The Digestive Machinery of Honey-Bees.

BY PROF. A. J. COOK.

We know from our study of Geology that early life-forms in any branch of animals are simplest, and later gain more and more in complexity. Among insects, bees and their near congeners were the latest to develop. Indeed, there were no flowering plants until the Cretaceous Age—the age just before recent time—and so of course there could have been no flower-loving or nectar-sipping animals. As bees were so late in their evolution, we should expect them to exhibit marvelous development, not only as a whole, but also in their various organs. And such is the case to a most marked degree. I know of no animals—nor need I except man in the statement

surely have reason to place the bee away in the lead among the marvels of God's creation.

The bee's food is peculiarly refined and complex. Its provident storing of food, social habits, long life, entire care of the young, are exceptional among all the lower animals. It fashions vessels for food depositaries, of incomparable mechanism and beauty. It has lunch-baskets and dinner-pails that challenge anything of man's device; while its brushes, its pincers, as also its industry, may well give it a first place among all God's creatures—man alone excepted.

The food of bees is for the most part the very concentrated pollen of flowers, which, like meal and flour, is rich in albumen, starch and oil; and honey, or the transformed nectar of flowers, which supplies the other element of a perfect food regimen. To prepare such food, we should expect the bee to possess a very highly wrought digestive organism. When we add to this the fact that the young or larval bees are wholly fed by the mature bees, and with a food so perfect in its composition, combination and preparation that almost all of it—essentially all—is assimilated, then surely we are in way to appreciate the alimentary apparatus of the honey-bee.

Once more, the queen-bee, also fed by the workers on prepared food, possibly the same that nourishes the immature bees, lays often 2,000 to 3,000 eggs daily. These actually

Mr. J. M. Young and Apiary, of Cass County, Nebraska.—See page 8.

—where the development of so many organs is carried so far. Man in his brain, and the hand that it directs, shows transcendent modification. The bee in its mouth-organs—almost all of them—in its glandular structures; in its leg development; in the very hairs that adorn it; in its wondrously modified ovipositor; and, lastly, in its marvelously modified digestive organism, shows structural modifications that are hardly surpassed in all the realm of life. If we add to these the functional differentiation into queen, male and worker, we

weigh nearly double the queen's entire weight. Does this not speak volumes for the excellence of the food given her, and of the organism that prepares it? I have already shown to the readers of the American Bee Journal how honey is the result of action upon the nectar of flowers, by the secretion from the large glands in the head and thorax, which is emptied just at the base of the tongue, and so mingles generously with the nectar as it streams into the mouth en route for the honey-stomach. This part of the bee's alimentary system and

allmentation is not superior or greatly different from that of many other animals, and I will not discuss it farther now.

The point of greatest interest is the source of the "jelly," the specially prepared food for the larvæ and the queen, and doubtless the drones. Some have thought this to be a secretion from the large lower head-glands. But as I have shown that charcoal finally pulverized and fed to bees is found in this "jelly," and in the "royal jelly"—the special food of the larval queen—it seems certain that the jelly cannot be a secretion. The most probable view seems to be that the pollen is mixt with the secretion from the lower head-glands and then past to the true stomach, possibly mixt with some honey, and digested or changed to the marvelous food—the jelly. This is probably regurgitated and served to the larvæ, queen and drones. If the secretion from the lower head-gland is not used to digest the pollen, it is difficult to know what is, as it does not seem possible that the stomach could secrete enough "gastric juice" to do it.

An objection to the above view is urged in the fact that a membranous tube hangs from the lower end of the honey-stomach into the true stomach, which acts as a valve like our ilio-colic valve, and would not permit any of the contents to pass from the true stomach back to the mouth. This would be so except that the bee doubtless has the power to draw the honey-stomach up, so that this tube ceases to hang into the true stomach, and thus loses its force as a valve. Just so our ilio-cæcal valve can be made to lose its valvular action, as in case of severe wrenching when the contents of the large bowel may be vomited up. Thus it seems more than probable that the incomparable food prepared by the nurse-bees is compounded of digested pollen and honey; that it is prepared in the true stomach, and regurgitated for the queen, drone, larvæ, and possibly for the older workers.

There is one more organ in the honey-stomach of the worker-bees which merits notice. It is a spherical organ with jaw-like segments that leave a central opening, thickly set with hairs that reach upwards. When the bee is taking honey into the honey-stomach these jaws are constantly opening and closing, which draws in the nectar and forces it back. Any pollen in the nectar is caught and held by the hairs, and thus these stomach-jaws, or this honey-stomach mouth is constantly ridding the nectar or honey of the pollen; and thus we see why honey is so free of pollen, even though the nectar may be rich in the same. This ever-active stomach-mouth is always screening it out, as the bee is gathering the precious nectar.

Los Angeles Co., Calif.

A Lady's Experience with Bees in 1897.

BY MRS. L. C. AXTELL.

We began the season with 150 colonies, one absconded, flew away, and we did not miss it until gone, but we knew all came through the winter alive. A very few were weak, but on the whole they wintered splendidly.

We did not open the hives until in May, when he hunted out the queens and clipped their wings. We found two or three queenless colonies, and gave them eggs and larvæ, and both reared themselves a queen. One had to have brood and a cell given the second time. When swarming began we took combs from the parent colonies and built up those colonies into strong ones, and put on sections. We increased from 150 to 162 colonies, and secured about 5,000 pounds of honey, 36 or more pounds per colony, spring count.

DID NEARLY ALL THE WORK ALONE.

As Mr. Axtell has now a peach orchard of about 1,600 trees, and 200 or 300 pear, plum and apple trees, besides raspberries, blackberries and strawberries to care for, I took the sole care of the bees the past season, after being taken from the cellar, up to October, except Mr. A. carried the honey to the honey-house for me after it was taken from the hives; also while resting in his hammock during the middle of the day he watcht swarming and caught in the queen-cages about half a dozen queens. The rest of the work I did myself, and enjoyed it. I felt burdened but little with my bee-work, because I took all needed rest, neglected nothing that needed to be done on time, and made every step count. I do not think we had a great honey crop, but surely our bees paid for my work. I sold all the best grade, delivered at our town, for 10 cents per pound at one sale, and the rest of darker grades are working off in small sales, and at stores, for about the same price.

FARMER BEE-KEEPERS INJURING THE HONEY MARKET.

If farmers would not be in such a rush to sell their honey, and ask a fair price for it, and hold it at that price, it would

not bring honey down every fall as it does. They act as if they were afraid they could not sell if they did not offer it lower than those who had larger crops. This seems to hurt our market more than honey adulterated, as people are learning that the honey in tumblers is sugar syrup with but a trifle of honey in it, and those who come for pure honey will not buy it in that way to a large extent, and yet adulterated honey is a drawback to good prices.

A HONEY SOCIABLE—CLEANING SECTIONS.

We had the "Aid Society" of the Christian church meet at our house one day about a month ago, with their pastor—some 20 ladies to help me prepare and clean the honey sections before selling. We requested them all to wear gowns that washing would not hurt, and bring sharp pocket-knives. Some came at 9 and 10 o'clock, and staid all day. I got dinner for them, and paid the society 10 cents besides, for every one who workt. They exprest themselves as having a very enjoyable time, and said they wanted to come again next year, and considering their being new hands they did their work well. They fitted up some 1,500 pounds that day.

To get the honey ready for market is the hardest and most difficult bee-work for me. To hire it done by young people, it is so often injured; honey cut, and sections sliced off or haggled, but to bring the best price, each section should be nicely cleaned. Those ladies being middle-aged, did their work better than I feared it might be done.

The honey should be in a pile in the middle of the room, or two or three rooms, so people could get around it easily to work.

HELPING WEAK COLONIES.

In the fall, when taking off honey, or even in midsummer when a few bees remain in the supers, and gather in a bunch on the window, which they will do (unless a large escape is given) as soon as they cluster, I take a milk-pan with warm water in it—just warm enough not to chill the bees—and brush the cluster of bees into it and carry quickly and pour them down close to the entrance of a weak colony, if we have any. I put all I can get in that way in front of one hive, until I am sure it is strong enough. If the weather is cool I would lay a soft cloth over the cluster.

LAYING WORKERS.

In September I found one colony that had laying workers. I took two combs and gave to colonies that did not have combs enough to make a full colony. Two other combs I gave to a similar colony, and took all the bees and gave them to a weak colony that had a queen, and the returning bees were allowed to go into another weak colony. I could not detect that scarcely any bees were killed, and those I carried away mostly remained, they having found a queen made them contented to remain, and put a shade-board over the front of the hive.

I felt that such a disposition of combs and bees at that time of the year was better than to help them rear a queen.

UNITING WEAK COLONIES UNPROFITABLE.

The uniting of weak colonies in the spring does not pay very well. After uniting, in a few days the colony seems just about as weak as before being united, but if strong to cover two combs well in April or May, exchange the two and giving one or two of brood with eggs and larvæ will carry them through until they can rear themselves a queen, and then build them up in swarming-time. I find it does not pay to fuss much with small colonies; fix them up so they can keep warm, and leave them alone, and give the extra care and time to the strong ones. It does not pay to take much brood from the strong to build up the weak until in swarming-time.

Warren Co., Ill.

Something About Swarming—How It is Done.

BY G. M. DOOLITTLE.

QUESTION.—"A bee-keeping friend and myself have had a dispute relative to how swarming is conducted, and we have agreed to leave the matter to an arbitrator. He has chosen you as that arbitrator, and I could not object. We also have agreed to ask you to answer, or give your views in the matter, in the American Bee Journal, as we both take that paper, and both think that your views may not be uninteresting to other readers also. My friend claims that when a swarm issues from any colony, that the old bees, or field-workers, go with the old or reigoing queen, leaving the younger bees with the queen-cells left behind to go out with any after-swarm which may chance to issue. He also claims that a young queen

hatches within a day or so after the first swarm has left, which drills the young bees till they are inclined to go out with her in an after-swarm. I claim that bees of all ages go with the old queen in the prime swarm, and that the young queen, or queens, which go with the after-swarms do not hatch out in several days after the first swarm went out. Which is right? Or is swarming conducted differently from what either of us think?"

ANSWER.—Natural swarming has always had a charm or fascination to me, and among my earliest recollections is the vivid picture of thousands of bees pouring out of their hives and whirling in midair, describing circles and passing each other in such rapid movements that I stood and wondered how they could possibly do it without hitting each other, while the settling on a limb and their march into the hive, when father put them down in front, astonished me as much as any of the rest of the performance.

From these first impressions, I presume, more than from anything else, has come my preference for natural swarming as a means of increase. Being thus interested I have experimented largely to know under what conditions swarms issued as a rule, and have found, as regards the age of bees, that bees of all ages in about equal proportions leave the parent hive with all swarms, from the old forager to the bee that has not been out of the cell more than from 6 to 12 hours. Many times have I seen the ground in front of the hive nearly covered with bees so young as to be unable to fly; and as often have I seen the old field-workers with their worn and jagged wings hanging with the swarm, and those having their pollen-baskets filled with pollen, side by side with the young, downy bees which had been barely able to fly to the cluster. Thus we have the field-bees, the wax-workers, and the nurse-bees in about equal proportions, so as to make a prosperous colony at once upon their entering their new home, this showing that the All-Wise Creator knew how things should be when he pronounced all that he had made good.

If it were not for young bees going with the swarm, the hive would be nearly depopulated by the bees dying of old age before the brood could hatch out to take their places, as it must be nearly two days before sufficient comb would be built so the queen could deposit eggs in the cells, and then it would take 21 days from that time before any bees would hatch.

Again, if all were old or field bees the hive could not be filled as profitably with comb; for when in a normal condition the bees between the age of 8 and 24 days old are the ones which do this work. That this division of bees in a swarm is just as it should be is another reason why I prefer natural swarming as a means of increase, altho I have made swarms artificially which have given as good results as have any natural swarms.

But let us look inside of the hive when preparations for swarming are being made, and see if we cannot arrive at the truth in the matter as regards the condition under which a swarm issues when the first queen hatches, etc.

The first indication of swarming is the laying of eggs in the drone-comb. While eggs in the drone-cells is not a sure sign that a swarm will issue, yet as far as I have observed swarms never do issue without eggs being laid therein. If the weather is propitious the next step is the building of queen-cells, soon after which the queen deposits eggs in them. In three days these eggs hatch into larvæ, and these larvæ are fed an abundance of food by the nurse-bees for six days, when the cells containing the embryo queens are sealed over. If no bad weather has intervened the swarm issues the next day, the old queen going with the swarm. Bear in mind that this is the rule with the black or German bees, and generally with other races; still, the Italians often swarm when the eggs are first laid in the queen-cells, and some without the least preparation at all except drones in a time when swarming runs high in an apiary.

All good authorities admit that the queen-larva remains seven days in the cell after it is sealed over, as my experience also proves, and any claim that a young queen would hatch within a day or two after the swarm issues would be fallacious, unless bad weather should occur at about the time the first queen-cell was sealed. When such bad weather does occur the thing is barely possible for the swarm to be kept back for four or five days after they would naturally issue, in which case the first queen might hatch in one or two days after the swarm went out. But this is something which I have had occur but very few times since I have kept bees, covering a period of nearly 30 years, and in nearly all such cases the bees destroy the queen-cells and postpone swarming for an indefinite period.

So I find, as a rule, that the first queen emerges from her cell from six to seven days after the swarm issues. If more swarms are allowed, they come forth two days after, or from

the eighth to the ninth day after the first, and never later than the sixteenth day. As soon as it is decided that no more swarms shall issue, all queens in the cells are destroyed, when in from five to nine days the young queen goes out to be fertilized, two days after which she commences to lay. If the apiarist stops all after-swarming by the cutting of the queen-cells, or by other means that keeps all of the bees in the old hive together after the first issue, I find that the young queen is much slower in going out on her wedding trip, and often does not commence to lay till from the twelfth to the sixteenth day.

Where one wishes to make artificial increase it is well to understand just how natural swarming is conducted, for with such knowledge one is more apt to succeed in having the right proportion of both old and young bees in the two parts after dividing.

Onondaga Co., N. Y.

The Bee-Moth—Its Ravages and Destruction.

BY C. P. DADANT.

A few days ago while removing the dry supers from which the honey was extracted in September, and which had been returned to the bees so that they might clean them up, our boys discovered a colony in which both the super and the brood-frames were invaded by the bee-moth in such a way as to give no hopes of redeeming any of the combs. The bees had dwindled to nothing. I suggested that this was a piece of carelessness on their part, that it was a mistake to return a super to a hive that must have been suffering of the moth at the time when the honey was removed. It was with difficulty, however, that I convinced them that they were at fault, and that it was at all possible to detect the presence of the moth two months ago in a hive which is well-nigh destroyed at this date by them.

There is too much neglect of this kind among many apiaries. We do not sufficiently recollect that the moth becomes more numerous as the season advances. In the spring combs may be left for two or three months without protection and without showing much of the ravages of the moth, because they are then very scarce, having been reduced in numbers by the winter; for it is now very certain that ordinary winters in this latitude kill all but those of the moth which happen to be sheltered in colonies of live bees. The only hives in which they thrive in any perceptible way are those whose bees have died at the close of winter. They have kept a few moths alive, and when they dwindle away no living insect is left in the box but the straggling and rustic moth-worm. The few moths that hatch in spring make a second breed that appears in full force about the beginning of August. If these find suitable lodgings, the third breed will become formidable, for the moths are sufficiently plentiful at that late date to take by storm any hive that may prove destitute of queen or hatching bees. The eggs laid in the early part of September may not all hatch, if the season is cool; but if a warm fall gives them the opportunity they thrive in an astonishing manner.

It is not to be wondered that our forefathers were afraid of the moths for their bees. Until the invention of the movable-frame hive it was next to impossible to ascertain the extent of the danger to the bee-industry on the moth's account, and altho Mr. Langstroth himself was of the opinion, when he first wrote his book, that the moth was but little injurious to a healthy colony of bees, he was compelled, owing to the general opinion then prevailing, to treat of them as "a powerful enemy" of the bee. But he had already divined the true cause of the decadence of colonies in the fall and of the triumph of the moth. He wrote:

"Every year large numbers of hives are bereft of their queens, most of which are either robbed by other bees or sacked by the bee-moth, or first robbed and afterward sacked, while their owner imputes all the mischief to something else than the real cause. He might just as well imagine that the carrion birds, or worms, which are devouring a dead horse were the primary cause of its untimely end."

This argument struck the right chord, and a few years afterward our friend, Elisha Gallup, if I am not mistaken, came out boldly in the American Bee Journal with the assertion that there was no more danger from the moth, for a colony of healthy bees, than there is danger for a healthy cow being destroyed by the grubs, or larvæ, or the carrion fly, which is sure to infest every decaying carcass of dead animals during warm weather. This assertion, which may seem too far stretch to the novice in bee-culture, is within the limits of facts. It must have seemed a bold statement in the days of patent moth-traps, but it proves more correct every day.

So we need not fear the moth if we keep our colonies healthy

and strong. The colony mentioned at the beginning of this article was evidently queenless. It is quite probable that in September, when the honey was removed, the bees were sufficiently numerous to make a fair show, but it is also certain that a closer examination of the colony than was given to it while the honey was being extracted, would have brought out the fact that it was fast dwindling, and that the bees were already discouraged. A large number of eggs laid at its door, or on the outside of its combs, during the last days of September by the moths produced the result mentioned.

To this state of things there is no remedy; the proper thing would have been to examine the hives more closely during the summer, to make sure of replacing the falling queens.

The most disagreeable feature of the existence of the moth appears when the first crop of honey has been removed from the hives. If moths are plentiful, and especially if a few of them have managed to invade the bee-house, those nice white sections begin to leak and show traces of their disgusting paths. There is only one way to avoid this. Burn brimstone in the bee-house or under those crates of comb honey once a week, or about, until you may feel sure that the moths have been destroyed. The fumes of the sulphur will not destroy the eggs, and for that reason several repetitions of the fumigation are necessary. The extent of the fumigation needed may be ascertained by the house-flies in the room. A fumigation that will kill them will also destroy the living moths.

To make the burning of brimstone more thorough and more easy, we melt it over a stove, and dip strips of rags or gunny in the molten sulphur. These act as a wick, and the brimstone burns more promptly and more evenly than otherwise.

Hancock Co., Ill., Nov. 27, 1897.

No. 1—Recollections of an Old Bee-Keeper.

BY DR. E. GALLUP.

I will endeavor to show the readers of the American Bee Journal the difference in starting in bee-keeping when I commenced and in starting now. I was born in the year 1820, in what is now called "Canada East," or Province of Quebec, 65 miles north of Vermont, and about 75 miles east of Montreal, on the St. Francis river. I mention this to show you that I was located in a far different climate from California.

From my earliest recollections I took a great and absorbing interest in bees. My father kept a few colonies at different times, but had no luck with them. In those days every success or failure was attributed to "luck." There were no books on bees to be had. In fact, I never heard of such a thing until I was about 23 years old. Father built a flouring-mill and sawmill when I was 15, and by an accident, or my luck, I was installed miller. The mill was located three miles from the home farm, so I coaxed and teased father to let me purchase a colony of bees. He finally reluctantly consented, as he said there was no luck in bees at all.

The ruling price of a colony of bees was \$2.50. There was a widow that I was acquainted with that had a lucky colony. She was very anxious to get some lumber, and I was just as anxious to get her lucky bees, so after bantering with her for several weeks, she finally consented to let me have her lucky colony for \$7.00 worth of lumber, at cash price, which was \$2.50 per 1,000 feet. Well, I moved the bees quick without consulting father, for fear she would change her mind.

Father was terribly worked up to think that I had been so foolish as to pay such a price for a colony of worthless bees, as he called them, but I consoled myself with the thought that I had not only got her bees, but her luck also. Well, as it turned out, she lost all her bees—some seven colonies—the following winter, and I got two good swarms and a box of about 20 pounds of nice honey. Then didn't I proudly boast of my trade in getting the lady's luck!

My bees all came through the winter in good condition, but the lucky colony always did the best. The idea of luck was never thoroughly established in my noddle, so I began to study the whys and wherefores.

That lucky colony was in an old-fashioned straw-skep, as it was then called, and it being circular and smallish at the top, every comb except one small one at one side was worker-comb. Bees were all wintered on the summer stands, which was usually an open shed facing the south or southeast. They were confined to the hives from the first of November until April 15, or thereabouts, and sometimes until the first of May. No one had thought of wintering bees in a cellar. The straw being porous, there would be no accumulation of frost from the breath of the bees in cold weather in the hive, and we frequently had cold weather, oftentimes 40° below zero for

six and eight days in succession. Then we would lose our bees in box-hives. I lost all but my lucky colony several times. I would shut my box-hives up, all except some small notches cut in the bottom at one side for entrance. My idea was to keep them warm.

I had an aunt get married, and settled across the river from the mill, and she was a great bee-keeper, that is, she could rattle tin pans and ring bells when they swarmed, and compel them to cluster, and then she could hive them without getting stung, etc. Well, she would make hives with a hand-saw, hammer and nails out of rough hemlock lumber, set them on top of a large stump, without any bottom-board, and place a large stone on top to keep the wind from blowing the hive off. The stump being cut uneven, it left plenty of bottom ventilation. Finally, she had one hive that cracked open from top to bottom, and the crack opened fully three-fourths of an inch at the edge of the combs, so we could look right in on the bees. I felt almost sure that colony would freeze to death, so when the mercury would get down to 35° and 40°,

Dr. E. Gallup—From a recent photograph.

I would go over and see how they were getting on. I could hear them roar and hum several rods off. I have stood and watcht them many times until I would get so cold that I could stand it no longer.

The bees on the inside of the cluster were all the time rushing to the outside for air, while those on the outside were rushing to the inside for warmth. There was a plain case of manufacturing warmth by activity, or, as we might say, electricity. They were a perfect dynamo. That colony wintered the best in the lot. My bees, that I kept warm, nearly all died that winter.

Orange Co., Calif.

[To be continued.]

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See offers on page 11.

Sorghum for Bees in Winter.—Fred S. Thorington, in *Progressive Bee-Keeper*, tells of a case in which the honey was taken from a colony, and a single dose of sorghum fed to the bees finished them. In another case the bees' stores were taken and sorghum given, and the bees absconded.

The New Fence with the plain or no-bee-way section, says Gleanings, can be used in old-style T supers or section-holders. All that is necessary is to have the fence or cleated separator made the right size to fit. The company will furnish the right fence to order, and can make them all ready put together at a cheaper rate than one could put them together himself, special machinery being used to glue the parts together.

Prevention of Swarms.—L. A. Aspinwall found this year that his hives were too small to prevent swarming by means of perforated dummies, and expects next year to use hives a third larger. In four cases, he secured the return of the swarm, queen and all, by vigorously smoking at the entrance as soon as the swarm began to issue. He thinks the swarm returned because they could not scent the queen.—*Review*.

Bee-Stings for Rheumatism.—Reports as to the effect of bee-stings on rheumatism continue to conflict, some reporting success, others failure. E. W. Moore says his mother, 62 years old, had for years lost the use of her left hand through rheumatism. Last summer, hiving a swarm alone, her hand was badly stung and swelled greatly, but when the swelling went down the joints were no longer stiff, and now she can use the hand as well as ever.—*Progressive Bee-Keeper*.

The Wells' System.—This system of having two colonies in one hive with a perforated division between, seems to be well liked by a few, but not to gain in popularity with the masses. Mr. Loveday, in the *British Bee Journal*, says he gets as much from one double hive as from three single ones; but that one Wells hive makes quite as much work as three single-queened ones. He says: "The more experience I have of this system the more I am convinced that it cannot be generally adopted."

Finding Queens.—The editor of *Gleanings* is asked the easiest way to find the queen in a hive just boiling over with bees. Says there is no easy way. If he doesn't find a queen in twice looking over the frames, he closes the hive and in two hours more takes another look. If he still fails to find her, which occasionally happens with black bees, he puts an empty hive in place of the one on the stand, puts perforated zinc at the entrance, shakes the bees on the ground in front, and if the queen isn't too small she's sure to be caught.

Uniformity of Supplies.—J. W. Rouse, in *Progressive Bee-Keeper*, gives expression to the often needed but seldom heeded advice to beginners, to try to use nothing but standard goods, and not to be in a hurry about inventing improvements. Believes in improvements, yet the inventions he has seen, even those possessing merit, are no better than the regular goods in use. Thinks most bee-keepers who are using odd sizes are doing so just because they got started that way, and would be glad to change into the regular style if it were not for the expense.

A New Way of Transferring, or at least of getting a box-hive colony to occupy a frame-hive, is given by C. Delmotte in *Le Progres Apicole*. June 5 he dug a hole in the ground the full depth of the box-hive that had stood there, put the hive upside down in the hole, covered it with a board, having a hole 12 inches in diameter, and placed on this the frame hive. A piece of comb to serve as a ladder for the bees was placed between the combs of the box-hive, extending up between the frames of the upper hive. Then earth was packed around both hives at the junction. An entrance was made in the frame hive an inch or two from the top at the front, obliging the bees to go in and out there. July 22, finding four frames of brood in the upper hive, he took out the box-hive, filled up the hole with earth, set the frame hive back in

its place and put the box-hive on top, with what brood and bees were in it, no communication being between the two hives. 23 days later he shook down in front of the frame hive all the bees in the box-hive, a young queen having been reared among them, and found in the box-hive neither brood nor honey. Of course the box-hive was then taken away.

Going to the Fairs.—Editor Hutchinson's description, in the *Review*, of the way he travels from one fair to another, makes a page of very interesting reading. He has his traps and calamities all with him in a freight car, in which he sometimes spends two days and two nights, but when it comes to being jounced off the car floor at night and being obliged to hold on your vitals while they're cooking on an oil-stove to keep them from being jiggled or jerked off, one might prefer to stay at home with cross hybrids so as to have a civilized meal and a stationary bed.

Fence Separators—S. Brantigam, in *Progressive Bee-Keeper*, says the fence makes a good, strong separator, the objection, however, is the time it takes to put together, a minute to each separator. (That needn't matter, however, if they are sold ready made up, and if the price is low enough.) He proposes to avoid the necessity for using them by having sections made with the usual inset, and then have a thin saw-cut on the outside of the $1\frac{1}{8}$ section, say $\frac{1}{8}$ inch from the edge, and $1/16$ or $3/32$ inch deep. Then when the section is filled, a knife will split off the $\frac{1}{8}$ inch, and you will have the no-bee-way section.

Rearing Queens on a Stick.—A. E. Dewar, of Australia, gives in *Gleanings* his plan of rearing queens. Cells are made after Doolittle's plan, a small quantity of royal jelly inserted, then a larva from choice stock. The frame with the cells is put in the upper story of a colony whose queen is kept below by a double honey-board, and when about ready to hatch the cells are given to nuclei. The same colony is kept at work starting the queens all through the season, fed at any time honey fails, and liberally supplied regularly with hatching brood, and 90 per cent. of the cells are accepted; 18 to 20 cells are generally put on one stick, but as many as 27 in one lot have been accepted.

Sweet Clover.—The October number of the *Busy Bee* was a sweet clover number, and it seems Editor Abbott could not stop all of a sudden, so quite a bit about sweet clover is found in the November number. Wm. Belshaw says: "As a bee-plant it is one of the best, equalling white clover in quality of flavor, doubling it in quantity on the same amount of ground covered, and it appears to possess the rare quality of being stored away as surplus honey rather than stimulating swarming." The editor thinks the last item valuable from the standpoint of the bee-keeper. But isn't the same thing true of buckwheat, or of any plant that comes as late as sweet clover?

Use and Abuse of Foundation.—Editor Hutchinson refers in the *Review* to the discussion in these pages concerning foundation by Deacon, Dadant and "Sage-Brush," copying the articles of the two latter, and then gives his own views by quoting a chapter from his book, "Advanced Bee-Culture," in which he finally sums up:

"If the bee-keeper lives where the honey-flow is light, but perhaps prolonged, he will find it more profitable to allow his bees to build their own combs. If he can't get perfect brood-combs, he certainly can allow bees to build their combs for the surplus comb honey. If honey comes in 'floods,' as it sometimes does in some localities, the man who allows his bees to build their store combs unaided at such a time, loses dollars and dollars."

Do Bees Freeze?—Asked whether bees may not freeze to death outdoors when the mercury sinks to 30° below zero, Doolittle says in *Gleanings* they may starve but never freeze. A small cluster may freeze, but not a whole colony. Quinby said that the bees inside the cluster, on a zero morning, could fly as readily as in July, should the cluster be suddenly thrown apart. Gallup, when in upper Canada, said, "The thermometer for 60 days in succession was not above 10° below zero, and for eight of these days the mercury was frozen; yet my bees, in box-hives, with a two-inch hole at the top, and the bottom plastered up tight, came through in excellent condition." (*American Bee Journal*, Vol. 5, page 33.) Doolittle finds in the hive, with the bulb of the thermometer touching the outside of the cluster, a temperature of 45° to 46°, and in the center of the cluster, 63° to 64°, when it is 10° to 25° below outside.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

The assembled bee-keepers were called to order at 10:45 a.m., in the New Briggs House, Chicago, by George W. York, who had issued the call for the meeting. Dr. C. C. Miller was then chosen President, after which Mr. York was selected as Secretary.

On motion of Jas. A. Stone, a committee was appointed to draft a constitution and by-laws for the consideration of the meeting. Motion carried, and Messrs. Jas. A. Stone, Herman F. Moore and George Thompson were appointed.

During the meeting the following had their names enrolled as members, not all present, however, uniting:

| | |
|------------------------|--------------------|
| M. M. Baldridge, | Dr. C. C. Miller, |
| E. J. Baxter, | M. S. Miller, |
| Dr. H. Besse, | Herman F. Moore, |
| Miss Mathilda Candler, | John Nau, |
| Stoughton Cooley, | W. H. Norris, |
| P. W. Dunne, | H. A. Rittenhouse, |
| J. D. Everett, | Rev. H. Rohrs, |
| Jas. Forncrook, | E. F. Schaper, |
| Jas. A. Green, | C. Schrier, |
| D. S. Heffron, | W. N. Smith, |
| Chas. Karch, | W. H. H. Stewart, |
| A. H. Kennan, | Jas. A. Stone, |
| L. Kreutzinger, | George Thompson, |
| W. C. Lyman, | J. C. Wheeler, |
| C. E. Mead, | E. Whitcomb, |

George W. York.

As had been the usual custom of conventions held in Chicago, the hat was past by the Secretary for the collection of questions for discussion. The first one read by Pres. Miller was this:

THE DIVISION OF LABOR IN THE HIVE.

"What is the division of labor in the hive, that is, the proportion of field-bees, nurses, sentinels, etc.?"

Pres. Miller—I don't think that is a question we should spend much time on.

Mrs. Taylor—I am responsible for that question. I am a novice in bee-keeping. It is a question that has interested me very much, and I have not found any books that have given me any light on the subject, and I thought possibly some people here might answer it in a few words.

Pres. Miller—it is a proper question, but one we should not spend much time on. We have our text-books and bee-papers that cover certain ground, and when we come here we take the ground they don't cover. Suppose I make a statement about this. In the first place, I don't know much about it. In the economy of the hive there are those different divisions—the field-bees, the nurses, etc. I very much doubt if there is a separate class as sentinels. There are those who do the home work, and the sentinels are amongst them. I think the nurse-bees and the sentinels are the same; they do the work of the hive up to 16 days, usually, but under stress these nurse-bees will go to work as field-bees much earlier. I have seen them at five days old doing field-work, and I know the old bees will do nurse-work if there are no young bees in the hive, but as to the proportion, the proportion of nurse-bees will be, in the earlier part of the season, very different from what they will be later; as they go on the nurse-bees will increase very rapidly up to about the time of the barvest, then they get maximum, and after that the field-bees will increase; that is a very rough statement, and there is not much information in it, and may be it is not true; correct me if it is not.

Mr. Stone—It seems to me that that is altogether according to the amount of brood there is in the hive to be kept warm, to use it plainly; and sometimes, when there is a hive full of honey, and only a little brood, it does not take as many bees to keep the brood warm as it does at other times. Of course, as you say, it is a good deal owing to the weather. I have noticed where the weather is very hot, if the bees are

not doing much work, they go out of the hive because it is too warm, and then they certainly don't need many nurses; but in the cold weather, at the beginning of the season when their heat is needed in the hives, I think there is always enough stay in there to keep the heat, and the others go out and do the field work.

Mr. Baxter—I have kept about 250 colonies for the last 20 years, and my experience is that you cannot tell definitely at any time how many or in what proportion—it depends upon the weather and flow of honey. When the weather is warm they often go out of the hives because it is too hot. Different conditions have got to be taken into consideration. I don't believe any one answer will answer the question for all.

Pres. Miller—One point I am waiting for somebody to bring out is this: As it is now, the nurse-bees depend entirely upon the amount of heat that is needed to be kept up in the hive; you are leaving out altogether the number of brood to be fed; that I think controls it very largely. If it is warm, they will go outside, it is true, and no matter how hot it is there must be nurse-bees enough to do all the work that is in there, so you must take that along with the heat of the hive.

LEGISLATION TO PROTECT AGAINST ADULTERATION.

"What legislation is needed to protect consumers against adulterated honey?"

Pres. Miller—How many of you think that legislation is needed at all with regard to it? Hands up. (7.) How many think there is no need of legislation? (3.) As I understand the question, it is, What legislation is needed? It depends something on what the kind is.

Mr. Dunne—It seems to me we ought to have legislation from Congress, exclusive of the State, because Congress could naturally control the correction of all abuses, and legislation from Congress would naturally send it back from the States, and we would have still further legislation. I think that is a very important factor with regard to any man who produces honey.

Mr. Baxter—I believe with Mr. Dunne, that we need National legislation. I hope that this association is not going to put itself on record as did the National Association. If you remember, during the Columbian convention there was a measure before Congress known as the "Paddock Pure Food Bill." I moved to endorse the passing of that Bill, and I believe it was referred to a committee to report back, and strange to say they fought my resolution, and failed to report back. It went by default. The proceedings of the association still show that much of it, and I think the society made a big mistake. We should take strenuous measures of all kinds against adulteration; we ought to have National laws; one State will prohibit, and another State, to make money out of it, will allow it; all those laws should be National.

Mr. Stone—I was going to ask Mr. York to report what he thought of our law that we had past last year in our legislature, with regard to pure food. It covers all food. As Mr. Baxter spoke of their shipping it from one State into another, our law does not allow it even to be sold if there is any ingredient that enters into any food that makes it impure. It contains a severe penalty.

Mr. Dunne—The beef exported, pork exported, all goes under the microscope, and is thoroughly examined by the Government; if there is an inspector at all, in the principal markets in honey, this thing could be stopt, because it would have to be analyzed. You take it in the English ports—everything that goes in there is examined, analyzed; every class of goods goes before the chemists, and is thoroughly examined at the expense of the Government, and the Government has the right to protect the farmer if he protects any one.

Mr. Moore—I feel very deeply interested in this question, because I have been in this market six years, selling honey to consumers. Illinois is all right; it doesn't need anything. I think the extreme penalty for violation of the law is up to five years in the penitentiary, and it requires the ingredient, if not pure, to be printed upon the label in every case. The law is very stringent in Illinois, but as any one knows, who knows anything about politics, it enters in all these markets, and it becomes finally a question whether it will be enforced. The law is strict enough, if it could be enforced. The General Government should take hold of it; it seems to enforce its laws more impartially than the local laws. I believe that that is the only remedy for adulteration. Adulteration is a great damage to every bee-keeper, and I can tell you so from my own experience. I asked one of the prominent citizens of Chicago, who has paid me considerable money for honey, "How much more honey do you buy than if you went to the store and bought it?" He replied, "Four or five times as much." My honey is pure honey; I tell them so, and get an order instantly. It means four or five times as much honey sold, if

people could understand the honey they get is always pure honey.

Pres. Miller—Let me tell you one thing as an illustration bearing upon this point. I live in a little town that has been without saloons for more than 30 years, but liquor is sold in it on the sly. Those who sell liquor have no permission from the town or from the State, and they are doing a crime when they are doing it. They don't take the trouble to look out for the State or town, but they do look out for the General Government and get a United States license; they are criminals in the eyes of the State law, but in the eyes of the General Government they are law-abiding citizens; in that case, at least, the General Government has a power, and law breakers are afraid of it; they are not afraid of State or county laws, or town laws.

Mr. Baxter—I was in Iowa last winter, and saw some very nice, presumably honey, in pound glasses. I asked the wholesaler if he didn't want to buy a barrel of honey at a low price, pure honey. I told him I had seen some of his honey in pound glasses in a grocery store. He said, "That is not honey." I told him he had it labeled "pure white clover honey," and that he was doing a wrong to bee-keepers and the public, and he said, "Everybody does that." I told him the first thing he knew we would have proceedings instituted against him for obtaining money under false pretenses. "I don't believe you can do that in Iowa," he said.

Mr. Stone—I would like to ask Mr. York if the United States Bee-keepers' Union is not likely to take hold of honey adulteration, especially in the city of Chicago, and apply the State law, and make it effectual?

Mr. York—Yes, they will, just as soon as we have sufficient funds to begin operations, and that is all we are waiting for—for a sufficiently large membership (which means sufficient money in the treasury) to warrant us in going ahead. The laws of Illinois are sufficiently strong, I think, to stop adulteration if they are once enforced. I think we are indebted to Mr. Moore for resurrecting the laws, and I should judge from the readlog of them that they were all we need to stop adulteration in this State. I, for one, should like to see them enforced, and am very well satisfied that just as soon as we have a large enough fund in the treasury of the United States Bee-keepers' Union we will begin to make an attempt to enforce laws against adulteration of honey in this State as well as elsewhere.

Mr. Baxter—Your law is a failure, if that is the case—if you have to have funds provided. You have a prosecuting attorney here—can't you proceed under that? If you have to have private funds to prosecute criminals, I think the law is a failure.

Mr. Dunne—This question brings us back to the fact that it is the United States that has a right to be at the expense of enforcing the laws; they do with the distilleries. Has not the honey-man the same right to have the protection of the United States that the distillery has? Is Mr. Armour to be protected by having his pork analyzed and branded by the United States Government as pure, and the honey-man to have no protection? It only requires an effort on the part of the bee-keepers of the United States to enforce the law, and you will have the same right as other citizens, because the Government has the right to protect this industry as well as any other industry. We are all citizens alike, and if honey can be adulterated the same as whiskey, they owe us the same protection. The distillers don't amount to 500 all over the United States, but the bee-keepers amount to thousands, and I claim it is the duty of the Government to protect this interest as well as any other. It will be our own fault if we don't get legislation that will protect it. The Government puts the stamp of the purity of the whiskey on the bottle; that is in the interest of the distiller and the Government; and the Government can have an office here just the same; put a tax on to pay for it, and let there be a depot and have honey inspected; then you will get value for pure honey.

Mr. Karch—I don't think Mr. Dunne makes the proper distinction between whiskey and honey. Adulterated honey will not kill quite so quickly as whiskey. (Laughter)

Mr. York—I would like to say one more word in referring to what Mr. Baxter said, that we ought not to be compelled to spend our money to enforce State laws. I don't think that we need to spend the money for the purpose directly, but we must be to some expense to have our General Manager and Treasurer come on the ground, to engage an attorney to start the case, to look after samples, to have them analyzed, etc. That all costs something. Still, if it were known that the United States Bee-keepers' Union has a good fund back of them, and that they propose to fight this thing through, we might not have to spend our money to enforce State laws, but it is a good thing to have it on hand. I presume we could get

the prosecuting attorney to take hold of it, but there would be some expense to start the suit; at least that is the way I understand it. I am not an attorney, but I understand there would be some expense in beginning suits of that kind.

Mr. Moore—I am perfectly familiar with legal matters here in Chicago. I will tell why it is necessary to put up the money. There are 500 prisoners in the county jail, and Mr. Deneo (the State's Attorney) is in duty bound to get those 500 men out of jail or into the penitentiary as soon as possible. In the second place, whenever railroad men want a scalper sent to the penitentiary, they hire Attorney Forrest, or some other eminent attorney, at great expense. I could name many other instances. It is the State's attorney's business, of course, to do this, because it is the people's prosecution, but he is so busy, and the question of politics may come in; he does not have time, so it seems to be an absolute necessity to raise some money, \$1,000 at least, before anything adequate can be done in Chicago. This \$1,000 is to pay for the expense of getting samples of honey, and paying an attorney to do it. I would like to hear from Mr. York a little further.

Mr. Baxter—I think if we had a United States pure food law under the supervision of the Department of Agriculture, or under the Internal Revenue Bureau, if there is a tax to be assest (altho I don't favor that), I think we would be very apt to get justice more speedily, and it would be general.

Pres. Miller—Do you want to take any action upon this, or shall we pass on to the next question?

Mr. Baxter—I would introduce a resolution that it is the sentiment of this association that a United States Pure Food Bill be past by Congress.

Motion seconded by Mr. York.

Mr. Baxter—I should say we are not prepared to draft such a Bill now. I think the proper way would be to refer that to the Executive Committee of the United States Bee-keepers' Union. I think they would have better recognition than we would.

Mr. York suggested that we recommend that the General Manager of the United States Bee-keepers' Union draft a proper Bill to be past by Congress, and moved this as an amendment to the former motion, to which Mr. Baxter assented.

Mr. Baxter—My motion is that it is the sentiment of this association that we have a United States Pure Food Bill, and that we recommend the Manager of the United States Bee-keepers' Union to draft such a Bill as regards honey, at least.

Mr. Dunne—Who is going to draft this Bill? Where is it to go?

Pres. Miller—As it now stands it would be referred to the General Manager of the United States Bee-keepers' Union, and I think that you would find that he would do his level best.

Mr. Dunne—I would like to add in that recommendation that we recommend that all adulterated honey be seized and destroyed forthwith.

The motion was then carried unanimously.

(To be continued.)

A New Binder for holding a year's numbers of the American Bee Journal, we propose to mail, postpaid, to every subscriber who sends us 20 cents. It is called "The Wood Binder," is patented, and is an entirely new and very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

See "Bee-keeper's Guide" offer on page 14.

The American Bee Journal

OLDEST BEE-PAPER IN AMERICA

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., CHICAGO, ILL.

\$1.00 a Year—Sample Copy Sent Free.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—W. Z. HUTCHINSON.
SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT. E. WHITCOMB. E. T. ABBOTT.
W. Z. HUTCHINSON. DR. C. C. MILLER. C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Vol. XXXVIII. CHICAGO, ILL., JAN. 6, 1898. No. 1.

Volume XXXVIII of the American Bee Journal is now begun. Just two more years, and then the two-secre volume will be commenced. Then it will have been a weekly just as long as it was a monthly bee-paper. But 38 years seems a long time for a periodical to exist—it is especially so in bee-journalism, for about all that have been started in this country past away at a very tender age. Perhaps it was just as well, as they may have in most cases served their purpose, in satisfying the desire of their publishers to "have their say" unchecked, and see their names in print as "editor." But how empty are such privileges and honors. To publish a really valuable bee-paper means more than to wield a free lance and print "editor" after your name. It means a lot of downright hard work, with no prospect of a financial fortune at the end. But, to us, the work is pleasant and agreeable, even if prodigious, so long as we are blest with good health.

Against Adulterated Honey in Wisconsin.

—We learn from Mr. F. Wilcox, the able President of the Wisconsin State Bee-Keepers' Association, that on Jan. 1, 1898, the new anti-adulteration law, which is very stringent, went into effect. Mr. Wilcox wrote us as follows Dec. 20:

EDITOR YORK:—I will enclose you herein a clipping from the Evening Wisconsin, of the 13th, which shows that the State of Wisconsin is making an effort to suppress the adulteration of food and drugs, and I think the Governor has found a man who will enforce it, in the person of Hon. H. C.

Adams, whose office our society occupied last February, when you were with us.

Very truly yours,
F. WILCOX.

The clipping which Mr. Wilcox sent us is headed, in large type, "Food Must be Pure." It contains a full text of the new law on adulteration, which was approved April 2, 1897, and also a number of rulings of Commissioner Adams. Under "Honey" we find the following:

"Honey containing glucose or any other foreign substance shall be marked upon the package or parcel with the words, "Adulterated Honey," as required by Section 2, Chapter 40, laws of 1881. No honey mixtures or compounds will be permitted, except when labeled in accordance with the foregoing section."

Hurrah for Wisconsin! Go for the infernal adulterators of honey! Down them, and make them quit or get out. We hope the bee-keepers of that State will back up Commissioner Adams in his efforts to enforce the law. He'll have a job of it for awhile, and will need the hearty co-operation of every honest citizen. Now is the golden opportunity of bee-keepers there to rid that State of the honey-adulterators.

Oh, that Illinois were as quick to defend and protect her producers of honest honey. But we're expecting shortly to have something very interesting to tell along this line here in Chicago. Honey adulteration here is more general than ever, and more daring in its devilish work.

Honey-Vessels in Foreign Countries.—Ph.

J. Baldensperger says in the British Bee Journal that in most countries on the continent except Turkey and Greece, wooden barrels are used for holding honey. In Turkey and Greece goatskins are used, giving a peculiar and not agreeable flavor to honey. In Syria, Palestine, and over the north of Africa, unglazed pottery is used, the honey soaking into the pores so the vessels cannot be used the second time, but in Algeria glazed pottery is used. Mr. Baldensperger uses kerosene cans, after cleansing them. This he does by exposing them to the sun for a fortnight, or washing them with lye, "and, when well dried, a few drops of spirits spread over the surface and ignited with a match, and the can becomes as clean as new, without the slightest trace of petroleum flavor." But such cans are strongly objected to in this country.

Bees vs. Pigeons as Message-Carriers.—Mr.

A. Maebert, a New Jersey subscriber to the Bee Journal, has kindly sent us an account of an hour's contest between homing pigeons and bees, in which the bees won the race. It was in Belgium, where the speed between four drones, eight working bees, and the same number of pigeons, was tested. They were liberated at a town one hour's distance from the hives. The bees were covered with flour so as to recognize them when they reach the hive. The bees and pigeons were all liberated together. A drone reached home four seconds in advance of the first pigeon. The three other drones and one pigeon came in neck and neck, according to the judges, and the eight worker-bees came in just a trifle ahead of the ten pigeons.

Mr. J. M. Young and Apiary are shown on the first page this week. When sending us the picture, Mr. Young wrote as follows:

Our photographer came out early in May and took the picture that I send you. The hives all face the east. The trees in the background are box-elders, and on the north side of the yard. The residence is situated at the extreme left, and, sorry to say, we could not show it in the engraving.

The large white hives are chaff hives, and all two-story. The smaller hives are the two-story regular dovetailed, and used mostly for extracting purposes. My name at the left is worked out in honey-comb, and is the same one that was sent with the advertising train that went from Omaha across the

continent a few years ago. I have also had it on exhibition at the Nebraska State Fair, and at our county fair a time or two.

☐ The small hive in the foreground with a handle is a shipping nucleus hive, used to ship nuclei in. They go by express just about like a traveling man's grip-sack.

J. M. YOUNG.

It will be very appropriate to add right here that Mr. Young just recently—Sunday, Dec. 19—took unto himself an apiarian helpmeet, in the person of Mrs. Martha E. Palmer. Life now will likely be sweeter than ever to our "Young" friend. The newspaper item announcing the "tie-up," closed with this paragraph:

"The happy pair are both well known and highly esteemed in this community, where they have resided for years, and their many friends will wish them a joyous and successful voyage on the matrimonial sea."

Yes, when things get *too* quiet they can let loose a few healthy bees to liven up the "voyage," and help themselves to the honey from their own hives to sweeten the sour places.

No "Injustice" Whatever.—Dr. C. C. Miller sends the following in reference to a statement contained in the article by Thomas G. Newman, published recently:

On page 807 (1897) Manager Newman says: "Dr. Miller's retraction is all right. But had I not learned of the statement having been made that the National Bee-Keepers' Union had given no aid to Dr. Besse—what an *injustice* would have been done!" If Mr. Newman had full knowledge of all the circumstances he could hardly think so. It must be remembered that Dr. Besse was *present* when the matter was mentioned, and that I referred to him to know what were the facts in the case. Of course, *all* present heard his reply, so I think Mr. Newman can see that no injustice could be done to him in the mind of any one present, and that his hearing of it could not change the least what any one present thought.

C. C. MILLER.

Exactly so. The convention report will show, when it appears, that Dr. Besse *then* and there corrected Dr. Miller's erroneous impression regarding the Union's aiding Dr. B. in his suit. Of course no "injustice" could have resulted under the circumstances. It now looks very much to us that there was some one present who wanted to stir up trouble, and so made a donkey of himself by reporting a thing that has simply resulted in "much ado about nothing."

The Grading of Comb Honey is a subject that *must*, sooner or later, be taken hold of in good earnest, and something definite be done about it. We were looking at some comb honey on South Water street recently, and were told that it was "fancy." It did look so, judging by the front row back of the glass. But we wish to see the inside of the case, and upon opening it we found unfinished, dark-colored combs that never should have been sent away from home at all.

We then thought, Why will any one who calls himself a bee-keeper sort his honey in that way? Is it possible that he knows no better? If we knew the producer's name we should be tempted to publish it. He deserves to be held up in some way so that he will never repeat his inexcusable blunder.

But there are many other honey-producers just like that one. He is by no means alone in his carelessness—shall we say dishonest?—sorting or grading. Only the very finest and whitest, best filled and cleanest sections of honey find ready sale these days. There is no need to expect any kind of satisfactory price for inferior and dark grade of comb honey, at least in this market.

Our opinion is that only the very best of any farm produce is good enough to ship to market. Only on such goods can the highest prices be realized.

"'BEEDOM BOILED DOWN' is the heading of a most excellent department in the American Bee Journal." So says Editor Hutchinson in the Review. He ought to be a good judge of such things.

MR. JOHN BODENSCHATZ, of Cook Co., Ill., recently sent us a picture of his neat little apiary. Mr. B. is a very young bee-keeper, but he is on the way toward making a good one. He no doubt will be heard from later.

MR. C. H. CLAYTON, is now manager of the California Bee-Keepers' Exchange, we learn from the Pacific Bee Journal. Since his selection, it is said that "a number of cars of honey have been moved at very good prices, white extracted bringing 4½ cents per pound."

MESSRS. CHAS. DADANT & SON, writing us Dec. 21, and referring to the new year, said:

"This makes our comb foundation business 'of age,' and our settlement here 34 years. We are getting to be 'old settlers.'"

MR. A. MIDDLEBROOK, of Lenawee Co., Mich., wrote us this when ordering a supply of the pamphlet, "Honey as Food," after having examined a sample of it:

"'Honey as Food' I believe to be just the thing. Without any flattery to you, I must say it is well gotten up."

MR. HARVEY FEATHERS, of Waupaca Co., Wis., writing us Dec. 28, said:

"I have taken the American Bee Journal ever since it has been printed weekly, and like it very much."

As the Bee Journal was changed from a monthly to a weekly Jan. 1, 1881, Mr. Feathers has been reading it just 17 years. He should be competent to speak of its value to a bee-keeper.

MRS. MATE L. WILLIAMS, of Wadena Co., Minn., has kindly mailed us a generous sample of the honey which we referred to awhile ago, and which she calls "the finest in the world." It is fine. We never tasted finer flavor, for a light amber honey. And for body—well, we never saw any honey so waxlike. Not beeswaxlike, but just waxy and stringy. Mrs. Williams may well be satisfied with her honey, and her local customers ought to be many and admiring. Thank you, Mrs. Williams, for your kind remembrance.

MR. E. S. LOVESY, of Salt Lake Co., Utah, lately sent to us two sections of comb honey and a pint Mason can of extracted. We believe that all was the whitest honey we ever saw, and it was also exceedingly thick and rich. We imagine it was sweet clover mixt with alfalfa, which made a delicious honey, indeed. For such honey there ought to be large demand and ready sale. We wish to thank Mr. Lovesy for his thoughtfulness and generosity. But it's just like those Utah people. It's a way they have. So our brother reports, who had been spending a month in Utah, and brought the samples of honey to us.

MR. J. W. SOUTHWOOD, of Huntington Co., Ind., in an article in Gleanings, had this very complimentary paragraph in reference to our new department of "Beedom Boiled Down:"

"It occurs to me that the one who boils down 'beedom' for the American Bee Journal must stand by nearly all the time and stir, as it seems to be boiled down pretty thick, and yet not scorcht."

You are quite right, Mr. Southwood, for—

The Boiler boils and also stirs
The stinging, seething mass;
Then skims it off, and still averse
'Tis yet but second-class.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Golden Italians and Adel Bees.

1. Last season I purchast a "golden" queen from a Southern breeder, thinking I would get something fine in color, but her workers are but a trifle more yellow than my hybrids. Would you consider her a pure-bred 5-bander?

2. Is there such a thing as a real yellow worker? If so, where can I get them?

3. Are the golden workers as good honey-gatherers as the common Italians?

4. What do you know about the Adel bees? Are they a superior race or strain?

ANSWERS.—1. Hardly. Of course it makes a difference whether it was a tested queen or a dollar queen. In the latter case you have to take the risk as to her mating, and if she met an inferior drone you might expect workers accordingly, altho some of them ought to be yellow. Possibly it may be well to mention that often there is a possibility of there being another queen in the hive, your yellow queen having been killed. If you had clipped her, it would be easier to detect any such occurrence.

2. Yes, there are workers that are as yellow to the tip of tail as the pure imported Italians are for the first three bands. I think G. M. Doolittle originated such a strain, and they can be had from him and others.

3. I think that's a good deal like asking whether a red cow is as good a milker as a black one. There are good and poor cows of each color. There are good and poor bees among the regular Italians, and so there are among the 5-banders.

4. Practically, I know nothing about them.

Using Old Combs or Foundation in Transferring.

Would you fasten old combs into frames in transferring, or would you transfer onto full sheets of foundation?

OHIO.

ANSWER.—It will make a nicer job, and perhaps more satisfactory in the long run, if you use the foundation. If, however, you transfer at a time when there is much brood in the hive, it will be advisable to save all comb containing worker-brood. There's no objection to your filling frames with worker-brood as far as it goes, and then having the rest of the frames filled with foundation.

A Beginners' Questions—Some Good Advice.

1. Please name plants which are especially adapted for honey, and of whom could I get the seed?

2. Describe a queen-cell, what part of the comb it is on, and about what size it is.

3. How can I tell brood which is fit for queen-rearing? Will uncapt brood do?

4. Will brown or black bees make any difference with the blood of a queen if eggs from a tested Italian queen are given them to rear a queen from? or must I have Italian bees?

5. I have a weak colony of Italian bees, and I do not wish to double them up. They seem to be on top of the frames some. Could I not give them some meal on a thin board over the cluster, and also feed them honey or syrup to cause the queen to lay? They are in the cellar: I think it is about the right temperature for increasing.

NEW YORK.

ANSWERS.—1. It would take more room than can be given in this department to name all the honey-plants, and it would be well for you to get a text-book on bee-keeping, which would give you much information on this topic and many others. Get a bee-book, by all means. Among the best honey-plants are white clover, white sage, linden, sweet clover, Alsike clover, buckwheat, raspberry, Spanish-needle, heart's-ease, etc. The seed of those which are raised from seed may be obtained of seed-dealers almost anywhere.

2. A queen-cell may be found anywhere almost in a hive,

oftener at the lower part of the combs, and looks very much like a peanut, and pretty much that size, altho some cells are very inconspicuous, especially if by accident or otherwise the bees have lost their queen. You're not likely to make a mistake in recognizing a queen-cell the first time you see it.

3. Bees can rear a queen from eggs or from very young brood. Some say the brood or larvæ should not be more than 24 hours from the egg, and that's perfectly safe, altho the same food is fed to both worker and queen for the first three days, so if the bees start with a grub or larva not more than three days old it is hard to see how it can be any better to take a younger one.

4. Scientists are not entirely agreed whether it makes any difference what kind of nurse-bees rear a queen, but in actual practice it is not generally supposed to make a difference. Get your eggs or larvæ from the right queen, then use any nurse-bees that are handy.

5. Now, look here, don't you try to rear young bees in winter. Let those bees die a peaceful death if they must die, and very likely they must if they're very weak, but don't stuff them with meal and syrup and things, to hasten their departure by giving them the diarrhea. Better change your mind and quietly lift the frames with the bees and put them in a hive with another colony, if you think they're too weak to come through as they are. But be sure you'll not make them stronger by trying to get the queen to lay in the winter. Instead of taking time to fuss getting the queen to lay, take the time to study a bee-book.

Giving Ventilation in Summer.

I have 150 colonies of bees. Nearly all of them were badly damaged last summer by the combs melting down. I had shade-boards on top and the hives raised off the bottom-board in front one inch.

Next spring I will bore a large hole in each end of the hives, and cover the same with wire cloth; also face each hive to the northwest, and put up an extra board to shade the southwest side. Can you give me a better plan, or suggest an additional remedy?

WESTLEY.

ANSWER.—Have you no trees? Under the shade of a tree with free access from all sides for the air, there ought not to be much trouble if the hives are not shut up too close. Possibly your hives are close to buildings, high fences or something of the kind that doesn't allow the air free play. Raise the hive not only in front but all around. It will help matters a good deal to have the hive raised an inch on all four sides. Don't put wirecloth on the holes you make, for the bees will shut them up with bee-glue. If the holes are not opened till after bees have been flying well for some time they will not be used as entrances, and perhaps it would be no harm if they should be so used. Instead of making holes, perhaps you'd like this better: Move the second story forward so there will be an opening of $\frac{1}{4}$ or $\frac{1}{2}$ inch between the two stories at the back end. You may also move the cover so there will be an opening at the top. But this wouldn't do for comb honey.

Hive-Ventilation in the Cellar.

Speaking of cellar hibernating of bees, C. P. Dadant says: "Bees should be given a certain amount of upward ventilation," meaning, I take it, an opening of some sort at the top of the hive. I believe some say no top ventilation to the hive is desirable, as it takes off too much heat. I have 19 hives in the cellar, raised $\frac{1}{2}$ inch off the bottom-board all around, but with the tops tight, as propolized by the bees. I aim to maintain the temperature at 40°, keeping the air pure. I would like some further opinion on top ventilation to hives.

MINNESOTA.

ANSWERS.—It's right to have a certain amount of ventilation. It's right to have the tops of the hives sealed up tight as a drum. It's right to have the tops entirely open. It's right to have the bottoms entirely open. It's right to have the bottoms entirely closed. This is a free country, and you can do almost any way you like. But you can't have the hives entirely closed both top and bottom. Not unless you want to kill the bees. Before I had any movable-frame hives, I wintered bees in box-hives in the cellar, and they were turned upside down. That left them entirely open at the top, and entirely closed at the bottom. Later I wintered bees in frame hives in the cellar, with rather small entrances, and with an opening at the top at the back end nearly as much as the bottom entrance. Later still, being less trouble, I left the

tops sealed tight, and gave a large entrance below. Either way is right. A few general principles must, however, be kept in mind. The air in the cellar must be kept good, for good air cannot be gotten into the hives if there's none in the cellar. There must be provision in some way for change of air in the hive. There should not be a strong draft through the hive. If the top is sealed tight there must be very free access for the air below, or the bees will suffer. It's an easy thing to have a hive closed up so tight that the bees will suffer for want of good air. If the air of the cellar is pure, of the right temperature, and there is no draft, it would be a hard thing to have a hive too open. Under such conditions a colony would probably winter well without any hive around it at all. As your hives are arranged, if dead bees are not allowed to clog any part, they ought to be not far out of the way, but a little more open wouldn't hurt.

You say you aim to keep the cellar at about 40°. Are you sure it wouldn't be better to have it a little warmer? The bees will try to keep the outside of the cluster somewhere in the neighborhood of 50°. If the cellar is 10° below that the bees must consume honey to raise the temperature, and if it's only 5° below they'll not need to eat so much. Generally it is considered that 45° is not far out of the way. But the best thing for you to do is to see at what point with your thermometer (there's a great difference in thermometers) the bees will be the most quiet. If they're more quiet at 40° than at 45°, then keep them at 40°.

A Question on Management.

On page 795 of the American Bee Journal for 1897, do I understand you to say that when you place the supers on the two-story hives, you would take the lower story away? Then what I want to know is, what would you do with the brood in the combs of that story? INDIANA.

ANSWER.—Sometimes there will be 10 or 12 frames of brood in the two stories. If there's brood in only one story, there will very likely be only six frames, possibly five. When the one story is taken away from a colony that has more than eight frames of brood, it is left with eight frames of brood, and any colony that has less than eight frames containing brood has its deficiency supplied, so as to make every colony in the apiary have that number. If there are any frames of brood left, and they are not wanted immediately for any particular purpose, they are piled up on one of the weakest colonies, making it three or four stories high, and if one pile will not take them all, then more piles are made. These piles are convenient to draw from when brood is needed, to make new colonies or for any other purpose.

Partnership Bee-Keeping.

What would be a proper division of income of 100 colonies of bees, where one person furnishes the bees and all necessary supplies, and the other person does all the work connected with or necessary in caring for 100 colonies, and a third party acts as superintendent or instructor? What we want to know is, what should each person receive as his part of the gross income from the honey crop, the party owning the bees getting the increase from swarming? NEW MEXICO.

ANSWER.—I don't know. Especially dense is my ignorance regarding the compensation or share the man should have who acts as instructor. If he should only give a passing word of advice now and then to a man who knew about as much as himself, he would not expect to get anything. If the man who took care of the bees knew so little about the business that the instructor had to be on hand all the time during the working season, he might hardly be satisfied with half the proceeds.

The other part is not so difficult, and yet circumstances vary so much that each case should be considered by itself. Perhaps in general, agreements are made to have an equal division between the owner and the apiarist, dividing both swarms and honey. If the apiarist gets no swarms, he ought to have more honey.

But the partnership business in bees is likely to lead to trouble unless there is a very clear and explicit understanding and agreement. And you can readily see that it may make a good deal of difference as to the skill of the apiarist. Suppose a man takes care of the bees who knows so little about the business that the bees do little but swarm, the honey crop not amounting to \$100. Then suppose another man who is thoroughly skilled in the business, and under his management the

proceeds amount to \$1,000. You can readily see that it would not be fair to give one man the same as the other. True, the unskillful man would get small pay at best, but in the hands of the skillful man the crop would be to a certain extent the result of that skill alone, and if he understands the matter rightly he will hardly be willing to allow the owner of the bees much more than a fair pay for the capital and risk involved. So it's hard to make a single rule to fit all cases.

Several Questions from Washington,

1. I have a colony that has been carrying out young brood. I think it is caused by the wax-worm. Would you leave it until spring, or hunt it out now? The hive has a fast bottom.

2. In filling my chaff ticks I got a mouse in the straw, and I have set a trap in the super, baited with cheese, but it doesn't tempt it. How can I get it? It is in a fast-bottom hive, with crooked combs.

3. We had an abundance of white clover bloom and no honey this year. There are hundreds of acres of ground "slashed" and lying idle. Would it pay to scatter seeds of wild flowers over this ground? If so, where could such seeds be had?

4. Is foxglove poisonous?

5. Do bees visit flowers that hang down from the stems as readily as those that stand upright? The frequent showers in spring wash the honey from those that stand upright.

WASHINGTON.

ANSWERS.—1. Better let it alone till spring. The worm in the hive is bad enough. You'd be worse than the worm.

2. Change the temptation. Try meat of different kinds. Perhaps if the cheese is toasted it may suit his mouseship better. Possibly he might be more tempted if the trap was at the entrance. Traps cost so little that you might have one in the super and another at the entrance. If you get him to eat anything that is not in the trap, then you might give him another feast of the same with poison in it.

3. If there's no objection to scattering the seeds, it might be a good plan to sow sweet clover seed. Any seedsman can get the seed for you. Any other of the plants that you see put down as honey-plants in your bee-book might do, such as catnip, plerisy root, Simpson honey-plant, etc.

4. No and yes. There's no likelihood that you will ever be poisoned by coming in contact with foxglove, nor that your bees will be hurt by its flowers, and yet a poisonous article—digitalis—is obtained from the leaves of foxglove.

5. Bees will readily visit a plant with flowers hanging down if only it furnishes a good supply of nectar.

50c worth of Books for 1 new Name.

Send us \$1.00 with a new name for the Bee Journal for 1898, and we will mail you your choice of the list below, to the value of 50 cents.

We make this offer only to those who are now subscribers; in other words, no one sending in his own name as a new subscriber can also claim a choice of this list:

GENERAL ITEMS

Joining the New Union, Etc.

Enclosed find our membership fee to the United States Bee-Keepers' Union. Kindly let us have any circulars or information you have regarding the duties, etc., expected of each of the members of the Union, as we wish to do our portion of the work to down the adulteration of honey, as we consider ourselves situated in a good field to look into this question, owing to there being a great deal of adulteration carried on in and around New York City at the present time.

We produce considerable honey ourselves, but not enough to supply our trade; we therefore have to buy outside, and it is while doing this that we come across the adulterated article. The glucose question is one which is a source of great annoyance to us at times, especially when we find we are obliged to lose a sale by not being able to compete with the adulterated article.

We started out with the intention of selling only the genuine article, and intend to stick to this resolution right along. We find it a source of great encouragement to see how some of our customers appreciate what we are doing for them, once they reach that point where they feel they are dealing with honest people, and can rely on what we tell them regarding pure honey.

We hope the Bee Journal and the United States Bee-Keepers' Union may be successful in the lines of work they are undertaking, by trying to enforce laws against adulteration, and by keeping the bee-keepers out of the clutches of the dishonest commission-men. **HOLDING BROS.**

Hudson Co., N. J.

[The New Union has very little printed matter to send out as yet, we believe. But the General Manager's First Annual Report is now issued, and can be had by addressing Hon. Eugene Secor, Forest City, Iowa. —EDITOR.]

Two Seasons' Report.

Next spring it will be two years since I started in bee-keeping; and if I should look back over the past two seasons I would have to confess to many "follies" or "fool capers," (as our Rip Van Winkle puts it). But then I always take courage, because I am not the only one liable to have mishaps, but the generals and the captains in the army of beedom are as prone to err and make mistakes as the humblest private in the ranks. I find that experience and practice are the ablest teachers in making a bee-master.

I started in the spring of 1896 with 4 colonies of 3-banded Italians purchased in Indiana. They arrived May 10. I increased them, through natural swarming, to 10, which with a colony of blacks, that I transferred from a neighbor's old-fashioned box-hive, (he getting the honey and I the bees,) made 11 colonies. I got no surplus. I wintered them on the summer stands, without a single loss. I used 8 frame, single-walled hives surrounded with an outer case of hemlock, the spaces between being stuffed with paper.

Starting with the 11 colonies, last spring, I increased them to 22. I worked exclusively for comb honey and have obtained a very fair crop. Buckwheat did not yield any honey, and all my surplus is white clover and raspberry in one-pound sections, and it is the whitest honey I ever saw. I believe that the majority of it is raspberry. I had a case of it at our county fair and it took first premium.

I prepared my bees, with the exception of 7 colonies, (which are in chaff hives) the same as last fall, only I used leaves instead of paper to fill out the spaces in the walls,

Only 6 cts. per Pound in 4 Can Lots or Over. Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Cypress Wood for Hives.

On page 745 I see the question: "Can cypress boards be used for bee-hives? If not, why?" And Dr. Miller's answer also: "Who can tell us?"

I believe I can. First, I will say I have no cypress timber, and am not in the lumber business. Yes, cypress can be used for hive-making in every part where wood is used, except sections. The objection to using it for sections is that it is too dark; again, it may not work so nicely at the corners.

