the Becker Milling Machine Company, Hyde Park, Boston, Mass., for die sinking work in connection with the drop forging industry. When equipped with a rotary table, however, it is specially adapted to heavy milling work. The machine weighs approximately 18,000 lb.; the greatest distance between the spindle and the main table is 22 in., and between the spindle and the rotary table 13 in. The greatest distance from the center of the spindle to the frame is 25½ in. Aside from its large size, however, the machine includes several important and interesting features.

It was necessary to make the movable knee (96 in. long) of specially heavy design; it is supported by telescopic screws at each end and on the frame by the Becker patent gib. The screws are accurately co-ordinated so that they work in perfect unison. The knee is elevated and depressed by a single control wheel when operated by hand, but this operation may be performed by power by simply throwing in a clutch. The knee has a vertical feed of 20 in. The saddle, of rigid construction, has three bearing points on the knee. It is of extra length (96 in.) and supports the movable table throughout its entire length.

All of the control levers are centrally located so that the operator can watch the work and control the machine without undue exertion. The table is provided with power rapid traverse in either direction and a fine hand adjustment from the operator's position in front of the knee or at either end of the table. Hand adjustment for the cross and vertical feeds is provided for at the center of the knee. The table has a working surface 20 in. wide and 96 in. long with an over-all working surface 110 in. long. It has a longitudinal feed of 79 in. and a cross feed of 20 in. There are three T-slots ¾ in. wide; also oil grooves on the sides of the table with an oil pan at each end for collecting the lubricant. Micrometer dials are provided on the transverse and longitudinal feeds and the Becker micrometer stop gage in the spindle head provides for operations requiring decimal accuracy.

The spindle is of the Becker-Barrell type construction and is provided in addition to the above-mentioned micrometer stop gage with an adjustable automatic stop, and a fine hand adjustment and quick return mechanism. The spindle has a vertical power feed of 13 in. and is back geared and driven by a 6-in. double belt in order to insure smooth action and the elimination of chatter. It has a main bearing 4 in. in diameter and 9⅞ in. long. The feed per revolution of the spindle with open belt is .003 in. to .09 in., and with back gears .013 in. to .46 in. Three changes of feed are obtainable by means of gearing in the feed box, but a wide range of feeds of any desired amount within the above limits may be obtained by the Becker patent friction feed.



Becker Standard Model D-1 Vertical Milling Machine.

When belt driven the machine is provided with a single pulley drive having a gear box with seven changes of speed, thus giving the spindle 14 speeds, ranging from 45 to 260 r. p. m. with the open belt, to 9 to 51 r. p. m. with the back gears. The machine may, however, be arranged for a 10 h. p., 850 r. p. m. motor, or for a motor having a speed range with a ratio of 4 to 1, in which case the speed box is not necessary.

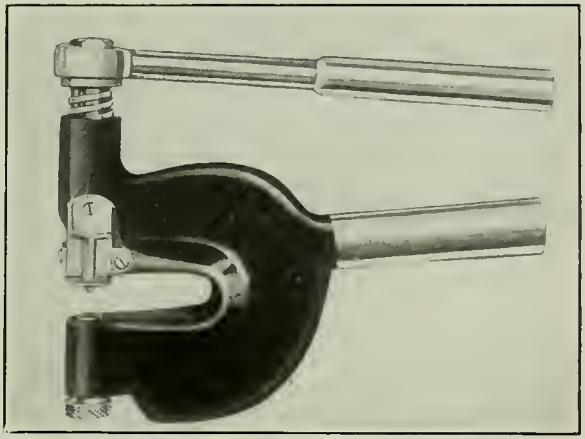
PORTABLE QUICK-ACTING HAND PUNCH

A PORTABLE and compact punch, which at the same time is powerful and quick-acting, has recently been placed on the market by Paul W. Koch & Company, Chicago, and is known as the "Jiffy" punch. It weighs five pounds, is 9½ in. long, will work in a small space, and punches holes up to ¼ in. in metal as heavy as 10 gage. Very little oiling is required and no adjusting.

As may be seen from the illustration, the throat is deep and this, with the one-piece, automatic, disappearing stripper, gives a clear view of the punch and punch mark for the next operation. Several sheets may be punched with one operation.

The crowned punches of the floating type direct the power to the center and will not twist or turn during the operation, thus reducing the possibility of punch breakage. These punches do not leave a burr on the metal.

Several features contribute to the convenience of the operator. Among these is the absence of long, clumsy handles; the operator is brought close to the material and can follow the punch marks quickly and accurately; only a half turn of the lever is required to drive the punch through the metal; the handle is above the center and naturally tends to keep the punch upright.

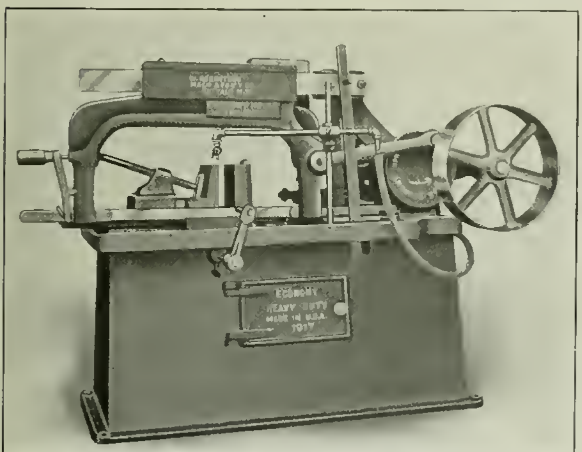


"Jiffy" Portable Speed Punch

The punches and dies may be changed easily. There may be some classes of work with which it is desirable to clamp the punch in a vise; this can readily be done with the Jiffy punch.

A POWER METAL SAW WITH TWO SPEEDS

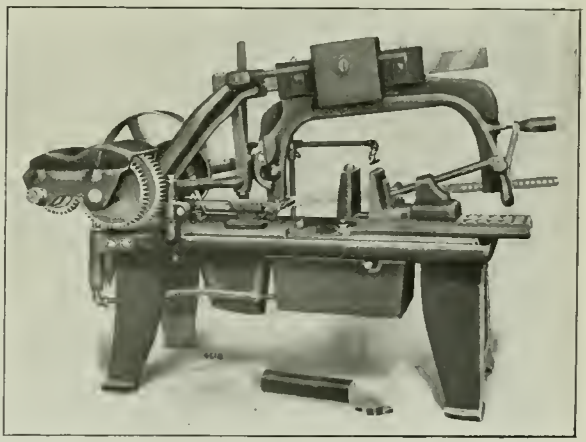
A HIGH speed power metal saw arranged to provide two speeds is being built by the W. Robertson Machine & Foundry Company, Buffalo, N. Y. The latest model, known as Economy No. 40, has a capacity for cutting material up to 8 in. by 8 in. in section. The two speeds make



Front View of Power Saw With Box Base

it possible to use the proper speed for either hard or soft metals. The arrangement for changing speeds is simple. Two pinions—24 and 32 teeth—are mounted on the back or driving shaft; they mesh with gears on the crank shaft having 58 and 50 teeth respectively. There is a hardened steel clutch between the pinions on the back shaft, which can be made to engage with either one of the pinions or take a neutral or central position, leaving the machine idle. The clutch is operated by the knob at the end of the drive shaft. The machine stops automatically when the cut is completed.

These saws are arranged to cut on the draw stroke and lift on the idle or return stroke, thus relieving the teeth of all drag. This is controlled by what is known as an oil lift which consists of a two-cylinder pump submerged in a tank of oil. One piston is connected with the frame which carries the saw and the other with the crank shaft. At the end of the cutting stroke, oil is forced under the piston connected to the frame, lifting it, and at the beginning of the cutting stroke the pressure is released as the piston passes a small port, a 1 in. steel ball acting as a valve; there are no deli-



Rear View of Power Saw Showing Back Gears for Obtaining Two Speeds

cate or complicated parts in this mechanism. It is impossible for the frame to fall and break blades while the work is being adjusted.

The cutting lubricant is supplied from a tank in the base of the machine by means of a plunger pump, the oil draining back into the tank. The vise is quick-acting and swivels to 45 deg. for cutting angles. Saw blades from 12 in. to 17 in. are used, No. 18 gage being recommended. A modification of this design, known as the 40B, is fitted with a box base forming a larger receptacle for the cutting compound. A machine of this latter design weighs 600 lb.

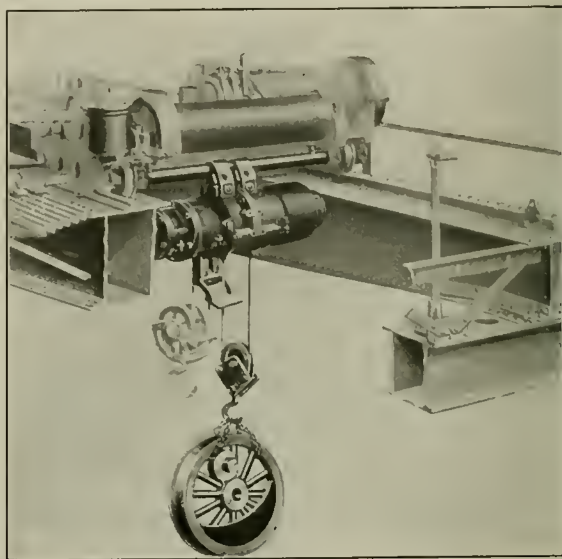
AUXILIARY HOIST FOR TRAVELING CRANES

A SIMPLE and practical auxiliary hoist for attaching to any standard overhead electric traveling crane, has recently been developed by N. B. Payne & Company, 25 Church street, New York.

This hoist can be quickly and easily attached, it does not take up any additional room overhead, does not require an extra trolley, does not shorten the travel of the trolley on the bridge and does not interfere with the accessibility of the main hoist.

The average traveling crane handles a far greater number of light loads than heavy loads. As cranes for lifting heavy loads are slow moving, their use results in a serious loss of time if they handle the light loads. Thus a 20-ton crane with a hoisting speed of 12 ft. per minute will handle a three-ton load at but slightly greater speed, but with the auxiliary hoist a load of three tons may be handled at a speed two to 10 times higher than the speed of the main crane.

This auxiliary also effects an important power saving. Very often the hook and block of the main crane together weigh more than the load handled, and as the auxiliary hook and block are much lighter it is evident that the power saving is appreciable. The labor saving with the auxiliary hoist is another item worthy of consideration, especially when a gang of men must wait to have a small piece slowly moved by a large crane.



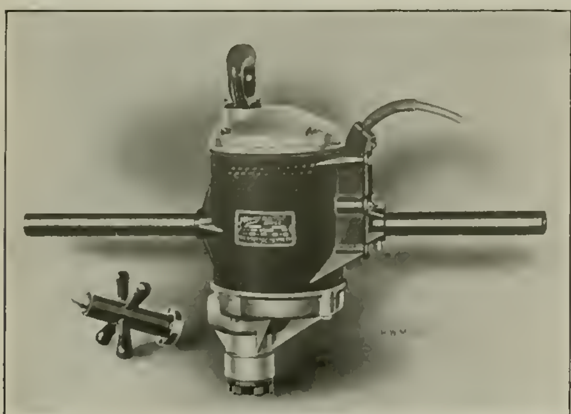
Application of Auxiliary Hoist to Traveling Crane

By the application of this auxiliary attachment any standard single hoist electric traveling crane may be equipped with two lines for drop bucket service. The control may be arranged from cage, floor or pulpit to suit the crane to which it is applied.

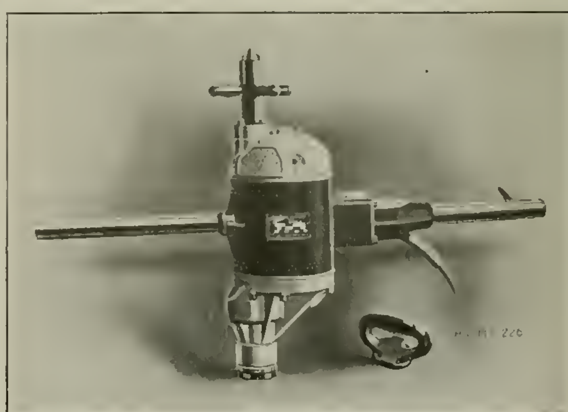
Usually standard auxiliary hoists of from one to five tons capacity, suitable for the type of crane, electrical equipment and type of control, are supplied by the makers to meet ordinary requirements, but larger special sizes are furnished when specified.

ELECTRICAL DRILLING AND REAMING MACHINES

PART of a new line of heavy duty electrical drilling and reaming machines has been completed by the Hisey-Wolf Machine Company, Cincinnati, Ohio. Typical examples of this line are shown in the illustrations. In order to secure the necessary capacity and yet keep the weight within reasonable limits, it has been necessary to use the very best materials and go to the greatest refinements in design. The motor is, of course, the critical part of the machine and special attention has been given to forced ventilation in order to keep the temperature as low as possible; this is accomplished by means of a fan attached to the armature shaft. The machines may be provided with either direct current or

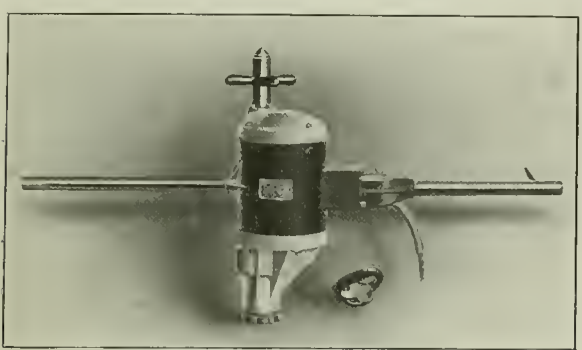


¾-Inch and 1-Inch Electric Drill



1¼-Inch Machine With No. 3 Morse Taper Socket

alternating current motors. The larger sizes are equipped with automatic switches, the instantaneous and positive ac-
contacts.
tion of which practically eliminates arcing and fusing of
The main spindle bearing is made of bronze and is large enough to withstand the effect of the irregular drilling pres-



1¾-Inch Machine With No. 4 Morse Taper Socket

sures. Ball bearings are used wherever applicable; all the bearings are completely enclosed and wherever necessary felt protector washers are supplied. The bearings, gears and other moving parts in the gear end of the motor are supplied with a lubricant from the gear transmission case. The ball bearing on the commutator end is packed with grease.

The side handle, opposite the switch handle, is removable in order to adapt the machines for close corner drilling. In some cases, it is necessary to have perfectly balanced machines, and two sizes of heavy duty drills have been designed with a center spindle drive, the drill spindle being in line with the center of the main body. One of these sizes has a capacity for drilling ¾ in. or reaming 9/16 in. holes in metal, or drilling 1½ in. in wood; the other size has a capacity for drilling 1 in. or reaming 11/16 in. in metal or drilling 2 in. in wood.

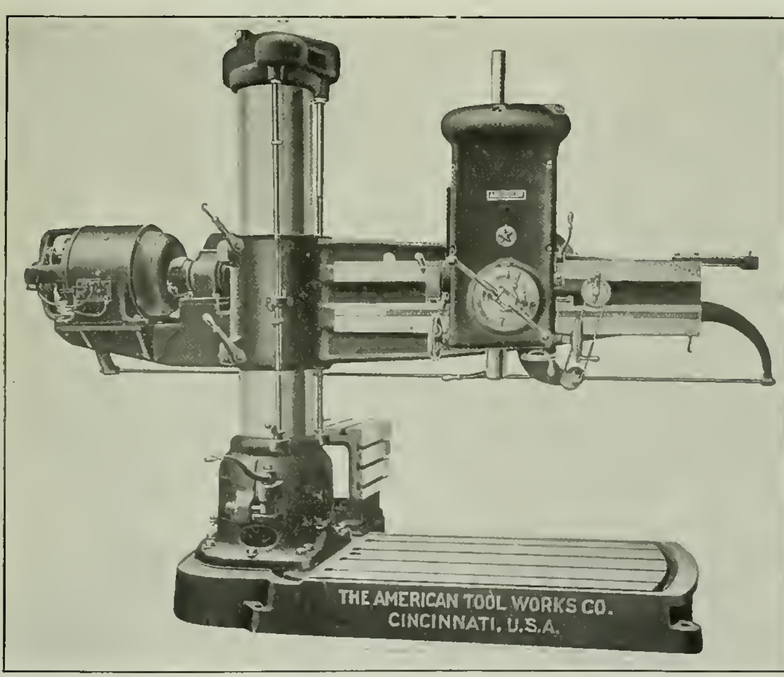
Certain of the machines are designed for two speeds, the change in speed being made by a gear shifting device operated by a thumb nut on the outside of the gear end cap. This insures positive engagement of the gears but speeds may be changed while the machine is in operation.

These drilling machines are not regularly furnished with a breast plate because there is seldom need for this attachment on the larger portable machines; it may, however, be furnished, if desired. The electrical connections are made by means of spring contacts wherever practicable. Provision is also made for renewing the attaching cable without disturbing other parts of the machine.

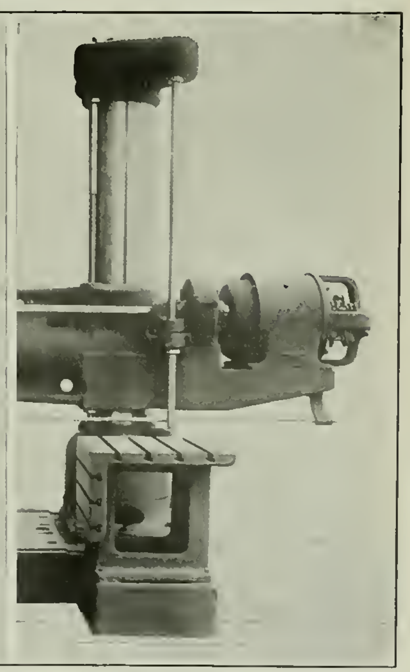
The heavy duty alternating current machines are now available for drilling metal in the following capacities: ¾ in., 1 in., 1¼ in. and 1¾ in. The direct current machines are made for drilling 1¼ in. in metal or 3 in. in wood. Other sizes up to a capacity for drilling 2 in. in metal are expected to be ready shortly.

SIMPLIFIED MOTOR DRIVE FOR RADIAL DRILL

The problem of applying power for driving radial drills has always been a difficult one and it was not simplified by the introduction of the individual motor for driving machine tools. Many of the earlier applications, for instance, required two motors—one for driving the machine, and the other for elevating and lowering the arm. Improvements in the motor drive have, however, been made steadily in recent years and a radical change has now been brought about by the American Tool Works Company, Cincinnati, Ohio, in the application of what it designates as a "Simplified



Simplified Motor Drive for 6-Ft. Triple Purpose Radial Drill



Rear View of Motor and Column

motor drive" to its "triple purpose" radial drills. As shown in the illustrations, the motor is mounted on the arm in such a way as to partially balance the weight of the working portion of the arm and the head; incidentally, this relieves the cramping tendency on the column sleeve, facilitating the swinging of the arm.

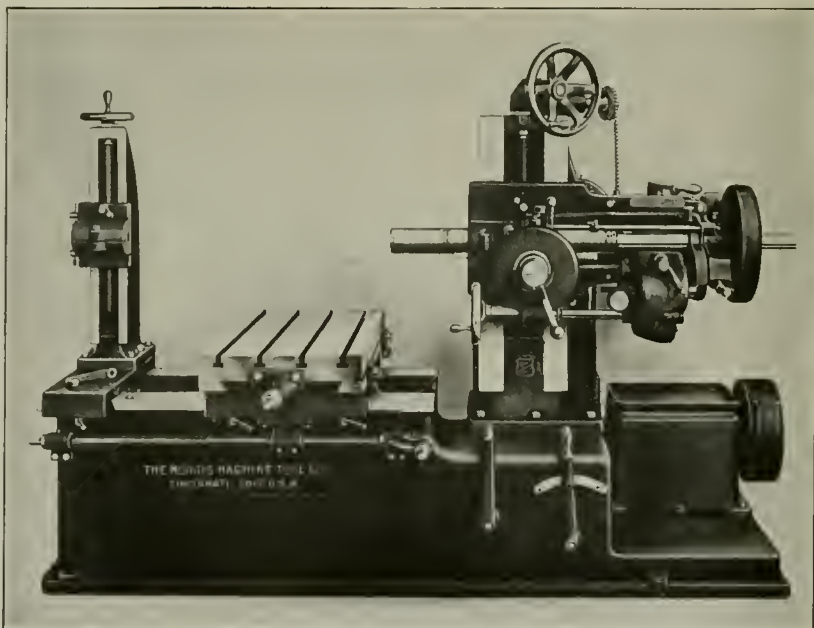
The principal advantages of the new application, however, are in the elimination of a number of bevel gears, spur gears and long shafts which are required when the motor is mounted at the base of the machine. It is estimated that 50 per cent of the gear friction in the drive is thus eliminated and that there is a corresponding decrease in the bearing friction. As a result the cost of maintenance should be very considerably reduced, as well as the amount of power required to operate the machine. Taking the motor off of the floor, away from the dust and dirt, is another desirable feature, not alone from the reduction in wear and tear on the motor, but also from the fact that the space formerly occupied by the motor can be utilized for working purposes. The problem of oiling the machine is simplified because of the smaller number of bearings. The control for the electrical equipment is mounted on the head of the drill making it possible for the operator to start and stop the motor at will and vary the spindle speeds without changing from his working position.

Four mechanical speed changes to the spindle are provided in the head but this is not sufficient where it is desired to handle a variety of work and it is, therefore, necessary to provide a variable speed motor. This limits the application to places where it is possible to secure direct current for the drive. A semi-enclosed 3 to 1, approximately 400 to 1200 r. p. m., direct current motor and a drum type, non-reversing, variable speed controller, of the smallest frame obtainable, are recommended by the makers of the machine. The 6-ft. "triple purpose" radial drill which is shown in the illustration was described in the *Railway Mechanical Engineer* of May, 1917, page 271.

HORIZONTAL BORING AND DRILLING MACHINE

A HORIZONTAL boring and drilling machine, adapted for drilling, boring, facing and tapping has recently been developed by the Morris Machine Tool Company, Cincinnati, Ohio. It is simple in construction and so arranged that all of the control levers are within each reach of the operator. The head, of heavy construction, is counterbalanced and slides on wide ways fitted with taper gibs which are adjustable for wear. The head may be raised and lowered by means of the hand wheel at the top of the column. A steel scale is set in the column and is graduated in sixteenths of an inch; this, in connection with the micrometer collar on the elevating screw, enables readings to be made in thousandths of an inch for the full travel of the head.

The spindle is 1-15/16 in. in diameter at the smallest section with a diameter at the nose of 3-11/32 in. It has a traverse of 17¼ in. The maximum distance between the spindle and the table is 20 in. and between the spindle and the outer support 48 in. The thrust of the spindle is taken by ball bearings. The spindle sleeve is graduated and is provided with a direct reading depth gage. The gears which drive the spindle are helical, the angle of the teeth being just great enough to have more than one tooth in mesh and at the same time avoid end thrust. This insures uniform power at the cutting point of the tool and eliminates any chatter. The feed box is mounted on the head, the feed gears being fully enclosed and running in heavy oil. Six feeds, ranging from .006 in. to .03 in., are available and are marked on a dial in thousandths of an inch advance per revolution of the spindle. The feed may be automatically tripped at any depth within the traverse of the spindle.