Cypress is of several kinds, but only two are generally recognized here, then only as cypress and red cypress. The first includes many shades of yellowish tinge. The red cypress resembles red cedar, and sometimes smells very much like cedar.

All cypress (heart) works most beautifully into moldings, banisters, scrollwork, panels, doors, windows, sash-frames, casings, and in fact all finish work.

Cypress is of the first class where a timber is wanted that will resist rot the longest.

I have some bees, and now use Root's dovetailed hive. I have used cypress hives, and would use them again if I could get dovetailed hives made of it. It is light, durable, and does not warp easily.

A Mr. Hart, near New Orleans, recommends never using pine of any kind for hive-making; he even uses cypress for one-pound sections. I have used cypress brood-frames.
 JAS. O. BURNS.

Tangipahoa Co., La.

[This seems to show satisfactorily that in regions where cypress is readily obtained it may be a very satisfactory wood for hives. It is hardly worth while to test its adaptability in the North, for the ease of obtaining and subsequent cheapness must always cut a large figure. On that account pine will probably continue to be the wood for all hives made in the North.—EDITOR.]

Wintering Bees—Swarming.

I have two colonies of Italian bees which have stored about 50 pounds of honey since late in June. I bought one colony that swarmed June 14; I moved them 10 1/2 miles a few days after that; on the 24th they sent out a swarm that filled a new hive and a super as full as it would hold. They have worked nicely, and would undoubtedly have done better had I gotten them sooner. But now here I am at this time of year, and no cellar fit to winter them in. I am very anxious to get the two through safely, and must winter them out-of-doors. Their summer stand was in a cold place for winter, so I moved them to the south of a small shed, and covered them over with leaves, and covered the tops of the hives with sheaves of straw. I also put a board in front of the entrance so as to shade it, yet give ventilation. I took the super off, took the sections out, and filled the super with clean straw, and put it on in its place again before covering the hive with leaves.

Now I would like some bee-keeper who has had years of experience in wintering bees out-of-doors, tell me what he thinks of my plan so far, criticize it all he pleases, and then tell me what to do if it will not do as it is. The bees are all right now, or I suppose they are. They are alive, anyway, and the hives are as full of honey as they can hold. I did not weigh them, but I could not carry them with the supers on, and I can lift as much as the average bee-keeper, too, I'll guarantee. I don't think they will starve. The hives are 8-frame.

I asked some questions about preventing swarming last summer. One of your read-

ers got it into his head that I did not want my bees to increase. He is very badly mistaken. What I meant by preventing swarming was some method of keeping the bees from getting away entirely, or settling on the top of some tree. I am willing to let them turn out a new swarm twice in a season, but I want to get it without climbing trees.
 H. J. WARNER.

Cedar Co., Iowa, Dec. 6.

[If you wanted to know how to keep swarming bees from settling on high trees, you wouldn't be likely to get much light by asking how to prevent swarming. You cannot prevent swarming without preventing increase at the same time, unless you resort to artificial increase. But preventing bees from absconding or settling on high trees when they swarm, is a much easier problem than the prevention of swarming. To prevent a swarm going off, clip the queen's wing. The bees may swarm out, and they may settle on a high tree, but they will not stay very long on the tree. When they find the queen is not with them, back they will come to the hive. The queen will of course jump off the alighting-board on the ground, when you will catch her, cage her, and when the swarm begins to come back have an empty hive ready in place of the old one for the bees to enter, and when fairly started to enter, let the queen run in.—EDITOR.]

Several Kinks in Bee-Keeping.

GETTING RID OF ANTS.—I have discovered several things in bee-keeping that have been of use to me, which may prove useful to others in the bee-business. Years ago the ants would make nests in the top of the hives to hatch their young. I sprinkled the cloth with strong brine that kept them out, but by accident I discovered a better way; I coopt up several hens with little chickens near the bees; they would run among the hives, and I pick up the ants and cleaned them out. The ants only go in the top of the hives to hatch their young. It is a good, warm place, but they are around on the ground to get their food and the chickens pick them up.

PAINTING HONEY-BARRELS—I extract all of my honey. I put it in alcohol barrels. I found that, drive the hoops the best I could, some of them would leak a little in hot, dry weather. I stopt it by painting the barrels all over the outside.

PREVENTING ROBBERING.—I have seen in the Bee Journal that you must not have any honey exposed near the bees in extracting-time or it would start the bees robbing. As fast as I extract the combs I set them out in the boxes near the bees and let them clean them up. It attracts the bees away from where I am taking out the honey, and they won't bother but very little, and I have no trouble with their robbing. It keeps them from robbing.

CHARLES INMAN.

Midland Co., Mich.

THE MONEY QUESTION

is easily settled by the poultry question. You can settle the poultry question by referring to our Mammoth Annual Poultry Guide. Contains 100 pages printed in finest colors, 30 varieties of poultry and how to treat them in health and disease and how to make money with them. Poultry house plans, recipes; postpaid 1c. 22Atf CHAS. MONDENO, Mgr. Please mention Bee Journal when writing.

In the multitude of counsellors there is safety.—Prov. 11-14.

Position of Sections Over the Frames.

Query 65.—1. Do the sections in the supers you use run the same way as the frames in the hive, or across the frames?

2. Don't you think the sections will be finished up better or be FILLED better, if they run the same way as the brood-frames?—EASTERNER.

Mrs. L. Harrison—1. Yes. 2. No.

W. G. Larrabee—1. Same way as the frames. 2. No.

R. L. Taylor—1. Yes, the same way. 2. I don't know.

E. France—1. The same way as the frames. 2. Yes.

Emerson T. Abbott—1. The same way. 2. I do not know.

J. M. Hambaugh—1. Yes, with the brood-combs. 2. Yes, I believe so.

Prof. A. J. Cook—1 and 2. I have used both about equally. I see no choice.

Rev. M. Mahin—1. They run the same way. 2. I cannot see that it would make any difference.

Jas. A. Stone—1. The same way. 2. I have always thought it the best way, but do not know as to that.

J. E. Pond—1. The same way as the frames. 2. Yes, most assuredly; at least that is my experience.

G. M. Doolittle—1 and 2. I use them both ways, and see nothing in favor of either as to better-filled sections.

Dr. C. C. Miller—1. Same way. 2. I don't see why it should make any difference, unless because the entrance is a freer.

Wm. McEvoy—1. Mine run the same way as the frames in the hive. 2. Yes, where my system is for working for section honey is followed.

Chas. Dadant & Son—1. They run with the frames. 2. It matters but little how they are turned, so the bees have broad access to them from below.

Dr. J. P. H. Brown—1 and 2. In some of my supers they run across the frames, and in others they run with the frames. I have never been able to detect any difference.

Eugene Secor—1. The same way as the frames. 2. I don't know about that. The reason I prefer them to be parallel with the frames is because I only have to level the hive one way.

C. H. Dibbern—1. The same way. 2. It is more convenient, owing to the shape of my hives, and also the only way I could place them, as I tilt the hive forward to make it shed rain.

G. W. Demaree—1. The sections in my section-cases run with the frames. 2. I don't know that their position in the hive has anything to do with the manner in which they are finished by the bees, if the hive is level on its stand. But I want my hives a little low at their

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

THE HATCHING HEN

HAS LOST HER OCCUPATION

and in the production and brooding of chicks she has been supplanted by the better and every day

RELIABLE INCUBATORS AND BROODERS

They Hatch and Brood when you are ready. They don't get lousy. They grow the strongest chicks and the most of them. It takes a 224 page book to tell about these machines and our Mammoth Reliable Incubator and Brooder Co., Quincy, Illinois.

37 D 17t Please mention the American Bee Journal.

WHERE OTHERS FAIL

the **SUCCESSFUL INCUBATORS** succeed, why? because they are properly constructed and the correct methods for operating them are plainly set forth in our 72 page **Direction Book**. Our machines will please you. Prices reasonable. All sold under a positive guarantee which we ask you to compare with others. Send 6c stamps for 128 page catalog and poultry book combined. **It will pay you.** Address **DES MOINES INCUBATOR CO., Box 78, Des Moines, Iowa.**

entrances to drain them, and in this case the section should run with the frames.

J. A. Green—1. Same way. 2. I do not think it would make any difference. The only objection I can see to having them run crosswise is that the hive must be leveled both ways, which is neither easy nor desirable.

A. F. Brown—1 and 2. My sections run parallel with the frames. For many reasons this is best. I do not think it makes much difference to the bees which way they run; they will fill them for me one way as well as the other.

Cupid's Dart Puzzle —The LOVER'S DELIGHT.

Cupid's Dart sped through space,
Aimed with much precision;
Its target—in a conspicuous place—
Was pierced beyond recognition.
Cupid at once withdrew the arrow,
Fearful of the result of his aim,
But the work was done—the escape narrow—
Perhaps you can do the same.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Dec. 13. - Fancy white 11 to 12c. No. 1, 10c; fancy amber, 8 to 9c.; No. 1, 7c.; fancy dark, 7c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c. The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special change. Beeswax is scarce.

Milwaukee, Wis., Dec. 13. - Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 9 to 10c.; fancy dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 4 1/2 to 5c. Beeswax, 25 to 27c.

This market has been fairly sustained on honey since our last report. Values remain about the same, as there has been a very good consumptive demand, especially for extracted, while the comb honey has seemed to accumulate with increased receipts, and we feel to meet the demand even if at a reduction from quotations. There seems to be more demand from those who eat honey than in former seasons, which is a good feature of the trade which we desire to encourage. We are expecting a good trade from this forward.

Cleveland, Ohio, Dec. 15. - Fancy white, 12 to 12 1/2c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

New York, N. Y., Dec. 22. - Fancy white 11 to 11 1/2c.; off grades, 9 to 10c.; buckwheat and mixt, 8 1/2 to 7c. Extracted, California white, 5 to 5 1/2c.; light amber, 4 1/2 to 4 3/4c.; white clover and basswood, 5 to 5 1/2c.; buckwheat, 4 to 4 1/2c.; Southern, 50c. a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of buckwheat, mixt, and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Dec. 15. - Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 10c.; No. 1, 9 1/2c.; fancy dark 9 to 9 1/2c.; No. 1, 8 to 9c. Extracted, white, 5 to 6c.; amber, 4 to 4 1/2c.; dark, 4c. Beeswax, 23c. Market holds firm at above prices. Good demand for extracted. Wax is quiet but firm at 23c.

Kansas City, Mo., Dec. 15. - Fancy white, 10 1/2 to 11c.; No. 1, 10 to 10 1/2c.; fancy amber, 9 1/2 to 10c.; No. 1, 9 to 9 1/2c.; fancy dark, 8 1/2 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c.

St. Louis, Mo., Dec. 13. - Fancy white, 12 to 12 1/2c.; No. 1, 10 1/2 to 11 1/2c.; fancy amber, 9 1/2 to 10c.; No. 1, 9c.; fancy dark, 8c. Extracted, white, 5 to 5 1/2c.; amber, 4 to 4 1/2c.; dark, 3 1/2 to 4c. Beeswax, 24 1/2 to 25c.

We would advise prompt shipments of honey. We do not see any probabilities of better prices. The stock of honey is ample for the demand.

Albany, N. Y., Dec. 13. - Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 8 to 9c.; No. 1, 8c.; fancy dark, 8c.; No. 1, 7 1/2 to 8c. Extracted, white, 5 to 6c.; amber, 4 1/2 to 5c.; dark, 4 to 4 1/2c.

There is an ample stock of comb on hand and selling freely at quotations. Extracted is not plentiful and from information received there is not much in the hands of producers.

Buffalo, N. Y., Dec. 24. - Strictly fancy 1-pound comb honey is more active at mostly 10c. occasionally 11c., but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c. down to 6c. Extracted is moving slowly at 5 to 6c. for fancy; dark, 4 to 4 1/2c. A liberal quantity can be sold; and, of course, the low grades can be forced off for what they will bring. If owners cannot do any better.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

Philadelphia, Pa., Nov. 13. - Fancy white, 13 to 14c.; No. 1, 12c.; fancy amber, 10c.; No. 1, 9c.; No. 1 dark, 8c. Extracted, white, 5 to 5 1/2c.; amber, 5c.; dark, 4 to 4 1/2c. Beeswax, 27c.

Honey is arriving very freely; market is a little off. Beeswax is in good demand.

Boston, Mass., Nov. 8. - Fancy white, in cartons, 13c.; No. 1, 11 to 12c.; fancy amber, 10c. Extracted, white, 6 to 7c.; amber, 5 to 5 1/2c. Beeswax, 28c.

No. 1 and fancy honey has sold well during the past 10 days, but off grades and light weight is going slowly. Beeswax is in good demand and but little here.

Detroit, Mich., Nov. 9. - Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c.; fancy dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c. Beeswax, 25 to 26c.

Indianapolis, Ind., Nov. 8. - Fancy white, 11 to 13c.; No. 1, 9 to 10c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25c.

Demand for fancy white comb honey and fancy white extracted is exceptionally good, while there is almost no demand for dark or amber comb or extracted honey.

Cincinnati, Ohio, Dec. 22. - There is no change in prices, but rather a slow demand for the holiday season. We quote 10 to 14c as the range of prices for best white comb honey, and 3 1-2 to 6c., for extracted, according to quality. Beeswax is in fair demand at 20 to 25c. for good to choice yellow.

BIOGRAPHICAL

MR. GEORGE S. WHEELER.

The following sketch of Mr. George S. Wheeler, of Hillsboro Co., N. H., was kindly written by Mr. H. A. Fish, who evidently is well acquainted with Mr. Wheeler:

The subject of this sketch was born in Hillsboro Co., N. H., on the farm where he now lives, as did his father and grandfather, who built the house over 100 years ago. The son, "George," had charge of the farm for several years before the death of his father, which occurred in 1892. Mr. Wheeler bought his first colony of bees in 1856. This colony was the center of attraction for a long time. When it was brought home it was set in a bee-house prepared for it. The hive was a box-hive, 12x12x14 inches, with a compartment on top for two 10-pound boxes of honey. Four dollars worth of honey was sold the first season, leaving enough in the brood-chamber for the winter. The cost of the bees was \$5.00.

An Italian queen was bought of K. P. Kidder, of Burlington, Vt., some time in the '60's, for which \$5.00 was paid. The next season some 20 colonies had queens introduced, reared from the Kidder queen, and about every bee reared from her queens showed three bands, and were as well marked as the old queen. When these queens took their wedding flight the yard was full of black drones, but Mr. Wheeler thinks the drones from the Italians must have mated with them all. But the next season, when about every drone in the yard was Italian, he could hardly get a queen but what would produce hybrid bees, largely black, so he later concluded that the first cross could not be told from pure Italians so far as stripes went, and he has never had reason to change that view.

Since Mr. Wheeler started with Italian bees he has never had over 50 colonies at one time, usually about 25. He has always had bees on the farm since 1856. The winter of 1868 found him in Mississippi, as foreman on a plantation, and being an expert at hiving wild bees, he soon had a section of a bee-tree in the yard. They swarmed twice in April, and were hived in hives similar to the one described in the beginning of this article. The natives thought a hive with glass in the back, and boxes on top, was a Yankee invention, and came from all parts to see the hives. There were many wild swarms in the woods then, and Mr. Wheeler found quite a number, and had lines of more that were never traced.

The most honey Mr. Wheeler has ever taken from one colony was 75 pounds, which was extracted with a Peabody extractor, which he has used for over 20 years. Mr. Wheeler has bought queens from all parts of the country, and is always coking for something new and better. He had seven swarms from one colony of Carniolans in one season. The old colony

swarmed twice in May, and the first of June these two cast two swarms each, and the old one another in August. He had never before nor since seen a second swarm swarm the same season.

He uses the Alley queen-trap, and says there is nothing like it. In 40 years of bee-keeping he has never had but one swarm leave for the woods, and that was last year. They were hived four times, and then were put into a new hive containing combs and honey, and carelessly left without a queen-trap, when they started for parts unknown.

Mr. Wheeler showed me a place on a limb of an apple-tree in his yard, and said that there have been hundreds of swarms alight on that limb, and always in the same place.

Mr. W. believes that bees go a long way for honey, as he has seen Italian bees five miles from his farm, and no others were anywhere around; and I can vouch for that statement

George S. Wheeler.

as I have seen them that far when I was hunting wild bees, and they had to go over a range of mountains to get home.

In 1896 I saw Mr. Wheeler's bees. He had a very few colonies, 13 I think, mostly very fine 3-banded Italians. I thought I would get some from him. In the spring he wrote

me he had not a colony of them left. They died of dysentery produced by honey-dew or "bug-juice," as he calls it.

Mr. Wheeler reads all the bee-papers, and has been a subscriber to the American Bee Journal off and on since 1866, when Samuel Wagner was editor. He remembers when "Novice" (A. I. Root) first began to write on bees, and was very interesting.

When a small boy it was a treat for me to go up to the old Wheeler farm, and see the queer things to be seen there—the different breeds of poultry, both land and water fowl; China sheep, with their funny ears, the large stock of cattle, etc.; but those long rows of bee-hives were what seemed to interest me most. I would look at them, and it seemed to me like a village, as some of them were built in fancy shapes (the old American). I have counted almost a hundred at one time, and as I look at what there are now, it seems quite different.

Mr. Wheeler, whom I have known from my boyhood days to the present time, is a very pleasant man to meet, and is an interesting talker. Say "bees" to him, or "poultry," and you are "in for it." Out you go amongst them, and if you get away short of a half day you can do better than I can, or want to. His time in service, I think, entitles him to be called one of the veterans in beedom, and I hope to see some of his writings in the bee-papers, as they would be interesting and helpful.

H. A. FISH.

Something on the Adulteration of Honey.

We have received the following from Hon. Eugene Secor, General Manager of the United States Bee-Keepers' Union, which every bee-keeper should read:

FOREST CITY, Iowa, Dec. 31, 1897.

MY DEAR MR. YORK:—I enclose a copy of three sections of the Iowa "Code," bearing on the subject of pure food, and naming the penalties for violating the provisions thereof.

In Iowa we have no pure food commissioner as is the case in some of the States. The enforcement of the law will rest largely with the people who are interested. I would like to have you publish the sections enclosed for the benefit of your readers in this State. I know of no better way to get the information before our bee-keepers.

You will notice that we have plenty of law on the subject of adulteration. It only remains for the bee-keepers in every community to see that its provisions are enforced.

If a groceryman is selling liquid glucose under the name of honey, call his attention to the law, and then if he does not quit it, have a sample of it analyzed, and if found to be adulterated, file an information before a Justice of the Peace under the advice of the County Attorney.

One such suit, if successfully managed, will drive the stuff out of a whole county. As a rule, grocers do not want to handle any article of food which is prohibited by law. If their attention is called to the matter they will, nine times out of ten, refuse to buy or sell it. I would not advise prosecuting every storekeeper who has been led to buy an adulterated article in ignorance of the law, until he has been notified. "Ignorance of the law excuses no man," but at the same time we can hardly expect every man to know all the provisions of an ever-changing code.

I hope, Mr. York, that you will call public attention to the laws in other States relating to honey-adulteration. Bee-keepers do not always have access to the laws of their own States, even.

Perhaps we have better protection than we are aware of. Arrangements will soon be made, very likely, to have samples analyzed; but before sending them it will be necessary to take such precautions to identify samples if they should be used in court. A letter to me with a statement of the case will receive attention and advice how to proceed.

EUGENE SECOR,
General Manager U. S. Bee-Keepers' Union.

The three sections from the Iowa Code, which Mr. Secor sent, read thus:

LAW RELATING TO ADULTERATION OF FOODS—IOWA CODE, 1897

SEC. 4986.—No person shall mix, color, stain or powder any article which enters into the composition of food, drink or medicine with any other ingredients or material, whether injurious to health or not, for the purpose of gain or profit, or sell or offer for sale any article so mixt, colored, stained or powdered, unless the same be so manufactured, used or sold or offered for sale, under its true and appropriate name, and notice that the same is mixt or impure is markt, printed or stampt upon each package, roll, parcel or vessel containing the same, so as to be and remain at all times readily visible, or unless the person purchasing the same is fully informed by the seller of the true names of the ingredients (if other than such as are known by the common name thereof) of such articles at the time of making the sale thereof or offering to sell the same; but nothing in this section shall prevent the use of harmless coloring material used in coloring butter and cheese.

SEC. 4987.—No person shall mix any glucose or grape-sugar with syrup or sugar intended for human food, or shall mix or mingle any glucose or grape-sugar with any article, without distinctly marking, stamping or labeling the article or the package containing the same with the true and appropriate name of such article, and the percentage in which glucose or grape-sugar enters into its composition. Nor shall any person sell or offer for sale, or permit to be sold or offered for sale, any such food, into the composition of which glucose or grape-sugar has entered, without at the same time informing the buyer of the fact, and the proportion in which glucose or grape-sugar has entered into the composition.

SEC. 4988.—Any person violating any provision of the four preceding sections shall, for the first offense, be fined not less than ten nor more than fifty dollars; for the second offense, not less than twenty-five nor more than one hundred dollars, or imprisonment in the county jail for not more than thirty days; for the third or any subsequent offense, not less than five hundred nor more than one thousand dollars, and imprisonment in the penitentiary not less than one nor more than five years.

We think that Mr. Secor offers a valuable suggestion when he says that he thinks it would aid materially if bee-keepers would show a copy of their State law on food adulteration to every grocer who they have reason to think handles adulterated honey. We will try it here in Chicago, and report the result. But Chicago dealers are so accustomed to seeing few laws enforced, that we are not very sanguine as to being able to frighten them by simply showing them the law. The only thing that will touch the hardened law-breakers here is a severe enforcement of law, we think.

Honey-Consumption—Working Up a Demand.

BY MRS. L. HARRISON.

During the autumn and early winter I have been watching the consumption of honey with much interest. Near my home is a grocer doing a fair business. Early in the season he purchast two 12-pound cases of section honey, glass, and showing well, and kept it near the window in plain sight of all who pass. It remained for weeks before the cover had even been loosened, and when I left home (Dec. 15) only a few sections had been sold from one case. Why? In another direction was another grocer with like experience.

Good grocers all over the city had a supply. Very white section honey, labeled "Mountain Honey," was quite plentiful, also pint Mason jars of the same kind, offered for 20 cents per jar. Honey could be purchast by consumers all the way from 8 to 15 cents per pound, but few apparently wanted it at any price.

While traveling from Peoria, Ill., to Mobile, Ala., most of the way during daylight, I saw but one small apiary, and by questioning passengers who got off and on along the route, I learned that but few colonies were kept, and those in a primitive way.

Mobile is an old Spanish city, and at the last census numbered 44,000, and has considerable trade. Large quantities of cotton comes down the Alabama and Tombigbee rivers, which is taken by steamers to Liverpool. Many commission houses handle large quantities of cured meats, flour, meal and distilled liquors. Vessels are arriving with cargoes of bananas and coconuts, while others depart laden with cotton, lumber, and mixt cargoes of merchandise.

I've been here at Mobile for a week waiting for a steamer to go to my winter home in Florida. Having leisure I visited many grocers in different parts of the city, enquiring for

honey, yet I found none—not a section, and also sought for it at commission-houses. Grocers would say, "We do not handle it; it's very cheap; retails for 10 cents per pound, either in comb or liquid." One grocer said that he had liquid honey that he sold for 55 cents per gallon. I asked if it was Cuban honey? He replied that he did not know where it came from.

The market for honey has never been developed; it would be folly to ship it here until a demand has been created. A dealer in bananas told the writer that a vessel brought a cargo of plantains to this port, but there was no sale for them, and they had to be taken to another city.

Those who undertake to develop a honey market should expect to receive very small pay for their labor. Our country is a great country, and let a demand for honey be created, and quick as a lightning flash the news is spread, and a supply comes.
Mobile Co., Ala., Dec. 25.

Various Notes and Comments.

BY J. M. YOUNG.

In continuing my notes to the American Bee Journal, for the present winter I will say that what I may write or advance will be as heretofore, directed to beginners and those like myself, thirsting after knowledge in apiculture. While I have been in this line of business more or less since 1870, I find that there is something to be learned almost every day. The bee-business is a trade to be learned and made up of many small matters, and to make a success of it financially, the apiarist must be informed. The carpenter, the machinist, the blacksmith, all learn something in everyday life, so will the apiarist.

GARDENING AND BEE-KEEPING.—For the last four or five years I have been running a small garden in connection with my bee-business, and from a financial point of view I find that they work together if carried on with the proper objects in view. For instance, take a season like the present one—a poor one for bees here, and a good one for gardening. Usually, when it is a good year for "garden sass," it is a good year for honey, but that dear old teacher, Experience, says that there are exceptions in all pursuits of life. Nevertheless, when it is true, when the cabbage and cucumbers and such truck need cultivating, the bees are wanting to swarm, or perhaps need a super of sections. Such will be the case, but if the bee-keeper is a rustler, gets up early in the morning, and works after he gets up, it will be surprising to see how much may be done before the night comes on.

Old Mother Earth has put on again (Dec. 31) her white winter robe by having three or four inches of snow spread over her beautiful surface. There have been all sorts of weather thus far this winter, the mercury having gone down to zero a time or two.

BROOD-FRAME SPACING-STAPLES.—I have been using and trying the past season the new short end staple improvement on brood-frames, and to make a long story short I will say that I don't like them. I condemned them in the start, from the fact that they are always getting out of place, or "bucking," to use a cowboy term, when the hives are being moved around.

BEEES ALL RIGHT.—Are your bees all in good condition for winter, with plenty of stores to carry them through until apple-bloom? Nearly all of mine are in chaff-hives with plenty of upward ventilation, and honey to last them through, with a seasonable winter. I have a few in single-walled hives that may get their "ears" frosted.

NEBRASKA APIARIAN EXHIBIT.—Supt. Stilson, of the apiculture department of the Trans-Mississippi Exposition at Omaha, has secured a large amount of honey from over the State that will be a fair sample of what Nebraska can do in the apicultural line. Mr. Stilson is a hustler, and nothing will be left undone to make a successful exhibit.

BEEES UNDER SNOWDRIFTS.—About 8 in. of snow fell Dec. 3, making good sleighing for two days, then a warm wave swept over us, and took it off, or nearly so. I had a few one-story dovetailed hives that were covered up with the drifting snow, but it did not hurt the bees any. Of course, when it began to thaw I took a scoop-shovel and just went for those snowdrifts. No, sir, bees covered up in a snowdrift will be all right if it keeps cold, I don't care if there is six feet of snow on

them, if the bees have plenty of good honey and a good, tight hive, with a good cover that doesn't leak. But look out for that thaw that usually comes sooner or later. Don't understand that I recommend this way of wintering, for there is not a bee-keeper living in all this western country, or in any country where snow falls, but will have some of his hives covered up with snowdrifts sometime during the winter months.

APIARIAN EXHIBITS AT FAIRS.—That report of the Buffalo convention is very interesting reading, but that part relating to exhibits at fairs I am afraid is too late to be put into force this fall, and before another fair time rolls around, the most of us will have forgotten all about it.

ALFALFA IN NEBRASKA.—I regret to say bees don't work on alfalfa very much in this neck of the woods, from some cause not clear to me. There was a patch near my apiary last summer on which I made some close observations during the blooming period. Farther west it is said to be a good honey-plant, and considerable surplus is obtained.

THE NO-BEE-WAY SECTION.—That new honey-section that has lately come into use is precisely the same section that I used many years ago, the only difference being that they were then made to hold two pounds, and were dovetailed all around. I used to put 12 of those two-pound sections in a frame or rack made of common lath that rested right on top of the frames. I found that one of these racks was filled as quick, or quicker, than the 12-pound super that is used today. The only reason I can assign for this was that when the bees are once up in the super, and started in the sections, they will run down a two-pound box just as soon as a one-pound section, from the fact that there are more bees to do the work, and the heat is retained better.

MY REPORT FOR 1897 is not an encouraging one, by any means. In fact, I don't care to allow it to appear in print, only to give the reader a gentle hint as to what the average per colony would be. It would be putting it rather mildly to say that if the number of pounds was computed, it would not reach over 10 pounds per colony, spring count, including both comb and extracted honey. The prospects for the early honey harvest were flattering in every particular. The white clover began to bloom early and continued all the season, or as long as it lasted, even up to the first of July. When the basswood began to bloom, the bees were up in the supers, filling and storing as fast as they could, but two or three days of hot winds came and stopt proceedings, as if a thunderbolt had struck them. The supers were left about two-thirds finish, or hardly so much, from that time on they (the bees) did comparatively nothing, only partly finishing a few sections, but leaving a greater part of the sections unfinished. The basswood bloom only lasted a day or two, giving the bees only a taste, as it were. But from reports west of here, where alfalfa abounds plentifully, I am happy to say a moderate yield was obtained. The reason that no surplus was obtained from white clover was, the bees were reduced in numbers by spring dwindling, so that there was not a sufficient force of workers to obtain the honey that was going to waste in the fields.

ADVICE TO BEGINNERS.—Now is a good time for beginners to post up and read everything that they have received during the summer, and then you will be prepared to make arrangements for the next season. I find in looking over copies received during the summer, of the American Bee Journal and Gleanings (I take 'em both) that there are many good articles that escaped my notice during the busy season, that improve my knowledge of beedom wonderfully. If a bee-keeper doesn't take a bee-paper of some kind he is not a bee-keeper that is up with the times. Constantly there are new devices coming up, or improvements made in the ones already in use, that the bee-keeper must adopt sooner or later in making apiculture a success.
Cass Co., Nebr.

Strength of Colonies in Spring—Wintering.

BY C. E. MEAD.

I have received the following question for reply, from Editor York:

"MR. EDITOR:—On page 707, an estimate is made that in a box or tight-frame hive, if I understand correctly, a colony will be five times as strong April 10 as March 21, and 25 times as strong May 11. Now on March 21 a good colony

will have enough bees to cover from 2 to 5 Langstroth frames. Does Mr. Mead mean that a colony having enough bees to cover 2 frames March 21 will have May 11 enough bees to cover 50 frames, and one that has March 21 enough bees to cover 5 frames will have enough bees May 11 to cover 125 frames?—INQUIRER."

ANSWER.—It seems I did not make my explanation as clear as it ought to be.

March 1 you have many old and a few young bees. March 21 the old bees are dying fast, and the young bees are hatching equally fast, if in a closed-end frame hive, or well packed loose frame, log or box hive. Introduce an Italian queen to a colony of black bees in October, and it is a rare thing to find a teacupful of black bees the first of next May. Reverse the process and you probably will find a few more Italian workers on May 1.

Now in a poorly-protected hive the ratio of increase will not be so large. Sometimes the increase is so slow that the old bees die so fast that the brood is left bare and the colony plays out. So the ratio of increase varies in proportion to the warmth of the space occupied by the bees. The colony is at a standstill in early spring in proportion to the death of the old bees. In a box or log, or closed-end frame hive, or well-packed hive, there will be a ratio of increase of 5 in every 21 days after the old bees are nearly gone, till the capacity of the queen is reached, which, in this locality, is June 1, on an average, or from 10 to 12 Langstroth frames of brood. If the queen could keep up the same ratio of 5 the summer through, but one queen would be needed.

Now, to show what I mean, I will explain again how I winter 4-Langstroth frame nuclei and small colonies:

I place a big hive on a large stand with the entrance in the bottom, with a slanting alighting-board. Around this hive the size of the stand I place a rim of $\frac{1}{8}$ boards, one foot high. I then pack the big hive as warm as I can. I put four one-inch blocks of wood on the rim $\frac{1}{8}$ inch from the top. On these blocks rest the long bottom-board of the nucleus. Make a bridge from the hive to the rim; have a 2-inch by $\frac{3}{8}$ -inch notch cut in the bottom of the next one-foot rim. The entrance should not be on the same side as the lower hive. Screw an alighting-board just under the 2-inch entrance. Set the second rim on top of the first rim, with clay in the joint. Put on the third rim and pack all around, and a foot above the nucleus. Put on a water-tight cover, that allows a free current of air to pass under it to carry off any moisture. I leave a full entrance to the lower hive till pollen comes in freely, then I contract it so as to make them uncomfortably warm so they have to fan all the time.

Now as to results: The nucleus is as warm, or warmer than the big hive colony below it, and will need more room early in the season. They usually equal, and often surpass in strength, the big 10-Langstroth-frame colonies below by June 1, which shows how bees can increase when in hives where the heat is economized. I have done this for the past 10 years or more.

Cook Co., Ill.

No. 2—Recollections of an Old Bee-Keeper.

BY DR. E. GALLUP.

(Continued from page 4.)

Studying about the wintering of the before-mentioned colony, the following winter I raised up all my box-hives from the bottom and placed an inch block under each corner, and then I had solved the wintering problem, providing they had a sufficient amount of surplus.

Canada was a great honey country in those days. The country was new, with large bodies of basswood, elm, willow, maple, wild flowers, hundreds of acres of red raspberries, acres of buckwheat, white clover, etc., and abundance of snow to protect the ground, so it did not freeze. The summers were warm, moist and sultry—just the right conditions for the secretion of large quantities of nectar.

Well do I remember the first time I saw an old "king-bee." The bees had swarmed and partially clustered, and before I could hive them they commenced going back to the old hive, and in watching them go back, I saw the old "king-bee" crawling on the ground. I got her out on a piece of shingle and helped her into the hive. People used to tell me that there always was an "old king-bee" that controlled everything about the hive, but never having seen one I was a Doubting Thomas up to that time.

Now I must tell you something about buckwheat. You know that millers always have fat hogs, altho you may not know whose grain they are fattened on. Well, I had about an acre fenced in for the hogs, and they rooted it over

and over, and of course manured it thoroughly in the course of four years. When sowing my patch of buckwheat for the bees, as I usually did, I thought that hog-yard is so rich and mellow, why not shut the hogs in the pen and harrow in some buckwheat? Well, the result was that patch turned out the most nectar to the rod that I ever saw. One could smell the perfume for rods, and it was literally alive with bees, while my other patch, that was seeded at the same time, and not manured, was visited by scarcely a bee. The lesson is that manure, or a rich soil, produces more nectar than a poor soil. I have noticed the same fact many times since. Here in California a heavily fertilized orange-grove shows it in a remarkable degree. In Iowa I had about six acres that I cleared up and yarded sheep on for two seasons at night, and seeded it to white clover, and the way the bees worked on that was a caution; while outside they scarcely visited white clover. Keep your eyes open and you can always learn.

About the year 1843 I hired a young man from Vermont to help in the sawmill, and he informed me of a man by the name of Weeks who had published a book on bees and got up a patent hive, so I obtained the book and right to use his hive. That was the first writing of any description I ever saw on bees. The hive was simply a box with a chamber for two drawers or boxes for honey, and the hive was suspended in a frame by two cleats, one on each side, with a slanting bottom, and the bottom-board fastened to the hive with hooks and staples at the corners. A button was at the back of the hive, so that when the bottom was buttoned forward the hive was closed except the entrance; when it was unbuttoned it left an inch space all around the bottom of the hive to allow for winter ventilation, or hot weather ventilation, also; and being so slanting, when a moth-worm fell onto it, he would roll out and break his neck in falling to the ground! Bees would winter in that hive with the inch ventilation all around the bottom, providing they had sufficient stores. I had demonstrated that fact by raising my box-hives on inch blocks at the bottom. I took a lesson from that in cellar wintering.

I received a good many good points from Mr. Weeks' little book, as well as erroneous points. Here is another fact that I discovered: Honey gathered in the forepart of the season, thoroughly matured and ripened, is the very best kind of stores for wintering; while honey gathered late in the season, or at a time when the weather is wet or cool, is not sufficiently ripened or matured, and is not good for wintering. Bees will consume more pounds, get the dysentery and die, or what some call bad spring dwindling, etc. An early swarm and a late one, weighed in the fall at the same time, the early swarm weighing considerable less, would winter well, while the late swarm weighing more would frequently starve before spring.

Have not many of you made a great mistake since the extractor has come into use, by not regarding the above fact? You have trusted to your late-stored honey for wintering purposes, and met with loss, and then, like the old lady who took her death o' cold by eating gruel out of a damp basin, you are ready to attribute your mishap to anything but the right cause. In order to cure remove the cause.

Orange Co., Calif.

[To be continued.]

Honey as Food is the name of a 24-page pamphlet, $3\frac{1}{2} \times 6\frac{1}{4}$ inches, which we are now printing for general distribution among those who should be users of honey. It is just the thing for bee-keepers to hand to every one of their customers, and also to those whom they would like to have as customers. It is very handy in size—just right to go into an ordinary business envelope. It contains 12 illustrations, five of which are somewhat comic, and help to make it attractive. There is a blank space for your name and address. About $\frac{1}{2}$ of the pamphlet was written by Dr. Miller, and then we added thereto many new and valuable honey recipes—for cooking and for medicinal purposes. In all, it makes a neat little pamphlet. Send name and address and we will mail you a sample of "Honey as Food."

Prices for quantities, postpaid—25 for 30 cents; 50 for 50 cents; 100 for 85 cents; 200 for \$1.40. By express, not prepaid, 500 for \$3.00; 1,000, \$5.00.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 7.)

WINTERING BEES OUTSIDE.

"What is the best way of wintering bees outside?"

Mr. Moore—Putting sheet iron covers over them.

Mr. Green—That is one of the ways; I use such covers, and find they are very practical.

Pres. Miller—Who has been very successful in outside wintering of bees? Let me ask this question: How many of you prefer for yourselves outside wintering of bees to cellar wintering?

Eight preferred outside wintering.

Pres. Miller—It might be interesting if we knew something of the location of those different ones. Mr. Green, for instance, is somewhat down in the State of Illinois. It might be expected that those farther south would be more in favor of outside wintering than those farther north, but it is not always the case; perhaps it would be interesting if we could know something of the amount wintered, and about the distance north or south.

Mr. Karch—I have been keeping bees from my boyhood. I have not a convenient cellar as some of my neighbors, who keep their bees in the cellar very successfully. My cellar is not large enough. I have to winter them outside, and that is why I ask this question.

Mr. Rohrs—I have been in the bee-business about five years. I have tried wintering bees in the cellar, but with poor success. Now I don't know whether it is on account of my cellar or because I don't know better, so I have tried to winter them under a bee-shed like they do in Germany, and I succeeded a good deal better in the cellar. Certainly I have lost, but I always think I am one of those who has to learn more to have better success than I do, and I have been of the opinion that it is well to have a hive that protects the bees all the year round. In the old country they leave them as they are, and they always winter perfectly well. I have been thinking of having a hive that would be good for winter and for spring, and I believe that we want protection for bees in spring. I think a bee-shed is a good thing, except there is one objection. After you have hives close together, you are bound to lose queens now and then; and I have been looking for another and better hive, so that the changes of winter will not affect the hives so easily. I would prefer to have the bees outside. I am from the southern part of Wisconsin. I have my bees on the sunny side of the house, towards the south-east. I hope I will have good success with the hives I have at present, because I know I have good protection. I have the Champion hive. I want a hive that in the spring I can take off the back and handle it easily. I want my bees packed again after that, because we have very changeable weather. In the spring we get a warm spell, then a cold spell. I want a hive that will give protection to the bees. This hive I can take apart and clean it easily. Then I want my bees packed again until the honey-flow comes. I have seen other parties in my neighborhood use chaff hives successfully, and I don't see why I cannot. I can ventilate this hive.

Mr. Miller—I am from eastern Pennsylvania. While I never kept bees on my own account, my father is a beekeeper and my life has been spent among them. At home we have tried wintering in the cellar with fair success; in a shed, with a loss of 30 per cent., and have tried them without any protection, far better than in the cellar or shed. The chaff hive was the best thing that we had. My father finally got some thin slabs and sawed these up and made a rough hive, set it over the other hive, and filled that up with chaff, and in the spring he took the chaff out and left the hive there, which gave protection against winter storm, and afterwards took it away—all but the front part of the hive—and then finally took that away altogether; in that way the loss during the winter was reduced to almost nothing, while before he lost in

sheds fully 30 per cent. during the winter; probably ten per cent. in cellar.

Mr. Green—That is practically the way I have followed for years, altho I prefer to have four hives together in one large case, two entrances facing east and two west, two or three inches apart and four inches between the hives and outside walls, often covered with one roof; a very simple, easy plan of protection, and it works very well indeed.

Mr. Whitcomb—If the cellar is extraordinarily dry and extraordinarily well ventilated, they winter nicely in the cellar, but we in Nebraska have best success in wintering in a 4-inch packing case, well hooked together with hooks in the corners, and if necessary to examine the hive you can remove one portion and let the other remain. We have tried corn chaff, but it is villainous stuff to get dry. Dry leaves are better than anything else. We have reduced the loss in winter to almost a minimum. The packing case is lower in the back and high in front, with one cover that covers the whole thing, painted red, made of the lightest lumber possible. Hundreds of them can be piled, one on top the other when not in use; the little board that covers the entrance is separate—everything is separate, with two books on each corner. We have been using them for 15 years, and I don't see but they are as good as they ever were. They are always ready; each one is made exactly alike, and they cost about 90 cents a piece. They are cheaper than the chaff hive, and are not cumbersome at all, and usually around the yard you can rake up leaves enough, but avoid as much as possible keeping bees under sheds or in a place where the packing will get wet. I would rather a little colony of bees would stand out without any protection than to be packed in wet packing, because then you will find your colony in bad condition in the spring. We avoid sheds of all kinds and descriptions. In the summer time, in Nebraska, the evenings are very cool; I find under the trees and buildings the mercury runs down three or four degrees more than it does in the open air. With us the sun comes out very early in the morning, and it is only the bees that get out in the morning that are able to lay up stores. In keeping a record of the colonies, I found the ones that are the farthest away from sheds and buildings always put up the most honey. I had a hive on the north side of a little plum tree—it was quite a small tree when I put it there, but as it grew, I noticed the stores in the hive were less and less every year, so I moved it away from there a few feet, and found the stores from year to year increased. I don't use any shed at all, except an artificial shed that shades the top and side of the hive, and gives free circulation of air. My hives always face the east for two reasons, first, the front and rear of the hive is not shaded. I want the sun to shine upon them as much as possible, and as long in the evening as possible. If you ever went to a beehive late at night, you heard the evaporation going on.

Pres. Miller—I see planer shavings are highly recommended for packing; have you tried them?

Mr. Green—I have used planer shavings extensively, and they are most satisfactory. I should be very careful not to use straw or corn of any kind, because it attracts mice. Chaff, of course, is one of the worst things in that respect.

Pres. Miller—I never heard of corn chaff before.

Mr. Whitcomb—In all the elevators of the great grain belt they have a great deal of corn chaff; corn chaff comes from corn that is shelled; you can go there and get a hundred wagon loads of it if you want; a few drops of water will spoil it; it must be kept dry.

Pres. Miller—What further upon the best method of wintering bees out-doors?

Mr. Baxter—I am in the bee-business for the money I can make out of it. I have been in it for about 20 years, and I have experimented a great deal, and never kept less than 250 colonies. After all my experiments I find that the Dadants plan beats anything else I ever tried. I have tried other plans, and find the Dadant gives the best results. I put a mat made of grass on top of the frames, then fill the cap with dry leaves, and invert it right on the hive. In the spring, if I think the bees are short of stores along the latter part of March or beginning of April, I can lift up the cap, with the leaves and everything, and just remove the mat and see how they look. If they need any feed I can feed them without unpacking them. I believe in unpacking them very late, as late as possible. I have unpacked them as late as apple blossoms, and have lost but very few colonies during the winter. There is a big difference in wintering, whether you are running them for comb honey or extracted honey.

Adjourned until 1:30 p. m.

(To be continued.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Using Unfinished Sections.

I have a lot of unfinished section that I want to use in the spring, in the white clover harvest. I let the bees take the honey out of them. Will it be necessary to use queen-excluder honey-boards to keep the queen from depositing eggs in them? and which is best, wood or tin? MISSOURI.

ANSWER.—If I understand you correctly, you expect the bees to empty the sections next spring so as to get them filled up afterward from the white clover harvest. I don't believe you better try it. Almost surely the honey in the sections will be more or less candied, and in that condition the bees will not make a perfect job of cleaning them out. If they leave the least bit of granulated honey in the cells, that will affect the character of the fresh honey. The only way to use safely unfinished sections, is to have them cleaned out thoroughly by the bees as soon as they are taken off, and before any granulation has taken place. Of course this can only be done in the fall, and not too late, at that.

Usually it is not necessary to use a queen-excluder to prevent the queen from going into the sections. A zinc excluder is the kind generally in use. Wood can hardly be made exact enough.

Making Grafting-Wax—Water-Wheels.

1. How is grafting-wax made?

2. Please give the proportions to build an over-shot water-wheel, three horse-power? I have 1000 inches of water and 20 or more feet fall. I want to put in a saw, etc., to get out my bee-supplies, etc. CALIFORNIA.

ANSWERS.—1. Make grafting-wax of equal parts of bees-wax, tallow and rosin. Possibly in California these proportions ought to be changed on account of the hot sun, but any local nurseryman ought to be able to tell you about it.

2. If you want to know the kind of woman to select for a bee-keeper's wife, I have some good advice on tap, but the matter of over-shot water-wheels is beyond me. Perhaps you will most readily get the information from some one near you who has had some experience in such things.

Honey vs. Sugar for Stimulative Feeding.

Dr. Tinker asserts, in his "Bee-Keeping for Profit," that honey is preferable to sugar syrup for stimulative feeding. Have you perhaps observed in this direction? If so, with what result? Does your experience bear out that of Dr. Tinker?

Anyhow, if syrup is of necessity used, what should be the proportion of water to sugar? Would one of sugar to two of water—by weight—make this feed too thin? And what quantity, and at what intervals, would you advise feeding average colonies?

I fed three or four bags of white sugar last year, with no apparent benefit. It was cheap; and I should not wonder if it were made of glucose. The bees used it up all right, but it certainly had no stimulative effect. Or is sugar of any kind ineffective for the desired purpose? SOUTH AFRICA.

ANSWER.—I can only work around the edges of your question, having never made any direct experiments. Tradition or something else gives the general reply that honey is better to stimulate the queen to lay than sugar. Perhaps a good reason for that lies in the small amount of floating pollen found in honey. Pure sugar is little more than fuel, keeping up the heat and tending to fat and laziness. In my early days of bee-keeping, I had a colony one spring which had neither eggs nor brood at a time when brood was present in other colonies. I don't now remember whether I look for a queen without finding one, or whether I took it for granted that no queen was present because there were no eggs. At any rate I decided it was queenless, and took steps to unite it with another colony. (My present recollection is that both colonies were so weak that it would have been a good thing in any case to unite

them, but at that time I had not yet reached the point where I cared more for numbers of bees than numbers of colonies, and every hive with bees is counted.) I simply put the combs with adhering bees in the hive with the other colony, each colony on its own side of the hive. After perhaps a day or so, the thought came to me that it was possible that no eggs were laid because the bees had no pollen. I hurried to the hive, and was glad to find that as yet the bees had not mixed (the weather was pretty cool) so I lost no time in getting the bees back in their old place. Not a particle of pollen could I find in the cells, so I gave them from another hive a comb containing pollen, and on my next visit I found eggs. All my observations and reading from that time confirm the opinion that bees will rear no brood without pollen. Now if there is not enough pollen floating in honey to start the queen laying in the spring, the case would be still worse with pure sugar with no sign of pollen, so it seems pretty clear that honey is at least a little better than sugar for stimulating.

But here comes in something else. Suppose there is plenty of pollen in the combs. Now feed pure sugar. That will excite the bees, using up their strength and calling for the consumption of pollen to repair the waste of tissue. The question arises whether that may not make them consume all the pollen needed.

As to the interval of feeding, perhaps they should be fed every day, and every day would be at least as well. Perhaps half a pound at a time as a minimum, and no harm could result from any larger amount unless it should result in clogging the combs.

No, I don't believe one pound of sugar to two of water would be too thin, and yet it might not be any better than equal parts.

Some of the German authorities speak in the highest terms of what they call "speculative feeding," that is, feeding in the spring to fill up the combs more or less. Geo. de Layens, one of the highest French authorities, who lately died much lamented, says that no amount or kind of feeding makes much difference about a queen laying outside the proper season for her to do so.

In England I think pea-flour is mixed with candy for feeding to stimulate laying.

Personally, I doubt whether I shall ever again do much to hurry up laying by feeding of any kind, other than to see that a bountiful supply of stores is always present in the hive, and every year I attach more and more importance to this.

How to Distinguish Glucosed Honey.

How can I tell glucose or adulterated honey from the pure? I have tried several tests, but they do not seem to have the desired effects. NEW YORK.

ANSWER.—As yet there is probably no way readily to detect adulteration of honey with glucose by means of ordinary appliances at hand, but if there's much glucose present you can tell pretty well by the taste. It might not be the safest thing however, for a novice to attempt to decide by the taste, for some kinds of honey might taste badly to him, altho perfectly pure.

Some Interesting Questions and Replies.

1. My bees are in 8-frame dovetailed hives. Would my honey crop for next summer be increased or diminished if they were changed to 10-frame hives, with two frames filled with foundation placed in or near the centre by spreading the brood say about May 15, the main honey-flow in July? or would it be better to put two 8-frame hives together and alternate the frames of brood with full sheets of foundation, and when the flow comes remove the top hive and put on the sections?

2. What is the inside width of the 10-frame dovetailed hive?

3. If you were to start anew in the bee-business, would you use the tall section instead of the $4\frac{1}{4} \times 4\frac{1}{4}$?

4. Are cleated separators preferable with the narrow section, to ordinary ones with the slotted sections?

5. Is a frame 11 inches deep as well adapted to comb-honey production as the standard $9\frac{1}{8}$ inch frame?

According to scripture, I haven't asked "a few" yet, but will quit and give some one else a chance. MICHIGAN.

ANSWERS.—1. You've struck one of the hardest questions with which bee-keepers have to grapple, that is, What is best to do with regard to swarming so as to get a big crop? I must confess I don't know, but I'll answer as far as I can your ques-

tion, and possibly give you just the least speck of help. If about May 15 you change to 10-frame hives and give two frames of foundation, your crop will be increased, *providing* those two extra frames induce the bees not to swarm. I very much doubt whether it would have that effect. I doubt whether it would be any different from what it would be if they started out in the first place with 10-frame hives. For I suspect that up to May 15 the bees would have all the room they needed in an 8-frame hive, and just as much as they would use in a 10-frame hive. But if you can get the bees to tell you just when they are going to make preparation for swarming, and give them two or more frames of foundation just before that preparation, you may do something to keep them from swarming. Yes, it may safely be said you will do something in that direction. If you take away enough frames of brood, replacing them with empty frames, they will be pretty certain not to swarm. Possibly, however, to prevent entirely all notion of swarming, it might be necessary in some cases to take all the brood away. And then it would be a problem whether that would practically be any different from letting the bees swarm. At any rate, if you attempt the plan at all, let the change be made just as late as you possibly can without having the bees actually start queen-cells.

Giving two 8-frame stories will be all right, and in some cases alternating the brood with foundation will be all right, but in most cases it will be all wrong. It will be all right if the colony is very strong and the weather keeps warm enough so no brood is chilled. The safe plan will be to do very little spreading of brood at the time of giving the second story. Don't give it till it is needed, or rather don't put brood in it till room is needed. Give the second story below, and don't do any spreading, but when the upper story is full, if the bees don't seem inclined to occupy the lower story, take one frame out of the upper story and put it below, taking this frame not out of the center of the brood-nest, but take one of the side frames, so there shall be no spreading in the upper story. For putting that one frame below will be spreading the brood emphatically.

2. I don't know, but I suppose you can get at it easily. The width of the 8-frame is $12\frac{3}{8}$ inches. If frames are spaced $1\frac{3}{8}$ inches, that makes $2\frac{3}{8}$ inches for two frames, which added to $12\frac{3}{8}$ makes $14\frac{1}{8}$ as the right width for ten frames.

3. I think I'd give both a trial, before deciding. My experience with the tall sections is so limited that I have as yet no intelligent opinion.

3. I don't know. I've never tried the cleated separators, or fence, but hope to give them a trial next season.

5. I don't know. The fact that $9\frac{1}{8}$ is so commonly used rather implies that such is the best depth, and perhaps it is, and yet some prefer the greater depth, among them some of our best men, so it leaves the question still an open one.

Send on your questions. As long as the answers hold out you're entitled to your share.

Rendering Beeswax.

How can I get the beeswax from the honey-comb? This is my first year with bees, therefore I do not know much about them.

BEGINNER.

ANSWER.—There are different ways of getting beeswax out of old combs, but there are some preliminary steps to be taken that should be the same in either case. The cells of old combs contain cocoons left by successive generations of young bees reared in them, and these cocoons act as a sort of sponge in soaking up the wax when it is melted. To prevent this you should get the cocoons soakt as full of water as they will hold, so that they will have no room for any wax. This can be best accomplished by breaking the combs up fine. You can't do this when the combs are warm, but the combs must be cold and brittle. Good weather for that now, so break them up fine, and then put them in water and let them soak perhaps two or three days. If you have them in too cold a place the water will not soak into the cocoons so rapidly, but you mustn't have the water much above blood heat or the wax will melt and defeat your object. After being well soakt you can get out the wax in different ways, one of the easiest being by means of a cook-stove and an old dripping-pan. Tear open one corner of the dripping-pan, put it in the oven of the cook-stove with the door of the oven left open, the split corner of the pan projecting out and something under the corner of the pan on the floor ready to catch the wax as it runs out. Put something in the oven under the inside end of the pan so as to raise it half an inch to an inch, thus allowing the wax to run down hill when it melts. Now put your soakt combs in the dripping-pan, and the heat of the stove will do the rest. It may be a good plan to put a little water in the pan that sits on the floor, so the wax

will more easily come out of the dish. If you melt it over again to form it into a better-shaped cake, be sure not to heat it too much.

Knowing a Laying Worker by Her Looks.

Please tell me how you can tell a laying worker by her looks. On page 806, (1897) W. W. McNeal says a laying worker can be seen and told by her looks, and that anyone who will take the trouble to open his eyes and look cannot fail to pick them out, but I cannot find that he tells anywhere how they look.

S. G.

ANSWER.—I hardly think Mr. McNeal meant you could tell a laying worker by her looks, but that you could tell her by her actions and by the actions of the bees toward her. To be sure he says she has a "soakt" appearance, but he says in the same connection that other bees look the same way. Mr. McNeal is evidently an interested observer, and I hope he will follow up the matter still more closely. I have seen a laying worker in the act of laying, and she had no soakt appearance. Of course I do not say others might not have such appearance, but the question might be raised whether there may be no possible mistake in Mr. McNeal's observations. It is now ascertained that instead of a single laying worker, a good percentage of the workers in the hive are of that sort. I have seen bees surrounding one of those soakt-looking workers, and was at first of the opinion that they might be laying workers, but soon found my mistake. I wish Mr. McNeal would watch closely the next time he has a chance, and see whether it is not the soakt-looking worker that is giving up honey to the bees encircling it.

White vs. Yellow Sweet Clover.

What variety of sweet clover is the best adapted for low land, rather wet for cultivation, and that cannot be under-drained? I want to sow red-top, Alsike and sweet clover. Please don't say you "don't know."

INDIANA.

ANSWER.—Now look here, what kind of fairness is there in asking a question and then shutting a body off from the best answer he can make? The two kinds of sweet clover are the white and yellow, and it seems rather a hard thing to get many to tell much about the yellow. It is said to be earlier, perhaps two weeks earlier, than the white. In places where white clover is plenty, that would probably be a disadvantage, for in a white clover country sweet clover is of no great value till the close of the white clover harvest, and white sweet clover comes plenty early for that. It is reported to be a better yielder than the white sweet clover, but that report comes only from one or two, and sometimes a plant does not act the same in all locations. The yellow seems to be a lower-growing kind than the white.

It would be a matter of benefit if some one who has tried the two kinds side by side, say in New York State, where both grow more or less plentifully, or indeed in any other State, would make a full report as to the comparative merit of the two, and in this there seems to be a chance for you to do the brotherhood a real service by trying the two side by side. But until you have fuller light on the subject you may do well to use mostly the white, for it is probably a settled thing that in your state (Indiana) white sweet clover will succeed well and give good results. Whether the yellow will grow as well, or whether there is any difference whatever as to the growth on the same or different soils, is a thing yet to be learned.

A New Binder for holding a year's numbers of the American Bee Journal, we propose to mail, postpaid, to every subscriber who sends us 20 cents. It is called "The Wood Binder," is patented, and is an entirely new and very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

EDITORIAL COMMENTS

Our Heartfelt Thanks are Due, and are hereby tendered, the many of our readers, who, when renewing their subscriptions for 1898, wrote us such kind words of appreciation of the Bee Journal and its work. Yes, and we want also to thank *all* who so promptly renewed their subscriptions, for by so doing they showed their cordial feeling toward us and for our efforts. Such things are exceedingly encouraging to an overworked editor, and spurs him on to do even more and better work, in the interests of his readers, if that be possible.

We have been greatly rejoiced, too, that so many of our present readers are doing what they can to help increase our list of subscribers. Those who read the Bee Journal regularly are the ones best able to speak of its merits and value, and we trust that every one of our readers will continue in the good work until all who are trying to keep bees may be found among its readers, and thus by reading it weekly learn how best to make a success of their bee-keeping. Surely, an educated bee-keeper is better as a neighbor than one who lacks the information that may be had by reading.

The Honey Market in Chicago.—During the past two or three years it has been our privilege, as well as duty, to help drive out several gangs of honey commission sharks, who were simply robbing honey-producers by getting in the goods and selling at any price, then remitting what was

left after deducting their commission, cartage, etc., or, as in some cases, not remitting anything at all to the shipper.

Having pretty well cleaned this market of such rogues, the past few months the legitimate commission men, as well as some others who are trying to sell pure honey to the retail grocery trade, have had another kind of competition to meet that is very discouraging, to say the least. It is none other than [some bee-keepers themselves, who live within driving distance of Chicago. It seems they have loaded up, and gone with their honey from grocery to grocery, offering it away below the market price—even below a fair living price. It is not only small bee-keepers that have done this, but some large bee-keepers as well.

Now, the question is, What are commission men to do under such circumstances? How can they be expected to hold up prices of comb honey, when a bee-keeper with 10 to 15 tons drives around among the retail grocers, and sells the best white clover comb honey at from 9 to 11 cents per pound? And what are city bottlers of pure honey to do when the same producers offer to hundreds of grocers their extracted honey put up in glass jars practically at cost?

Of course, such things cannot last longer than until the producers' crops are sold, but that is just long enough to fix the price, and when that price has been fixed at a low point, it is not an easy matter to soon raise it again. If it were in a small town, where perhaps not more than half a ton of honey is used in a year, it wouldn't be so bad. But here in Chicago, where over a half hundred carloads are shipped annually, it can readily be seen that a few foolish bee-keepers are not only getting less for their own honey than they might, but they are causing a loss to the thousands of shippers who send in their honey from a distance, and must pay the expense of freight, cartage, commission, etc.

We feel very much like publishing the names of a few of the producers who have come into Chicago the past two or three months, and who have gone up and down the streets, among the retail grocery trade, and have sold their honey away under the prices asked by the reliable honey commission men. But we forbear doing so this time, tho if the thing is repeated another year we may have to name them in cold print. It would seem that a bee-keeper who is bright enough to produce a good crop of honey would also be bright enough to see what a great mistake he is making by doing as we have described, and also the manifest injustice to his fellow bee-keepers.

The 13th Annual Report of the National Bee-Keepers' Union is on our desk. We expect soon to publish the major portion of it in these columns. General Manager Newman says in his opening paragraph "that notwithstanding the more than usual number of appeals to the Union for protection and defense, it has been successful in every completed case, with good prospects for victory in every one." That is good.

During the past year 20 new names have been added to its membership list, making \$20 additional for the treasury. The balance in the treasury shown in the preceding report was \$541.20; in the present one there is a balance of \$327.65, the expenditures during the year being \$233.56. It would seem that with the balance on hand, and at the rate it is being used, it was hardly necessary to call for any dues from the members for 1898, but the call is made for another dollar from each, as per the decision of the General Manager and the Advisory Board.

Shamrock.—Statement having been made in British Bee Journal that the shamrock was not a honey-plant, quite a discussion arose as to what the shamrock is. It seems hard to come to any agreement, the name being applied by different

persons to different plants. The editor starts out by saying that shamrock is "the tiny-leaved wood-sorrel (*Oxalis Acetosella*), bunches of which are worn in the button-hole of patriotic Irishmen on every St. Patrick's day." Then "An Irish Reader" says shamrock bears a yellow, not a white, flower, and is *trifolium minus* *T. major*, preferably the former. Then others mix in the discussion, and besides the plant named, the term shamrock is applied to white clover, white honey-suckle, black medick, *Trifolium procumbens* and *T. filiforme*. The editor finally agrees that every one may select his own shamrock, giving first choice to the Irish.

The New Union Vote for General Manager and Treasurer, with six as a Board of Directors, which was taken in December, resulted as follows, 141 ballots being cast:

FOR GENERAL MANAGER AND TREASURER—Hon. Eugene Secor, 127 votes.

FOR BOARD OF DIRECTORS—Dr. C. C. Miller, 126 votes; C. P. Dadant, 120; Hon. E. Whitcomb, 119; W. Z. Hutchinson, 119; Ernest R. Root, 116; and Rev. E. T. Abbott, 86.

It will be noted that all are re-elections. Mr. P. H. Elwood received 50 votes for the position of Director, he being named by Mr. W. F. Marks, in Gleanings for Dec. 15, the latter gentleman thinking that New York State should be represented in the Board of Directors. We also would have been glad to have urged Mr. Elwood's election through the Bee Journal had the suggestion been made in time. He is an able man as well as a large and practical bee-keeper, and would make a capital member of the Board. Why not let his name stand as a candidate next time?

Sweet Clover.—In the California Cultivator Prof. A. J. Cook is asked several questions about this plant, among them as to whether farmers can afford to let it spread. A part of his reply reads thus:

"I have grown sweet clover for years for bee-feed in Michigan. It is very excellent as a honey-plant. The quality and amount of honey from it is rarely surpassed. I never could get my horses or cows to eat it. I think it is worthless except for bees. I never found it difficult to get rid of it."

Just how Prof. Cook could say of sweet clover that he "thinks it is worthless except for bees," after all we have published in the Bee Journal in its favor as a forage and hay plant, is more than we can understand. It would seem that we have given sufficient from those who have had large experience with it, to establish beyond successful contradiction the value of sweet clover to the farmer aside from its use as a honey-plant. Can it be that Prof. Cook has failed to read what has been published along this line?

Holding the position he does in the estimation of California farmers and others, we don't think Prof. Cook can afford to let it go out that he even "thinks" that sweet clover "is worthless except for bees." We hope he will follow closely the discussion on sweet clover in the report of the Northwestern convention now being published in these columns. Mr. M. M. Baldrige could also give a good many valuable pointers on this subject.

THE BEE-KEEPERS' REVIEW for December came printed on better paper, with a new, neat faced type, and other indications of prosperity. Editor Hutchinson is doing his share toward keeping his paper abreast of the procession.

MR. E. L. CARRINGTON, a queen-breeder in Walton Co., Fla., wrote us Jan. 2, that his wife, Mary Carrington, had passed away Dec. 27, 1897, after a lingering illness of four years. We know from personal letters received from Mr. Carrington the past few years that he has had quite a struggle, and that his wife was a great sufferer. We extend to our bereaved fellow-worker our deepest sympathy in his great loss—a dear wife—Heaven's best gift to man.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., writing us Jan. 4, had this to say:

"Our winter has been quite severe of late; but prior to Christmas it was open and fine weather the most of the time. We have about eight inches of snow, if it could have staid as it fell, but it is piled up in the roads and behind fences on account of the many high winds we have had. The mercury touched 7° below zero last night, but it is warming up now under a strong south wind which is keeping the air full of whirling snow."

MR. DAVID N. RITCHEY, of Franklin Co., Ohio, writing us Jan. 5, said:

"I have been confined to my bed for eight weeks, with erysipelas, but am getting better slowly. I have not been able to perform any work since I came back from Buffalo."

Eight weeks is a long time to be laid up, and especially for so naturally active a man as Mr. Ritchey. We shall not soon forget the lively part he took at the Buffalo convention, especially in the singing. It did us good to see how he really enjoyed the musical part of the meeting. We trust Mr. R. may soon be fully recovered, for he's too valuable a man to be laid on his back.

HON. J. M. HANBAUGH, our Illinois friend who removed to Southern California about two years ago, has met with sore affliction in the loss of his little boy, who died the day before Christmas. Mr. G. F. Merriam, a neighbor bee-keeper, wrote us as follows about it, on Christmas Day:

"This is a very sad Christmas for our friend, J. M. Hambaugh and family, for their youngest child, a very bright and promising boy of 4 years, lies dead at their home down the valley. He died yesterday forenoon, of pneumonia, being sick only 3 or 4 days. We go to-morrow to the funeral, and all his neighbors will go to testify their warmest sympathy for the family in their affliction."

Surely, Mr. Hambaugh has the heartfelt sympathy of his thousands of friends in this great bereavement that has come to him. Many of us know just how sad his heart is, for have we not passed through a similar sorrow? But the thought that some sweet day there'll be a reunion of separated hearts, brings cheer and comfort to the sorrowing.

EDITOR E. R. ROOT, of Gleanings, some thought at the Buffalo convention resembled another member of that meeting, Mr. D. W. Heise, of Canada, or *vice versa*. After referring to this, and the comment we made thereon in these columns some time ago, Editor Root says this in Gleanings for Dec. 15:

"By the way, this is not the only instance of mistaken identity at the Buffalo convention. Two men, of about the same size and height, who attended, looked decidedly alike; when the two sat near each other it was almost impossible to tell which from the other. One was a quiet, genial, pleasant man; the other was always bobbing to his feet, and making himself notoriously disagreeable—always throwing out objections, and never harmonizing with the discussion. I said to the first-mentioned person, after I had learned to distinguish one from the other, 'Why, you look almost exactly like——'

"I am not flattered," said he. "I have no sympathy with his ways of doing. Such men are always a bore to a convention, and a drag to good discussion."

Yes, and we were also remarking about the resemblance to that "quiet, genial, pleasant man," when he said he felt like going home long before the convention closed, as soon as he learned that he was being mistaken for the one "making himself notoriously disagreeable." And we didn't blame the first gentleman for wanting to get as far away as he could from his disagreeable "double." Perhaps it was kind for the convention to endure as much as it did from the disturber, but it certainly was not *just* to those who had come a long way to listen to helpful discussions. We hope that hereafter there may be no more disturbing elements present.

Coffee-Grounds for Smoke are recommended by a German bee-keeper as better than tobacco, because producing more smoke and not stupefying the bees.

Receptacles for Wax, according to a writer in the British Bee Journal, should be of earthenware, as iron, tin and copper have a bad effect on the color of the wax.

Bee-Keeping on Shares.—A. Weathelet, of Rucher Belge, has three out-apiaries in care of bee-keepers who receive one-fifth of the harvest. That would be considered rather a small share in this country.

Box-Hives for Wintering.—Le Rucher Belge says a movable-frame needs 33 to 40 pounds of stores for winter, and a fixt hive 22 to 26 pounds. If that is true it must be that box-hives are about 50 per cent. better than frame hives for wintering in Belgium.

Bees for Cheaper Work.—On the Island of Ceylon, formerly the flowers of vanilla were artificially fertilized by the hand of man. After bees were introduced this was no longer necessary, and the price of the product fell to a lower point.—Mrs. Wilma Bumler, in *Bienen-Vater*.

Save the Fragments.—*Bienen-Vater* advises that before throwing away the accumulation of dead bees and gnawings found on the floor of the hive in winter and early spring, the whole should be past through a coarse sieve to save the little particles of wax. German thrift sometimes goes a good ways, but it might be a good thing to have enough of it to temper our American wastefulness.

Introducing a Queen, by Doolittle's plan, putting her in a cage made of foundation, M. von Rauschenfels says is an entire success with him, and he does not even care to open the hive afterward to see if the queen has been received. The plan has had little success in Europe, he says, because the trouble was not taken to make two or three little holes in one end of the cage so the queen could be fed.

Free Hive-Entrances.—Thaddeus Smith relates in *Gleanings* that 55 years ago his father had hives set on flat stones, the hive being raised $\frac{3}{4}$ of an inch all around by nails at the four corners. These hives were left thus summer and winter, and he thinks there was never too much ventilation. Many of these hives remained 8 to 10 years thus without change, and there never was any loss in wintering unless stores ran short.

Split Sections.—While on this side the new-old no-bee-way section is having the floor, in England quite a stir is being made over something that has been in limited use ten years or more, the split section. Some split the whole section in two, then put the sheet of foundation between the two parts and then bring them together. Others have only the top and two sides split. When sections were first used in this country, a saw kerf was made part way through the top-bar of the section to receive the foundation.

Paraffine Paper Over Sections.—Some discussion has been taking place in *Gleanings* with regard to the benefit of paraffine paper over sections for the purpose of preventing the bees from daubing propolis on the sections. It seems that Mr. Danzenbaker claimed great advantage for its use, and took out a patent thereon, the understanding being that bees were averse to touching paraffine. F. L. Thompson, in the *American Bee Journal* and elsewhere, reported adversely, and Dr. Miller said in *Gleanings* that his bees did not hesitate to put bee-glue directly on the paraffine surface, admitting, however, that he had not followed instructions to weight down the paper with some sort of packing. E. R. Root insists that instructions should be followed, but admits that they did not achieve a glittering success when using "a super that Mr. Danzenbaker had prepared as just right." In Dec. 15 *Gleanings* Lee L. Esenhower takes middle ground; thinks the

paraffine paper effective not because of the character of the paraffine, but because it covers the sections air-tight; while in the same number S. D. Matthews is enthusiastic in praise, claiming a saving of several dollars in cleaning sections, and a higher price for the honey.

Beating Unfair Discrimination.—In Belgium, a tax on sugar makes it expensive for winter feeding. The law allows a rebate on sugar not directly consumed, but used in making confections, etc. Bee-keepers applied for same rebate on sugar used for feeding, but were refused. Le Rucher Belge now proposes to have a manufacturer of conserves make a syrup of prunes, 80 per cent. sugar, call it "syrup apicole," eat the prunes and feed the syrup to the bees, thus getting advantage of the cheap rate.

Keeping Queens Over Winter.—Doolittle relates in *Gleanings* that after trying somewhat faithfully in several ways he has never made a great success of keeping queens over winter except a single queen in a tolerably strong colony. With what is called a 4-frame nucleus he could sometimes succeed in getting queen and bees through to the harvest. Oftener they would waste away in late April or early May till they die entirely or were robbed. He could keep several queens caged all right till about February, when they would get uneasy and die with diarrhea, or the cluster would move to get at fresh honey and leave the caged queens to their fate. Then he tried nucleus boxes with frames 6 to 7 inches square, putting several over a strong colony in the cellar and tucking them up warm with blankets over them, but it ruined the strong colony, and out of 30 nuclei he only got through two queens. So he gives it up for a bad job and appeals almost pathetically for any little help that any one can give toward solving the problem.

Production of Wax.—Reidenbach thinks he has determined that wax is produced from pollen in the large intestine of the bee. In his opinion, honey serves only to keep up heat during its production, making only a small amount of honey necessary for wax-production during warm weather. Careful analysis of the contents of the large intestine fixt him in his decision. He thinks more wax might be secured without loss of honey if the bees always had opportunity for building, as in the super, and in late summer in warm weather toward the outside of the brood-nest. In a time of dearth, in very hot weather, he took from a strong colony half its combs, they being densely covered with bees. In place of the removed combs he gave frames with starters. The bees began lively to gather pollen, and in eight days had built a half-pound of beautiful comb, with no loss of honey. Having enough of the old combs for brood, the queen did not occupy the new combs. At the same time the other colonies lay idle.—Pfaelzer *Bienenzucht*.

The New Section and Fence.—Dr. C. C. Miller discusses these in *Gleanings*, not entirely agreeing with the editor as to their merits. The former raises some doubt as to the fence separator being cheaper in the long run, not quite seeing the force of the argument that the fence is cheaper because used year after year, while the plain separator is thrown away after one year's using. For he says that the plain separator can also be used year after year, only it's cheaper to buy new. He indulges in a sly dig at the editor's preference for section-holders over T supers, saying that while certain advantages claimed for the fence don't count for the T super, they do count for the section-holder, so the fence is a good thing for those who have nothing better than the section-holder.

The Doctor is hardly ready to admit that the new section will be more free from pop-holes in the corners, for on examining sections produced in a Danzy super with fence on one side of the sections, he found the pop-holes were worse than the common section with plain separators. The editor replies that observation has been the reverse.

Dr. Miller admits the saving in shipping-cases, and figures it down fine, making the saving \$5.60 on 4,800 sections, which \$5.60 will go a long ways toward paying the \$1.00 per 100 for the fence. He also thinks there will be an advantage in the new section from the fact that when standing on a table one section cannot possibly be pushed into another, as may be the case if the sections have the usual inset. He thinks grocers may be inclined to use cuss words when trying to get the first section out of a case when the sections fit so tight together that there is no room to get the thumb-nail between them. To this the editor replies that all shipping-cases should be supplied with a follower and wedge, both for safety in shipping and for convenience in taking different sizes of sections.

GENERAL ITEMS

Notes from Western Iowa.

This section of the country enjoyed a very warm, dry autumn up to Thanksgiving Day, and since then we have had solid winter weather. To-day there is five or six inches of snow, and still snowing. Bees went into winter quarters in good condition, with plenty of stores.

I found the 10-frame hives very little heavier than the 8-frame ones, tho the 10-frame hives seemed to have the most bees. The yellower the bees, the heavier the brood-chamber, with me. I find the strong, cross colonies of hybrids very hard to get into the cellar, where one leaves the bottom-board off. I have carried them and set them carefully close to the cellar door, loosened the hive from the bottom, and let it set two or three hours, then carefully lift off the bottom without any jar whatever, and still they would roll out all the way down cellar and till the cellar was darkened. But they generally came out strong in the spring. I suspect a hundred or two make a pretty big show in the air, but are not enough to weaken the colony to any harmful extent.

I shall respectfully beg leave to use the 8-frame hives unless future experience differs from the past in regard to swarming, in which I could see no difference. The 8-frame size is heavy enough for me when it comes to stacking them up in the cellar.

I find the "home market" has its off years, as well as everything else. Two or three years ago I was wishing for honey to sell at 18 and 20 cents per pound, but now the home market is 10 cents, and nobody wants honey, either. If I should have pushed all my crop on the home market, in addition to what was already bound to sell there, it would have been less than 10 cents.

Bee-keepers are the only class I know of who are always urging others into their business. I have noticed those who are always booming the bee-business as the best paying thing on earth, always have something to sell to the prospective beginner. I have the same motive in not wanting so many to go in. So you see I don't claim to be "holier than thou." Let bee-keepers beware lest in inducing their neighbors to keep bees, and educating them in the business, they destroy their own. "He that provides not for his own is worse than an infidel." E. S. MILES.

Crawford Co., Iowa, Dec. 3.

A Beginner's Experience with Bees.

I think I saw a little instance of late which I have not seen explained in the valuable Bee Journal—valuable because I would not sell the information I have obtained through its columns, since I subscribed for it in September, for four times the subscription price.

Bees will go a long way to sting me when a good chance is open, but I am such a lover of honey that I always thought if I ever got a chance to catch a swarm I would try it, and May 16 I got the chance, and with the aid of a visitor (an old bee-man) a box was made and the bees successfully gathered in. They staid and worked, of course. As I then had a colony of my own, I got bee-crazy at once, and closely eyed every paper and askt every man where I saw a bee-hive, for information.

Being unusually busy the past summer, I did not disturb the bees until in August, when I got a hive with instructions to get my bees into it; as it had movable frames, I could examine them at will. I came home, got ready, and the next morning I went at it.

I gave up smoking before I had the habit fairly learned, but of course it was all right to do anything to help the bees! So I hunted up an old keepsake pipe and home-

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipmt with best machinery, all combine to enable this firm to furnish the

That Queen-Clipping Device Free!

PLEASE READ THIS OFFER TO PRESENT SUBSCRIBERS:

Send us just one new name for the American Bee Journal a year (with \$1.00), and we will mail you the Queen-Clipping Device FREE of charge. Or, the Queen-Clipping Device will be sent postpaid for 30 cts. But why not get it as a Premium by the above offer? You can't earn 30 cts. any easier. Almost every bee-keeper will want this Device.

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

spun tobacco (as I had no other), and put in a full day with the bees. One might think it strange that I could occupy all of the time between sunrise and sunset at that time of the year, but if any one doubts my statement, just let them make it known and I will explain.

But thinking of the old adage, "A faint heart," etc., I stuck to the bees, and we stuck together, and I have them yet; and as the desired information in regard to wintering is given in the Bee Journal of Nov. 25, I feel confident that they will be with me in the spring.

Nov. 24 I had occasion to call on a neighbor who was fortunate enough to get a colony last spring; they swarmed, so that he had three colonies in the fall. During a conversation with him he spoke of his bees, and asked me to go and look at them. On approaching the first hive he said, "This is the strongest; it has the bottom full, and has stored some honey besides."

Upon removing the cover, I said, "No live bees in that hive."

He replied, "Yes, it is nearly full." The super was removed, and the frames taken out one by one, until all were out—10 in all (Langstroth, I think) and examined. Each frame had a full comb, and some honey on each side, in spots varying in size from about one to three inches in diameter, all near the top of the frame, the other parts being eaten out. There was a small bunch of dead bees in the top of the frames near the front of the hive, but not a live bee to be found. The hive was a new one, and apparently clean otherwise. The hive entrance was open the full width. The man said he looked at them about two weeks before, and they were all right. Were they robbed before it became cold, or what was the trouble? SUBSCRIBER.

Dane Co., Wis., Nov. 29, 1897.

Superseded Queen—Good Season.

In regard to the colony of bees I wrote about on page 809, having lost their queen, the weather turned warm here today and gave me a chance to examine the hive, and I found it contained a beautiful queen and a strong colony of bees, with plenty of winter stores. It seems to me now that the old queen died of old age, and the bees, seeing her condition, superseded her some time ago. This is another proof that two queens can exist in the same department of a hive at the same time, under certain conditions.

The past season was good in this locality, principally white clover, of which I never saw so much. My colonies yielded a surplus of 136 pounds per colony, all white clover extracted honey.

I have only a small apiary, situated at my home in Kentucky, a suburb of Cincinnati. I keep bees for pleasure only, still they yield a nice little sum every year, which pays me for any little trouble I may be put to in attending to them. Extracted honey sells at 15 cents per pound here, and I don't have to go out of the house to sell it either. J. N. LADENBURGER.

Newport Co., Ky., Dec. 8, 1897.

Appreciated All Around.

DEAR SIR AND PUBLISHER:—Please find enclosed money order for \$1.00 (the price received for 10 pounds of nice honey sold) to renew my subscription for 1898. I see many write that they can't get along without the "Old Reliable." Now I could get along, but I don't intend to so long as I can trade the surplus labor of one colony of bees for 24 hours for 12 months' reading of the Bee Journal—52 copies of the American Bee Journal for one day's surplus, and a fine premium thrown in! Who of the many thousands in this "Grand Old Union of States," that have a few colonies of bees, would not be glad to give twice 10 pounds of their best honey to some old, practical bee-master, for a half hour's visit every Friday afternoon; who would go out somewhere among the bees with you, sit down and tell of his travels, experience, discov-

The Bee-Keepers' REVIEW

Closes Its Tenth Year With Substantial Improvements.

Increase in Size.

Beginning with the Dec. No., eight more pages are added; making thirty-six in all.

Better Paper.

Heavy, white, sized and super-calendered paper is used in printing the Dec. No., and its use will be continued.

New Type.

The Dec. No. is printed with large, clear, *new* type of that beautiful style called the Ronaldson.

A Beautiful Cover.

The cover is of extra heavy, smooth, cream-colored Paradox, printed in that warmest and richest of all colors—claret.

A Fine Frontispiece.

As a frontispiece, printed on 80-lb., Ivory Enamelled paper, is a half-tone, made from a photograph, of a comb badly infected with foul brood. A more perfect picture of such a comb has never been made. In short, the Review will now compare favorably with the high-class magazines, as regards typographical neatness and beauty. As to the value of the information that it contains, here is a partial list of

CONTENTS FOR DECEMBER.

Foul Brood.

Many descriptions of foul brood have been given, but none the equal for detail, exactness and clearness, of that given by Mr. R. L. Taylor in the Dec. Review. With this description, aided by the accompanying engraving above mentioned, no one need fail in positively identifying foul brood. Not only this, but Mr. Taylor also gives plain, simple and *exact* methods for getting rid of the disease.

The Plain Section.

Mr. L. A. Aspinwall has used this style of section for several seasons, and in the Dec. Review he enumerates its many advantages, and illustrates and describes the style of super and separator with which he uses it. He also illustrates a simple machine for cleaning propolis from sections of this style, nearly as rapidly as they can be handled.

First Premium Wax.

The finest wax, that of a clear, pearly, "dandelion yellow," wax that for two years in succession took first premium at the Wis. State Fair, was made by Edward Ochsner, and in the Dec. Review he tells exactly how it was rendered.

Shipping Comb Honey.

The bee-keepers who never have cause to mourn the loss of honey broken in shipment, would be more plentiful if all could read in the Dec. Review of the simple yet novel method employed by J. E. Crane to prevent the trucking and "dumping" of heavy crates of honey.

But there is not room to tell more; better send \$1.00 for the Review for 1898, and receive the Dec. No. free; or, if you prefer to see that issue before subscribing,

Send Ten Cents,

In silver or stamps (either U. S. or Canadian), and the Dec. No. will be sent you, and with it will be sent two or three other back numbers. This will give you a fair idea of the Review, and, if you should then wish to subscribe, the ten cents that you have paid may apply on the subscription. A coupon will be sent entitling you to the Review one year for 90 cents, if sent in during 1898.

W. Z. Hutchinson, Flint, Mich.

eries and mistakes in beedom, and what he had learned and read since his visit the week before, and answer any question you askt about bees—and just as he arose to go tell you where to get the best supplies cheapest, buy the best queens, and the price of honey in the several markets; then along in January, when there was little to do, come for a week's chat, board himself, and tell where you had made several mistakes, so you would be posted next time and avoid them; answer all the questions you askt him about bees you could think of, and many you would never think of?

I think the old man would be as popular as Santa Claus, and go away loaded about as heavily as some of our bees are loaded during white clover bloom.

Well, here's the "Old Reliable," ready to do all this, and more, for just one day's surplus from one good colony of bees. Let him in, cranks, and give him the 10 pounds of honey, and then write to him once in awhile, between his weekly visits, and tell him that you appreciate him and learned very much from his last visit. It will encourage him to greater effort to instruct you. And, above all, don't forget the 10 pounds of honey; pay him his just due in advance—he needs it to limber up his tongue and smooth his voice.

So opines an old soldier of '61.

CYRENE E. MORRIS.

Carroll Co., Iowa, Nov. 28, 1897.

Bee-Keeping in Virginia.

I have now 18 colonies of bees, and most of them will winter all right, but I have eight that I have given about 40 pounds of white sugar syrup. I mean 40 pounds of sugar dissolved in boiling syrup. I think they will stand it all right if the winter is not too hard. I had eight old colonies in the spring, and I saved 15 swarms, 13 in May and two the first of June. Some few went away. I thought I was going to get a fine lot of honey, but about the time they stopt swarming the dry spell set in, which lasted about 10 weeks, and the pastures all dried up; then when it rained it was a cold rain, and the weather continued cool some days, so the fall flowers were a complete failure, and I lost three of my last swarms by starvation before I knew anything of it. I thought, of course, that as long as the weather kept open they could get a living, but I found it not so. I also lost two colonies by what we call the "web worm." I have had bees for the last 18 years, and I have been bothered more this year with the worms than all the rest of the time. I use the Langstroth 10-frame hives, and always change my bees from one hive to another in early spring, so as to clean the hives of all filth. This part of the world is very flat; I have the James river on the southwest of me, and there is but little open land, and no such thing as pasture fields. Some few little truck farms are northeast of me, and the woods that are real near me on the east are almost all native pine and oak trees.

GEO. C. ELLIS.

Warwick Co., Va., Nov. 15.

Bees Killing Each Other.

There appears a strange article on page 663, which I wrote to a queen-breeder, yet it is true. In about 40 days after Italianizing one colony, they commenced war between the reds and blacks. It took the red bees two days to kill them off to the last bee. There were plenty of each race for a strong colony, but the blacks didn't show any fight at all, but seemed willing to be superseded. After that they got to killing their own bees, and as I said before, it was not a case of robbing, as some would think, as there were no yellow bees in this settlement except mine. I had Italianized other colonies, but their yellow bees were too young to work.

I might be mistaken about the super controlling the fighting, and I might have been mistaken in there being too many bees. I was transferring at that time to movable

frame hives, and the red bees would sneak into the black colonies and get some honey. If there is such a thing as bees scenting each other, it is just possible they lost their scent by being in the black colonies too long, or got the scent of the black bees on them. The red bees seemed to be heavily loaded when they returned home, but when they alighted their red sisters would begin to nibble on them, and in a very short time they would sting them.

Some one says I was mistaken; that they were red bees from somewhere robbing mine. No, indeed. Some one says they were diseased. I think not. I never knew but one bee-disease in these cold mountains; it is a bad one, too—starvation. Very likely some of the old bee-keepers are acquainted with it. It is very bad on late swarms and old colonies that have swarmed too often, if not in the right man's hands, for we have no fall honey in this locality.

The fighting bees are in good condition, and very strong, and as healthy as I ever had. When I finish transferring, I thought I had advanced a little in bee-culture. Blount Co., Tenn. G. W. WILCOX.

Several Notes and Comments.

I brought my 16 colonies out of the cellar on March 28. They were in good condition except two. I had the first two swarms on June 11, and the last one on July 24, a second swarm from a prime swarm. I doubled up some and some did it themselves, so I had 42 colonies, but one that had swarmed three times and one twice, were queenless. I took off over 500 pounds of comb honey, and have sold 350 pounds for 10 and 11 cents.

The bees had a good play Nov. 20, and on the 23rd I opened the cellar window, and they went through into the cellar. I hived three swarms without any covering, not one bee stinging me, and I don't care if I have half a dozen, it is just as if a mosquito bit me; it swells but little on the fleshy places. Not any of my swarms escaped, even if I don't use propolis.

When my hives are ready I put them into the cellar, so they are cool when the bees swarm. Then I wet old carpet and put it over the cover. There was something new to me this summer. When I hived my first second-swarm, about six bees with a queen came out of the hive; after this there came bees out of the entrance, which were stung.

Does selling comb honey by the section mean for one pound, even if it doesn't weigh it? If so, that isn't right.

In Appleton, 13 miles from here, a farmer's wife sold eight full sections of comb honey for 50 cents to a consumer. It is good that not all farmers are fit for bee-keeping.

When I took honey from one hive last summer, in wide frames, holding eight sections, I renewed them with starters, but took three frames out and put three in where it was already worked in the sections. It commenced to get dark, so I held the frames before the entrance, some bees crawled off and "called" at the entrance, but the rest came to the other end, which I held in my hand. I put a stick under that end, and left them over night; early in the morning they were there yet. That brought me to the conclusion that bees can't hear.

The American Bee Journal is what it claims to be on the first page: "Devoted," etc. That is why I like it.

WM. DUESCHER.

Brown Co., Wis., Dec. 14, 1897.

Bees and Horticulture, Etc.

Some of the late numbers of the American Bee Journal are worth the whole subscription price. I was especially pleased with Mr. Taylor's paper on "The Relation of Bees to Horticulture," on page 757. I have handed it to the editor of the Farm and Orchard, at Las Cruces, and it will appear in that paper soon. There has been considerable complaint around here that bees injure or damage the grapes, some even thinking that the bees injure fruit by

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. **R. B. Leahy** and **G. M. Doolittle**, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Somnambulist**. "Experience and Its Lessons," by **R. C. Aikin**. This series of articles will be reviewed by Mr. Doolittle, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The somnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. **Dr. C. C. Miller** and other popular writers also contribute to its columns. The PROGRESSIVE is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the PROGRESSIVE BEE-KEEPER is but 50c. The PROGRESSIVE and that "one only" book for beginners, the **Amateur Bee-Keeper**, by **Prof. J. W. Rouse**, both for 65c. A sample copy of the PROGRESSIVE for your name, and a beautiful, illustrated catalog of apiarian supplies for the asking. Address,

LEAHY MFG. CO., Higginville, Mo.

taking the nectar from the blossom. It is very hard to convince this class of people that they are wrong, especially for a bee-keeper. They think he is prompted by self-interest, and a desire for gain at their expense.

If all the charges which I have heard brought against bees were true, I would quit the business quick. It would not suit me. I am not built that way. I believe the same would be true of a large majority of the bee-keepers.

Mr. Golden's method of controlling increase and producing comb honey is the most valuable method of management that has been advanced in 10 years. So I think, tho I practice the plan a little differently from the way which he gives. I believe I have improved on it, at least for this locality, or anywhere where bees are greatly inclined to swarm, and seem stubborn when returned. I believe the Golden plan, or some other that is practically the same, that is, some modification of it to suit conditions in different localities, is sure to come into general use.

I have practiced the plan given on page 708, by "Sage Brush," for getting colonies supplied with worker-comb without the use of foundation. I consider it much better than giving full sheets of foundation.

I have most of my combs built in nuclei, one at a time, according to Mr. Doolittle's plan, and they are perfect. It is very seldom that I put in a full sheet of foundation.
W. C. GATHRIGHT.

In the multitude of counsellors there is safety.—Prov. 11-14.

Cutting Out Drone-Comb—Are Drones of Value in a Hive?

Query 66.—1. Do you practice cutting out all drone-comb from your colonies?
 2. Don't you think that some drones stimulate a colony, and by their extra heat are a benefit to a colony in a cold, backward spring?
 —NEW ENGLAND.

- E. France—1. Most of it. 2. No.
- Mrs. L. Harrison—1. No. 2. I do.
- Eugene Secor—1. No. 2. It may be, but I am not sure.
- R. L. Taylor—1. No. 2. I would prefer workers to the drones.
- Prof. A. J. Cook—1. Very nearly. 2. I prefer workers to drones.
- G. M. Doolittle—1. I allow 4 to 6 square inches of drone-comb to each hive. 2. Theoretically, yes; practically, no.
- Jas. A. Stone—1. I do not. 2. I cannot say as to that. Their presence would certainly be a help in keeping up the heat in the hive.
- C. H. Dibbern—1. I cut out all the drone-comb but a very little. 2. Yes, in early spring I like to have a few drones in every colony, as it seems to give them life and energy.
- W. G. Larrabee—1. No, but I have very little drone-comb, as I use full sheets of foundation in the broad-frames. 2. I would rather have the same number of workers.

Dr. C. C. Miller—1. Yes, if I've time. 2. I never saw any excitement caused

Cupid's Dart Puzzle —The LOVER'S DELIGHT.

Cupid's Dart sped through space,
 Aimed with much precision;
 Its target—in a conspicuous place—
 Was pierced beyond recognition.
 Cupid at once withdrew the arrow,
 Fearful of the result of his aim,
 But the work was done—the escape narrow—
 Perhaps you can do the same.
 The most interesting puzzle for sweethearts out. Sent on receipt of 10 cents, postage prepaid. **GINDER & BOTTOME,**
 1A2t St. Paul Building, New York.

Cash PAID FOR Beeswax

For all the **Good, Pure Yellow Beeswax** delivered to our office till further notice, we will pay 25 cents per pound, **CASH**; or 27 cents for whatever part is exchanged for the Bee Journal, Honey, Books or Seed, that we offer. If you want **cash, promptly**, for your Beeswax, send it on at once. Impure wax not taken at any price. Address as follows, very plainly,

GEO. W. YORK & CO.
 118 Michigan st., CHICAGO, ILL.

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

See the premium offers on page 11!

by drones except when the workers were killing them off. A pound or pint of workers would make as much heat as the same quantity of drones, and where can you get drones in a cold, backward spring?

J. M. Hambaugh—1. I do when not too shiftless. 2. There will always be sufficient drones for practical purposes. I am not sure they could be of any use in the manner mentioned.

Dr. J. P. H. Brown—1. My rule is to cut out all drone-comb, but there will always be more or less drone-cells formed around the margin for their development. 2. I agree with you.

Emerson T. Abbott—1. No. 2. In a "cold, backward" spring there would not be any drones, in all probability. They may be some benefit, and they may not. I am free to confess I don't know.

Wm. McEvoy—1. No. I shnt out all the drone-comb by filling the frames full of foundation. 2. No. As a rule, when the colonies have some drones reared they are pretty strong in worker-bees, and don't need the heat of the drones.

A. F. Brown—1. To a certain extent nearly all colonies will manage, notwithstanding the best of care by the apiarist to the contrary, to have a few square inches of drone-comb somewhere on the frames. 2. A few drones in a hive do no harm, in my estimation.

J. A. Green—1. I used to, and would prefer to do this now, but most of my colonies have not had a brood-frame removed in two years or more. 2. You cannot keep all drones out without extraordinary care. Workers are just as warm as drones, and a lot more useful otherwise.

Chas. Dadant & Son—1. Yes, and replace it with worker-comb as much as possible. 2. No, No, NO. You will always have more drone than you need if you cut out drone-comb ever so carefully. As to the heat, we would rather have that of the workers reared in the same space.

Rev. M. Mahin—1. I do not. 2. I am not able to give an authoritative answer. I have had very prosperous colonies that had large numbers of drones, but if nearly all of the drones had been workers, I think they would have been more so. I think it wise to restrict, but not to suppress the drones.

J. E. Pond—1. I do not. 2. I think Nature provides the rule, and attempts to follow it, by allowing a small amount of drone-comb in the brood-chamber. I do not, however, think that any extra heat produced by drones amounts to anything of value, my idea being that a colony should contain some drone-comb in order to be normal.

G. W. Demaree—1. I have quit doing so much work with the bees. If I find a surplus of drone-comb in a hive I remove it, giving worker-comb in its place. The work is done at such times as gives the least fuss and labor. 2. A reasonable number of drones in a hive is a natural and normal condition in their season. I have had colonies do well with large numbers of drones, and do equally well with few or no drones.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Dec. 13.—Fancy white 11 to 12c. No. 1, 10c.; fancy amber, 8 to 9c.; No. 1, 7c.; fancy dark, 7c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c. The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special change. Beeswax is scarce.

Milwaukee, Wis., Dec. 13.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 9 to 10c.; fancy dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 4¼ to 5c. Beeswax, 25 to 27c.

This market has been fairly sustained on honey since our last report. Values remain about the same, as there has been a very good consumptive demand, especially for extracted, while the comb honey has seemed to accumulate with increased receipts, and we feel to meet the demand even if at a reduction from quotations. There seems to be more demand from those who eat honey than in former seasons, which is a good feature of the trade which we desire to encourage. We are expecting a good trade from this forward.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 23c.

New York, N. Y., Dec. 22.—Fancy white 11 to 11½c.; off grades, 9 to 10c.; buckwheat and mixt, 6¼ to 7c. Extracted, California white, 5 to 5½c.; light amber, 4¼ to 4½c.; white clover and basswood, 5 to 5½c.; buckwheat, 4 to 4½c.; Southern, 50c. a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of buckwheat, mixt, and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Dec. 15.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 10c.; No. 1, 9½c.; fancy dark, 9 to 9½c.; No. 1, 8 to 9c. Extracted, white, 5 to 6c.; amber, 4 to 4½c.; dark, 4c. Beeswax, 23c.

Market holds firm at above prices. Good demand for extracted. Wax is quiet but firm at 23c.

Kansas City, Mo., Dec. 15.—Fancy white, 10½ to 11c.; No. 1, 10 to 10½c.; fancy amber, 9½ to 10c.; No. 1, 9 to 9½c.; fancy dark, 8½ to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

St. Louis, Mo., Dec. 13.—Fancy white, 12 to 12½c.; No. 1, 10½ to 11½c.; fancy amber, 9½ to 10c.; No. 1, 9c.; fancy dark, 8c. Extracted, white, 5 to 5½c.; amber, 4 to 4½c.; dark, 3½ to 4c. Beeswax, 24½ to 25c.

We would advise prompt shipments of honey. We do not see any probabilities of better prices. The stock of honey is ample for the demand.

Albany, N. Y., Dec. 13.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 8 to 9c.; No. 1, 8c.; fancy dark, 8c.; No. 1, 7½ to 8c. Extracted, white, 5 to 6c.; amber, 4½ to 5c. dark, 4 to 4½c.

There is an ample stock of comb on hand and selling freely at quotations. Extracted is not plentiful and from information received there is not much in the hands of producers.

Buffalo, N. Y., Dec. 24.—Strictly fancy 1-pound comb honey is more active at mostly 10c., occasionally 11c., but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c. down to 6c. Extracted is moving slowly at 5 to 6c. for fancy; dark, 4 to 4½c. A liberal quantity can be sold; and, of course, the low grades can be forced off for what they will bring, if owners cannot do any better.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

Philadelphia, Pa., Nov. 13.—Fancy white, 13 to 14c.; No. 1, 12c.; fancy amber, 10c.; No. 1, 9c.; No. 1 dark, 8c. Extracted, white, 5 to 5½c.; amber, 5c.; dark, 4 to 4½c. Beeswax, 27c.

Honey is arriving very freely; market is a little off. Beeswax is in good demand.

Boston, Mass., Nov. 8.—Fancy white, in cartons, 13c.; No. 1, 11 to 12c.; fancy amber, 10c. Extracted, white, 6 to 7c.; amber, 5 to 5½c. Beeswax, 28c.

No. 1 and fancy honey has sold well during the past 10 days, but off grades and light weight is going slowly. Beeswax is in good demand and but little here.

Detroit, Mich., Nov. 9.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c.; fancy dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c. Beeswax, 25 to 26c.

Indianapolis, Ind., Nov. 8.—Fancy white, 11 to 13c.; No. 1, 9 to 10c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25c. Demand for fancy white comb honey and fancy white extracted is exceptionally good, while there is almost no demand for dark or amber comb or extracted honey.

Cincinnati, Ohio, Jan. 8.—There is no change in prices, but rather a slow demand for all kinds of honey. We quote 10 to 13c. as the range of prices for best white comb honey, and 3½ to 6c., for extracted, according to quality. Beeswax is in fair demand at 20 to 25c. for good to choice yellow. Cincinnati is no place for dark comb honey.

CONTRIBUTED ARTICLES

The "Golden" Section-Honey Cleaner.

BY J. A. GOLDEN.

I herewith present a picture of the greatest labor-saving piece of machinery for bee-keepers that has ever been shown to the fraternity. Every man, woman and child that knows anything about preparing section honey in first-class style for the markets, knows that scraping sections is a tedious kind of work, or at least that is my version of the matter; and when I got ready to dress my crop of nice, white clover honey of 1897, it really made me tired to think about it. I wasn't able to hire, and of course I was feeling pretty badly about having all that unpleasant work to do. When I retired I couldn't sleep, and as I was tossing about, my good wife wanted to know if I were sick, or whether I had the fidgets. I said I had the fidgets, I guess, and the result of that wakeful night brought to light a section-cleaner—just what you see in the picture.

Having an old sewing-machine table, I nailed some boards together and cut out a wheel, which is 36 inches in circumference, and has a 4-inch face. I attach it on the old table, covered the face of this wheel with medium-fine sand-paper, by gluing it on, and arranging a cover so that the face of the wheel protruded from $1/16$ to $1/4$ inch, as shown by the picture, where Flora is in the act of passing a section over the wheel. (Just as I was ready to take the view, Flora turned her head and said, "Tell Mr. York that I am just pretending to clean this section"—when I toucht the button and caught her and her smile.)

It will be observed that there is plenty of room for a full super of sections to be placed on the table at a time.

Now as to how the machine works. Well, it was just fun to clean sections with it, and so clean and bright that no one could tell by looking at them afterwards, that they ever had propolis on them, excepting at the scallops, which have to be scraped out. But if the plain, no-bee-way section is used, a knife will never be brought into use, as the machine does it all, and very speedily.

There isn't a bee-keeper in the world who likes nice, clean section honey, that after seeing this machine and its work, but would make or procure one. As I am generous to bee-keepers, I here publicly present to them the right to use, and also how to construct it. If there is any bee-keeper in America, or any other country, that after dressing a half dozen sections of honey isn't in love with the machine and its work, let him "arise" like Mr. Doolittle's old man, and explain the objections.

I had intended to send a picture and explanation of this device last summer, but having quite a serious time in a financial way, caused by dishonest persons (but thanks to my bees, every dollar has been canceled), the matter was forgotten until I received the December Review, where I was surprised to see that L. A. Aspinwall, of Michigan, had invented nearly the same arrangement.

In conclusion let me add: Bread and table knives, pen-

knives, scissors, or any small edge tools, can be quickly ground on this wheel the same as an emery wheel, so our women-folks will now have no excuse for not having sharp knives, as any one who can run a sewing-machine can run this section-cleaner.
Morgan Co., Ohio, Jan. 5.

The Expenses of Bee-Culture—Does it Pay?

BY C. P. DADANT.

Does bee-keeping pay? This is a question which is often on the lips of a beginner, and on which many an old bee-keeper is ready to take the negative. But this is not to surprise any one, for there are plenty of farmers who are ready to

The Golden Section Cleaner.

tell you wheat-growing doesn't pay, and who still continue to grow wheat.

I propose, in this article, to show that bee-culture, if properly managed, does pay, even at the low prices of honey. We are producers of extracted honey almost exclusively, and as extracted honey is now as low in price as it ever was, if we

can make it pay now we ought to be satisfied that it will pay at any time.

The expenses of an outfit for bee-keeping, when running for extracted honey, are about as follows, figuring upon an apiary of 80 colonies, which is about the number that is best suited to all sorts of locations, and is probably the limit of numbers that an efficient man can properly examine and attend in a day's labor at each visit:

| | |
|---|----------|
| 80 colonies of bees in large extracting hives..... | \$400 00 |
| 160 supers with combs for same, two to each hive..... | 160 00 |
| Extractor, pane, tunnels, smokers, veils, etc..... | 20 00 |
| Empty hives (20)..... | 20 00 |
| Total..... | \$600 00 |

The labor we give to this number of colonies, when running for extracted honey, is about as follows:

| | |
|--|-------|
| | Days. |
| In February, examination to see that all is well..... | ½ |
| March, ditto, cleaning out dead colonies, feeding needy ones..... | 1 |
| April, taking out packing, examining queenless colonies..... | 1 |
| May, removing drone-combs, transferring small patches, looking up young queens, feeding, giving room to strong colonies..... | 2 |
| June, putting on supers, making a few artificial swarms..... | 3 |
| July, removing supers, extracting honey, returning supers..... | 4 |
| August, one examination for all purposes..... | 1 |
| September, equalizing, removing supers, extracting honey..... | 3 |
| October, removing empty supers, helping weak colonies, feeding needy ones..... | 2 |
| November, putting into winter quarters..... | 3 |
| Total..... | 19½ |

| | |
|---|---------|
| A total of 19 1-2 days. This is the outlay in labor. Figuring it at \$2.00 per day, the labor amounts to..... | \$39 00 |
| Interest on the capital, at 7 per cent..... | 42 00 |
| Annual sinking fund to replace hives as they grow old..... | 20 00 |

Total expenses.....\$101 00

The average crop of honey extracted one year with another is with us about 50 pounds per colony. Most practical apiarists put it at a much larger figure, even with comb honey, having better locations, but ours is probably a fair one. So we may count on an annual crop for the 80 colonies of 4,000 pounds of honey. Figuring this at 5 cents per pound, we have \$200, or about double the amount of the actual expenses for the year. If you have done the work yourself it will figure the wages for work necessitated at about \$7.00 per day, all expenses paid. I figure nothing for help needed when extracting, because I do not figure any profit from the beeswax. We have always found that the beeswax produced by extracting, which amounts to over one pound per hundred pounds of honey, more than pays for the help needed, and is in proportion to this help.

As a matter of course, there are seasons when there is next to no surplus honey, and in such seasons less help and less labor is needed. But there are also seasons when the crop is much greater, and in such years the additional beeswax, harvested from the cappings, more than makes up for all the extra labor. In the best honey season we ever had, which was in 1889, if my recollection is right, we had 600 pounds of beeswax from the cappings of something like 48,000 pounds of honey. This at 25 cents per pound made a snug little sum, and we know it not only covered our extracting labor, but also paid for the odds and ends.

When figuring up the labor, we gave the actual time employed by us in work of this sort. Much more time may be spent on the bees, and profitably too, for they usually repay their owner for the attention given them. There are plenty of bee-keepers, "died in the wool," who spend a great deal more of their time in the apiary than is absolutely necessary. These are the true ones, the "fast colors," "warranted to wear," who would keep bees in Greenland if they went there to live. But I do not know that we should take all of their time into account; for their labor is its own reward.

I know an old bee-keeper, a good friend of mine, who after he has put his bees into the cellar for winter, goes to see how they are every morning after he gets up. If he reads this article he will probably recognize himself, and perhaps many of our readers will think it is of themselves I speak. I askt him once, when I accompanied him with a little lamp in his silent visit, whether he did not think that this daily visit was rather injurious than otherwise, as it was likely to disturb the bees more or less. He evaded my question.

In keeping bees in the way above mentioned, if they are properly managed, the summer increase should make up for winter losses. It does with us, usually. The number of colonies should not vary more than 20, say from 75 to 95. If they become less numerous a little more time and expense should be put upon them till they have regained their loss.

If they become more numerous they may be equalized with other apiaries less fortunate.

Readers who are unaccustomed to bee-culture may think that this is only theory, but it is bona-fide practice. We have carried on this method for 25 years or more, with from 3 to 6 apiaries, and the wages figured in this article are the wages we have paid for this kind of work for 15 or 18 years past.

Hancock Co., Ill.

The Use of Shallow Extracting-Frames, Etc.

BY EDWIN BEVINS.

In reply to Mr. Tyrrell's question (see page 732, for 1897) as to why I prefer to use frames 6 inches deep for extracting, I will say that in the production of extracted honey I prefer to use a hive of greater capacity than the 8-frame or even the 10-frame Langstroth. I use some of the Dadant hives, which are 21 inches long and 12¼ inches deep, outside measure, and take 10 frames.

I now make for my own use a modified Dadant hive, 20 inches long and 12 inches deep, to take 10 frames. This change was made because these hives take the same length of top-bar and bottom-bar as the Langstroth or dovetailed hive. Every supply dealer handles these, and any supply manufacturer will cut the end-bars of the proper length at a trifling additional cost. Besides, if one wants to use these hives for comb honey, they will take the same sized super as the 10-frame Langstroth.

It is impracticable to tier up hives of this capacity. The frames are too large for convenience in extracting, and putting on another hive gives too much additional room at one time. Hence, I use a super taking 10 frames six inches deep. These frames are much nicer to handle than the Langstroth frame, and of course much nicer than any frame of a larger size than the Langstroth.

When using the 8-frame Langstroth hive for extracted honey it is almost, or quite, a necessity to use bee-zinc, and if bee-zinc is used the 8-frame hive does not give the queen sufficient breeding-room. This is true of most of the queens in my yard. How it may be with those in Mr. Tyrrell's I am unable to say. If his queens are of only 8-frame Langstroth hive capacity he had better turn his attention to their improvement.

With brood-chambers the size I have given, the queen so seldom goes above that bee-zinc is not needed. Some claim that bees will work just as well with the zinc as without it, but I have not found it so.

On the subject of the production of all extracted honey it is not worth while to make any further remarks. It was not expected that those already made would influence anybody's actions.

Yes, Mr. Tyrrell, if you kick those 8-frame hives when full of bees and honey, better kick them very carefully. Valor is not half so commendable as discretion in a case like this.

Marketing Honey—Influence of Early Reports.

BY C. DAVENPORT.

During the last few years great progress has been made in the science of producing honey; few if any other branches of agriculture have kept pace with us, but in one most important respect—the marketing of our product—we are not much farther advanced than were the bee-keepers of 50 or even 100 years ago; and altho of late our product is secured in a much more convenient and attractive form, which requires more labor and expense to the producer, the price has in the last few years steadily declined until at present it does not much, if any, exceed the cost of production, at least to those in the Northern and Middle States. Numerous reasons have been advanced as to the cause or reason of this steady decline in price, such as overproduction, under-consumption, adulteration, increase production, cheaper prices of fruit, etc. Now, in my opinion (and also in the opinion of all the bee-keepers with whom I have discussed the matter) many bee-keepers themselves have unintentionally done a great deal towards lowering the price of late, by reporting large, or very large, expected crops. I think all will admit that the actual crop, as a whole, has been greatly overestimated and exaggerated the last two years.

If I am right, all the large buyers and dealers in honey take one or more bee-papers, and while it is not likely that they read them as closely as a bee-keeper does, they look them over closely enough, no doubt, to see what the crop is ex-

pected to be, and when they see reports of such bright prospects, and accounts of immense yields coming in, or expected, they naturally decide that the actual crop will be very large, and hesitate to buy unless at a very low price, or if they receive shipments on commission they feel that it will be best for the shipper if they sell as soon as possible, even at a low price, for they may not, and probably do not, know much about the great uncertainty of a honey crop.

Of course, bee-keepers themselves know that no matter how bright or favorable the prospects are, there is no certainty of the crop until it is actually secured, and, with comb honey, I might say until it has been taken off the hives and graded, for sometimes it may happen that there will be a fair crop stored in the hives in sections nearly ready to come off, when the flow may suddenly cease, and a large part of the sections may be partly or wholly unsealed; or in some cases the honey may be sealed and off the hives, and upon coming to grade it part of the crop may be unsalable on account of bee-bread in the sections. Such instances have occurred with me, and no doubt with thousands of others.

The past season a man wanted to buy one of my yards, with the bees, hives, supers, honey and all, complete. As it was in the best part of the white clover flow, this yard was being run for comb honey, and an experienced bee-keeper who has handled bees the best part of his life, and myself, spent half a day in looking over the yard and estimating the amount of honey we thought was actually on the hives. His estimate was 2,500 pounds; mine, 2,100. The sale was not made at that time, and owing to a sudden cessation of the flow, and bee-bread, there was only about 1,300 pounds of salable honey, and but little of this would grade even No. 1.

Now, another thing that dealers and buyers do not know when forming their estimate of the crop from the reports sent to the bee-papers, is the fact that some of these reports are from beginners who have not had experience enough to form any correct estimate of the crop, or even the prospects of one; or some of the most favorable estimates may come in from old, experienced bee-keepers who have but a small number of colonies, and overlook the fact that some seasons 20, or even 40 or 50, colonies may secure a fair crop, when a yard or range fully stocked in the same, or a locality fully as favorable, may secure but a small crop, or none at all.

To show that I have reason to believe that some beginners are not able to form a correct estimate of even the prospects, I will relate an incident that took place here last spring. A young man living but a few miles from me, who knew nothing about bees, bought 15 colonies, and expected in the course of time to make his fortune, or at least a good deal of money out of them, for the man from whom he bought the bees helped him to figure out how he could increase them to over a thousand colonies in a few years, if he wisht, when the revenue from so many, even if but a small amount per colony, would be considerable.

He came down to see me a number of times, and was very enthusiastic about his bees and the prospects. He used to look over my bee-papers, and intended to subscribe for all the bee-papers himself, as soon as he sold some honey; and as some of these papers had a good deal to say about dishonest commission men, and developing the home market, he decided not only to sell his crop in the home market, but to sell *at once* for fall delivery, the large crop of comb honey—1,500 pounds at least—which he felt sure to get; and actually did travel over a large extent of territory in the spring, taking orders for fall delivery, at 8 cents per pound for white honey, clover or basswood—"customer's choice"—and 7 and 6 cents for amber and dark, with special prices on 100 pounds or more.

Now, last spring was one of the most unfavorable for bees that I have ever known; there were hard frosts every few nights, until the night of June 1, when we had our last severe one, and altho the bees were pretty strong in stores the previous fall, I had to feed nearly 2,000 pounds to the colonies in the home yard.

On one of his visits I askt this young man if his bees had enough stores. He said they had plenty, for the man he bought them from told him that each colony had enough to last it until June, even if they were unable to gather any until then. But, besides, he said that they were bringing in more honey, almost every day, than they could use, in fact some days, for awhile, they were bringing it in so fast that he had to enlarge the entrance to some hives in order to let them in and out fast enough, and he had put on some supers, altho no work had been done in them as yet.

His visits suddenly ceased, and I did not see him again for some time, but when I did he informed me that his bees had all died but one colony.

As some may not believe that these reports in the bee-

papers, such as I have described, do influence buyers and dealers, I will in my next, among other things, show how they actually do. Southern Minnesota.

The Amalgamation of the Two Unions.

BY WM. MUTH-RASMUSSEN.

You are entirely correct, Mr. Editor, when you, in your foot-note on page 807 (1897), say that I "meant that nobody had recently brought up the amalgamation subject *previous* to the Buffalo convention, in the bee-papers." In my article on page 759 (1897), I used the expression, "as nobody has brought the subject up." If I had had any reference to what was done at the convention, I should have written, "as nobody brought the subject up." I wonder that Mr. Newman failed to see the difference which the word "has" gives to my meaning, and to what he implies.

Since the question of amalgamation was first brought up, Mr. Newman has, it seems to me, shown an entirely unnecessary touchiness on this subject, and he appears to regard all who favor amalgamation as enemies of the National Bee-Keepers' Union. If Mr. Newman should take his son out of a primary school and place him in a graded school for the purpose of a better education; or if he should interest himself in having the primary school elevated into a graded school, would he then regard himself as an enemy of the primary school?

As a matter of fact, I did not know what was done at the Buffalo convention in regard to amalgamation, until I saw (in the Bee Journal received by last mail) the printed report, containing Mr. Newman's communication to the convention, and also his reply to my article on page 759. Mr. Newman uses, unfortunately, in both of those articles, as well as on a number of previous occasions, such offensive language that it must necessarily detract from the respect which otherwise would be accorded him on account of his various official positions and his administrative ability. I admire the spirit of dignity and forbearance with which the convention past by Mr. Newman's communication without comment or discussion.

I do not think that anybody seriously questions Mr. Newman's integrity or honesty of purpose, and his zeal for the welfare of the old Union is certainly commendable. But he should consider that many others are as honest and intelligent as himself. He may be a better lawyer than those who framed the constitution of the new Union, and he may be correct in his criticism of its defects; but he lacks the spirit of progress, which overlooks unimportant technicalities, and, irrespective of old usages, "goes ahead," doing "the greatest good to the greatest number."

I agree with you, Mr. Editor, in the concluding sentence of your foot-note on page 807. If amalgamation is not consummated, the members will gradually leave the old Union and join the new one. But this will mean a gradual decrease in the funds, until there will not be enough left for any practical purpose. In view of this contingency would it not be better, as contemplated, to transfer the funds to the new Union, while they amount to a respectable figure, and keep them up to a certain standard, such as I proposed? Mr. Secor is probably as capable as Mr. Newman to handle the funds to the best advantage, and if they, as I proposed, are only used for defence, and are even, through a large membership, kept up to a certain standard, deemed sufficient for the purpose—while in the old Union they must have been fluctuating—I fail to see what objection anybody can have to the change.

In proposing the sum of \$500 as the standard defense fund, I did not mean to restrict the fund to that figure. I simply considered it as the lowest amount that would make a respectable showing. If the directors in their wisdom should deem it advisable to make the standard higher, I, for one, shall raise no objection.

Inyo Co., Calif., Dec. 30, 1897.

No. 3—Recollections of an Old Bee-Keeper.

BY DR. E. GALLUP.

(Continued from page 20.)

My next bee-keeping was in Fond du Lac county, Wis., in a prairie country, and away from the basswood, willows, etc. There was a basswood grove three miles west of me, at Fairwater. As soon as I was settled I began to look around for bees. I found a man west of me that had five colonies in large box-hives, that had never swarmed, and he had never

taken any honey from them. By doing an immense amount of talking, I persuaded him to let me have the bees for half the honey and half the increase. I took them home, cut the hives down to about the right size to suit me, and returned him about 150 pounds of honey in a very few days. I kept them two years, got a good start, and returned him 10 colonies, and I do not remember the amount of honey.

In the meantime I had found some wild bees. The first swarm I found when I was hunting for my cows, about three miles from home, and in my shirt sleeves. I had just found the cows, and came across a fair-sized swarm clustered on a bush. I never could think of leaving a swarm of bees, so off came my shirt. I fastened up the neck by tying up the sleeves, cut off the bush, and put the bees, bush and all into the shirt, gathered up the flaps, carried them home across lots, as the country was new and not fenced. Then we had a season that the bees clustered out and did not swarm or produce any honey.

The following season I heard of a Hollander, by the name of Wellhausen, that made bees swarm at will. He made swarms at 25 cents each. A neighbor had three colonies, and said he was going to get the old "gent" to come and "swarm them" for him. So I made arrangements for the neighbor to be sure and have him come over and make some swarms for me. I also paid the neighbor for a day's work to come over and interpret, as Mr. W. could not talk English intelligently. So I wormed what information I could out of him before he commenced operations. This Mr. W. held out the idea to his neighbors that no one else but he could do what he did, as he possess the power to enchant the bees, etc.

He smoked the bees at the entrance, from his tobacco pipe, then turned the hive bottom up, inverted a half-bushel measure over the mouth of the hive, wrapt a sheet around the hive and measure, so the bees could not get outside, and began rapping on the sides of the hive, and in the meantime kept time with his rapping with a peculiar kind of chant (of course to charm the bees!). After about 20 minutes he untied the sheet, raised up the half-bushel, and behold there was a good, fair-sized swarm of bees in it! He then set it open side out, at about an angle of 45°, set the old hive back on its stand, and began to explain through the interpreter that they were thoroughly enchanted, that he would hive them and set them wherever I wanted them, and they would go to work exactly like a natural swarm.

He then took a long-handled spoon and began poking over the bees, and soon found the queen, or "king," as he called her, and after about 30 minutes he violently shook them up and poured them into a hive, as one would so much wheat. He gradually and slowly turned over the hive, and set it where I wanted it. Of course, I watch every motion with wide open eyes, and perhaps gaping mouth.

He then commenced on another colony, and in the meantime I had sent one of the children to a near neighbor's and procured another half-bushel, prepared a roll of rags and set fire to one end, and went to work on another colony, and had it done and the queen found before the old gent got through with his, and he was quite angry. He made his old tobacco-black teeth snap good at the interpreter. Then turned around to me, and said, "Ghanky man no good. Don't believe in de witches."

Well, I paid his price for making the two colonies, and offered him more, but he refused it with scorn. That lesson made a great advance in my bee-knowledge. He explained through the interpreter how the old colony replaced their queen, etc. He lived in the adjoining township, and I met him at different times. I obtained much important information from his methods, and experimented somewhat with his hives, made in the form of a sugar-loaf, out of willows woven basket fashion and plastered inside and out with green cow-manure, and dried in the sun. He made 108 colonies in two seasons from one, and wintered them successfully on the summer stands. Of course, I might have told you that he drummed out the bees, found the queen, and then hived them, but I am telling you just how I had to learn.

Orange Co., Calif.

[Continued next week.]

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 21.)

FIRST DAY—AFTERNOON SESSION.

The afternoon session was opened at 1:30 p. m., and Pres. Miller read the following question:

BENEFIT OF DRONES ASIDE FROM MATING.

"What is the benefit of the drone, aside from mating?"

Pres. Miller—How many think that the drone has any other use?

Dr. Besse—I have always been a rather close observer, and I think that drones are of a good deal of use in keeping up the warmth of the hive to the right temperature; and they let that many more workers go out to gather honey. I have noticed that where there are plenty of drones you get more honey frequently than where there are no drones, other things being equal.

Mr. Thompson—It seems to me, if you keep as few drones as possible, that there can't be enough to do much good in the way of warmth. I can't see any use in that direction.

Dr. Besse—I think in certain times of the year it is very well to have a good many drones in the hive.

Mr. Thompson—What time of the year?

Mr. Besse—When they are working, gathering honey, and putting it away.

CONDITIONS DETERMINING THE LIFE OF BEES.

"What conditions determine the life of the honey-bee?"

Mr. Besse—I think they will live longer when there isn't much to do than they do when they are working hard.

Mr. Whitcomb—If we were to ask the average bee-keeper what the average life of the honey-bee is, he would say about 40 days, and that would be correct, in the main. But my own observation has been that the life of the honey-bee is not gauged by years, months and days. We find in Northern Russia, where honey is produced away up—well, up into Siberia—that the honey-bee must remain in the hive there at least 8 or 9 months—not less than 5 or 6, at the least calculation—and the condition of the life of the honey-bee is gauged entirely by the amount of work that it has done, the stages of life it has past through. If they can be kept from the conditions of work, their age does not count until they have past through them.

Mr. Baxter—I think more bees are killed by accident than by old age; and that is why I believe that in the winter time a bee will live much longer than in the summer time. Take it when they are hard at work, every bee that can be out in the field, etc., the average life is very short—probably 20 or 30 days would be a big average. I do not believe that bees die in the winter time of old age, but that it is from poor wintering, poor packing. They very likely starve to death with their honey in the hive. I have seen that, time and again. And why? Simply because they were not packed properly. The moisture remained in the hive. It condensed, and became a sheet of ice over the comb. They were not examined right away, but after the weather became warm, the sheet of ice thawed away, and the man that found them found five or six pounds of dead bees in the hive, and he jumped to the conclusion that they died of old age. I am satisfied that is the case nine times out of ten.

Mr. Baxter—In reply to that, I will say that the bees that have worn wings are not the only ones that work.

USING FULL CELL-DEPTH STARTERS.

"Is it best to use full-length cell-starters, in brood-frames and for comb honey?"

A somewhat rambling discussion ensued as to what was meant by this question, and incidentally there was shown a confusion of understanding as to the terms "Weed process" and "drawn foundation," some insisting that the two terms meant the same thing. Secretary York then explained the difference.

Mr. York—The Weed process applies only to the sheeting of the wax. That is all. And that wax is sheeted the same, whether it is put into a shallow-wall foundation or a deep-wall foundation. The old process, or the new Weed process, is really the process of a year or two ago, and the later foundation is only the drawn foundation or deep-cell foundation. They are both Weed foundation. You might as well drop those terms. It is all Weed process. But the drawn foundation has the deep cells, deeper than the ordinary foundation. That is all the difference.

Mr. Moore explained that he had put in the question, and that drawn foundation was what he referred to.

Mr. Cooley said he would the next day bring in samples of sections of honey built upon drawn foundation, so it was decided to postpone discussion of the question till the samples were present.

USE OF FOUNDATION IN SECTIONS AND FRAMES.

"Is it best to use full sheets of foundation in brood-frames and in sections?"

Mr. Heffron—I would say, from my experience and observation, use full sheets, if they are convenient, but have them fastened so that there is no sagging, and use them only as a center, simply to guide the bees.

Mr. Green—I think we might consider it the universal practice of bee-keepers to use full sheets; and if anybody thinks differently, let us hear arguments against it.

Pres. Miller—I very much doubt whether the majority of bee-keepers use full sheets in sections. How many present use full sheets of foundation in sections? [Ten signified affirmatively.] How many use starters, or less than full sheets, in sections? [Ten signified affirmatively.]

Mr. Stone—I decided to use just little strips, because I had heard so many people say that comb honey was manufactured, and just as soon as they began to find out that the comb foundation was manufactured then they took it for granted that comb honey was manufactured. If they find there is simply a little strip put in the top of the section, or a little in the top and bottom, too, they won't object like they would if there was a full sheet.

Mr. Green—I have used both starters and full sheets, altho for several years I have used nothing but full sheets, because I think under all circumstances I can get more honey, fuller sections of smoother honey, and consequently a larger crop of nicer honey. If you have a small strip in the top the consumer can tell it; if not, nine times out of ten he can't detect it.

Mr. Thompson—The public has been used a good while now to foundation. I don't see how you are going to stop it.

Mr. Baxter—My experience has been that it always pays to have full sheets, invariably, in the brood-chamber. If you use a full sheet the sections when finished are well sealed all around the edge, in shape, and there is little danger of breaking them; while when you use only starters the bottom very often is not fastened well. As far as the objection by the public is concerned, I think that wouldn't hold good. Either you have to do away with it altogether or you may just as well use full sheets, because you must be able to tell them there is nothing artificial in that section. If you tell them there is just simply a starter you might as well tell them a full sheet. The question of using full sheets, in the quantity of honey produced, and the way it is finished up, I think will counter-balance all other considerations, even the cost, if it were five times as much as you pay now.

USING UNFINISHED SECTIONS OF PREVIOUS YEAR.

"How many have produced first-class honey in sections that had been partly filled with honey the year before?"

Dr. Besse—I have produced it that way, considerable last year. The great objection is that it gives it too dark a shade—don't get it so white.

Mr. Green—That is not first-class, then.

Dr. Besse—By shaving it down pretty thin, if it is built late in the fall, or partly drawn out, it will make very fair honey, but I have never succeeded in getting first-class honey from the previous year's drawing.

Mr. Green—Sometimes the honey will be inferior because this old comb is hard and dirty, and the bees don't seem to clean it properly. Moreover, this hard comb is worse than the worst foundation you ever saw; and besides this, the honey that is stored in these cells and then taken out just as soon as sold, very often is not properly ripened, and, after standing awhile, that part filled with drawn comb will very often, after it has stood awhile, be very much worse in appearance than the other. The honey will ooze out of it, and if the honey is stored in any moist place it will show in those

cells almost every time, and that part of the honey will be decidedly inferior.

Pres. Miller—How many have produced first-class honey under the circumstances stated in the question. [Two answered affirmatively.]

Mr. Heffron—The appearance will be against it.

Mr. Wheeler—I think the trouble comes in when the sections are unfinished; we are apt to leave them in the fall, and the bees are apt to deposit their glue over the section. It is my impression if the section is taken off just as soon as the bees stop work, and put on when they commence the next season, you can't tell the difference; but I am not certain.

Pres. Miller—That honey left in there becomes candied honey, and that acts as a yeast upon any honey put into that section afterwards. I am inclined to think this: If when the white honey harvest stops you take off every section promptly, and then allow the bees to have full access to those sections, to rob them out, they will make a clean job of it, and those sections will be just as good as if you gave them foundation the next year. I don't say I know that. As to leveling them down, I don't agree with my good friend, the editor of *Gleanings*, about that. He says it must be leveled down to at least $\frac{3}{8}$ of an inch. For the purpose of getting them clean on the edges, that is valuable. If they are clean and good, I don't see any reason why a cell $\frac{3}{8}$ of an inch deep is not just as good as one $\frac{1}{2}$ of an inch deep. If it is a good thing to have a cell $\frac{1}{2}$ of an inch deep, I think it is better to have it three times that deep, providing the cell and the comb are as good.

Mr. Baxter—I will say that I used, this year, foundation for two-pound sections that was cut into sizes for the sections, in 1889, by my wife, and I used them in connection with fresh foundation this summer, and I couldn't see the least difference. I could see some difference on the fastening it in the section, tho. The old foundation was a little harder. It took more heat to get it to stick.

DRONE-COMB IN SECTIONS.

"Have you any objection to drone-comb in the sections?"

Mr. Baxter—No objection at all in the sections, but in the brood-chamber I say I invariably use full sheets of foundation.

Mr. Green—I would object to drone-comb in the sections because honey stored in drone-comb has not nearly so nice an appearance. The consumer may not be able to tell why, but he knows it doesn't look as nice, and he doesn't buy it as readily.

Mr. Thompson—Drone-comb looks very coarse in sections.

Pres. Miller—Did you ever know drone-cells to be kept empty in sections for some time, when the worker-cells in the same section were filled with honey, Mr. Green?

Mr. Green—Yes, sir.

Pres. Miller—That is a serious objection to drone-comb in sections. It will not apply, probably, if there is a large amount of drone-comb in the brood-frames, but we generally limit the amount of drone-comb in the chambers, and you have that condition.

Dr. Besse—I have noticed that.

GETTING UNFINISHED SECTIONS CLEANED OUT.

Pres. Miller—How can we get the sections cleaned out without having the combs torn?

Mr. Thompson—Put them out-doors.

Dr. Besse—I used to do that a good deal, and the bees would clean them out.

Pres. Miller—And they will tear them all to pieces.

Dr. Besse—No, put out enough of them, and put them out late in the evening. If you uncap them thoroughly they will clean them up. I never had the bees tear them down.

Pres. Miller—I have.

Mr. Baxter—Yes, and they will clean every living person off the plantation.

Mr. Baldrige—I would extract the honey from the sections, and put them under instead of over the hive. I would sprinkle them with an atomizer before I did so, and the bees would remove every particle of honey from them.

Mr. Stone—One point has not been touched upon that has bothered me some. I have taken the sections off the hives, and when the bees were done working, and just taken them off in the cases, and set them in the honey-house; and sometimes in the spring of the year I have kept them just as dry as I could, and as warm as I could, and in the spring of the year I would find that some of those sections that were partly filled, the honey would be sour in them, or a little tainted, and the bees don't like to accept it, and if they do they don't make a good grade of honey. I have got to refusing them entirely, and I don't put in anything except what is fresh foundation, and where they are just partly filled that way I have just extracted them of late years. And the past summer I

have tried a little extracting. I would like to know whether it is practicable with any one else. I don't see many objections to it. I take the sections that are partly filled, and cut them out and put them into my wax-extractor, and extract both honey and wax at the same time. You get them both in the same vessel, and the wax is on top, and easily separated from the honey, and you have an article of honey that I don't think has deteriorated at all. I can't see any difference between that and what is extracted with the honey-extractor. As far as the comb foundation is concerned, Mr. Dadant puts little slips of paper between his sheets of wax, saying, "This foundation will not deteriorate in years, or will keep for years, if kept from the sun and dust," or "from the heat and dust." I think that is not a question that needs to be settled.

Dr. Besse—I would say that I never have had any torn sections, and I have had hundreds of them. I save them all and store them, and put them all out that I have, some afternoon—when they have been all extracted that I can extract—and I put that into the bee-cellar—a place where my honey is never sour, but it doesn't dry out. Set them out two or three hours before sundown, and the bees will clean them out as nice as a pin, and never tear a section.

Pres. Miller—Will you tell us how many supers or sections you put out?

Dr. Besse—Perhaps a hundred or two hundred supers.

Pres. Miller—How many colonies of bees?

Dr. Besse—For a hundred colonies.

Pres. Miller—Then you are all right. You have B. Taylor's plan, and that works all right. But if you put out one super that will be a different thing. They will tear it all to pieces.

(To be continued.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Hive for Comb Honey and Wintering.

1. I have my bees all in box-hives. Wishing to transfer them into new hives, what is the best hive for comb honey?

2. I winter my bees on the summer stands. Is a 10-frame Danzenbaker hive big enough to winter bees successfully?

NEW YORK.

ANSWERS.—1. It isn't so much the hive as it is the management and the man. The plain, simple Langstroth hive is perhaps as good as any, and I would have it in its latest form, the dovetailed.

2. That depends somewhat on the size of the colony. Possibly it may be large enough for any colony, but I should be full as well satisfied with two stories. The trouble is that with only one story, if there's a big lot of brood late in the season, there may not be room in the hive for all the honey a very strong colony ought to have. But if you make sure that honey enough is present there ought to be no trouble with one story.

Managing Double Brood-Chamber Hives.

See on page 794 (1897) in answering Washington's questions, and also Penn's, you advise using two 8-frame brood-chambers for one hive. I wish you would tell us how you manage your bees. As I understand it, you removed one hive when you put on the supers. How many supers did you put on at the time you removed the hive? and what do you do with the frames in the hive you removed?

You said if you wintered your bees on the summer stands, you would use two stories. Would you put most of the honey in the upper story?

I suppose I ought to tell you how the seasons are here. In the spring the bees get honey from fruit-bloom, vine maple and willow. From the last they get more pollen than honey. We have a good deal of wet weather, sometimes in fruit-bloom, so they don't get very much honey from that. Then about the middle of June or first of July white clover commences, and lasts from four to six weeks. Last summer there was no honey in the white clover to speak of, so the bees did not store any more than enough to winter on. In this part of the coun-

try we do not have any fall flow, not enough to keep up breeding, which is the worst feature in keeping bees here. Last winter I lost half of my bees on that account. The white clover stopt all of a sudden and the bees stopt breeding. Those that I lost had plenty of honey, and the others I had to feed came out all right in the spring. That goes to show that we must have plenty of young bees as well as honey to winter well.

WASHINGTON.

ANSWER.—Only one super is put on a hive at first, and the second one is put under it when the first is a third, half or two-thirds filled, depending upon circumstances.

When it comes time to put on supers, there usually isn't a great deal but empty combs in the lower hive, and a pile of empty combs can be left at one end of the apiary till needed, keeping watch that worms don't monopolize them. If a colony has more brood than will go in one story, it is given to a less fortunate neighbor, and if there's an overplus after putting eight frames of brood in each hive, it's piled up on one of the weaker colonies to be drawn from when needed.

Yes, if I wintered two stories outdoors I'd leave the honey mostly in the upper story, just where the bees themselves will probably have left it.

Wintering Bees in a Damp Root-House.

1. Will bees winter safely in a root-house where drops of water hang overhead, altho the hives are perfectly dry?

2. Would it be all right to have a slow fire to dry the water out?

WISCONSIN.

ANSWERS.—Reports have been given of success in such a place, and yours may also be successful. Still, I think I'd just as soon do without having any drops overhead.

2. Yes, providing it does not run the temperature above 45° or 50°, and no light shines from the fire. Of course no smoke must be allowed to get to the bees.

Sound of Bees in the Cellar.

Are the bees all right if I can hear them buzzing every time I go into the cellar?

MINNESOTA.

If you hear the bees you may be sure they're alive, but if they make much noise it's not so good as to have them very quiet. A colony that is wintering in the best condition will be so still that you will have to put your ear close to the hive to hear any noise. By spells, however, it will rouse up for a little time and be more noisy, as if the bees were turning over in bed. When a cellar is full of bees, some say they should be perfectly quiet, but I have never found mine so. If I hear a soft, low murmur on entering the cellar, I feel satisfied. If the thermometer gets down below about 45°, they become more noisy, and they become more noisy if it goes above that. Perhaps in your cellar and with your thermometer, 45° may not be the point of greatest quiet, but if you watch closely you will find some point not far from that at which they are most quiet, and you should try to keep the temperature at that point.

A Winter Bee-Repository.