Morris Horizontal Boring and Drilling Machine

As may be seen, the speed box is mounted on the end of the bed. It is fully enclosed and the gears run in a light grease. The two vertical levers at the front of the bed directly below the column control the six speeds provided by the speed box. The left-hand lever controls the double friction clutch on the pulley shaft and the right-hand lever three sliding gears. There are 18 spindle speeds in all.

The back gears are made of 3½ per cent nickel steel, are fully enclosed and are mounted on the back of the head. The bearings throughout are of bronze arranged with oil chambers, the oil being drawn into the bearings by felt wipers.

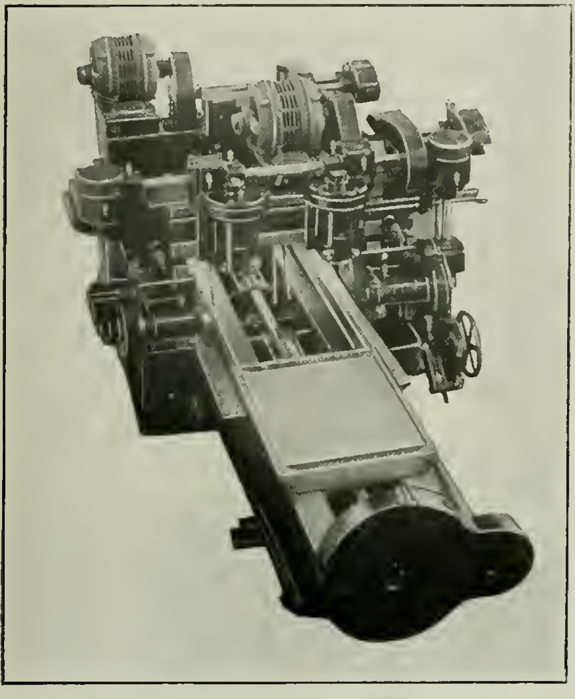
The table has a surface of 20 in. by 36 in., a longitudinal movement of 31 in. and a cross movement of 28¾ in. The top of the table is 31 in. above the floor. The bed is a one-piece box section heavily ribbed; the column is also of box section with as large an area as possible where it rests on the bed.

The machine may be arranged for either a 3 to 1 variable speed motor, connected to the lower shaft by a single pair of gears, or for a 5 h. p., 1200 r.p.m. constant speed motor.

HEAVY HORIZONTAL CONTINUOUS MILLING MACHINE

THE elimination of all possible lost motion and unproductive time in operation is the keynote in the design of the horizontal multiple unit milling machine shown in the illustrations which records a notable advance in the development of this type of machine tool.

Each pair of uprights with its bank of spindles constitutes one milling unit; as many spindles may be mounted on a unit as is considered necessary, and as many units may be attached to the bed as are required to do the work, although two, as shown in the illustrations, are usually considered sufficient. The feed driving mechanism is carried on one unit only.



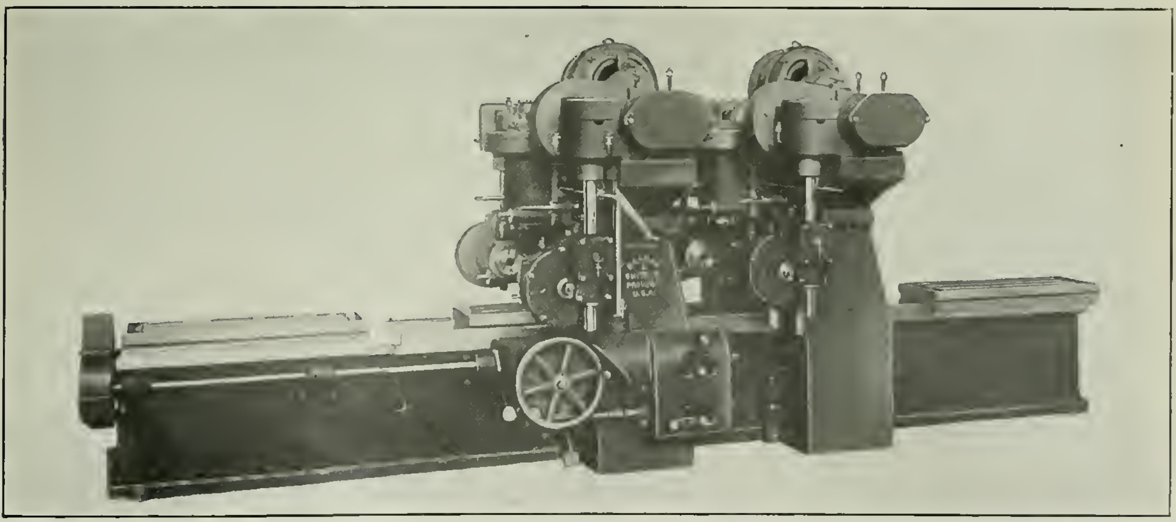
Looking Down Upon Continuous Milling Machine

Removable tables, carrying the work, feed continuously along the bed, taking a fast motion when the cutters are idle and a slow motion when the cutters are working. After passing all of the cutters, the tables are lifted from the bed and the finished work removed. Another table with the work already attached, is placed on the front end of the machine and the process is repeated; as many tables are furnished as are necessary to maintain continuous milling. Such machines will handle on one trip of each table, any milling required on two sides and the top of any piece within its capacity, and by loading the tables to capacity, a large amount of work may be handled in a comparatively short time. The machine once started need not be stopped until it is desired to change the cutters or to accommodate new work.

The bed ways on which the tables travel are flat, with slight tapers on the inside edges to accommodate corresponding tapers on the bottoms of the tables. These center the tables without wedging them and allow them to be put on and taken off rapidly. The tables hold themselves in position by gravity while traveling, except while passing by the cutters, where they pass under gibs, fastened to the bed, which hold them against all vertical movement while the cuts are being taken. A feature of the table design is the narrow guide which is tapered; this makes for the maintenance of a greater degree of accuracy through a longer period than the common wide guide; there is a taper gib to take up the wear.

A feed shaft, which runs the entire length of the bed and is driven from the front end, carries a series of worms which engage in a rack on the bottoms of the tables and are spaced at such intervals that the traveling tables are picked up by one worm before they have completely left the other. The spacing of the worms makes it impossible to set a table in the wrong position on the bed, so that no matter where it is set, it will pick up and travel instantly. The tables have feed in one direction and fast motion controlled by hand in both forward and reverse.

There are four changes of feed through the gearing, providing a variation of from approximately 3 in. to 8 in. a minute, with a fast motion of about 12 ft. a minute when the cutters are idle. Two changes of feed are possible through



Continuous Milling Machine

change gears at the end of the gear box and two more are possible through a feed gear shifting lever. The feed and fast motion are controlled by one lever which makes it impossible to throw in both at the same time. The object of the feed gear shifting lever is to slow down the feed as occasion may require. The feed mechanism is driven by means of a vertical shaft connected through bevel and reducing gears to the main drive shaft.

Each unit is motor driven. The motor and driving mechanism are carried on the crossrail, and the drive shaft is geared direct to the motor which, through reducing gears, drives the vertical and horizontal spindles. Through change gears which are easily accessible the spindles can be given various speeds.

The heads are of rigid construction, cast in one piece, and are adjustable along the ways by means of hand operated screws; the wear may be taken up by taper gibs. When a cutter is located the head is clamped firmly in position.

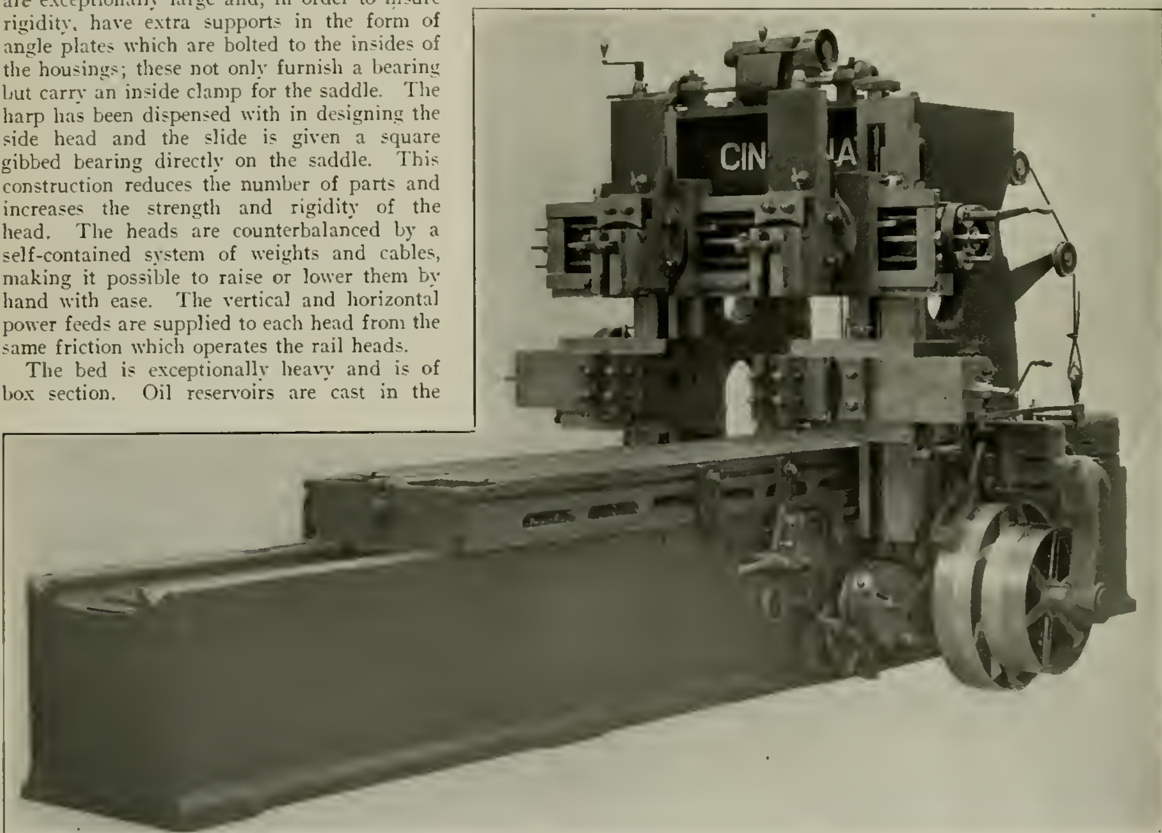
Spindles are furnished in three standard sizes, the largest diameter in the front bearings being $3\frac{5}{8}$ in., $4\frac{5}{8}$ in. and $5\frac{5}{8}$ in. All sizes may be incorporated on one machine and in heads located as the occasion requires; they are furnished with adjustment in and out of the heads, by pinion and rack. The pinion is held in the head and the rack is on the spindle quill. The quill is held in its final position by being clamped and the machine is controlled at the unit which carries the feed gears. One of the illustrations gives an idea of the relative proportions and arrangements of the machine from the starting end and shows a work table in position for feeding toward the first unit.

These continuous milling machines are manufactured by the Beaman & Smith Company of Providence, R. I.

EXTRA HEAVY DUTY OR SPECIAL FORGE PLANER

What is known as a 30-in. Cincinnati special forge planer has recently been built by the Cincinnati Planer Company, Cincinnati, Ohio, for extra heavy work. Special attention was given to the design of the side heads; some idea of the substantial construction of these heads may be obtained from the photograph. The saddles are exceptionally large and, in order to insure rigidity, have extra supports in the form of angle plates which are bolted to the insides of the housings; these not only furnish a bearing but carry an inside clamp for the saddle. The harp has been dispensed with in designing the side head and the slide is given a square gibbed bearing directly on the saddle. This construction reduces the number of parts and increases the strength and rigidity of the head. The heads are counterbalanced by a self-contained system of weights and cables, making it possible to raise or lower them by hand with ease. The vertical and horizontal power feeds are supplied to each head from the same friction which operates the rail heads.

The bed is exceptionally heavy and is of box section. Oil reservoirs are cast in the girths at each end in order to catch all of the used oil and hold it until it may be drawn off through the plug in the end of the bed. The improved box type table is specially heavy and of unusual depth. The bottom side is entirely closed; chips cannot, therefore, drop through the table but are collected on the inside and may be removed through the cored holds at the sides. Heavy ribs at short intervals tie the top and bottom of the table securely together, thus preventing any possibility of springing either when clamping the work on the table or while the table is at the limit of its travel. The table is also gibbed to the bed to prevent any tendency to raise as the tools enter a heavy cut.



Thirty-Inch Cincinnati Special Forge Planer

The housings are of box type and in addition to being keyed are securely bolted and pinned to the bed. They are tied together at the top by a heavy arch, thus insuring rigidity when the rail is in its highest position. As may be seen, the rail is quite deep and has an extra deep box brace on the back to provide additional stiffness. The two heads are right and left hand and can therefore be run very close together. The slides are of extra length and have a full bearing on the harp at all times. The heads are equipped throughout with taper gibs to compensate for wear. It has also been necessary to provide special tool blocks of heavy design which are so arranged that the tool will be held in a perpendicular position.

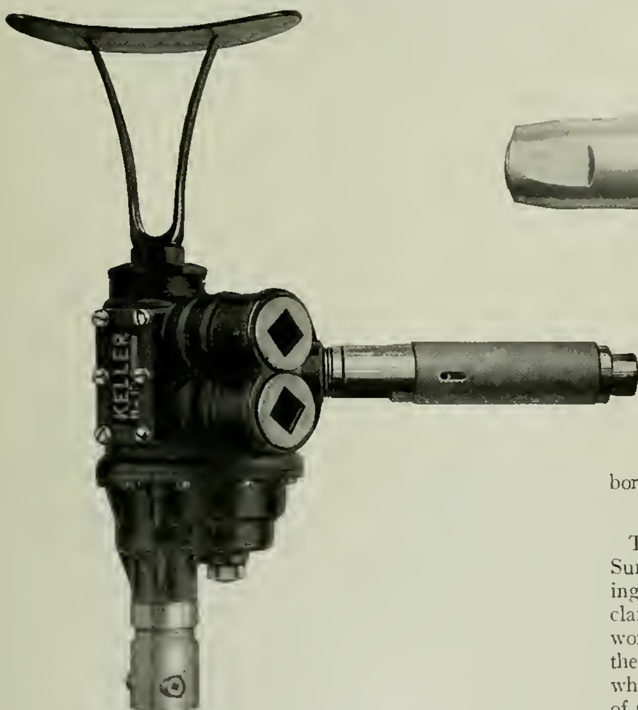
The side heads may be run down completely out of the way of the rail heads. The planer is arranged for a motor drive from the top of the housings but it can be modified to suit any other type of drive. Steel gearing and racks are used throughout. The driving gears are of chrome nickel steel; all high speed bearings are of bronze.

VALVELESS AIR DRILL AND NEW CHIPPING HAMMER

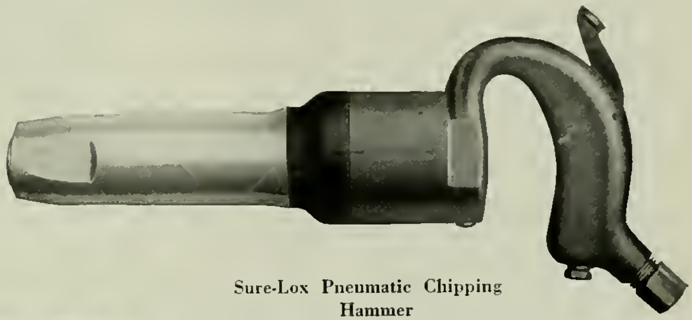
PROBABLY no tools used in a railroad repair shop require more ingenuity in design and more accuracy in workmanship than do the air operated drills and hammers. Two new tools have recently been placed on the market by the Keller Pneumatic Tool Company, Grand Haven, Mich., which possess novel features. The one containing the most radical improvements is a valveless drill.

Valveless Air Drill

Because of the elimination of the delicate valve mechanism it has been possible to make an air drill which is exceptionally light and compact. It is claimed that it will stand up under the most severe service and that it is exceptionally economical in air consumption. These features should, of course, be reflected in the cost of maintenance and the amount of time that the drills will be out of service for repairs.



Keller Master Valveless Air Drill



Sure-Lox Pneumatic Chipping Hammer

Four single-acting pistons are arranged in pairs at right angles, each pair connected to opposite wrists of the crank shaft. This is said to insure smooth running and freedom from vibration. The one-piece cylinder body is provided with handhole openings which are covered with removable plates, affording ready access to the crank connections. The connecting rods and pistons are made of vanadium steel; the rods are fastened to the pistons by ball and socket joints secured by ingenious locking devices which permit replacement of either the connecting rod or the piston. The crank shaft is a drop forging, hardened and micro-ground, and is amply large to prevent springing. It is mounted on liberal size annular ball bearings, thus insuring a minimum amount of friction and wear. The connecting rods are attached to the cranks by means of toggle joints secured with lock nuts; these also serve to stiffen the rods.

The main gear is cut from a solid blank of high-grade steel and is enclosed in a separate case which is filled with grease, thus insuring independent and continual lubrication. The spindle bearing is extra long with an additional bearing where it joins the crank shaft, thus protecting the spindle and the casing from heavy stresses when used on severe work or when the drill is used in a horizontal position. These drills are built in non-reversible or reversible types, including a reversible wood boring machine and a reversible grinder.

Sure-Lox Pneumatic Chipping Hammer

The new type of pneumatic chipping hammer, known as the Sure-Lox, is so named because of the peculiar manner of locking the handle to the cylinder. This eliminates the old-style clamp-bolt which was often objectionable, particularly for work in close quarters. The new handle is locked directly to the cylinder in a positive and rigid manner by means of a key which is inserted in the cylinder and engages one of a series of slots in the handle. The key is securely held in place and the entire lock arrangement is covered by a neat spring clip. All projections or obstructions which might interfere with the convenient handling of the tool are eliminated.

Another novel feature of this hammer is the extra long striking end on the piston. This is 5/8 in. instead of 3/16 in. as commonly used. The retaining wall in the cylinder is also correspondingly strengthened, adding to the durability and adaptability of the hammer. The moving parts are all hardened, ground and lapped to size. The parts are absolutely interchangeable. The hammers may be furnished with either open or closed handles in 10 sizes, ranging from 1 1/4-in. to a 4-in. stroke.

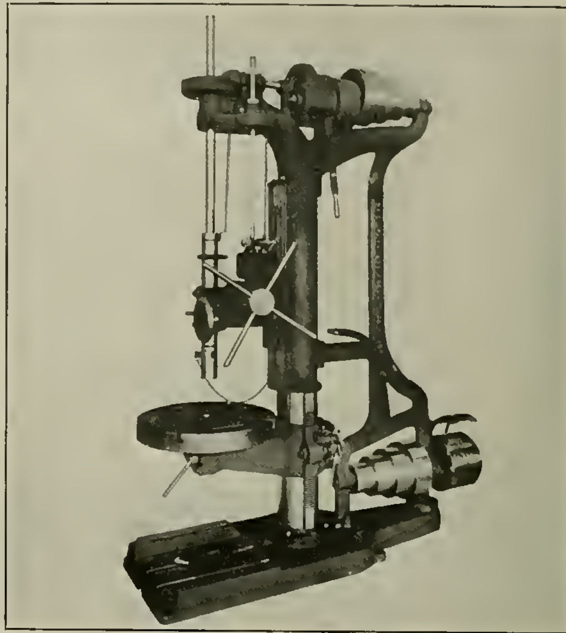
UPRIGHT DRILLS COMPLY WITH STATE LAWS

The Aurora Tool Works, Aurora, Ind., has recently improved its 28-in., 32-in. and 36-in. sliding head drills by the doing away with the so-called gear covers and thoroughly enclosing the gears to have them comply with the various state laws. Incidentally this has added greatly to the appearance of the machines, as is indicated by the illustration.

These drills are designed for heavy duty. The column, spindle, sleeve and all shafts are ground. The spindle is provided with a ball thrust bearing and is driven by bevel gears having a ratio of 3 to 1. The maximum distance from the spindle to the base on the 28 in. machine is 50 in., while the maximum distance from the spindle to the table is 36 in.; the machine will drill to the center of 28½ in.

The spindle has a diameter of 1-11/16 in. above the sleeve, and has a traverse of 12 in. The feeds are positive and easily controlled by the operator; they are .007, .012, .016, .021, .033, and .046 in. per revolution of the spindle. An automatic stop is provided so that the feed may be disengaged at any predetermined depth; the sleeve is graduated. The table on the 28 in. machine is 24½ in. in diameter and has a traverse of 15½ in. The table arm has a large flat bearing on which the table rests; the arm is bored and faced in place, thus giving each drill a thorough test before leaving the shop. The head has a traverse of 23½ in. It has a long bearing on the column and slides on wide ways, being controlled by means of a rack and pinion.

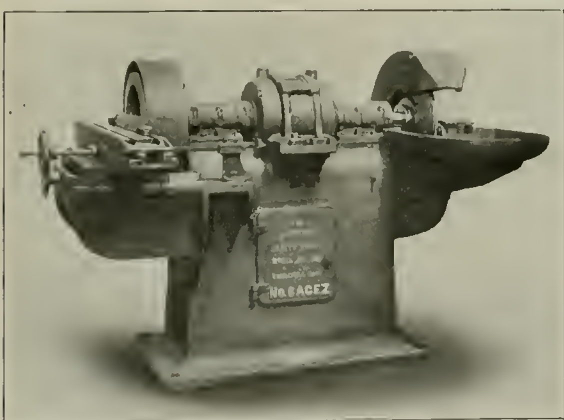
The machine shown in the illustration is arranged for a belt drive, hut a 3 hp., 1,400 r.p.m. motor may be applied.



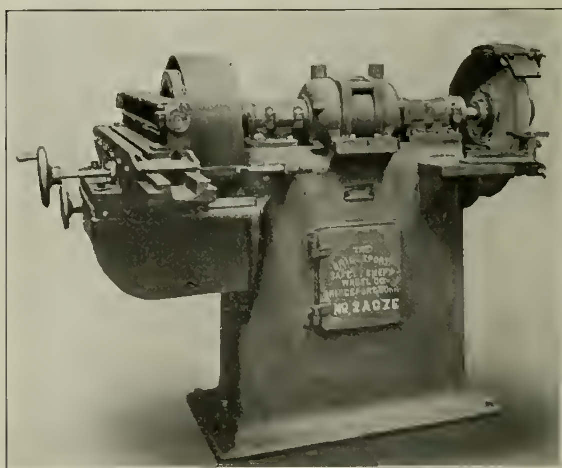
Aurora 28-Inch Upright Drill

COMBINATION MOTOR DRIVEN GRINDERS

The combination grinders shown in the illustrations are specially valuable where there is only a limited amount of work of any one kind and where floor space is limited. The combination practically furnishes two machines to occupy the space of one. These machines, which have been developed by the Bridgeport Safety Emery Wheel Company, Bridgeport, Conn., may be made in a number of different combinations, but in each instance the heavy bracket is cast at the left-hand end of the cabinet. The top of this bracket is finished to receive a dove-tailed table which is gibbed to the bracket and is fed back and forth on the base by means of the hand wheel and screw. On the top of this table and pivoted at the center is a bed which may be tilted in such a way as to grind slightly concave or it may be set square to grind perfectly flat. Clamping screws at each corner will hold it securely in any desired position. On top of this bed and dove-tailed to it is a carriage (34 in. long and 6 in. wide) with two T-slots. This is gibbed to provide for wear and is operated back and forth in front of the grinding wheel by means of a rack and pinion which is controlled by a hand wheel. The work may be clamped to the carriage, or if desired a magnetic chuck may be provided.