I have not a very good cellar, in my judgment, for bees, so I have put up a building from rough boards, the outside space of 15 inches filled with sawdust, then another wall of 4-inch boards and paper on both sides, leaving an air space of 2 inches all around, except the floor, which I packt with sawdust 6 or 8 inches next to the ground, then boards and paper, and boards again. The ceiling is made the same as the four walls, except a ventilator 5x6 inches, which is covered by the roof. There are two doors on the south side. Eight inches from the floor I have placed two planks, 2x6, and 4 inches apart, all around the room, where I put the first hives on, about 4 or 5 inches apart, with the bottom-boards off, and then tier up three hives high. Do you think they are all right?

WISCONSIN.

ANSWER.—I don't know. I'm afraid not. The walls are constructed to act as non-conductors, and a very cold spell would have little immediate effect on the bees, for the temperature inside would change very slowly. But you must remember that the temperature will change just as slowly if the outside weather becomes warmer. If the average temperature should keep above 35° or 40°, continuing thus for two or three months, the bees would not feel the occasional spurts of low temperature sending the mercury down below zero. But

suppose the average for two or three months should be not more than 10° above zero, then the bees would stay at that mark or a little above it, without any benefit from a chance day with the thermometer up to 50°, which a colony has that stands outdoors. The larger number of colonies in the building the warmer they will be, but there again comes the danger that the air will not be so pure as with a smaller number. You will be doing a service to others if you report next spring how the bees come through. If you find the temperature stands below 40° or 45°, perhaps you could put in a little stove with a fire of hard coal.

Queen Laying in December in Indiana.

Is it a common thing for a queen to lay at this time of the year? I have one that is laying, or at least she was Dec. 20. Along in October I introduced a yellow queen to a black colony of bees, but did not expect any increase so late; but late in November, one fine day, the bees were flying, and I thought I saw a yellow bee go into the hive, so I opened it, and to my surprise there were young bees from eggs up to flying bees. So Dec. 20 the sun came out nice and warm, and I had to have another peep. I lifted out three frames, and they had patches of brood as large as a man's hand, with eggs and larvæ. I thought perhaps it was not a common thing, in a Middle State like this, for bees to breed so late in the season.

INDIANA.

ANSWER.—Bees often have eggs in the hive in winter weather, say in February, when the queen begins leaving for the coming season, but your case is very unusual, in December. One reason for it is that there had probably been a cessation of laying before the introduction of the new queen, but even then it was a very unusual occurrence.

Queen that Stopt Laying in August.

I had a young queen in a nucleus, and after she mated and began laying I clipped her wing, using the Monette device. After two weeks I looked over the hive and found that she stopt laying, as there were no eggs nor brood of any kind.

1. What was the trouble with that queen, that she stopt laying the middle of August?
2. Could the clipping have frightened her so as to stop her laying?
3. Do you think she would lay next season if she is successfully wintered?
4. What would be the best to do with a queen like that?

WISCONSIN.

ANSWERS.—1. I don't know. It is just possible that she was all right, but there's hardly one chance in a million that she was, if I am right in supposing that you clipped her within a few days after she began laying, and then two weeks later no eggs nor brood were present. It almost seems, however, that there must be a mistake somewhere, for if there were brood and eggs, or even eggs only in the hive, what became of them in two weeks?

2. I don't think it could.

3. I doubt it.

4. As a matter of curiosity it might be a good thing to keep her for a time to see what she would do, but a queen that would stop laying in the middle of August when she hadn't laid two weeks in her whole life ought not to be encouraged to live.

Wintering Bees in a Barn, and on Canded Honey.

1. I have bees in a barn, with the entrance on the side of the barn, the hives covered with blankets and hay. They have been in the barn all summer, the same I suppose as the bees of your questioner on page 803 (1897), as he says "if bees are in a barn," implying that they were not put there for the purpose of wintering. Now are not these bees in nearly the same condition for wintering that bees are when well packed in chaff hives outside? If not, why not?

1. In September I had some bees short of stores, and I fed them some extracted clover honey. The honey was all right, but now seems to have candied nearly solid. Will the bees be likely to winter on this kind of stores?

CONN.

ANSWERS.—1. I am exceedingly obliged to you for calling my attention to that reply on page 803. Those questions on page 803 were answered just after returning from Buffalo (where they should have been answered), and it is evident that

in my hurry I lost sight of the fact that there were entrances in the side of the barn. That's not sufficient excuse for such carelessness in answering, I'm only explaining how it happened.

The 40 colonies referred to in the answer were put into the barn and packed there without any entrance at all. With the entrance it's an entirely different thing, and you are right in thinking that they are much the same as being in a chaff hive, the main difference being that more packing is around them.

2. I don't know for sure just how it will be, but perhaps they'll come through all right if they have a sufficient quantity of stores. You will probably find that they will waste a good deal, throwing out the solid grafts of candied honey.

Exhibiting Bees in a Store.

There is a store here called "The Bee-Hive," and it is doing a bee-hive business. This summer I let them have my observatory hive to put in their show window. They were well pleased with it, as it attracted a great deal of attention, and secured free advertising in the papers. Now they want to know whether I could put a full hive in the window, and let the bees fly out. I told them I didn't know as such a thing could be done. For I was afraid the bees would buzz themselves to death on the window. I told them the bee-keepers have a Solomon out West that would answer all such questions. If it can be done, please say in what way.

NEW YORK.

ANSWER.—Solomon hardly lives in this region, but any bee-keeper who has tried it will tell you that you are right in suspecting that the bees will buzz themselves to death against the windows if they are allowed to come out of the hive in the store. Besides that, they would be very annoying by flying about the store. The best you can do, it will be rather hard on a colony of bees to have one or more sides of the hive covered with glass, but you may be able to have one last through the season by giving it an outside entrance, and by keeping the hive darkened when no one is inspecting the bees. A heavy black curtain might hang over the glass, to be held up while the bees were on view, then dropt down when no one was looking at them. The passage from the hive out through a hole in the wall would have to be boarded up in such way that no bee could get out of the hive into the store, altho having free passage to the open air. It might be easy to accomplish this, and it might not be easy. If the entrance of the hive opened out on the sidewalk it wouldn't do at all. It would have to open out at some part of the building where the bees going out and in would not disturb any passers-by.

Bees Clustering Up Against the Cushion—Marks on Drones.

1. I put my bees into winter quarters Nov. 17, if I remember rightly, and they are all right, but what puzzles me is that they have clustered up against the cushion. They are in one room of the barn, where they were last winter. The cushion is of ground cork in burlap sacks in empty supers. They all cluster the same. Four of the hives are dovetail, one is 15x15, and 18 inches high. The other one is the same except 12 inches high. All have plenty to winter on. What I am afraid of is that it might get cold and remain so, and they starve. Or can they work down to food, as well as up, with breaking cluster? It gets pretty cold in there. I have small sticks to let them pass over the frames.

2. I sent to a queen-dealer in this State for two tested queens. They were of the 3-banded strain. Those queens hatch nice workers and young queens, but the drones were what I called hybrids. Some of them were almost as black as the old stock, but not as small.

IOWA.

ANSWERS.—1. It isn't so very easy to understand just what the situation is. But from what you say I rather understand that there is an open space in some way between the brood-frames and the cushions, and that the bees are clustering in the empty space. Part of the cluster no doubt extends down to the combs and the bees will keep up connection with the base of supplies. But it is not a good thing to have very much space over the brood-combs, and the first day it is warm enough it might be a good plan to crowd the cushions down into the space.

2. If the worker and queen progeny are all right you needn't pay much attention to the drones. They vary very much, and I have yet to see anyone give the marks whereby a pure Italian drone can be determined.

The American Bee Journal

OLDEST BEE-PAPER IN AMERICA

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., CHICAGO, ILL.

\$1.00 a Year—Sample Copy Sent Free.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—W. Z. HUTCHINSON.
SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT. E. WHITCOMB. E. T. ABBOTT.
W. Z. HUTCHINSON. DR. C. C. MILLER. C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Vol. XXXVIII. CHICAGO, ILL., JAN. 20, 1898. No. 3.

Order Bee-Supplies in Time.—Yes, you are right, we were about to offer the annual advice regarding the purchase of supplies early—in ample time for the honey season. Judging from the reports we have read from some of the factories, it looks as if there might be an unusually early rush this year. We shouldn't wonder if last season most bee-keepers had a chance to use up all the supplies they had left over from previous poor seasons, and the coming season they will have to lay in another supply. This will make a larger business this year than even that of last year, which was considered almost phenomenal by the manufacturers of apiarian supplies.

The wise bee-keeper will always have on hand, in advance of the season, nearly all the supplies that will likely be needed. Don't get caught without having at least the necessary goods on hand when the time comes to use them.

The New Union's Membership is growing steadily. Almost daily we are receiving and forwarding the dues of new members to the Treasurer and Manager, Hon. Eugene Secor, of Forest City, Iowa. We hope the increase may continue right along, until there shall be a membership of at least 1,000. All who prefer to do so, can send their dues (\$1.00) when writing to us, and we will continue to forward them to Mr. Secor, as we are now doing. The membership now must be about 350. Why not make it 1,000 by the next annual meeting, which will doubtless be held in

Omaha—or Cincinnati (?). It would mean a good deal if the United States Bee-Keepers' Union had a membership of 1,000. It would then be the largest organization of bee-keepers ever known on this continent. Are you a member? If not, you'd better join at once, and lend your aid in carrying out the important objects of the new Union.

The Mich. Apiarian Experiment Station, the Superintendent of which, Mr. John M. Rankin, reports in the American Bee-Keeper, is by no means idle. Among other things they have been at work to increase the length of the tongues of bees, and during the past season made an increase of two-tenths of a millimeter in the length of tongue of one strain by means of crossing. Experiments are also being made in the way of mating queens to desirable drones.

Sweet Clover is both illustrated and clearly described by Harriet Mason, of Lorain Co., Ohio, in the Ohio Farmer of Jan. 6. The writer shows that she knows sweet clover all right, and says, "As a weed it is not troublesome." Of course it is not hard to destroy, if one only knows how. The illustration given is a very fine one, and Ohio farmers would do well to teach their larger stock to eat. The bees know already how good it is as a nectar-yielder.

Honey as Food—our 24-page pamphlet gotten up for general distribution among consumers of honey—is being liberally quoted from by the public press. The Chicago Record—that magnificent daily newspaper—lately printed a half column taken from it. As the Record's circulation is more than 200,000, several people probably learned something about honey. We hope our readers will see to it that the editors of their local papers are invited to copy from "Honey as Food." It's brief, correct, and interesting to all.

The Vermont Bee-Keepers' Convention—the 23rd annual meeting—will be held at the Van Ness House, in Burlington, Jan. 26 and 27. Railroad rate, two cents per mile each way. Of course, every bee-keeper is invited to be present. It will afford a good opportunity to visit the State Experiment Station and Farm. A portion of the printed program reads as follows:

Comparative Value of the Italian and Black Races of Bees—A. E. Manum.

Spring Management of Bees—J. E. Crane.

The Bees and the Flowers—Prof. L. R. Jones.

Report of Work Done by the Experiment Station Apiary During the Past Year—Cassius R. Peck.

Would it Be Practical for Vermont Bee-Keepers to Organize a Bee-Keepers' Exchange—J. E. Crane and O. J. Lowrey.

Song—M. A. Everest.

Can an Out-Apiary Run for Comb Honey be Made Profitable With No One to Hive Swarms? If So, How to Manage It?—W. G. Larrabee.

Shall We Adopt the New No-bee-way Section and Fence in Place of Our Present Section and Separator?—H. L. Leonard.

Recitation—Albert M. Cram.

For a copy of the full program, and further particulars, address the Secretary, H. L. Leonard, Brandon, Vt.

The Chicago Honey Market Again.—Last week we had something to say regarding the prices of honey in this market. Since then the Chicago Record (one of the great dailies here) gave a write-up on the honey-business as it appeared Monday, Jan. 10, on South Water street—the great farm-produce street of this city. Here is what the Record's reporter had to say:

Honey's lack of activity is material for considerable speculation among South Water street dealers nowadays. This is a season of the year when the product of the bees is

supposed to be in its glory, and to be enjoying all kinds of prosperity. Its comparative sluggishness is attributed by some to unions, by some to rheumatism, but by most to an inconsiderate, unappreciative people. It is a well-known fact that honey came to Chicago this season with great expectations tucked away among its comb and other chattels. Upon the passing of the autumn the sweet thing associated very much with buttered toast and other representatives of the bread brigade, but as time wore on a chillness sprung up between them, and now the affiliations are far from brotherly. There is a hope among the dealers that when the next spell of cold weather drifts along, honey will retrieve some of its lost popularity.

Fancy, high-colored white clover honey, tipping the beam at a pound, is sold these days to retailers at a dime a pound, and imperfect off-color stock is markt at a shade less. Buckwheat honey, resembling a Malay in color, lounges around with a 7-cent tag around its neck, and alfalfa stock, from the rolling plains of Colorado, pags along at 8 cents per pound. Extracted honey, amber to dark, is as slow at a nickel a pound as time is when a night train is being waited for.

In connection with the foregoing there appeared a section of comb honey as a poor, sick man's head, with a crutch under one of his arms, and a bottle of some tonic for "that tired feeling" which he seemed to be enduring just then. Also one of his feet was bound up, and, all in all, the old gentleman, whom they called "W. Clover Honey," appeared to be in pretty bad shape.

We attribute the lack of a general demand for honey here just now, to two causes, viz.: The very warm and unseasonable weather, and the great quantities of adulterated liquid honey (or glucose) being put upon the market by the unscrupulous wholesale grocers. Much of it is unfit for a dog to eat, and when people once get a taste of such stuff, it simply kills their desire for any kind of honey, and they are slow to buy again.

Complete Volumes of 1897.—We have on hand about 40 complete volumes of the American Bee Journal for 1897, which we will mail to any one upon receipt of 60 cents. We also have about the same number of the first six months' copies of 1897, which we will mail for 30 cents. As there were 832 pages of the Bee Journal last year, here is a chance for our new subscribers to get a good deal of valuable reading-matter for a very little money. Better order at once, before they are all gone.

MR. W. L. COGGSHALL, of New York State, with his two sons, a part of one of his many apiaries, and his elegant home, are all shown in Gleanings for Jan. 1. Everything indicates general prosperity and comfort. Good for W. L.

MR. J. F. MCINTYRE, of Ventura Co., Calif., writing us Jan. 3, said:

"We are having a dry year so far. The grass has dried up, and prospects are poor for a honey crop next season."

DR. G. L. TINKER, of Tuscarawas Co., Ohio—once a prominent apiarian writer, manufacturer, etc.—recently visited the A. I. Root Co., and afterward wrote up his trip, which appears in Gleanings for Jan. 1. It's a deserved boom for the Rootvillians.

THE BRITISH BEE JOURNAL completed its 25th year with its last issue of 1897. So did Gleanings, we believe, for if we mistake not they both were started in 1873. We congratulate them. The American Bee Journal is just 12 years their senior, having been established in 1861. The three bee-papers named are the oldest printed in the English language. There

may be older ones in Germany, and there may not. We do not know. In this country the next to Gleanings in age is the Review, which completed its 10th year with 1897.

MR. WM. RUSSELL, of Hennepld Co., Minn., writing us Jan. 11, said:

"I congratulate you on the improved appearance of the Bee Journal for 1898. If I could only remember one-half of the good things it contains, I would make fewer mistakes."

MR. GEO. SPITLER, of Crawford Co., Pa., wrote us Dec. 31, 1897, as follows:

"We are now having a week of the first winter weather. We have good sleighing, but the mercury has not gone below 12° above zero. Bees are hibernating (?)."

MR. W. J. FOREHAND, of Lowndes Co., Ala., wrote us Jan. 10:

"This is an ideal location for the purpose of queen-rearing, which is almost a constant honey-flow. Bees to-day are bringing in loads of pollen."

MR. A. I. ROOT has been spending some of his leisure time lately in defending the Weather Bureau that so many like to poke fun at, and in trying to reform the Agricultural Department which is offering prizes for articles on growing tobacco. Mr. Root, why didn't you offer the Department a bee-smoker, to swear off?

MISS FANNIE C. DAMON, of Middlesex Co., Mass., lately sent us 25 cents for the Langstroth Monument Fund. If each bee-keeper in the United States and Canada would contribute 25 cents, it would amount to a very nice sum, and purchase and erect a splendid monument to the great Langstroth—the revered Father of American apiculture.

DR. C. C. MILLER, who has for years so ably conducted the bee-department of the excellent National Stockman and Farmer, has begun to write for it some illustrated articles for beginners in bee-keeping, the first appearing in the number for Dec. 30, and is devoted to the queen-bee. The Doctor can do some good work in that line, and he will.

MR. JOHN G. KNUPPEL, of Kings Co., N. Y., has kindly sent us a photograph of his city apiary, regarding which he wrote Jan. 11:

"We had a very fine crop of both comb and extracted honey the past season, in all 2,000 pounds, which we sell in our own home. The bees are doing nicely so far."

MR. WM. M. WHITNEY, of Geauga Co., Ohio, gave us a pleasant call Jan. 13. He has 28 colonies of bees, and is making quite a success of the business though he is quite advanced in years, and began only about two years ago. He is doing what he can to get local bee-keepers to study the subject, and to keep their bees in an up-to-date way. Mr. Whitney will likely be heard from later on.

MR. C. THEILMANN, of Wabasha Co., Minn., called on us last week, when in Chicago with a carload of hogs. He had a very poor season with his bees the past year. He secured only about 1,700 pounds of comb honey, and had to feed over 3,000 pounds of sugar to carry his bees through the present winter. He has never had a final settlement with the crooked Chicago commission firm to whom he shipped his 1896 crop of comb honey, some 12,000 pounds. All he has been able to get so far was about one-fourth of its value.

THE POULTRY SHOW OF THE YEAR will be held in Chicago Jan. 24-29, under the auspices of the National Fanciers' Association of Chicago. The Borden Building, 214 East Madison street, has been secured for the purpose, and the number of entries promises to be very large. Every preparation is being made for the care and comfort of the poultry and pet stock when in the showroom. Railways and hotels are convenient, and those who visit the show will find the surroundings pleasant, and the exhibits highly entertaining. The Secretary, W. W. Hogle, 1015 Benson Ave., Evanston, Ill. (a Chicago suburb), will be glad to furnish particulars. The railroads are making special rates for those outside of the city who desire to attend.

The Fence Separator with the no-bee-way section has a stone shied at it in the American Bee-Keeper, and a good word for it in Pacific Bee Journal.

Thin Foundation for Brood-Combs.—The editor of Gleanings thinks thin, but not extra-thin, foundation might be used in the brood-nest in shallow frames well wired.

Bees Gnawing Out Bottom Starters.—W. H. Eagerty complains in Gleanings that when late in the season he gave to the bees sections with nearly full sheets and bottom starters, the bees gnawed away the bottom starters and finish up the combs where the top starters ended.

Triangular Bottom-Bars.—L. L. Skaggs recommends in Southland Queen that bottom-bars be made triangular like the old-fashioned top-bars, the sharp edge or comb-guide being turned up in the bottom-bar. He says they are much stouter than a flat bar of the same weight, and the bees will fasten to them much better.

Bee-Diarrhea is Contagious, as shown by experience. Strengthen with sound bees a colony reduced by diarrhea, and the dying off will steadily continue. Weygandt says the evil is readily communicated from bee to bee if they eat the same food, and especially, as is the case with bees, when the same food is carried from mouth to mouth.—Editor J. B. Kellen in Luxemburg Bztg.

Well-Ripened Honey.—The editor of Gleanings, after describing some honey in such a way as to make one's mouth water, closes up by this sentence, which, by changing "dry room" to "warm dry room" is worth pasting in one's hat: "Any honey, if of good flavor, when allowed to stand in an open vessel in a dry room, will become thick and waxy if given time enough."

The Long-Idea Hive.—G. M. Doolittle having spoken against the long-idea hive, O. O. Poppleton comes to its defence in Gleanings. He thinks it probable that Mr. Doolittle never had a properly-constructed hive of that kind, as neither the Gallup nor the Langstroth frame can be profitably used in that manner; only a deep frame that will allow the brood to remain compact.

Castors for Shipping Comb Honey.—The most dangerous part of shipping honey is the rough handling by freighthands when shifting to or from the car. J. E. Crane explains in Review that he prevents rough usage by putting castors on each under corner of a box containing 15 or 20 cases. No two-wheeled truck is then used. The expense is perhaps $\frac{1}{2}$ cent for each pound of honey.

Hauling Bees at Night.—In Germany it is a common thing to move bees from one place to another, generally at night, in search of better pasturage. The editor of Centralblatt says that in the region of Hannover the law requires that when hives are thus hauled and are open (it isn't easy to close skeps or straw hives), a lighted lantern must be carried 22 yards in advance of the wagon.

Four-Piece Sections have been almost entirely displaced by one-piece sections, but a return to the four-piece for Californians is advocated in Pacific Bee Journal. It is claimed that with glue, or even without it, they are more rigid and perfect than the one-piece, and give a better effect to the honey, and can be made on the Pacific Coast to compare with Eastern manufacturers, counting the difference in freight.

Fastening Foundation in Brood-Frames.—The A. I. Root Co. has adopted as one of its regular productions a top-bar with a kerf in the underside to receive foundation. The kerf is $\frac{1}{8}$ inch wide and $\frac{1}{4}$ inch deep. Parallel to it is another kerf just like it, with a film of wood $\frac{1}{32}$ thick between the two kerfs. The sheet of foundation is split into one kerf which is in the center of the top-bar, then a wedge-shaped strip the length of the underside of the top-bar is forced into

the other kerf, crowding the film of wood hard against the foundation, thus holding it fast. This plan has been in use some years in England, but for some reason has not before been introduced here. A German plan a little like it has been used to some extent here. A single kerf is made in the top-bar, the sheet of foundation is split in, then a drop of melted wax here and there from a burning beeswax candle keeps it in place till the bees fasten it.

Empty Comb for Winter Cluster.—While authorities are telling us that bees don't occupy empty cells in winter, and others tell us bees winter best on solid combs of honey, M. A. Wathelet, editor Le Rucher Belge, urges with emphasis that in preparing for winter, care must be taken not to take out center combs that contain little honey to replace them with others better filled, thus dividing by full combs the cluster, and thwarting the bees in the effort they have made to arrange themselves in the best manner possible for the severe season. Where does the truth lie?

Austrian Bee-Keeping.—The central society of beekeepers in Austria numbered 3,667 members for the year 1896, the report for 1896 being given in Bienen-Vater for December, 1897. These members had 23,344 colonies, or a little more than 6 colonies per member. The average per colony was about 9 pounds of honey and $\frac{1}{2}$ pound of beeswax. Not quite two-thirds of the colonies were in movable-comb hives. Of the 15,468 movable-comb hives, only 91 opened on top, as most hives do in this country; 28 of them opened at the side, 439 at the bottom, and 1,243 at the back.

A Machine for Cleaning Sections is described and illustrated in the Review, being the invention of L. A. Aspinwall. It is especially adapted to clean plain sections, altho it might be used with more or less advantage with the old style. A strong frame-work holds something that looks a little like the relic of a thick grindstone that has been worn down to a very small diameter, and the section is applied to this as it revolves, the surface being such as to rapidly remove all traces of propolis and stain. A rapid motion is given to this grinding surface by means of a larger wheel and belt. A treadle for the foot gives motion to the larger wheel.

Temperature of Brood-Nest in Winter.—It is a somewhat troublesome thing to get at the temperature in the middle of a cluster of bees in winter, as explained by G. M. Doolittle in the American Bee-Keeper. After a good deal of experimenting he settled upon the following: When the mercury stands at zero outside, the temperature in the cluster of bees is 64°, and for every 15° of change from this point (outside), the change in the cluster is 1°. Thus 16° below, gave 63°; zero gave 64°; 15° above gave 65°; while 30° above gave 66° in the cluster. He thinks bees must burn a lot of fuel in the shape of honey or some substitute in a time of severe cold, in order to bring the cluster from below zero up to 63°, and raises the question whether those who are recommending out-door wintering may not be making a mistake that costs a good many dollars.

Curing Foul Brood Without Drugs, shaking off the bees, or any loss of their work, can be done by even a novice, says M. M. Baldrige in Bee-Keeper's Review. Cage the queen and put her in the top of the hive where the bees can have access to her. Bore an inch hole in front of the hive a few inches above the entrance, and toward sunset fasten over the hole outside, a metal bee-escape. Let it stand till next morning. Take from any strong, healthy colony one or two combs of brood, with or without adhering bees, put in an empty hive and fill out with frames of foundation or starters. Any time in the forenoon, or when the bees are getting honey from the flowers, place this prepared hive on the stand of the diseased colony, placing the latter close beside it, but turned end for end, handling it very gently, and leaving the entrance open. Within two or three days nearly all the bees will be in the new hive, when toward sunset the queen is to be taken from the old hive after driving the bees away from the cage with a little smoke, and she is then to be run in at the entrance of the new hive. Gently turn the old hive end for end, and close the entrance. No bee can get out of the old hive except through the escape, and no bees can enter, so all will go to the new hive. In about three weeks all healthy brood will be hatched in the diseased colony, and soon thereafter all the bees will be in the new hive, and no loss of bees or labor. Then dispose of the old hive and contents by burning or otherwise.

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All
Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the

BEE-KEEPERS:

We are making a strictly A No. 1 line of

Hives, Sections, Shipping-Cases, Frames,

etc., and are selling these goods on their merits.

We do not claim to sell at cost as we are not in business merely for what glory there may be attach to it.

We do claim that our goods are as fine as can be produced anywhere, and that our prices will be found fair and reasonable.

We are in a position to serve you promptly and satisfactorily, and we ask you to give us a chance to do so.

Why not write to us to-day for our **Free, Illustrated Catalog?** Or, better still, send us a list of what goods you will require for next season's use, and we shall take pleasure in quoting prices on same. Very truly yours,

G. B. LEWIS CO., WATERTOWN, WIS.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail YOU a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

In the multitude of counsellors there is safety.—Prov. 11-14.

Cold and the Secretion of Nectar

Query 67.—Does a light freeze or cold spell just previous to the opening of blossoms seem to prevent the secretion of nectar?—N. C.

E. France—Yes.

Eugene Secor—I believe it does.

Mrs. L. Harrison—I think it does.

J. A. Green—I have not noticed this.

G. M. Doolittle—Not that I ever discovered.

W. G. Larrabee—I think it would be liable to.

Dr. C. C. Miller—I don't know. Hardly think so.

Prof. A. J. Cook—I don't know, but think not.

C. H. Dibbern—I do not know, but I think not.

Chas. Dadant & Son—It surely has a depressing influence.

Dr. J. P. H. Brown—It curtails the secretion very much.

R. L. Taylor—With some kinds of blossoms, but not with all, I think.

Emerson T. Abbott—Not if it does not freeze hard enough to injure the plant.

J. M. Hambach—I am not sure on this point. A frost during the bloom I believe to be more injurious.

Jas. A. Stone—I think not, unless it is cold enough to kill the blossoms, providing it is favorable weather after blossoming.

Rev. M. Mahin—I think not. I know that a light freeze sometimes increases the secretion of nectar after the blossoms are out. This is especially true of cherry-bloom.

J. E. Pond—This is a matter to which I have given no attention, but ordinarily I should not suppose it would affect the matter of secretion unless sufficiently severe to destroy the life of the blossom.

Wm. McEvoy—Yes, I believe that it does check it some. In June, 1888, we had a cold rain followed by a hail-storm just as the clover was beginning to bloom, that checked the flow then. And on the night of May 28, 1889, we had a frost that checked the honey-flow for a long time afterward.

G. W. Demaree—Not if the flowers are uninjured by frost. The condition of the weather at the time when in bloom has much—all—to do with the secretion of nectar in flowers. I have noticed the rather curious fact that the most favorable conditions for the early honey-flow are often *reversed* in the late (fall) honey-flow.

A. F. Brown—I think not. I remember one year in March, when colonies were gaining two to four pounds per day from orange, when, on the 19th, we had a cold wave, the mercury dropping to 24° two nights in succession: the following days the colonies carried

in 8 to 12 pounds each, and kept it up for several days. This cold damaged the bloom just enough to cause it to secrete nectar very heavily. With bright, fair warm, days following a light freeze, I think in case of some flowers the cold is a benefit rather than otherwise.

Good Average Per Colony.

I have 21 colonies of bees put away for winter, and 2,000 pounds of comb honey was the season's result last summer.

J. H. LOGEMANN.

Worth Co., Iowa, Dec. 17, 1897.

Bee-Management in Washington.

I notice on page 747 items from Chehalis and Lewis counties, Wash. I would like to know how these writers manage their bees. Perhaps they will let us know. It has been a poor season, my average being 53 pounds per colony, two-thirds comb.

HERMAN ABLERS.

Clatsop, Co., Oreg., Dec. 10, 1897.

Good Honey Season.

The past season was a good one for honey in this locality, altho the crop of white honey was quite short, owing to the cold weather nearly all the month of June. My 134 colonies increased to 155, and gave me 9,000 pounds of honey, about 1,100 pounds of it being comb.

A. W. SMITH.

Sullivan Co., N. Y., Dec. 13, 1897.

Electric Swarm Notifier.

I find the American Bee Journal a great help. My bees had a nice flight yesterday. I notice on page 288 an item by J. H. Williamson, saying he would publish the working of his electric swarm notifier, but he has not done so yet. I for one should very much like to hear from him through the Bee Journal.

B. W. HALL.

Merrimack Co., N. H., Dec. 13, 1897.

Bees Did Well the Past Season.

I put 46 colonies of bees into a shed boarded tight on the north and west, with open front to the south, with some boards tacked up to shade them from the sun. I put on empty supers, and a Hill's device of my own make, and filled them with cushions or blankets, old clothing, etc., and packed behind and between with straw. They will be left as they are now till time to put on sections next season. My bees did well the past season. I sold my honey in the home market at $8\frac{1}{2}$ and 10 cents; swarms at \$1.25, and colonies this fall at \$3.50.

NOAH MILLER.

Johnson Co., Iowa, Dec. 10, 1897.

Results of the Past Season.

The past season has been about an average one for honey. The yield in many localities in this county has been better than for years, owing, I think, more to the condition of the colonies than to the nectar secreted by the flowers. My reason for thinking so is, that last spring I was unable to attend to my bees "at the right time," on account of illness, resulting from my "experience" in Dixie Land, some 30 years ago, and as a result some colonies stored quite a fine lot of honey, while others did nothing. I believe that if all my colonies had been alike strong, I would have had the best yield I ever had.

I cannot agree with my friend from Somerset county, this State, that bee-keeping

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |

BEE-KEEPERS! Let me send you my 64-page Catalog for 1898
J. M. Jenkins, Wetumpka, Ala.

Please mention Bee Journal when writing.

"don't pay," for our bees have always paid us better (except one year) for labor expended than have our cows, when we sent milk to a cheese factory or made butter at home.

There was less swarming last year than for years, as far as I have heard.

I have sold all my honey in the home market, for 12 cents wholesale for comb honey, and 10 cents for extracted, for white clover.

It doesn't seem possible, but the "Old Reliable" seems to be getting better all the time.

GEO. SPITLER.

Crawford Co., Pa., Dec. 15, 1897.

Bees and the Apple Yield.

We have come to look at the American Bee Journal as a fixture in this household, from oldest to youngest. I have 12 colonies of bees that are on the summer stands, with plenty of stores and a very mild winter so far.

I wish to say to the bee-men that the apple crop was a complete failure in this State, but I have four apple trees that have borne three years in succession. People came here and asked as to the cause; and in fact I was not able to tell the reason until a gentleman from Pennsylvania said it was the blessed bees. Anyway, I got about a dozen barrels of apples, lots of fun, and some honey.

NATHAN A. SLEEPER.

Hillsboro Co., N. H., Dec. 13, 1897.

A Report for 1897.

The first part of the season, in this locality, bees did fairly well, better than an average on fruit-bloom, raspberries and white clover. The honey gathered was very nice.

The last part of the season was unusually good, the best we have had for eight years. Golden-rod yielded abundantly. The honey from it was good, milder in flavor than usual.

The close of the honey season left my bees in good condition for winter. This is the first season for years that I have not had to feed more or less for winter stores.

As usual I reduced the number of my colonies by uniting about one-third. They are now in winter quarters on the summer stands, with outer cases over the hives.

J. P. SMITH.

Sullivan Co., N. H., Dec. 14, 1897.

Not A Good Honey Season.

I have had my bees nearly two years. This has not been a very good season for honey, only receiving about 80 pounds from the strongest colony, while the others did not do much of anything. A year ago last spring I started with two colonies, and now have but 10. I started with five colonies last spring. One colony cast a good prime swarm, and in about six days they cast another heavy swarm; the next day still another, and I look through the hive and found four more queens. I took out three queens, so they did not swarm any more, and were in good condition when I put them away for winter.

A. G. TOWERS.

Polk Co., Wis., Dec. 26, 1897.

Bee-Keeping of Ancient Egyptians.

We have before now seen accounts of migrating apiaries. Writers tell us that the season in Upper Egypt is some six weeks earlier than in Lower Egypt along the coast. Maillet tells us the ancient Egyptians were well aware of this. He says there was an abundance of bees and honey in that country, and that it was the custom of that ancient people, each year, about the first of October, to send their hives from all parts of the country into Upper Egypt, where they were placed on boats, numbered and registered. As the waters of the Nile subsided after the inundation, the flora in that hot country came on rapidly. The bees were allowed to remain a few days, until it was thought they had foraged about all they could, when they were moved

REID'S TREES

ARE RELIABLE.
 Everything grown in Reid's Nurseries is healthy, well-rooted and true to name. Every effort is made to save expense to customers. We sell direct and ship direct, saving fifty per cent. on Trees, Shrubs, Vines. Write for catalogue, estimates or suggestions. Try Star Strawberry, Eldorado Blackberry.
REID'S NURSERIES, Bridgeport, Ohio.

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. **R. B. Leahy** and **G. M. Doolittle**, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Somnambulist**. "Experience and Its Lessons," by **R. C. Aikin**. This series of articles will be reviewed by Mr. Doolittle, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The somnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. **Dr. C. C. Miller** and other popular writers also contribute to its columns. The PROGRESSIVE is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the PROGRESSIVE BEE-KEEPER is but 50c. a year. The PROGRESSIVE and that "one only" book for beginners, the **Amateur Bee-keeper**, by **Prof. J. W. Rouse**, both for 65c. A sample copy of the PROGRESSIVE for your name, and a beautiful, illustrated catalog of apian supplies for the asking. Address,

LEAHY MFG. CO., Higginville, Mo.

This Very Remarkable Social Story,

The thought of which is the application to all life of the test question, "What would Jesus do?" has had an extraordinary sale, even during the "dull times" of summer. In the guise of a dramatic story, the book makes a powerful appeal to the public conscience in the lines in which interest is now so deeply aroused, namely, the social conditions affecting the relations of employer and employe, rich and poor, the Christian and the world, the saloon and the voter, etc. The author believes his test—"What would Jesus do?"—to be nothing less than revolutionary, and applies it with searching directness, not only to commercial and social, but also to religious life. The deep interest which the story has awakened is indicated by the thousands that have been sold, and the many voluntary testimonials, among them being the following:

"The reading of the book will search many a heart, and ought to lead to a simpler, holier, and more fully consecrated Christian life."—Sunday-School Times.

"Singularly impressive... It is a sermon in action, and one that cannot fail to touch the heart."—New York Christian Advocate.

"Mr. Sheldon's book makes a strong impression as a plea for more simplicity of living, for more economy and more principle in the matter of personal expenditure, and for the application of the laws of righteousness and justice to the methods of business-administration."—New York Independent.

Price, in paper cover, 25 cts., postpaid; bound in cloth, 75 cts. Or, we will mail a copy of the paper-covered edition for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00, or for sending us TWO NEW subscribers we will mail you a copy of the cloth-bound edition. We will send the paper-covered book and the Bee Journal one year—both together for \$1.10; or the cloth-bound book and the Bee Journal one year—both for \$1.50. Address,

a few leagues down the stream, and another stop of a few days made, and then another move, until the coast was reached, about Feb. 1. Thus going, their bees had the advantage of the best bee-pasturage the kingdom afforded, the whole length of the river country.

As to their hives: Hasselquist tells us they were cheaply made of clay, about 4 feet long and half a foot in diameter—curious hives, we would think, but perhaps not more unique or less practical than many receptacles our bees pre-empt in stumps, trees, logs, etc.

I wonder what those postdeluvians would think, could they now take lessons of Doolittle, Miller, Root, and others.

Indeed, I wonder what they'd say To see bee-keeping in our day; Methinks they'd open wide their eyes, To see our hives, frames, and bee supplies. Some stories big at home relate, How bee-men here manipulate The hives, frames, combs and bees, And anything just as they please, And think success is fairly won As honey comes in by the ton, While Miller's face would light with smiles, To think of living in new tiles; They'd think they knew but little of the bee— But, then, they never had Root's "A B C."

Will Co., Ill., Dec. 13. A. W. HURT.

Bees in Good Condition.

I have 115 colonies of bees in winter quarters in good condition. In 1897 I got half a crop of honey. E. R. WRIGHT, Scott Co., Iowa, Jan. 8.

Bees Did Poorly.

Bees did very poorly here this year, altho Alsike was abundant, but there was very little seed in it, making a double loss. Ontario, Canada. M. G. WILLIAMS.

Results of the Season of 1897.

I had 30 colonies the past season, that I work mostly for extracted honey, and got 3,700 pounds, but no increase in bees. J. E. CAMPBELL, Clinton Co., Iowa, Jan. 1.

In Good Condition for Winter.

I had 30 colonies, spring count, increased to 60. I got 1,500 pounds of comb honey from white clover, last season. I got no fall honey. My bees are in good condition for the winter. JOHN N. MICHAEL, Caldwell Co., Mo., Jan. 1.

Was Successful with Bees.

I was successful with my bees last summer. I harvested about 1,500 pounds of comb and extracted honey. The market here is very low and dull. JULIUS HERMANN, Bureau Co., Ill., Dec. 27.

Bees in Good Condition,

I have 5 colonies of Italian bees in the cellar, and in good condition. I am looking forward with great hopes for the next season with them. I love to work with the bees. I can't do without the "Old Reliable." A. G. FREEMAN, Neosho Co., Kans., Dec. 29.

Not Enough Flowers for the Bees.

My honey crop actually will not pay the subscription price of the Bee Journal. True, I had only five colonies, but I did expect some little remuneration, for the care that I gave them. This is my third year with bees, and it seems the more experience the less honey, but I think I know what's the matter—too many bees and not enough flowers!

I use full sheets of foundation on wired frames, in good hives (Hilton's) sheltered from the noonday sun, and still no honey. Screw loose somewhere. May be I'll find it after awhile. I have "A B C of Bee-Cul-

ture." "Bees and Honey," several copies of the Review, and, last but not least, the American Bee Journal; and if my renewal one year hence is not in on time, you can attribute it to the fact that it is another of my "off" years again.

L. F. CHURCHILL.
Cheboygan Co., Mich., Dec. 15.

The Bee-Keeper Won.

I would like to let you know how the bee-case or fight came out. I would refer you to pages 494 and 495 (1897) for further details. Well, my neighbor had to return the bees and pay the costs.

AUGUST BACHMANN.
King Co., Wash., Dec. 28.

Not a Good Honey-Flow.

I like the American Bee Journal first-rate, and could not do without it. I started with two colonies of bees four years ago, and have 15 colonies now. I put 11 into the cellar, and 4 on winter stands. The honey-flow was not very good. I got only 460 pounds last fall.

R. H. BERGFELD.
Hardin Co., Iowa, Dec. 30.

Bees Did Well.

Bees did very well here the past season. I harvested 2,500 pounds of comb honey and 500 pounds of extracted of very fine quality, from 48 colonies, spring comb, and and increased to 77 colonies, with plenty of honey to winter on. I attribute my success to the American Bee Journal, and could not keep bees without it.

Nemaha Co., Kans. A. W. SWAN.

Stored Honey of Fine Quality.

Bees did well here last season, and the honey stored was of a fine quality. The fall forage was good, tho I expect it was injured and cut short by the drouth of autumn. Bees seem to be wintering quite well so far. Have had but few days at a time of real cold weather here yet, with but little snow, the first coming Dec. 2.

FRED S. THORINGTON.
Livingston Co., Mo., Dec. 16.

Report for the Past Season.

I began the season of 1897 with 60 colonies, and have 80 now. They averaged 25 pounds of honey per colony, mostly comb. The forepart of the season started out grand, but by July 10 the honey-flow broke off all at once, everything dried up, and there was no more honey after that to speak of, altho bees are in good condition. I hope for a better season in 1898.

A. WICHERTS.
Cook Co., Ill., Dec. 17.

Appreciates the Bee Journal.

The American Bee Journal has been a close and constant friend ever since its birth, and I have watcht its development and growth, as it has made its regular visits weekly for so many years, and should it from any cause stop during my life, I should be very lonely without its visits.

My lawsuit is set for the January court. I will report later in regard to it.

H. BESSE, M. D.
Delaware Co., Ohio, Dec. 31.

Hogs Eat Sweet Clover.

The sweet clover seed I got last spring grew all right, and at the present writing it is green. They need not tell me that stock will not eat it, for I cannot keep our pigs off of it, as it is not fenced. We sowed white clover last spring, and if I get the Simpson honey-plant started, don't tell me I will not have any surplus honey.

I think this is a good location. We are near the Republican river, where abound cottonwood, sumac, prickly-ash, box-elder, grape-vines, golden-rod, smart-weed, and

Bee-Keeper's Guide—see page 43.

any amount of wild flowers that I do not know the names of.

I am very much interested in bees. The Bee Journal is a great help to me. There are so many things a beginner wants to know, and the Bee Journal is the place to find almost any question answered, that you want to ask about bees.

I began last spring with two colonies, increased by natural swarming to six, got 85 pounds of comb honey in one-pound sections, and they all have plenty of winter stores. They have been out for a play-spell at three different dates in this month—Dec. 6, 7 and 8.

I am experimenting a little in wintering my bees; if they winter all right you may hear from me again.

MRS. LIZZIE FRELAND.
Republic Co., Kans., Dec. 15.

Managed a Number of Apiaries.

I have managed alone over 20 small apiaries, starting with 144 colonies, spring count, and increased to over 300, and but 2 swarms. I got 1,371 one-pound sections filled from one divided colony. The Bee Journal has been a great help to me.

THOS. CHANTRY.
Clay Co., S. Dak., Dec. 28.

Bee Journal Likely to Cause Trouble.

I am well pleased with the Bee Journal. It is full of reliable news, and comes regularly, but I am afraid it will cause me trouble, as there is a dispute as to who shall read it first, wife or I, as she has taken great interest in the bee-business.

Los Angeles Co., Calif. J. H. MILLER.

Results of the Poor Season.

I have about 20 colonies of bees that were put into winter in good condition. They produced between 1,000 and 1,100 pounds of comb honey, which sold at 15 cents a pound. About all is sold. I am nearly 66 years old, and have kept bees 19 years. I produce altogether comb honey, and use the Langstroth hive. I have tried many other hives, but for easy handling, and all other purposes, it is ahead of any other I know of. I have taken the Bee Journal about 11 or 12 years, and could not get along without it and keep bees. Bee-keeping here is away back, say 40 years.

ALEXANDER ROSE.
Shelby Co., Ill., Jan. 1.

Selling Honey at Home.

My honey crop has been this year, the summer and fall supply, 600 pounds from seven colonies. The light honey sold readily for 12½ cents, and 10 cents for dark. All pronounced it fine. Have sold it all, and there has been a call for more. All was sold in the home market. I have no trouble in selling my honey, as it goes on the market clean and all in good shape. Some so-called bee-men will bring their honey to market just as it is taken from the hive, and not being able to get a good

price for it, will sell at a reduction. Then the people say, "Well, your honey looks nice, but Mr. So-and-so sells his for much less than you do"—which means at 6 or 7 cents, when, if they had any pride in the good work, they would clean their honey up in good shape, and get as good price as any one. I am very proud of my small apiary, but wish to have more experience.

CHAS. A. BILLINGS.

Wayne Co., N. Y., Dec. 28.

Please Send Us the Names of your neighbors who keep bees, and we will send them sample copies of the BEE JOURNAL. Then please call upon them and get them to subscribe with you, and secure some of the premiums we offer.

New York.—The Ontario County, N. Y. Bee-Keepers' Association will hold its fifth annual convention at Canandaigua, N. Y., Jan. 27 and 28, 1898. An interesting program is in course of preparation. All are invited. RUTH E. TAYLOR, Sec. Bellona, N. Y.

The Successful Incubator.—We have before us the new catalogue of the Successful Incubator Co., Des Moines, Iowa. These people have been advertisers in our columns for several years past, and we presume that many of our readers now own and operate the Successful machines. So far as we are able to ascertain, the results of this machine in actual operation are such as to give a hearty endorsement of the same. We see by reference to the annual catalogue that the manufacturers' guarantee is such as to leave very little to be desired. If there is any point of construction, material and actual incubating ability that is not completely covered by the guarantee, we fail to discover it. By the way, this 130-page catalogue is crowded with good things that ought to be in the hands of every man or woman who is interested in poultry in any way. It is a handsome and valuable book, and worth many times more than they ask for it. Send along 6 cts. in postage stamps and secure it before another day passes. It will repay you handsomely. When writing them, please say you saw their advertisement in the American Bee Journal.

HONEY and BEESWAX MARKET QUOTATIONS.

Chicago, Ill., Dec. 13.—Fancy white 11 to 12c, No. 1, 10c; fancy amber, 8 to 9c; No. 1, 7c; fancy dark, 7c. Extracted, white, 5 to 6c; amber, 4 to 5c; dark, 4c. Beeswax, 26 to 27c.

The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special change. Beeswax is scarce.

Milwaukee, Wis., Dec. 13.—Fancy white, 12 to 13c; No. 1, 11 to 12c; fancy amber, 9 to 10c; fancy dark, 8 to 9c. Extracted, white, 5 1/2 to 6c; amber, 4 1/2 to 5c. Beeswax, 25 to 27c.

This market has been fairly sustained on honey since our last report. Values remain about the same, as there has been a very good consumptive demand, especially for extracted, while the comb honey has seemed to accumulate with increase receipts, and we feel to meet the demand even if at a reduction from quotations. There seems to be more demand from those who eat honey than in former seasons, which is a good feature of the trade which we desire to encourage. We are expecting a good trade for this forward.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12 1/2c; No. 1, 11 to 12c; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c; amber, 4 to 5c. Beeswax, 22 to 23c.

New York, N. Y., Dec. 22.—Fancy white 11 to 11 1/2c; off grades, 9 to 10c; buckwheat and mixt, 6 1/2 to 7c. Extracted, California white, 5 to 5 1/2c; light amber, 4 1/2 to 4 3/4c; white clover and basswood, 5 to 5 1/2c; buckwheat, 4 to 4 1/2c; Southern, 50c, a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of buckwheat, mixt. and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Dec. 15.—Fancy white, 11 to 12c; No. 1, 10 to 11c; fancy amber, 10c; No. 1, 9 1/2c; fancy dark 9 to 9 1/2c; No. 1, 8 to 9c. Extracted, white, 5 to 6c; amber, 4 to 4 1/2c; dark, 4c. Beeswax, 23c.

Market holds firm at above prices. Good demand for extracted. Wax is quiet but firm at 23c.

Kansas City, Mo., Dec. 15.—Fancy white, 10 1/2 to 11c; No. 1, 10 to 10 1/2c; fancy amber, 9 1/2 to 10c; No. 1, 9 to 9 1/2c; fancy dark, 8 1/2 to 9c. Extracted, white, 5 1/2 to 6c; amber, 5 to 5 1/2c; dark, 4 to 4 1/2c. Beeswax, 20 to 22c.

St. Louis, Mo., Dec. 13.—Fancy white, 12 to 12 1/2c; No. 1, 10 1/2 to 11 1/2c; fancy amber, 9 1/2 to 10c; No. 1, 9c; fancy dark, 8c. Extracted, white, 5 to 5 1/2c; amber, 4 to 4 1/2c; dark, 3 1/2 to 4c. Beeswax, 24 1/2 to 25c.

We would advise prompt shipments of honey. We do not see any probabilities of better prices. The stock of honey is ample for the demand.

Albany, N. Y., Dec. 13.—Fancy white, 12 to 13c; No. 1, 11 to 12c; fancy amber, 8 to 9c; No. 1, 8c; fancy dark, 8c; No. 1, 7 1/2 to 8c. Extracted, white, 5 to 6c; amber, 4 1/2 to 5c; dark, 4 to 4 1/2c.

There is an ample stock of comb on hand and selling freely at quotations. Extracted is not plentiful and from information received there is not much in the hands of producers.

Buffalo, N. Y., Jan. 14.—Strictly fancy 1-pound comb honey is more active at mostly 10c, occasionally 11c, but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c, down to 5c. Extracted is also very dull at 4 to 6c. We cannot recommend the shipping of honey here unless it is strictly fancy 1-pound sections.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand, and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

Philadelphia, Pa., Nov. 13.—Fancy white 13 to 14c; No. 1, 12c; fancy amber, 10c; No. 1, 9c; No. 1 dark, 8c. Extracted, white, 5 to 5 1/2c; amber, 5c; dark, 4 to 4 1/2c. Beeswax, 27c.

Honey is arriving very freely; market is a little off. Beeswax is in good demand.

Boston, Mass., Nov. 3.—Fancy white, in cartons, 13c; No. 1, 11 to 12c; fancy amber, 10c. Extracted, white, 6 to 7c; amber, 5 to 5 1/2c. Beeswax, 28c.

No. 1 and fancy honey has sold well during the past 10 days, but off grades and light weight is going slowly. Beeswax is in good demand and but little here.

Detroit, Mich., Nov. 9.—Fancy white, 11 to 12c; No. 1, 10 to 11c; fancy amber, 9 to 10c; No. 1, 8 to 9c; fancy dark, 7 to 8c. Extracted, white, 5 to 6c; amber, 4 to 5c. Beeswax, 25 to 26c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c; No. 1, 10 to 11c; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Cincinnati, Ohio, Jan. 8.—There is no change in prices, but rather a slow demand for all kinds of honey. We quote 10 to 13c, as the range of prices for best white comb honey, and 3 1/2 to 6c., for extracted, according to quality. Beeswax is in fair demand at 20 to 25c, for good to choice yellow. Cincinnati is no place for dark comb honey.

CONTRIBUTED ARTICLES

Proper Size of Brood-Chamber—Swarm or Parent Colony for Honey?

BY G. M. DOOLITTLE.

A subscriber to the American Bee Journal wishes me to tell through its columns how many standard Langstroth frames I would use in a hive, when working exclusively for comb honey; and also which will do best at producing comb honey, the prime swarm or the old colony, where but one

swarm is allowed from each old colony in the spring. As these are reasonable questions, I will try to answer as best I can.

Regarding the first, I would say that I would use just as many standard Langstroth frames in the brood-chamber, when working for comb honey, as the queen had occupied with brood when the honey harvest commenced in earnest from clover, basswood, or whatever else gave, in my locality, a sufficient flow of nectar so the bees could make a business of storing surplus honey, according as any one honey tree or plant abounded in the locality where I resided. For this reason I would use a 10-frame Langstroth hive; that is, I would use a hive that would hold 10 Langstroth frames, and have it so arranged that I could reduce it to only a four-frame hive, should I find any queen at the commencement of the honey harvest that would not keep more combs than that number occupied with brood; or a five, six, seven, eight, or nine frame hive, just in accord with the prolificness of the queen.

There are a very few queens which will fill 10 Langstroth frame with brood, when they are laying at their best, hence

Official Bird's-Eye View of the Trans-Mississippi and International Exposition, Omaha, Nebr.

we wish a 10-frame hive for these queens; and as we do not know just which will have such a queen year after year, as queens change in prolificness so often, we had better make all our hives to hold 10 frames. Far more of our queens will keep only nine frames filled with brood, and for this reason we wish some way of reducing the 10-frame hive to a 9-frame, when it is required. When the hanging frame is used I know of no better way of doing this than by using an inch board, the same being a little smaller than the inside of the hive below the rabbets, and having a top-bar of a frame nailed to one side of it, so it will hang in the hive the same as a frame.

When we find, at the beginning of the honey harvest, a queen capable of keeping only nine frames filled with brood, and we have 10-frames in the hive, take out the one the queen does not occupy, and slip in the prepared board to take the place of it. But, as a rule, we shall find by far the larger part of our queens will occupy only eight frames with brood, and in this case we will use one of the boards on each side of the hive, instead of both on one side, as this brings the top of the hive in better shape for the bees to work to the best advantage in the sections.

A few of our queens may not come up to this average as to prolificness, consequently we wish to reduce the size of the hive still further in such cases, and for this further reduction I prefer to use two frames spiked together, having $\frac{3}{8}$ lumber nailed on each side, thus making what is known as a "dummy." With these boards and dummies we can make the hive so it will suit the prolificness of any queen at the commencement of any honey harvest, and thus secure the best results in comb honey.

If we allow the bees to make a start at storing honey of any amount in the brood-chamber, they will be loth to enter the sections, and instead of doing so they are apt to keep on storing in the brood-chamber, crowding the queen more and more in her brood space, till at the end of the season we will have very little honey in the sections and few bees in the hive for winter. If there is any one thing which tends toward poor success in the production of section honey more than another, I believe the having much empty comb in the brood-chamber at the beginning of the honey harvest is the worst.

Strive to have every queen do her level best at brood-rearing for a month or six weeks before the expected harvest, so that the maximum number of bees shall come with the beginning of the harvest, then take away all comb unoccupied with brood, putting on the sections, and we are as near perfection, according to my views, as we are likely to get; and should the season be a good one, we shall have no cause to complain at the results secured.

But I think I hear some one asking, "Why not kill all the unprolific queens we may happen to have, before the honey harvest?" Should we do this, we shall throw the colony into an abnormal condition which will work against our securing as good results from that colony as we would have secured had we left the poor queen till the end of the harvest and then replaced her. By "abnormal condition," I mean this:

If a young, prolific queen is given near or at the commencement of the honey harvest, she will not be content with the number of combs which the old one occupied, and if confined to these, swarming during the middle of the harvest will be the result, which would blight our prospect for honey of any amount from any colony which gets the swarming-fever at this time; and should we give this queen all the room she needed, say eight or nine frames, it would either result in the crowding her down with honey, as spoken of above, or in their using the most of the honey brought in from the fields in feeding the large quantity of brood she would bring about, which brood would hatch so late that the bees from it would become consumers instead of producers, and thus we would nearly or entirely lose the use of that colony during the season.

In regard to which will produce the most comb honey, the swarm or the parent colony, that depends upon when the swarm issues. If it comes 10 days or more in advance of the harvest, and the old colony is not allowed to swarm again, with proper management the old colony will give the best results. On the other hand, if the swarm comes at the commencement of, or during the harvest, then every advantage should be turned to the account of the swarm, for the old colony would do little more than to secure honey enough for winter under the best of management, while the swarm can be made to give good results by throwing the main force of bees to it.

Ontario Foul Brood Inspector's 1897 Report.

BY WM. McEVoy.

During 1897 I visited bee-yards in the counties of Welland, Lincoln, Wentworth, Brant, Norfolk, Kent, Huron, Grey, Perth, Oxford, Waterloo, Cardwell, York, Ontario and Simcoe. I examined 66 apiaries, and found foul brood in 34 of them. I found several of the largest and best apiaries in the Province very badly diseased through the bees robbing foul-broody colonies that had been brought from other parts of Ontario, and placed near them. Some of the owners of these fine apiaries had invested from \$500 to \$800 in bees, one man over \$1,000, and to get their good apiaries badly diseased through foul-broody colonies being shipt into their localities, was pretty hard to bear with, but I am satisfied that none of the parties that either bought or sold the diseased colonies that had been shipt knew that they had foul brood at the time of sale.

I also found many colonies very badly diseased through the owners using old combs that they got from parties that had lost all of their bees with foul brood. None of these men knew that the old combs were diseased, or were able to tell the stain-mark of old foul brood on the lower side of the cells. Comb foundation is a very safe and very valuable thing to use, and those that need combs should use plenty of it, and not run any risk by using the old combs from apiaries where all the bees had died.

When going through, examining every colony in a diseased apiary, I mark them according to the condition I found them in, putting one pencil cross on the front of one hive, two crosses on another, and three on all very bad ones. After we get through examining all the colonies, we know the true condition of things by the number of crosses on the front of the hives. Some of the colonies I advised to be doubled the same evening, and the combs made into wax, and when the work was done in the honey season I had considerable increase made from those least diseased, and, as a rule, ended the season with more colonies than I began with, and all in grand condition.

At our annual meeting that was held in London, in 1892, I said that my method of curing diseased apiaries of foul brood would in the near future be followed by the bee-keepers of every land. I am very much pleased to say that my method of treatment is not only followed by the bee-keepers of Canada and the United States, but is "all the go" in far-off Australia, and for this nice state of affairs I thank the editors of all the bee-periodicals. Everywhere that I went the past season to inspect the apiaries, I found every bee-keeper pleased to have me examine his colonies, and for the very nice way that I was treated by every person I return to them my most heartfelt thanks.

I burned two colonies in one apiary, two in another, two in a third place, and a quantity of diseased combs, and three in a fourth locality. The owners helped to burn some of the diseased colonies, and the other bee-keepers were consenting to have the few worthless colonies burned. I am also pleased with the way all the other bee-keepers took hold, and cured their diseased colonies, that had foul brood in the summer.

While examining their colonies to see if the bees had enough honey for winter, some people found things not right and I found it to be pure foul brood. I explained how to cure it in the most profitable way, and put everything in order.

My time, carefare and livery-hire, was \$525.90

Ontario, Canada, Dec. 6, 1897.

No. 4—Recollections of an Old Bee-Keeper.

BY DR. E. GALLUP.

(Continued from page 36.)

Now I propose to tell of things I learned from Mr. Wellhausen. His queen-cage was a hollow reed, or milkweed, about the size of my little finger. At one end he inserted a common plug, and at the other end he used a long, sharp plug of wood. In one side he cut out a slat nearly $\frac{3}{16}$ of an inch wide, and nearly as long as the hollow. This was for the queen and workers to communicate through. When all was ready he would raise or tip up the hive, smoke back the bees, and stick the long, sharp plug right into the comb. For introducing, instead of the lower plug he would insert a piece of comb and honey, and then take a long, fine needle and pierce through the center of this comb, then the bees would cut all out, and liberate the queen on the most approved plan now used, only we use candy.

For a queen-cell protector he used a short piece of reed

without the side slit, fit the cell into the top end so the point was only exposed, insert the sharpened plug, and insert the cage among the bees as above, and he had a perfect cell-protector. He used them for hatching-nurseries also. Now, if I am not mistaken Jewell Davis derived or received hints from me that enabled him to get up his queen-nursery; at all events, we corresponded on the subject, and he sent one of his first ones to me.

The old gentleman saved all his natural queen-cells in the above manner, and then his hive being small at the top, a very small quantity of bees would commence right, by giving them a queen or a protected queen-cell. He had his queens fertilized from those small nuclei.

Then to build them up, he would draw out bees from any populous colony, hunt up the queen and return her, sprinkle the bees well with diluted honey, shake them down in front of the nuclei, and the reinforcements would stay where he wanted them to.

Now you can readily see where I obtained my ideas of rapid and safe increase. His hives and all his appliances were primitive, but as effectual as the most approved appliances we have now, with the exception of the movable combs, honey extractor, etc. The fact is, I received my first real insight into successful box-hive bee-keeping from Mr. Wellhausen, even if I did not believe in the witches!

His method, or one of his methods, of introducing queens was to drum out a sufficient quantity of bees, deprive them of their queen, sprinkle with diluted honey, and then liberate a queen among them, either a virgin or fertile one; hive them in an empty hive, and they have been accepted every time. I do not remember ever making a failure by introducing in the above manner. You understand they have neither comb nor brood of any description. Then if sprinkled and completely gorged with sweets, there is every incentive for them to behave themselves, and they do.

By the way, the past summer I reared a fine batch of queen-cells, and made nuclei consisting of two frames of brood and the adhering bees, and inserted eight cells in the West queen-cell protector on the tenth day, and I lost five out of the eight. Too much cool metal about the cell, which caused them to perish. With the milkweed cell-protector I could have saved every one. Our nights here are quite cool. I have lost some, where I introduced them in the center of strong colonies early in the season. I do not say that I lost them by bad handling of the cells, for I do know how to handle queen-cells.

Bees did remarkably well in the prairie country in Wisconsin in an early day, but before I left all was under cultivation, and the white clover had not gotten into the pastured land sufficiently to produce much, and the golden-rods were killed out pretty effectually, so that bee-keeping was not so profitable except in the vicinity of timber, and especially where the linden was abundant.

About the time I had tried Mr. Wellhausen's methods pretty effectually, I searched the book-stores, both at Fond du Lac and Milwaukee, for bee-literature, and found "Quinby on Bee-Keeping," and that was quite a help. Soon after a Langstroth agent began selling the Langstroth hive and rights, and that disgusted me pretty effectually. Don't fly in a passion, and I will tell you the reason why. He introduced a 7-inch deep, 10-frame hive, and never gave any instructions about collar-wintering, and the consequence was every colony put into them perished in wintering, and any person of common sense (as I said) ought to know better. The frame was but a trifle over 6 inches in depth.

When the agent came around to me and began to "ex-platterate" on the advantage of his hive, I gave him a grand blowing up, and plainly told him that bees could not winter in such a shallow hive, and gave my reasons why. I informed him that the principle was grand, but that he was bumbugling people out of their money and their bees.

Orange Co., Calif.

Use of the "Divider" in Producing Honey.

BY S. T. PETTIT.

Believing it might be interesting to the readers of the American Bee Journal to know of the success the past season of my system of taking comb honey, I send a brief account.

The fact is, the gratifying success attending the new way was simply a marvel to myself. My bees were very strong—they were all that could be desired, with few exceptions, when the flow began; and of course I neglected nothing, everything was done just at the right time and in the right way, according to my judgment, and the work went on nobly, the filling up and finishing satisfactory indeed, the quality and finishing

up of the sections so far ahead of anything I could ever get under the old way.

It would be gratifying to me, and profitable to all who try my way, if they would follow instructions carefully. This year I used a large number of dividers with $\frac{3}{8}$ -inch holes, and they worked all right; no bulging of the combs and no burr-combs. The bees can just walk right through those $\frac{3}{8}$ -inch holes leisurely and easily, and that is the way they move when building combs. Of course, the holes must be pretty close together—there are 122 in each divider, as I make them now.

Here is a point I must call attention to, that is, if it be necessary to use followers to fill up space, there must be no passage-ways for the bees outside the followers; the bees must be kept, and obliged to do their coming, right against the divider.

I have thought a good deal about it, and can hardly tell why I would like to have the space outside the divider, that is, the space between the divider and super wall or follower, if one be used a little more than a quarter inch. Very likely you will say, "Let well enough alone." Good advice, I agree, but for all that I shall test the matter pretty largely, all being well, the next season, with a five-sixteenth inch space.

Ontario, Canada.

Leveling Down Unfinished Sections.

We received this question some time ago, which we referred to the bee-keepers named for reply, and their answers follow:

MR. EDITOR:—Two or three of the men replying on page 734 (1897) say they would use unfinished sections with cells full depth, providing they are clean and white, but the others all want them leveled down. According to some there is great advantage in using such sections, the bees being thereby saved time and labor. But I don't want to spoil my sections by using too deep cells. On the other hand, I don't want to lose any advantage by cutting down more than is necessary. Will you kindly ask Messrs. Doolittle and Larrabee to tell us why they would cut the cells down to $\frac{1}{2}$ inch in depth, providing they are white and clean?

It would also help decide what to do if Messrs. Brown, Dibbern, Demaree and McEvoy would tell us why it is necessary to have the cells less than $\frac{1}{2}$ inch in depth.

LEARNER.

MR. M'EVoy's ANSWER.

I get a finer quality of honey, and more fancy finished sections.

WM. M'EVoy.

Ontario, Canada.

MR. BROWN's ANSWER.

In reply to "Learner's" inquiry for more light on Query No. 63, I would say that my experience with cells full depth, or deeper than half inch, gives a somewhat tougher comb of honey; that is, when said combs are kept over from one season to another before being filled. Also, in my limited experience it has seemed that the honey stored in sections having full-depth cells was not as thick and of as nice quality as the same honey in sections that the combs were reduced to $\frac{1}{4}$ to $\frac{3}{8}$ inch in depth, or those built from foundation starters. Partially drawn combs are very good for "bait sections;" that is, to get a start made in the supers; but farther than this I should only class them as of no more value than full sheets of foundation of the weight of about 8 square feet to the pound.

Volusia Co., Fla.

A. F. BROWN.

MR. DOOLITTLE's ANSWER.

As far as I know there is only one reason for the comb-leveler, and that is to get rid of the thick edges to the cells (which generally are of a dingy-colored wax), so that the bees will lengthen out the cells with new wax the next year, thus completing the combs so that they will look equal to those built out entirely new from the foundation. Comb honey sells from looks, and if the old comb which is carried over winter is allowed to remain full-depth cells, then the bees simply fill them with honey and use the heavy rim of old wax to cap the cells with, thus giving the honey a dingy or inferior look. The leveler is used to remedy this, and the less comb that is melted away, only that we may accomplish our purpose, the better. As I use sections whose combs are only $1\frac{3}{8}$ thick, it is necessary to level them down to about one inch to accomplish what I wish. If I used 2-inch sections then I should leave the combs after leveling about $1\frac{1}{2}$ inches. I think this will make the matter plain to "Learner."

G. M. DOOLITTLE.

Onondaga Co., N. Y.

MR. LARRABEE'S ANSWER.

I have never had any very great experience with leveled combs, but have had quite an experience with unfinished sections, and I find those that are about an inch in thickness the most desirable.

The thickness of the comb in a 1½-inch section with separators (which I always use) is about 1¾ inches. If the combs are leveled down to one inch, the bees are obliged to thicken the combs ¾ of an inch, or lengthen out the cells 3\16 on each side; this is enough to cause white wax to be put on the ends of the cells and also cap white. If the combs are soiled in any way the stain will be covered up by the white caps.

I do not think it necessary to cut the cells down any more than just enough to cause the bees to lengthen them a little. If they are cut down more, in my opinion it simply makes unnecessary work for the bees to draw them out again.

If the cells are left full depth after extracting, they will not be capped as smooth nor as white as they would if cut down a little.

I think this explains why I said the combs should be cut down to about one inch. W. G. LARRABEE.
Addison Co., Vt.

MR. DIBBERN'S ANSWER.

Years ago I always used unfinished sections from one year to another, but invariably in handling over the finished sections afterwards I could pick out all the sections having contained unfinished comb, and they were always unsatisfactory. I tried extracting all the honey from such sections, and having the bees clean them up, but the result when again completed by the bees was much the same. The combs would be rough, unsightly, and many combs would bulge off the capping, showing that the honey was souring.

At one time, in my desperation, I advised bee-keepers to extract the honey from all unfinished sections, cut out and melt up the comb, and make kindling wood of the sections. This policy, however, while overcoming my objections, looked too much like a wasteful proceeding, and then, too, these sections were so nice for "baits."

Well, finally, I adopted the policy of destroying all sections and combs that were much soiled by propolis, and cleaning up new ones containing white comb, and cutting down the cells with a thin, sharp knife, to about ¼ inch of the base. This worked very well, and the bees built readily in them, and the finished comb was nice and smooth, and no tendency to the honey souring appeared. This convinced me that it was in the depth of the cells where the trouble lay.