Combination Grinder with Wet Grinding Attachment at the Right



Combination Grinder with Knife Bar at Left

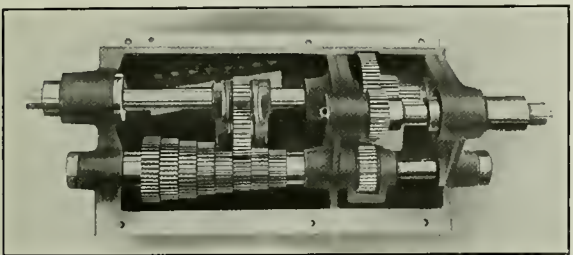
One of the illustrations shows a knife bar on this carriage for grinding machine knives; by means of this arrangement, the knives may be set to grind at any angle or square across. The photographs show two different arrangements of grinding wheels at the right-hand side of the machine. In one instance, a wet tool grinder is furnished, while in the other an ordinary type of floor grinder is used. If desired a twist drill attachment may be furnished.

The motor is equipped with a special frame, so that it fits well down into the base of the machine; it has a large spindle, the diameter in the bearings being 1¾ in. The distance between wheels is 35 in., and the length of the shaft over-all 50 in. The height from the floor to the center of the spindle is 40 in. There are two sets of balls in each of the ball bearings, these bearings being 10½ in. in length.

The machine covers a floor space, not including the overhang, of 45 in. x 23½ in., and weighs 1,800 lb., when crated for domestic shipment.

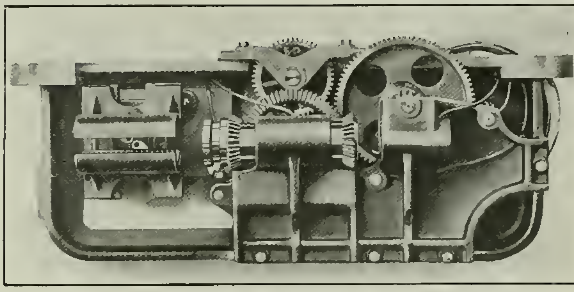
THIRTY-SIX INCH MOTOR DRIVEN GEARED HEAD LATHE

The Pittsburgh Machine Tool Company, Braddock, Pa., has recently redesigned its line of heavy lathes. In general, the 36 in. x 12 ft. lathe, which is described herewith, is typical of the other sizes. This particular lathe has a swing over the ways of 36¾ in., a swing over the carriage of 25½ in. and a distance between centers of 5 ft. The headstock is of the enclosed type and so constructed that it can be easily dismantled. Twelve changes of speed are provided through the head and are controlled by two clutches and three gear shifts; the ratio of the gearing in the head is 63.5 to 1.

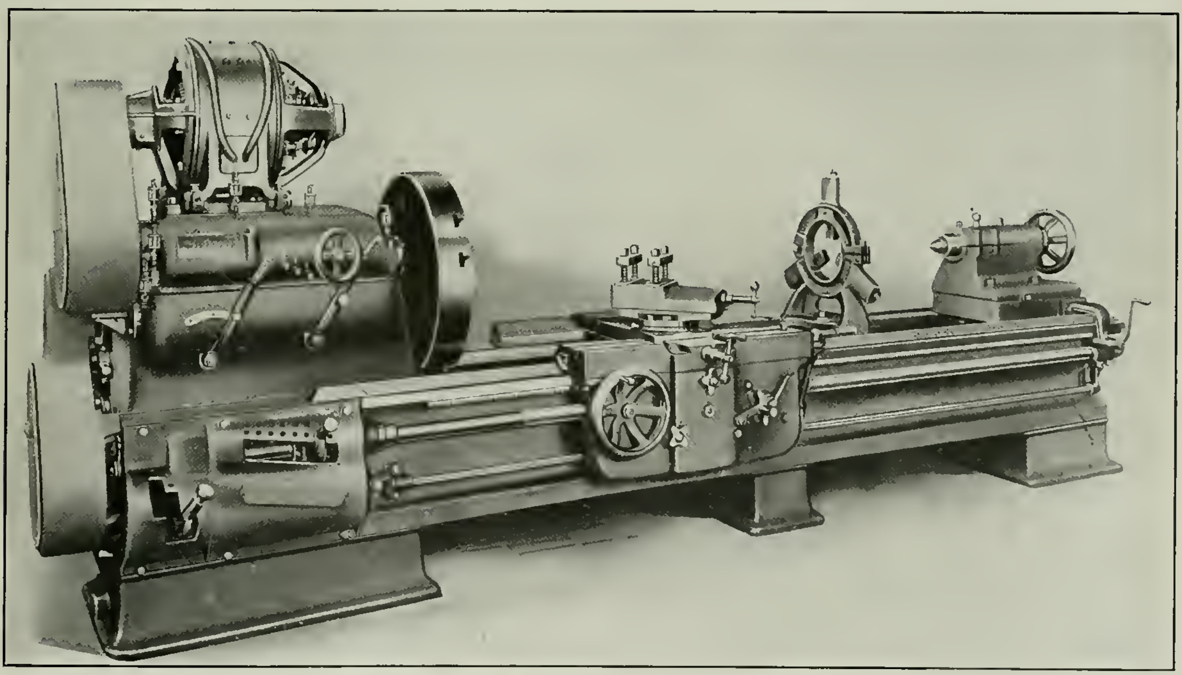


Interior of Feed Box

A motor drive may be supplied as shown in the illustration. With a direct current motor any reasonable number of spindle speeds may be obtained by the use of a variable speed controller which is operated from a handle at the right hand end of the carriage. If an alternating current motor is used, it is controlled by a Cutler-Hammer rotary switch and automatic starter. If a belt drive is desired, a 6 in. belt is used and 24 spindle speeds may be obtained with a two-speed countershaft. The main spindle is of hammered steel and hollow. The front spindle bearing is 6 in. in diameter and



Interior of Apron



Pittsburgh 36-Inch Geared Head Lathe With Motor Drive

8 in. long, while the rear spindle bearing is 4 in. in diameter and 6 in. long.

The feedbox furnishes 41 different lateral feeds; power cross feed is also supplied. The tailstock is of heavy design and is arranged with a pawl which engages with a rack cast in the center of the bed. The tailstock is moved by power through gearing. The tail spindle is 4½ in. in diameter. The apron is of double bearing construction; its arrangement is clearly shown in the photographs. A locking device prevents the throwing in of two feeds at the same time. The carriage is fitted with wipers which ride on the vees, keeping them clean and well oiled. The bridge is 12 in. wide and the carriage has a bearing on the ways of 44 in.

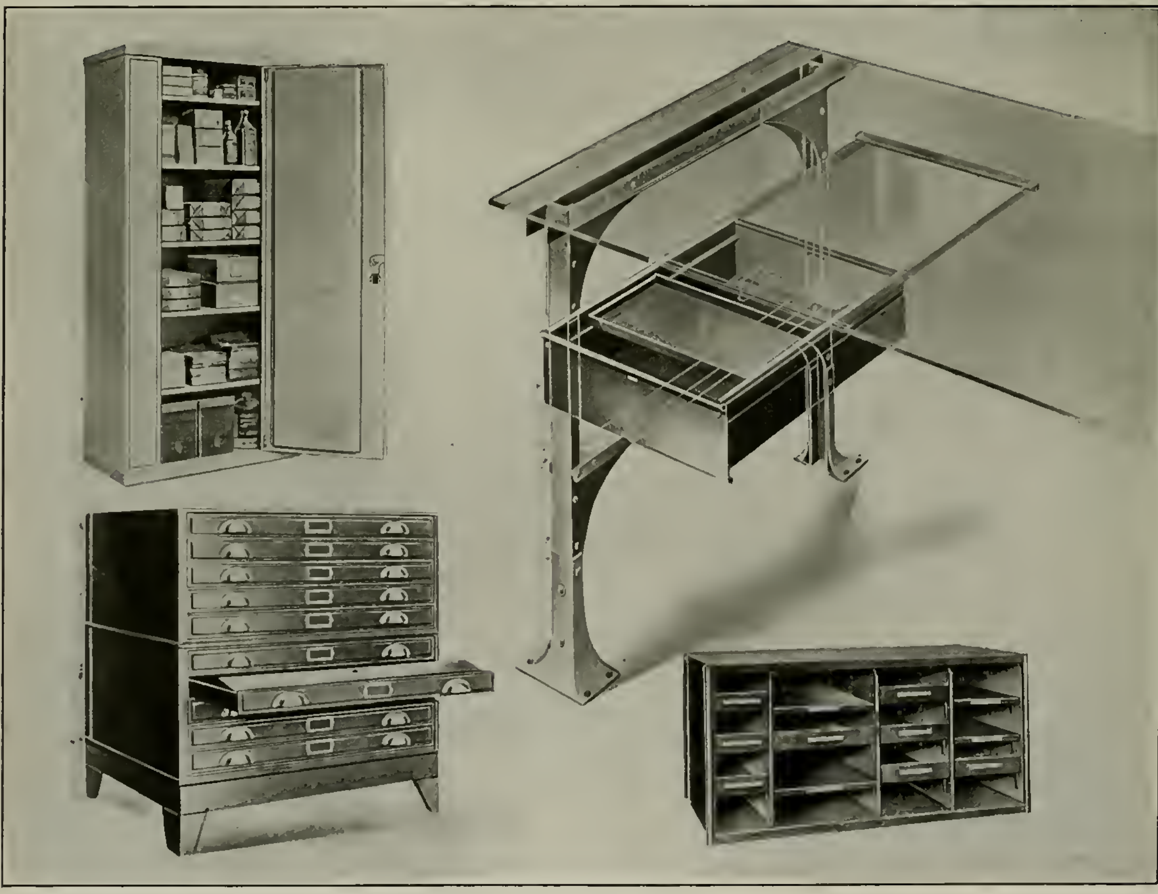
The bed is 29 in. wide and 20 in. deep. The front vee is exceptionally large to provide ample front bearing for the carriage. The taper attachment is of strong and rigid construction. The net weight of this machine with a 12 ft. bed is 16,000 lb.

PRESSED STEEL EQUIPMENT FOR SHOPS AND OFFICES

The many small cabinets, bins, drawers and boxes used around shops and roundhouses are as a rule made in the car shop. The cost of manufacturing them is necessarily high but there has been no alternative in the past as suitable equipment could not be secured otherwise. To meet the demand for such articles the Lyon Metallic Manufacturing Company, Aurora, Ill., is now producing a number of the types most commonly used in a variety of sizes suitable for railroad use. Being made of steel they are light and strong and more durable than similar equipment constructed of wood.

For tool rooms and store rooms a subshelf has been developed which simplifies making small compartments. The unit is collapsible and adjustable and fits into the standard Lyon shelving, which consists of a number of uprights into which clips can be set to hold the shelves. By reversing the shelf the compartment may be made into a bin. The shelves can be adjusted on 1½-in. centers without the use of tools and when not in use can be knocked down so that they consume practically no space.

Another useful adjunct for shops and roundhouses is a blueprint cabinet so arranged as to permit the storing of many sizes of drawings in a single size of cabinet. One of the principal advantages of these cabinets lies in the fact that they are fireproof. The cabinets are finished in baked enamel and can be furnished in five drawer sections ranging in size from 24 in. by 24 in. to 48 in. by 36 in. This device is shown in the illustration as well as a different type designed for the storage of a workng supply of stationery and printed forms. The size of this cabinet as regularly made is 36 in.



Shelving, Cabinets and Drawers Designed Specially for Shop Use by 18 in. by 75 in. It has movable shelves and can be securely locked.

Shop men who have been troubled with the loss of valuable tools will be interested in a thief-proof, steel bench drawer. It is equipped with a one-piece steel top which is also used to form the slide. Although the drawer may be torn from the bench and be entirely separated from it, the contents will still be secure.

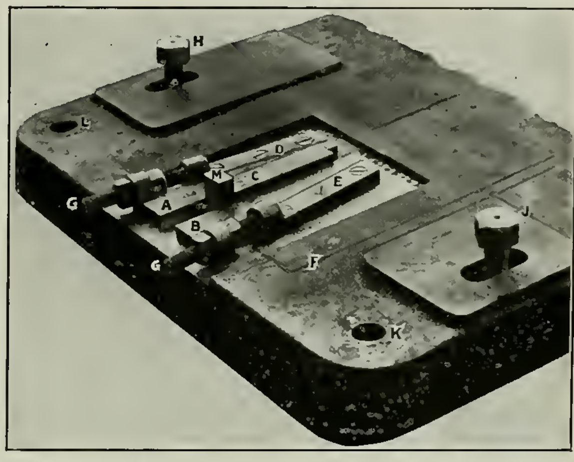
ADJUSTABLE ANCHORAGE FOR MOTORS

A DEVICE designed to insure accurate alinement and permanent anchorage for electric motors is being marketed by the Adjustable Anchorage Company, 1502 Ford building, Detroit, Mich. This anchorage permits a limited adjustment of the motor in all directions and may be used on either direct connected or belt-driven motors.

A half-view of a bed plate with the anchorage applied is shown in the illustration. The motor is set on the bed plate with keys *C* set tightly in slots in the bottom of the motor at both ends, the lugs *M* pressing against the motor base. To rotate or move the motor to either side, the bed plate bolts *H* and *J* are loosened and the wedges *A* and *B* moved alternately in or out by means of the screws *G*. The wedges bear on the surface of the guides *D* and *E*, the taper of the wedges thus moving the keys laterally, which in turn move the motor with them.

This anchorage, by providing universal adjustment of the motor in a horizontal plane, makes possible an accurate alinement, which once obtained is permanently held by the key *C*. This is of particular value in the adjustment of magnetic clutches and in the perfect alinement of the shaft, which eliminates eccentric movement and thus prolongs the life of the journal bearings.

To tighten or loosen a chain or belt the key *C* is loosened by drawing out the wedges slightly and moving the motor by means of a screw set in a lug cast on or a stud tapped in the bed plate at *F*. This device may be installed on old motors or on new work at a comparatively small cost.



Arrangement of Adjustable Anchorage for Motors

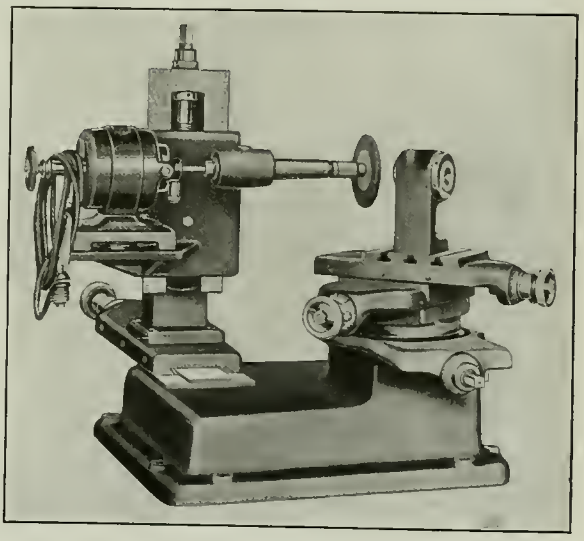
SOLVING THE CUTTER GRINDING PROBLEM

THE truth of the old adage that "Necessity is the mother of invention" is brought out in the production of a new profile grinder, which was originally designed and constructed exclusively for the requirements of a large milling cutter establishment. The performance of this machine, which is shown in the photograph, in its grinding of concave and convex cutters, cutters for fluting drills, rounding corners on side and face mills, and other special grinding jobs, has been considered of sufficient value to cause its originators and manufacturers, the Cleveland Milling Machine Company, Cleveland, Ohio, to place it at the disposal of manufactories and repair shops for installation in their tool rooms.

The wheel carrying spindle is direct connected to the shaft of the type *D* Dumore universal 110-volt motor which is furnished with the machine. The spindle has adjustable bronze bearings and carries a wheel 4 in. in diameter, ¼-in., face with a ⅜-in. hole. The bracket carrying the motor and wheel spindle is mounted on a vertical housing and is adjusted by a screw provided with a micrometer dial.

Arbors for holding the work are held in a sleeve which revolves freely in the work holding posts. Four posts are furnished with No. 9 and No. 7 Brown & Sharpe tapers, one with a ½-in. straight hole and one flat block for holding flat tools, in order to cover all classes of work capable of being done on the machine. The posts fit into three T-slots in the upper compound slide, thus providing for a wide range of work. The two upper slides are used to bring the work in the proper sweep across the face of the wheel, and are in turn mounted on a swivel block, which is pivoted to the bottom slide.

The maximum radius that can be ground is 3 in. on either concave or convex cutters up to 12 in. in diameter. A gage is furnished to set the work in the proper relation to the wheel and when the slide is set for any given radius the machine will always grind that radius regardless of the continued adjustment of the two upper slides. A simple and



Motor Driven Profile Grinder

convenient tooth rest is furnished with range enough to cover all work within the capacity of the machine. All screws are provided with readable micrometer dials and the slides are accurately scraped and provided with gibs for taking up the wear. The machine occupies a bench space of 24 in. by 30 in. and weighs 217 lb.

A HIGH POWER MULTIPLE SPINDLE DRILL

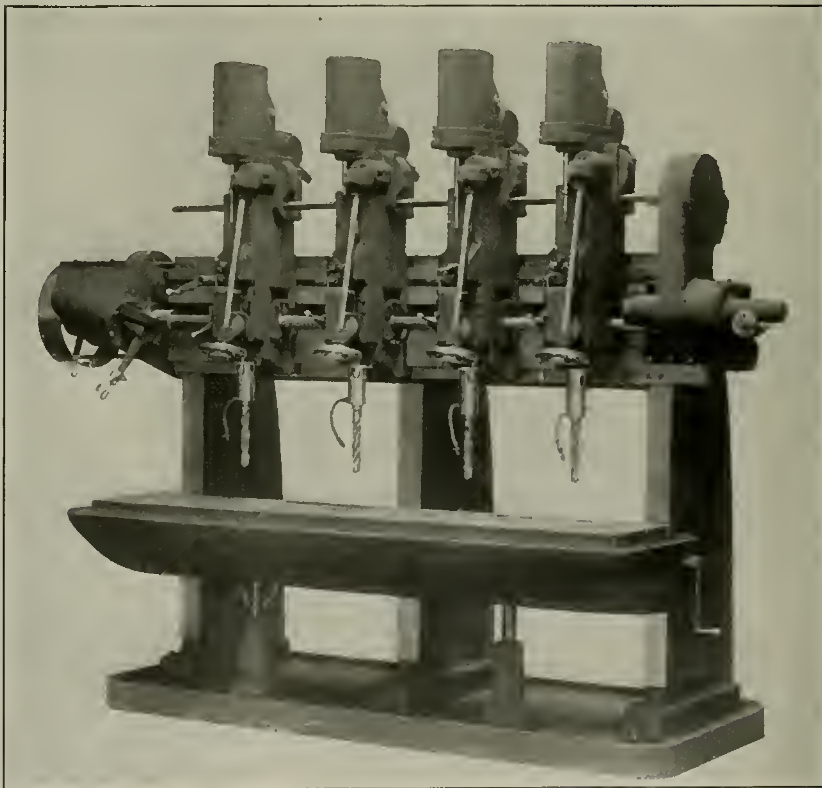
The multiple spindle drill shown in the illustration is a heavy service production tool especially intended for use in locomotive and railway shops and will be found useful where the work includes heavy gang drilling or heavy jig drilling. When used on jig work the compactness of this drill enables one operator to keep a greater number of spindles—either singly or in groups—continually in operation, and as a result the operator is kept constantly reloading the jig while some of the drills are kept constantly producing.

The speed mechanism is attached to the upper end of the upright at the left end of the frame and provides a range of six speeds from 25 to 186 r.p.m. It consists of two cones of hardened steel gears, back gears, and a hardened roll-in gear. There are three gears on each of the cones and these when used in conjunction with the back gears furnish the speed changes which are selected by sliding and dropping the roll-in gear into mesh with the various sets of gears on the cones. The shafts in the speed box rotate in Hyatt roller bearings, and the drive shaft, which transmits the power from the speed mechanism to the spindles, rotates in combined radial and thrust ball bearings. Power is applied to the speed box through a constant speed pulley and is transmitted through a Johnson friction clutch.

The feed mechanism gives three changes, namely, .006 in., .009 in. and .014 in. and is tightly encased and fastened to the upper end of the upright at the extreme right end of the frame. The changes are obtained through two cones of three gears each which are driven by the spindle drive shaft. Each of the two cones is fitted with three gears. The feed changes are effected by a slip key method which is operated by an indexed hand lever. The feed is transmitted from the two cones of gears to the feed shaft through miter gears and a worm and worm gear, with end thrust taken by ball bearings. A handwheel is also provided for quickly advancing or returning each spindle.

The minimum distance between spindle heads is 8 in. from center to center. The heads are gibbed to a heavy crossrail by a dove-tail method and are adjustable along the rail by means of a crank handle which operates a rack and pinion. The spindles are provided with No. 5 Morse taper and are driven by spiral gears. The spindle thrust is taken by S. K. F. ball bearings. The drive is located at the lower end of the head, which reduces torque in the spindle to a minimum. Each spindle is counterbalanced and can be driven and fed independently of the others. The levers used to apply the feed and drive to each spindle are interlocking so that the power feed cannot be engaged when the spindle is not being driven. Adjustable stops are provided automatically to disengage the feed when the holes have been drilled to a given depth.

The table, which affords a total working surface of 20 in. by 98 in. and a vertical adjustment of 12 in. by means of a crank handle which actuates two jack screws through a worm and worm gear mechanism, is a substantial box type casting. The jack screws supporting the table maintain its original alinement by receiving the trust of the



Multiple Spindle Rail Drill

cutting tools on the direct center line with the spindles. A cored section of the table serves as a reservoir for the cutting compound, and the table casting is shaped on all four sides so as to form a trough in which the cutting compound flows back to the reservoir. The pump which forces the cutting compound to the work is fastened to the upright at the left and is driven directly from the countershaft.

Lubrication is provided by a force feed, gravity flow and splash system combined, which is made possible by the all-enclosed unit construction. The speed mechanism, feed mechanism, and each of the spindle heads are provided with an independent and self-contained oiling system, which insures positive lubrication and economical maintenance.

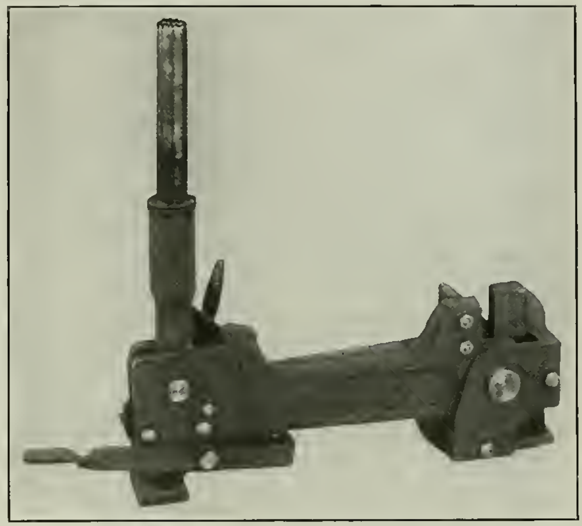
The contents of each unit are partially submerged in a bath of oil, while the bearings are lubricated by a force feed through individual leads which carry a sufficient flow of oil to flush all enclosed parts on its return to the reservoir.

The machine is operated by a 10-hp. motor, weighs about 15,000 lb. ready for shipment, and will occupy a floor space of 56 in. by 144 in. It is known as the No. 23 rail drill and is built by Defiance Machine Works, Defiance, O.

A POWERFUL HAND OPERATED BAR CUTTER

THE frame of the bar cutter shown in the photograph is of cast steel and is reinforced by heavy steel plates at the two main bearings; the cutter blades are made of specially treated tool steel in order that they may cut high carbon steel such as is in bars for reinforced concrete construction work.

The shear is fitted with a quick return arrangement which is made operative by throwing a pawl out of engagement by means of the short lever. The shearing blade may be brought into position quickly up to the point where the blade comes in contact with the bar to be cut by the use of a foot lever, whereas the actual cutting of the bar is only accomplished by operating the long lever and ratchet. The quick adjustment saves a great deal of time, as the ratchet operation is necessarily slow on account of the great leverage required to cut off heavy bars. The only spring used in this machine is one for holding the ratchet pawl out of engagement, in order that the movable cutting jaw may be returned to the starting position by its own weight.



Convenient and Powerful Bar Cutter

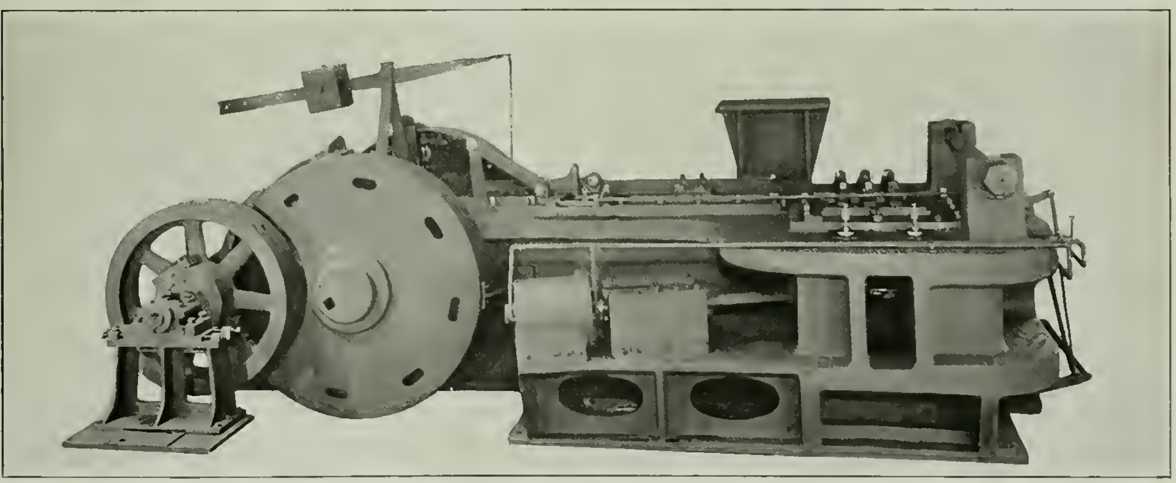
This bar cutter weighs 178 lb. and is light in comparison to its shearing capacity. It will cut square twisted reinforcement bars, or mild steel bars, cold, up to 1¼ in., round mild steel bars up to 1⅜ in. diameter, and flat mild steel bars ¾ in. thick by 3 in. wide. It is known as the Wallace No. 167 bar cutter, manufactured by the Wallace Supplies Manufacturing Company of Chicago.

The machine is 8 in. wide by 35 in. long and the lever, which consists of an ordinary piece of iron pipe, is 6 ft. in length. The height from the floor to the top of the cutting jaw is 11 in.

SPECIAL AJAX UPSETTING FORGING MACHINE

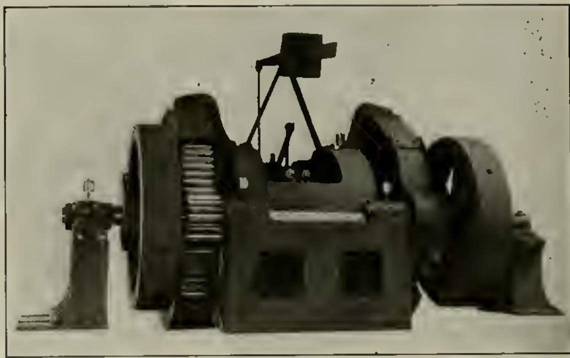
STERN necessity, under war conditions, forced many of the machine tool manufacturers quickly to develop new and unusual designs in order to assist the government in the production of munitions and supplies. As an example many interesting articles might be written on what was done in the manufacture of forgings, some of them of the most intricate designs and others of simple design but of unusual proportions. Fortunately, some of the special machines which have been designed and many of the lessons which have been learned may be applied to advantage under normal industrial conditions.

Many large forgings are required in the manufacture and



Side View of Ajax Upsetting Forging Machine with Extra Large Stock Gather.

maintenance of railroad equipment and doubtless an upsetting forging machine with an extra large stock gather, which was designed by the Ajax Manufacturing Company, Cleveland, Ohio, for making forgings required in the construction of artillery at the Ford motor car plant at Detroit, Mich., may be used to advantage for some of this work. This machine, which is shown in the illustrations, was so designed that an extra long stroke may be obtained after the gripping die has closed, thus holding the stock while the upsetting ram or tool performs its upsetting operation. The moving or gripping die is operated by an air cylinder and the heading tool or ram has a travel of 24 in. after the dies are closed. This stroke can, in cases of emergency, be increased to 26 in. The die space will accommodate a die 35 in. high and 27½ in. long. The crank shaft has a gear on either end, giving a double gear drive, thus protecting the shaft from torsional stresses. One of the views shows clearly the double gear drive with the two safety flywheels which are provided with safety shear pins. The crank is 13 in. in diameter.



Showing Double Gear Drive with Two-Safety Fly Wheels.

The air cylinder operates under 100 lb. pressure. The floor space occupied by the machine is 24 ft. by 15 ft. and the total weight of the machine is a little over 100 tons.

A NEW ANGLE ON MILLING MACHINES

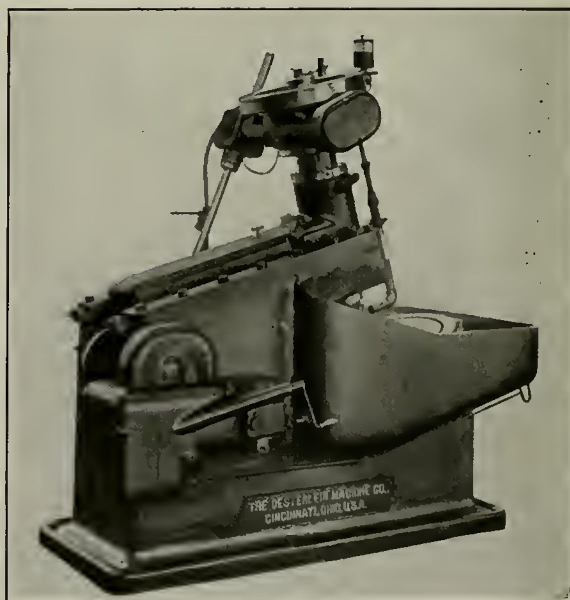
THAT there is apparently no limit to which the designer will go in the search for the practical application of every possible principle which will influence the efficiency of machine tool production, is strikingly illustrated in the tilted rotary milling machine shown in the illustration, in the design and construction of which will be noted an entire disregard for all precedent.

It is stated that the successful development of the Ohio tilted rotary milling machine, which will be exhibited at the June mechanical conventions at Atlantic City by the Oesterlein Machine Company, Cincinnati, Ohio, has produced a continuous production milling machine which has eliminated a large part of the idle time between cuts, has increased the rigidity by a reduction in the number of parts, and insures a sufficient supply of lubricant for cooling the cutters.

The usual time spent in returning a longitudinal feeding table, removing the finished work, clamping the new piece in the fixture and again bringing the cutter to the position for cutting, is obviated in this type; by the substitution of continuous milling, this time is converted into production time, with a consequent increase in the output per hour. This is accomplished by the rotary table which carries the work to the cutting position; during the cutting operation the finished work is removed at the opposite side of the table and new work is set up.

This continuous operation not only eliminates lost time, but it sets the pace for removing and setting up the work. The cutter may be held in a fixed position and the table rotated continuously by automatic feed for continuous milling, or the cutter may be reciprocated radially in combination with an intermittent motion of the table controlled by an indexing mechanism. This indexing mechanism provides for from 2 to 72 divisions and the table revolves rapidly between divisions, in order to reduce the idle time. By feeding the cutter radially over the surface of the work the loss of time between milling surfaces is avoided on such jobs as cannot be compactly spaced. Other advantages are that the nonproductive time of cutter approach is avoided, the cutter travels the shortest possible distance, two or more simple fixtures may be used instead of one large fixture, and the machine is practical when applied to small quantity lots.

The body of the machine is cast in one piece and no bolts, elevating screws or gibs are subjected to the load of the cut. The general lines of the machine may be said to resemble a punch press or shear. The working surface of the table and the cutter spindle are both contained in this body casting and the possibility of relative deformation under load of the cutter and work is avoided. As the body of the machine is directly under the circular table there is nothing to depreciate the anvil-like rigidity from the table bearing to the floor.



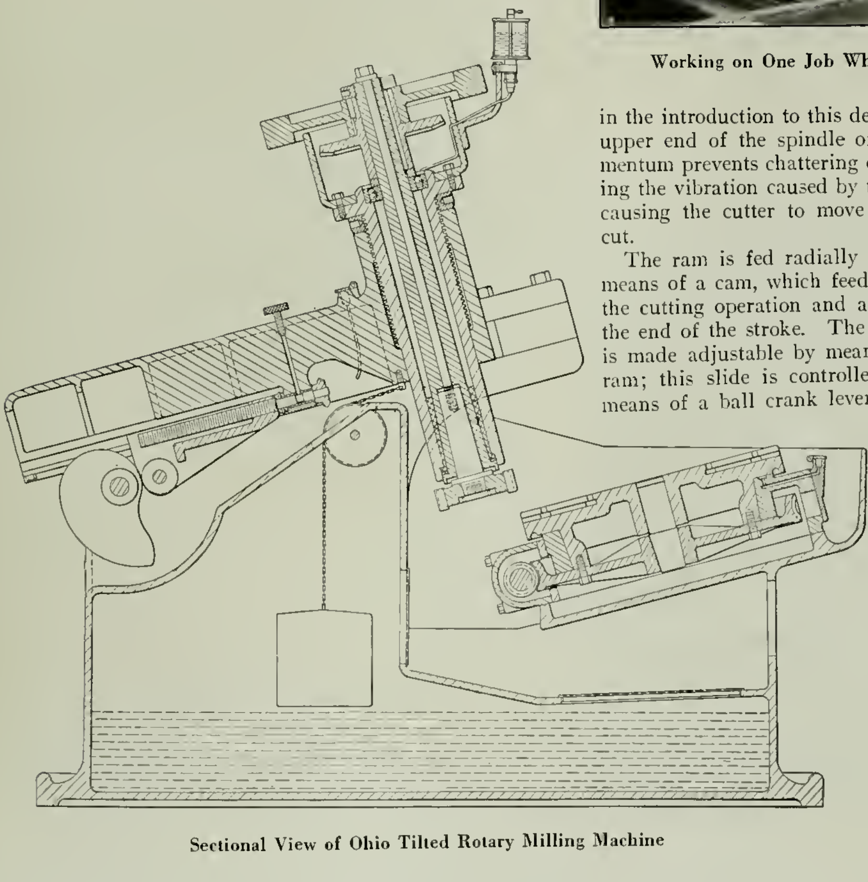
Ohio Tilted Rotary Milling Machine

There are no overhanging parts on the machine; the ram bearings are extended in front so that even in the advanced position of the cutters the full length of the ram is effective.

A worm wheel of 28-in. pitch diameter driven by a worm of 1¼-in. pitch and 4-in. diameter drives the 30-in. diameter table which is set at an angle of 150 deg. This worm wheel is set as close to the table surface as the taper table bearing will permit and is bolted and pinned to the table at the extreme end of the bearing; the central stud merely serves as means for alining the worm and the table. The latter is provided with two circular and four radial T-slots for the purpose of clamping the fixtures. The ram bearing has a surface of 1,000 sq. in. and three gibs permit of adjustment in all directions.

The machine is driven by a 4-in. belt over the pulley located on the side of the machine, either from a line or a jackshaft, or by a motor mounted on a special base plate placed on the top of the machine. Power for driving the spindle which carries a No. 16 Brown & Sharpe taper is transmitted from the pulley through mitre gears to an intermediate shaft which connects with the first change gear shaft in the speed box by means of a second pair of mitre gears. A single pair of change gears connect the first and second change gear shifts; "pick off gears" are used on the two shafts and give 30 spindle speeds, using 15 pairs of change gears.

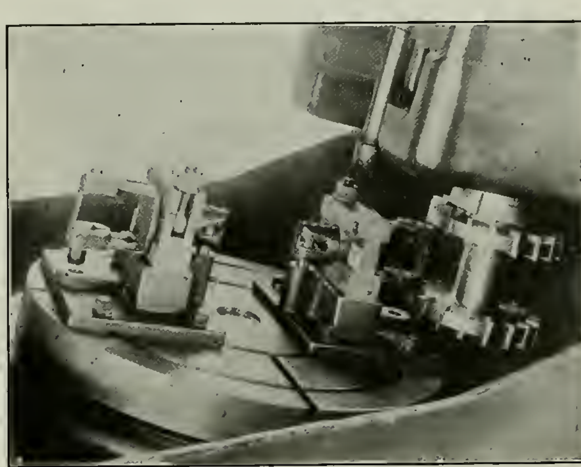
The intermediate shaft is made in two sections, which are connected by a coupling, by the releasing of which and turning the first change gear shaft through half a revolution, the opposite end of the upper half of the intermediate shaft couples with the lower section. This reverses the direction of rotation of the spindle and allows the use of either right hand or left hand face mills as desired. The intermediate shaft is splined at the upper end, and permits the pulley shaft and first intermediate shaft to trunnion, to allow reciprocation of the ram. Ball bearings are used wherever practicable throughout the driving mechanism.



Sectional View of Ohio Tilted Rotary Milling Machine

The spindle, which is adjustable vertically by means of a graduated collar, is carried in a sleeve, on the upper end of which is attached the speed box casting. The lower spindle bearing is 4½ in. in diameter and runs in a phosphor bronze bushing. The upper spindle bearing is a radio thrust ball bearing. A clutch in the end of the spindle provides for a positive driving of the arbors.

An example of one of the practical applications of principles which influence the efficiency of production referred to in the introduction to this description, is the mounting on the upper end of the spindle of a 250-lb. flywheel, whose momentum prevents chattering of the cutters as well as eliminating the vibration caused by the lacklash in the driving gears, causing the cutter to move smoothly into and through the cut.



Working on One Job While Another Is Being Set Up

The ram is fed radially over the surface of the table by means of a cam, which feeds the ram forward slowly during the cutting operation and allows it to drop back rapidly at the end of the stroke. The relative radial travel of the ram is made adjustable by means of a slide mounted under the ram; this slide is controlled from the side of the ram by means of a ball crank lever and is clamped by means of a knurled knob. A double row ball bearing serves as a cam roller.

The pulley shaft extends through the machine and drives the feed box mechanism; the operations of the feed box are controlled by a push rod extending along the side of the machine to within reach of the operator. The cam shaft is driven by a worm and worm wheel in the feed box. A four-gear feed change mechanism regulates the feed of the table when the continuous table motion is used or the rate of revolution of the cam when the indexing mechanism is used. The cutting feeds, therefore, are established by the ratio of these change gears. The index mechanism may be omitted for a machine on which only the continuous feeding table is desired, or the indexing mechanism may be added to a continuous feeding machine at any time. It should be noted that the feed change gears regulate the rate of travel of the ram and the throw of the cam regulates the length of travel of the ram. A crank operated shaft is provided so that the feed mechanism may be operated by hand when setting up or trying out a job. A lever is also provided for tripping the index mechanism.

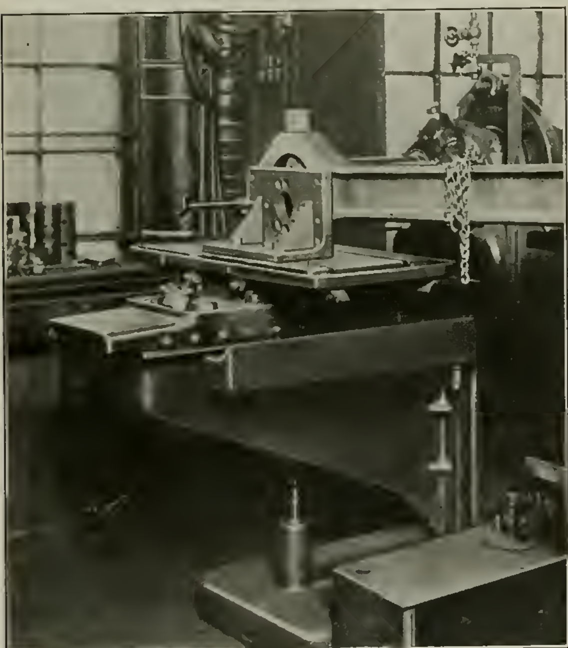
Lubrication is provided for by a pump of 35 gallons per minute capacity, attached to the side of the machine and driven by a belt from the pulley shaft. The lubricant is raised under pressure to a distance above the machine and expanded in a large pipe before it falls on the cutter and work; it drains from the chips which are deposited in a pocket provided in the base at the low end of the table, into a 60 gallon reservoir in the base. A large central distribution oiler on the speed box provides for speed box and spindle requirements and a similar oiler lubricates the pulley shaft. A central oiling point located at the top of the ram provides distribution to the ram slide and similar provisions are made for feed box mechanism and for the table bearings. Ample provision is therefore made for the lubrication of all parts.

THE INTERNAL GRINDER IN THE LOCOMOTIVE SHOP

THOSE who have benefitted by their recognition of the cylindrical grinder's place in the locomotive shop for finishing piston and valve rods, and crosshead and other pins will be interested in the internal grinding machine shown in the illustrations.

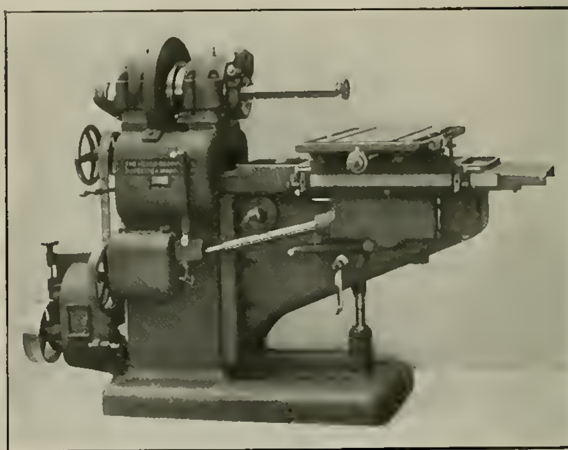
In repairing valve motion levers, parallel rods and various other similar parts, where the holes in the rods or in the bushings are worn oblong or rough, or the holes in the levers have become distorted, the use of this type of grinder will commend itself; these holes can be ground true and thus avoid the necessity for renewing the bushings or reaming the lever. Reaming would in some cases be the quicker operation, but it would not produce as true a hole and would result in enlarging the hole more than by grinding. On parts which have been warped in casehardening it is much easier to true the holes by grinding than by any other method.

Then, too, this machine may be used to good advantage on various air brake parts, including triple valves. The valve chambers in the top heads of air compressors when worn, may also be refinished on it. Steam and air cylinders may be refinished when worn or cut. To refinish a very badly worn cylinder may require more time than on a boring machine, on account of the large amount of metal to be removed in order to true up the entire surface, but even if this be the case, grinding will generally be the more economical when considering the life of the cylinders.



Trueing Up the Bushing Fit in a Side Rod

The article to be ground is secured to the table, which may be adjusted so that the work will be brought in line with the grinding wheel spindle. The illustrations show a No. 60 internal grinding machine manufactured by the Heald Machine Company, Worcester, Mass. This company expects to exhibit a machine of this type at the June mechanical conventions at Atlantic City.



Heald No. 60 Cylinder Grinder

Notable features of the machine are a large crosswise adjustment of the work, large vertical adjustment of the knee, multiple speeds for the rotation of the head, quick change gear boxes for speeds and feeds, and micrometer readings throughout.

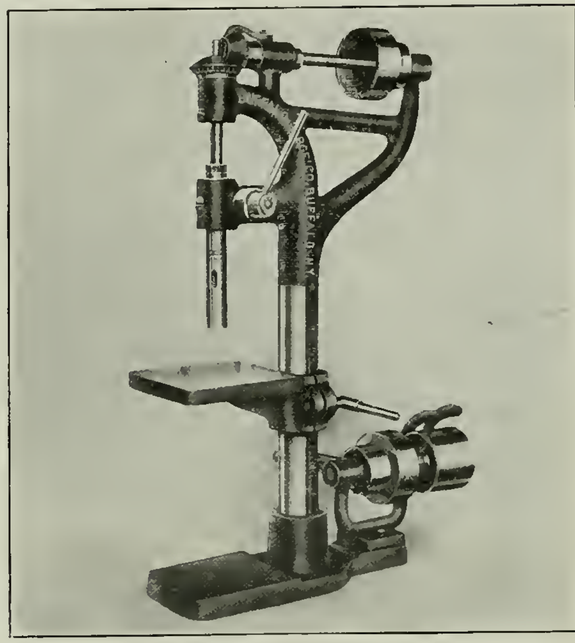
The proportions of this grinder, which occupies 38 in. by 90 in. of floor space and is driven by a 3-hp., 1,200 r.p.m motor, are well conveyed by the general photograph; another photograph illustrates the grinder performing a characteristic railroad shop operation in the grinding of an elongated bushing fitted in a locomotive side rod. The main table is 13 in. wide by 52 in. long, with a finished top 10 in. wide by 24 in. long, and has two T-slots and alining grooves. The cross slide table is 18 in. wide by 36 in. long, provided with a finished top 14 in. wide by 28 in. long, with two T-slots. The vertical adjustment of the knee is 3½ in. Micrometer dials are furnished for horizontal and vertical adjustments. Spindles regularly furnished with the machine will grind holes of three or more inches in diameter by 15 in. long; the standard grinding wheels used are 3½ in. and 4 in. in diameter by ¾-in. face, and are rated from 4,400 to 5,800 surface ft. per minute. The maximum distance of the finished pad on the cross slide table below the center of the grinding circle is 7½ in.; to the main table, 12 in.; the minimum distance is 4 in. and 8½ in., respectively.