When Mr. Taylor brought out his comb-leveler I at once adopted it as a much handier and neater operation, and it has proven entirely satisfactory. C. H. DIBBERN.
Rock Island Co., Ill.

MR. DEMAREE'S ANSWER.

The letter of "Learner," relating to the use of sections that have been brought over from the preceding year gives the writer the opportunity to answer the question referred to by "Learner" more fully than could be crowded into the limited space assigned to the "Question-Box" of the American Bee Journal.

In the first place, I use all fairly-preserved sections of the preceding year as a matter of economy. If such sections have been nicely kept over the winter, and properly managed, the quality of the honey will not disappoint the apiarist. Let it be remembered that climatic causes—state of the weather—during the time the honey is being stored by the bees in drawn-out, or partly-drawn combs, has much, if not everything, to do with the quality of the finished sections. If the state of the weather is in every way favorable—in my locality—fully drawn combs will give first-class honey. But the uncertainty of the condition of the atmosphere in the general way makes it safer to level down the combs with a hot plate, and take no risk.

Some may ask why it is that good, dense honey is taken with the extractor from fully drawn combs. We have only to answer that the conditions are decidedly not the same. In a set of extracting-combs the bees instinctively spread out the honey in the (extracting) combs, and thereby aid in the evaporation of the excess of water in the nectar; while in the section-cases the work is more concentrated, and the drawn-out combs are sometimes filled and sealed before the nectar is thoroughly seasoned. Before I began to thin down the combs, I sometimes in the same season had first-class honey and a poor quality of honey in full-depth combs—notwithstanding only a week or two intervened between the storing of the grades. The conditions of the weather made the difference in the quality of the honey.

It is a fact worthy of notice here, that I have had the quality of honey injured by being stored too profusely in full-sized Langstroth frames when the weather was unpropitious.

When you apply the uncapping-knife to a sealed comb, if the surface of the honey in the cells lies smooth and placid, all is well; but if sparkling, little, beadlike bubbles lie on the surface of the uncapped honey, you had better keep that honey to itself, as slight fermentation is present.

Every well-informed apiarist ought to know his environments best, and shape his course accordingly.

After testing the matter, and finding that in some seasons I can get a good quality of honey by using the brought-out sections just as the bees left them the year before, while in other seasons the quality of the honey is injured by slight fermentation, which produces pressure against the cappings and gives the water color, I now prefer the extra work to avoid all danger of loss, by thinning down the combs to ½ or ¾ inch. Shelby Co., Ky. G. W. DEMAREE.

Various Things and a Report for 1897.

BY L. M. WILLIS.

Fifty-two copies of the "Old Reliable" are worth the best dollar made, to any one interested in the pleasing pursuit of sweetness and health-giving products. No, this isn't "taffy," Mr. Editor, but just a plain statement of facts, which, if necessary, I can substantiate. I have been so absorbed of late in the writings of those so much better qualified than myself to tell of their honied experiences, that I came very near forgetting to pay for those droppings of wisdom and information, which have been, and will always be, of interest to me. For a lingo I have sold out and intend to quit the keeping of bees in this locality, it doesn't matter, I shall want the paper just the same; and were I to take up millinery as a means of livelihood, if only for the pleasure of keeping in touch with the generous hearted and indefatigable old liners and promising recruits who so ably assist you in doing a noble work. And if perchance I should find myself transplanted to the peach orchards of Michigan, or among the orange groves of California, you may be assured of my kindest regard for you and them.

Our honey crop here was cut short by too much rain in the early part of the summer, for a lingo we had an abundance of clover blossoms, very little white honey was stored in the surplus boxes, and for nearly three weeks the sections were neglected almost entirely after being about half filled. Later we were favored with a flow of yellow honey with which the bees filled and capped the sections; and while this made us feel a little "down in the mouth," we were obliged to admit that it was an improvement upon the previous state of affairs.

Basswood was cut off by a late frost. My surplus amounted to about 1,700 pounds from 31 colonies, spring count, and increased to 50. My best colony filled six 24-pound supers, and eight Langstroth frames above the main hive. Of course they did not swarm.

And now I've a nut for that genial gentleman, Mr. C. P. Dadaot, to crack for us. The colony just referred to is one of the first I bought eight years ago. It is in an 8-frame hive. The frames are eight luges in depth, and 17¾ inches long. The hive contains but seven frames with V-top-bars. This colony has always carried off the honors in honey-producing; some seasons they have cast a swarm, but only one. These swarms do well, but not much better than others I had. The bees are 3-banded, and the most docile of any I had in the yard. The bottom of the hive they are in is nailed fast, so it can only be ventilated by raising the cover. Now, is it the bees or the hive?

I think the past summer was the banner summer for cross bees in this section. I never saw them so utterly depraved before.

Taking my information from careful inquiry, I can report a falling off of about 50 per cent. in the honey crop from that obtained last year, and the most of this is second and third grade goods, tho there is a decided improvement in the manner of preparing it for market.

I was exceedingly pleased with Dr. Miller's report of his grand crop of honey, and it's all right, too; he deserves it, for the Doctor is a real nice man, even if he will tell people that he "don't know" the answer to their questions—when he doesn't. And then just think of all that sugar he fed his bees a couple of years ago for winter stores! His bees hadn't forgotten that. Clark Co., Wis.

[Mr. Willis desired very much that the above article appear before Jan. 1, but that was quite impossible, we regret to say. We have quite a good deal of valuable correspondence that has had to wait its turn.—EDITOR.]

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Placing Bees Near Line Fence.

How near to the public highway, and how near to another boundary line fence, by the laws of Illinois, can bees be kept? Can one's own bees be followed and hived on another's land? SUBSCRIBER.

ANSWER.—By referring to the American Bee Journal for Dec. 23, 1897, page 810, you will find an answer to the same questions.

Ants in Hives.

My bees were troubled with ants last summer. They got in under the super between the super and the hive.

WISCONSIN.

ANSWER.—As a rule, ants in the North are not likely to do any material damage. Perhaps their chief object is to secure the heat of the hive for their nests. Bees will not suffer them in the hive, and the easiest way to be rid of them is to have no places to shelter them where a bee cannot also enter.

Wintering in a Bee-House.

Last winter I lost 51 per cent. of my bees. This winter I made a bee-house by digging $3\frac{1}{2}$ feet into the ground and walling it up $4\frac{1}{2}$ feet, and covered it with straw and dirt. I keep some potatoes in it. It does not freeze. It has double doors, and the temperature I keep at 40° . I put the bees in on 2×6 inch scantling edgewise. I have 40 colonies in it, and 9 out-doors in chaff hives. Ought I to take off the bottoms of the hives, or the tops, or both? I put them in about four weeks ago. Do you think my bees are all right?

IOWA.

ANSWER.—It seems that your bees ought to be pretty well off. Possibly 40° is not so well as 45° , but that's not certain, as your thermometer may mark low. The true test is the quietness of the bees. That point of temperature that will come the nearest to making a dead stillness is the best. If you think it would be better to have it warmer, that can be accomplished by banking up around the walls above ground with earth or straw.

If the tops of the hives are close, and the entrance at the bottom not more than $12 \times \frac{1}{2}$, you will do well to give more ventilation. The easiest will probably be to have the bottom entirely open and leave the top closed.

Eight Questions with Replies.

1. Should I look inside of my hives to see how the bees are getting along in midwinter? Or should I leave them until spring and take the chances?

2. I have one hive of bees that is without any honey. I gave them sugar syrup. Is there any danger of it drying up so they cannot eat it?

3. Is there any danger of the bees smothering to death if I make the hive top air-tight, with a $\frac{3}{8} \times 2$ inch entrance at the bottom?

4. Will thin foundation do for brood-frames when you have it on hand?

5. Will stiff paper do for separators?

6. Are separators necessary when you use starters or full sheets of foundation?

7. Do bee-keepers use separators when using large frames for extracted honey?

8. Will the bees work as well with the entrance at the side of the frames?

VIRGINIA.

ANSWERS.—1. Probably they'll do better if you let them alone.

2. You probably mean the syrup was fed in the fall. Generally there is no trouble about its granulating in the win-

ter, and yet some cases have been reported where it turned back to sugar in the combs, even after tartaric acid had been used to prevent granulation. But if it was fed early, and not too thick, you hardly need expect any trouble.

3. Yes, there's considerable danger. Better raise the whole hive at the front at least a quarter of an inch, putting a block under each front corner, and then keep a sharp lookout that the entrance doesn't become clogged with dead bees.

4. Not very well. It will stretch and sag too much. By wiring close enough you might make it do.

5. Hardly. Bees would tear it down. Even a very thin wood separator will be gnawed more or less.

6. I fill my sections full of foundation, and it would be hard to hire me to do without separators. If you don't care to ship the honey, then it doesn't matter so much. The sections of honey will eat all right on your own table, if you use no separators.

7. Very few do so, and probably none.

8. Probably there is little difference. In Germany it is quite common to have the entrance at the side of the frames, which is called "the warm system," while the opposite or cold system is mostly used in this country.

One or Two Glasses in a Solar Wax-Extractor.

In making a solar wax-extractor is it better to use two glasses with a space between, in the cover, instead of one glass?

MONTANA.

ANSWER.—Only one glass is used. It is doubtful if a second glass would be any improvement.

A Question About Bee-Stings.

When a bee stings a human being severely, its sting is torn from it, and remains in the flesh of the person stung. Now, when one bee stings another, why is not its sting also torn from it?

MASS.

ANSWER.—I wouldn't like to speak with too much positiveness on this question, but I think usually when one bee stings another the sting is thrust into one of the breathing holes from which it can be withdrawn without being torn from its owner. Occasionally, however, the sting enters one of the joints, and then the sting remains fast as when a person is stung. I think I have in more than one instance seen a bee with a sting sticking in it, the sting having been torn from its owner.

Out-Apiaries, Bee-Houses, Etc.

1. If out-Apiaries are kept, how far should they be from the home-Apiary?

2. How many colonies do you think likely to return the best results in a single Apiary in Northern Illinois?

3. If colonies are kept at home in winter when should they be removed to the out-Apiary in the spring, and when returned in the fall?

4. Do you think it would be practicable to keep the colonies of an out-Apiary in a bee-house and winter them in it?

5. Those who have reported on the bee-house, have noted bad results from the cool shade on the west side in the forenoon and the east side in the afternoon. Do you think it would be practicable to make a long, narrow house with all the hives facing south?

6. Could 50 or 60 colonies be kept in such a house without confusion, if it were painted in various colors and otherwise marked?

"CHUCKLEHEAD."

ANSWERS.—1. If we accept that bees work to advantage as far as $1\frac{1}{2}$ or 2 miles from home, then an out-Apiary should be at least three miles from the home Apiary.

2. That's one of the very, very hard questions. I've been trying to get all the light possible upon it for years, and I confess I'm very much in the dark yet, with no brilliant prospect of ever seeing a great light in that direction. One year, where Jones lives, 30 colonies will overstock the locality, while in Smith's locality 150 colonies will not crowd each other. The next year the conditions may be exactly reverse, and the year following each place will be alike overstocked with 50. There being no sort of regularity about it, how are you going to establish any rule? There seems to be a more or less general idea that 100 colonies in an Apiary cannot be far out of the way, but likely one reason for that is that 100 is a round number. On the whole I've rather settled down to the opinion

that I don't want to start the season with more than 80 colonies in each apiary in northern Illinois. Six hundred colonies have been kept in one apiary in California all right, but it may yet be an open question whether in a series of 10 years 300 colonies might not give better results than 600 in that same place.

3. After being taken out of winter quarters they can't be moved any too soon to the locality they are to occupy for the season. As a rule, very early pasturage is none too plenty, and by moving part of your bees you are practically increasing the pasturage both of the ones moved and of the ones left at home. The later they are brought home in the fall the better, *provided* they have a good flight after moving and before putting in the cellar. Perhaps the safe thing is to haul them home not later than the middle of October. After that time there is little chance for gathering, and if left much later they may lose their chance for a flight. Still, most years they're safe for a flight as much as a month later.

4. Some report success at it.

5. Certainly, only it would cost more. But some report just as good success with hives facing some other direction.

6. Probably there need be little trouble in that direction, but I'd put more confidence in some other things than color, altho I think color helps. When you decide you will make something of the kind, ask further about it, and I'll be glad to give what help I can toward having colonies mark the right places.

Drones from Queen and Laying Worker.

Are drones reared from drone-eggs laid by a queen in drone-cells the same size as drones from eggs laid by a laying worker in worker-cells?

IOWA.

ANSWER.—A drone reared in a work-cell is smaller than one reared in a drone-cell, no matter whether the egg is laid by a worker or a queen. The reason seems to be that there is not room enough for a drone to grow to his full size in so small a cradle.

Sweet Clover—Sowing and Growing It.

Would it be best to sow sweet clover along with oats in the spring, or wait until the oats are harvested? How much seed to the acre? Will it grow from the root like other clover, or will it kill it to cut it for hay?

IOWA.

ANSWER.—Sow in spring, using rather less seed than you would of red clover. Better cover the seed deep, and let the soil be well packed. If you sow shallow, and the ground is loose, it may heave in the winter and every plant be killed. Remember it lives over only one winter, not blooming till the second year, after which it dies root and branch. You are not likely to hurt it by cutting first year, but some report that they have killed it the second year by cutting too low and then having a dry spell follow. Of course, cutting it late the second year can make no difference, for it will die the second winter anyhow.

Higher or Lower Elevation for an Apiary.

Does an apiary located on quite an elevation have as good a chance to secure a crop of honey as one that is located on rather low ground, with nearly all the pasturage on higher ground than the apiary? Mine is located upon quite a high hill, and nearly all the nectar has to be carried uphill, some of it for two or three miles. It seems to me that I have to pay more attention to keeping up the strength of my colonies to get the same amount of honey that I would get on lower ground, as they seem to wear out faster. Would it be a good plan to remove them to lower ground? I get as much honey per colony as any one in this section of the State. How much difference is there per colony with the same management between the two localities with about the same amount of forage?

MAINE.

ANSWER.—Your question is an interesting one, and in some cases an important one. Without an experimental knowledge on the subject, I should suppose that the matter of elevation must be a decided factor. Of course, comparing an elevated site with a lower one, if the pasturage is poor for a mile about the lower one, and good in the other case, it is not hard to decide that the elevated site should be the better, but no doubt your desire is to know the comparative merits of the two places, supposing the pasturage is the same. Unless there is some factor in the problem that I don't see, it is

simply a question as to the difference made by lifting the loads of nectar to a point so many feet higher. I doubt whether any definite answer can be given to your question farther than to say that there will be a difference in favor of the lower site. For I think it must be that the extra labor involved in carrying a load up a greater height must allow a bee to carry fewer loads in the course of its life.

Now there's very little satisfaction in an answer of that kind, but you see there's very little in the way of data to base a fuller answer. For nothing is said about the difference in elevation. A difference of a foot in elevation would probably make no appreciable difference in results, while a difference of half a mile might make all the difference between failure and success.

Even if exact figures were given as to difference in elevation, I don't know enough to say what difference there would be in results, and will gladly yield the floor to any one who can throw light upon the subject. Until you do know more about it, if it is at your option to choose between the two sites, why not divide your bees between the two places, and then you could have a better chance to know what was best for you? Of course it would not fully decide the question you ask, for you must remember there may be local differences that do not appear on the surface, making one site better or worse than the other, regardless of the matter of elevation. But the important question with you is to know which place would give you best results, and that you would have some chance of learning by keeping bees in the two places at the same time.

After you've considered all other points, don't forget that as you already get as much honey as others in your section, it may not be wise to be in too much of a hurry as to making a change.

Why Do Absconding Swarms Fly West?

In my locality absconding swarms nearly always go west. It is a very rare thing to see them do otherwise. I wish to know why they do so.

W. VA.

ANSWER.—I don't know why it is, unless it results from the persistent repetition of Horace Greeley's advice. Possibly timber to the west of you may be nearer or more suitable. And yet it seems to me that others have reported that swarms almost invariably went west where there seemed no reason for it in the surroundings. I give it up, and leave the question open for any one who has the right answer.

Alfalfa—How to Grow It?

I see much said about alfalfa clover as a bee-plant. When and how should it be sown? Should it be sown with some other grain or grass? How much seed to the acre should be sown?

TENNESSEE.

ANSWER.—In its favorite haunts in the West, alfalfa is one of the finest honey-plants, but in other places, even if success is obtained in getting it to grow, I don't remember seeing any reports that bees paid much attention to it. So it will be well for you to attempt it on only a small scale until you see whether it will be worth while. Give it the same treatment as to sowing that is successful with red clover in your vicinity. The hardest part is to get it through the first year.

Korean Bee-Keepers, says L. Lionville in *L'Apiculteur*, call the queen the "king," or rather the "general," and the drones "females" or else "soldiers." They don't harvest the honey till the last of November, as they say it won't keep.

Hornets and Wasps.—W. F. Reid, in the *British Bee Journal*, says he has been making a careful study of hornets, and has come to the conclusion that instead of being an enemy to bee-keepers they should be considered as a friend and cherished accordingly. Several hundred hornets were caught and their prey examined, and in only a single case was a bee found to be the victim. Toward the close of the season at

least 80 per cent. of their victims were wasps which are generally considered in England as deadly foes of bees. And now comes "The Bee-Master" to say a good word for the wasps. It says if people only knew the benefit wasps are, they would never kill one; that a good wasp-year is a good honey-year, and that wasps do more than bees to help the fruit crop.

The Plain Section.—says F. A. Gemmill in Gleanings, needs very careful handling on the part of the retailer, so as not to stick his clumsy fingers into the surface of the comb when removing sections from the shipping-crate, causing them to bleed, etc.

The French Section.—While there is some talk in this country of a section higher than $4\frac{1}{4}$ inches, Revue Internationale mentions the "French section" advocated by it some years ago, measuring $5\frac{1}{2} \times 4\frac{1}{2} \times 2$, and weighing when filled a little more than a pound.

Spoiling the Market.—E. T. Abbott thinks it isn't the farmer with his poor honey and low prices—rather the poor honey helps to sell the better by its contrast—but the mixer with his adulterated goods put up in attractive form, and the producer who ships to a glutted city market and then cuts the price.—Gleanings.

The Capacity of Brood-Chamber, says abbe J. B. Voirnot in L'Apiculteur, should be in a box-hive 40 liters (2,439 cu. in.), and in a frame hive 50 liters (3,049 cu. in.). Quinby, in his day, put the capacity of a box-hive at 2,000 inches. A hive with 11 Langstroth frames would be about Voirnot's standard for a movable-comb hive.

Foul Brood Finishes an Apiary in 3 Years from the time it is first introduced if left entirely to itself, according to the experience of R. C. Alkin. He tells of a well-read bee-keeper in whose apiary he lately found foul brood that had been present, he thought, for two years. He allowed his bees to swarm, and never opened a brood-chamber. A case of too little handling of bees.—Gleanings, page 8.

Honey-Vinegar.—Lefebvre-Duchange relates in L'Apiculteur that after extracting he soaked the extracted combs 24 hours in a tub of water, then upon extracting them got a dilution of honey of 6 ounces to a quart of water. One who had no other use for his time might find this a good way to make vinegar. In rare cases it might be a good plan to clean the combs in this way where not convenient to have the bees do it.

Tin Packages for Honey Safe.—Some discussion has occurred in the British Bee Journal as to whether tin packages would damage honey. Otto Henner, President of the Society of Analysts, examined a large variety of articles put up in tin. Very acid fruits corrode the tin; in animal foods (sardines, salmon, etc.) only a trace of tin was to be found, and only the slightest trace in honey. He considers it very foolish to arouse any fears in this regard.

Rearing Queens.—"If the 'South African Deacon,' as Mr. Edwin Bevins calls him, will fill a 10-frame hive with combs of brood, place it over a prosperous colony with an excluder between, and 11 days later remove all cells in the upper story and shake all bees from the bottom body into it, placing the latter with queen elsewhere, he will have bees in the right condition to accept, start or build cells, and the brood or prepared cups should be given as soon as the bees show the queenless sign."—W. H. Pridgen, in Southland Queen.

Three Side-Cut Sections.—In the British Bee Journal there seems to be much discussion with regard to sections split in two on top and two sides, some controversy as to the invention, and mention of a patent. The section is folded and locked, then pulled apart sufficiently to admit the foundation, after which the parts are tightly prest together, and the foundation holds them together. Simmins' plan is to have a sheet of foundation long enough to fill three or four sections, and after the sections are put together the foundation is cut apart. Sladen's V-slit section has, as its name implies, a V groove running lengthwise, cutting nearly or quite through the section, the V groove being the same as the familiar one cut crosswise in the one-piece sections. These sections have been used more or less for more than ten years in England, but have not seemed to waken very general interest until lately. Possibly one reason for the interest in this matter in England,

and the lack of interest in this country, is the fact that little is known comparatively in England of the different machines, Parker, Daisy, etc. for putting foundation in sections. In that excellent work by Mr. Cowan, the "British Bee-Keepers' Guide-Book," even as late as the 1896 edition, no mention is made of any of these foundation fasteners. An Englishman would probably ask whether Americans knew nothing of other ways of fastening foundation that they should use the machines they do, and an American would wonder how Englishmen can putter as they do and not adopt a beated-plane fastener.

Temperature for Brood-Rearing.—In a normal colony, with brood-rearing going on, Doolittle says 92° is the lowest he found in the brood-nest when the air was down to freezing outside. When the mercury stood at 90° in the shade, the brood-nest was 94° , and it never went above 98° in the brood-nest, even when it was a little higher than that outside. So he concludes the bees have the ability to raise or lower the temperature, keeping it from 92° to 98° . And it seems they have the ability to raise Doolittle's temperature tremendously, for after working with bees nearly 30 years, as he relates in American Bee Keeper, his bee-fever is now at white heat.

The Winter Consumption of two colonies in a twin hive with partitions, according to Devauchelle, in L'Apiculteur, is $6\frac{1}{2}$ to 7 kilograms (about 14 to 15 pounds), while a single colony consumes 5 to 6 kilograms (11 to 13 pounds). That agrees with the generally received opinion that a strong colony consumes less according to its weight than a weak one. According to Devauchelle's figures, a colony twice as large as one that consumes 12 pounds, instead of consuming 100 per cent. more, will consume only about 23 per cent. more. Hence economy of stores in uniting two weak colonies in the fall rather than to wait till spring.

Bright Yellow Beeswax is secured by the following method, says Edward Ochsner in the Review:

"The material for such wax comes only from white comb, cappings and burr-combs, and these are always kept separate from the old, dark brood-combs. To render the wax f heat a boiler half full of water, then put in the cappings and burr-combs until the boiler is $\frac{3}{4}$ full, and keep a slow fire until all the wax is dissolved, when the boiler is set off. Just before the wax is too cool it is dpt off, care being taken to get no water, and strained through cheese-cloth into tin or earthen vessels that have been moistened with honey or water."

Prevention of Swarming.—G. M. Doolittle gives in Gleanings a plan that he thinks well worthy of trial, as in a single season's experience the plan has proved entirely successful with him. First, as many queen-cages as necessary, $4 \times \frac{1}{8} \times \frac{1}{2}$ made of wire-cloth with a wooden plug $\frac{1}{2}$ inch long in each end, tacking fast the plug at one end. When swarming-time comes, say a week or ten days before honey harvest, cage the queen and lay the cage on top of a bottom-bar four or five inches from the entrance, cutting away enough comb, if necessary, for that purpose. Wait 9, 10, or 11 days, at your convenience, then make sure to destroy all queen-cells, remove the stopper from the queen-cage and replace it with a stopper two inches long having a $\frac{3}{8}$ hole bored lengthwise filled with fresh queen-candy. That's all you do. The bees do the rest, and will not swarm unless the honey-flow continues more than four weeks.

The Plain Section, which is the better name (certainly the plainer name) for the no-bee-way section, is one of the things L. A. Aspinwall has been working with for some time, as he relates in the Review. Instead of the fence separator, he uses a tin separator with openings cut so as to allow ready passage from one section to another throughout the entire length of the upright pieces or sides of the sections.

He uses a super of peculiar construction, a sort of knock-down affair, that is held together by rods or bolts with screw and nut, allowing expansion, so that 20 sections may be used in a super, and as easily 24, 28, 32 or 36.

The plain sections, he claims, cost about 20 per cent. less than the old style. They look better, and will bring a better price, especially as the consumer buys $1/9$ less wood in the plain than in the old-style section. A saving of 20 per cent. is made in shipping-cases. The plain section admits of being cleaned by machinery.

Mr. Aspinwall is especially enthusiastic as to the beauty of the finish product as secured with his supers and separators, his honey bringing the highest price in spite of the ruinous prices at which honey is sold right beside it by farmer bee-keepers.

OLDEST BEE-PAPER IN AMERICA

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., CHICAGO, ILL.

\$1.00 a Year—Sample Copy Sent Free.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—W. Z. HUTCHINSON.
SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT. E. WHITCOMB. E. T. ABBOTT.
W. Z. HUTCHINSON. DR. C. C. MILLER. C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Vol. XXXVIII. CHICAGO, ILL., JAN. 27, 1898. No. 4.

The Langstroth Monument Fund.—It has been a long time since we have had much to say in regard to this undertaking in honor of the lamented Langstroth. But Editor E. R. Root (who has had some correspondence with Mrs. Anna L. Cowan, the daughter of Father Langstroth) suggests that bee-keepers *at once* raise the fund to at least \$75. He reports that in all, so far, \$60 has been contributed. If we mistake not, nearly half of that amount came from bee-keepers in foreign lands. Now we think that at least a total of \$100 should be raised, and that it can be done before March 1, if each bee-keeper at all interested will send in his contribution during February. Why not do it?

Send to us, if you prefer, what you feel like giving, and we will report it in these columns; also on March 1 we will forward all in our hands to Editor Root, who will put it in with what he has received, and forward all to Mrs. Cowan, to be used in the purchase and erection of a monument which shall serve to mark the resting place of the body of Rev. L. L. Langstroth—the bee-keepers' loving friend and greatest benefactor.

Now let the contributions come in lively from this time until March 1. Don't delay because you can't give largely. Give just what you feel you can.

Trans-Mississippi Exposition Notes.—On the first page of this number we show a fine view of the Trans-Mississippi and International Exposition as it will ap-

pear when it opens, June 1, 1898. It is through the kindness of the Department of Publicity and Promotion that we have the illustration to show to our readers. Mr. Edward Rosewater, editor of the Omaha Bee, is the chief of that department.

The Bureau of Bee-Industries is in the good hands of Hon. E. Whitcomb, of Friend, Nebr.—the tireless worker in behalf of American beedom. He suggests that bee-keepers and supply dealers who contemplate taking space in his department should not forget the advertising facilities offered them through making displays in that section of the great Exposition. In addition to the space accorded exhibitors, the Exposition will furnish each exhibitor ordinary light, ordinary guards, 20 words each in 100,000 official catalogs free of charge, and all expense pertaining to the jury of awards. These items alone will cover every cent received by the management for space received by exhibitors.

Rev. Emerson T. Abbott, of Missouri, a State Commissioner, has been appointed on the committee of his commission on horticulture, etc. We may reasonably expect some good displays from that State.

Mr. R. C. Alkin, President, and Secretary F. Raufuss, of the Colorado State Bee-Keepers' Association, are making a determined effort to have that State properly represented in the Bureau of Bee-Industries.

Mr. Pollock, Secretary of the Wisconsin Commission, visited Omaha the second week of this month, so we will likely hear from Wisconsin in the near future.

Wisconsin Convention.—The 14th annual meeting of the Wisconsin State Bee-Keepers' Association will be held Feb. 2 and 3, 1898, in the Dairy and Food Rooms of the Capitol Building at Madison. Many prominent bee-keepers have promised to be present, and also with a grand display of bee-supplies. Important subjects pertaining to present methods of bee-keeping and marketing of honey will be discussed; also as to what shall be done to make the Wisconsin honey display a credit to that State at the International Exposition to be held in Omaha from June 1 to Nov. 1, 1898. The State Bee-Inspector's report, and the free for all question-box with answers and discussions will pay any Wisconsin bee-keeper to attend and take part. All are invited to attend, of course. Mr. N. E. France, of Platteville, Wis., is the Secretary. Address him for further particulars if desired.

California Favors Amalgamation.—We learn that at the recent annual meeting of the California State Bee-Keepers' Association, held Jan. 10 and 11, the subject of the old and the new Bee-Keepers' Union was taken up for discussion, and the result was the passage of the following resolutions, there being 43 votes in favor, and no opposition:

Resolved, That the new Union should absorb the old.

Resolved, That the Secretary be instructed to inform the respective managers of the Unions of this action.

We think that extended comment on the foregoing is hardly necessary, as it is so evidently wise an action that it must commend itself to bee-keepers of all sections of the country. And coming from California, where is located such a large proportion of the membership of the old Union, it seems to us it can scarcely fail to have great weight in bringing about a speedy uniting of the two Unions. We trust it may, and that thereafter there may be a bending of every energy on the part of all to build up an organization that shall do even grander work than has the old Union, if that be possible.

The New Union's Amended Constitution.—In the Bee Journal for Oct. 14, 1897, page 649, we printed six amendments that were approved by the Buffalo convention, and which were submitted to a vote of the mem-

bership of the New Union in December—last month. We are informed by General Manager Secor that there were 108 votes cast on the amendments, and as the highest number of unfavorable votes cast on any one of the six amendments was only 8, all were practically carried unanimously.

That our readers may see just what the United States Bee-Keepers' Union stands for, and upon what plan it is organized, we follow this paragraph with the Constitution as amended, trusting it may now meet with such favor at the hands of bee-keepers everywhere that they will rally to its loyal support, and thus generally unite in an attempt to carry out all its objects—every one of which is in the interest of bee-keepers everywhere:

Constitution of the United States Bee-Keepers' Union.

ARTICLE I.—NAME.

This organization shall be known as the United States Bee-Keepers' Union.

ARTICLE II.—OBJECTS.

Its objects shall be to promote and protect the interests of its members; to defend them in their lawful rights; to enforce laws against the adulteration of honey; to prosecute dishonest honey commission-men; and to advance the pursuit of bee-culture in general.

ARTICLE III.—MEMBERSHIP.

SEC. 1.—Any person who is in accord with the purpose and aim of this Union, and will work in harmony with the same, may become a member by the payment of one dollar annually to the General Manager or Secretary; and said membership shall expire at the end of one year from the time of said payment, except as provided in Section 8 of Article VI of this Constitution.

ARTICLE IV.—OFFICERS.

SEC. 1.—The officers of this Union shall be a President, a Vice-President, a Secretary and a Board of Directors which shall consist of a General Manager and six Directors, whose term of office shall be for three years, or until their successors are elected and qualified, except that the term of office of the two Directors having received the smallest number of votes at the time of voting for Directors in December, 1897, shall expire Dec. 31, 1898; and the term of office of the two Directors having received the largest number of votes at the said time of voting shall expire Dec. 31, 1899; and that the term of office of the two Directors having received the largest number of votes at the said time of voting shall expire Dec. 31, 1900.

SEC. 2.—The Board of Directors shall choose their own chairman.

ARTICLE V.—ELECTION OF OFFICERS.

SEC. 1.—The President, Vice-President, and Secretary shall be elected by ballot by a majority of the members present at each annual meeting of the Union, and shall constitute the Executive Committee.

SEC. 2.—The General Manager and the Board of Directors to succeed the two whose term of office expires each year, shall be elected by ballot during the month of December of each year by a majority vote of the members voting; and the Board of Directors shall prescribe how all votes of the members shall be taken.

ARTICLE VI.—DUTIES OF OFFICERS.

SEC. 1.—*President*—It shall be the duty of the President to preside at the annual meeting of the Union; and to perform such other duties as may devolve upon the presiding officer.

SEC. 2.—*Vice-President*—In the absence of the President the Vice-President shall perform the duties of President.

SEC. 3.—*Secretary*—It shall be the duty of the Secretary to keep a record of the proceedings of the annual meeting; to receive membership fees; to furnish the General Manager with the names and postoffice address of those who become members whenever requested of him; to make a report at the annual meeting of the Union, and, whenever requested to do so by the Board of Directors, of all moneys received and paid out by him since the last annual meeting; to pay to the Treasurer of the Union all moneys left in his hands after paying the expenses of the annual meeting; and to perform such other duties as may be required of him by the Union; and he shall receive such sum for his services, not exceeding \$25, as may be granted by the Board of Directors.

SEC. 4.—*General Manager*—The General Manager shall be Secretary of the Board of Directors, and shall keep a list of the names of members with their postoffice address; receive membership fees, and be Treasurer of this Union. He shall give a bond in such amount, and with such conditions, as may be required and approved by the Board of Directors, for the faithful performance of his duties, and perform such other services as may be required of him by the Board of Directors, or by this Constitution.

SEC. 5.—At the time of sending the ballots to the members for the annual election, he shall also send to each member a list of the names of all members, and an itemized statement of all receipts and expenditures of the funds of the Union by the Board of Directors, and a report of the work done by said Board of Directors.

SEC. 6.—The Board of Directors shall pay the General Manager such sum for his services as said Board may deem proper, but not to exceed 20 per cent. of the receipts of the Union. Said Board shall meet at such time and place as it may decide upon.

SEC. 7.—*Board of Directors*—The Board of Directors shall determine what course shall be taken by the Union upon any matter presented to it for consideration, that does not conflict with this Constitution; and cause such extra, but equal, assessments to be made on each member as may become necessary, giving the reason to each member why such assessment is required; provided that not more than one assessment shall be made in any one year, and not to an amount exceeding the annual membership fee, without a majority vote of all the members of the Union.

SEC. 8.—Any member refusing, or neglecting, to pay said assessment as required by the Board of Directors shall forfeit his membership, and his right to become a member of the Union for one year after said assessment becomes due.

ARTICLE VII.—FUNDS.

SEC. 1.—The funds of this Union may be used for any purpose that the Board of Directors may consider for the interest of its members, and for the advancement of the pursuit of bee-culture.

ARTICLE VIII.—VACANCIES.

Any vacancy occurring in the Board of Directors may be filled by the Executive Committee; and any vacancy occurring in the Executive Committee shall be filled by the Board of Directors.

ARTICLE IX.—MEETINGS.

This Union shall hold annual meetings at such time and place as shall be agreed upon by the Executive Committee, who shall give at least 60 days' notice in the bee-periodicals, of the time and place of meeting.

ARTICLE X.—AMENDMENTS.

This Constitution may be amended by a majority vote of all the members, provided notice of said amendment has been given at a previous annual meeting.

MR. P. H. ELWOOD, we learn through Gleanings for Jan. 15, "lost, the day after Thanksgiving, the light of their household, a bright little boy of three years."

MR. ALEX. SCHROEDER, of Austria, Europe, writing us Jan. 3, 1898, said:

"Up to this we have had hardly any winter. I hope it will continue so all the time."

MR. THOMAS G. NEWMAN, the General Manager of the National Bee-Keepers' Union, has removed from 2096 Market street to 1429 Market St., San Francisco, Calif. His correspondents will please notice this change from 2096 to 1429. It brings his office several blocks nearer the business center of the city than before.

MR. L. KREUTZINGER, of this (Cook) county, has just engaged Mr. J. T. Hammersmark as manager of his apiaries for the coming season. Mr. Kreutzinger also has an apiary in

Pasadena, Calif., with some one there to look after it. Mr. Hammersmark spent one season with E. France & Son, the great extracted honey producers of Wisconsin; and also one season with W. D. Wright, a comb honey producer in New York State. Hence Mr. H. ought to be fully able to run Mr. K.'s apiaries successfully.

Mr. Kreutzinger, when sending us the foregoing information Jan. 15, also added:

"When passing on the north side of Madison St., Chicago, east of Fifth Ave., yesterday, I found some one in front of the store piling up comb honey, and selling two sections for 15 cents. So you see your reference, on page 24, to some beekeepers around Chicago, and complaints, appear justified."

MR. W. J. CULLINAN, of Quincy, Ill., after an invalidism of years, past away last week. He was a brother-in-law of Hon. J. M. Hambaugh, of California. Mr. Cullinan left a well-appointed apiary of 40 colonies of bees. He has for years been a reader of the American Bee Journal, and frequently contributed to its columns in years gone by. Our sympathy goes out to the bereaved wife and relatives.

MR. H. C. MIDDLETON, deKalb Co., Mo., when renewing his subscription for 1898, said:

"I am more than pleased with each year's work on the American Bee Journal. Let us ever fight adulteration to the end, and the victory will be won."

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 38.)

FIRST DAY—AFTERNOON SESSION.

A committee, of which Mr. Stone was chairman, appointed in the forenoon, then reported on constitution. On motion the report was received and the committee discharged.

The constitution, as prepared, was then read by Secretary York, and adopted, section by section. It reads as follows:

CONSTITUTION OF NORTHWESTERN BEE-KEEPERS' ASSOCIATION.

ART. I, NAME.—This organization shall be known as the Northwestern Bee-Keepers' Association.

ART. II, OBJECTS.—Its objects shall be to promote and protect the interests of its members.

ART. III, MEMBERSHIP.—Any person interested in bees may become a member upon payment of a membership fee of 50 cents annually to the Secretary-Treasurer.

ART. IV, OFFICERS.—SEC. 1. The officers of this Association shall be a President, Vice-President, and Secretary-Treasurer, who shall form the Executive Committee. SEC. 2. All Presidents of the State associations represented shall be Honorary Vice-Presidents of this Association. SEC. 3. The term of office of all officers shall be for one year, or until their successors are elected and qualified.

ART. V, ELECTION OF OFFICERS.—SEC. 1. The election of officers shall be by ballot, at the annual meeting, and a majority of votes cast shall elect. SEC. 2. Vacancies in office shall be filled by the Executive Committee.

ART. VI, DUTIES OF OFFICERS.—The officers shall perform all such duties as usually devolve upon similar officers in other organizations. Any other questions shall be decided according to "Robert's Rules of Order."

ART. VII, PLACE AND TIME OF MEETING.—The place of meeting shall be in Chicago, at such time as shall be determined by the Executive Committee, notice of which shall be given to each member, and published in the bee-papers.

ART. VIII, AMENDMENTS.—This Constitution may be amended by a two-third vote of the membership in attendance at any annual meeting, provided that notice of such proposed

amending be mailed to the members by the Secretary not less than 30 days before the annual meeting.

Dr. C. C. Miller was then elected President of the revived Northwestern Bee-Keepers' Association; Hon. E. Whitcomb, Vice-President; and George W. York, Secretary-Treasurer.

Invitations from Omaha, to hold next year's meeting there, were then read.

CHEAPEST AND BEST WAY TO REAR QUEENS.

Mr. Rohrs—What is the cheapest and best way to rear queens?

Mr. Schrier—If a man only wants a few he would better buy them. He can get them cheaper of a specialist in queen-rearing.

Mr. Thompson—In rearing queens there is a great difference in the size of the queen-cells. I would like to know how many here produce good queens from small cells, or from the biggest they have?

Mr. Baxter—It depends upon whether he means the inside or outside. I have had some of the very best queens produced from what you would think was no cell at all, but when you come to examine the inside it was just as big as in larger looking cells. If the inside is large enough for the purpose, it is sufficient.

Pres. Miller—Another question may come in along with that: As a rule, will those cells that are large inside be larger than common outside?

Mr. Baxter—I would answer no to that.

Pres. Miller—If you are selecting cells, and you have a number in the hive, will you look for one that has a large outside, or would you consider that at all?

Mr. Stone—I always do. If it doesn't have a large outside it is possible for it to have a very small inside.

Mr. Baxter—That depends upon the way the cell is built. If the bottom of the comb projects, the result is it is very large outside. It makes a big difference where it is placed.

Mr. Thompson—The larva is hatched in the bottom of the cell proper, where it is built out, and then they build it out after the larva has hatched. How comes that? Does the larva crawl out of the cell proper, or does it stay in?

Mr. Baxter—The larva is always at the bottom of the cell, anyway.

Pres. Miller—Let me see if this is what will agree with your experience: Isn't it true that you will sometimes find in a comb a cell which hardly projects from the surface? Unless you have been careful you hardly notice it at all as a queen-cell; but out of that cell will come just as good a queen as you get from your largest cells. That sometimes happens. But that is because the bees have been forced into that, not left to their own devices.

Mr. Thompson—Do you call the bigger queen the better queen?

Pres. Miller—No, no. I would have a medium-sized queen; but as a rule the larger cells will have the better queens.

Mr. Thompson—If it is the quantity of the food that produces a good queen in a large cell, then there cannot be so much food in a small cell, and consequently they will not be so good.

A Member—I have often noticed, after a queen has hatched, that there was an abundance of royal jelly at the bottom of the cell left that was not utilized, and I think it is, no matter what size of cell it is, as long as that larva had a sufficient quantity of royal jelly to develop it. The size of the cell will not make any difference in the queen.

Mr. Wheeler—I have found this to be true, that a cell that hangs at the bottom of the comb, and hangs under, is quite apt to have a dead bee in it, for some reason or other. When I pinch it I very often find that queen dead; but I very seldom find a queen dead that is reared in a comb, imbedded—hanging down but imbedded in the comb along with other brood. They are almost always very lively and strong when they are hatching. I very often pinch them out just when they are hatching.

Pres. Miller—Will you tell us why that is, Mr. Wheeler?

Mr. Wheeler—I think that one reason is that where they extend down below the cluster they are apt to be exposed to chilly winds and such things; but where they are right in the brood and imbedded in it alongside of it—I prefer to have a cell of that kind rather than one that hangs below the frame.

Mr. Rohrs—My experience with rearing queens has been just the same. It is that from the bottom of the brood-frame we very often find dead queens, but those on top are better, and I coincide in that with Mr. Wheeler, that I think they are kept better warmed through, and a more regular temperature than at the bottom.

[Continued next week.]

GENERAL ITEMS

Bees Did Very Well.

My bees did very well the past season, having received 500 pounds from 17 colonies. **GEO. BISCHOFF.**
Des Moines Co., Iowa, Dec. 24.

Bees a Failure—Prospects Not Good.

Bees have been a complete failure here the past season, and prospects are not very good for next season. **B. VOLKERING.**
Polk Co., Wis., Jan. 4.

Bee Journal a Great Help.

I am more than pleased with the Bee Journal. It has been a great help to me. I would have it if the price were two dollars per year. **ROBT. NORTMAN.**
Jackson Co., Wis., Dec. 18.

Bees Did Well.

Bees have done well here this year. White clover was fine. The fall crop was not so good as last year, being too dry. Bees are in good condition for wintering. **C. V. MANN.**
Sangamon Co., Ill., Dec. 20.

Best Honey from Cotton-Bloom.

The honey-flow in this part of Texas was excellent. The best honey we get is from the cotton-bloom. We credit our success to the American Bee Journal **TENA S. EDZARDS.**
Lamar Co., Tex., Jan. 5.

Good for Arkansas.

I had six colonies, spring count, took off 1,000 pounds, and increased to 10 colonies. I took the prize on fine comb honey at our county fair. How is that for Arkansas, where bee-culture is in its infancy? **C. S. ROBERTS, M. D.**
Johnson Co., Ark., Dec. 23.

Made a Good Record.

My bees made a good record the past season. From 19 colonies, spring count, I secured 2,400 pounds of honey, all comb but 140 pounds—in round numbers 126 pounds per colony. I increased to 42. Not bad for Cook county, is it? **G. W. STEPHENSON.**
Cook Co., Ill.

A Valuable Kind of "Weed."

My report is as follows: 10 colonies, spring count, and received 500 pounds of nice white clover honey, besides increasing to 22 colonies. I can't get along without the American Bee Journal. **GEO. W. WEED.**
Carroll Co., Ill.

Drouth and Frost.

I started last spring with 32 colonies, had 17 swarms, and got about 300 pounds of white clover honey, when the drouth set in and the flow stopt until fall, then I got 800 pounds of honey. I would have gotten more if the frost had not killed the smart-weed, which was in its prime at that time. **S. BURTON.**
Woodford Co., Ill.

A Lady Bee-Keeper's Report.

Bees did fairly well here the past season, and went into winter quarters in good condition. From 18 colonies last spring I increased to 41, and have 450 pounds of surplus honey, and an abundance of winter stores for all. This is not a large yield of surplus for this country, but an average crop. The latter part of the summer and early fall

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.
The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6 1/2 cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipmt with best machinery, all combine to enable this firm to furnish the

Best Goods at the Lowest Prices.

Send for Circular and see the Prices on a Full Line of Supplies. Please mention the American Bee Journal. **7Atf**

BEE-KEEPERS:

We are making a strictly A No. 1 line of

Hives, Sections, Shipping-Cases, Frames,

etc., and are selling these goods on their merits.

We do not claim to sell at cost as we are not in business merely for what glory there may be attach to it.

We do claim that our goods are as fine as can be produced anywhere, and that our prices will be found fair and reasonable.

We are in a position to serve you promptly and satisfactorily, and we ask you to give us a chance to do so.

Why not write to us to-day for our **Free, Illustrated Catalog?** Or, better still, send us a list of what goods you will require for next season's use, and we shall take pleasure in quoting prices on same. Very truly yours,

G. B. LEWIS CO., WATERTOWN, WIS.

STARK Fruit Book free, write quick,—a marvel of exact orchard information; fine colored plates of 21 fruits, 100 photos. **We PAY FREIGHT** **STARK BROS.** **LOUISIANA, MO.** **Stark, Mo.** **Rockport, Ill.** **Dansville, N.Y.**
Millions of market sorts **No Trees** cost LESS, yet better quality is impossible.

That Queen-Clipping Device Free!

PLEASE READ THIS OFFER TO PRESENT SUBSCRIBERS:

Send us *just one new name* for the American Bee Journal a year (with \$1.00), and we will mail you the Queen-Clipping Device **FREE** of charge. Or, the Queen-Clipping Device will be sent postpaid for 30 cts. But why not get it as a Premium by the above offer? You can't earn 30 cts. any easier. Almost every bee-keeper will want this Device.

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

were too dry for a good honey-flow, and as most of our honey-producing plants bloom at this time, the honey-flow was cut short. We never have such large yields as are reported from some parts of the country, but we seldom fail to get some surplus, and nearly always get plenty of winter stores. I am well pleased with the Bee Journal, and I am greatly interested in the busy bees. I want to learn more of them.

Saline Co. Nebr. Mrs. E. J. TROUT.

Expect to Begin in March.

If the winter and spring are favorable, we will commence business in March with 500 good, strong colonies. G. W. WEEKS. Orange Co., Calif.

Bees Nearly a Total Failure.

Bees have been as near a total failure as we ever had in this locality. The most of them stored enough to winter on, but very little surplus, and that of poor quality. We had late frosts in the spring, and in June a hail-storm. Bees stopt swarming, and took the honey in the sections below.

Dodge Co., Minn. D. E. WHITING.

Had a Fine Rain—Prospects Good.

We have just had a fine rain of about 1½ inches, with prospects of plenty more, which means a good honey crop for 1898. I wish we were like the bees in the production of honey, in that we would not have to figure on profit, but we seem slow to learn from them, that uses are the true motive in production. W. B. HUNTER. Riverside Co., Calif., Jan. 11.

Did Well the Past Season.

I have been reading the Bee Journal for some time and like it very much. I obtain much information from it, and would not like to be without it. I have not been keeping bees a great while. I have 10 colonies, and they did well the past season. I hope they may increase next year. They are all in good condition for winter.

WILLARD ALDRICH.

Allamakee Co., Iowa, Dec. 23.

Credits the Bee Journal with Half.

I commenced last spring with 10 colonies, increased to 22, and produced 873 pounds of very fine honey, 256 being comb honey in one-pound sections, which I sold to my neighbors at 10 and 12½ cents. I give the "Old Reliable" credit for at least one-half of my success. O. B. MONTFORT. Shelby Co., Ky., Dec. 27.

Report for 1897.

I commenced the spring of 1897 with about 200 colonies in one yard, increased to 280, and got about 16,000 pounds of honey, half comb and half extracted. Bees are in fine condition for another year. I weighed 25 colonies, and they averaged 58 pounds each, without tops and blankets. They are wintering finely. I could not do without the American Bee Journal. Long may it live and prosper. N. STAININGER. Cedar Co., Iowa, Jan. 10.

A Report from West Virginia.

There are no regular bee-keepers in my neighborhood, but each farmer keeps a few colonies. It seems to be too rainy here in early spring to be a good bee-country. In 1897 it was very wet till August; from this fact the honey-crop was light, as we have no fall flow. I harvested only 586 pounds of comb honey from 25 colonies, spring count, and increased to 30.

This winter is very open so far (now Dec. 21). I have packed my bees all ready for the cellar, but the weather keeps so open they are still on the summer stands. I have not as yet introduced the Italian bee; my bees are all blacks, or the old German bee, and they seem so healthy I am afraid

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|---------------------------|-----|--------|--------|--------|
| Sweet Clover (white)..... | .60 | \$1.00 | \$2.25 | \$4.00 |
| Ailsike Clover..... | .70 | 1.25 | 3.00 | 5.75 |
| White Clover..... | .80 | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | .60 | 1.00 | 2.25 | 4.00 |
| Crimson Clover..... | .55 | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

if I go to importing other stock I will import disease, but I am thinking of trying a few Italians next spring. My bees are very gentle. My wife and I can handle them by the day, as it were, and never get a sting, but we use a little smoke, but no gloves or veils.

I appreciate the American Bee Journal very much. I feel that I could not succeed with my bees as I do if it were not for this valuable help. IRA SHOKEY. Randolph Co., W. Va., Dec. 21.

Need to be Re-enthused.

The cheapness and slow sale of honey have knocked the enthusiasm out of bee-keepers in this locality, but I am in the business to stay awhile at least, unless I starve out. I could not get along without the American Bee Journal, and I wish it prosperity. The honey-yield was rather below an average crop in this section the past season. A. D. WATSON. Tioga Co., Pa.

No Winter Protection Needed.

My bees are doing well on the summer stands without any protection whatever. They have flown every day except two, when it rained all day. The currant bush will bloom in about two weeks now, which will start the bees in their spring work. Think how pleasant it is here! I have sat till bedtime, the past two or three nights, with the door wide open, and without a fire. MRS. M. M. DUNNEGAN. San Patricio Co., Tex., Jan. 6.

A Winter Experiment.

I can't do without the American Bee Journal. I have 40 colonies put away for winter—30 colonies in the cellar, and 10 on the summer stands. I set them in a row about 6 inches from the ground, and about 6 inches apart in the row. Then I put boards on the northeast and west, 8 inches from the hives, and packed under and between, and on top solid with forest leaves, then I put good cases on top. This is an experiment with me. W. L. MITCHELL. Whiteside Co., Ill., Jan. 10.

Report for 1897.

My report for the year 1897 is, 900 pounds of comb honey of good quality; spring count, 30 colonies, increased to 70. Honey is rather dull sale at 12½ cents per pound. I sell mostly direct to consumers. I ran out of supplies last season. I would advise my bee-keeping friends to lay in their supplies in time. "A stitch in time saves nine." I found it so last season.

I don't see how a beginner can get along without the "old reliable" American Bee Journal. "Beedom Boiled Down" is very fine.

We have had steady winter in this part of the State since Dec. 3, with five to eight inches of snow. J. E. ENYART.

Gentry Co., Mo., Dec. 25.

Moving Bees Around for Forage.

I have had only two years' experience with bees, but with fair success. Last season I commenced, in the orange groves, with 25 colonies, had to transfer nine of them, and when the orange bloom failed I moved them seven miles to the mountain white sage, and when that failed, on Aug. 15 I moved six miles to the alfalfa range, and that lasted until the last of October. I now have the bees back in the orange grove, ready for the bloom about April. 15. I wound up the season with 2,800 pounds of extracted honey, and increasing to 57 colonies, with plenty of stores for the winter.

To prepare for moving I took some laths 1½x1½ inches, ript in the center, cut them off about six to eight inches in length, then push them down between the frames at one end of the frames only, picking out different sized sticks so as to fill the space in each; and both bottom and top boxes, fastening the top and bottom boxes to

Prices were never before so low—stock was never better. Everything in the REID NURSERIES is healthy, well rooted, fully up to grade. You will get exactly what you want at one-half price. Write for estimates, suggestions, illustrated catalogue. Try the STAR STRAWBERRY and ELDORADO BLACKBERRY.
REID'S NURSERIES, Bridgeport, Ohio.

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. R. B. Leahy and G. M. Doolittle, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Somnambulist**. "Experience and Its Lessons," by R. C. Aikin. This series of articles will be reviewed by Mr. Doolittle, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The somnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. Dr. C. C. Miller and other popular writers also contribute to its columns. The PROGRESSIVE is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the PROGRESSIVE BEE-KEEPER is but 50c. a year. The PROGRESSIVE and that "one only" book for beginners, the **Amateur Bee-keeper**, by Prof. J. W. Rouse, both for 65c. A sample copy of the PROGRESSIVE for your name, and a beautiful, illustrated catalog of apian supplies for the asking. Address,

LEAHY MFG. CO., Higginville, Mo.

This Very Remarkable Social Story,

The thought of which is the application to all life of the test question, "What would Jesus do?" has had an extraordinary sale, even during the "dull times" of summer. In the guise of a dramatic story, the book makes a powerful appeal to the public conscience in the lines in which interest is now so deeply aroused, namely, the social conditions affecting the relations of employer and employe, rich and poor, the Christian and the world, the saloon and the voter, etc. The author believes his test—"What would Jesus do?"—to be nothing less than revolutionary, and applies it with searching directness, not only to commercial and social, but also to religious life. The deep interest which the story has awakened is indicated by the thousands that have been sold, and the many voluntary testimonials, among them being the following:

"The reading of the book will search many a heart, and ought to lead to a simpler, holier, and more fully consecrated Christian life."—Sunday-School Times.

"Singularly impressive.... It is a sermon in action, and one that cannot fail to touch the heart."—New York Christian Advocate.

"Mr. Sheldon's book makes a strong impression as a plea for more simplicity of living, for more economy and more principle in the matter of personal expenditure, and for the application of the laws of righteousness and justice to the methods of business administration."—New York Independent.

Size 5x7½—nearly 300 pages.

Price, in paper cover, 25 cts., postpaid; bound in cloth, 75 cts. Or, we will mail a copy of the paper-covered edition for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00, or for sending us TWO NEW subscribers we will mail you a copy of the cloth-bound edition. We will send the paper-covered book and the Bee Journal one year—both together for \$1.10; or the cloth-bound book and the Bee Journal one year—both for \$1.50. Address,

Bee-Keeper's Guide—see page 43.

gether by drawing a wire tightly around the whole, including the bottom-board. I am satisfied with the experience of moving, and expect, if I live, to manage them so next season, provided all other conditions are favorable. I have heard of different ways of preparing bees for moving, and finding this plan very efficient, I thought it might be of use to some one else.

W. J. LINVILLE, San Bernardino Co., Calif., Dec. 27.

Wintering Well.

My bees are wintering well so far—170 colonies in the cellar, and five on the summer stands.

Linn Co., Mo., Dec 28. J. D. BLOOD.

A Good Year for Bees.

The past was a very good year for bees in this locality. We had a good crop of white clover honey, but the fall flow did not amount to much. The American Bee Journal is first-class.

CHAS. D. HANDEL, Carroll Co., Ill., Jan 2.

Bees in Good Condition.

I bought a colony of bees the spring of 1895, and now have 14 in apparently good condition. I have obtained much valuable information from the American Bee Journal.

D. W. WILL, Somerset Co., Pa., Jan. 1.

Prospect Unfavorable for 1898.

I would not miss the American Bee Journal for anything, as it's a great help to me. My bees did well the past year. It is very dry now, and not much of a prospect for honey for next year.

B. P. SHIRK, Kings Co., Calif., Dec. 30.

Poor Season—Some Fall Honey.

We had a poor season in 1897, with some fall honey, so that the bees went into winter quarters with ample stores. Success to the American Bee Journal.

F. E. WYMAN, Kewanee Co., Wis.

Prospects for a Better Clover Year.

Honey is a little slow sale here, but I have 100 colonies of bees now in winter quarters in splendid condition, with the prospect here of a better clover year coming than we had last.

CHAUNCEY REYNOLDS, Sandusky Co., Ohio, Dec. 21.

Stopping Robbing.

I have read much concerning robber bees. I had a colony last spring which was weak in bees; some of the rest took to robbing, and I tried all remedies given in the Bee Journal, but to no purpose. I moved the colony away, and put another strong one in its place. They stopt robbing in one hour.

SOL HARPST, Mercer Co., Pa., Dec. 25.

Prizes the Bee Journal.

I feel much attacht to the Bee Journal, and look for it every Friday, as it comes without fail. I have two volumes bound, and the one of 1897 will be as soon as I receive all the numbers, for I think with the help of the index they are as good as the text-books, for I get the opinions of the best writers.

JOHN SUTER, Ontario Co., N. Y., Dec. 22.

A Good Word for Bee-Papers.

The bee-keepers throughout America should feel very thankful that they are so abundantly supplied with weekly and monthly publications devoted to the interest of the busy bee. I cannot think but it is stupidity on the part of a good many who pretend to keep bees, to think they

can get along without subscribing for one or more of the many good journals now offered at such very moderate prices, which would enable them to keep abreast of the times, as well as keep well-informed of the advancements of the pursuit. I have often thought that one can judge pretty well, as soon as entering a man's bee-yard, whether he is a subscriber and reader of a bee-paper or not, wherewith to keep himself posted. Not less than five different bee-periodicals come to my address every month, and I read every one of them, from cover to back; and although my "other half" says I read too much, I tell her the result of the honey harvest always decides the matter. Long live the American Bee Journal.

D. W. HEISE.

Ontario, Canada.

Enjoys His Bees.

I have 34 colonies of bees altogether—26 in the country 10 miles from the city, and eight in the city. I started with three colonies in my city apiary last spring, and I increase by artificial swarming to eight. I never get hungry or tired while working for my bees. I enjoy them thoroughly; it is a pleasure.

J. R. FELT.

Monroe Co., N. Y.

Making a Success with Bees.

In 1895 I had a few colonies in old box-gums. I got very little honey from them, so after I began to read the Bee Journal I thought I would try the Langstroth hives. I transferred the bees, and I started last spring with 13 colonies, increase to 23, and I have taken and sold about 1,100 pounds of comb honey. My bees are all Italians, the only ones in this part of the country, that I know of. One of my neighbors got me to send south for 13 Italian queens; I did so, and introduced them for him, and did not lose a queen. So much, Mr. Editor, for the American Bee Journal.

P. McDOWELL.

Mason Co., Ky., Jan. 5.

"Started" by a Bee-Keeper.

I am a brand new bee-keeper, only a little over a year old in the business, but I like it very much so far.

I want to say "Amen" to the editor's reply to John A. Pease, of California, as I am one that was "started" in the business by a bee-keeper. I secured a little over 78 pounds of comb honey per colony, spring count, from 14 colonies, and increase to 24 the past season, which I am wintering on the summer stands. I like the American Bee Journal very much.

J. S. DOWDY.

Logan Co., Ill., Dec. 27.

Fairly Good Season in 1897.

I had a fairly good season in 1897. I commenced with 65 colonies, bred up to 90, and obtained 5,200 pounds of comb honey, nearly all white, not over 400 pounds of amber and dark. I am selling this crop at a lower price than ever before—10 cents for white and 8 cents for amber and dark. I have yet about 2,500 pounds on hand, but it will all go in good time. Clover is nearly all killed in this vicinity by drouth. I have kept bees 30 years at this place, and I have never had an entire failure. I do not keep nearly as many now as I have in years past.

S. FAOE.

Carroll Co., Ill., Jan. 10.

Poorest Season for Years.

I have been a constant reader of the American Bee Journal ever since I have been interested in bees, which will be 11 years in the spring, and I would not like to do without it now.

The past was the poorest year for surplus honey since I have had anything to do with bees, still not quite a total failure, as I harvested perhaps 18 or 20 pounds (mostly extracted) per colony, spring count, but some of the bee-keepers in this locality having larger apiaries had to feed some to carry the bees through the winter. I never aim

to keep more than 20 or 25 colonies, and try to have them good and strong.

S. C. BOOHER.

Woodbury Co., Iowa, Dec. 29.

Bees in Good Condition.

I have 81 colonies of bees in winter quarters in good condition. I had 57 last spring, increase to 81, and took 2,357 pounds of mostly comb honey, and 24 pounds of beeswax. Quite a number of swarms went away, as I lost my wife July 5, and that day I had six swarms, but paid no attention to them for the next two days. I am left with three little boys.

AUSTIN REYNOLDS.

Monroe Co., Wis., Jan. 10.

Will Test the Danzenbaker Hive.

What I mean on page 715 (1897) concerning the Danzenbaker hive being too expensive was, that to handle a colony of bees it requires two hive-bodies and two supers, which at catalog prices would cost as much as a double-wall hive, and not nearly so good for this climate. Mr. Danzenbaker's hive is a good one for a warm climate, and also for anyone that likes a single-wall hive. I did not mean to harm Mr. Danzenbaker, nor his hive. I want to try them for 1898, and of course his hive must stand on its own good qualities. I will give it a fair and impartial test.

DAVID N. RITCHEY.

Franklin Co., Ohio.

Has Kept Bees 14 Years.

This is my 14th year at bee-keeping, and I have produced \$2,500 worth of honey. I commenced the first season with six colonies, and the last with 70, and the past season I got \$425 worth of honey, besides increasing from 70 to 96 colonies.

While at the Buffalo convention I introduced myself to Messrs. York, Doolittle, Miller, Hutchinson and Root. I had become so well acquainted with them through reading their writings that I felt as if they were old friends of mine, altho I was an entire stranger to them. I am engaged in farming and peach-growing, and cannot give my bees as careful attention as I would like to do.

Belona, N. Y.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Dec. 13.—Fancy white 11 to 12c. No. 1, 10c.; fancy amber, 8 to 9c.; No. 1, 7c.; fancy dark, 7c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special change. Beeswax is scarce.

Milwaukee, Wis., Dec. 13.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 9 to 10c.; fancy dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 4¼ to 5c. Beeswax, 25 to 27c.

This market has been fairly sustained on honey since our last report. Values remain about the same, as there has been a very good consumptive demand, especially for extracted, while the comb honey has seemed to accumulate with increase receipts, and we feel to meet the demand even if at a reduction from quotations. There seems to be more demand from those who eat honey than in former seasons, which is a good feature of the trade which we desire to encourage. We are expecting a good trade from this forward.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

New York, N. Y., Dec. 22.—Fancy white 11 to 11½c.; off grades, 9 to 10c.; buckwheat and mixt, 6½ to 7c. Extracted, California white, 5 to 5½c.; light amber, 4½ to 4¾c.; white clover and basswood, 5 to 5½c.; buckwheat, 4 to 4½c.; Southern, 50c. a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of buckwheat, mixt, and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Dec. 15.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 10c.; No. 1, 9½c.; fancy dark, 9 to 9½c.; No. 1, 8 to 9c. Extracted, white, 5 to 6c.; amber, 4 to 4½c.; dark, 4c. Beeswax, 23c.

Market holds firm at above prices. Good demand for extracted. Wax is quiet but firm at 23c.

Albany, N. Y., Dec. 13.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 8 to 9c.; No. 1, 8c.; fancy dark, 8c.; No. 1, 7½ to 8c. Extracted, white, 5 to 6c.; amber, 4½ to 5c. dark, 4 to 4½c.

There is an ample stock of comb on hand and selling freely at quotations. Extracted is not plentiful and from information received there is not much in the hands of producers.

Buffalo, N. Y., Jan. 14.—Strictly fancy 1-pound comb honey is more active at mostly 10c., occasionally 11c., but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c. down to 5c. Extracted is also very dull at 4 to 6c. We cannot recommend the shipping of honey here unless it is strictly fancy 1-pound sections.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

St. Louis, Mo., Jan. 17.—We quote honey nominal, but very little selling. Demand is light. White comb, 1-lb., 10 1-2 to 12c.; amber, 8 to 10c.; dark, 5 to 7c.; broken comb, 4 to 7c. Extracted, in cans, white, 5½ to 5 1-2c.; light amber, 4½ to 5c.; amber, 4¼ to 4 1-2c.; dark, 3 1-2 to 4c. Beeswax, 25 to 25 1-2c. To sell honey in lots above prices would probably have to be shaded a little.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Kansas City, Mo., Jan. 20.—Fancy white, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. The market is well supplied, and demand is light.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3¾c. Beeswax, 28c. Late arrivals of California honey have demoralized our market.

Cincinnati, Ohio, Jan. 17.—There is no change in prices, but rather a slow demand for all kinds of honey. We quote 10 to 13c. as the range of prices for best white comb honey, and 3 1-2 to 6c., for extracted, according to quality. Beeswax is in fair demand at 25 to 27c. for good to choice yellow.

Detroit, Mich., Nov. 9.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c.; fancy dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c. Beeswax, 25 to 26c.

A New Egg-Producer.—With many years of experience and careful study I have discovered by feeding sunflower seed to poultry it almost doubled their laying qualities. I prefer the New Mammoth Russian Sunflower seed, which is a much larger seed, and contains more egg-forming material than the common sunflower. For several years I have experimented with it on our Light Brahmas, and found that by feeding it the Brahmas laid equally as well as the Leghorns or any of the other smaller breeds. It much improves them in size if fed to chicks while growing. It can be grown much more cheaply than any other grain, with much less labor, and it will grow in any climate and on any soil. We have sold in the last few years hundreds of pounds of this New Mammoth Russian Sunflower seed, and have received hundreds of testimonials saying that it is just as we claim regarding ability to make hens lay and grow more rapidly than if fed on any other food. The

fanciers and farmers should not overlook this or anything else pertaining to their poultry, for they bring more money according to capital than anything else on the farm. If your poultry is kept up well, new blood added each year, the mites and hen-lice kept out, fowls better protected from sudden changes of weather, and more care taken as to what you feed them, you will find on a year's income your poultry is the best payer on the farm; while it is just the opposite with those farmers giving them no care whatever, letting them hunt whatever waste food they can find, and hunt their own shelter, saying it won't pay to build a poultry-house or get any new blood, as there is not enough money in poultry. Surely not under such conditions, as such fowls will not lay many eggs nor weigh much when sold at market. Take my advice and try it for just one year, keeping an account of just what you make on your poultry if proper care is given. I publish a book, price 15 cents, on the care and management of poultry in full, with many years of practical experience. Do not fail to get one of these before all are gone. Address, JOHN BAUSCHER, JR., Box 94, Freeport, Ill., and mention the American Bee Journal when you write to me.

Basswood Honey FOR SALE

We have a limited number of barrels of very best Basswood Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash,

CONTRIBUTED ARTICLES

Bee-Moth or Wax-Moth—Some Experiences.

BY C. THEILMANN.

On page 723 (1897), Prof. A. J. Cook has kindly answered the questions I have asked him regarding the bee or wax moth, for which we tender him thanks. Some of the ways he describes about the moth are not yet clear to me, or don't agree with my experience, and that of other bee-keepers. He says: We always find the moths lurking or flying about where there are combs, bee-hives with bees, empty hives or boxes with combs, etc. Some years ago I stood before a big, dry elm in my timber, whose bark was loose one inch or so. By accident I pulled the bark from the tree about 8 inches, and to my surprise I saw several bee-moths running around on the inside of the bark, just as they do when disturbed elsewhere in their hiding-places. This was nearly a mile from my apiary. Now I am tempted to ask the Professor, How did the moth get there? or where were they hatched out? and what did they live on?

A bee-keeper tells us in the *Acker and Gartenbau-Zeitung* that he knows several bee-trees in his vicinity which are stocked with bees nearly every year, but are always destroyed in two to three months by the bee-moths. W. Buechner, from Texas, writes on same page: "I have found dozens of moths in the pupa state mostly in winter time in hollow trees, but nowhere except where a colony of wild bees were destroyed by the moths." This evidence was given in opposition to my theory, but are they not a strong argument on my side of the question?

Those wild bees were surely not Italians, else not all of them would have been destroyed by the moth alone. But I would ask again, Where did these moths come from, and on what did they live the other seven or eight months of the year?

By the way, does any one know how old a bee-moth gets to be? and how far away from her birth or hatching-place she is likely to move or fly? It would surely interest many of the readers to know. Will Prof. Cook kindly give us some information on this question also?

I am with the Professor when he says, "If possible she (the moth) goes to the combs, else she lays her eggs as near to them as she can reach, as I have had combs attacked that could not possibly be reached by the moth." The latter has been just my experience, and therefore, and for other reasons, I believe that the moth-eggs are in the pollen of combs before taken from the center of strong colonies of Italians, where it is impossible for moths to lay eggs, and if there were newly-hatched moths on such combs, they would be visible in three or four days on the combs after taken from the bees. But that is not the case, for it takes from 7 to 12 days in warm weather before any signs of moth-worms are visible on such combs, and then always on the pollen. Besides, my bees carry and clean more or less moths, of all stages of development, out of their hives all the year around, which I have

often witnessed in my winter cellars, when they are generally left at the entrances of the hive.

I doubt very much that the moth lays eggs in a temperature of 40° to 42°, as in the case of my bee-cellars for five months while the bees are in them, and if any eggs were laid in or near the hives in summer, they would have been hatched long before real winter set in, in this latitude as a rule about Nov. 10.

Taking all these connecting evidences, and the fact the moth is a night-caterpillar, whose nightwork is hard to understand and observe, I cannot see any other way than that the bees carry and store the eggs with the pollen, and that the moths live and thrive elsewhere besides at or around beehives and apiaries.

Before I close I will give another experiment I witnessed not long ago. As the season here was a poor one, I had to feed my bees for winter, for which I boiled sugar and water together and added some honey until I had a 50-gallon barrel nearly full. This was on the evening of Oct. 13, 1897. The

Father Joshua Terry, of Utah—See page 68.

barrel was left open about 15 rods away from my home apiary, in the open air to cool of. The night was warm for the time of year, and on the morning of the 14th the thermometer showed 65° above zero. I went to the sugar-honey barrel and found it nearly covered with dead and dying bee-moths, with their wings spread and fastened to the sweet mass, and after I pulled them out and had thrown them away, I was

sorry that I did not look for eggs about them. I counted 23 bee-moths, and 2 of those little wee ones described in Prof. Cook's Manual.

Now, I'd like to know where so many moths came from all at once, for I had not seen any around my bees for a long time before this. There was surely many more that ate of the sweets that did not get stuck fast. I am quite sure that they were not all reared around my bees, for everything that would induce the moth is kept snugly out of their reach. I am aware that we can trap quantities of moths with sweets in the summer time, but I never saw them in such numbers as late at October, when we supposed they were nearly all dead or asleep.

The little, wee moth does sometimes considerable mischief with comb or section honey. Some 15 years ago I had about 6,000 pounds of very fine, delicate linden honey in my honey-house for about four weeks. I had to close it tightly as the bees began getting in and robbing. The room got warm and very damp. I sold 4,000 pounds of it to a Minneapolis firm, not noticing anything wrong about the honey when shipped, neither did the receivers of the honey. About four weeks after, I saw part of this honey stored in a large airy room on the second floor, when one of the firm told me that my honey was wormy. I looked and found little perfectly round holes (the size a common needle would make) over much of the cappings of the honey, and some little webs and nealy stuff, and here and there a little worm in the corners and edges of the combs, but there was not quite enough to spoil the sale of the honey.

Three years ago I bought 500 pounds of white honey from a neighbor bee-keeper, who kept the honey for about two months in a tight, close room under the roof of his house, and when he delivered the honey about one-half of it was unfit for market. On some combs there were small patches where the little holes joined and left the honey almost bare of cappings.

These are the only instances of this moth which came under my observation. It seems that they live mostly on the cappings of the combs, and probably some honey, for it is a rare thing that I have any pollen in my section honey that they could feed on. I believe when honey is kept in a warm, airy room, that this moth will do but little harm to the bee-keeper, neither will the bee-moth if the bee-keeper understands the business.

I have never seen the wee "winged" moth that I could be sure of. The two in the barrel above-mentioned compared well with the picture in Prof. Cook's Manual, so it is probably a night-caterpillar, in that respect like the bee-moth.

I cannot agree with Prof. Cook when he says: "I do not think the bee-moth ever lays her eggs in the pollen in the flowers; we never see her about the flowers as we certainly should if her nits were there."

Does not the flower furnish all the elements the moth exists on? Why should she not visit them, when they contain her very life? Does not every critter like to be and live in its elements, or is the moth an exception? By no means do I think that every flower is stocked with moth-eggs; we may examine thousands and not find an egg, but every indication of my experiments leads me to believe that many eggs are stored in the combs with the pollen. That we never see the eggs on the pollen is no proof that the moth will not lay them there, at distances away where they cannot find a better chance to do so. No one would claim that we have no north pole because no one ever saw it.

Ripening Honey—Sweet Clover Eaten by Stock.

BY J. A. BEARDEN.

I see Mr. E. B. Tyrrell, on page 731 (1897), is in favor of everybody who reads the Bee Journal giving their opinion as to the ripening of extracted honey, but as he does not say whether he wants it ripened naturally or artificially, but leaves us to infer that he meant naturally or as the bees ripen it, I will give my opinion be it ever so light.

The subject is a very important one, as it means good or bad honey according as the bee-keeper wills, altho the honey may be from a good source; for of all kinds of honey, that which is extracted from the combs in a watery stage is the worst yet; still, it can be left on the hives too long.

For instance, a friend of mine had a fine lot of aster honey in his hives in the fall of 1896, but as he had no extractor he got me to take out the honey after there had been a few cool nights, and as aster honey becomes candied very quickly after it is gathered, this lot was about one-sixth candied in the combs, and of course it would not throw out of the combs,

altho I run my extractor very fast. So you see one kind of honey at least must not be too severely ripened.

But I don't think there is any need to be in a hurry about extracting most kinds of honey, for I have my first lot to taste that was taken out before it was capt, that was as good as that which was thoroughly capt over before it was extracted.

I have a rule which acts well for me, to determine when honey is ripe enough to extract. It is this: When a honey-flow is on, you can hear the bees making a very loud humming, at night especially; this is the bees' automatic evaporator at work on the newly-stored honey, and as soon as this night humming has almost ceased, your honey is all right and ready to extract. But of course you will not get as much honey as if you had extracted twice or more times during the flow; but your honey will be of heavy body and better taste than that taken off too soon.

If a man (or woman) has a good reputation for producing a fine grade of honey, he or she can ruin that reputation very easily by selling a few lots of thin, foamy or half-soured honey, for such will be the case if the honey is from basswood, not thoroughly capt or ripened.

Mr. O. O. Poppleton, on page 690 (1897), says he has never had basswood honey so thin as to drip from the combs as Mr. C. P. Dadant has; still, such is the case with me, if it should happen to be very damp, rainy weather at the time of gathering, but if very dry weather is on hand at gathering time the honey is of course very much thicker, but not thick enough.

HOGS, SHEEP AND COWS AFTER SWEET CLOVER.

I have been trying to get some sweet clover to grow on some waste lands about me, but, pshaw! the hogs just hunt it up and dig for the roots as long as they can smell one. And sheep and cows just look it up and eat the last sprig that they can find, for 'tis so much earlier than common red clover.

Lincoln Co., Tenn.

Comments on the "Golden" Management for Producing Comb Honey.

BY W. W. M'NEAL.

On page 742 (1897), Mr. Golden asks for comments. All right, Mr. Golden.

How do you manage to keep pollen out of this double super during the first five days after the swarm is hived? Just why the bees should fill these sections with such choice honey and leave no pollen is decidedly a wrinkle I fail to see. My experience is that bees are inclined to place themselves and their brood between the entrance and the stores. Now, pollen being something that cannot be so easily carried away, is often given a place close to the entrance. This is more noticeable in early spring, and especially so if the frames run parallel with the entrance. The runways provided at the sides of the super may have something to do with it; but why the field-bees, upon their return to the hive, would run up through these to the brood-combs above, and there leave the pollen, returning to the sections below with the honey, is the query with me.

Of the two evils, honey stored in comb built the previous season, and that which is stored in comb built the present season, but containing more or less pollen, I would choose the former for two reasons: 1st, The average consumer of honey would hardly detect the harshness of the comb at all if the precaution had been taken to break away the varnished face of the combs before giving them to the bees. 2nd, But they would detect pollen were it there, and so would the little wax weevil! It is a rare thing to find pollen in sections placed over the brood-combs, save in hives where such room is limited; and when a case of partly-filled sections has been given to a swarm newly hived on frames with only starters in them.

I have tried to get a swarm to build comb under nearly the same conditions that Mr. Golden outlines, but failed in every instance. My hives were prepared thus: If a colony run for extracted honey cast a swarm, I took its surplus cases and placed them over an empty brood-chamber—with starters—with a queen-excluder between the two apartments. Now if there chanced to be any uncapt brood in these upper cases the bees would sulk until they could cap over some kind of a cell and call it a queen, when the swarm would then abscond. Should there be nothing but honey in the combs, they will continue to sulk until something happens. The queen being caged, and the excluder removed, may cause the bees to behave in a vastly different manner, tho like a great many other things it does look that way.

Still, I cannot see why a colony that does not swarm

shouldn't store as much honey as tho it did. Of course, if the swarm issues very early, and the season be prolonged, then the two may exceed what the one would have done. If we can gain for the colony without its having to swarm, that which it gains by swarming, then wherein does Mr. G.'s method have any advantage? I mean the desire and ability to build comb. Nothing so incites a colony to good work as the presence of newly-built comb in the hive. To obtain this vantage ground, a frame of foundation can be hung in the brood-chamber some little time to the giving of the supers, providing the strength of the colony and the state of the weather will permit. Place the frame of foundation between two combs of brood, and in due time follow this up with a super alternated with frames of comb and frames of foundation or starters. A half-depth case is always preferable for the first one given. Sometimes it works better to give a case of combs entire until they have been coaxed above, when this can be lifted and a section super placed between. It is always well to look to it that the queen be not in the upper case when raising it, for her presence there would work disastrously in that the capacity of the small frames would not be equal to the ability of the queen, which would tend to dissatisfaction; and her absence from the combs below would cause queen-cells to be started, and swarming would be the result. Arranged in this way, a colony can be run for both comb and extracted honey with the incumbrance of a queen-excluding honey-board.

The queen will not now pass the section super to again occupy the upper one, tho the queen-cells in this upper case must be taken away or destroyed as soon as they reach the proper age, or swarming may result just the same had they been built below. But how much easier done in the shallow-case than in the deep brood-combs, heavy with brood and honey.

You may say, Why not put on the excluder at the time the combs are given to the bees, and thus prevent the queen ever going there at all? Well, the point is to get the workers there as quickly as possible; and you all know that if the queen goes there honey will not be long in finding its way there. So when the case is raised and an empty one placed beneath it, the presence of brood tends to draw the *hive-force* away from the brood-combs, and lessens the tension there. The field-force will then get a hustle on themselves that tells you something is going to be done. O how they—the *hive-force*—then need air! Give it to them, plenty of it, and always from below. Nothing so causes the upward march of the bees to roll back upon the brood-combs as does the giving of cooling drafts of air from above.

I think that when thus managed bees will store as much honey as they will by the Golden method; and without the great danger (so it seems to me) of getting pollen in the sections.

I will here admit that I have never tried Mr. Golden's way, as he arranges and describes, but I intend to do so. Mr. Golden must use a small brood-chamber, and certainly his bees were not started off properly or they would not swarm with but one super partly filled.

I do not see it exactly, that by having a swarm in the double super you get such a large amount of honey that the bees otherwise would have used in building combs for the new hive and storing the same after they are constructed. Let's see. We will suppose a swarm is issuing, or has just issued; I need a few more extracting-combs, or that some I now already have are crooked or contain more or less drone-comb, all of which is tolerably new. I cut the comb out, save an inch or so next the top-bar. These frames are put into a shallow extracting-case, which case is then placed over a similar one the empty; and the two constitute the brood-chamber to the hive the swarm is to occupy. On this I place a slatted queen-excluding honey-board, and then place the section-cases that were on the parent hive. The swarm is to occupy the old stand, the old hive is given a new location, but before doing this, a portion of the yet remaining bees are to be driven out with smoke. This so weakens them that there is little danger of second swarms. Contract the entrance, and shade the hive well. Now, see here, the presence of the empty super gives sufficient room till the fever subsides; the absence of old brood-combs causes the bees to gather less pollen for the first few days after being hived, and what they do bring in, the narrow strips of drawn comb will catch the most of it by the aid of the honey-board, for a bee cannot easily pass through the perforations with pollen on her legs. The brood-chamber is thus left for about a week, when the empty case is to be taken away, the other now being placed on the bottom-board. The hive may now remain till the honey season is over, or the colony may be re-united with the parent colony about the time the extracting-combs are completed.

All this has been done with only supers for a hive, the increase has been kept down, the extracting-combs have been secured, a few choice queens reared, and I think with as much really *marketable* honey as if the swarm had been treated according to Mr. G.'s method. However, I am open to conviction. If it can be shown that the bees *do not* store pollen in the section-comb while the super sits beneath the brood-chamber, then perhaps there is no quicker, yet profitable, way of disposing of a swarm.

Ipecacuanha for Bee-Stings—Figwort.

BY D. S. HEFFRON.

From the Popular Science News, of January, 1897, I take the following:

"A Calcutta physician who was attacked by a swarm of bees was severely stung on the hands, head, face and neck, no fewer than 150 stings being afterward taken from his neck. Fortunately he had some Ipecacuanha powder with him which he immediately had made into a paste and smeared over the head, face and neck. The effect was most marked, preventing to a large extent the swelling and pain which invariably follow the bees' stings."

Ipecac, as we call it, is the powdered root of the plant of a light brown color, as fine as flour. It is kept by druggists, and is not expensive. The sting of bees used to pain me severely, and swell badly, sometimes closing an eye, or otherwise disfiguring the face. For the last season, tho stung more than a dozen times, I have escaped both pain and swelling by as prompt a use of Ipecac powder as I could procure.

SIMPSON HONEY-PLANT OR FIGWORT.

If I do not mistake this plant, its botanical name is *Scrophularia nodosa*. Prof. Asa Gray says, in his Manual of Botany, it was "so called because a reputed remedy for *scrofula*;" while Prof. Wood says in his Class-Book of Botany, "So named from the resemblance of the roots to *scrofulous* tumors." Both the authors quoted agree in the description of the plant, in the form of the flower and fruit, its stem, leaf and habit. It is entirely hardy, found in Canada, the Middle and Western States, but rarely in New England. It is perennial, flowering the second year, and its habitat is along the edges of woods and in hedges, and in other damp and more or less shady places.

The writer has been acquainted with the plant that was recently figured in the American Bee Journal for 50 years, and never found it growing in an open, dry prairie. It begins to flower in July, and continues for about three months. But why should this old plant, introduced from Europe, be called the Simpson honey-plant? In an article in the Bee Journal of Oct. 14, 1897, the writer says: "I consider one acre of the plant worth at least ten of sweet clover." I have no competent personal knowledge. I think it may be worth testing in a small way.

Cook Co., Ill.

No. 5—Recollections of an Old Bee-Keeper.

BY DR. E. GALLUP.

(Continued from page 51.)

I saw that the Langstroth movable-comb principle was correct at a glance, so that was how the Gallup hive came into existence. My hive was 18 inches wide, 12 inches from front to rear, and 12 inches deep. This was in conformity to my ideas of starting with a nucleus or a small swarm and controlling the animal heat with a division-board and building up to a strong colony by enlarging as the bees increase. The top-bar of the frame, V and all, was in one piece with shoulders cut for the end-pieces. The ends or sides of the frame were of the same width as the top-bar, and 3/16 thick; the bottom-bar was 3/8 square, nailed in corner up.

My reason for using so thin an end was that the bees would cluster clear past that, and the queen would occupy every cell, even those adjoining the wood, and by using the 3/8 bottom-bar the bees would build down and on to it, and if necessary past it, down to near the bottom-board. The only objection to this is, the bees are more liable to build onto the top-bar of the breeding apartment from the super combs.

I use my Langstroth frames with the 3/8 bottom-bar. I like a comb built solid to the frame all around. If we have a flat bottom-bar in wintering, even in this climate, there is an accumulation of bits of pollen, cappings from hatching brood, etc., that lodge on this bottom-bar and make a place for moths. Taking every advantage and disadvantage into consideration, I prefer the 3/8 bottom-bar every time. The only

disadvantage is, the combs are a trifle harder to get out of the supers. Still, if we leave the flat bottom-bar in the super long enough for the bees to ripen and mature the honey, as it ought to be, we often find them as bad as the others. Now you have my reasons for modeling a Langstroth hive to suit my fancy.

Mr. Langstroth had the misfortune to have many agents that did not fairly represent him, and one in particular that cheated him out of a large percentage of his just dues. I had the supreme satisfaction of balking him in at least two of his schemes.

Along about this time in my bee-keeping, I obtained my first Italian queen, and along with her directions for rearing queens in small nuclei boxes, 4 by 6 inches, and of course went into rearing worthless queens with all the enthusiasm imaginable. After two seasons I found all was wrong from beginning to ending, so I studied up a far better plan.

About 1864 I sold out and moved to Iowa, and settled in Mitchell county, in an excellent locality for bee-keeping. The next question was, where to get a stock of bees to start with. The country was new and only partially settled, and no bees kept that I could hear of anywhere near. I finally obtained an old worthless colony 45 miles east, moved them home in midwinter, and put them in the cellar. In March I found a colony in a hollow tree, cut and moved them home, and sent off to Wisconsin for a queen, but did not receive her until July. In the meantime I had coaxed the old queen until she had a fair-sized nucleus. The found colony was a fair-sized one. I had transferred both in the spring.

After the first of July I built up to 7 good Italian colonies to put into winter quarters. Now I must tell of a mishap that came very near ending Gallup's career in this world:

I set the hives on a platform up over a pile of potatoes. One Sunday, along in the winter, while at dinner, I heard a crash down cellar, and on going down with a light found one end of the platform broken down, and five of the hives had slipped off and rolled down the pile of potatoes. The combs had nearly all rolled out, and were mixed promiscuously together on the potatoes and cellar-bottom. Well, I righted them up and placed the right number of combs in each hive, and then allowed the bees to crawl in as best they could. But I was stung fearfully. I would work as long as I could, then rush up and out into the cold air, brush off the bees, and back again. I bloated all up, turned a dark purple, and if I had not known what to do, I should surely have "past in my checks."

The remedy in such cases is a cold, wet-sheet pack. I have cured other cases in the same manner. One in particular, where the patient had become helpless and speechless. For a horse that gets badly stung, put on blankets wet in cold water, and pour on cold water. I cure rattlesnake bites, both in man and beast, by the cold-water process.

Well, I borrowed a great sight of trouble the balance of the winter for fear I did not get a queen in each hive, but good luck came in, and they were all right. So much for luck. Orange Co., Calif.

Something About Queens—Stopping Robbing.

BY C. B. ELLIOTT.

While I am somewhat a novice in apiculture in Colorado, I have been noting with much interest the articles of Dr. E. Gallup and others on establishing a standard for queens—see page 660 (1897). All I shall speak about is my own experience. I give it for what it's worth, and there may be some points in it worthy of consideration.

The last week in September, 1896, I by chance found queen-cells in one hive that for some reason had lost their queen. For fear the young queen might be lost in mating, I took out one cell and gave it to handful of bees in an American hive, which was full of honey. I did this simply to be on the safe side in mating. The colony rearing the queens was rather weak.

On Oct. 3 to 5 I found both queens had hatched about the 15th, both to my surprise laying. Now, what to do with both queens was the problem. As the handful had plenty of honey, I decided to let them chance it. I do not think there was one pint of bees.

To my surprise, about Jan. 1 the handful of bees was about double in size, and the queen was still laying. There was brood in three frames. Monthly, from then on till spring, I watch them. She was laying continuously, gaining ground all the time, and by June they were one of the strongest colonies I had, out of 190, spring count. This colony produced as much, if not more, honey than any other I had. By an

oversight I failed to keep track of the number of supers filled by them, but as nearly as I can tell it was eight or nine. They did not swarm during the season. I kept three to four supers on all the time. They still would hang out of the hive, as all could not get inside.

The sister queen I lost track of, as I bunched my hives together for wintering, and would have known nothing about this one had she not been in an odd hive with a handful of bees, and keeping track of them through curiosity.

I am now experimenting with 10 October queens, started laying about the 15th; now they have a nice lot of brood. The 10 colonies are all weak. I started into the winter with 354 colonies, all with plenty of honey, and all strong, with the exception of the 10 mentioned.

HOW TO STOP ROBBING.

I noticed an article on stopping robbing. My plan is this, and it is effectual: Close the hive all but a half inch, or such a matter, then every few minutes sprinkle or spray the front of the hive, bees and all, with a strong solution of salt water. The water should be quite briny. Don't fear, it won't hurt them, but on the contrary it will do them good, and will stop robbing in a short time.

By the way, I spray my bees fall and spring, with salt water quite strong, about a half teacupful to the hive. I raise the cover and spray down, and I don't believe you can find a livelier lot of bees anywhere than we have. Also during the summer, if I find a colony not doing as they should, I treat them to a dose of salt water.

Arapahoe Co., Colo., Nov. 2.

JOSHUA TERRY—A UTAH PIONEER.

[The following biographical sketch was kindly sent us by Mr. Terry's friend—and our friend, too—Mr. E. S. Lovesy, President of the Utah State Bee-Keepers' Association:—Ed.]

Joshua Terry came to Utah 50 years ago. He is one of the few now living, of that noble and honored band of the long ago. He is one of those who received the homage of a grateful people in our jubilee year of 1897. Mr. Terry says our grand jubilee, in bringing together old faces, old friends and acquaintances, made him feel for the time being almost as if he were again living over again those eventful times of 50 years ago, when they traveled over one thousand miles of a trackless wilderness and settled here on what was then known as the Great American Desert. But they formed the nucleus that has now grown into a great State.

Joshua Terry was the son of Parshall and Hannah Terry, and was born in Home District, Canada, Aug. 11, 1825. When he was 13 years of age he moved with his parents to Sheridan Co., Mo., and from there he moved to Illinois, where he followed farming for five years. He then went to Iowa, and from there to Utah in 1847, and settled with his parents at Draper, on a very fertile plat of land near the base of the Wasatch mountains about 20 miles south of Salt Lake City. But having formed an acquaintance with some mountaineers in crossing those wild plains where the States of Nebraska and Wyoming are now located, and being then a young man about 22 years of age, with a strong, robust constitution, and a romantic turn of mind, of a roving disposition, he determined to push out into the wilds of what is now a part of the State of Wyoming, in the vicinity of the headwaters of the Green river, a section of country then virtually unknown to white men.

For ten years he lived as a hunter and trapper, trader and mountaineer, in those mountain wilds with an old, trusty Delaware Indian as a friend, and sometimes accompanied by other white men. The thrilling incidents told by Father Terry of his many exciting adventures and narrow escapes causes the blood to tingle in one's veins, and almost makes one feel that the same scenes were being enacted over again. It is almost certain that only for this tried and true friend,

the Delaware Indian, Father Terry would not be with us today. In rehearsing those wild and trying scenes, enacted nearly 50 years ago, we find that it was then, as it is now, man's greatest enemy was man, and wicked men roamed those mountain wilds; and the more an honorable man became possessor of this world's goods, the greater was the schemes of unprincipled enemies to get possession of it. As the old adage goes, that dead men tell no tales, thus we see that in many instances those cruel enemies of mankind would sooner take the lives of their victims than to spare them. Thus many lost their lives for what they possess. Of course, many of the red men lookt upon all white men as their natural enemies. Thus, we see that their lives were often in extreme danger. For this reason they always had to carry their rifles with them for protection, and they often lay down with them in their arms. They would often camp ostensibly for the night, build a fire, cook and eat supper, then replenish the fire and travel many miles over a mountain or across a valley before camping for the night; and then no matter how inclement the weather, Mr. Terry says that on those occasions they dare not for their lives light a fire unless they found a cave or hole in the rocks where the fire could not be seen. By this and other stratagems they many times saved their lives. Sometimes their enemies would rush on them as they thought, only to find that the birds had flown to parts unknown.

After ten years of this venturesome, risky life, his old Indian friend died, and Mr. Terry returned to Utah, and settled at the old homestead. He married Miss Mary Emma Reid, an estimable lady of Draper, Jan. 20, 1857. Fifteen children have been born to them, 8 of whom are still living; and from that time till now he has been extensively engaged in the bee industry, farming and fruit-growing. Some years ago Mr. Terry is said to have owned the finest orchards in Utah.

In 1870 Mr. Terry imported 200 colonies of bees from California, at a cost of \$2,200, or \$11 per colony. During the winter 50 of them died, causing a loss of \$550. But by thrift, energy and perseverance he has made a success of the bee and fruit industries, and also of other pursuits in life. We sincerely wish him yet many years to enjoy the fruits of his labors.

E. S. LOVEST.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. O. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Was the Colony Queenless?—Combs of Honey for New Swarms Next Spring.

1. On Jan. 1 I sold a colony of Italian bees to a neighbor, he to furnish the hive. On a warm day I lifted the frames of bees out of my hive and into his; on doing so I discovered by one frame that they were queenless, and altho I did not search for the queen I united them with another colony. Was I right in calling them queenless?

2. In the fall having more colonies of bees than I wanted, I killed four colonies by the sulphur plan, and I now have the combs of honey; they are nice, straight combs, well filled with honey, but the honey is too dark to eat. Can I utilize them by giving two or three frames to each new swarm in the spring?

CALIFORNIA.

ANSWERS.—1. Can't tell for certain. If the drone-brood was only in drone-comb, it is just possible they were all right. If it was more or less in worker-comb, they either had a bad queen or laying workers.

2. Yes, your plan will work all right. Keep the combs where the honey will not granulate.

How About Bees Under Snow?

What danger is there of bees smothering under snow if the entrance to the hive should not be opened? Some contend that they will smother, while others say no, and the snow is a help to them.

COLORADO.

ANSWER.—Testimony is somewhat conflicting, as you have found. That's probably because results have been different in different cases. One man finds his bees come out in

the best condition after having been buried completely by snow for a certain period. Another, with some change of circumstances, finds his bees ruined. In one case the bees have been covered in such a way, and the temperature has been such, that the bees have had all the air they needed, and the bees have remained at that temperature that allows them to be most nearly dormant. In another case snow has thawed and afterward frozen so as to close the entrance and smother the bees. In still another case the bees have been buried under a deep bank, where they have remained a long time, the snow gradually receding from the hive and leaving an open space, the air coming through the surrounding snow in sufficient quantity for their needs, and the bees have been kept very warm. They start brood-rearing on a pretty large scale, become too active, and diarrhea makes bad work with them. Better not put too much trust in a snow-bank, as yours might not be one of the very successful cases. At any rate, better not leave the entrance closed too long.

Dividing Colonies—Stimulative Feeding, Etc.

1. How early in the spring can I commence dividing?
2. What time can I commence feeding sugar syrup for stimulating, as I wish increase of bees?
3. Can I take queen-cells from frames, and after putting them into queen-cell protectors with spiral cages, fasten them in the combs of the same colonies until I need them, when I commence to divide? I have six colonies, and wish to increase six or more, if the plan would work all right, and save sending south for queens.

KANSAS.

ANSWERS.—1. That depends mainly upon the strength of the colony, and you will find that in general colonies will not be strong enough to divide profitably till about the time of natural swarming. That may come in May or June in Kansas. Of course, you could divide in the first part of March, but it would be a losing game.

2. You may begin stimulating as soon as it is warm enough for bees to fly freely every day. But don't count on too big a gain in that way, and you may not be so much disappointed.

3. You are not likely to make the plan very successful. The virgin queens will not be very well received after being caged some time, unless the bees to which they are given have been queenless for some time. Better try it on rather a small scale.

Wintering—Catnip Honey—Early Queens from the South.

1. When bees are prepared for winter on their summer stands, and they are quiet, are they all right? If they are not altogether quiet, is there something wrong with them? (Of course the hives all have ventilation.)

2. How long may these same bees stay in their hives without a flight and come out all right in the spring?

3. If you were to sow a small piece of ground (say an acre) for bee-pasture, what would you sow?

4. What kind of honey does catnip yield? Some special honey came into my apiary last summer, and I thought it might be catnip. I thought of sowing a piece in the spring to test it. If your answer condemns it, I shall not sow.

5. What is the earliest that I could have queens shipped to me in the spring, and have safe shipment?

ILLINOIS.

ANSWERS.—1. If they are not dead, and if they are perfectly quiet, they are probably all right. But they may be all right without being altogether quiet. If you go to a strong colony to-day that is so quiet that you can hear no noise whatever by putting your ear to the hive, and if the thermometer sinks or rises 10° to-night, you will not find it so quiet to-morrow.

2. It would be a rare case if it came out all right after five months of confinement. The chances would be greatly increased if the confinement were only four months. Some would stand it that long, some wouldn't.

3. That would depend upon circumstances. It would hardly be anything that had no other use except for honey. If no buckwheat were grown in the neighborhood, and if the bees had nothing else to work on at the time buckwheat yields, that might be the best thing. For most places probably sweet clover might be best.

4. I don't know what catnip honey is like. I saw a fine piece of catnip years ago beside the apiary of Jesse Oatman, but I think it was not considered sufficiently profitable to continue.

Unless you have a large family of children of tender years for which to provide catnip tea, I doubt whether it will be advisable for you to use anything for waste land for its occupation.

5. Probably you could have them safely shipped from the south as early as you would be likely to want them, say in April.

Drones—Transferring Bees.

1. If I use full sheets of foundation in every frame in each hive will there be drones enough to supply the apiary? If not, what ought I to do?

2. The colony I wrote you about feeding are doing all right so far. They are in a log 20 inches long, just as I brought them from the woods. If they get through all right, I want to transfer them to a hive. What time would be best, before or after the first swarm comes out?

3. I have one colony in a log that had plenty of honey of their own gathering when I put them into winter quarters. At what time would it be best to transfer them? I want to increase as fast as it is profitable.

4. How late in the fall would it be safe to transfer from a log to a hive with eight frames filled with full sheets of foundation, and properly packed and left on the summer stand?

5. What is the proper width for the alighting-board? Why?

6. How would you transfer a colony from a log to a hive?

MICHIGAN.

ANSWERS.—I. Don't worry. You may do your best to keep down drones and the bees will probably rear a good many more than are needed. If you feel the least anxiety, just break out an inch square from one of the combs and the bees will fill the gap with drone-comb.

2. You can transfer them in time of fruit-bloom, and perhaps with more satisfaction three weeks after swarming.

3. Either in fruit-bloom or three weeks after swarming.

4. If you mean to feed them, it might be done early in September. If you expect them to lay up their own stores, it depends altogether on the pasturage. If nothing but white clover, it might not be safe some years after the middle of June, while other years it might do a month later. If they have plenty of fall flowers, they might fill up after the first of September. Your safe plan will be to take them early.

5. That's a matter about which there is no fixt law; 15 inches is a good width, because it gives the bees plenty of room for a front porch, and keeps weeds from growing up in the way. Two inches is a good width, because it is not in the way so as to split off. Perhaps a still better way is to have the bottom project about three inches for an alighting-board, and then have a loose board lying in front.

6. Follow the directions given in your bee-book for transferring from a box-hive, using your judgment for what variation must take place to fit the particular log in hand. Perhaps you'll do well to saw up as close as possible to the combs at each end, then drum out the bees, and split the log in two at that part which you think will break the fewest combs.

Complete Volumes of 1897.—We have on hand about 40 complete volumes of the American Bee Journal for 1897, which we will mail to any one upon receipt of 60 cents. We also have about the same number of the first six months' copies of 1897, which we will mail for 30 cents. As there were 832 pages of the Bee Journal last year, here is a chance for our new subscribers to get a good deal of valuable reading-matter for a very little money. Better order at once, before they are all gone.

A New Binder for holding a year's numbers of the American Bee Journal, we propose to mail, postpaid, to every subscriber who sends us 20 cents. It is called "The Wood Binder," is patented, and is an entirely new and very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

Uniting Colonies.—The Bee-Master says instead of gradually moving together weak colonies to be united, unqueen the colonies to be moved, 11 days later destroy queen-cells, and 2 days later they'll stay where put. Or, remove queen and all brood, and unite two days later.

Brood-Rearing in Winter.—Doolittle says in Progressive that Quinby was correct in saying that brood-rearing would commence in all good colonies about Christmas, but that meant in colonies wintered outside. In the cellar, with perfect wintering, there is rarely any brood when set out in April.

The Pettit Comb Honey System.—The A. I. Root Co., in connection with the fence separators, propose to make use of the Pettit plan, by having a fence between the outside rows of sections and the sides of the super. S. T. Pettit thinks this will not be so good as his "dividers" with $\frac{3}{8}$ holes, for with sufficient space between the slats the sections will be made ridgy.

Honey in Kongo.—W. Housiaux says in Progres Apicole that in Kongo honey is used as fresh as possible, as it sours in a little more than a week. As Kongo lies under the equator the continuous hot weather favors souring, but it must be pretty thin stuff. It is used under different forms, in cakes made of bananas and rice, but usually in place of sugar with rice.

To Hasten Laying of Hens.—The Bulletin Horticole de Liege gives as a condiment to hasten the laying of hens the following: 6 parts honey, 3 parts flour, 1 part wood ashes. Warm the honey and stir in the flour. When cold beat well. Spread the ashes thinly on a molding-board, and roll on it the paste till the ashes are absorbed. The ashes may be replaced by ground pepper or ginger, and lime may be added.

Average Yield Per Colony.—Doolittle says that in the last seven years of the 70's his average yield was 106 pounds, nearly all comb honey, in one year 134 pounds; and in 1877, 166 $\frac{2}{3}$; one colony giving 309 pounds comb, and one of the two worked for extracted giving 566 pounds. But the woodman's ax and the farmer's plow have brought down the average of the past five years to 70 pounds.—Progressive Bee-Keeper.

Keeping Honey.—Not only is it necessary, says Doolittle in Gleanings, to keep honey in a warm, dry room, but it must have sufficient ventilation to carry off the moisture from evaporation. Soured honey may thicken in such a room, but it will never be as good as new, especially in sections. Sections of honey placed near the floor will not have so good a chance as those higher up, so it is well to have a platform a foot above the floor.

Strap-Iron Frame-Spacers.—These are pieces of strap-iron $2\frac{1}{2}$ inches long, let in perpendicularly into saw-kerfs in the end-bars. They are meant to be an improvement on the Hoffman frame, and the editor of Gleanings calls attention to them as used by W. F. Marks, to avoid the propolis of the regular Hoffman. The same thing has been in use for some time with others, and it is likely that it has been originated in more than one place.

The California Foul Brood Law.—This law has been chased down by the Pacific Bee Journal after a long hunt, and it seems it has been in existence about 15 years. It authorizes the Board of Supervisors of any county to appoint an apiary inspector and fix his pay. If any one complains to the inspector that foul brood exists in a certain apiary, the inspector must visit such apiary as soon as practicable, "and direct the person in charge thereof to destroy all hives ascertained to be so affected, together with the combs and bees therein, by burning or burying; the same to be done the following night." A section that the editor thinks is known to but few, directs that any one owning or having charge of an apiary who finds out in any way that he has a case of foul

brood, must destroy the hive, bees and combs under penalty of \$5 to \$25 for the first offence, and not more than \$50 for each subsequent offence.

Little to Learn.—A letter in British Bee Journal from Mr. Hooker, who is visiting in or near Philadelphia, says: "From what I have seen and the conversation I have had with bee-keepers, who have been most pleasant and communicative, I think we have little to learn from our American friends as to management, etc. They have, however, a much longer honey season than we." Maybe neither side could learn from the other, and maybe either could.

Moths Eating Colonies.—Doolittle took Aikin to task in Progressive for saying something about colonies being attacked by worms or moths, and D. L. Tracy comes to the rescue and says moths don't have such power in Colorado, but in Iowa he has seen the moth literally eat up a colony that was lively, with no sickness or languishing; "10,000 bees to the frame, and 10 frames to the hive, yet the moths completely annihilated them." Won't that make Doolittle gasp?

Winter Food.—A. S., in British Bee Journal, says that after having fed tons of sugar syrup, feeding in all sorts of ways, he is forced to the conclusion "that the best course, with regard to feeding, is to avoid it altogether, by leaving the bees sufficient natural stores to last till honey comes again," whenever this can be done. He says: "Again and again has it been made plain to me beyond dispute that colonies requiring no spring feeding are ready for work in supers before those that are fed in the most careful and judicious manner."

Development of Foul Brood.—P. Beuhne says in Australian Bee Bulletin that Mr. McEvoy is right, that perisht brood will develop foul brood, if he should add, germs are present. He thinks there is no occasion to be at cross purposes with scientists, who contend that no foul brood can develop without germs. No use ignoring the fact that nothing can spring from nothing, and where there are no germs no amount of rotten brood will develop the disease, while in places where germs exist neglected brood makes disease more liable to develop.

Bees and X-Rays.—Henry W. Brice, a bright writer in the British Bee Journal, refers to Roentgen's discovery, and thinks it possible that bees make use of rays invisible to human eyes. How can bees come out of the absolute darkness of a hive's interior and fly without hesitation, when a human eye would be blinded by the sudden change? What power of vision enables bees to work with such beautiful accuracy in complete and utter darkness? Does the queen utilize the X-rays to allow her to see through the wall of wax, so as to place her eggs exactly opposite those laid on the other side of the comb?

"The Alcohol Test is a very simple one for detecting the presence of glucose in honey. Glucose seems to have an affinity for alcohol; and when a small amount of the latter is poured over the surface of the mixture the glucose will send up little threads and balloon-like bubbles into the alcohol. Alcohol placed upon the surface of pure honey creates no agitation whatever." So says John H. Martin in Gleanings among items in his "California Echoes." So much has been said that is false with regard to testing with alcohol, that this test will probably be fully tried before entire dependence is placed upon it.

Prevention of Swarming.—Lacoppe-Arnold in Le Rucher Belge says the following plan has been successful with him: Take from the hive all the frames with adhering bees, and put them in an empty hive. Then brush off all the bees at the entrance of the old hive, and as fast as they are brushed off put them back in the old hive, first removing all queen-cells, in place of two of the frames, however, putting in frames of foundation. Then add the super. When he had done this, he says the bees were completely disconcerted. They found combs to build, plenty of room, and the next day killed the drones and gave up all notion of swarming.

The Bee-Space.—Hardly a farmer was without bees in the neighborhood of F. Greiner when he first commenced bee-keeping, as he relates in Gleanings—soap-boxes, barrels and nail-kegs being among the hives used, and bees were kept rather successfully as to wintering as well as to producing

honey. After he sold them new-fangled hives and transferred the bees, one after another of the old bee-keepers dropt out of the ranks and converted their hives into kindling-wood, until he was left practically possessor of the field. He thinks the bee-space was to blame for this, as bees would not winter in frame hives with the same care that was sufficient for box-hives. The lesson seems to be that while with proper care bees may winter in frame hives even better than they formerly wintered in box-hives, yet for those who will not give them that care, and who make no especial use of the advantages offered by movable frames, box-hives may be more profitable.

Queen Introducing-Cage.—Take the lid of a tin can, cut a large hole in the top, put a piece of wire cloth inside, and fasten it there neat and flat with solder in three or four places around the edge. Place the queen on a comb where there are empty cells and some honey, place the cage over, press lightly, turning the cage to right and left until it cuts in deep enough to stay, then hang the comb in the center of the hive. Next day make a hole through the comb at the back side with a lead pencil, daub honey on the outside of the hole, return it to the hive and the bees will do the rest. If the queen isn't valuable the hole in the comb may be made at the time of changing the queen. This plan is given in the Australian Bee-Bulletin by W. Reid.

Tall vs. Square Sections.—Of 2,000 sections put on 16 colonies, half were Danzy sections and the remainder square, says B. F. Onderdonk in Gleanings; 728 of the Danzy sections were finisht, and 468 of the square sections. The Danzy sections were an ounce heavier than the square, were glazed at a cost of 1 1/8 cents each, and brought 7 cents apiece more than the square ones with cartons and no glass. That for white clover. A rather curious circumstance is that while there was only 1/2 cent difference between the white and fall honey in the square sections, the fall honey in the Danzies brought 4 cents less than the white sections, which brought 20 cents each. Rather has the appearance that the shape of the section, or the glazing, or both, had something to do with getting a fancy price for the tall sections.

50c worth of Books for 1 new Name.

Send us \$1.00 with a new name for the Bee Journal for 1898, and we will mail you your choice of the list below, to the value of 50 cents.

We make this offer only to those who are now subscribers; in other words, no one sending in his own name as a new subscriber can also claim a choice of this list:

| | |
|--|------|
| 50 copies "Honey as Food" | 50c. |
| Wood Binder for the Bee Journal | 20c. |
| 50 copies of leaflet on "Why Eat Honey?" | 20c. |
| 50 " " on "How to Keep Honey" | 20c. |
| 50 " " on "Alsike Clover" | 20c. |
| 1 copy each "Preparation of Honey for the Market" (10c.) and Doolittle's "Hive Use" (5c) | 15c. |
| 1 copy each Dadants' "Handling Bees" (8c.) and "Bee-Pasturage a Necessity" (10c.) | 18c. |
| Dr. Howard's book on "Foul Brood" | 25c. |
| Kohnke's "Foul Brood" book | 25c. |
| Cheshire's "Foul Brood" book (10c.) and Dadants' "Handling Bees" [8c.] | 18c. |
| Dr. Foote's Hand-Book of Health | 25c. |
| Rural Life Book | 25c. |
| Our Poultry Doctor, by Fanny Field | 25c. |
| Poultry for Market and Profit, by Fanny Field | 25c. |
| Capons and Caponizing | 25c. |
| Turkeys for Market and Profit | 25c. |
| Green's Four Books on Fruit-Growing | 25c. |
| Kopp Commercial Calculator No. 1 | 40c. |
| Silo and Silage, by Prof. Cook | 25c. |
| Bienen-Kultur [German] | 40c. |
| Kendall's Horse-Book [English or German] | 25c. |
| 1 Pound White Clover Seed | 25c. |
| 1/2 " Sweet " | 25c. |
| 1/2 " Alsike " | 25c. |
| 1 1/2 " Alfalfa " | 25c. |
| 1 1/2 " Crimson " | 25c. |
| The Horse—How to Break and Handle | 20c. |

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

See "Bee-Keeper's Guide" offer on page 43.

The American Bee Journal

OLDEST BEE-PAPER IN AMERICA

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., CHICAGO, ILL.

\$1.00 a Year—Sample Copy Sent Free.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—W. Z. HUTCHINSON.
SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT. E. WHITCOMB. E. T. ABBOTT.
W. Z. HUTCHINSON. DR. C. C. MILLER. C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Vol. XXXVIII. CHICAGO, ILL., FEB. 3, 1898. No. 5.

Indiscriminate Copying from other papers than bee-periodicals has its dangers. A bee-paper which contains much valuable matter has an article, probably copied, in which it is stated that the drone which meets the queen dies in mating, "his organs being torn from him, and remaining in the body of the queen, forming what is called the spermatheca." The last six words could hardly be written by any one at all familiar with bee-matters, and the editor should be more careful in clipping.

The California State Convention.—Prof. A. J. Cook, now ex-President of the California State Bee-Keepers' Association, has very kindly sent the following paragraphic notes regarding the recent meeting and some of the visitors present:

The California State Bee-Keepers' Convention, held in Los Angeles, Jan. 10, was a very pleasant meeting. We were greatly honored in the presence of Mr. Thos. Wm. Cowan, of England, editor of the British Bee Journal, and Mr. W. L. Porter, of Colorado.

The subject of two Unions was discussed, and all felt that there should be but one Union; and that the one last formed was to be preferred, in that it stood ready to attack any and every evil that confronts bee-keepers. A vote expressing the above was unanimous. It was the opinion of all that adulteration of honey is now our greatest enemy, and should receive no quarter. A national pure food law was stoutly advocated.

The work of the Bee-Keepers' Exchange was praised. It is a general opinion that this organization is very desirable.

It is to be hoped that it will receive the aid and support that it deserves.

Mr. C. A. Hatch, formerly of Wisconsin, was elected President of the Association, and Mr. J. F. McIntyre Secretary. With such officers the California State Bee-Keepers' Association will surely prosper.

Mr. Cowan recently addressed the large farmers' clubs institute, and the students of Pomona College, on the relation of bees to horticulture. This address is a very valuable statement of most important truths. It should be heard by all our people.

A. J. Cook.

Dr. Besse's Sweet Clover Lawsuit.—We have received the following from Dr. H. Besse, of Delaware Co., Ohio, dated Jan. 18, in reference to his suit against the township trustees who cut down a field of sweet clover just as it was about to be valuable for his bees:

MY DEAR MR. YORK:—As I promised to keep you informed in regard to my lawsuit, I take the present opportunity to inform you the jury found in favor of the defendants. This was a surprise to nearly every one present. The court house was crowded during the two days that the trial continued (last Thursday and Friday). I think that the jury were much prejudiced against sweet clover, as the defendants' attorney claimed that I had sowed sweet clover seed along the roads all over the country, and it was such a nuisance!

And further, that I had not rented the field on which the clover was of the legal owner, who was my wife, altho she has been in peaceable possession for the period of 24 years, or since the time her first husband died. My wife has one son now living, but was in the far West when his father died. Then in a few weeks after his father died he came home, and staid about six weeks, when he returned West and was changing from one place to another, and in a few years stopt writing to his mother, and for 16 years she never heard from him, until in 1893, when she found that he was living in New Mexico, and wrote him to come home, which he did in February, 1896. When he last left home he left the farm in his mother's care, and she never had her dower set off. Now, the sweet clover was sown the year before he came home, and he found no fault about the growing of sweet clover on the farm until I sued the trustees, and that made him very angry with me, as well as with his mother. You see, the defendants claimed that when my crop was destroyed, the ground was not under my wife's or my control, and the son and trustees had the right to destroy my crop. I think that they had no more privilege to do so than they would have to destroy a field of wheat.

My attorneys have made a motion for a new trial, and if the Unions stand by me, I will push it as long as they will assist me. I think that we should not surrender at this stage of the fight.

Very respectfully yours,

H. BESSE, M. D.

Feeding Sweet Clover to Farm Stock.—We believe in giving both sides of a question when there are two sides. It seems from the following that "locality" has quite a good deal to do with the eating of sweet clover by farm stock:

MY DEAR MR. YORK:—On page 25 I notice your editorial regarding Prof. Cook's statement with reference to sweet clover being "worthless for anything except bees." I fully agree with him. There is a great deal of both the white and yellow varieties of sweet clover around my home, but not one of the animals on the place will touch it. I have tried feeding it in its various stages—young, old, fresh, dry, cut and growing. In the early spring before the other pastures are fit for use, one would naturally suppose cattle would be crazy for green food, but they wouldn't touch the sweet clover. They would sniff at it, look at me so sorrowfully and say as plainly as an animal can, "Say, what yer givin' us? Aren't you heartily ashamed of yourself for offering us this kind of stuff to eat?"

This matter of feeding sweet clover was not given up after a few trials, but after many, and during the last few attempts I was so ashamed that I couldn't look the animals in the face. My stock may be very peculiar and particular—about that I don't know, but I do know they simply will not eat sweet clover in any form. I have no goats—they might eat it.

Prof. Cook being asked for his opinion regarding its feeding value, could not answer contrary to what his experience had been. If you will remember, at St. Joseph during the

convention of the North American Bee-Keepers' Association, this matter was discussed pro and con. That discussion was what prompted me to make the trials. This question was also freely discussed at the Nebraska bee-keepers' convention held in Omaha two years ago, in which discussion both sides were presented.

To be sure, stock may be starved until they will eat anything that will answer for roughage, but I suppose we are all talking about stock that is kept in an intelligent manner. A week or two ago I took a cow out of the barn and picketed her in a place where there was dead grass and also a lot of fresh, green, young sweet clover. She ate the dead grass all right, but wouldn't touch the sweet clover.

The white variety of sweet clover is excellent for bees, but they don't seem to care much for the yellow variety here.

Yours truly,

LOUIS R. LIGHTON.

Douglas Co., Nebr., Jan. 14.

We believe it would be a good thing to have a few more testimonials on this subject, from those who have had actual experience with sweet clover as a fodder plant. Perhaps Mr. Wm. Stolley, of Hall Co., Nebr., can give some new light on this matter. He has had large experience with sweet clover for hay, and doubtless can tell how to educate stock so that they will eat it the same as the other clovers.

California Bee-Keepers' Exchange.—Ex-Secretary John H. Martin sends us the following report of the late meeting of the Exchange:

At 2 p.m. Jan. 11, the Bee-Keepers' Exchange was called to order by Vice-Pres. C. H. Clayton. The Secretary read the minutes of the last annual meeting, and the minutes of all of the meetings of the Board of Directors and Executive Committee, which were approved.

Mr. Clayton reported upon the financial condition of the Exchange, which showed favorable progress when we consider that the first season was a failure in honey-production, and this season the markets have not demanded honey as in former years.

The present Board of Directors will hold over until another year, or until a special meeting is called.

The present Board of Directors met with Vice-Pres. Clayton in the chair. J. H. Martin, who has served as Secretary, owing to poor health and the fact that he never felt himself qualified to handle the honey proposition, desired to retire from the office, whereupon C. H. Clayton was elected Secretary and Manager. R. Touchton was elected Vice-President, and J. H. Martin one of the Executive Committee. The Board then adjourned.

Something About Marketing Honey.—Mr.

Wm. A. Selser is a bee-keeper who has also had much experience as a honey-dealer in Philadelphia, Pa. He has kindly written the following advice, which he feels ought to be heeded by at least the more extensive bee-keepers, if they wish to realize the most from their honey crops:

— The late arrivals of California honey has demoralized our market. As fancy white comb honey as I have ever seen is selling at 10 cents a pound. I have urged the bee-men for years to ship their honey to the city markets early in the fall. All honey should be marketed before Thanksgiving. History repeats itself every year, and I am getting letters every day from Eastern bee-keepers who want to sell their crop at any reasonable offer. The result is, they can't compete with California, and they will carry their crop over or sell it through a commission house at a few cents a pound.

The reasons are obvious. Commencing in August the California Exchange and shippers offer through the brokers (of which each Eastern city has an immense overstock) their honey in car lots. The wholesale grocers, the bakers and dealers take hold, and car lots are arriving continually till about Dec. 1, when these buyers all get filled up. Then California realizes the outlet in this direction is closed, and then the damage begins by their shipping car lots to these brokers and commission men, drawing on them for half the value of shipment, and the receivers paying the freight. These brokers and commission men finding the car-lot buyers filled up, after holding it a few weeks and being out of the money they have advanced, they sell it out in small lots to the retailers at any reasonable offer.

— I have again and again insisted on the bee-men selling their honey in September, October and November, before such

conditions of affairs begin. Yet every year after Jan. 1 bee-men wake up to the fact that they have a big crop of honey on hand, without any prospect of selling it.

I do not sell honey on commission. I have a number of apiaries under control that produce for me all the honey I can sell, and in giving the above facts I have no interest except for the good of the honey-producer. Wm. A. SELSER.

MR. JOHN BAGSHAW, of Ontario, Canada, wrote us Jan. 24:

"Keep at the dishonest commission men and adulterators. We are all with you."

MR. C. THELMANN, of Wabasha Co., Minn., writing us Jan. 24, said:

"The weather is fine, but no sleighing. Bees are seemingly wintering well."

MR. JOHN H. MARTIN (Rambler), of Los Angeles Co., Calif., writing us Jan. 22, said:

— "We are having continued dry weather, and the prospects are not flattering for a flow of honey during the present year."

MR. LUTHER S. HILDRETH, senior member of the firm of New York honey-dealers—Hildreth Bros. & Segelken—died Jan. 17. We are informed by Mr. Henry Segelken the business will be continued as heretofore under the same firm name, and without change of capital.

MISS GRACE PRINGLE—daughter of the late Allen Pringle, of Selby, Ont.—in a letter written us Jan. 24, said:

"Mother and I are making arrangements to leave the farm in March. I have given the most, or, in fact, all my bees out on shares."

REV. L. J. TEMPLIN, of San Diego Co., Calif., writing us Jan. 10, said:

"This is the first day this winter that my bees have not been able to fly and gather both nectar and pollen. Their sources of supply are orange, lemon, pepper and eucalyptus trees."

ROSE KENNICOTT, of Delta Co., Colo., when sending us her membership fee for the United States Bee-Keepers' Union, wrote:

"I have made a success of bee-keeping, managing 250 colonies with no other knowledge than that I have gotten from always doing what the American Bee Journal advises."

MR. A. W. HART, of Stephenson Co., Ill., was the victim of heartless and almost hurtful errors on our part, which appeared on page 45, where we printed his name H-u-r-t instead of H-a-r-t. We also put him in Will county in place of Stephenson. We beg his pardon, and trust that we will not soon have the "Hart" to "Hurt" him again; nor to move him from one county to another.

CATALOGUES FOR 1898 have been received from the following, who patronize the advertising columns of the American Bee Journal:

Interstate Manufacturing Co., Hudson, Wis.—Bee-Keepers' Supplies.

F. A. Crowell, Granger, Minn.—Queens, Bees, and Bee-Keepers' Supplies.

R. H. Schmidt & Co., Sheboygan, Wis.—Bee-Keeper's Supplies.

— The A. I. Root Co., Medina, Ohio.—Bee-Keepers' Supplies.

MR. ALBERT VOUGHT, a bee-keeper in East Carroll Co., La., writing Jan. 15, reported the arrival of a fine 8-pound boy who fully intended to make his permanent abode with them. Mr. L. W. Trumbull, of this (Cook) county, called recently, and he also informed us that a son had come to brighten their home. We sincerely congratulate these fellow

bee-keepers on their good fortune, and only wish that our two dear babies, that came to us within the past three years, could also have remained with us. But as they were both taken we can only rejoice with others who are more fortunate, for we have been assured that they with many others sorrowed with us in our losses.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL-REPORTER.

(Continued from page 58.)

FIRST DAY—EVENING SESSION.

DRAWN COMB.

"What is drawn comb?"

Pres. Miller—Any comb made by the bees is drawn comb. That is all there is of it. I don't know why it should have that attach to it, and yet of late it has been used quite often. If you have comb made by the bees, it is drawn comb. If any have any amendment to the definition I would like to have it. Drawn comb and drawn foundation are two different things. If no one has an amendment, we will pass to the next question.

PACKAGES FOR RETAILING EXTRACTED HONEY.

"Which is the best and cheapest package of 10 pounds for extracted honey?"

Dr. Besse—A 10-pound pail.

Pres. Miller—Has any one any other package to suggest than a tin package?

Mr. Schaper—I have purchast 100 wide-mouth stone-jars, also crocks; their cost is about eight cents apiece by the hundred.

Pres. Miller—What will be the cost of the tin ones?

Mr. Baxter—Ten cents a piece, they cost me. I sell the whole thing, and if they are returned all right; if they empty it out I take so much off. I sell it at 15 cents a pound on the market right along. This year I didn't extract any.

Pres. Miller—Mr. Schaper has the advantage in the matter of price if his package is as satisfactory as otherwise. The question probably would come in as to whether the stone package would be considered as desirable to the customer for use afterwards; that is a thing we must always consider.

Mr. Rohrs—I have bought this year different sizes of tin pails; some were five pounds, others seven, others about 14 and 14½, and if I remember correctly they cost me, on an average, about 6½ and 7 cents. They have only a plain cover, and as I ship my honey to friends who distribute them among their friends, I like these little packages; they were packt in a box and the board was nailed pretty close, some tight, some not. Some boxes arrived at their place of destination dry and clean, and some of them with nearly all the contents gone, and so I ask, Will that lid close tight enough to prevent leakage? I want a pail where I can take off the cover, because if I show the honey to a customer, I want him to see the stuff I want to sell him, but if I have a tin screw on top, about an inch and a half in diameter, they cannot look into the pail, and I cannot show them what is in there. I should prefer this common pail that I can take off the cover, but want a lid that will close tight, so that in shipping if it is turned upside down no honey will leak out. I see that Mr. Dadant says if he seals it with wax and rosin mixt, when it is warm, it will not leak.

Pres. Miller—Will Mr. Baxter tell us something about the Dadant pail, the circular of which he has handed me?

Mr. Baxter—I consider that the best package for granulated honey. For liquid honey I don't know of a good package on the market. You can turn it upside down or anyway if granulated. For the home market this will do very well, because you can take the lid off, but if you want it shipt away it has to be made so it won't leak. The way I do, I take a piece of wax and tallow and heat it, and invert the bucket into the melted wax and take it out quick, and the wax will adhere all around the rim of the bucket, and the lid will be

tight. That is my method, but it is a great deal of work. I know of no package that fits so tight but what the extracted honey will leak out when it is inverted. There are some, I know, but they are not desirable because, first of all, they are very costly, and the shape and so on are not what we want.

Mr. Wheeler—I know of two or three packages that fill the bill very well for me. There is a can made with a 4-inch screw cap, similar to the 60-pound can cap; they hold 12 pounds. It has a little wire handle on top about three inches long. I don't know what that size costs, exactly, but I should judge not over a shilling.

Mr. Whitcomb—I doubt whether there is anything better for the purpose than a half gallon screw-top can.

BEST RETAIL PACKAGE FOR CITY TRADE.

"What is the best retail package for city trade in extracted honey?"

Mr. Wheeler—In the screw-top can you have one that you may ship anywhere and may liquify in, and also by removing the top show the quality by turning a little honey out on a piece of paper. Honey can be exhibited to customers better that way than any other way. We sell our own honey to our own customers, and usually put it up in that way, where orders from a distance come in, but in the store we keep it in 60-pound cans, and always show the honey on a piece of white paper. I think 10 and 11 cents would cover this 10 and 11 pound can; they are very neat. The freight rate on them is the same as on syrup, or nearly the same. It is almost impossible to put it in a bucket and seal it down so it won't leak; if it is thrown down by freight men, that starts the cover at once, and it leaks out, and you not only lose the honey, but it makes your customer feel ugly, and he doesn't want any more of it. I doubt if we can get anything in the world better for all purposes than the screw-top can.

Mr. Rohrs—It was suggested to me to put a little rubber ring on top of the can, and then put the lid on, and that it would prevent all leakage. Has any one experience with that?

Mr. Wheeler—That will answer all right until the baggage smasher gets hold of it; the minute he turns that upside down your honey will leak out. You cannot afford to do that. I have had no complaint shipping these 10 pound pails to Kansas and Missouri. I have had customers there for 12 years, and they would not have a bit of honey in screw-top cans. I have tried it in both of my own markets and Fort Madison.

Mr. York—I would like to ask whether Mr. Baxter shipt to private families or to dealers.

Mr. Baxter—Both.

Pres. Miller—Is your honey candied or liquid?

Mr. Baxter—I ship it just as soon as I get orders.

Mr. Baldrige—For the retail family trade I don't want anything better than common house-pail; a two quart pail will hold five pounds net, with about ¼ of an inch space above it, and the families who buy the honey have the pail to use afterward, and it is a useful article in every household. Those pails can be bought by the gross for less than 5 cents each, and it makes a cheap package; but if you want to ship it, that is a different question. When a family wants 10 pounds I take them two pails, so as to have a uniform size package.

Mr. York—I should judge from the question that it asks about the retail trade. What package would you suggest for city retail trade?

Mr. Baldrige—For family use I don't see that you want anything different than for retail. I should rather have it in a 60-pound can and draw it as it is sold into any kind of package desired.

Pres. Miller—How many have had any experience with extracted honey for the retail trade? [Seven members had.]

Dr. Besse—Most of my shipping is at Columbus. I have a pretty good trade there. I attend the State fairs, and put the honey in 10-pound pails, in boxes, just the right height, and when the lid is down onto it, I mark it, "This side up with care." I bored holes through the end of the box and slip a rope through and tie the knot on the inside, and two men carry it and keep it right side up every time. That is the way I carry it to the grocery. □ □ □

Mr. Wheeler—I have sold considerable honey to the retail trade, but I don't know what is the best thing to be used. I use a half-pint jar, open top, with rubber screw cap; that sells the best with me yet. □ □ □

Mr. Thompson—I find nothing better than a 5-pound pail for the home trade.

[Continued next week.]

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See offers on page 71.

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash MUST accompany each order.

☞ A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

Drones—Their Advantages and Disadvantages.

Query 68.—1. Do you think the advantages gained from the elimination of drones to be as great as is generally claimed, or are they over-estimated?

2. Are there not in your opinion counterbalancing advantages derivable from their presence in the hive in numbers more approaching to what Nature proportions them, and which we may possibly have overlooked?

3. Given an equal number of colonies, with queens of one age, and all of equal strength, one set with combs of their own building, and hence no restraint as to drone-rearing, and the other set with only worker-combs, and hence incapacitated from rearing drones, what, in your estimation, would be the difference, approximately, in amount of surplus honey harvested?—S. A. D.

Prof. A. J. Cook—1. Yes. 2. No. 3. No difference.

E. France—Too long a question for this department.

Mrs. L. Harrison—1. Over-estimated. 2. Yes. 5. I don't know.

Emerson T. Abbott—1, 2 and 3. Ask somebody that knows. I do not.

W. G. Larrabee—I never experimented on this, but I hardly see the use of a lot of drones when they are not needed.

C. H. Dibbern—1. They are probably somewhat over-estimated. 2. Yes. 3. I can only guess, but I should prefer to "bet on" the one with worker-comb only.

Engene Secor—1. That's one of the things I am not sure of. 2. Possibly, quite possibly. 3. Now my "sad" friend, you are getting the matter down too fine. Please excuse me.

R. L. Taylor—1. First clause, I am inclined to think so. 2. No. Who would follow Nature and keep as many roosters as hens? 3. Having no definite facts to go on, I could give nothing better than a guess.

J. A. Green—See query 66. While it would be hard to estimate the difference in pounds and ounces, I feel sure that four-fifths of the drones a colony will naturally rear are not only useless but detrimental to its interests.

G. M. Doolittle—1. Probably over-estimated. 2. Very doubtful. 3. You are going to the other extreme in keeping out all drone-comb. Six square inches of drone-comb to each colony puts them in a normal condition and secures the best results.

J. E. Pond—1. No, I do not. 2. In my opinion a normal colony contains some drones, my belief being that Nature is the best regulator we have. 3. The question is too broad for me to answer without some qualification. There should be an equalization of affairs. A few drones are necessary to the best working of the colony. When the season is advanced properly the drones will be

destroyed. With me, drones are reared in worker-comb when no drone-comb is supplied, which leads me to believe that drones should be allowed to some extent. As to difference in honey supply in the one case or the other, I know of no means of determination.

J. M. Hambaugh—I think the advantages as much or more than are claimed. 2. The advantages to be gained, except as fecundators, is infinitesimally small, in my opinion. 3. Possibly $1/5$ to $1/2$ more in favor of the colonies prepared with worker-combs.

Jas. A. Stone—1. I think so little of it that I have never practiced it. 2. However that may be, I have never thought the drones in the way till they became very perceptibly numerous through some fault with the queen. 3. I could not say, as I have never observed in that direction.

Dr. J. P. H. Brown—A hundred or two drones in a colony may be admissible; but more are a detriment, as they would consume the stores uselessly. In case your apiary consisted of one colony, more drones might be reared. Nature always looks toward the perpetuation of the species.

A. F. Brown—An excessive number of drones in a colony is certainly a detriment, and is at the expense of the honey crop. 3. With me the colonies having their excess of drone-comb removed and worker-comb in its place, will gain nearly, if not quite, double the yield of surplus the other would.

Rev. M. Mahin—1. I am inclined to think that the advantages are over-estimated. 2. I think that drones in moderate numbers are no detriment to a colony of bees. It is Nature's way. But the cost of production and maintenance is such that the numbers should not be great. 3. I cannot tell.

G. W. Demaree—1. It holds good in the supervision of man over the domestic animals under his charge, that intelligent control of number of drones in the hive is not an "extravagance," but rational treatment. 2. Let the apiarist use his intellect, and he may find out what is most profitable.

Dr. C. C. Miller—1. I don't know how much the advantages are esteemed, but I think they should be highly esteemed. 2. No, I don't believe anything of the kind. 3. The difference would be much the same as the difference in drones. The more drones the less honey. So there, you dark-continenter.

Wm. McEvoy—1. Yes, just as great. 2. No, positively no. 3. One hundred colonies which have been wintered over with nothing but nice worker-combs in every brood-chamber which have been made out of foundation will produce over one hundred dollars worth more honey in a good season than 100 colonies that have been allowed to build all the drone-combs they wish, and reared all the drones they could.

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|---------------------------|-----|--------|--------|--------|
| Sweet Clover (white)..... | .60 | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | .70 | 1.25 | 3.00 | 5.75 |
| White Clover..... | .80 | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | .60 | 1.00 | 2.25 | 4.00 |
| Crimson Clover..... | .55 | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

Your orders are solicited.

J. M. Jenkins, Wetumpka, Ala.

Please mention Bee Journal when writing.

GENERAL ITEMS

Short Crop Last Year.

My bees seem to be coming through all right on the summer stands. There was a rather short crop of honey last year.

WM. A. SCOTT.

Cherokee Nation, Ind. T., Jan. 24.

Good Season for Bees.

I am lost without the American Bee Journal. The last was a good season for bees here. I had 13 colonies, and all but four were new swarms. I bought 6 from a neighbor at swarming-time, and from 11 colonies I extracted 1,000 pounds. The other two were weak and I just got them built up in time for winter. I think that I will devote more of my time to the bee-business, and less to my farming, as I believe it will pay better.

F. S. FRY.

Audrain Co., Mo.

Good Year for Sweetness.

The old Keystone State has been in for a good year of sweetness in 1897—the best since 1894. The best yield from one colony was 158 one-pound sections of honey. I had but two swarms from 18 colonies; one was from a four-year-old queen. She did not swarm for want of room. The other one was for want of room, for they were literally crowded out. I favor large bives and young, vigorous queens for non-swarmers and good honey-producers. I have increased to 24 colonies. I sold my honey at 15 cents per pound before the holidays.

Berks Co., Pa., Jan. 2.

C. C. Yost.

Honey Reported Broken in Shipment.

I got 1,567 well filled sections from 20 colonies, spring count, but I do not know how I am going to come out. I shipped 1,027 pounds, gross weight, to a Chicago commission firm Oct. 6; they receipted "in bad order," and I have not heard anything from them since. I do not see how it is, but it appears to me that shippers of honey are the worst imposed on of any shippers. I am afraid to bury the firm, for if I do that they will claim they have to force sales, and take what they can get for it.