A POWER BENCH DRILL FOR ACCURATE WORK

THE 10-in. power bench drill shown in the photograph is rather small for use in a railroad shop and yet there are places in the tool room or in other departments where it is desirable to have a machine of this kind for small and accurate work. The frame, excluding the base, is in one piece, simplifying the construction, and helping to keep the shafts and gears in perfect alignment. The machine will drill holes quickly and accurately up to 9/16 in. in diameter and to the center of a 10-in circle. The height over all is only 33½ in. and the machine weighs 110 lb.

The spindle is ¾ in. in diameter in the sleeve and has a travel of 3 in.; the column is 2½ in. in diameter; and the table measures 7 in. by 8 in. The greatest distance between the base and the spindle is 16 in., while the greatest distance between the table and the spindle is 9¾ in. The work table is adjustable up or down on the column or may be pushed to one side, thus allowing the base to be used as the table. The base is accurately planed and has countersunk bolts.

As may be seen, the upper cone pulley is supported between the bearings instead of being overhung, thus tending to balance the machine and relieve the frame from undesirable stresses. The countershaft is supplied with tight and loose pulleys and a belt shifter. The feed lever and spindle are held in position when idle by means of a friction spring, thus preventing the spindle from slipping down on to the work or the table. These drills are made by the Buffalo Forge Company, Buffalo, N. Y.



10-Inch Power Bench Drill

A NOTABLE ADVANCE IN GRINDING

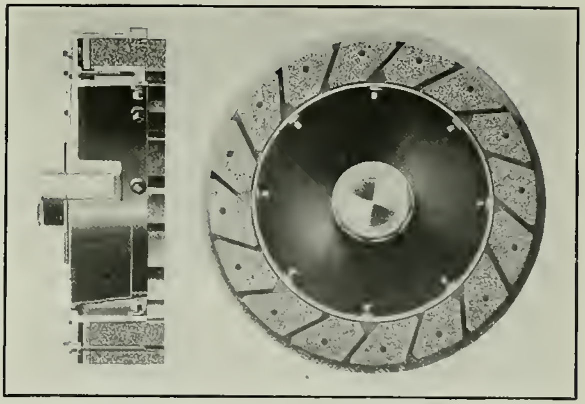
THE guide bar grinder illustrated herewith is noteworthy because of two significant steps forward in the development of large surface grinders. The basic improvement—a radical departure—is the grinding wheel whose chief characteristic is in its sectional or built-up construction. The origin of the design of this wheel emanated from an analysis of what happens between the wheel and the work, and practice is bearing out the value of the theory of a special provision for the regular and constant elimination of grindings and loose grit from the face of the wheel, which is achieved by the clearance between the blocks.

It will be seen that 16 blocks of the required abrasive material are inserted between the inner and outer flanges on the face of a carrying disk or chuck and are held in place through the adjustable pressure of wedges set in at the bases of the blocks and controlled by set screws and lock nuts through the inner flange, the combination forming a grinding wheel which is 32 in. in diameter.

The sectional view gives a clear idea of the manner in which the grinder blocks are controlled for lateral adjustment and shows the adjusting screws retained by collars at the back of the carrying disk, and screwed through the plates into which the grinding blocks are securely dovetailed. It will be noticed that sufficient adjustment has been provided to allow for practically the entire wear of the blocks. It is claimed that the sectional wheel will not "gum up," because it throws off through the grooves between the blocks the refuse from the wheel and the metal, which otherwise being unrelieved, imbeds itself in the face of the wheel, gumming it up, making necessary frequent redressing. Due to this chip relieving feature, it is stated that continuous fast and heavy grinding may be done with a sectional wheel of 4-in. width of face, where the limit of face for a solid wheel is usually 1½ in.

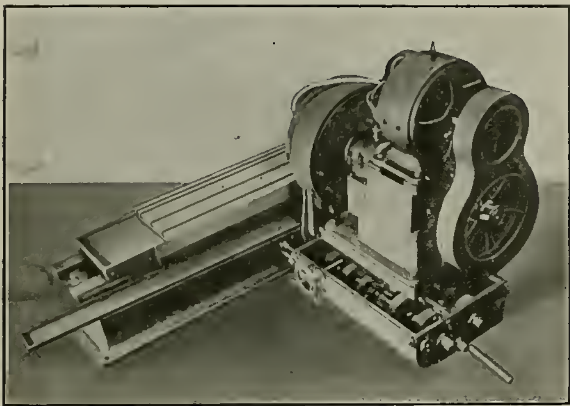
The grinding machine is heavy and rigid. The main bed is of cabinet base construction and supports a three T-slot carriage that travels back and forth on a flat track in front of the grinding wheel properly gibbed to take up wear.

Firmly bolted to this bed at the rear, midway between the ends, is a short back extension bed at right angles to



Showing Construction of Sectional or Built-Up Grinding Wheel

the main bed, with wide flat tracks on which a carriage is mounted, suitably gibbed, and arranged with a screw extending through the main bed, operated from the front side of the machine by a handwheel or by automatic feed, or by hand from the back of the machine, to bring the grinding wheel up to the work. On top of the carriage is a turret, pivoted at the center for grinding flat faces or by swiveling around to grind slight concaves as desired. The grinding wheel spindle is mounted on this turret and is 5½ in. in diameter, running in ball bearings both radial and end thrust, with adjustable take-ups for end wear, either forward or backward. The spindle is driven by means of a large spur gear which meshes into a wide faced fiber pinion on the shaft of the 25 H.P. motor mounted upon the turret.



Rear View Showing Application of Motor and Arrangement of Gearing

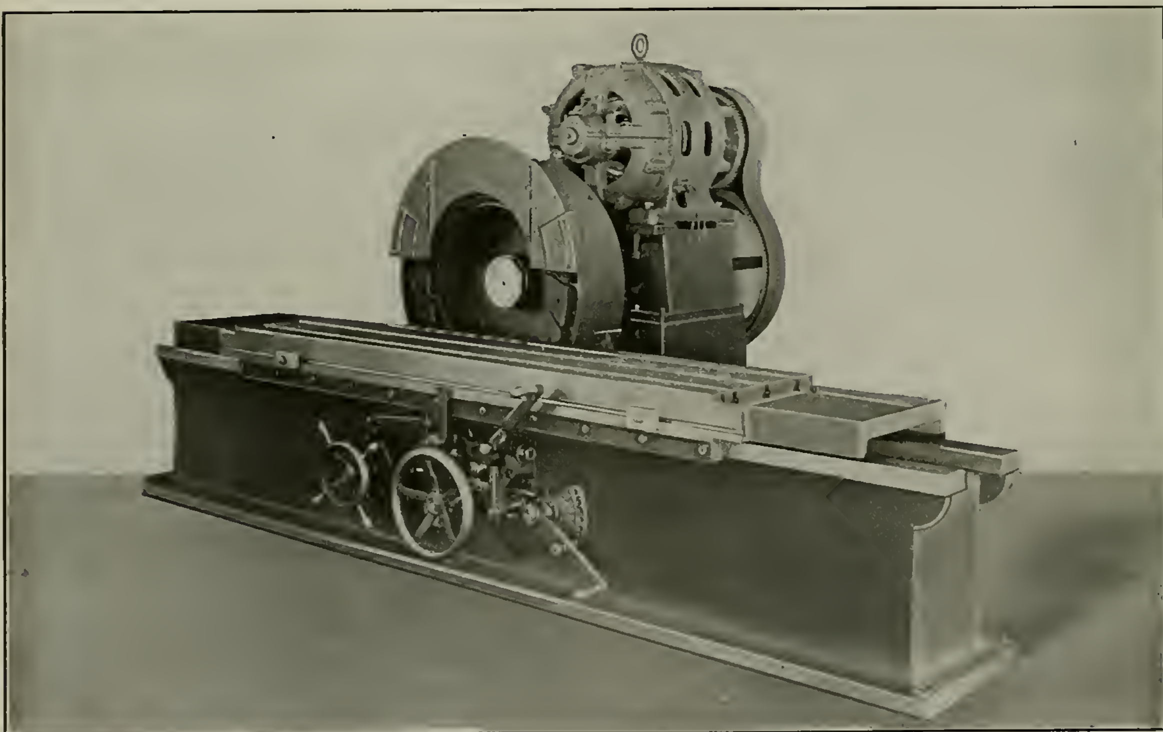
The second important feature in the machine is the multiple speed working table or carriage. For convenience in showing the location of change speed gears, which provide a carriage speed of 3, 6, 9 and 12 ft. per minute, respectively, the extension bed in which they operate is partly uncovered in one of the photographs. The desired speed is obtained by adjusting the speed control hand lever, shown at the right in the front view of the machine, in its proper position as indicated on the dial behind it. The lever is locked when in position for any desired carriage travel speed. The hand lever at the left in front of the machine is a carriage control and is locked in both working and neutral positions. There is a corresponding lever at the back of the machine for the convenience of the operator. The large hand wheel is for moving the carriage back and forth in adjustment to the work.

The dogs on the front side of the table may be adjusted for any length of travel up to the capacity of the machine. A centrifugal pump for supplying water to the grinding wheel is furnished with each machine. The front part of the back extension to which the pump is connected has a closed bottom, forming a reservoir. Drip pans on the back of the machine carry the water to the reservoir, thus using it over and over.

At the right and rear of the back extension are gear boxes with removable lids, allowing easy access to the working parts for oiling and making adjustments. One of the gears in the train of backgearing is a friction gear, arranged to slip under excessive load in case anything should get caught.

This machine, which should find many uses in railroad shops, particularly on the grinding of guides, is made in four lengths, 66 in., 86 in., 110 in., and 140 in., and ranges in weight from 12,330 lb. to 18,250 lb.

This sectional wheel guide bar grinder is manufactured by the Bridgeport Safety Emery Wheel Company, Bridgeport, Conn., who manufacture a general line of grinding machines of all types and sizes, the pioneer among which was one of the first grinding wheels regularly manufactured and sold under a safety slogan based upon the rigidity of its wheel guards.



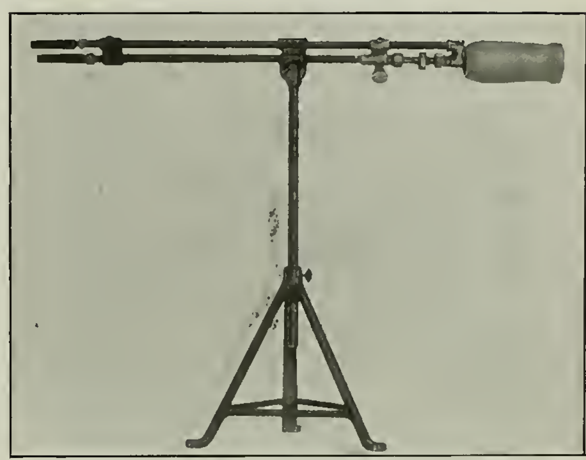
View of Surface Grinder From Operating Side

A KEROSENE TORCH FOR PREHEATING

A KEROSENE preheating torch has been perfected by Smith's Inventions, Inc., Minneapolis, Minn., which uses compressed air at about 40 lb. pressure, but requires no pressure on the kerosene. The compressed air in passing through the valve draws the kerosene with it and converts it into a vapor. This vapor, as it passes from the torch or nozzle, may be lighted instantly with a match without heating the nozzle. The flow of the kerosene is controlled by a separate valve and the torch flame may be made to vary from 6 in. to 4 ft. in length.

The nozzle shown in the illustration may be replaced by an elbow or other casting, thus deflecting the flame at a right angle or any other direction. The kerosene is drawn into the torch by simply dropping the end of the tube into a barrel or tank of kerosene.

The nozzle may be screwed off, in which case the torch may be used to spray the kerosene in cleaning motors, transmission cases, differentials, and for various other purposes. The adjustable stand is of simple and substantial construction and will be found specially convenient for many classes of work.

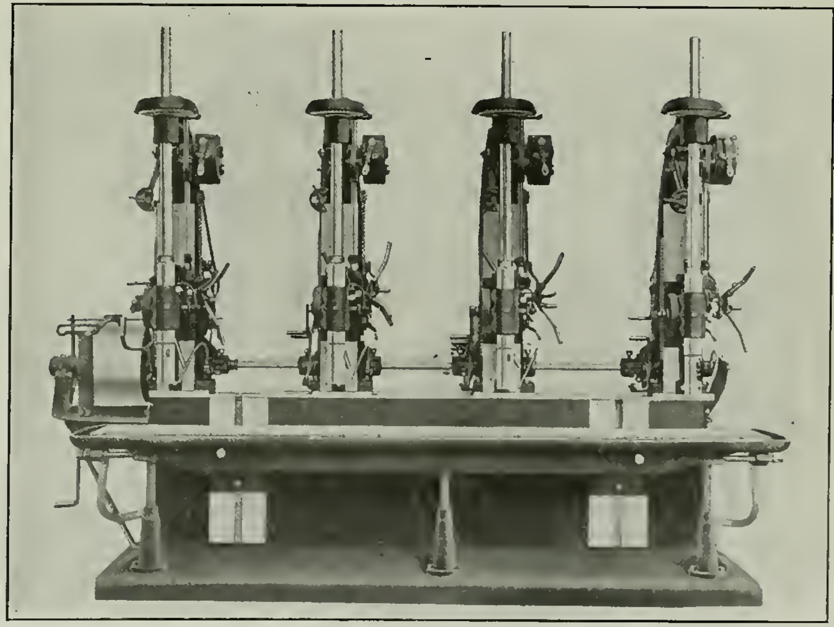


Kerosene Preheating Torch and Stand

TWENTY-SIX INCH ADJUSTABLE HEAD GANG DRILL

THE Barnes Drill Company, Rockford, Ill., has designed a 26-in. gang drill to permit a lateral adjustment of the spindles. In other respects the machine is similar to its standard line of all-geared gang drills. The spindle at the end of the machine nearest the driving pulley is fixed, but the three other heads may be adjusted laterally by means of rack and pinion. This provides a range in centers varying from 18 in. to 96 in. Each spindle will drill to the center of 26 in. and has a vertical travel of 14 in. The table, itself, has a vertical movement of 14½ in., while the sliding heads have a vertical adjustment of 23 in. The greatest distance from the top of the table to the floor is 36½ in., and the greatest distance from the spindle to the table is 37½ in. The table has a plain surface of 19 in. by 120 in., and the machine occupies a floor space of 51 in. by 138 in.

There are eight changes of geared speeds and eight changes of geared feeds on each spindle. The spindles operate independently of each other and all of the adjustments may be made by the operator from the front of the machine. The heads and spindles are counterbalanced, the weights being suspended by the roller bearing sheave wheels. The heads are gibbed to the column faces and may be securely held at any point by quick-acting screw clamps. Each head may be readily raised and lowered by means of a rack and pinion. An adjustable stop is provided which may be clamped on the column face in order that the sliding head may be brought back quickly to exactly the same place each time the head is raised, a most desirable feature.



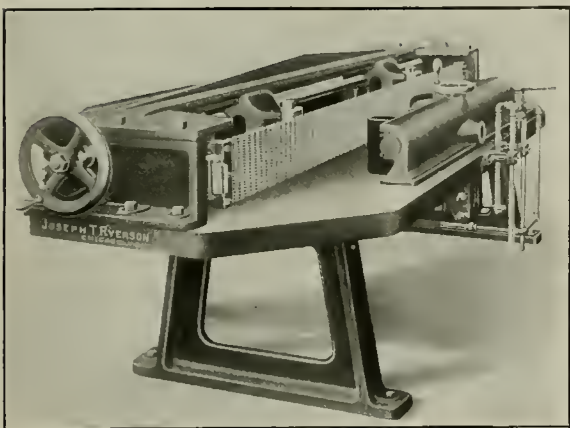
Gang Drill With Spindles Having Lateral Adjustment

A hand lever reverse is ordinarily provided but if desired an automatic reversing mechanism may be furnished. This is desirable for depth tapping; the trip may be set so that the instant the tap reaches the required depth the spindle will automatically reverse, backing out at an increased speed. The shifting lever may be so set that when tripped automatically or by hand, it will return to the neutral position, thus stopping the spindle instantly, instead of reversing it. The machine has a net weight of 9,700 lb.

UNIVERSAL ELLIPTIC SPRING FORMING MACHINE

UNTIL recent years, very little attention was given to the design of spring machinery for use in railroad repair shops. The greater part of the equipment in many shops was home-made and such machines as were available on the market were not designed from the viewpoint of operating the spring repair department as a unit. Joseph T. Ryerson & Son, Chicago, undertook the problem of developing a line of spring machinery specially adapted for railroad shops and with the idea of simplifying and co-ordinating all of the operations to as great an extent as practicable.

The latest addition to this line of spring machines is shown in the illustrations and is known as the Ryerson universal elliptic spring forming machine. It is made in four sizes and will form elliptic spring leaves of any size and curvature used in ordinary practice; it requires but one operator. This work in many railroad shops is now largely done by hand and the possibilities of the new machine in turning out more accurate and more uniform work at a considerably reduced cost are great. The hot spring leaf is formed upon a cold one against which it is to mate, thus giving it accurate camber and fit. A second heat for tempering is unnecessary as the leaf may be quickly passed from the machine to the tempering bath. The machine, when properly operated, will form leaves free from twisting or warping and will straighten out any twist that may be present in the original bar.



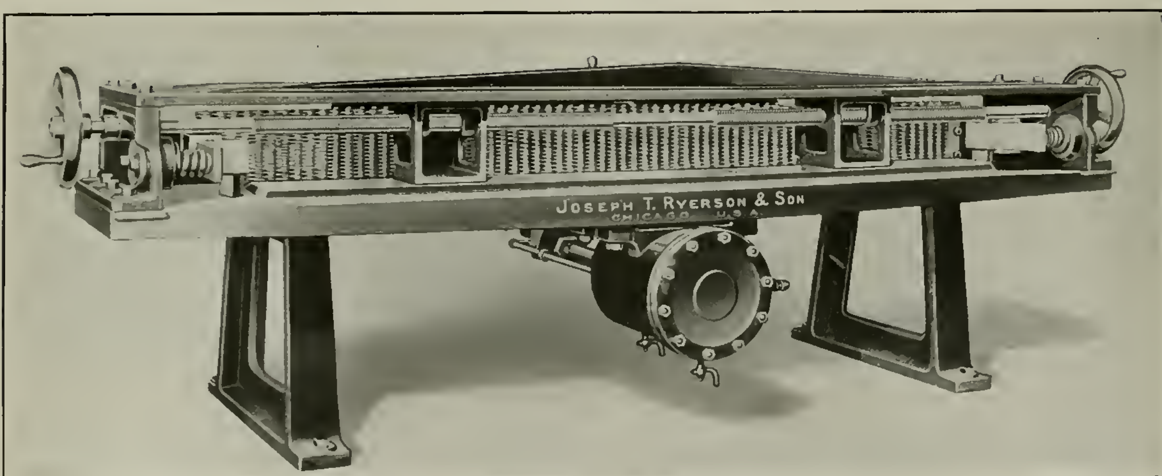
Elliptic Spring Forming Machine

One road which has installed a machine of this type was asked by the *Railway Mechanical Engineer* as to the results which had been obtained. Extracts from the report follow:

"Springs made by this method give more than triple the length of service compared with springs constructed by previous methods used in our shops. This means more continuous service from the locomotives so equipped because of less frequent spring renewals, less wear and deterioration to the locomotive because of the use of better springs, and a saving of wear to the track. All of this is reflected in increased mileage of the locomotives. The improvement is presumably due to the fact that the leaves are made more rapidly, at lower temperatures, permitting them to go to the spring baths at more uniform temperatures, and that the plates are fitted together more accurately so that each does its proper proportion of the work.

"The springs are not going back to the spring shop for repairs as frequently as they did formerly; for instance, a tye of spring used on a heavy Pacific locomotive was given careful study. An average of 38 of these springs were being made each month before the introduction of the spring forming machine. After the machine was introduced, the rate of manufacture of these springs dropped until it finally reached four per month, indicating conclusively the greater length of life due to the new method. It does not overstate the fact to say that springs made by this method have an increased life three times that of springs made by the best methods previously used."

The machines range in weight from 3,250 lb. for the smallest size to 4,000 lb. for the largest one. A special foundation is not necessary with this comparatively light weight, particularly since the machines are free from vibration in operation. What is known as the crosshead former is operated back and forth on the table by means of compressed air or hydraulic power through the cylinder attached underneath the table. The plunger is connected to the lower end of a vertical slide lever, the upper end of which is attached to the crosshead former. This provides for a maximum stroke of the former of 10¾ in. The three-way valve,



Rear View of Elliptic Spring Forming Machine

which controls the operation, is conveniently located for the operator.

There are three projections on the inner side of the crosshead former; the two outer ones are adjustable lengthwise to suit the length of the spring leaf and the central one may be adjusted crosswise with the table to suit the curvature of the leaf. The adjustments to suit the different leaves may be made quickly by means of a hand wheel.

In actual operation the cold leaf, against which the new one is to be formed, is placed next to the crosshead former and the hot leaf is placed just inside of it, the leaves being centered by nibs. When pressure is applied, the crosshead former forces the hot leaf against a metal chain forming band which rests on edge on the table top and is securely held in position by a double set of springs which furnish the necessary resistance to forming the spring plates. Directly back of the chain forming band is a set of what are designated as "laterally adjustable lengthening anvils." These anvils or formers may be adjusted lengthwise with the table by means of hand wheels at each end of the machine and provide means for lengthening or shortening the effective length of the metal chain to accommodate any length of spring plate and to form perfect contact at each end of the plate. They are quite clearly shown in the rear view.

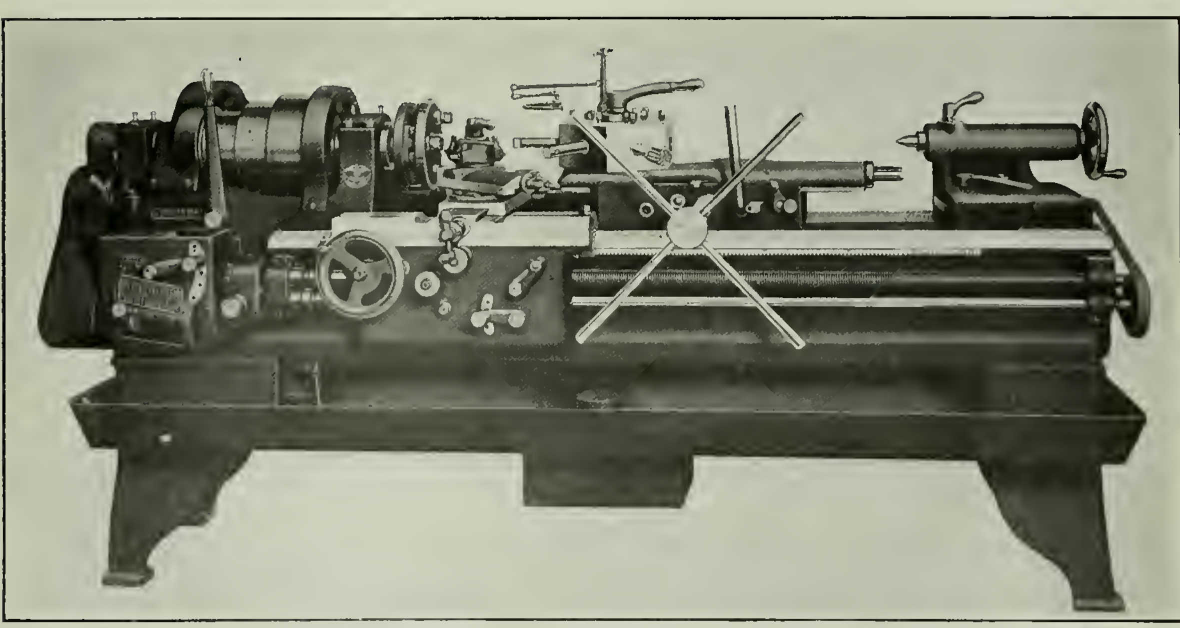
After the newly formed leaf has been dipped in the tempering bath and cooled, it is used as the cold plate for forming the next leaf, this being done successively until a full set of leaves is built up, after which they are assembled and banded. To provide the necessary camber for the hot leaf, the adjustable dies on the crosshead former are set to spring the cold template the desired amount, thus causing the radius of curvature of the new leaf to be reduced sufficiently to provide the desired camber.