There are quite a number of bee-keepers in this town, and the two adjoining towns, but it is impossible to get them to subscribe for a bee-paper. I was trying to get one of my neighbor bee-keepers to subscribe for the American Bee Journal, and he said, "O, pudle Dick, I know all that is necessary to know about bees." The same man will have from five to ten colonies and not get enough honey for his family use. I shall subscribe for the "old reliable" Bee Journal as long as I can see to read it, and get the dollar.

DANIEL SMETHURST.

Crawford Co., Wis., Dec. 23.

Report for 1897—Honey-Dew.

I started in the season of 1897 with 39 colonies, increased to 54, and got 1,700 pounds of comb honey and 100 pounds of extracted. Bees are all in fine condition for winter, but there is a poor prospect for next year, as there is no white clover.

The first I ever saw of honey-dew was in 1852, in Iowa. I saw it in drops on hickory leaves; it looked clear and tasted sweet. This was in May or June. I have since noticed bees working in the fall on oak trees, and they filled up on it and the honey had the oak taste. I also saw them, in 1871, working on trees very strong, and I examined them and they were working on places on the young twigs that had been punctured by some insect, and the sap was issuing from the wound. If they stored any of this I did not notice it.

But 5 or 6 years ago we had the heaviest

\$300. for Six Potatoes!

We shall introduce this year for the first time the wonderful new **MORTGAGE LIFTER** POTATO and shall pay the above sum in prices for the best six potatoes grown from one seed potato. **THE EARLIEST POTATO IN THE WORLD.** Tested 4 years. It is white, of excellent quality and a **MAMMOTH YIELDER.** Be the first in your neighborhood to try it; next year you can sell it to others. Price this year, 50 cents for single potato. **First in the Market Cabbage** is the earliest to head; beat your neighbors by weeks. **Sure Head Cabbages**, all head and sure to head large size, good quality and good keeper. Single heads have weighed up to 60 lbs. **Climbing Cucumber**, entirely new—a perfect wonder. Climbs any trellis or support 6 to 8 feet high; prolific early fruiter. **Six Week's Turnip**; earliest grower, easy grown, good size and white as snow. **EARLIEST TOMATO IN THE WORLD**—greatest success for earliness, smoothness and quality. Has fruited in 50 days. **Big Prizes Awarded** for ripe tomatoes grown in least number of days. Instructions with seed. **One whole potato by mail** (packed from frost) instructions for prizes and a packet each of the five early vegetables and catalog of "SEEDS THAT GROW" for 25c. **Fairview Seed Farm, Box 28, Rose Hill, N. Y.**

Prices were never before so low—stock was never better. Everything in the **REID NURSERIES** is healthy, well rooted, fully up to grade. You will get exactly what you want at one-half price. Write for estimates, suggestions, illustrated catalogue. Try the **STAR STRAWBERRY** and **ELDORADO BLACKBERRY.**
REID'S NURSERIES, Bridgeport, Ohio.

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginsville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. **R. B. Leahy** and **G. M. Doolittle**, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Somnambulist.** "Experience and Its Lessons," by **R. C. Aikin.** This series of articles will be reviewed by **Mr. Doolittle**, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The somnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. **Dr. C. C. Miller** and other popular writers also contribute to its columns. The **PROGRESSIVE** is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the **PROGRESSIVE BEE-KEEPER** is but 50c. a year. The **PROGRESSIVE** and that "one only" book for beginners, the **Amateur Bee-Keeper**, by **Prof. J. W. Rouse**, both for 65c. A sample copy of the **PROGRESSIVE** for your name, and a beautiful, illustrated catalog of apiarian supplies for the asking. Address,

LEAHY MFG. CO., Higginsville, Mo.

THE HATCHING HEN

HAS LOST HER OCCUPATION and in the production and brooding of chicks she has been supplanted by the better and every way **RELIABLE AND BROODERS.** They Hatch and Brood when you are ready. They don't get lousy. They grow the strongest chicks and the most of them. It takes a 224 page book to tell about these machines and our Mammoth Reliable Incubator and Brooder Co., Quincy, Illinois.

37D17t Please mention the American Bee Journal.

\$1.00 for 25 cents.
AND FIVE MINUTES WORK.

WE want the names of your neighbors who buy seeds, and, if you will send us the addresses of five persons whom you can recommend as being interested in gardening or flowers, we will send you the following assortment of seeds worth \$1.00 for only 25 cents: Market Gardeners' Beet, Washington Wakefield Cabbage, Pink Aromatic Celery, Astro Cucumber, 30 varieties of Lettuce, mixed, Iowa Mastodon Musk Melon, Canary Island Onion, Improved Guernsey Parsnip, 40 varieties of Radishes, mixed, Honor Bright Tomato, Snow Ball Turnip and New Rainbow Pansy. Total, 12 full sized packets, making a complete garden supply, value \$1.00, for 25 cents and the five names. Large, beautifully illustrated catalogue free to all. Mention this paper when writing. Address

IOWA SEED CO., (Established 1871,) Des Moines, Iowa.

WHERE OTHERS FAIL

the **SUCCESSFUL INCUBATORS** succeed, why? because they are properly constructed and the correct methods for operating them are plainly set forth in our 72 page Direction Book. Our machines will please you. Prices reasonable. All sold under a positive guarantee which we ask you to compare with others. Send 6c stamps for 128 page catalog and poultry book combined. It will pay you. Address **DES MOINES INCUBATOR CO., Box 78, Des Moines, Iowa.**

Bee-Hives, Sections, Shipping-Cases—everything used by beekeepers. Orders filled promptly. Send for catalog **MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.**
CHAS. MONDENO, Mgr.
22 Atf Please mention Bee Journal when writing.

Please Send Us the Names of your neighbors who keep bees, and we will send them sample copies of the **BEE JOURNAL.** Then please call upon them and get them to subscribe with you, and secure some of the premiums we offer.

flow of honey-dew I ever saw, in fact, it was all the surplus of that year. My bees had been working on honey-dew for several days, but one morning my son came in and said he never saw honey-dew dropping off the trees before. I went out, and sure enough, everything was covered. I went to a small hickory tree that stood in the apiary, and the honey was dripping; it was as clear as any honey I had ever seen, and, oh, my, but the bees were carrying it in that day and the next. The honey was as clear and nice as any white clover or basswood I ever saw. The next day it was a little dark, and the next two days it was very dark, then it rained, and it was all gone. I sold \$150 worth that year, but sold none of the dark honey; I fed that back to the bees the next spring.

Now the trees, and especially hickory, spoken of had nothing over them for anything to fall from except the canopy of the heavens. It is still a puzzle to me where it comes from. I am satisfied that some comes from insects or sap of trees, but I never can think that the nice, clear stuff that I saw the bees gathering, and saw dripping from the trees, could ever come from insects.

The Bee Journal is good enough every year. I find some article that pays for it, and sometimes several.

R. R. STOKESBERRY.
Vermillion Co., Ind., Dec. 22.

Bees and Grapes—Fruit-Drying.

Noticing that the interesting paper on "Bees in Horticulture" (page 757, 1897) by Hon. R. L. Taylor, is to be put in type, I beg to inquire where copies may be procured. [When it appears in leaflet form, we will likely announce it.—Ed.]

Apropos of this subject, there is one other point which should not be ignored in the discussion. That is the annoyance and trouble caused by bees in fruit-drying. Those engaged in sun-curing fruit in California complain bitterly of this, the trays whereon are spread cut fruit being at times literally swarming with bees, yellow jackets, etc., sapping the juices from all fruits exposed.

This is quite within my own experience, as during the past season we were obliged to cover our trays with mosquito-netting to somewhat stop these depredations; of course, thereby much retarding the process of curing, if not injuring by interrupting the sun's rays and consequent desiccation.

I think in my part of the country this is the subject of greater complaint than the sapping of a few broken grapes on the vine.

Prunes, to illustrate, are dipped in lye to crack the skin and hasten evaporation. This affords a splendid opening for the bees, but makes mighty poor honey. In a large drier it would be out of the question, I think, to cover thousands of trays.

Santa Clara Co., Calif. **GEO. H. STIPP.**

Foul Brood in New York State.

The warm and rainy weather has made our roads very muddy. Until yesterday morning the thermometer dropt to 10 degrees above zero, and through the day two inches of snow fell. My bees flew up to Nov. 20. Then all were put into the cellar.

Foul brood has been raging in some parts of our county the past season. When the season was about over Frank Boomhower of Gallupville was appointed Commissioner, and since that time he worked faithfully examining bees in and around Schoharie and Central Bridge, where foul brood was making bad work. Some yards of bees and bives I understand were all condemned, and had to be burned. Other yards that were examined, the hives that contained foul brood were markt, and had to be burned. Mr. Boomhower worked until late in the fall examining bees, doing his best to prevent the further spread of the dread disease. We bee-keepers are on the lookout, and are watching our colonies very cautiously. If I have foul brood in my beeyard I ought to be the first one to know it, and to take care of it at once, and so ought

every intelligent bee-keeper. But I am fearful of the careless and the don't-care-for-anybody-else bee-keepers who keep but a few colonies themselves.

The honey crop in this section has been about two-thirds of that of 1896. Farm crops were extra good—barns filled and stacks out-doors. Potatoes rotted, so there will be barely enough raised for home demand.

N. D. WEST.
Schoharie Co., N. Y., Dec. 21.

Report for Three Seasons.

I commenced, for the second time or period in my life, bee-keeping with one colony of black bees in a "cubical hive" in the spring of 1895; not a very auspicious year for beginning. In 1896 I purchased 10 colonies of bees in the standard frame style. By purchase and renting I started the season with 14 colonies, and ended with 32, and 1,400 pounds of honey, all but 100 pounds being comb honey, which I sold at 10 cents for the extracted, and the comb at 12½ and 15 cents per section, to my neighbors and friends. I wintered the bees on the summer stands, and every one of the 32 colonies. In 1897 I got over a ton of honey, all comb except 50 pounds, and sold as before, and could sell more if I had produced it. I increased to 57 colonies, and bought 11 in the new Falconer hive for \$22. I doubled up last year's increase in consequence of fall failure and light brood-nests, and now have 57 colonies of my own, and 4 rented from neighbors for increase.

JAMES H. KELSO.

Erie Co., N. Y., Dec. 17.

How One Bee-Keeper Manages.

Three years ago I commenced bee-keeping with one colony and the American Bee Journal. I have been fairly successful. I have kept down swarming by plenty of ventilation and room for storing honey. As soon as the honey-flow commences I put on a super; when nicely at work in that, I put on another one under it. If the bees begin to hang out on hot days, I raise the hive from the bottom, and sometimes move the cover forward a little in the hottest part of the day. The past summer I had a number of colonies that did not swarm, that stored 150 pounds of honey, and went into winter quarters strong in numbers and heavy in stores.

I consider wintering the greatest problem in this northern latitude. I have a very dry cellar under the house. I keep vegetables, etc., in there, too. I have part of it partitioned off dark, but well ventilated. After the first hard freeze in the fall I take off the honey-cloth, have a 1-inch hole inside of the cover, with wire screen on, then put them away. I put hives eight inches apart, one on top of the other, and leave them there till the spring is well advanced. If it should turn cold after taken out, I cover them up with blankets or anything handy, to keep the brood from chilling. I have strong colonies when the honey-flow commences, and rush them while it lasts.

I find the Bee Journal indispensable to the beginner. Long may it live.
Polk Co., Wis., Jan. 10. J. H. DOTY.

Bee-Keeping in Oregon.—Bee-Stings.

This is one of the greatest fruit countries in the world. There was 750,000 pounds of dried prunes raised here this year. We can grow anything but oranges and lemons. I think it will make a fine bee-country. A good many have a few colonies in old gums, but the dovetailed hive is coming to the front. The bees will store some honey every year; 100 pounds is about the best they can do, but 25 to 50 is what they do. The bees can live on the summer stands all winter; can fly some nearly every day when it doesn't rain. We are having lots of rain now. There will be some snow after about a week. There are some flowers all winter for the bees to work on.

I cut six bee-trees the past summer. One had 50 pounds in, another 70, one 10, and the rest about 2 pounds, so you see honey

The American Poultry Journal,

323 DEARBORN ST.,
CHICAGO, - ILL.

A Journal that is over a quarter of a century old and is still growing must possess intrinsic merit of its own, and its file must be a valuable one.

Such is the American Poultry Journal. 50 cents a year.

isn't very plenty. The bees can live on a very little; they never use up the honey in the brood-combs.

I am a tenderfoot at the business, but the first thing I did was to find something to kill the bee-stings. I take a small vial and put in some carbolic acid, one part water. When a bee stings I put some of this on, and it kills the sting or poison, and nine times out of ten it never swells. The hands will stand more than under the clothing.

This is a mountainous country, covered with timber and narrow valleys. It is wet six months and dry six, with some rain. There is no fall honey gathered.

I'm 48 years old, and never had eaten 20 pounds of honey up to two years ago; I never had seen a bee-paper, nor any bees to speak of. I lived on the prairie in Iowa, and 21 years in South Dakota. Why don't you send your honey to such places where they can't keep bees, where the people never see or taste honey?

I plant everything that will make flowers for the bees.
M. W. PRUNER.

Douglas Co., Ore., Dec. 15.

The Large Hive the Leader.

Replying to the question of Mr. L. M. Willis, on page 52, I'll take my best nut-cracker; but it seems to me it is only a hazel-nut he is giving me, and not one of those old, hard, bony black-walnuts.

That colony which did the best of all for him is evidently the best because it is pure Italian, and this is evidenced by its being so gentle. As to the hive, I do not believe that I ever held that the hive made the crop, but that it should be large enough to give the best, or rather the best queen, a chance to spread herself. I see that in this instance, that was just what Mr. Willis did, for he gave his 7-frame colony another brood-chamber of 8 frames above. That was really overdoing our methods, for we aim to give our bees only about the capacity of 12 Langstroth frames altogether, and in this instance the colony had 15. But he was fully repaid for his additional room, and I would suggest that he try it again on other colonies if they also prove prolific enough. And they don't swarm! That is our way. See?

Fairview Seed Farm.—We wish to direct the attention of our readers to the announcement of the Fairview Seed Farm, Rose Hill, New York, which makes its first appearance for the season of 1898 with this issue. It will be observed that the advertisement contains some extraordinary offers in the way of special collections of seeds and tubers. Their new Mortgage Lifter Potato is well spoken of, and should prove of special value to our readers. Every farmer or gardener should have an experimental plot where new varieties may be tested each season. Many of the best standard sorts of fruits, berries and vegetables have been given to the public in this way. Try this new collection; it does not cost much, and may result in much profit to you. Write then for a catalog, and say you saw their advertisement in the American Bee Journal.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Dec. 13.—Fancy white 11 to 12c. No. 1, 10c.; fancy amber, 8 to 9c.; No. 1, 7c.; fancy dark, 7c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special change. Beeswax is scarce.

Milwaukee, Wis., Jan. 24.—Fancy white 1-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 13½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

Detroit, Mich., Nov. 9.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c.; fancy dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c. Beeswax, 25 to 26c.

New York, N. Y., Dec. 22.—Fancy white 11 to 11½c.; off grades, 9 to 10c.; buckwheat and mixt., 6½ to 7c. Extracted, California white, 5 to 5½c.; light amber, 4½ to 4¾c.; white clover and basswood, 5 to 5½c.; buckwheat, 4 to 4½c.; Southern, 50c. a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of huckwheat, mixt, and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Dec. 15.—Fancy white, 11 to 12c.; No. 1, 10 to 11c.; fancy amber, 10c.; No. 1, 9½c.; fancy dark 9 to 9½c.; No. 1, 8 to 9c. Extracted, white, 5 to 6c.; amber, 4 to 4½c.; dark, 4c. Beeswax, 23c.

Market holds firm at above prices. Good demand for extracted. Wax is quiet but firm at 23c.

Albany, N. Y., Dec. 13.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; fancy amber, 8 to 9c.; No. 1, 8c.; fancy dark, 8c.; No. 1, 7½ to 8c. Extracted, white, 5 to 6c.; amber, 4½ to 5c. dark, 4 to 4½c.

There is an ample stock of comb on hand and selling freely at quotations. Extracted is not plentiful and from information received there is not much in the hands of producers.

Buffalo, N. Y., Jan. 14.—Strictly fancy 1-pound comb honey is more active at mostly 10c. occasionally 11c., but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c. down to 5c. Extracted is also very dull at 4 to 6c. We cannot recommend the shipping of honey here unless it is strictly fancy 1-pound sections.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

St. Louis, Mo., Jan. 17.—We quote honey nominal but very little selling. Demand is light. White comb, 1-lbs., 10 1-2 to 12c.; amber, 8 to 10c.; dark, 5 to 7c.; broken comb, 4 to 7c. Extracted, in cans, white, 5½ to 5 1-2c.; light amber, 4½ to 5c.; amber, 4½ to 4 1-2c.; dark, 3 1-2 to 4c. Beeswax, 25 to 25 1-2c. To sell honey in lots above prices would probably have to be shaded a little.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Kansas City, Mo., Jan. 20.—Fancy white, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. The market is well supplied, and demand is light.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; A No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3½c. Beeswax, 28c. Late arrivals of California honey have demoralized our market.

Cincinnati, Ohio, Jan. 17.—There is no change in prices, but rather a slow demand for all kinds of honey. We quote 10 to 13c. as the range of prices for best white comb honey, and 3 1-2 to 6c., for extracted, according to quality. Beeswax is in fair demand at 25 to 27c. for good to choice yellow.

San Francisco, Calif., Dec. 8.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 4¾c.; light amber, 3½ to 3¾c.; dark tulle, 1½ to 2¼c. Beeswax, fair to choice, 22 to 24c.

Improvements in the Rearing of Bees.

BY ADRIAN GETAZ.

Can it be done? That is, can we by judicious selection create a race of bees far superior to those we possess now?

Certainly we can. See what has been done in the line of other domestic animals—cattle, horses, dogs, chickens, pigeons, etc. And in the line of bees themselves a careful selection has brought the 5-banded and the Albinos out of the common Italians.

What are the qualities to be sought? Well, hardiness to stand the winter; prolificness of the queens; activity; longevity; beauty; and other minor points.

THE SIZE OF BEES.

In connection with the above-named qualities, the length of the bee's tongue has an important bearing. There is no possible doubt that bees with longer tongues than those our actual strains of bees possess, would be able to gather nectar out of many flowers which are too deep for them under present conditions. One of these flowers is the common red clover. And if we consider that with the progress of agriculture, the white clover, forest trees, and wild plants, are disappearing, while the red clover will hold its own, and even increase in area, the importance of having bees able to gather the nectar from it is incontestable.

It is evident that a larger-sized bee would have a longer tongue, so in that respect an increase of size is desirable. The question whether it would be otherwise an advantage has been very much discussed. For my part, I say unhesitatingly yes, and a big YES at that.

We may presume that a larger bee would fly as fast, if not faster than a smaller one. It is said that large insects are sluggish compared to small ones; and that is often true in comparing different species, because there is a difference of constitution, shape, etc., besides the difference of size; and even then it is not always true. A fly and a mosquito are much smaller than a bee, and certainly do not fly any faster.

Supposing that the larger bee does not fly any faster, and does not gather the nectar any quicker than the smaller one, there would be yet a considerable saving of time in going and coming. For instance, if the large bee can take in one load twice as much as the small one, the time to make one trip to the fields and back would be saved each time, and this would be a considerable item, especially during a heavy flow.

Among the different kinds of wild bees of our country, only the largest (bumble-bees) gather honey in anything like a quantity. In India, there are quite a number of different kinds of bees similar to ours, some not larger than ordinary flies, but only the large kinds store more honey than they need, and the largest kind, the famous *Apis dorsata*, build combs several feet in length, and produce more honey than any other wild bee known.

INFLUENCE OF FOUNDATION ON BEES.

The first step to take would be to use a larger size of foundation cells. The size of the cells limits the size of the bees, as any one who has had drones reared in worker-cells knows. Before the foundation was in general use, there was a considerable difference in the size of the different strains of bees, as can be ascertained by consulting the old text-books. Now, we do not hear any more of it, because the general use of a uniform foundation has brought all the strains of bees to a uniform size.

A difficulty to avoid would be an over-production of drones. The only prevention that I can see would be to increase the size of cells only of a small proportion at first, say one-fifth, and when the new strain of bees should be well established, make another increase, and repeat the process if found practicable.

SELECTION FOR BREEDING.

But the increase of the size of the cells is not the only requisite to obtain larger sized bees. Besides that, other qualities have to be considered. So it will be necessary to select the queens producing the largest and best bees, all considered. Here we meet with serious difficulties. In improving cattle and other large animals, every individual can be

examined, all its qualities and defects considered and tabulated, and a proper selection as to mating can be made. With bees the case is altogether different. We cannot examine each bee and put down in a book her qualities and defects, and the length of time she may live. Worse than that, we cannot select the drone even if we could ascertain beyond doubt which individual drone is the best. Practically, the only way is to rear the queens and drones from the colonies having given the best results, and destroy the drones from the other colonies by cutting the drone-comb or using the queen-trap.

CONCERNING THE PERFORATED ZINC.

Perforated zinc to control the production of drones and prevent swarming is an old invention, but never came into general use until the use of a uniform foundation produced uniform-sized bees, for perforations entirely too small for the workers of large size would have permitted the queens of small strains to go through. As to preventing the drones, the case is much easier. The difference of size between queens and workers, so far as the thorax is concerned, is very small, while between workers and drones it is considerable. The small drones reared in worker-cells cannot pass through the zinc. With larger bees we would have to adopt larger perforations. Probable the increase in size of the perforations would have to equal the increase in size of the cells. If the zinc were to retain the queens, it would be necessary, in selecting, to choose not only the queens producing the largest workers, but the largest queens themselves, which is entirely another thing.

Perhaps I should add that larger bees and larger foundation cells would also require a larger hive, or, rather, a larger brood-nest.

APIS DORSATA.

An increase of size in bees is necessarily connected with the introduction of *Apis dorsata*. As to its desirability we find as much divergence of opinions as concerning an increase of size in our common bees. I think these bees would likely be a valuable acquisition. They undoubtedly produce a larger quantity of honey in their native country than all the other kinds of bees. They are as manageable as our bees, according to Frauk Benton, who is unquestionably a competent bee-keeper. The fact that the natives climb the trees almost naked, and cut off the combs to take the honey, shows that they can be handled as well as common bees.

It is not likely that they could stand much cold weather, so it would be well to introduce them at first only in the most southern States.

The fact that they build their combs in the open air is not an objection. It is merely a question of climate. All kinds of bees build in the open air in the tropical countries.

One objection exists: Their drones and workers are said to be reared in cells of the same size. If it is really so, the control of the over-production of drones by cutting the drone-combs could not be resorted to, which would certainly be a disadvantage.

INFLUENCE OF THE NURSE-BEES.

Some incidental questions merit consideration. One is the influence of the nurses, that is, the bees nursing the brood. It has been claimed by some superficial writers that the characteristics of the nurse-bees were transmitted to the young bees through their feed. It would take quite a long article to show the error of his opinion, however I may state here that the food taken by the brood is so completely transformed through the chemical processes accompanying the digestion, that whatever "moral" or "intellectual" qualities it might have before being eaten by the young bees, have certainly disappeared by the time the process of digestion and assimilation is completed.

The influence of the nurses or the adult bees is one of example. If the old bees are cross or inclined to rob, the young ones will more or less follow their example, and this is why these characteristics will sometime persist after the queen has been changed.

It has also been said that the ability to stand bad winters must be transmitted by the nurses, for how can the queen, which is always in the hive, transmit to her workers the faculty of resisting the cold when she does not possess it herself? This seems a strong argument at first, but it is none at all, after all.

Here are two queens, No. 1 and No. 2. No. 1 produces workers able to resist the cold weather, while the workers of No. 2 cannot. Well, when the winter comes, the workers of No. 2 will die out; so will the queen, necessarily; so by the next summer only queen No. 1 will remain, and produce not only workers but young queens, which, like herself, will have

workers able to withstand the cold. It is a mere question of the survival of the fittest, and the influence of the nurses is a question of good and bad example to the young generation.

The quality and quantity of the food have, however, an influence on the development of the eggs and larvæ, and in that way the nurses have an indirect influence through the food they provide. This influence is strong enough in bees to change the development of a fecundated egg from a worker to a queen. But the germs of the organs of both worker and queen were present in the egg, and the difference is that a certain set of organs was developed in one and not the other.

INFLUENCE OF THE DRONE UPON THE QUEEN.

Another point has been erroneously advanced. It is well known and incontestable that the drones are born of unfecundated eggs, and that all the eggs of an unfecundated queen, if she is otherwise sound, will hatch, but hatch only drones, while all the fecundated eggs of an impregnated queen will hatch workers or queens, according to the food they receive. Well, some have claimed that the drones will have some of the qualities of the drone which fecundated their "mother." This seems hardly possible. When a queen is fecundated the male germs enter a little sack inside of the queen's body, and remains there completely separated from her eggs or any other of her organs. Her eggs are produced in another and entirely different part of her body. As they mature and come out they pass before the opening of the said little sack. If the sack is kept closed up, the eggs come out unimpregnated, and hatch out drones. If the sack is opened, one or more male germs come out, enter the egg as it passes, and that egg will produce a worker or a queen.

A CAUTION.

A fact often overlooked is that the bees of an apiary will always mix, more or less, from one hive to another. Many apiarists have thought that the queens they bought were not pure, or that their 5-banded queens did not produce all 5-banded workers, when the faulty bees they saw had come from other hives. I have had proof of such cases time and again in my own apiaries. To be sure, in every case it is necessary to observe carefully the very young or hatching bees.

Knox Co., Tenn.

Snow in the Apiary—Its Advantages.

BY C. P. DADANT.

Since our fields have put on their warm white winter clothing, it is well for us to consider what is best to be done for the colonies that are wintering under this white sheet in the apiary. Is it necessary to remove the snow from the hives, or should it be left for a protection?

That this snow is a protection to our fields and our meadows all our farmers well know. It is a non-conductor of heat or cold, and the ground under it retains its natural warmth. When the snow melts, the wheat and grass show, by their green blades, that this mantle has been beneficial. The hives, likewise, if partly or entirely buried in the mound of snow, will retain the warmth of the bees, and many of our old apiarists purposely pile up the snow over their hives.

In Canada, in Siberia, bees live well through the winter and come out strong and healthy if a sufficient shelter of snow has protected them. The conditions, in those countries are, however, somewhat different from what they are at our latitude. The sun there has but little strength during the winter months, and when the hives are entirely buried their natural heat alone has any effect upon the snow. It causes it to melt away from the wood slowly but by a steady action, and the openings of the hive are thus liberated, and ventilation secured.

In our latitude of central Illinois there are but very few days when the sun does not more or less cause a thaw, the snow changes to ice, and an additional freeze-up by a sudden change of wind may completely close up the entrance and air passages. This condition would lead to the suffocation of the bees so confined if protracted beyond a few days unless some aperture or crevice at the upper part can give a chance for the ingress of pure air. So there is a danger against which we must guard and a little snow, enough to close the air-holes with ice is much more dangerous than a drift in which the hive is ensconced as in a cellar.

That a few degrees in latitude make a great difference as to the results for the protection to be derived from the snow, is not to be doubted. I have had occasion to visit northern New York and a part of the Province of Ontario in the winter, and I have noticed with what faith in the thin coat of snow the vehicles of all kinds embark into trips on sleds. Every-

thing is on sleds from the omnibus to the dray cart, and it looks as if they might be tempted to put the electric cars on runners as well. Hereabout, if we venture ten miles from home in a sleigh we run great risks of having to come home in a skiff.

So the snow is not to be trusted too far, and the south side of our hives is in danger of being quickly uncovered of its shelter when it is of this flimsy material. Acting upon this experience we have been in the habit of banking up the snow, when there is plenty of it, on the north and west sides only, and carefully cleansing the apron-board on the first warm day after the snowfall. If the weather gets mild enough for a bee-flight, our bees then find themselves dry footed in front of their hive.

We have seen many bee-keepers close their hives on a warm day in snow time to keep the bees from flying and getting lost on the trip. We have never found any benefit in this method. When the weather is warm enough for the bees to fly, if they are confined they will fret and worry, and if their abdomen is loaded with fecal matter or excrements they may be compelled to discharge these excrements in the hive to the discomfort of themselves and their sisters. Better let them fly, and run the risk of their not returning. Not only is this reasonably plausible in theory, but practice has confirmed our view of the matter, for we have invariably noticed that those colonies which take the freest flight on warm days, and consequently seem to lose the greatest number of bees on the snow, prove to be the best colonies in the spring.

All things considered a heavy snow is to be taken as more beneficial than injurious to the interests of the apiarist, for if it is a sign of protracted cold—which is by no means always the case—it is also a prophet of prosperity since it shelters the land and promises us a healthy growth of grass, clover and other plants, and adds moisture in the ground, which slowly penetrates to the roots of the plants.

Hancock Co., Ill., Jan. 27.

Bees Clustering Between Brood-Frames and Cushion—Feeding Bees in Winter.

BY EDWIN BEVINS.

I shall have to confess to my inability to see what there was in "Iowa's" first question (see page 39) that led Dr. Miller to infer that there was an open space between "Iowa's" brood-frames and his cushions, unless this inference can be accounted for on the ground of surprise that any bee-keeper should be surprised at feeding his bees clustered up against the cushions when the cushions rest on the frames, or having a Hill's device or some sticks between the frames and cushions. If "Iowa" were to come into my yard now he would find the bees in every hive, except a few colonies in two-story hives clustered up against the cushions. This gives me no surprise and no uneasiness. I know that there is plenty of honey in all the hives for present needs, and that the bees will get it when they need it. The bees cluster up against the cushions for the sake of the warmth which rises from the cluster and is arrested and held by the cushions.

If my bees were in a barn without any packing around the hives except a cushion in an empty super over the frames, I might feel some of "Iowa's" apprehension that they might not winter safely.

It seems that "Iowa" has yet to learn that a building of any kind where the temperature varies much is about the worst place in the world to winter bees in. If I had some bees in a barn, as "Iowa" says he has, I should lose no time in getting them out of the barn and into a winter-case such as I now make for all of my bees. These cases are cheap, and I have found a way to make them so that it does not take the apple-orchard and calf-pasture to store them in when not in use.

If "Iowa" or anybody has bees that are getting short of stores, no time should be lost in making some cakes of candy from granulated sugar as recommended by Mr. Abbott. And here let me say that in time it will come to be recognized that Mr. Abbott has given us a cheap, easy and sure method of saving a colony of bees that happens to be starving in cold weather. I may be pardoned, perhaps, if I enlarge a little on what he says about making the candy:

If I want but one cake to help out a colony that has nearly enough honey to carry it through, I put a pint of water into a kettle that has a rounding bottom with short legs to keep it from tipping. When placed on the stove the center of the bottom of the kettle just touches the top of the stove. I remove a stove-cover at first and set the kettle next to the

fire till the water boils, then I pour in five pounds of granulated sugar and stir constantly while pouring it in.

Then if the fire gets quite hot, and the syrup begins to foam up, I raise the kettle and put the stove-cover under it. The boiling will continue in the center of the kettle, and there is no danger of burning unless your wife or your daughter, or your hired girl, comes around and builds up a big fire to bake some bread or heat the flat-irons. In that case you may have to move your kettle to some other part of the stove. If the bee-keeper happens to be unmarried, he will remain undisturbed, as it is not likely that his sweetheart will be around on such occasions.

Keep stirring while this slow boiling is going on till the water is nearly evaporated. You can tell when this takes place by the manner of the bubbling which is going on in the kettle. If the bubbles are few, and the bubbling labored, you may know that the job is nearly completed. Put a spoonful or so of the bubbling mass into a cup of cold water and you can tell for sure.

Pour the mass out into a common-sized, oblong baking-tin, and you will find the tin is just even full. When sufficiently cool, place the cake over the cluster, bottom side up, with two or three sticks half-inch thick under it. You may have to take a little of the stuffing out of the cushion, and then it will tuck down nicely over and around the candy. My sacks for cushions are made somewhat longer than the supers and left open at one end, so that it is an easy matter to remove part of the chaff. Decatur Co., Iowa.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL-REPORTER.

(Continued from page 74.)

FIRST DAY—EVENING SESSION.

GRANULATION OF HONEY IN WOOD, TIN OR GLASS.

"Will honey granulate sooner in a wooden or tin pail than in glass?"

Pres. Miller—Who knows anything about that? I will venture a suggestion, that it ought not to granulate quite so soon in wood or tin, because it is generally supposed that light has a little to do with it; on that account, other things being equal, it ought to granulate just a little sooner in glass than in wood or tin, but I don't know anything about it.

Mr. Baxter—I don't believe that light has anything to do with the granulation of honey. I never found that out. I believe it depends upon the temperature altogether. The variation of temperature causes it to granulate much sooner than an equal temperature. That has been my experience. The way I can get honey to granulate the quickest is to take barrels and move them around often, and especially if they are down in the cellar. But if I take liquid honey and put a few grains of granulated honey into it, it will granulate very fast. I think it is owing to variations in temperature.

M. S. Miller—I askt that question, and the reason I askt it was, I have had it stand around in tin packages and glass, and while that in glass did not show any signs of granulation, in tin it did. There was another thing in my mind: The honey in tin packages had been more exposed to air, having been opened several times; perhaps that had something to do with it. I don't know what to think of it. It made quite a difference in selling honey to the city trade.

Pres. Miller—Was the honey put in at the same time?

M. S. Miller—It was, and the same kind of honey.

Pres. Miller—Was there any difference in the handling afterward? Was one shaken any more or handled any more than the other?

M. S. Miller—If it was, the one in tin was the most. I am not sure whether there was much difference. The cans were filled about the same time from the same honey.

Mr. Baxter—Mr. Christle, who used to attend these meetings from northwest Iowa, told me that he sells his Spanish-needle at retail by canning it, and sealing it up tight; it never

granulates then. The more exposed to air it is the more it will granulate.

Pres. Miller—To what point would you heat it?

Mr. Baxter—It wants to be so the air is thoroughly driven out.

Pres. Miller—If you go beyond 160° you are in danger, you know.

Mr. Baxter—By putting the cans in warm water there is no danger.

Pres. Miller—It hurt my honey; it may not dark honey.

Mr. Baxter—It won't white clover honey. Put it in hot water. I put my jars on a board in the bottom of a boiler, so the glass does not touch metal at all, and I have never had any trouble.

Mr. Green—Have you ever heated heart's-ease honey to that point?

Mr. Baxter—Yes, I have?

Mr. Wheeler—Some samples of heart's-ease honey we find granulating in a day or two after they are put in jars, especially if put in while warm, but I have a sample of honey which I had on exhibition at the World's Fair which was shipped down here in November, and after it was sent home it was shown at the Nebraska State Fair twice, and has not granulated yet. Those samples were treated differently. I took it off in the fall, carried it in a warm room in combs; it was extracted in April, and put into jars and shipped down here; it weighed 13 pounds to the gallon. I have had it show the effects of granulation while I was shipping it 100 miles. If honey is taken off and extracted and put into jars while yet warm from the hive, it will granulate much quicker than if it is kept on hand to ripen more.

Pres. Miller—I have no doubt that Mr. Wheeler has struck an important point; if we don't want honey to granulate it should be very ripe.

Dr. Besse—I have had some experience in keeping honey from granulating, and am satisfied that if you bring it almost to the boiling-point and put it in fruit-jars and can it up with sealing-wax, air-tight, you can keep it for years without granulating; and by adding a little cream of tartar with it—I want to ask whether or not that would be adulterating it.

Mr. Wheeler—How much to 60 pounds?

Dr. Besse—Well, to 100 pounds I should think about a tablespoonful.

Mr. Wheeler—What effect has that on the honey as to its color?

Dr. Besse—No effect at all. It will keep sugar from crystalizing, and I should think it would honey. I don't think there would be any harm in adding it.

Mr. Baxter—If the secret in keeping honey from granulating is to have it thoroughly ripened before extracting it, why is it that in California they extract it before it is ripe, and it never granulates?

Mr. Wheeler—It does not granulate in extremely dry air like California so quickly as it does here, because it does not gather moisture from the air.

Pres. Miller—All familiar with honey know that the character of the honey itself has a great deal to do with granulation.

Dr. Besse—I have some honey put up in one-half pound and pound jars, that has been put up for four or five years; some of it did not granulate at all, but the greater part did.

Mr. Wheeler—I think that point by Dr. Besse is a good one, about adding cream of tartar, if it works. I would like to find out what experience he has had; in what shape he adds it, and so on. I think there is a great demand by the people for honey that does not granulate, and if we can find something that will not be considered adulteration, I think that is one of the greatest helps to the sale of extracted honey there is.

Mr. York—I would like, as Mr. Wheeler asks, that Dr. Besse tell us a little more about what has been his experience in using cream of tartar to prevent granulation of extracted honey.

Dr. Besse—I have never used it, but I have been tempted to use it. I am against adulteration.

Mr. Green—Perhaps my experience with cream of tartar would be of some use. I used to use it for putting up sugar syrup for winter—a piece to 10 pounds of sugar. I think I used a piece of tartar about the size of a hazel-nut mixt with hot water, and added to hot syrup; boil a little after that, and it would never granulate or crystallize, and if used in honey in the same way it might have the same effect.

Dr. Besse—I am satisfied it will keep honey from granulating the same as sugar from crystalizing. I should like to have our friends here experiment on that. I don't think there would be anything wrong in it at all.

Mr. Wheeler—I have tried using it in sugar syrup, and it

didn't work at all. It granulated just as quick with it as without it.

Pres. Miller—H. D. Burrell reported that he used tartaric acid, and his syrup granulated solid in the combs.

Mr. Green—I should suppose the reason of that would be, it was not boiled after the tartaric acid was added; it must be boiled slowly afterward.

Mr. Wheeler—Mine was boiled at the time I put it in.

Pres. Miller—I don't believe you can settle "why;" you will find it sometimes will and sometimes won't.

Mr. York—I read in one of the monthly bee-papers, about a year ago, that to prevent the granulation of extracted honey if $\frac{1}{8}$ water were added it would do it. It was written by one who ought to know what he was talking about.

Mr. Green—I should think that would make some honey granulate more readily.

Mr. Wheeler—I am pretty sure it would sour it.

[Continued next week.]

Report of the California State Convention.

BY JOHN H. MARTIN.

The California State Bee-Keepers' Association held its annual meeting in Los Angeles Jan. 10. The meeting was called to order by Pres. A. J. Cook at 2 p.m. There was no set program, and a committee was appointed to prepare one—composed of C. A. Hatch, J. F. McIntyre and H. E. Wilder. While the committee were out, Prof. Cook gave a short review of topics that should be discussed by the association: 1st, The old vs. the new Union. 2nd, Adulteration. 3rd, The Bee-Keepers' Exchange.

Mr. W. L. Porter, a prominent bee-keeper of Colorado, and Mr. Thos. Wm. Cowan, editor of the British Bee Journal, England, were present, and were introduced, also elected honorary members.

The report of the committee on program was presented, and the first topic considered was

THE TWO BEE-KEEPERS' UNIONS.

Mr. McIntyre was in favor of the amalgamation of the two Unions. The National Union had been a great success in defending bee-keepers against prosecution by fruit-men and others who considered bees a nuisance; but it was not disposed to prosecute the adulterators of honey. The United States Union proposes to take this very important matter in hand, and he was decidedly in favor of uniting the two.

The tendency of the discussion was in the same strain. Several who had heretofore been opposed to the amalgamation of the two were now in favor of it. Mr. C. A. Hatch presented the following resolution:

"Resolved, That the new United States Union should absorb the National Union."

Upon putting the resolution to vote, 43 favored it, with none opposing.

Upon a motion by R. Touchton, the Secretary was instructed to inform the respective managers of the two Unions of this action.

The next subject for discussion was

THE ADULTERATION OF HONEY.

Mr. Hatch said that the adulteration of honey was practically stopt in Wisconsin by the enactment of stringent laws and the enforcement of them.

C. H. Clayton, author of the present law in this State against adulteration, said that the proper enforcement of the law in this State would have the same effect; but as the greatest amount of adulteration was practiced in the East, a general pure food law should be enacted under which we could work more effectively.

BEE-KEEPING IN ENGLAND.

This topic was on the program, and the announcement meant that Mr. Thos. Wm. Cowan would give the assembled bee-keepers something interesting upon that subject, and they were not disappointed. We wish that we could give a more perfect report of the address, but we trust that the report we do give will repay perusal. Mr. Cowan, in substance, said:

That while in California large apiaries are common and encouraged, in England there are but few large apiaries, and large apiaries are not encouraged; the small apiary is the rule in England, and many of the apiaries are kept in fruit-growing districts for the purpose of fertilizing the fruit-blossoms.

Bee-keeping, according to improved methods, began about 1860. The Langstroth hive was introduced at that time, and was used by the most progressive bee-keepers, but the

real advance did not become general with bee-keepers until 1873. Up to this time many straw and other rude hives were used, but now the Langstroth hive is gradually superseding all others. In 1874 the British Bee Journal was started and an association organized; something of an impetus was also given to the industry through the exhibits of honey in the Crystal Palace in London.

In organizing the British Bee-Keepers' Association it was difficult to get bee-keepers to attend. The Association is now made up from affiliated societies. The various county societies are obliged to elect two delegates to represent them in the council, which meets every month. Often the delegation from a county society will number eight or ten, and a large attendance at the council is the result. Refreshments are served, and then follow papers and discussions upon topics of interest to the various societies.

Through its thorough organization the British Bee-Keepers' Association is doing excellent educational work, several books upon the different branches of apiculture having been published. The Association grants certificates to the most proficient in the manipulation of not only frame hives but straw hives as well, and in the management of foul brood and other diseases. When an examination of candidates for certificates is to be held, several counties unite and select a place where bees can be manipulated. After the candidate is examined, the examination papers are sent to London and past upon by the council. In order to secure a certificate the candidate must be able to give a lecture upon any subject in the practice of bee-keeping.

Experts for the handling of foul brood are appointed and compensated according to the work done. The expert does not visit keepers who are well up in their business, but it is the careless or ignorant bee-keeper whose bees are found diseased. In many districts in England the bees have all died from this disease. It was virulent because many bee-keepers had no knowledge of the interior of a bee-hive; straw hives, or something equally inaccessible, were in use; such bee-keepers would defy the expert, for there was no law to compel the destruction of diseased bees. The Association had adopted a system of payments where foul-broody colonies were to be destroyed, and tho the payments were small it satisfied the owner of the bees, and enabled him to purchase healthy colonies if his own were all destroyed.

The honey market is developed by the holding of honey-shows in the various counties, and a central show in London. A system of labels has been adopted. These labels are issued by the county association. Each member is allotted a number which is stamped upon his label; if he sells inferior honey it is traced to him, and his name is stricken from the Association.

The Association employs an analyzer, and if a person is caught adulterating honey or selling it under an Association label he is imprisoned; they are not left off so easily in England as they are in this country.

There are about 53,000 bee-keepers in the British Isles. They will average five colonies each; in favorable localities the yield is from 100 to 150 pounds per colony, but the general yield is from 50 to 60 pounds.

The bulk of the product is extracted honey, and is put up in 50-pound, 28-pound, and in as small as 4-pound tins; packages smaller than that are of glass.

The wholesale price for comb honey is from 14 to 20 cents; extracted honey 12 cents. The value of the annual product is about \$750,000. Besides the home production there is a monthly import of from 10,000 to 15,000 pounds, the greater portion of it from the United States and Canada.

Imported honey is not inspected until it is put upon the market. American honey was held in good repute until in 1879; in that year Mr. Hoge, who represented Thurber & Co., of New York, sold a large amount of adulterated honey, and American honey has not regained the prestige then lost.

The sources of honey in England are white clover, sainfoin, linn, buckwheat, and the heather honey of Scotland. Heather honey is darker even than buckwheat, but it sells for a better price on account of its delicious flavor; it is usually sold for 60 cents per section. It is so thick that it cannot be extracted. To secure it in the liquid form the comb must be submitted to pressure; this honey sells for 36 cents per pound. The best imported honey comes from America and the Sandwich Islands. Granulated honey sells readily, and the bee-keepers' association is educating people to use it in that form.

The bee-keeper and the fruit-grower are in accord; the fruit-men recognize the utility of the bee in the fertilization of blossoms, and seeks to have the bees near his orchards.

An orchardist in Gloucester planted 200 acres of fruit; the orchard was a complete failure in fruit-bearing until a Scotch bee-keeper put in 50 colonies of bees. When properly fertilized by the bees the orchard began to bear. The acreage

was then extended to 500 acres, and the apiary was increased to 200 colonies; the orchard now produces a large amount of fruit, a large jam factory is operated on the tract, and all of this prosperity is owing to the beneficial intervention of the honey-bee. Several instances of a similar nature might be cited. The honey-bee is certainly a great factor for the production of perfect fruit.

The following committee was appointed to draw up a memorial to Congress in reference to the passage of a general pure food law: N. Levering, R. Touchton and J. H. Martin.

DEEP-CELL FOUNDATION.

This foundation has not been tried to any extent yet, and it is still problematical if it ever becomes a commercial success. Several bee-keepers had noted that bees would not work deep-cell foundation as readily as they will foundation. The new Weed process foundation was considered by those who had given it an impartial trial as superior to all other foundation.

The election of officers was next in order, and with the following result:

C. A. Hatch, President; Elon Hart, Vice-President for Los Angeles county; Delos Wood, for Santa Barbara; M. H. Mendleson, for Ventura; Dr. E. Gallup, for Orange; F. G. Reynolds, for San Diego; H. E. Wilder, for Riverside; and J. C. Kubias, for San Bernardino. J. F. McIntyre, Secretary; J. H. Martin, Treasurer. G. S. Stubblefield and R. Touchton, executive committee.

EVENING SESSION.

The evening session was opened by Mr. Geo. W. Brodbeck upon

THE BEST SECTION FOR COMB HONEY.

He exhibited honey in the new no-bee-way section, and pointed out the advantages of the same, viz: that the section appeared better filled, and that more of them could be packed in a case. The disadvantages were that the combs were too near in contact with each other when packed in a case, giving inducement for miller-worms to work; and if the face of the comb was not perfectly even there was liable to be abrasion and leakage. From a side view the section appeared to be light weight.

M. H. Mendleson had used the Danzenbaker or tall section, and had excellent success in producing a first-class honey and selling a portion of it for a good price. He proposed to use them exclusively in the future.

Under the head of the keeping qualities of comb honey Mr. C. S. Stubblefield said that he had kept white sage honey for three years without detriment to the honey.

NATURAL VS. ARTIFICIAL SWARMING AND THE METHOD OF INCREASE

was the next subject for consideration. Mr. Mendleson said that if his bees swarmed freely he let them swarm, but if they did not then he resorted to division.

Mr. McIntyre desired to prevent swarming, but if he wished to increase he usually let the colony swarm, then removed the hive from which they issued, and made as many nuclei as there were good queen-cells. The swarm that had issued was returned to the old location, and put into a hive filled with foundation as soon as the queens were laying in the nuclei, or even before the nuclei could be built up with brood from other colonies that had swarmed. In this method good queens were secured and a rapid increase made. Ten from one could be easily made.

J. K. Williamson said that he could make 25 colonies from one by the nucleus plan, and have them all strong enough to winter; it however required a long season. He usually made his increase on a diminishing honey-flow.

MOVING BEES.

In the process of moving bees Mr. Mendleson used a wagon upon which he could carry 200 colonies, but for long-distance moving it made the load too top heavy, and he usually put on only 150. The springs on his wagon would bear a burden of six tons.

Mr. Brodbeck preferred to move bees in lighter loads and travel faster. He desired to so move his bees as to prevent night travel as much as possible.

SECOND DAY—MORNING SESSION.

FOUL BROOD.

Mr. Mendleson, foul brood inspector for Ventura county, said that the sure-cure remedy was the total destruction of the colony. He had burned a large number of colonies and their hives. There is no chance for an annihilated colony to spread the disease.

Mr. Brantigam had found that foul brood was especially virulent in Napa county, with not much effort to eradicate it.

H. E. Wilder, inspector for Riverside county, said that one cause for the spread of foul brood is in the apathy of bee-keepers. The State law will not allow inspection unless a complaint is made, and bee-keepers are careless about making complaints.

Mr. Cowan said that in England in many districts the bees had all died from the disease. It was virulent because many bee-keepers had no knowledge of the interior of the bee-hive. There were bees in churches and other inaccessible places which were liable to spread the disease. The church bees were being removed, and in this thorough way of treating it the disease was much better under control than formerly. Mr. Cowan believed in destroying the hive and the frames, for a germ of the disease would live in a crevice of a hive for several years, and if at any time it became exposed the colony was sure to become inoculated.

Mr. Mendleson favored a law to prevent the moving of a foul-broody apiary into a location where there was no foul brood. A person in moving bees should be compelled to secure a certificate from the foul-brood inspector, guaranteeing his bees to be in good condition.

It was demonstrated that the disease could be cured if it was handled in a thorough and systematic manner. Mr. Touchton said that the cure should be in the hands of an experienced person, for a remedy in the hands of such a person was all right, but in the hands of a novice it was many times worse than useless. The washes that were recommended were salsoda and lye; the latter would take off paint, and ought to penetrate the most obscure crevices of the hive.

THE BEST BEE-HIVE.

Mr. Brantigam said that the manipulation of bees for the highest profit depended more upon the man than the hive.

Mr. McIntyre used a 10-frame hive, but had recently introduced into his apiary 60 12-frame hives, and prefers them to the 10-frame hives. He thinks that this hive three stories in height will have a tendency to give the queen the highest capacity for brood-rearing, and for the prevention of swarming.

Mr. Hatch said that he had kept bees in Wisconsin, Arizona and California, and had found that if the bee-keeper wants a bucketful of honey he must have a large hive.

Mr. Martin said that he uses the Heddon hive. The regular Heddon hive is made to take eight frames, but he uses ten frames, and finds that by adding stories as the season advances the hive can be enlarged to any desirable size.

HONEY-CANS—SUPER-HOLDER.

Honey-can manufacturers were in evidence with their wares. A Mr. Boyle exhibited tin cans lacquered in imitation of brass. The cans presented a very neat appearance, and in being so treated they did not have the appearance of coal-oil cans.

Some of the bee-keepers advocated that our honey should be put up in 50-pound cans, and two in a case. The present cases, weighing about 135 pounds, are too unwieldy to handle. There was also an inquiry for 10-pound cans.

Mr. Heath exhibited an apparatus for removing the super from a hive and holding it in an elevated position while the queen-excluder or an empty super was being adjusted under it.

After a very pleasant and profitable session in a social way the Association adjourned.

JOHN H. MARTIN, Sec.

Complete Volumes of 1897.—We have on hand about 40 complete volumes of the American Bee Journal for 1897, which we will mail to any one upon receipt of 60 cents. We also have about the same number of the first six months' copies of 1897, which we will mail for 30 cents. As there were 832 pages of the Bee Journal last year, here is a chance for our new subscribers to get a good deal of valuable reading-matter for a very little money. Better order at once, before they are all gone.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

Finding Queens in Bee-Houses is made easier, according to a writer in Magyar Meh, by having a looking-glass arranged on a pivot so as to throw the light of the sun where desired.

Dark and Light Honey for Winter.—The dark, strong honey of inferior quality that his bees gather in the fall, says Ed Jolley in American Bee-Keeper, is bad for wintering bees in the cellar, but excellent for wintering out-doors, while clover or light honey is excellent for cellar but poor for out-doors. The reason he gives is that the fall honey is strong and aromatic, "and very conducive of heat."

Foul Brood.—In November, shake one or more colonies of diseased bees on about five combs of solid sealed honey. That's all. Even if some diseased honey is carried away with the bees, if there are no empty cells in which to store it, it will be used up long before any brood is present. But be sure there is no infection in the sealed honey or in the hive. So says F. Alexis Gimmelario, in Canadian Bee Journal.

Do Bees Injure Grapes?—Prof. Troop, of the Indiana Experiment Station, has been investigating this question afresh. From a Worden grapevine with ripe grapes, all defective berries were removed and a colony of bees enclosed with the vine under mosquito netting, allowing the bees 300 cubic feet of room. The bees soon got used to the confinement, and after three weeks not a single grape had been injured.

A Good Plan.—D. W. Heise, the man who does some browsing around among other journals for the Canadian Bee Journal, while speaking a kind word for the "Question and Answer" department of this journal, mentions a practice of his that might be followed with profit by those of less experience than Mr. Heise. He reads the question, then settles an answer in his own mind before reading Dr. Miller's answer. In this way a more lasting impression is made.

Density of Honey.—From the unfinished report of the convention of the Ontario bee-keepers, in Canadian Bee Journal, it appears there is more or less unripe honey put on the market in that country, samples analyzed at Ottawa showing a range of from 12 to 33 per cent. of water. Agitation for a law is suggested, making the honey fall under adulterated if more than 25 per cent. of water be found present. Prof. Shutt thought 48 to 20 per cent. of water was not far from the average.

The Ontario Bee-Keepers' Convention.—D. W. Heise says in Canadian Bee Journal that the convention at Hamilton past off with a harmony that must have been bewildering to those accustomed to the stormy scenes of previous years. The editor, however, says that at the last end, when a large proportion had left (probably D. W. among them), they had a repetition of the worst scenes of former years. Which goes to show what an unwise thing it was for Mr. Heise to leave "before meetin' was out."

Temporary Asphyxiation of Bees.—This is recommended by Le Rucher Belge when for any reason drumming cannot be used to dislodge bees, as in the fall when it is so cool that bees remain stubbornly on their combs in spite of the drumming. Take a wet cloth the size of the hand, sprinkle over it a quarter of an ounce of powdered saltpeter, then roll it up into a cigar shape. It must be prepared in advance, so as to be thoroughly dried. Dig in the ground a hole 6 inches deep, and a little smaller than the mouth of the hive. Cover a good-sized cloth over the hole. Give the bees a little smoke, just to keep them in the hive, and set the hive over the cloth. Pile earth around it so as to make all tight, then light the saltpeter cigar, put it in a smoker, and with the nozzle of the smoker in the flight-hole blow in the sharp smoke. In a few seconds the rag will be burnt up, when the flight hole is to be plugged up. Then comes an intense roaring, a cry of agony that gradually becomes feebler, then the silence of death. With watch in hand wait *exactly* four minutes, in the mean-

time giving the hive some sharp blows to dislodge any bees that have not fallen. Raise the hive and give the bees fresh air. When the bees begin to stir let them enter the desired hive. In half an hour they will be ready to take flight. Operate toward evening. Two or more colonies thus treated may be unted without any precaution.

Honey for Winter Stores.—The quality of the honey which the bees consume has also a great influence over their health. A good grade of honey, light in color and free from ferment, or of floating grains of pollen, which are often found in dark honey, furnishes an article of diet which leaves but little residue after digestion, and their bowels are therefore not overloaded by their dejections, as is the case if their provisions are composed of dark or unripe honey; or worse yet, of honey-dew, of the juice of fruits such as apples, grapes or peaches, which is sure to work and ferment, and sours in the cells long before the cold weather compels the bees to remain in the hive.—C. P. Dadant, in Busy Bee.

Experiences in Bee-Keeping.—Bee-keepers' autobiographies seem to be somewhat the order of the day. Gallup in American Bee Journal, Aikin in Progressive Bee-Keeper, and now A. E. Manum starts in to give his 27 years' experience in Gleanings, giving a sort of promise that at the close one will be able to answer the question whether it is "safe for a man with a family to depend upon bee-keeping alone for the support of his family." His bee-fever was contracted through the reading of Quinby's book, which a neighbor forced upon him, and he was soon the possessor of two colonies in box-hives. The first number of his story is mainly taken up with telling what his neighbors didn't know about bees, and closes like most continued stories with the reader's interest all alert, for he promises to tell in the next about his first crop of honey, which netted him 33½ cents a pound in Boston.

Bees as Weather Prophets.—An article on this topic published in Cosmos was thought worthy to be translated for The Literary Digest, and has been copied by the British Bee Journal. The writer says he noticed 40 years ago in old straw hives with two entrances, that about the beginning of October the bees stopt up these two entrances with wax, so as to leave passage for only one bee at a time. He also says that bee-keepers of all countries agree in saying that every time the bees have taken care to seal hermetically the entrances to the hive, so as to leave but a minute passage for air, the winter has been of extreme rigor, while in years when the bees have done nothing to preserve themselves from the cold, the winters have been relatively mild, with no heavy frosts. Just how the bees can tell so surely beforehand the severity of the coming winter, he considers too hard a problem to solve. If this Boiler were not afraid of getting into hot water, he would tentatively suggest that one solution of the problem might be given by saying that the whole affair has no foundation in fact, and that intelligent bee-keepers don't believe the amount of propolis at the entrance has any direct relation to the severity of the coming winter.

Cross-Breeding of Bees.—In Progressive Bee-Keeper Dr. C. C. Miller, taking a hint from a German writer, figures out what the stock will be if one starts with a black drone and an Italian virgin queen, breeding continuously from the same stock. One might guess that the result would be half-bloods, but a little figuring shows differently. As is well known, the first generation after making this cross a drone will have 100 per cent. of Italian blood and a young queen 50 per cent. Putting the matter in tabulated form, and following it for ten generations, gives the following:

| | DRONE. | QUEEN. |
|----------------|------------|-------------|
| 1st Generation | 1.00 | .50 |
| 2nd " | .50 | .75 |
| 3rd " | .75 | .625 |
| 4th " | .625 | .6875 |
| 5th " | .6875 | .65625 |
| 6th " | .65625 | .671875 |
| 7th " | .671875 | .6640625 |
| 8th " | .6640625 | .66796875 |
| 9th " | .66796875 | .666015625 |
| 10th " | .666015625 | .6669921875 |

The figures are followed up to the 18th generation with no material difference, only that the numbers in the two columns constantly approximate. That is, if you start with a pure sire and a pure dam, by the time you reach the sixth generation you will have settled that your stock will be two-thirds the blood possess by the dam.

Vol. XXXVIII. CHICAGO, ILL., FEB. 10, 1898. No. 6.

Chicago Food and Health Exposition.

As a good many know, such a show embraces the exhibition of various kinds of table food, free samples or "tastes" of which are given to thousands of visitors who call to inspect them. This particular Exposition was under the management of the Chicago Journal, one of the daily newspapers here, with a gentleman by the name of A. E. Miller in charge. It was held during the month of October, 1897.

Battery D, on the Lake Front, was the place which was divided into compartments or booths, and the illustration on the first page this week shows the booth we put up to exhibit pure honey. It was in charge of Mrs. W. H. Harris, an estimable Chicago lady, whose likeness is shown in the picture, tho the flash-light with which the original photograph was taken seemed to pretty effectually close her eyes, and give her the appearance of being somewhat sleepy, but that is far from her real disposition.

Perhaps right here we may as well let our friend "Emm Dee" give his impression of the show, after having made a careful inspection:

THE FOOD SHOW.

The exhibition, in Chicago, of thousands of varieties of health-giving foods has been of greater practical interest this year than ever before since its organization. Indeed, the recognized importance of this exhibit has become so fully appreciated by the increasing attendance that it has not only been extended a week longer than the allotted time, but a strong influence is being exerted to hereafter make it one of

the great features of an annual industrial exhibition, such as proved so attractive some years ago.

It is impossible to enumerate all the descriptions and qualities of food and other useful articles exhibited at this exposition. Many were of great interest as encouraging, in an inviting manner, the substitution of foods long in use for more healthy and palatable ones. Conspicuous among the gaily-adorned booths was York's honey display, of both comb and extracted honey, presided over by a lady of gentle manners and persuasive charm—Mrs. Harris. Many will know of and appreciate the great value of honey as a food since chatting with the fair saleslady. Editor York is evidently very alive to the interests of the bee-keepers. EMM DEE.

The following paragraph appeared in a local suburban paper, called The Lake Breeze, and published where we reside:

"Those who have been so fortunate as to visit the Pure Food Show at Battery D, will not soon forget the honey-booth, and surely will never forget the honey itself. As the proprietor of the honey-booth, George W. York, is a Ravenswood man, it is not strange that Ravenswood has been well represented at the show, and Mr. York and his honey have made many friends there. Mrs. Harris, who has presided over the booth during the show, is also from this suburb, and her friends have not failed to sample the excellent bee-product kept in stock."

Now we might write several pages on our experiment along the line of an attempt to educate the public by wholesale as to the value of pure honey as a daily food. But we can only say here that thousands of people at least for once in their lives knew what it was to taste *pure* extracted bee's honey—a thing to which Chicago people have been almost strangers. We also gave away great numbers of the "Honey as Food" pamphlet, which must result in untold good, provided those who took copies of it will read its truthful contents.

We feel that we did at least something for the future of honey in this city, by our month's exhibit at the Chicago Food and Health Exposition. It was a pretty big undertaking, and financially we can hardly say that it proved a success for us; still, "York's Pure Bees' Honey" became quite well known, and for awhile in Chicago many grocers "caught on" to its popularity, and kept it for sale. Since then country bee-keepers have come in and cut the prices, and the glucose-mixers have also gotten in their criminal work, so that it is quite difficult to try to do even a fairly profitable business in pure honey here. What is needed is a vigorous enforcement of our Illinois anti-adulteration law, and then following up of every grocer with pure honey, both extracted and in the comb.

While our honey exhibit was practically a financial failure to us, yet we believe for the bee-keepers who ship their honey to this market it will eventually prove a good thing, because of the advertisement pure honey received, thus creating a greater desire on the part of consumers for the genuine bee-product.

Call for a Pure Food Congress.—A call for a Pure Food and Drug Congress has been issued, signed by Alex. J. Wedderburn, as Secretary, who is also the special chemist of the Department of Agriculture. It is proposed to hold it March 2, in Washington, D. C. Here is the "call" as printed:

The question of the character of the food, drink and drugs consumed by a people is unquestionably one of the most important that can be discussed by them. Adulteration, misbranding, sophistication, substitution, and imitation undoubtedly exist to an alarming extent, to the detriment of health, legitimate business, and sound morals, and it becomes needful to secure legislation that will check this growing evil and permit an honest man to do an honest business.

The extent of adulteration can only be estimated by the number of industries engaged in producing food, drugs and liquors, for no sooner does a legitimate business succeed than illegitimate imitators follow in its wake. These unfair practices have become so general that remedial legislation is demanded to protect the health, morals, and business interests of the people. Our foreign trade is threatened, and unless

check every honest man will, ere long, be compelled to quit business.

Many of the States have good laws which cannot be enforced, owing to the "Original Package" decision of the Supreme Courts, which prevents the several States from effectually controlling this matter—hence, it becomes necessary to enact a Federal Statute to prevent the Inter-State Traffic in such commodities. House Bill No. 5441, introduced by Hon. Marriot Brosius, of Pennsylvania, is now soon to be considered by the Committee of the House.

As there are divergent views as to some minor points of this measure, which should be reconciled by a consultation of the interested parties, and believing that it is the desire of the great mass of manufacturers, producers and consumers to reconcile all such differences to unite in urging the adoption of a Pure Food Law by Congress, so as to sustain the good name of the Nation, and preserve the health and integrity of our people, therefore, the undersigned hereby call a Pure Food and Drug Congress, to assemble in the city of Washington, D. C., at the National Hotel, at 12 o'clock, m., on Wednesday, March 2, 1898.

Arrangements have been made for reduced railroad transportation and hotel rates, the latter being fixed at \$2.00 to \$2.50 a day.

Address all communications to the Secretary, A. J. Wedderburn, Headquarters Food and Drug Congress, Parlor 11, National Hotel, Washington, D. C.

By order of the committee.

|------------------|----------------------|
| FRANK HUME, | J. D. HIRD, |
| MATTHEW TRIMBLE, | BERIAH WILKINS, |
| WM. C. WOODWARD, | ALEX. J. WEDDERBURN, |
| R. N. HARPER, | <i>Secretary.</i> |

Washington, D. C., Jan. 18, 1898.

An appointment of delegates is made in connection with the foregoing call, which embraces, as far as possible, every interest involved in the production, manufacture and sale of food, drug and liquor products—in proportion to the numbers engaged therein. It embraces scientists and health departments, as well as those who have charge of local laws in the various States and Territories.

Of course honey producers are greatly interested in this subject, and we may say that each State bee-keepers' association is authorized to appoint one delegate, and three each by the National and the United States Bee-Keepers' Unions.

As chairman of the Executive Committee, we expect by another week to be able to announce the names of those who will represent the United States Bee-Keepers' Union. We regard it as a very important occasion, and trust that the efforts of the proposed Congress may result in something of great value to the producers of pure food in this country. Just now we believe that there is no other subject that should so concern the bee-keepers of this land.

THE LEAHY MFG. Co. reported in a letter sent us Feb. 1, that they were running their factory day and night.

— MR. GEO. F. ROBBINS, of Sangamon Co., Ill., has gone to Uvalde Co., Tex., to keep bees. He reports that there are more bee-keepers down there than he ever thought there were anywhere in the same extent of territory.

MR. JAS. A. STONE, Secretary of the Illinois State Bee-Keepers' Association, will read a paper on "Bee-Keeping in Illinois," before the State Farmers' Institute, which meets at Champaign, Ill., the last week of this month.

THE A. I. ROOT Co., writing us Jan. 29, said that altho they had sent out five carloads of bee-supplies that week, they still had on hand orders for ten carloads more. About three or four carloads a week, with the small orders, is about the limit of their factory capacity.

WEDDING BELLS as well as sleigh bells have been ringing at "Rootville" this month, and at least two of the Rootvillians are supremely happy. Miss Constance M. Root, daughter of Mr. A. I. Root, was married, Feb. 1, to Mr. A. L. Boyden, one of The A. I. Root Co.'s most faithful and trusted employes. Our heartiest congratulations are hereby extended to the happy pair.

We don't know whether there is any rule about it or not down there among the Roots, but if we remember rightly Mr. Calvert, the business manager, after being in the employ of Mr. Root for awhile, won the hand and heart of his eldest daughter; then, Ernest R. Root did the same thing with one of their charming lady employes—Miss Elizabeth Humphrey; and now Miss Constance captures (or more likely was captured by) Mr. Boyden. And so it goes. But so long as everybody is happy and contented, and each has the "best companion in the world," what more can be desired?

Our congratulations to the Root-Calvert-Humphrey-Root-Boyden-and-A.-I.-Root combination of Roots and Rootlets.

DR. MILLER, in McHenry Co., Ill., writing us Jan. 26, said:

"What a blizzard it was yesterday. We're snowed in. Made no attempt to get farther than the barn yesterday, and we seem quite lost to go a day without the mail. Oh, for free rural delivery! After I get this letter in the envelope, I'll take the cutter and a shovel and see what I can do toward getting to town. At the back door the snow is five to six feet deep."

"LATER.—Feb. 2—9° below zero yesterday; snow 18 inches on a level, but not much of it left level—piled up in drifts and drifting all the time; 9° higher to-day, but as I'm writing without coat or vest, I've no reason to complain."

MR. JOHN A. PEASE, in the Pacific Bee Journal, tries to come a rather bright trick on us by training our own battery on us, by asking us to use the same argument for encouraging the making of new bee-keepers that we used for publishers of new bee-papers. But we fail to see wherein the two can be compared. Good deal of difference in a bee-keeper and a bee-paper. When a new bee-keeper stops he generally loses only his own money; but a short-lived bee-paper usually loses some money for its subscribers, also, and almost invariably proves of no benefit to its publishers or the public. But Mr. Pease writes very well.