The four sizes of machines differ principally as to the length of the table, this being such as to provide capacities for four sizes of spring leaves as follows: 5/8 in. x 7 in. x 60 in., 5/8 in. x 7 in. x 72 in., 5/8 in. x 7 in. x 84 in., and 5/8 in. x 7 in. x 96 in. The floor space required varies from 4 ft. x 9 ft. 6 in. for the smallest size to 4 ft. x 12 ft. 6 in. for the largest one.

CONVERTIBLE HEAVY ENGINE AND TURRET LATHE

Circumstances frequently arise in railroad shops where a heavy production turret lathe is called upon to perform somewhat spasmodically. It may stand idle for a period during which an expected order for 100 or 1,000 pieces, all of one kind, is not forthcoming, thus putting the "quantity producer" on a more or less non-dividend paying basis in proportion to the time it may actually be inoperative.

A suggested reliever of situations of this kind is offered in the design and construction of the severe duty engine lathe shown in the illustration, which provides all of the advantages of a heavy all-round engine lathe and at the same time can be quickly rigged up for quantity production by the attachment of a quick-acting hexagonal turret on the lathe bed and a turret tool holder on the cross slide.



Cincinnati Standard Engine Lathe With Quick-Acting Hexagonal Turret.

These lathes are all constructed to permit the addition of a taper attachment which is mounted on the carriage and has a long bearing on the lower side, insuring accuracy. Graduated on one end in degrees and on the opposite end in inches, this accessory will accommodate work up to 12 in. long in one setting and turn up to 10 deg. and 4-in. tapers per foot. This lathe is the product of the Cincinnati Lathe & Tool Company, Oakley, Cincinnati, Ohio, and is made in sizes from 16 in. to 28 in., inclusive, in either cone type belt drive, or geared head for belt or motor drive, with 2-ft. variations in length of bed from 6 ft. to 20 ft.

The headstock is made in three styles—four-step cone, single back gear; wide three-step cone, double back gears; and double friction back gears. The spindle, of high carbon forged steel, has a collar at the nose end supplying a stiff bearing when chucks and plates are attached. The thrust bearing at the rear end of the spindle provides a hardened tool steel collar for adjusting the wear; the end thrust is taken against the front end of the rear box.

The apron is of box type construction, giving a double support to all shafts and studs mounted in it, and providing for accuracy as well as long life of all the working parts. The rack pinion is made of steel, well supported close to the rack on the bed, and motion to it is transmitted by compound gearing. Longitudinal and cross friction feeds can be started, stopped or reversed while the lathe is running, but cannot be engaged when cutting screws. A thread chasing dial is provided, which permits the half nuts to be opened, the carriage to be run back by hand and the thread to be caught or picked up at any point without reversing the lathe, so that a backing belt is unnecessary. The machine is also provided with an automatic stop.

The reverse plate for cutting right and left hand threads is on the outside of the headstock and is used only for reversing the lead screw when cutting threads and not for reversing the feed. These machines have feed reverse in the apron. A device with a quadrant permits a combination of extra or metric pitches with U. S. standard lead screw, or vice versa, besides those obtained in the gear box.

The screw cutting and feed mechanism is characterized by its simplicity, compactness, ease of manipulation and strength. Changes from one standard thread to another can be made at once without duplicating or removing a gear, by simply operating two levers conveniently placed a few inches apart. The index plates are so placed on the box that the operator will know at a glance the correct setting for any thread or feed.

The tailstock is of the offset type, which allows a compound rest to be set in a plane parallel with the bed.

TWENTY-INCH AUTOMATIC TURRET LATHE

Not a few railroads now have manufacturing departments in their larger shops for quantity production of small standard parts. The automatic turret lathe occupies a prominent place in such departments.

The 20-in. automatic turret lathe shown in the illustrations has been designed to be convenient in adjustment, rigid and powerful in use, and all of its motions and operations are automatic except the insertion and removal of the work; even the automatic removal of work may be accomplished on some pieces if an air chuck is used. It has turret feeds ranging from .003 in. to .333 in. and cross slide feeds ranging from .0015 in. to .166 in. per revolution of the spindle.

Safety to the operator has been given special attention. The gears have been covered and all revolving parts protected. Dangerous projecting parts have been eliminated. and the turret has been designed to turn toward the front, instead of in the usual way, so as to protect the operator and avoid the danger of the tools catching him and drawing him against the machine. The lathe has an over-all length of practically 12 ft., with a maximum distance from chuck to turret of 48 in. It is built for either belt or motor drive by the Gisholt Machine Company, Madison, Wis.

When the shape of the work permits, it is possible to arrange the chuck jaws so that, after the piece has been finished on one side, it may be reversed in the chuck by the operator and the other side finished with tools mounted on the remaining faces of the turret.

Either standard 18 in. scroll chucks, or air chucks may be used with these machines. When an air chuck is used, the pressure is automatically controlled by a valve operated by a dial below the pulley shield, so that in taking roughing cuts a maximum air pressure of about 80 lb. or 90 lb. is used, but when taking light finishing cuts, this pressure is reduced to 20 lb. or 30 lb., to relieve the strain and prevent distortion of the part that is being finished. The dial mentioned above also automatically controls the electric signal,

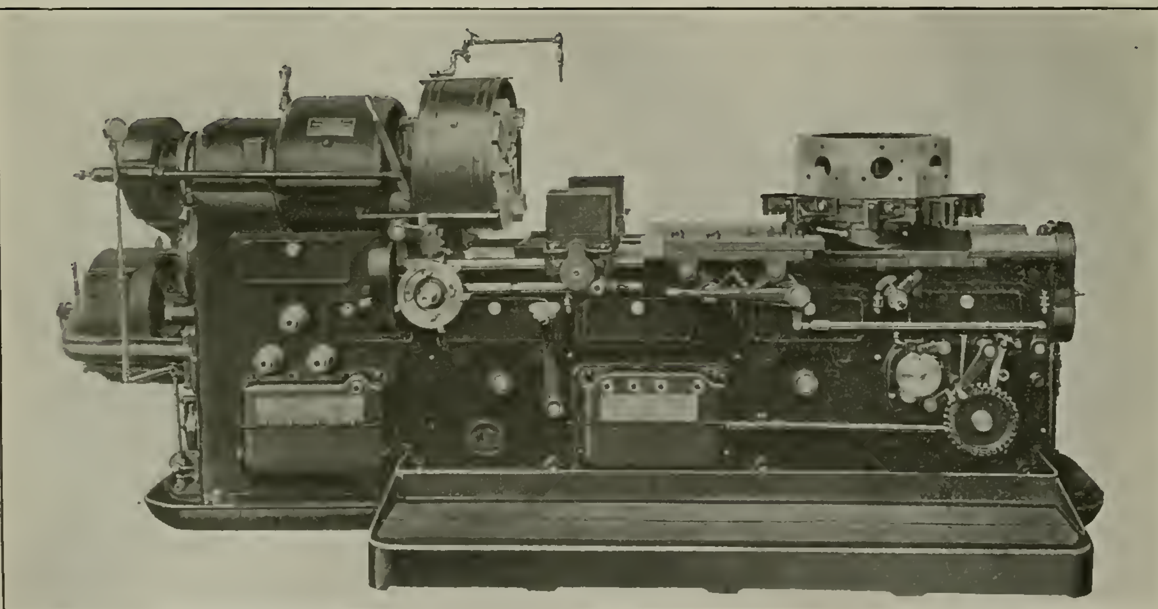


Fig. 1. 20-in. Gisholt Automatic Turret Lathe

which notifies the operator when the piece is completed. The air cylinder is operated in either direction, by a lever conveniently located, and is adapted for either internal or external chucking, without any adjustment of cylinder or chuck, except the provision of proper top jaws on the chuck

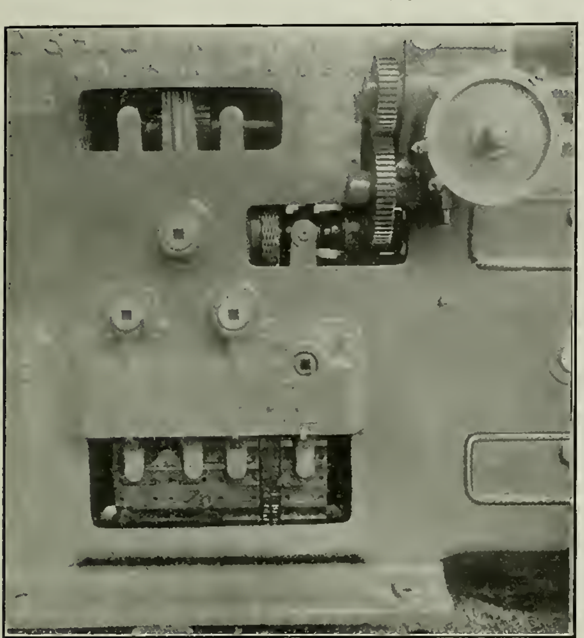

Fig. 2. Drum Blocks Which Control the Spindle Speeds

cross feed screw, lead screw and the like, are provided with jaw bases. A positive spindle brake is provided for the convenience and safety of the operator when chucking.

The machine, as a whole, is constructed on the unit principle. The main driving shaft runs from end to end. All

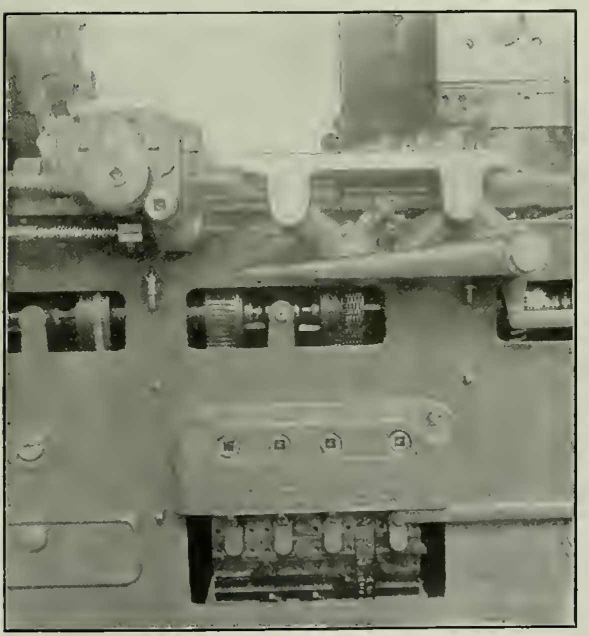

Fig. 3. Drum Blocks Which Control the Feeds and the Traverse Movement of the Turret and the Cross Slide

shafts for headstock and turret-drum levers, as well as the square socket holes, of uniform size, so that one hand crank can be used for convenience in setting up for a job.

The spindle bearings have ring oilers and all fast running shafts have sight-feed oilers. There are four changes of spindle speeds running in geometric progression. All spindle speeds are obtained through friction clutches by the operation of two levers, automatically controlled by blocks on a drum underneath the headstock, as shown in Fig. 2. By the use of these blocks, with the assistance of the pointers

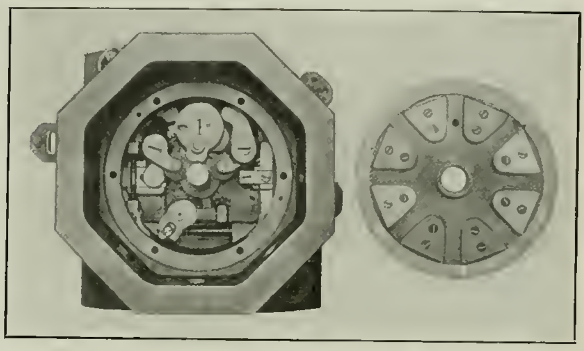

Fig. 4. Inside of Turret Indexing Mechanism

and speed tables shown, the shifting levers are easily set for any available speed.

Thirty-three feeds obtained by change gears are available for feeding the cross slide in or out, or for feeding the turret forward. The independent trip blocks for the in and out cross feed, are shown on the dial under and a little to the

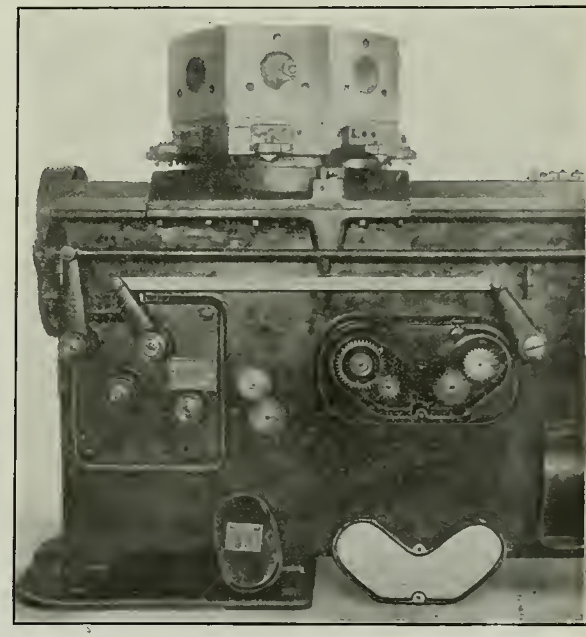

Fig. 5. Rear View Showing Covers Removed from Change Gears

left of chuck in Fig. 1. Rapid traverse movement in either direction for the cross slide and turret are also provided. The feeds provided are suitable for roughing, finishing, reaming and facing. Any feed is available for the tools on any face of the turret, or for either the front or back tool block on the cross-slide by applying the proper drum blocks on the drum shown in Fig. 3. These drum blocks also control the traverse movement of the turret and cross slide.

The turret has independent trip blocks for each face, which strike blocks on a trip table, as shown in Fig. 1. This photograph also shows the convenient position of the hand-tripping lever, just below the trip table.

The headstock and turret drums referred to, are provided with 31 spaces, making 30 changes possible, with one space for starting. When all the spaces are not to be used the front row of studs on the outer diameter of the index dial rim which is shown near the lower right-hand corner of Fig. 1 causes the drum shaft to be brought rapidly back to zero, or the starting point, for the chucking of the next piece.

The rear row of studs on the outer diameter of the index dial rim is used to set the timer in motion, the speed of which is controlled by gears interchangeable with the feed change gears. These change gears give the timer a speed of from 2.9 to 6.4 revolutions per one revolution of the spindle. The purpose of the timer is to give a "clean up" or "dwell" period for any feed of the turret or cross slide for any predetermined number of spindle revolutions. It may also be used for stopping any feed after a certain number of revolutions of the spindle. After completing a "dwell" or "feed period" the timer automatically trips the machine for the next operation. The timer dial is shown in Fig. 1 a little above and to the left of the index dial.

The row of studs on the side of the index dial next to the bed of the machine is used for setting the brake on the turret lead screw during a "dwell" or "clean up" cut, thus preventing the tool from being forced away from the work.

A desirable feature, to which attention should be directed, is the easy removal of the "index dial," "cross feed dial," and the "turret stop table," with all stops assembled. This feature makes the "setting up" of various jobs on the same machine very convenient in that it preserves the relative positions of all the stops for any particular job.

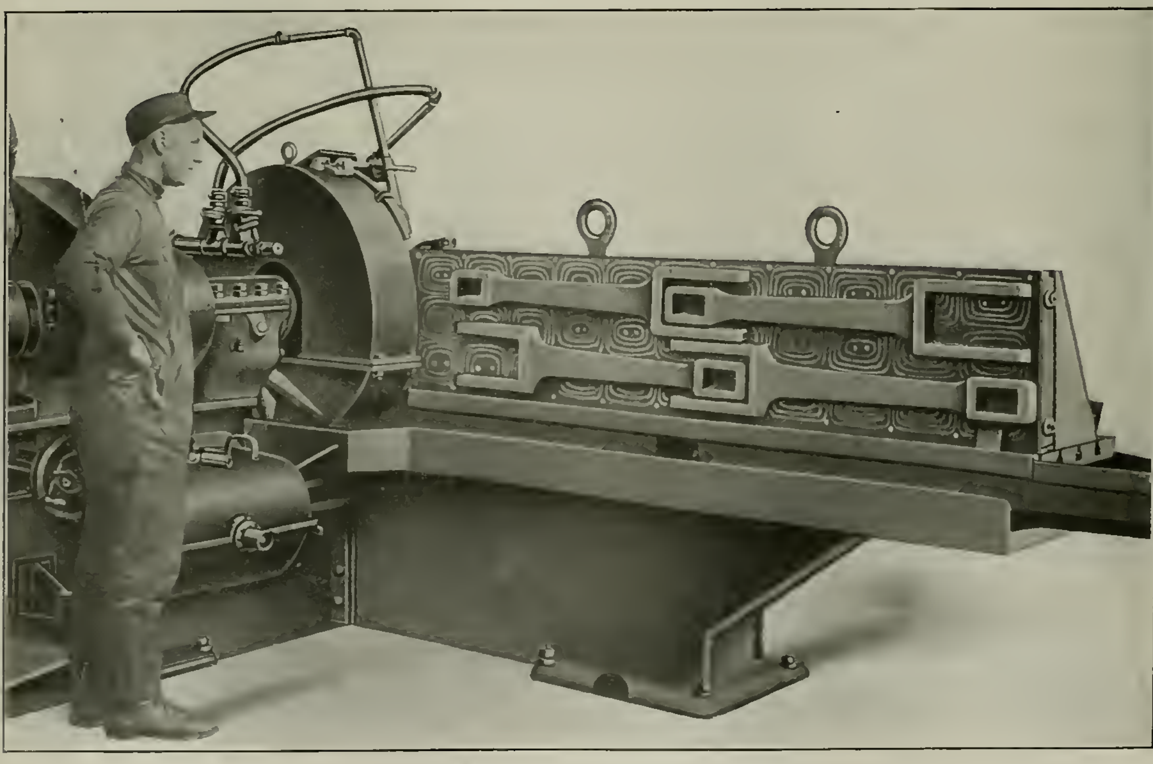
The inside of the turret indexing mechanism is shown in Fig. 4. In order to expose the indexing and locking mechanism the top plate is shown removed and placed bottom side up to the right of the turret. From this it will be seen that the turret is revolved by a crank movement, a roller on the end of the crank working in the spaces between the blocks which are doweled and screwed to the bottom of the turret as shown.

In order to give an idea of the placing of the change gears a part of the back of the machine is shown in Fig. 5, with the gear covers removed. The gears are easily slipped off or on by hand.

CUTTING DOWN THE CHUCKING TIME

IN keeping with the steady progress in the use of the individual electric motor drive for machine tools in railroad shops, the acquisition of electrically operated accessories and small tools is receiving much consideration. The large magnetic chuck shown in the photograph is offered as a suggestion in the chucking of parts for face grinding.

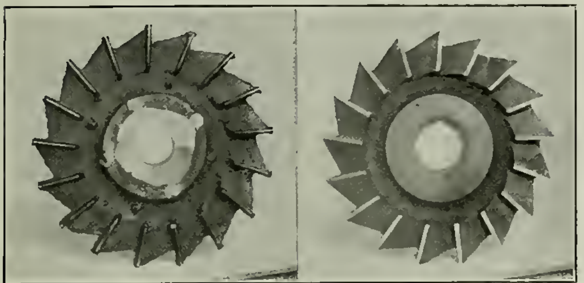
The face of the chuck is 18 in. by 84 in. and is shown in operation bolted to the bed of a heavy duty face grinding machine manufactured by the Diamond Machine Company, Providence, R. I. The four connecting rods are being ground



Grinding Machine Equipped with Magnetic Chuck from the rough without any previous machining. The question immediately arises as to how the work is held magnetically in view of the unevenness consequent to the rough forging, and in view of the fact that at the start of the work the links will not be held by a smooth surface. The answer is that a very light cut is taken from the surfaces in the rough and then the links are turned over so that the fairly smooth surface is against the magnetic face.

REMARKABLE DEVELOPMENT OF CAST TOOL STEEL

The perfection of a method of casting all-but-finished machine tools devoid of blow holes, crystallization, or strains, providing a homogeneous casting throughout with remarkable metal removing ability, seems to have been successfully achieved. A varied collection of steel tools and tool steel, manufactured under the Davidson process of casting formed tools, will be exhibited at the June mechanical conventions in Atlantic City by the exclusive distributor for the railroads in the United States, Oscar F. Ostby & Co., Inc., New York.



(Left) Rough Casting of Milling Cutter. (Right) Finished Cutter.

The story of the development of the process by Arthur C. Davidson, president of the Davidson Tool Manufacturing Corporation, New York, who has had a wide experience in the production and heat treatment of tools for different purposes, is a romance in steel making interrupted by discouragements, disappointments, accidents and the usual setbacks incident to the development of any revolutionary process.

In April, 1918, Mr. Davidson had no works of his own and it was necessary to rent a furnace which had at one time been used for making crucible castings, but which had been out of use for some months. This furnace was of poor design and in a bad state of repair, but it was thought that it would serve for a demonstration heat. Ten 100-lb. crucibles were accordingly charged and put into the furnace, one of which was charged entirely with high speed steel scrap, largely that resulting from previous melts made by Mr. Davidson. This was done to prove whether or not the gates and risers resulting from the casting operation, could be worked up in subsequent heats, with the object of gaging the value of the process if these had to be thrown away.

The furnace worked so badly that the heat instead of coming out in six hours, as it should have done, was in the furnace about ten hours, and only three pots became hot enough to pour at all, the metal even from these being entirely too dull for the best results. After this number had been poured, the cover over the furnace flue collapsed and the heat had to be terminated. The conditions surrounding the test were therefore in every way unfavorable and disadvantageous. Nevertheless a number of milling cutters, countersinks for ship rivets, and forming tools were cast, some of the best of them coming from the pot charged entirely with scrap. Two of the cutters and one of the countersinks were taken from the works, etched with private identification marks, turned back to Mr. Davidson for annealing, machining, hardening and grinding and were then tested. In order to have a fair standard of comparison, a side milling cutter of one of the best brands of high speed steel was bought directly from the works. The tests were made at the Quintard Iron Works, and although it was by no means a perfect casting, nevertheless it stood up favorably against the stock cutter under the most extreme test that could be given it.

A 2½-in. by ½-in. side milling cutter of the cast steel was then put in the machine and tested at gradually increasing speeds until finally the limit of the machine was reached. The cutter was taking a depth cut similar to a keyseat in a bar of steel of 0.30 or 0.40 per cent carbon, this cut being the width of the cutter by ¼ in. deep. On the final test, the cutter was run at a speed of 400 r.p.m., with a feed of 7 in. per minute. This is a linear cutting speed of about 250 ft. per minute, and, as stated, was the limit of the machine. The cut was run as far as the clamps on the test bar would permit, and as it was not possible to test the cutter any more severely, the trial was stopped, the cutter taken out, and it showed no sign of the gruelling test.

In spite of the fact that the casting conditions were bad, the results of the test seemed to indicate the probability that tools could be produced by this process free from blow holes and sufficiently true to form to be finished merely by grinding the cutting edges.

The structure of the steel appeared to be so good and the tests were so satisfactory that Mr. Davidson was advised to proceed with the commercial development of the process, and accordingly a small foundry was obtained in Brooklyn, N. Y., a crucible furnace built, molding machines, and machine tools for finishing or partially finishing the product installed, and production, which was started in August, has proceeded regularly ever since. An electric furnace has since been installed for melting the steel.

For convenience of comparison, an ordinary milling cutter, just as it comes from the mold, is shown in the illustration; adjoining it is shown the same cutter, ground and finished and ready for work. It will be noted that the milling cutters are cast with a projecting lip on the cutting edges; these are finished entirely by grinding and with little more expense than the grinding of a machine tool. A perfect edge is obtained in this way with a minimum of labor and lost steel, while the possibility of local defects is avoided.

The material used for "killing" the steel during the casting process is a secret; it may be said, however, that the results are striking in the last degree, and the metal, instead of having a comparatively sopey pour, is thin and fluid, more like good hot cast iron than like steel. As a result the details of small cutters are cast practically perfect.

It is well known that most steel, when cast, has a coarsely crystalline structure, but an examination of the fresh fractures of Davidsonized steel shows that this is almost wholly absent; in fact, the structure of this steel, as cast, looks more like that of forged steel than it does like a casting.

Davidsonized high speed steel milling cutters have machined chrome vanadium *D* type, showing scleroscopic reading of 40 points at 98 ft. per minute, depth of cut ⅜ in. and a feed of 6 in. per minute. They ran continually without grinding for six hours, after which it was only necessary to stone up the edges, after which they were run under the same conditions for eight hours. The teeth then required grinding of .005 in. off the diameter.

UTILITY STEAM OR COMPRESSED AIR HAMMER

WHAT is known as a 30-in. Cincinnati special forge operated either with compressed air or steam, has been developed by the Sullivan Machinery Company, Chicago, Ill., for such work as the making of chisels, wrenches, small tools of all kinds, small levers, keys and wedges, etc. It may also be used for welding and straightening rods and bolts, or for the sharpening of picks and crowbars, or similar jobs. An important advantage is its rapidity of action which is made possible by the use of an air or steam thrown valve; a maximum speed of 600 strokes per minute is possible.

The guide block is bolted to the rigid cast iron frame and supports a small vertical engine, as shown in the photograph. The small pin which is shown projecting from the lower end of the valve chest is held up, when the machine is not in operation, by the levers which are operated by the foot treadle. The upper part of the pin projects into the valve chest and abuts against the lower end of a floating valve. When the treadle is depressed, the end of the lever drops away from the pin and allows it to fall away from the valve. This uncovers the ports and the valve starts operating, and the hammer begins to strike. A single blow may be struck or many in succession, either light or heavy, at the will of the operator. The operation of the valve is similar to that of a rock drill valve; indeed, the hammer part of the machine is a Sullivan FF-12 rock drill.

Since the travel of the foot treadle is long as compared with the travel of the valve, the operator can feel out the action of the valve and closely and accurately control the action of the hammer. Because of the rapidity of action, the operations may be performed at a moderate heat.

The distance from the center of the die across the throat to the frame is 15 in. Work may be done upon material up to 2 in. in thickness. The hammer cylinder is 2⅝ in. in diameter and has a stroke of 5¾ in. The air consumption at 90 lb. per sq. in. pressure, is 93 cu. ft. per minute. The rebound of the hammer is controlled in such a way that some of the air or steam is held in the upper end of the cylinder, thus cushioning the piston on the return stroke, or rebound, and preventing a jar or jolt to the machine.

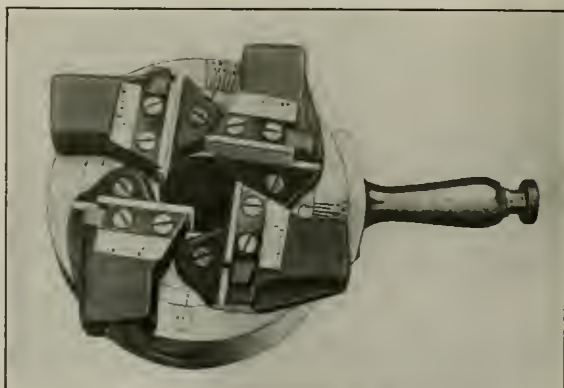
The weight of the striking parts is 100 lb., including 52 lb. for the upper guide, 27½ lb. for the upper die and 19 lb. for the weight of the piston, rings and springs. The machine has a net weight of 1675 lb., a height of 6 ft. 6 in.; the base is 26½ in. wide and 29 in. deep. The use of compressed air in operating the hammer has an important advantage in that the exhaust air may be utilized to blow chips, scale or dirt from the face of the die.

Power Hammer for Small Work

AUTOMATIC SCREW CUTTING DIE HEAD

ACCESSIBILITY is the keynote of the screw cutting die head shown in the photograph. The thread chasers which can be easily and quickly removed for grinding or changing, are supported on the face of the head. The head is opened automatically by retarding the forward motion of the carriage, is closed by hand, and is locked by the operating handle which contains a latch having a tongue milled on the lower end. This tongue is milled off center, thereby permitting of roughing and finishing cuts; to adjust the head for either merely requires a half turn of the latch to suitable graduations.

The head is graduated for all sizes of bolts and pipe, both right and left hand, within its range. It is adjusted to size by means of an adjusting screw which engages the head body. Since the operating, adjusting and closing rings remain in a fixed position when the head is closed, the rotating of the head body within these rings gives the diameters within the range of the head. To set the head for left hand threading,



Landis Automatic Die Head

the screw which locks the latch pin is removed and the latch pin is rotated to the left hand graduation; the locking screw is then replaced and the left hand holders attached.

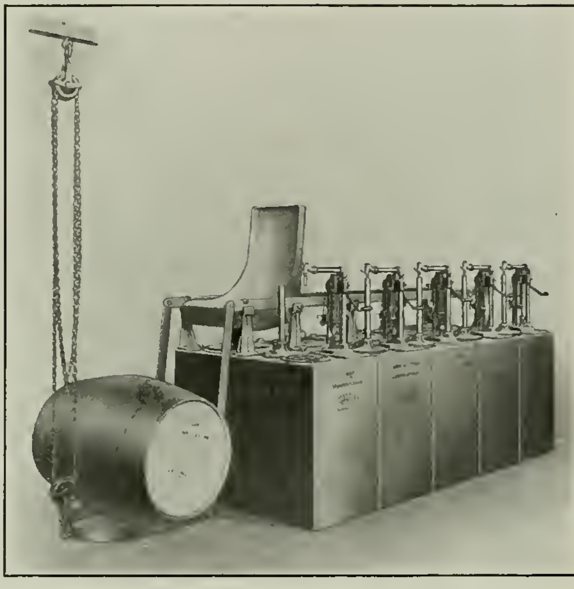
This head which is applicable to practically all makes of screw machines and turret lathes, which have sufficient space to swing heads of these diameters, has been recently designed by the Landis Machine Company, Inc., Waynesboro, Pa., and will be ordinarily furnished with a standard shank. Special shanks may be furnished provided they are not required to be larger than the standard shank.

STORAGE SYSTEMS FOR LUBRICATING OILS

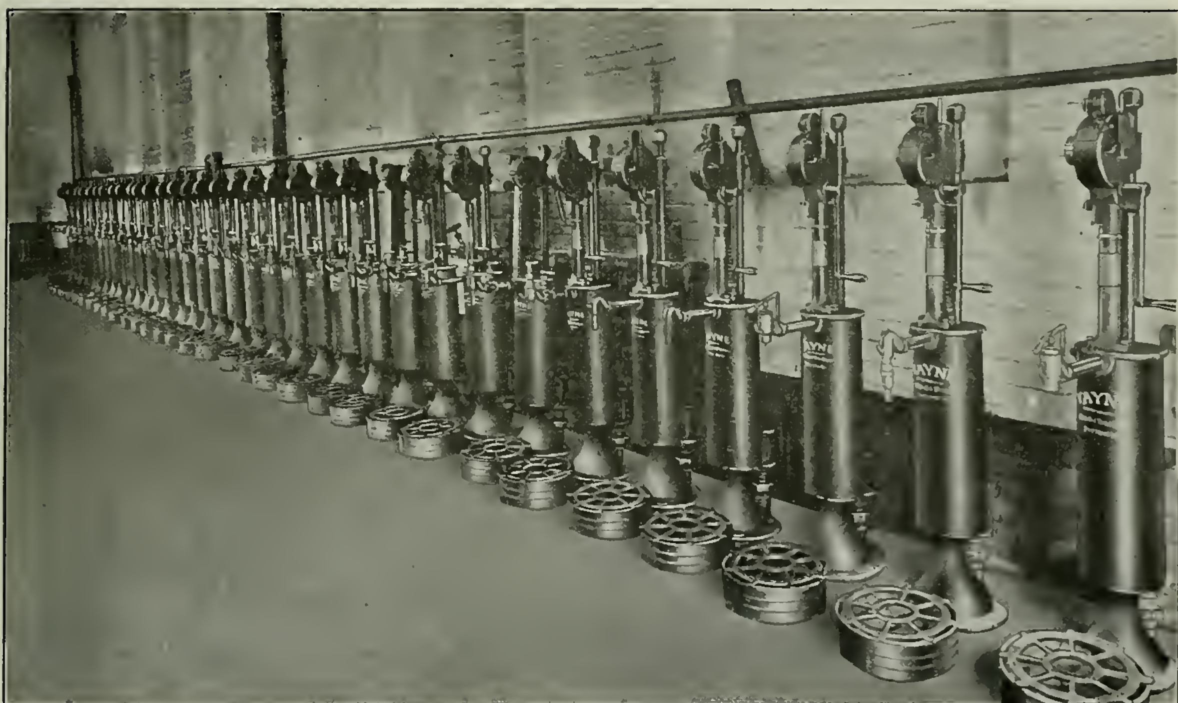
THE battery of oil pumps shown in the photograph is an example of progress which has been made in the orderly arrangement and safe storage of oil.

The battery storage equipment for lubricating oils is illustrative of a system for handling, storing and distributing lubricating oils in a manner which insures the entire draining of the barrels, as well as providing safe storage of the oil in practically fireproof containers free from dust and dirt, with the added advantage of accounting for every gallon used. The tanks are made in capacities of from two barrels up, in batteries formed as shown which can be added to as required, the height and length from the front to the back of the entire battery remaining uniform and the width of each unit across the front varying according to capacity. The equipment may be placed where the liquid is used and the arrangement of the barrel cradle, track and dash affords a means by which the entire contents of either iron drums or wooden barrels may be handled and emptied into storage tanks without waste and with a minimum of labor. Each equipment is fitted with an individual dip gage, providing a check on incoming oil or the contents of the tank. Likewise a measuring pump equipped with pump locks provides a check on all outgoing oil.

The oil storage equipment described is manufactured by the Wayne Oil Tank & Pump Company, Inc., Ft. Wayne, Ind.



Battery Storage Equipment for Lubricating Oils



Battery of No. 32 Model E Pumps in Railroad Oil House

HEAVY DUTY HORIZONTAL MILLING MACHINE

THERE is no clearer index of the growth of the American locomotive than is reflected in the tendencies in the design and construction of special heavy railroad shop tools for machining modern locomotive parts. A conspicuous example of recent improvement along this line is afforded in the new heavy duty horizontal milling machine, designed and built by the Newton Machine Tool Works Company, Inc., Philadelphia, Pa., for the Altoona shops of the Pennsylvania Railroad, upon which the heaviest locomotive driving rods are milled two at a time.

Reference to Fig. 2, a general view of the machine from the rear of the operator's side of the table, conveys at once a general idea of its proportions and strength and reflects credit upon the designer's study of the convenience of its operation in the "easy reach" of all feed and control levers; the driving motor located on the opposite side of the operator and out of his way, and the grouping of lubricating cups for table guides, drive and driving gear, bearings, etc., at the base of the pedestal in plain view of the operator, thus tending to minimize the dangers of damage from "running dry." The strict observance of "safety first" is indicated by the enclosing of all gears.

The base is of the closed top safety type and is one and three quarters times the milling length of the table. Cheeks cast as an integral part of the base for the upright mounting are extended. The uprights are of deep box section carried to the floor line and bolted, keyed and doweled to the base.

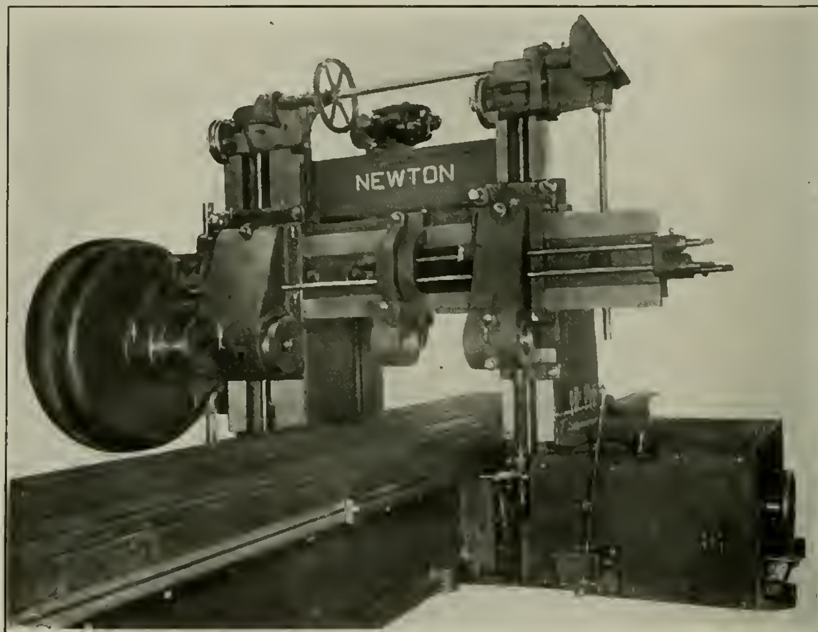


Fig. 1—View from Operator's Position Showing Convenient Location of Control Levers, etc.

Fig. 2—View of Newton Horizontal Milling Machine from the Rear of the Operator's Side of the Table

The machine is driven by a 75-hp., 400-1,200 r. p. m. motor. Fig. 2 shows the convenience of arrangement of control levers from the operator's position as well as the additional lubricator cups on important spindle bearings and crossrail slides.

The table is supported its full length and has five T-slots planed from the solid with drill stop pin holes at each end. It has a 20-ft. travel, and four changes of speed provided by a steel angular rack and phosphor bronze spiral pinion from a box in which there are mounted adjustable sleeves which give the changes without the removal of gears. An adjustable automatic stop is provided and the table is surrounded by a pan to collect overflow oil which is drained to the reservoir at the base. The rapid traverse and feed clutch are interlocked to prevent simultaneous engagement. The working width of the table is 42 in.; the maximum distance from top of the table to the center of the spindle 31 in., and the minimum distance, 4 in. The width between uprights is 51 in.

The crossrail is of the straight faced type and provides 10 in. of side adjustment to the spindle by a screw from the right hand end of the machine. The crossrail is supplied with one outboard bearing, and one intermediate bearing. The intermediate bearing provides for quick removal with the arbor. The crossrail is counterweighted and has a power rapid traverse in both directions through double lifting screws operated by a separate motor. The 5-hp., 1,150- r. p. m. lifting motor is mounted on the tie beam which also serves as a gravity tank, to which the lubricant is pumped from the reservoir in the base. Hand adjustment is made to the crossrail from the end of the rail. There is a boss on the bottom of the crossrail at the right hand side which, in connection with a gage stop on the upright, is used for gaging heights. The counterweight ropes are of such length as to allow the weights to operate in a pit, and the wheels are so arranged that the ropes follow the contour of the uprights.

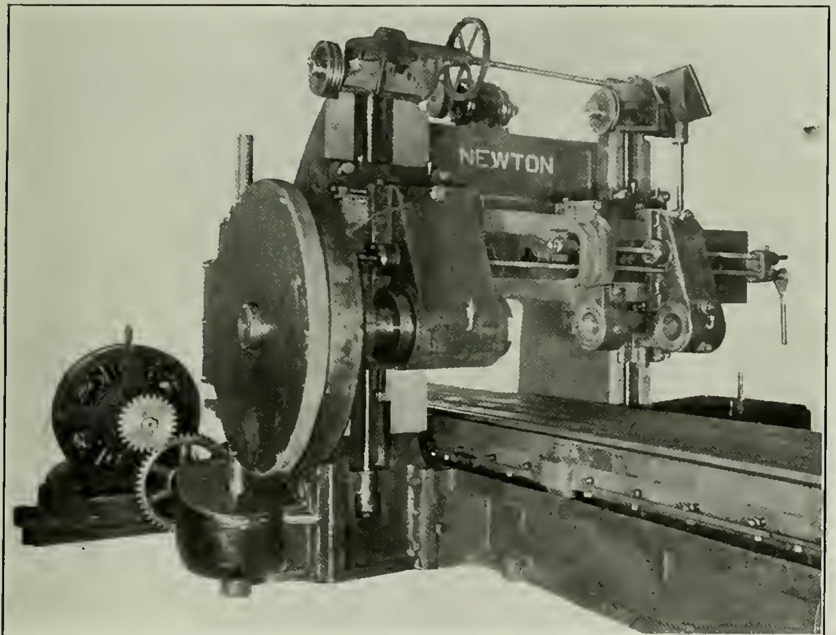

Fig. 3—Showing Application of Motor Drive

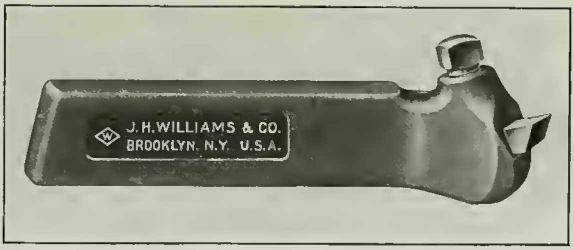
The bearings for the driving worm and driving worm wheel are cast integral with the crossrail, and have sliding sleeves for the spindle. The crossrail is gibbed to the main or wide upright only, with the narrow guide construction to assist in maintaining alinement, and is fitted with a continuous steel taper shoe for taking up wear. The crossrail is carried on two lifting screws, which are held in tension at both ends to prevent buckling.

The spindle is of taper end construction for taking up wear and maintaining alinement, is provided with an internal taper hole, has a through hole for an arbor retaining holt, has a broad faced keyway for the cutter arbor, and is bronze bushed throughout. The spindle diameter through the driving worm is 7 in.; the diameter of the large end is 11 in.; it is driven by a phosphor bronze worm wheel and hardened steel worm having roller end thrust bearings, all of which are encased and run in oil. The driving worm shaft is double splined and the bearings in the worm box are protected by sleeves which are keyed to the driving shaft, rotating with it in bronze bushings, so that the keyways do not come in contact with the bearings.

A view from the right hand or motor drive side in front of the spindle is shown in Fig. 3 and gives convincing evidence of the strength of design and construction of the driving part of the machine.

NEW DESIGN OF SET SCREW TOOL HOLDER

A SET screw pattern toolholder has been added by J. H. Williams & Company, Brooklyn, N. Y., to their line of Agrippa toolholders. It is made with both the right and left hand offset and straight shanks. Where the cutter fastening device is in the shape of a cam the range of contact is limited. The set screw fastening has been provided for use where the steel used in the cutters is not ground to size and varies beyond established limits. The set screws are made of alloy steel, thus insuring strength and toughness. The holders have a bevel on the nose in order that they may be used in close quarters. They are drop forged and are given special heat treatment.



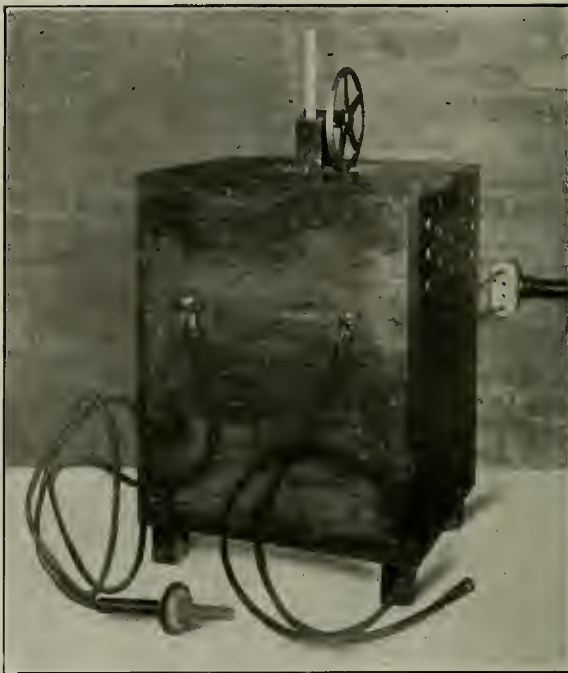
Set Screw Type of Tool Holder

ALTERNATING CURRENT ARC WELDING EQUIPMENT

THE new Zeus arc welder, manufactured by the Gibb Instrument Company, Detroit, Mich., has been designed to overcome the disadvantages of bulk and moving parts which are inherent with all types of motor generator welding apparatus. The new welder consists of a simple transformer with no moving parts. The Zeus welder is comparatively small, making it unnecessary to set aside special space for its accommodation. It is built on the unit system, which makes it possible to connect a duplicate machine in parallel with the original when the work becomes too heavy for a single machine to handle.

One of the outstanding features of the welder is its arrangement for regulation. It is not necessary to change any connection for the purpose of regulating the arc. A hand-wheel is conveniently located on the top of the machine and furnishes a means whereby the secondary winding may be raised and lowered to provide for the regulation necessary for various conditions of work and sizes of electrodes. It is claimed by the manufacturer that the inherent reaction of the transformer automatically stabilizes the arc for different arc lengths and that the current consumption is from 20 to 40 per cent less than that for motor generator welding equipment. It is also claimed that, due to its inherent characteristics, the machine is particularly adaptable to overhead welding.

The particular advantages offered by a welding outfit of this kind lie in the fact that it is portable and that it may be operated from almost any alternating current circuit used for power or lighting. Because of these characteristics, it is frequently possible to use the welder in many places without having special circuits for the purpose.



The Handwheel and Connections Are the Only Exposed Parts

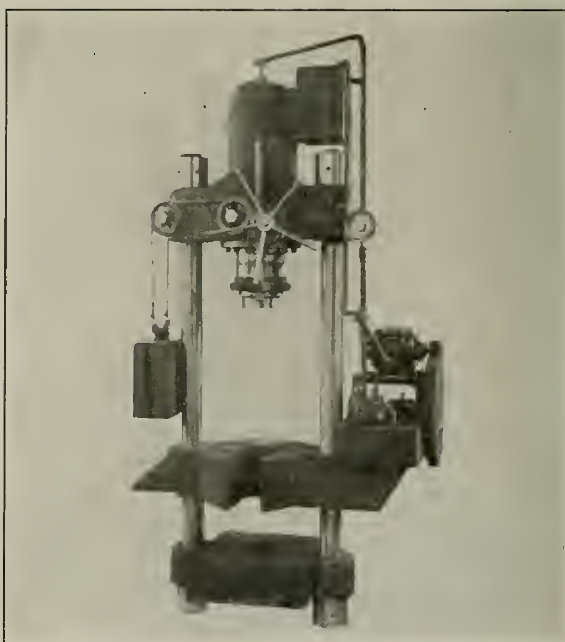
SPECIAL HYDRAULIC PRESS FOR RAILWAY SHOP USE

AN improved type of 200-ton hydraulic forcing press has recently been furnished the Pennsylvania Railroad by the Hydraulic Press Manufacturing Company, Mt. Gilead, Ohio. It is especially designed for the purpose of quickly pressing driving brasses in and out of boxes and piston rods into pistons, and occupies very little floor space.

The bottom base—72 in. from the face of the raised ram—and the cylinder are of cast steel securely mounted on the substantial perpendicular steel uprights or strain rods; they are secured by steel spanner nuts held in place by set screws bearing on copper slugs. The lower base is provided with an 8-in. hole and is designed to stand the effect of full force of the press. The intermediate base, which is 45 in. from the face of the ram, is held in position by screwed collars through the lugs cast on the base and bearing down against the collars on the strain rods. The intermediate base is also of cast steel and is provided with a U-shaped opening 8 in. wide, through which the driving brasses are intended to fall as they are pressed from the boxes.

The press is furnished complete with pump attached, ready to operate by motor drive as shown, or it may be provided with a belt drive. It is equipped with automatic knock-out valves for maximum pressure, also with spring relief valves. The discharge from the main press cylinder, as the ram is raised, is forced into the surge tank at the top, and any surplus liquid which flows into the surge tank overflows to the pump reservoir.

A part of the stroke of the ram is made without any pressure registering on the gage; this is taken care of by a

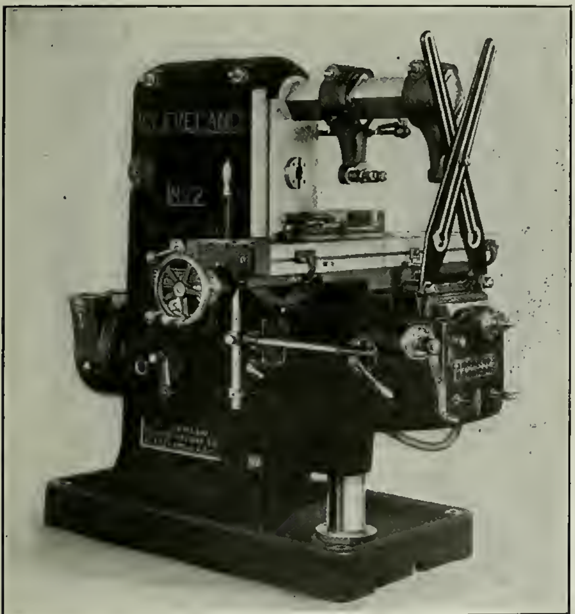


200-Ton Inverted Forcing Press With Two Bases rack and pinion, so that the ram can be brought down to the work by hand. When this is done the cylinder is filled with water from the surge tank which is bolted to it; the water enters the cylinder from the tank through a check valve. When the ram stops the pump delivers the water to the main press cylinder through another connection and the check valve closes. The ram is counterweighted and will stay in any position where it may be placed.

MILLING MACHINE WITH SPECIAL ATTACHMENT

The design of the milling machine shown in the illustration is noteworthy in respect to several features, most conspicuous of which is the square overarm and the handy and easily attachable vertical spindle milling attachment, a combination provided to meet the demand of those who, having a certain amount of vertical or face milling work, are unable to keep a vertical milling machine continuously busy. This machine, of the plain and universal types, as well as the vertical milling attachment, are the products of the Cleveland Milling Machine Company, Cleveland, Ohio. The machine is made in two sizes and the following details of construction apply to both models.

The column is of rigid construction—a complete box section—and is cast in one piece with the base, a heavy, ribbed, semi-steel casting, with heavy vertical and horizontal walls, the only openings in which are those necessary for the change gear levers on the front, the pulley drive housing in the rear, and the cutter lubricant tank on the left side of the machine. All of the interior parts are lubricated automatically, and all adjustments on the bearings are made from the outside. The dove-tail knee slide extends upwards to the overarm, affording ample surface for clamping the attachments. The depth of the column has been carefully determined in order to place the spindle and the shaft bearings in proper relation to each other to secure maximum rigidity. The horizontal wall separating the lubricating oil reservoir from that of the cutter cooling compound is designed to give added rigidity to the column; the lower surface of the base is finished so as to give it a firm foundation, while the contour of the upper surface of the base is pan-shaped with depth enough to catch oil and chips, thus keeping the surroundings clean.



Cleveland Plain Milling Machine

The knee is designed with an improved dove-tail slide and the bearing of the saddle is on the flat, wide surface, the narrow slide acting as a guide only. The bearing of the knee on the column is carried well above the top of the saddle slide, thus giving the knee a longer bearing on the column, reducing the bearing pressure to a minimum. The feed box, as well as the knee, is entirely enclosed. The elevating screw is large in diameter and in one piece. By the use of the post the telescopic screw has been eliminated, as it acts as a support to the elevating nut and as a guide in the knee. The screw is operated with a double bevel gear, the hand feed and power feed being independent of each other.

The table is machined all over to insure proper alinement and the bearings on the table are at the top of the saddle instead of at the bottom of the dove-tail, which method secures a large bearing surface and locates the bearings, which are automatically lubricated by rollers, a greater distance apart. The bearing on the saddle is also at its widest portion, and both saddle and table bearings are taken up with long taper gibs which are provided with adjusting screws at both ends.

The square overarm provides positive alinement of the arbors and maximum rigidity of the arm pendants. It is impossible for the operator to place the arbor supports on the overarm and on the arbor in any other way than exactly in line. Owing to the firmness which the square overarm imparts to the machine a great variety of work can be performed.

The flanged spindle eliminates the overhang on the end of the spindle as well as the trouble caused by cutters screwing fast into it, and also allows the cutter to be run in either direction. On the flanged spindle is a face keyway, inserted into which are hardened steel jaws for driving arbors and face mills. It is unnecessary to remove these at any time to change from a face mill to an arbor, as the driving is done by the hardened steel jaws. The strain is therefore taken off the taper hole. The spindle is provided with a positive lock that enables the operator to loosen the arbor nuts with the least possible difficulty and is also provided with a handwheel to revolve the spindle, which feature the operator will find convenient on boring jobs and other milling operations. The spindle lock cannot be operated while the machine is running, nor can the main driving clutch be thrown in while the spindle is locked.

All the bearings in the column and knee are thoroughly covered with lubricant while the machine is running, thus relieving the operator of the responsibility of oiling the most important parts of the machine and eliminating the necessity of oil holes in any of these parts. The oil reservoir requires refilling but twice during the year. As high speed steel cutters are used almost entirely there has been provided a reservoir of ample size for cutter cooling lubricant, which is circulated by a centrifugal pump operating only when the spindle is in motion.

The speed and feed arrangements are both of the sliding gear type. Changes of speeds as well as feeds are made by two levers conveniently located for the operator. The spindle speeds are 16 in number, in either direction, and the feeds are 16 in number in either direction also, so that this machine will handle all classes of cutters. Speeds and feeds being in geometrical ratio, the correct changes of speed and feed for the work to be done can be made without trouble. All gears and shafts in the drive, as well as the feed, are of hardened steel, automatically lubricated, running in bronze bearings, and protected against breakage by a safety device.

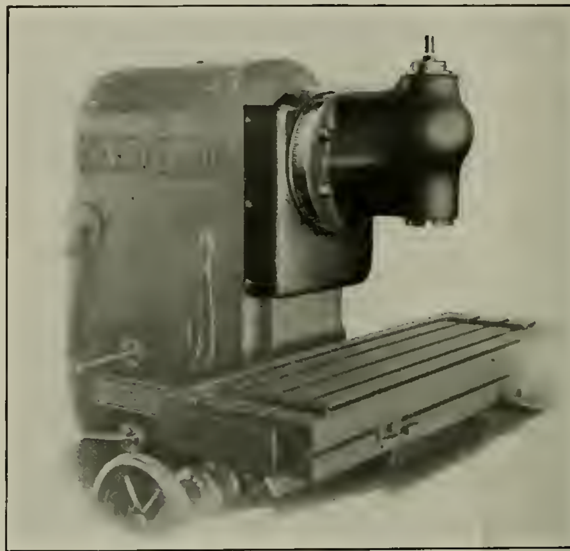
The power is transmitted through a constant speed drive pulley and the machine is so designed that it requires no loose gears on the spindle. All shifting of gears is done on the secondary shafts below the spindle. The starting and stopping lever may be operated from both sides.

The principal dimensions of the smaller machine which occupies a floor space of 70 in. by 60 in., include a table whose working surface provides an area of 44 in. by 12 in. and has three ⅝-in. T-slots and a right and left adjustability of 50 deg. In the larger model, occupying a floor space of 92 in. by 98 in., the table swivel right or left is the same as that of the smaller machine, while the working surface is 50 in. by 13 in.

The smaller size has a longitudinal range of 22 in., a cross range of 8 in. and a vertical range of 15 in., while the larger type has 28 in., 10 in. and 15 in. ranges, respectively. The overarm is 3¼ in. square on the small size and 3¾ in. on the large; the motors recommended are 5 hp. and 7 hp., respectively.

The vertical spindle milling attachment referred to is shown in one of the photographs. It is bolted to the column and ready for action and is manufactured in three sizes, the distances from the face of the column to the center of the vertical spindle being 10¾ in., 12½ in. and 15 in., respectively. The minimum distances from the nose of the spindle to the table are 1¼ in., 1½ in., and 2 in., and the maximum 16½ in., 16½ in. and 18 in., respectively. The spindle taper holes are No. 10, 11 and 12 Brown & Sharpe and the shipping weights range from 225 lb. to 415 lb.

The drive is taken from a gear fastened to the nose of the spindle, which drives a spur gear on the horizontal shaft and the spindle is in turn driven by a large mitre gear. All gears and shafts are made of steel and enclosed, running in bronze bearings throughout. The bearings on the spindle are the same as the milling machine spindle and form two



Vertical Spindle Milling Attachment

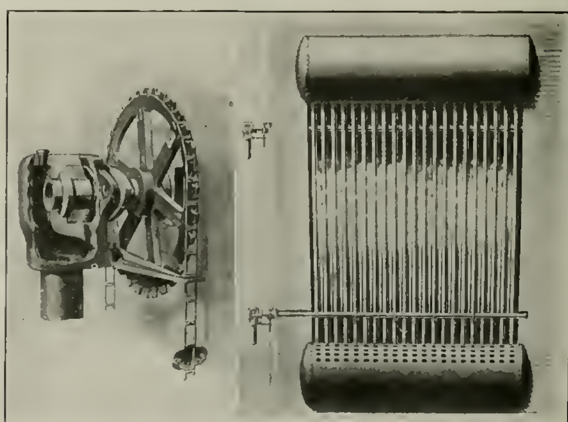
taper cones in opposite directions, adjusted by a nut on the outside of the spindle. The base of the head is graduated so that it may be set at any angle in a vertical plane parallel with the elevating screw, and the attachment when clamped in position on the dove-tail slide of the column which extends above the center line of the spindle, is as rigid as if it were a part of the milling machine.

AN AIR TIGHT SOOT CLEANER SWIVEL HEAD

An improved soot cleaner swivel head which provides for easy and convenient operation, and does not leak steam or permit air infiltration is shown in one of the illustrations with a part of the swivel head cut away to show the relation between the steam delivered to the swivel head from the vertical riser or pipe, and its entrance into the movable horizontal element or spray pipe. The latter is fitted with steam turbine nozzles through which steam at high velocity is sprayed upon the boiler tubes, thus blowing off soot deposits as the spray pipe is revolved by means of the chain operated sprocket to which it is keyed.

A detail which merits attention is the method of packing the stuffing box in the swivel head. It will be seen that the spray pipe has a collar near its end which fits against metal on one side and the packing on the other. It is designed in such a way that when steam is turned on friction is relieved and turning the element by hand becomes easy. As the vertical riser expands or contracts the swivel head rises or falls, carrying with it the end of the spray pipe. Air infiltration, as the result of this movement, is prevented by the use of an air tight sliding joint between the sprocket wheel and the metal housing, which is mortared into the brickwork.

A typical installation of the Vulcan soot cleaner, which is manufactured by the Vulcan Soot Cleaner Company, Du Bois, Pa., equipped with the new Vulcan swivel heads is also shown and it will be noted that the installation is well anchored in the brick walls, the spray pipe being supported on the tubes at four intermediate points. Convenient stops on the sprocket chain limit the amount of rotation and a pointer on the sprocket wheel indicates direction of sprays.



(Left) Sectional View of Swivel Head of Soot Cleaner. (Right) Application to Stirling Boiler

FOUR-SPINDLE AUTOMATIC SCREW MACHINE

THE improvements in the new automatic turret lathe illustrated herewith, are intended to overcome some of the inaccuracies which often result from mismanagement by relatively incompetent operators. The machines are built in three sizes, the smallest type accommodating stock up to and including ½ in. in diameter, the medium type taking up to and including 1 in. in diameter and the largest size capable of machining metal up to and including 1¼ in. in diameter; an additional model is in prospect for work up to and including 1½ in. in diameter.

An outstanding characteristic of the new lathe lies in its compactness and rigidity of design. A stripped bed is shown in Fig. 2 for convenience in illustrating this feature of rigidity and it will be noted that the bed is a solid casting from the bottom of the feet to the top of the tool knee, thus avoiding bolting on of brackets and bosses.

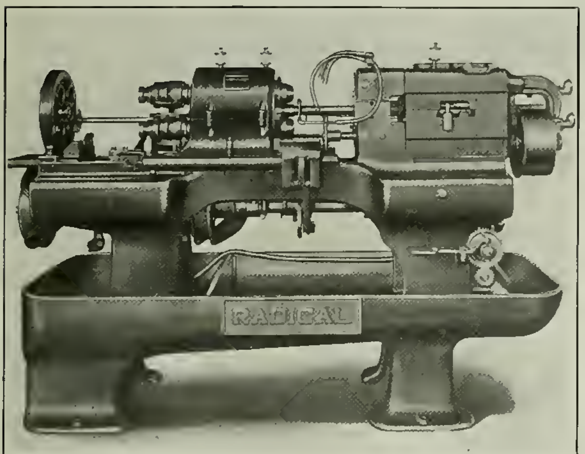


Fig. 1. Radical 4-Spindle Automatic Turret Lathe

The cylinder and cylinder housing are of semi-steel. The length, diameter and weight of the former compared to the length of the cylinder bearing and of the carriage ways, prevent jumping, tilting or lifting of the cylinder or the carriage. The cylinder carriage movements are to and from the tools to the roll which is held on the bottom of the carriage by a pin. This roll engages the groove on the face of the lead cam, the hub of which is keyed to the cam shaft, which is driven through the cam shaft gear box located on the end of the bed within the pan. Through this gear box the cam shaft is revolved at different speeds to give a fast or slow travel to the carriage as may be required.

The spindles are one-piece steel forgings, heat treated and ground. They run continuously in one direction and are gear driven. Four changes of speed are provided and by removing a split collar and placing it on the opposite side of the driving gear four more changes of spindle speeds may be obtained. The machine provides 10 changes of cam shaft speeds and the eight changes of spindle speeds without pulley change.

Adjustments have been simplified and all adjustable strips on drives eliminated by the use of the so-called "stay-put" cams, one of which is illustrated in Fig. 3.

Ingenuity has been shown in the development of the different mechanisms for controlling the indexing. On the rear of the cylinder is a separate jigged gear which meshes with a pinion gear on the indexing shaft. This pinion gear is keyed to the index shaft and moves forward and backward with the shaft and cylinder carriage travel. As the cylinder carriage reaches its receded position the pinion gear, also keyed to the shaft, meshes with a segment which moves upward by a lever and cam movement. This upward movement is of sufficient duration to give the cylinder a quarter revolution, bringing each one of the spindles in line with the next tool. The connecting rods between the cam and the segment have lock nut adjustment to take care of the wear. The entire mechanism is located at the side of the machine at about the height of the carriage ways. The index shaft carrying the pinion gear extends back to the stock reel frame and on that end carries a pinion gear which meshes with an indexing gear in the reel. In this way the reel is indexed with exactly the same motion as the cylinder, the advantage of which feature lies in doing away with the strain from indexing the reel with bars of stock projecting from the spindles.

The mechanism for locking the cylinder after it has been indexed, is interesting. A hardened and ground bushing fits into a ground hole in the cylinder. A hardened and ground plunger operates through a hardened and ground bushing in its boss, being withdrawn by hand by a lever and automatically by a locking pin cam. The plunger is seated by a spring and is held in position by the cam. The end of the plunger is externally tapered to fit a corresponding taper in the bushing. Provision against wear is made by two additional inside tapers, one in the plunger and one in the bushing; these two sets of tapers check each other at all times. Should either set of tapers become worn, the other set will complete the locking until such a time as the worn set reseats itself. A double throw cam prevents the possibility of any rebound of the plunger from the bushing in the cylinder.

The chuck operating slide and the stock feeding slide are designed to permit of free and positive action for the entire chucking and feeding mechanisms without the use of levers and arms, by using slides which are carefully scraped and operate in scraped bearings, the operating, hardened and ground rolls being assembled directly on the bottoms of the slides so as to come into direct contact with their cams.

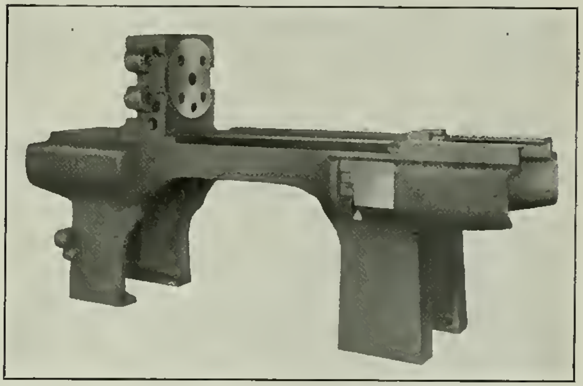

Fig. 2. The Stripped Bed Gives Some Idea of the Rigidity of the Machine

The throw from fast to slow cam shaft speeds is effected by shifting the trip dogs on the worm wheel, these dogs operating to throw the lever, which in turn operates the Johnson clutch within the gear box. The securing of different cam shaft speeds for cutting is accomplished by pushing the shifter handle in or out, operating on a graduated rod, which throws into mesh different trains of gears within the gear box. This rod is graduated for eight changes of speed, four being obtained with the gears in one position and four additional by substituting other gears.

The gage stop is capable of simple adjustment and of being easily pushed out of the way for the operator's convenience. A rod, 1½ in. diameter, projects from the lower front of the tool knee between the fourth and first positions and has crosswise slots ⅜ in. apart, into which drops a lip from the tool knee. This lip holds the shank securely in any selected position; on the end of the rod is a cap for finer adjustment.

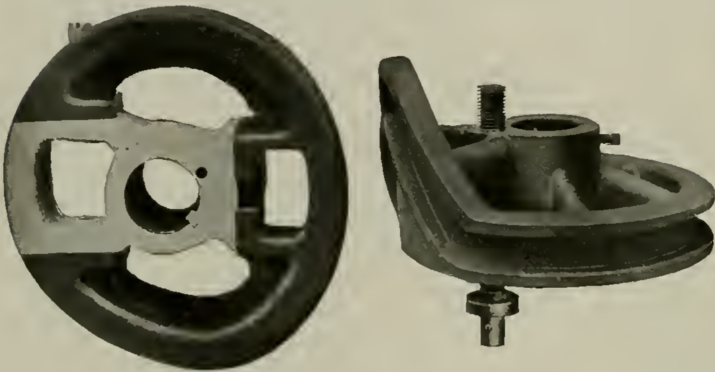

Fig. 3. Two of the "Stay-Put" Cams

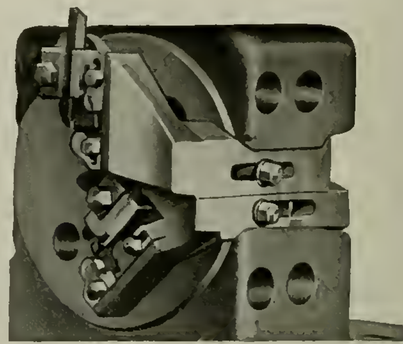

Fig. 4. Turner Slide for Holding Tools

The threading device proper is installed in two boxes, one in the third position and one in the fourth position, which boxes are interchangeable. Changing from one threading position to another does not require stripping the machine, but rather the simple loosening of a screw which holds the box in place on its dove-tail slide.

The lubricating oil is drawn by a chain driven, geared pump and forced into a reservoir within the tool head, where it is held under pressure for distribution to the cutting tools.

The familiar tool known as the box mill has been superseded by what is known as a Turner slide type of tool, which is illustrated in Fig. 4; a micrometer adjustment is used for raising and lowering the cutting blades.

This machine is the product of the P. W. V. Automatic Machine Corporation, Fitchburg, Mass.

PORTABLE TRANSFORMER FOR LEAD BURNING

THE most modern method of burning terminals in place on storage batteries, removing old connections, cutting off or building up posts, or in fact almost any form of lead work, is to do it by the electric welding process. The General Electric Company, Schenectady, N. Y., has recently developed a lead burning transformer especially designed to meet this need.

This transformer is designed to be connected to the ordinary 110-volt alternating current lamp socket, a 10-foot cord with a plug being provided for this purpose. This attaching cord is protected by a special rubber covering against the hard wear, dirt or acid with which it may come in contact. Connection to the transformer itself is made by means of a plug and socket connection so that this plug can be used in place of the snap-switch in the lamp socket for turning the current on and off.

Two separate rubber covered terminal leads are used to convey the low voltage heat producing current to the parts of the battery to be welded. The lead having the "Big Brute" clip is for fastening to the battery plate or posts which are to be worked on. The other lead has at its end a carbon holder which is arranged with a heavily insulated handle so that the operator's hand is guarded from the heat. The carbon holder takes any ordinary arc welding carbon, this carbon forming the second terminal.