DR. P. C. GRESS, of Atchison Co., Kan., met with a heavy loss by fire Jan. 27. There were destroyed 153 colonies of bees, numerous empty hives, 5,000 pounds of honey in cases ready for market, 100 pounds of beeswax—in fact, everything connected with his well-appointed apiary. The total loss was estimated to have been about \$3,500, partly covered by insurance. Dr. Gress had been working 12 years to build up his apiary, and had one of the finest in the State.

REV. E. W. PFAFFENBERGER is the editor of the Western Christian Union, published at Boonville, Mo. He has been reading the Bee Journal lately, and in a letter dated Dec. 6, wrote us:

"I am much pleased with your style of editing the Bee Journal. The matter is well and tastefully arranged, and is always pure and wholesome reading. . . . Since becoming acquainted with the Bee Journal we have been eating a good deal of honey at our house."

MR. JOHN H. MARTIN, of Los Angeles Co., Calif., reported Jan. 31, as follows:

"We are having a continuation of dry weather, and the prospects of a honey-yield for the coming season are getting very discouraging. We must have rain, and soon, in order to revive the hopes of the bee-keepers."

MR. A. F. BROWN, of St. Johns Co., Fla., wrote us Jan. 28:

"Another disastrous freeze has visited our State this winter—Jan. 2 and 3—and as a consequence thousands of orange-growers feel extremely 'blue,' myself among them, as my groves are cut back badly."

MR. J. Q. SMITH, of Logan Co., Ill., President of the Illinois State Bee-Keepers' Association, wrote us Jan. 29:

"My bees are wintering nicely on the summer stands packed in leaves."

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Moving Bees into a Bee-House.

I want to move my entire stock of bees into a bee-house. When will be the best time to do it? INDIANA.

ANSWER.—Any time now will do, as they have now been so long in winter quarters that they will be likely to mark their location whenever they fly next. After moving them, try to make the old spot look as different as possible.

Question on a Bee-Repository.

I have read your answer to my question, on page 38, and notice what you say about the repository which I have put up after a plan given in the "A B C of Bee-Culture," page 327, where Mr. Root says that he and a neighboring bee-keeper used buildings constructed very much the same as mine, only I thought that I would make a sure thing of it, and where they had 8 inches of sawdust I had 15, and a two-inch airspace inside. The bees have wintered in them successfully. The way I understand, the loss was in putting them out too early in spring.

If these buildings were not put up the right way, please give a plan for a repository where we could winter bees successfully nowadays.

In my question on page 38, where it reads, "then another wall of four-inch boards," it should read—then another wall of four inches, with boards and paper on both sides.

WISCONSIN.

ANSWER.—I don't find what you refer to in "A B C of Bee-Culture," and probably have not the same edition. But I very much doubt that bees will winter successfully in such a building above ground unless there is some way to warm it up when it becomes too cold. If entrances were allowed, so the bees could fly out every time the weather permitted, the case might be different. I must say, however, that I have had no personal experience in the matter, and will gladly yield the floor to any one who has.

Boring a Well near a Bee-Cellar.

I would like to have a well bored close by the house, but I fear it might disturb the bees in the cellar. WISCONSIN.

ANSWER.—I think I'd go ahead whenever it suited best. I very much doubt whether it will make any difference to the bees.

Moving Bees by Railroad—Wintering in Cold Climate—Out-Apiaries.

1. I am thinking about sending a colony of bees on a chartered emigrant car to my son living in North Dakota. They are in an 8-frame dovetail hive. How can I best prepare them for the trip? I suppose I would send them about the last of March, or the first of April.

2. Would eight frames hold enough stores to winter a colony in that climate? It is said they would be confined to the hive in some seasons from Nov. 1 to Apr. 1 without a flight.

3. In such a climate could they be wintered out-doors, by proper packing? If so, how should they be packed?

4. I am getting a little interested in out-Apiaries, having about as many colonies as can be profitably kept in one yard, where neighbors have bees all around, but I have no experience in out-yards at all, and there is no one near me who has, whom I can consult. Can you not give us an article on it?

ENQUIRER.

ANSWERS.—1. As the frames in dovetailed hives are self-spacing, the only thing to do with them is to see that they are wedged up firmly at the side. Fasten the entrance with wire-cloth, secure the bottom to the hive, and cover the entire top

with wire-cloth, removing the cover. A good plan is to make a frame an inch or two deep just the size of the top of the hive; cover this frame with wire-cloth, and fasten securely to the hive. A good way to fasten the bottom on the hive is by means of what are called tobacco-staples, $1\frac{1}{4}$ or $1\frac{1}{2}$ inches wide, with legs about $\frac{3}{4}$ inch long. Set the hive in the car so the frames will run the same way as the rails of the railway. Don't set a cook-stove on top of the wire-cloth.

2. An 8-frame hive will hold all the honey needed. But it needs closer watching than a 10-frame hive, to make sure that enough honey is present at the beginning of winter.

3. Probably packing all sides but the front with some kind of packing at least two inches thick would answer. Better consult, if you can, those who have wintered successfully right on the spot.

4. If you have any thought of starting an out-Apiary, it will be worth while for you to consult Root's "A B C of Bee-Culture," where the whole subject is very fully treated, occupying about eight pages, and in Gleanings for 1889, commencing with Feb. 1, is a series of articles in which I gave very fully what I knew about out-Apiaries.

Starting with Bees—Wintering in Bee-House.

I started in with a glass hive in the house, to see the bees work, and two colonies in an orchard to help fertilize the fruit blossoms. We caught a stray swarm one Sunday afternoon, then, fool-like, divided the one in the house, also those in the orchard. It was a very poor season, only one day during basswood bloom, in which bees could fly. I found one colony nearly starved, and gave them all the honey the others had stored. I got only three or four sections, and then had to buy 80 pounds to winter them on.

I now have seven colonies, all strong, and I think they have enough honey to carry them through the winter, if they are only economical with it, and they generally are, I believe. I built them a nice house, 8x16 feet, facing south, with place for two tiers of hives, eight in each story. They are packed nicely, the top of the hive being filled with straw. They have no ventilation. Do they need any? The face of the hive is exposed to the sun and weather. I find a good many dead bees in front of the hives, and on the snow where they have fallen while flying during sunny days. The openings are about $1\frac{1}{4}$ inches long by $\frac{3}{4}$ high. NEW YORK.

ANSWER.—Your arrangement will probably work all right, only $1\frac{1}{4} \times \frac{3}{4}$ is too small an entrance for winter and very much too small for summer. Better wedge up each front corner $\frac{1}{4}$ inch. See that the dead bees don't clog the entrance. Take a heavy wire with one or two inches bent at right angles at the end, and clean them out. But don't be alarmed at finding a good many dead bees on the ground. Bees are dying off all the time, and make quite a show on the white snow. It is generally recommended, however, to scatter straw on the ground at such times as bees may come out to fly when the ground is covered with snow, covering it for a few feet around. When the air is too cold for the bees to fly, say at 40° , bees are tempted out sometimes by the very bright sun shining in the entrance, and at such times it may be well to put a board before the entrance to keep out the sun.

A Beginner's Questions.

Last spring I had three colonies of bees, but one of them died. I am a carpenter by trade, and about May 1 I went to build a house some 30 miles away from home, so I left the tending of the bees to my wife. Of course they swarmed. My wife, with the aid of a neighbor, succeeded in hiving two of the swarms. Everything seemed to go all right, but in about three days one of the old colonies came out, but she could not make them stay. They were hived twice, but left. In about three days the other old colony sent out a swarm, but my wife could not make them contented, and they finally left. The hives used were some old ones that I got from a friend. They have eight frames in the lower part, but did not have on any sections.

Now the four colonies which I have left seem to be all right. One of them is in a hive 12x12 and 30 inches high, with two honey-boxes of about 10 pounds each. I opened the door in front of these boxes, and the comb in them is almost empty, but I can't tell how the bottom is, altho it seems to be heavy. Must I feed them? Two of the hives are of the 8-frame kind, but there is no place on top to put any feed. There are eight frames, and then a board for a cover. Will it do any harm to take the board off and put a box on to put

feed to at this time of the year? The hives all stand on the east side of the house, with loose boards to cover them, but the bees seem to be all right.

There is one more hive which is only a box 12x18x12, with two sticks across. This I can't look into at all, altho it seems to be quite heavy. They seem to be all right, but they may not have enough to last all winter. I did not rob them during the summer.

What do you think is the best hive? KANSAS.

ANSWER.—The probability is that your colonies don't need any feeding. The box-hives are very large, and as you took nothing from them they had abundance of room to store enough for winter and to spare if the season was at all favorable. If they are heavy, as you say they are, they likely have 30 pounds or more of honey, and may be safely left. If I understand you correctly, they put honey in the boxes, then emptied it out, strong evidence that they have a good store below. The 8-frame hives are all right if hives and all weigh 45 or 50 pounds. Of course they are not so heavy now as at the beginning of winter. If you think they are not heavy enough, it will do no harm to take off the cover and put on a box with some comb honey in it, covering it up warm.

It's doubtful if anything is better than the dovetail hive.

Moving Bees—Putting on Sections.

- 1. I have bought 10 colonies of bees, which I wish to move two miles. They are on the summer stands with supers on. When would be the best time to move them?
2. When is the best time to put on sections in the spring? Would the queen lay in them if put on too soon? IOWA.

ANSWERS.—1. At the distance of two miles you can move them at any time, but it will be better to wait till spring, so it will be warm enough for them to fly every day. It will stir them up to move them now, so that diarrhea might be induced, unless a warm day should come right after moving them.

2. The queen is not likely to lay in them if put on too soon, but they will keep nicer and fresher off the hive. Put them on about a week after you see the first clover blossom, or as soon as you see bits of white wax along the upper parts of the brood-combs. But don't rely too much on the white wax business, and it is better to get them on too soon rather than too late.

Honey Granulation—Moving Bees—Cutting and Putting Foundation in Sections.

- 1. What are the causes and conditions that make honey granulate? Is there any preventive?
2. Is now a good time to move bees a short distance? They have not been flying for about eight weeks.
3. Is it all right to put foundation in sections now for next season? If so, how do you keep them?
4. In putting full sheets of foundation in 4 1/4 x 4 1/4 sections, what size are they cut, and how many sides of the foundation are fastened to the sections? NEW YORK.

ANSWERS.—1. There is a very great difference in honey as to granulating, some kinds almost never granulating, and some kinds granulating before it leaves the hives. I don't know any reason for this any more than the difference in honey coming from different flowers. Honey that is very ripe and thick is slow to granulate. Cold, especially freezing cold, hastens granulation. Stirring, or agitation of any kind, hastens granulation. It has been supposed that one reason why extracted honey granulates so soon is because of the thorough agitation it gets during the process of extracting.

From this you may learn that you will retard and in some cases prevent granulation if you leave it on the hives till the close of the harvest, when it is sealed and well ripened, and keep it in a place where it may be as warm as possible. Some recommend heating it up to 160° and then sealing it up, as in canning fruit.

- 2. Yes.
3. A few bee-keepers say they don't want foundation in sections till about the time they are to be put on the hives. I have not discovered any material harm from having them ready several months or a year in advance. As fast as foundation is filled in my sections the sections are put in the supers and piled up in the shop.
4. Generally they are cut 3 1/2 x 3 1/2, and fastened only at the top.

Drone-Brood and Watering Bees in Winter.

1. Here I am again. Well, I carried the five box-hives into the cellar the evening of Nov. 30, and all is fine. I have watched them very closely and find them very quiet at 45° or 50°, which I can regulate easily. I often take a lamp and peep in where the hives of bees are. One time between Christmas and New Year I noticed young white drone-brood on the alighting-board. This hive cast an after-swarm in September, and while removing sections from this hive I happened to find the young queen on top of the brood-combs, and in between my thumb and finger her wings were caught and clipped. I have seen worker-brood late in October. Why do they rear drone-brood as early as this in the cellar? Also, they don't allow me to come in their parlor department with a lamp, for when I stay in for a moment there will be one rousing buzz, and the best is to stay out. The dead bees are dragged out, but few so far. I have eight colonies in this curtained-off department.

2. The three colonies 20 miles away are not packed, and all these at home are. I find more dead bees with those 20 miles away. They or we have had no zero weather so far. They all have plenty of stores. Do you think the packed ones will winter out best? Bees had several good, brisk flights.

3. Would you supply these cellar-bees with water toward spring, by dipping a sponge in water, and lay the sponge on the alighting-board? or would you leave them alone? PENNSYLVANIA.

ANSWERS.—1. I don't know why there should be drone-brood in a hive between Christmas and New Year, unless the hive is without a proper queen, and even in that case one would hardly expect to find brood present. As the hive was cellared Nov. 30, it is barely possible that the brood is from eggs laid just before being taken in the cellar. for it may have been lying at the entrance a few days when you found it. Better keep a sharp lookout for that colony in spring.

2. It is quite likely the packed colonies will come out best.

3. At one time I tried to give my bees water in the cellar, but never succeeded in getting them to take any. In this country I don't know that any one practices watering his bees in the winter, but the Germans have a good deal to say about the winter thirst of bees (durstnoth). Whether bees are likely to be more thirsty in the German language I don't know. At any rate you better not fool with watering more than one colony till you see that the bees will take the drink.

50c worth of Books for 1 new Name.

Send us \$1.00 with a new name for the Bee Journal for 1898, and we will mail you your choice of the list below, to the value of 50 cents.

We make this offer only to those who are now subscribers; in other words, no one sending in his own name as a new subscriber can also claim a choice of this list:

Table listing books and prices: 50 copies 'Honey as Food' 50c, Wood Binder for the Bee Journal 20c, 50 copies of leaflet on 'Why Eat Honey?' 20c, 50 ' ' on 'How to Keep Honey' 20c, 50 ' ' on 'Alsike Clover' 20c, 1 copy each 'Preparation of Honey for the Market' (10c.) and Doolittle's 'Hive I Use' (5c.) 15c, 1 copy each Dadants' 'Handling Bees' (8c.) and 'Bee-Pasturage a Necessity' (10c.) 18c, Dr. Howard's book on 'Foul Brood' 25c, Kohnke's 'Foul Brood' book 25c, Cheshire's 'Foul Brood' book (10c.) and Dadants' 'Handling Bees' [8c.] 18c, Dr. Foote's Hand-Book of Health 25c, Rural Life Book 25c, Our Poultry Doctor, by Fanny Field 25c, Poultry for Market and Profit, by Fanny Field 25c, Capons and Caponizing 25c, Turkeys for Market and Profit 25c, Green's Four Books on Fruit-Growing 25c, Ropp Commercial Calculator No. 1 40c, Silo and Silage, by Prof. Cook 25c, Bien-en-Kultur [German] 40c, Kendall's Horse-Book [English or German] 25c, 1 Pound White Clover Seed 25c, 1 ' ' Sweet ' ' 25c, 1 1/2 ' ' Alsike ' ' 25c, 1 1/2 ' ' Alfalfa ' ' 25c, 1 1/4 ' ' Crimson ' ' 25c, The Horse—How to Break and Handle 20c.

GENERAL ITEMS

Great Deal of Rain.

I am trying to prepare for a fine honey-flow next summer. We have been having a great deal of rain, which I imagine will be good for next season's clover.

Erie Co., N. Y., Jan. 31. E. W. BROWN.

One or Two Glasses in an Extractor.

In answering a question on page 53, Dr. Miller says: "It is doubtful if a second glass would be any improvement."

I differ from this opinion. Some 20 odd years ago, while at work devising and making a solar wax extractor that would do practical work, I experimented with and afterwards used both single and double glasses, with the result that I used double glass altogether for the last few years I was in Iowa, and should still use them were I keeping bees in any of the Northern States. If one wishes to get all the work possible out of an extractor, I think it will be well to use double glasses.

Dade Co., Fla.

O. O. POPPLETON.

A Little Girl Reports.

There was no honey to amount to anything last year, as in the spring everything was frozen down, and in the fall it was very good for a few days, but it was just long enough to get the bees good and strong for winter. I had only one colony in the spring when I wrote my last letter, and in the summer I had a new swarm, and now I have two colonies. My first colony swarmed just in the right time to get good and strong for next summer's work, if there is anything for them to work on. Pa says that they are fixt up better this winter than he has ever had them since he has kept bees. We fed them 400 pounds of sugar in the fall to get them ready for winter. My bees were carrying in water and pollen in the middle of October.

Pa says that my bees are the gentlest bees we have among our whole 75 colonies. We had only 60 colonies, spring count, and increased to 75. It is more than we have had for a good many years. In the honey season pa has them tiered 3 and 4 stories high, according to the strength of the colony; but pa put them on, and when he got ready to take them off he was fooled sure, because there was nothing in them.

I think it is a very nice business to keep bees. It is nice to work among them in the summer time. We had to work after night to take our honey, and it workt like a charm.

I guess I will close for fear this will be put into the waste-basket, and not be put into the Bee Journal at all. I am 11 years old.

EMMA BANKER.

Brown Co., Minn., Dec. 22.

No Honey to Spare.

I have 14 colonies of bees in the cellar, and they are very quiet. The temperature is 42 degrees. I had 13 colonies last spring, and there were 4 swarms during the summer. 3 of them I hived, and the fourth, after trying for two days to hive them, were sent back to the hive they came from. They were Italians. The rest of my bees are all blacks or hybrids. One colony in the spring was robbed. I think they must have been queenless. Another was robbed in the summer. The super was taken off and emptied, and left. I know pretty well where it went to, but I did not take any pains to look it up. A third colony the bees robbed, when I went to it, supposing it was all right, I found neither bees nor honey. Another, when I was making a general examination, I found the worms had taken full possession, and it was not many days before that I had examined

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 8 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

TREE PLANTING

may be a way to wealth or a waste of money—depends on the kind of trees. All trees, plants, vines, from the Reid Nurseries are No. 1 stock, true to name. You gain by buying now. Prices were never so low. Write for illustrated catalogue, suggestions, estimates. Try **Star Strawberry**, **Eldorado Blackberry** for profit.

REID'S NURSERIES, Bridgeport, Ohio.

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginsville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. **R. B. Leahy** and **G. M. Doolittle**, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Sonnambulist**. "Experience and Its Lessons," by **R. C. Aikin**. This series of articles will be reviewed by Mr. Doolittle, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The sonnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. **Dr. C. C. Miller** and other popular writers also contribute to its columns. The PROGRESSIVE is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the PROGRESSIVE BEE-KEEPER is but 50c. a year. The PROGRESSIVE and that "one only" book for beginners, the **Amateur Bee-keeper**, by **Prof. J. W. Rouse**, both for 65c. A sample copy of the PROGRESSIVE for your name, and a beautiful, illustrated catalog of apian supplies for the asking. Address,

LEAHY MFG. CO., Higginsville, Mo.

them all, or took off the covers, and everything had the appearance of being all right.

My colonies are all heavy; about 4 had a little spare honey, and the rest have all their gathered, and that was no more than the law allows. People must look to some other quarter than Minnesota for spare honey this winter.

My bees have been uglier the past season than I supposed it was possible for them to be. What little honey they stored they mixt in with pollen, as tho it was done on purpose for the millers to work on. Pollen makes a millers' paradise.

J. V. B. HERRICK,

Hennepin Co., Minn., Jan. 4.

Unite to Down Adulteration.

I am glad to see that the bee-keepers of the United States have seen fit to have grit enough to raise a voice against the burden of adulteration. I see by the Bee Journal that there are so many bee-keepers who are farmers, and as I am a farmer myself, I think if farmers and bee keepers could only bring their heads together as a body, and bring this dreadful adulteration business to a higher point in the minds of the people, I firmly believe that something could be done. We know there is no class of people that is defrauded more than the farmer and the bee-keeper, for they try to raise a pure article for an honest living, and for the welfare of the masses of the people, but they are headed off by adulteration or imitation. The farmer is the victim of adulteration from the fertilizer he buys to raise his crops with down to the pepper he uses on the table; and the bee-keeper is cheated on every hand. Fellow-men, let us put the brake on that destructive wheel.

GEORGE SAGE.

Greene Co., Ind., Dec. 24.

A Good Year for Honey.

The past was a good year for bees in this part of Iowa. My bees came out of the cellar in good condition. Three starved to death in the cellar, and one spring dwindled. It was the worst spring for robbing I ever saw. I had to cover lots with hay. The best way I have found to stop robbing is to cover the hive with a sheet, and occasionally turn it.

It paid last year to send South to get 50-cent queens. The colonies of the queens I got from there did not swarm. From several of them I got 168 sections of honey, and from the best of my own I got a little over 100. I got 11,000 pounds of honey, 1,700 being comb and the rest extracted. I think that is pretty good from 89 colonies

in the spring and 138 in the fall. The mistake I made was leaving my fall honey to extract late in the fall, only finishing extracting Dec. 16, and it was candied badly.

I always winter my bees in the cellar, and in cold weather I always have a fire over them night and day. The chimney comes from the bottom of the cellar, and has a six-inch hole in it for ventilation. I put one-inch blocks under the front of the hives to raise them from the bottom-boards. I never lose a good colony unless they starve to death. CHAS. BLACKBURN.
Buchanan Co., Iowa., Dec. 18.

Report for Last Season.

I had nine colonies last spring in the Higginsville hive and three in box-hives. I increased to 18 by natural swarming, and extracted 1,200 pounds of nice honey, with 300 pounds of comb honey. My bees did well. We had a drouth which cut off the fall flowers, or I would have gotten a larger yield. My bees were in good condition to go through the winter. I have them packed on top, on both sides and one end, with the open fronting southeast. I have no cellar, so I winter them on the summer stands.

I have been taking the Bee Journal for a little over a year, and I owe my success to it in managing my bees. I would not be without it for double its cost. I hope the United States Bee-keepers' Union will be a success. I would like to see the two Unions united. I think they could do better work, as it would be stronger and better able to fight the enemies of the pursuit.

W. S. SMITHEY.

Monroe Co., Mo., Dec. 20.

Bee-Conventions and Fairs.

I do not want to be elast among the critics, but I noticed the report on page 821 (1897), by J. P. West, President of the Minnesota Bee-keepers' Association, that met in St. Paul, Dec. 8, 1897, one day and then adjourned. Well, perhaps they did the right thing to decide to meet in St. Paul the same time that the State fair meets, but at the time of the fair you will find that you must neglect either one or the other. To have your exhibit will be all right, but to have a convention at the same time you will find that you will neglect both. As Mr. West says, a great many members are horticulturists; very true, and that is the very reason they cannot do justice to both. As far as the reduced rates are concerned, that part is all right. It is a better season of the year, I will acknowledge, but we had an experience with the Southern Minnesota Bee-keepers' Association; we appointed the time of meeting at the same time the

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

Please mention Bee Journal when writing.

Street Fair in Winona was held last fall, and the result was that we unanimously decided that we wanted no more conventions at the time of a fair.

In the first place, those very men that are interested in horticulture and bee-keeping are bound to neglect one or the other, and the one that they neglect is the convention. Such was our experience. Men that at other conventions would be on time and the sessions were too short for them, during the fair they would come in the convention, stop a few minutes, and then they were absent for the rest of the day; then the man that has bees, honey, tools, and supplies on exhibition can put his time in at his place of exhibit, in answering questions, as there is nothing that attracts the attention of the sight-seers as an observatory hive with a colony of bees in it. There are so many that never saw the inside of a bee-hive, and when they see the bees and honey they become perfectly excited. I had on exhibition a hive with glass sides and top, with screen front, and one man was not able to answer all the questions that were asked about the bees. I had a hive standing by the side of it, but empty, just to show the condition the hive was in when the bees took possession of it, but I could only be present until 8:30 in the morning, and then half an hour at noon, and about the same time in the evening. Thus you see we had to neglect the fair in order to transact the business of the convention.

The fairs and exhibitions are all right, but my experience is that they do not work well together, for when you get too many irons in the fire some of them are bound to get too hot.

I could not think of doing without the Bee Journal, and would advise all bee-keepers to subscribe for it; I often find one article that is worth more than double the year's subscription.

I put 31 colonies into winter quarters, and they seemed all right before putting them away. I took a scale on a wheelbarrow, and went through my apiary and weighed every hive and marked the weight upon the hive, and in the spring when I put them on the summer stands I will weigh them again. By so doing I will ascertain what amount of honey they will have consumed.

We are preparing for next season, getting everything in shape; also for the Southern Minnesota Bee-keepers' Association, which meets Oct. 22 and 23, 1898. I have been stirring up our members to prepare their little speeches for that occasion, as the long winter nights give us plenty of time to think and write, and every bee-keeper should improve the opportunity.

E. B. HUFFMAN.

Winona Co., Minn., Dec. 30.

Fine New Hampshire Honey.

I must have the Bee Journal. I would not want to go without that and try to keep bees. The experiences of others are a great help to me.

I had nine colonies in the spring of 1897, and have 17 now. I had 265 sections of as fine honey as New Hampshire can produce. I sold over 150 for 18 and 20 cents each.

I love my bees, but what kind they are I have yet to learn. There is no particular honey-plant around here.

MRS. RUA A. FIFIELD.

Cheshire Co., N. H.

Worms in Honey—Laying Workers.

Perhaps this may be the last year that I shall be able to take the Bee Journal, for the reason that I am not able to care for my bees properly, on account of my age. My next birthday, if I live until then, I shall be 88 years old. I shall have to give it up for my health is poor, not able to care for them properly. I am able to do but little work of any kind. If I live this will be the last year that I shall try to keep bees. I have kept them over 50 years, and have taken the Bee Journal the most of that time.

I have read of some complaining about

PAID FOR Cash Beeswax

worms getting in their honey after it was taken from the hives. When I take honey from the hives, for several years, I have kept it in a small room. I get a number of stalks of green tansy, and spread it on the floor, then put the cases of honey on the tansy. I have not found any worms or ants on my honey for a number of years. This may be of some use to young bee-keepers.

All the way that I can tell when there is a laying worker in a hive is by the number of eggs in a cell. When I find that, I find no queen. My hives are all numbered. For instance, there is a laying worker in No. 1, and Nos. 10 or 20 are good, strong colonies; I take No. 1 and set it where No. 10 stood, in the middle of the day when the bees are flying well, and change places of the hives. When the bees from No. 10 come in from the fields they go into No. 1. They kill the laying worker. I have gotten rid of 5 laying workers in this way in about two hours. This may be of some benefit to some new bee-keepers.

WM. C. WOLCOTT.
Winnebago Co., Wis.

Second Wintering Experience.

I am very much interested in the American Bee Journal. I can hardly wait for Friday morning to come, as that is the time for it.

This is my second wintering of bees. I now have five colonies; I had three colonies in the spring, transferred all, had two swarms, and got about 100 pounds of comb honey.

NORMAN O. JARVIS.
Madison Co., N. Y.

Bees Did Well.

Bees did well here in swarming as well as in honey-gathering. They nearly doubled by natural swarming. Some of the swarms produced as high as 50 pounds of honey. Of fall honey we got none, as the dry weather put an end to all honey-gathering. The fall of 1896 was the best we had since the pioneer days of this country. Honey-gathering held out splendidly until really natural ripeness put slowly an end to all flowering of plants.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Feb. 1.—Fancy white, 11 to 12c. No. 1, 10c.; fancy amber, 8 to 9c.; No. 1, 7c.; fancy dark, 7c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

The demand for comb honey is not satisfactory, and it can be bought at even lower prices than quoted, where it is not in the hands of regular dealers. There seems to be no outside demand. Extracted without special charge. Beeswax is scarce.

Milwaukee, Wis., Jan. 24.—Fancy white 11-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

New York, N. Y., Dec. 22.—Fancy white 11 to 11½c.; off grades, 9 to 10c.; buckwheat and mixt, 6½ to 7c. Extracted, California white, 5 to 5½c.; light amber, 4½ to 4¾c.; white clover and basswood, 5 to 5½c.; buckwheat, 4 to 4½c.; Southern, 50c. a gallon. Beeswax is in good demand at 25 to 27c.

Our market remains quiet. Fancy grades of white comb are about cleaned up, and these would find sale on arrival at quotations. We have a large stock of buckwheat, mixt, and off grades of white, and, as the demand for these is very light, we cannot encourage further shipments for the near future. Extracted of all kinds is selling fairly well.

Minneapolis, Minn., Jan. 31.—Market is in an overloaded condition on comb honey. Good chance for fancy white extracted at 5½ to 6c., but comb is at a standstill, particularly if other than fancy white. Best price available on fancy white combs 10½c., and buyers are slow at that. Darker grades or broken lots are unsalable. If shippers would send in their extracted when it is wanted, and not push undesired comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

Buffalo, N. Y., Jan. 14.—Strictly fancy 1-pound comb honey is more active at mostly 10c., occasionally 11c., but all other grades are dormant and have to be cut to almost any price to move them, ranging from 8c. down to 5c. Extracted is also very dull at 4 to 6c. We cannot recommend the shipping of honey here unless it is strictly fancy 1-pound sections.

There is no selling pressure of consequence on desirable lots of water white, either comb or extracted, such being held as a rule at full quotations. Amber grades are in greater supply than the demand, and market for this class presents an easy tone. Dark qualities are in poor request, despite low asking figures. Beeswax is firm at current quotations, with very little offering, either from first or second hands.

St. Louis, Mo., Jan. 17.—We quote honey nominal, but very little selling. Demand is light. White comb, 1-lbs., 10 1-2 to 12c.; amber, 8 to 10c.; dark, 5 to 7c.; broken comb, 4 to 7c. Extracted, in cans, white, 5½ to 5 1-2c.; light amber, 4½ to 5c.; amber, 4¼ to 4 1-2c.; dark, 3 1-2 to 4c. Beeswax, 25 to 25 1-2c. To sell honey in lots above prices would probably have to be shaded a little.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Kansas City, Mo., Jan. 20.—Fancy white, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. The market is well supplied, and demand is light.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12¼ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3¾c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Cincinnati, Ohio, Jan. 17.—There is no change in prices, but rather a slow demand for all kinds of honey. We quote 10 to 13c. as the range of prices for best white comb honey, and 3 1-2 to 6c. for extracted, according to quality. Beeswax is in fair demand at 25 to 27c. for good to choice yellow.

San Francisco, Calif., Dec. 8.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 4¾c.; light amber, 3½ to 3¾c.; dark tulle, 1¼ to 2¼c. Beeswax, fair to choice, 22 to 24c.

All for the Fruit-Grower.—After a careful examination of the 1898 catalog issued by Reid's Nurseries, Bridgeport, Ohio, we wish to say that it is one of the most complete catalogs (devoted entirely to the nursery), tastily arranged and illustrated that come to our desk. There are no catch-penny schemes in it, but it is sound business from cover to cover, nothing over-drawn, but the plain truth boiled down, and beautifully illustrated with many costly engravings. They have done away with the highly-colored covers, that are now being sent out, and instead they have opened the way to a new field, giving their customers something of art and beauty—something that is new and refined. If you need anything in the nursery line, send your name and address for their catalog, not forgetting to mention that you saw their advertisement in the old American Bee Journal.

CONTRIBUTED ARTICLES

Sweet Clover—An Occasional Forage-Plant.

BY PROF. A. J. COOK.

The note of reproof from the editor, on page 25, regarding my statement in reference to mellilot only gives me pleasure. I am glad to have my position criticised, at all times. If I am wrong—and we all make frequent mistakes—I wish to be corrected, and the correction cannot be too speedy or too thorough. If I am correct, another's errors will be likely to be corrected. Thus candid, courteous criticism is always in order. Any other kind is always to be deeply regretted. How common were harsh criticisms, bitter aspersions, and sharp, cruel, cutting invective in the olden time of American bee-culture. Happily it is now rare. We can almost always criticize kindly, reprove gently, and after such criticism and reproof are none the less friends. Thus, Mr. York and I are none the less friends, tho he so sharply questions my act.

I have noticed all the recent words of commendation regarding sweet clover in the several journals. That occasional cases of cattle and horses eating mellilot clover may occur I do not doubt. Frequent statements to that effect may have been made, and I am always slow to impeach another's veracity in such case. Cattle and horses may be crowded by hunger to eat what is really distasteful and unappetizing. In all such cases the food is of doubtful value.

Again, mellilot may be grown on exceptional soil, or under exceptional conditions which may be more appetizing. If this be true, we may believe it exceptional. Usually the quality of sweet clover does not attract any of our stock. I still believe that mellilot, while it is excellent for honey has little value as a forage plant. It has one other value. It is a legume, and so takes nitrogen from the air, through the aid of the nitrofyng microbes. It is thus valuable for green manuring. I wish much to find this plant valuable for hay and pasture. I have often seen it in pasture and by roadside, left wholly undisturbed by horses, cattle, etc.

Again, white mellilot is strictly, so far as I have observed, a biennial. It grows vigorously for one season, storing up starch to push its growth and development the second season, when it blooms and forms the seed. The first year the stems and foliage are tender and succulent, and, were they savory, would furnish much good feed. But this would be of no use to bees, as the flowers do not come till the next season. The second season, the stalks are coarse and large, and would be of little or no use for pasture or hay. Yet, now the bloom comes with sweet scent and big load of nectar. This again would discount the value of sweet clover except for honey and green manuring, even tho it were appetizing.

The yellow sweet clover here in Southern California appears to be an annual, to grow vigorously, and tho of doubtful value for hay and pasture, may prove to be valuable for trapping nitrogen, and enriching the soil.

The objection urged to mellilotus alba in the above remarks, applies somewhat to alfalfa. It is of incomparable

excellence and value for hay and pasture, especially for hay. When it blooms it is very valuable for honey; but it is better for hay to cut it just before it blooms, and so is often of no avail at all for the bee-keeper. If, like red clover, it were permitted to bloom fully and freely, before cutting, it would take very high rank as a honey-plant; as it is, there is much bloom, so that in some portions of California it furnishes generous quantities of nectar, and so adds materially to the honey-product of the State. In one respect, it is very valuable. It secretes liberally in seasons of drouth. As the alfalfa is irrigated, it grows and blooms even in drouthy years.

Los Angeles Co., Calif.

Anti-Bee-Space—A Reply to Criticisms.

BY "COMMON-SENSE BEE-KEEPING."

Mr. Chairman:—I rise to a point of order. I have waited a long time for the subject under discussion to get cool, because some of those who take up their pen to defend the bee-

C. Theilmann—See page 100.

space seem more disposed to hack on the "Common-Sense Bee-Keeper" than they are to discuss the three points at actual issue, which are: That the bee-space is opposed, first, to the successful wintering of bees in cold climates; and, second, the booming of the colonies in the spring; and, third, the early storage of surplus honey in the section-boxes.

In the title of my former articles, and in my purpose in writing, I have not desired to irritate the feelings of any one, but I mistrust that the word "detestable" has displeased some readers, and so I will volunteer to change the caption to the one shown above. But it is not necessary for me to say at present whether I am "aunty" or "uncle," for it is not the name that may be tagged to an article that will determine the measure of brains used in writing it, but the sound logic presented on the main points at issue; but racket proves nothing to the point.

On page 562 (1897) Mr. W. C. Gathright, of New Mexico, writes in a gentlemanly style, and no doubt reveals his nature by his article, which men are apt to do, but still he is out of line in more than one particular. In the first place, he is so far south that the warm climate, in some cases, might justify the bees in getting along without a hive altogether, while they might live on the limb of a tree, and be happy all the year round; but wherever the climate is cold enough to depress the normal temperature of the colony to an unsafe degree in wintering, then it must follow, just as certain as eternal laws require effect to follow cause, that the depression of the comfort of the bees in wintering must result in weakenlog them to a corresponding extent, and in the same proportion that this weakness obtains they will be found weak in the spring, and consequently backward in the storing of surplus honey.

I think Mr. G. is much mistaken in saying that the "bee-space" was really the most important part of Mr. Langstroth's invention." If I understand Father Langstroth, his leading idea was to get the combs in movable frames for the purpose of readily opening up the interior of the hive, when necessary, for the purpose of study and other improvements, and when this was obtained the bee-space recommended itself as a convenience, which we have never denied, but it is the evil side of it that we are opposed to.

Mr. Gathright likes the bee-space because "it serves almost the same purpose of a double-walled hive." But the common-sense hive is a double-walled hive, for it has a box outside, and the closed ends of the frames inside with a thin air space (not a bee-space) between the closed ends of the frames and the sides of the box. This helps to resist the fluctuations of the outside temperature by keeping out much of the cold in the winter and much of the excessive heat in the summer. He says "that this escape of warm air from the cluster to the adjoining space is the best thing that could happen, since it allows the pure fresh air to take its place." If that is true, then wire screens in the place of the usual top and bottom-boards would be an improvement for admitting "pure fresh air" to the bees all the winter through. If this would work at the Gulf, it would not in the region of snows.

No matter how much mistaken he may think, I admire the spirit of Mr. Gathright's criticism, but on page 594 (1897) Mr. Peter Schartz turns his gun on the "Common-Sense Bee-Keeper," loaded with things witty, wise and otherwise; over which I had a hearty laugh at the first reading, notwithstanding the severe discourtesy of some of his remarks. He does not quote me truthfully by saying that I called the bee-space hives clap-trap inventions. If he will refer to my article he will see that I spoke of clap-trap inventions that might be called improved hives or bee-palaces, and I have seen some clap-trap inventions by those names that were not worthy of any use whatever, in my estimation, beyond the kindling-wood pile.

After his exprest virulence to my position, Mr. Schartz shows that he does not like the bee-space himself over his bees for wintering, and it seems that he eliminates it by fixing a quilt down on the tops of his frames. Doubtless there are thousands of bee-keepers who do the same thing just because they dread to let that dangerous bee-space hold sway over their bees through the fatal winter. He declares that I am all wrong, and then proceeds at once to show that he puts out the bee-space himself from above his bees, for wintering, by the use of that quilt. Why does he practice the principle which he opposes me for asserting? If the bee-space is no disadvantage in wintering, why does he, and a thousand others, take such pains to crowd it out by fixing down that quilt? See? Now, if he is not astride the fence, I would like to know which side is he on.

That was not a happy remark for Mr. Schartz to make, "If a man isn't man enough to sign his own name his article ought not to be published," and using the uncalled for remark about being "called a liar." Now, Peter, you ought not to assume an attitude that would make one think of seeing somebody with clenched fists, and grating teeth, and spitting fire, when you have not been touched nor insulted. And, besides, it is not nice to use such language in writing for ladies and gentleman to read. And, furthermore, in striking at me be-

hind the screen you gave a left-handed swat in the face of the editor of the American Bee Journal, just as if he did not know enough to judge what pieces out to be published in his paper. Peter, let us both be calm.

The editor knows my name, and has approved of my propriety in withholding it for a season, and the demand to know it is a strong reason why it should be still withheld for a time. How do you know that I lack so much manhood that I deserve to be accused of it by you in public print, just because I use a "nom-de-plume," which is one of the most common things with authors? Such personalities in writing are like an old gun that kicks against him that uses it worse than it shoots the man at whom it is aimed.

If the editor would permit, I should be glad to see the subject criticised by bee-keepers of long experience in cold climates, using kindness on both sides, for if we dive at each other as if either would swallow the other, the victor might find, after the supposed dinner, that he had more brains in his stomach than he ever had in his head.

Pennsylvania.

Wintering Bees on the Summer Stands Without Packing and Without Loss.

BY JOHN CHRYSOSTOM, C. S. C.

The report of the Northwestern Bee-Keepers' convention, published in the columns of the popular Bee Journal, has attracted my attention, especially the questions and answers relating to the best method of wintering bees—a subject to which I have devoted some attention with varied success.

One plan has proven satisfactory in every respect. Since 1894 the hive has not been moved from the summer stand, and has never been packed for wintering. I had only to put on the surplus supers and to remove them when filled.

The hive consists of two 8-frame supers of full depth, each super having a window five by ten inches. I have also another colony wintering on almost the same plan. Now for results:

Since Nov. 10 they have had four cleansing flights, viz.: December 8th and 26th, and Jan. 5th and 8th, on which days they were out from morning till evening. I searched closely during and after each flight for dead bees, and the total number found in front of both hives was 20, and a few of this number was chilled, hence unable to get back into the hive. One of these is a strong colony of 5-banded bees, on 16 frames in two stories; this colony had 18 funerals, while the other, which is a weak colony of dark Italians on 16 frames in two stories, had only two.

As the wintering of bees seems to be a subject of great interest to the fraternity, I have thought it best to be exact in every particular. If the above should be thought successful, and four years a sufficient length of time to test its merits, I shall write in detail the three essential elements necessary to bring our bees through the long winters without loss, and in a healthy and vigorous condition. When I say *without loss*, I mean that the total number of deaths occurring in a colony of health bees should not exceed 200. I cannot understand why, during winter and spring, the mortality should be greater in a colony of bees than in a flock of sheep or herd of cattle.

St. Joseph Co., Ind., Jan. 22.

[We should be glad to publish the details of the above plan of successful wintering of bees out-doors, if the writer will kindly furnish them. Too much cannot be known about the proper way to winter bees.—EDITOR.]

A Chicago Bee-Keeper's Report for 1897.

BY EDWARD H. BEARDSLEY.

I see on page 713 (1897) Mr. I. J. Stringham, of New York State, says one of his customers has taken five 28-one-pound section supers from one colony, and asks, "Can Chicago beat that much?" Well, I have waited to see if some one that knows how to write better than I do would not send in a report, but here goes for mine:

I started in the spring of 1897 with 7 colonies—5 in 10-frame dovetailed hives, and 2 in 9-frame Simplicity hives. I have increased to 16 colonies by natural swarming. I have taken, by actual count, 1,485 sections of honey. I have weighed only a few dozen sections, and the heaviest weighed 12¼ pounds to the dozen sections, and the lightest weighed were 22¼ pounds for 23 sections. I have some lighter, but none that are counted in so light but if I were buying I would

have to pay for the full section. I have over 60 that were nearly finished, some not capt at the lower edge, some one side finished, and the other side not capt. I had nearly 100 all the way from a half round piece 3 inches deep to the section half full. The latter I tried to have the bees clean out; I scratch the caps with a sharp 4-tined table-fork, and put them on my lightest colony, but they did not do as well as I expected.

My hives are all very heavy, except one which is a late swarm (Aug. 18). It was the largest swarm I ever had. It swarmed out of the best colony I had, and I was working it three supers high.

Some of the hives were so full of bees that they clustered on the outside for several days after I took the supers away. Every colony I had except the late swarm were working in the supers when the honey-flow stopt.

I lost 3 colonies in the fall of 1896. No doubt they became queenless, but I did not know it. I kept the 7 on the summer stands. I placed a rim two inches deep between the hive-body and the bottom-board, then put on an empty super and some sticks across the frames like a Hill's device, and covered with two thicknesses of coarse sacking, then put in a bag of ground cork to fill the super full. I made boxes (from old meat-packing boxes that cost 5 cents each) to set over them, with a space of three inches around them, except front $1\frac{1}{2}$ inch, and filled with plauer shavings. I kept them packed until dandelion bloom was quite plenty. Then part of the hives had the space below the frames filled with drone-comb and brood, and the young drones were just hatching out.

The season was later than the year before. That year I saw sweet clover May 28, and bees worked strong on it June 6. In 1897 I did not see a blossom on it till June 28, nor a bee till July 6, and from that time till Sept. 30 it was lively; then the dry weather spoiled it.

I have hived my swarms on full sheets of foundation, set the new swarm where the old one stood, and turned the old one partly around, and the seventh day carried the old one to some other stand. In 1896 I moved the super from the old colony to the new one; last year I did not, but the third day I put a super with some partly-filled sections on it, and they seemed to go right to work in them, but "they got there all the same" in the brood-chamber, too.

Well, I have learned some things that I did not know before, and some things I thought I did know I had to learn differently. Those books are a good thing to have on hand, but a person wants some bees also, and they help a fellow out wonderfully.

In 1896, when the first super was $\frac{1}{2}$ or $\frac{3}{4}$ full, I would raise it up and put another under it, and the bees would nearly finish the first before working much in second. In 1897, if the first was $\frac{1}{2}$ full in the middle of it they would cap it and work down through the second supers about the same width, and fill the spaces between solid full, then swarm out. I could give no reason for it unless it was because the nights were very cool at that time.

I tried one colony with three supers; they left the top one less than half full, the second nearly finished, the lower stuff full, also the bee-space, then they swarmed out, and I waiting for them to fill the top one. It was the largest swarm I ever saw. I filled an 8-frame dovetailed hive, then run a lot back where they came from, and put on more empty supers, and everything was all right.

I tried one super without separators, and won't do it again. The middle row of sections was $2\frac{1}{2}$ inches thick; those next to it were one-sided and bulged into the next all through the super.

My bees are the common, and some hybrid, with one and two yellow rings. (Perhaps the Italians would have done better.) They show their bringing up. They are nice and kind to work with.

The first 900 or 1,000 sections were the nicest honey, as clear and white as water. After the golden-rod bloomed it was tinged with yellow, but that is more in the wax than in the honey. None of it is as dark as some here in a store labeled "White Clover Honey—2 for 25 cents."

I have sold over 1,000 sections, and got 15 cents each, except for four dozen I put into one of the groceries, and they allow me 14 cents for that.

My bee-yard has not a shrub or thing in it, and I keep it mowed close. There are some small trees 150 feet away. Just before swarming-time I cut some willow branches and set them in clusters in the yard and kept them well watered, and they kept green quite awhile. To make them attractive to the bees I got some ladies' black hose and tied them in bunches on the willow twigs. When the bees swarmed they would fly but a short time then settle on or close to a bunch of the hose. Only two of the swarms went out of the yard (which is 40 feet square). One of the two went about 100

feet, and before I could hive them they got homesick and went back to see mamma.

My winter boxes are made sides and ends separate, and when put up are held together with one hook and staples. The sides make splendid shade-boards in hot weather, and it takes but little space to pile them up when not in use.

Can't some of the bee-keepers around Chicago tell a little better story than this? It *does* make me feel a little cheap when I read in the papers of some one getting 500 pounds of extracted honey, and I writing about my bees when they did not average 200 pounds, wax and all. Cook Co., Ill.

Cogitations of an Old-New "Bee-Crank."

BY WM. M. WHITNEY.

Altho in my 70th year, I am only a three-year-old bee-keeper. Among my many regrets, because of the things I have not done, which should have been done, is, that I did not begin bee-keeping in my youth. No subject for study have I found more fascinating than the honey-bee; indeed, as young as I am in the business, my friends point to me as "an old bee-crank."

Not that there is so much money in the business, that it interests me, for I doubt (taking a series of years together) whether the average bee-keeper makes any money from his bees; but, O my, what a field for investigation and thought! there is no end to surprises for those who intelligently investigate in this, as in all other departments of nature.

In talking with an old Ohio bee-keeper not long ago, I said to him: "You must have the bee-business down pretty fine by this time." He replied that he had been in the business since boyhood, liked it, had tried to learn what he could, had run his apiary for comb and extracted honey, increased by natural swarming and by artificial means, reared queens, adopted the most approved methods in the general management of his bees; but, when he felt like congratulating himself that the whole field had been explored, some surprise was sprung upon him, causing the reflection that he knew but little about the business. Tho having read "A B C of Bee-Culture," Langstroth's original work, also the revision by Dadant, and other writings on the same subject, as well as bee-papers, even in my own limited experience, there have been surprises not mentioned in the books.

It is with the greatest pleasure that the American Bee Journal is greeted on its arrival each week. I am highly entertained by Drs. Gallup and Miller, Prof. Cook, Messrs. Hutchinson, Dadant, Doolittle and others. I never met either of them, excepting as I see them in the "Old Reliable." I am sorry for that. I think I would know any one of them at sight. May not be a good judge of faces, but as they appear in the American Bee Journal, it doesn't occur to me, that any one of them, in stating a matter of fact—such as, for instance, whether he had ever seen two laylog queens on being introduced make faces at each other and call each other names, or not—would with premeditation deliberately (to use no stronger term) prevaricate. No, sir; I don't believe it, do you? You need not commit yourself; I will not press the question.

Fellow bee-keepers, while we may fortify our position with all the facts and logic at our command, let us be courteous and gentlemanly withal.

We are told that, "In the multitude of counsellors there is safety." Now, I don't know about that. I dislike to fly in the face of Solomon, but sometimes I wish we could know that the above proverb is true.

The novice in bee-keeping is confronted with so many conflicting theories, on the management of bees, that he becomes confused, and is left to his own experience for positive knowledge, which at times becomes an expensive teacher.

The conflicts among our teachers, respecting the manipulation of the apiary to obtain specific results, sometimes reminds me of the quarrel by the two knights about the color of the shield—each observing and reasoning from his peculiar standpoint.

Mr. A., located in Florida, Texas, or California, where the climate is mild; hence, the season long, conducts his operations quite unlike those of Mr. B., in Wisconsin, or any other bee-keeper in any of the northern or eastern States. Differences in construction of hives, in seasons, honey-flow, and various other things, materially affect the conditions, and should modify the management of the apiary. The same conditions seldom obtain two seasons in succession in the same locality; hence the necessity for the bee-keeper to keep his eyes open and clear. A drowsy head for a week or ten days, often means a total loss of profits, as well as endangering the

existence of the apiary. No "sleepy head" has any business to keep bees.

It pleases me to hear Dr. Gallup and Dr. Miller say, "I write from the standpoint of my own locality; as much as to say, "If there is anything you can appropriate in what I have said, all right, use it; or, modify it to suit your locality and surroundings."

But, what do you know about bee-keeping, did you say? Well, I'll be candid. What I don't know would make a big book; but I've a few good teachers—my pets—and I'm learning a few things, some of which are not in the books.

I may see you later, unless, like Mr. Bevins, I take a Rip Van Winkle sleep. Geauga Co., Ohio.

MR. C. THEILMANN.

The subject of this sketch was born June 6, 1833, in Kieselbroun, near Pforzheim, in Laden, Germany. His ancestors escaped the massacre of what is called "The Cruel Bartoloma Night in France," and found safety across the river Rhine, in Baden.

Mr. Theilmann attended common school from his 6th to his 14th year, besides one winter term in his 20th year, in a drawing school at Pforzheim; otherwise he staid at home and helpt his father to work his land until he came to America. He landed in New York in April, 1854, after a voyage of 42 days. He rambled for two years, going to Albany and Buffalo, N. Y.; Cleveland, Columbus, and Cincinnati, Ohio; Louisville, Ky.; Memphis, Tenn.; and to New Orleans, La., where he worked on a sugar plantation, got sick, and nearly died with yellow fever; when recovered he went to Shreveport, La., Pittsburg, Pa., then to St. Louis, Kansas City and Council Bluffs, and back to St. Louis, Mo. In June, 1856, he started for Minnesota, and took up a Government claim in Wabasha county, on which he still lives. During all his rambles he earned enough to make his living and pay his way, as he had given nearly all the money he brought with him from Germany to a distrest friend, when he landed at New York.

In the fall of 1856 he was married in St. Louis, and took his wife to his new home in the wilderness, among the Sioux Indians, wolves and rattlesnakes, tho they have never done any harm to them. A cat, that came to them, was the first domestic animal they possesst for many months. Speckled trout in the creek were plentiful, as the Indians would not eat them.

The first year Mr. T. had to carry his provisions on his back from Wabasha (13 miles), making the round trip in a day, sometimes without his dinner.

In 1857 he hired four yoke of oxen and a 24-inch breaking plow of some of his nearest neighbors three miles away, and broke up the first six acres on his claim in two days, *all alone*; and paid for the outfit with 17 days of 14 hours each, or 50 cents a day, mowing grass for hay by hand. The boys and young men of to-day would say, "I wouldn't do that;" but many of them would get along far better if they would.

Mr. Theilmann kept on working and improving his claim, and after awhile bought a cow and a yoke of oxen. Boys and girls were born until there were five in the family. They grew up rapidly, and soon helpt their father and mother. The country settled up rapidly, a school district was formed, and school was held in a primitive log house first.

In 1860 the Indians disappeared, just a little while before the New Ulm massacre, and never came back. In 1863, Mr. T. raised over 1,100 bushels of wheat on 25 acres of land, of which 200 bushels where sold out of his granary for \$500; he has also had wheat in succession for 17 years on a 16-acre piece, and never had less than 25 bushels per acre, and up to 45 bushels without the least fertilizing.

In 1869 Mr. T. found a bee-tree in his woods, and took it home; from this and two more swarms he found, he started his bee-keeping, transferred them to frame hives, Italianized and increast them to 74 colonies. In 1871 he lost all but four colonies, but by May, 1872, he hunted and found 15 colonies in trees and rocks in his vicinity; this gave him a start

again. For nine years after this he tried all kinds of wintering methods without satisfaction, until in 1882 he built a beecellar all under-ground, which stood the test, and since then his losses have been very light in wintering, and they have averaged him an income of about \$1,000 a year.

On Jan. 25, 1885, one of his bee-repositories, in which 87 colonies were wintering, burned down, but fortunately he had 100 colonies in two other beecellars. He started the season of 1885 with 90 colonies, which he increast to 170, and produced 6,500 pounds of very fine honey, which sold for from 15 to 20 cents per pound.

The season of 1889 was the best with him, 185 colonies, spring count, producing 25,000 pounds of comb honey. His honey crop and bees sold that year amounted to about \$2,500. The best from one colony and its increase he ever got in one season was five good swarms and 600 pounds of honey; this was in 1872.

A carload of the honey crop of 1896 was sent to a Chicago commission man, who has tried to swindle him out of it for the past 18 months; it is still in court.

The season of 1897 was almost a total failure, getting 1,700 pounds of honey from over 200 colonies.

In 1877 a railroad was built from Wabasha to Zumbrota, with a station on Mr. Theilmann's land. Mr. T. saw the opportunity, and laid out a village, calling it Theilmanton; it is now a village of about 100 inhabitants, with nearly all conveniences farmers generally need, and is quite a big shipping point for grain and stock. Mr. T. also built a warehouse and grain-elevator, which is the handiest and most substantial building on that line of the road. It works wholly automatically, without machinery of any kind, from the farmer's load to the cars. The grain can be weighed going in, also going out, without shoveling or other hand work except moving a light lever. Mr. Theilmann planned it himself and prepared the drawings for it. The warehouse and the station agency were run by him for five years, when he sold it and went West on a trip to California and Oregon, and got interested in medical lakes and healing mineral waters in Washington, 16 miles west of Spokaue Falls; also in general mercantile at the Lake. He was the first bee-keeper that took two colonies of bees from Walla Walla across the Snake river as far north as Medical Lake. The bees were left in care of his oldest son, George; they did fairly well for five years, or until Mr. T. sold out there.

In the meantime the farm and bee-culture were carried on at the old homestead, and Mr. Theilmann is satisfied and contented that he cannot find a better place in the Union for his taste than what he has, especially after seeing Texas and some other Southern States three years ago.

Mr. Theilmann's farm now consists of over 700 acres of land, some of it rather rough, but good pasture for his bees, cattle, swine and fine-bred French Percheron horses; with substantial buildings for all of them, also a good house for himself, wife, and two children, a boy and a girl. Two sons and one daughter are married and have homes of their own.

Mr. Theilmann learned enough in the drawing school to make his own plans and drawings for the many structures he has built on his own land, and otherwise, to almost perfection in handiness, work-saving, durability and comfort. He has also caused a nice little church to be built at Theilmanton, in which to worship and give thanks to the Giver of all good things for what we receive from his Fatherly hand.

A FRIEND.

Bees and Poultry in Winter—An Experiment.

No. 1—FARMER GREENY—"I believe I'll just put these bees in with the chickens over night. I don't think they'll disturb each other."

[See No. 2 on page 103.]

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL-REPORTER.

(Continued from page 85.)

FIRST DAY—EVENING SESSION.

FEEDING BEES WHEN GATHING POLLEN, OR FOR STIMULATIVE PURPOSES.

"Is it profitable to feed bees as soon as they carry in pollen?"

Pres. Miller—How many have had experience in feeding bees as soon as they carry in pollen in the spring? [Three had.]

Mr. Green—I never tried it but once: that year it was very successful, but was much trouble. I might say I fed at that time by placing a case of candy under the hive, and there was flour mixt with candy; I never knew the bees to build up so well, but it was troublesome and expensive.

Dr. Besse—I have to feed as early as the bees fly readily, whether they gather much pollen or not. I put my feeders out in the yard, if it is warm weather enough so they can have a little taste every day. It stimulates the queen to go to laying sooner. I have practiced it for the last three or four years.

Mr. Baxter—I don't practice it any more; I used to do it; as soon as the weather began to warm up in the spring I would feed them a little before they began to gather pollen, so as to induce them to breed; and as they began to extend their brood, and the weather was warm, I would move the frame of brood over and put a frame of honey in between, that had no brood in it, so as to force them to extend as fast as they could take care of them; the result was very favorable; produced very big crops that way. In 1889 I had 41 colonies fed in that way that produced 23 barrels of honey, an average of over 275 pounds to a colony; one colony produced 600 pounds. My mother practiced it up to within three years ago; since that I have taken care of the bees, but she used to get a great deal more honey to the number of colonies than I did when I didn't do that. It is good, and it will pay.

Mr. Whitcomb—That would depend entirely upon conditions, it seems to me. In Nebraska there is no honey-flow until Aug. 15, and then we get a couple hundred pounds after that. I would not want to commence in the spring and stimulate a colony. I watch the honey-flow, and about 30 days ahead of that I do the stimulating; the less bees you have in the hive the better you are off until this flow comes in. Conditions have a great deal to do with it when you have to feed.

Mr. Baxter—I agree there. I presume the question meant where there was a white clover flow, of course. We are so accustomed to have it all through the Mississippi valley; we base our assertions on that, I suppose.

Pres. Miller—The plan in Germany is very popular; they call it "speculative feeding" there.

Mr. Baldrige—I would like to ask these persons how they feed.

Mr. Baxter—In the hive, always. My first feeder is simply an oyster-can. Take a piece of flour-sack, put it over the can, tie a string all around it, and put a little piece of wood in to keep it as tight as possible. However, of late years I have been using the Hill feeder, the end full of little holes.

Mr. Green—The only feeding I ever did early in the season was by candying; but later in the season I have practiced stimulative feeding considerable. I much prefer it to feeding out-of-doors, unless there are too many bees in the neighborhood. That is the most economical, and less laborious, and stimulates all the bees much more than feeding in the hives.

A Member—I have had a little experience in feeding bees, following the advice given me, of putting the feed outside for just an hour before sundown; then the bees would not rob, and only your own bees (if you have other bees in the neighborhood) would get the honey. I fed them that way in the spring and late in the fall the past season. I tried to induce them again to rear some young bees, but I have several

neighbors that have bees in my neighborhood, and I thought I would see whether their bees noticed my feeding; when I came over they were more lively than mine were, so I have changed now, and am using an entrance-feeder. I have a Mason fruit-jar placed in front of the hive, so that only bees from the inside of the hive can get through, and none from the outside. I like this better because I can put the feed into the Mason fruit-jar, and do easier work than feeding outside.

Mr. Wheeler—I don't believe out-door feeding is good economy at all. Let your strong ones alone until such times as they need it, and feed the weak ones.

A Member—I differ from Mr. Wheeler. I believe in not feeding the weak colonies at all.

Mr. Rohrs—I believe in building up the weak colonies by feeding the strong ones.

Dr. Besse—I expect to make my money from spring colonies. As early in the spring as I can I equalize them; then I use stimulating feeding, and I saw the benefit of it this year. I produced more comb honey from my colonies than ever before.

Mr. Rohrs—As I understand this, it is stimulating feeding, not feeding to keep alive, and therefore my practice is to feed spring colonies; those are the ones that want stimulating; the weak colonies have all they can take care of; you want to stimulate the strong ones, and when the weak colonies get strong, they can take care of more brood, then it is time to begin feeding them. You must be careful; it requires judgment if it is done properly.

Mr. Baldrige—I don't feed any, and don't believe in it now; I have plenty of honey in my hives, and find the colonies get strong enough to swarm about May 20, without any feeding; if I had 20 colonies, and 10 were somewhat weak and 10 very strong, I would simply exchange places at the proper time. I should prefer to do it in the middle of the day, when they are at work.

Mr. Baxter—That will equalize them, but not stimulate them. I have never found a colony yet that was too strong for me.

Mr. Baldrige—I don't claim the colonies can get too strong. I claim that the best way is to equalize them, and make them all strong. There should not be any weak ones when the honey harvest begins, and there will not be if you follow that plan.

Mr. Baxter—I am afraid to practice that again. I have lost queens in just that way.

Pres. Miller—The question is about feeding in the spring to stimulate.

Mr. Baldrige—I wish to say I have practiced this 10 years in large apiaries.

Mr. Wheeler—I have lost many queens that way. If you change hives in the spring you will have trouble; it comes the time just before the white clover flow, and if a queen is lost then swarming begins, and they are thrown clear out. It is all right to experiment with a few, but I would not go at it by the wholesale.

Pres. Miller—Perhaps we must take this into consideration, that what is safe under certain circumstances may not be safe under others. Mr. Baldrige kept bees and worked at it before most of us knew anything about it—certainly before I did—and what might be perfectly safe with him might not be safe with others, because he would be on his guard as to the dangers of the situation.

NUMBER OF COLONIES AND SIZE OF CROP.

"How many colonies has each member, and what has been his crop this year (1897)?"

Mr. Thompson—Spring count 15 colonies, increased to 17, and harvested 400 pounds of comb honey and 800 of extracted.

Mr. Kennan—Spring count, 4, increased to 7, and secured 450 pounds of comb honey.

Mr. Rohrs—Spring count, 24, now 48; and got about 2,300 pounds of extracted honey.

Mr. Kreuzlinger—102, spring count, 143 at present; 5,000 pounds of comb honey, and a small quantity of extracted.

Mr. Green—I had about 90 colonies in the spring, and about 140 now. I took about 12,000 pounds of honey, half comb and half extracted.

Mr. York—I had four colonies in the spring; increased to 8, and had 400 pounds of sweet clover comb honey. My apiary is right in the city.

Mr. Wheeler—Spring count 370, and at present 458. I took 6,000 pounds of comb honey and 18,000 of extracted. I have six apiaries.

Mr. Baldrige—16 colonies in the spring, and 30 now. I don't know how much honey, but I know of about 400 pounds

of comb and 2,000 of extracted. I don't know how much more there is.

Dr. Besse—60 colonies in the spring, increase to 122, and I took off a little over 3,000 pounds of comb honey, and about that much extracted.

Mr. Baxter—About 250 colonies in the spring, and took about 40 barrels of honey for my share, the barrels averaging about 575 pounds net, making in the neighborhood of 22,000 pounds of extracted honey; and about 500 pounds of comb honey. I had four yards, and gave one-fifth of the three yards for the privilege of keeping the bees; that would be about five barrels for their share. Then I have 15 colonies of my mother's in the same yard, which I take care of for her and give her all the honey, and she got two barrels.

Mr. Norris—10 colonies in the spring, 14 now, and about 500 pounds of comb honey.

Mr. Whitcomb—Started in the spring with 12, increase to 30, and have 1,500 pounds of extracted honey, besides 500 of comb.

Mr. Finch—Started with 15 colonies in the spring, increase to 45, and have now about 600 pounds of honey, half extracted and half comb.

Mr. Kartch—I had 10 colonies, spring count. I got them a little late, so I was a little slow in getting to work. I increase them to 20, and I have taken off about 300 pounds of honey.

Mr. Schaper—About 50 colonies in the spring, now about 85, and I took 2,000 pounds of honey, 500 of it being comb.

Mr. Nau—About 12 or 14 in spring, 18 or 20 now, and took about 500 pounds of comb honey.

Pres. Miller—239 colonies, spring count, 295 now, and I took a little over 17,000 pounds of comb honey, with perhaps 300 of extracted.

[Continued next week.]

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. O. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Hive-Ventilation in Winter.

My bees are in original Langstroth hives, with wooden honey-board and tight bottoms. I have opened all holes in the honey-board, and packed with chaff cushions on top, making them air-tight on top. How much ventilation should they have at the entrance? VIRGINIA.

ANSWER.—The tendency nowadays is toward a good deal. The stronger the colony the more they need. Perhaps the whole width of the hive by one-half inch is none too much, keeping watch that the entrance isn't clogged.

Bees in a New Bee-Cellar.

I built a bee-house or bee-cellar by digging in the ground $3\frac{1}{2}$ feet, and then built a wall $4\frac{1}{2}$ feet high. The cellar is 10x14 feet. I set two rows of posts through the center and made a roof of green oak poles, then put on straw and then dirt, then straw and then dirt, with a 6-inch hole for ventilation. The doors are so arranged as to be double. The mercury stood about 45° the first part of the winter. The green timber began to mold, and the mercury went down to 40° . I then closed the ventilator, but was afraid to leave it closed on account of the mold. I see some mold in the front of some of the hives.

I put 6-inch scantling on the ground edgewise to keep the bees off the ground. I left the hive tops and bottoms on. This wall was green, laid up late in the fall, so it did not get a chance to dry out, and the poles were green. I had a stove in there for two or three weeks. I had it pretty well dried out. The mercury stands at 38° now. Do you think the bees are all right? If not, what can I do to help them? I have 40 colonies in the cellar. I had a heavy loss last year in wintering. IOWA.

ANSWER.—Very likely you are doing about as well as you can. The best thing will be to repeat the fire if it goes below 45° much, unless indeed there should be something objec-

tionable about the way the fire is managed. Of course it will not do to have a fire without a pipe to carry the smoke clear out of the cellar, not even as some think allowable, if an oil or gasoline stove is used, 38° is too low, and it will probably do no harm to start a fire whenever it gets down to 40° . Still, 40° is not so very bad if not continued too long, and it is just possible you may find it all right, for there is a great variation in thermometers. The best test is to see whether the bees are very quiet. That temperature is the best for them at which they make the least noise.

Don't Disturb the Bees—Section-Cleaner.

Last fall my bees had plenty of stores for winter. I packed them with one foot of straw and planer chips on top, bottom and sides. There are 34 colonies in one row, with 3-inch space between each colony. I am afraid they are too warm, and have used up their stores rearing brood. I send you a sample of bees which I think is this year's rearing. If so, will I have to feed them before warm weather? The bees I send you flew out and died on the snow.

Tell Mr. Golden to put a cushion of felt between the wheel and the sand-paper on his section-rider, and it will work nicer. It will make the section-rider smooth. He can glue each succeeding piece of sand-paper on without taking the old one off.

Did you ever try drying out your bee-cellar with the heat of a good stove, and then let it cool down to the right temperature just previous to putting the bees in?

WISCONSIN.

ANSWER.—I think the bees you send were reared last summer or fall, and I don't believe you need worry. Probably the best thing you can do is to let your bees severely alone till weather comes warm enough for them to fly nearly every day. It is barely possible some of them may not have stores enough to last till that time, but I'd take the chance rather than do the mischief of disturbing them.

How Often to Open Hives—Winter Packing.

1. How often should the body of the hive be opened to see that all is going right when we have both time and inclination to give our bees first-class care, commencing with February and ending with the packing for winter?

Out of 10 swarms I had three that became queenless in the spring or early summer. I soon knew of it, and remedied the evil. A friend told me that I fust with my bees too much, and suggested that I killed the three queens in handling the frames, but I always tried to be very careful.

2. I would like to have your judgment on the way I pack my bees for winter. If it is advisable, it is a way farmers can easily do:

I use the 8-frame Langstroth dovetail hive. I work mostly for extracted honey. The super is the same size as the body. In the fall I lookt through the hives, and if any contained less than 25 pounds of honey, I fed up to that amount, then as there is a bee-space between the tops of the brood-frames and the queen-excluders, I left the excluders on several of the hives, and took out the excluders and put Hill devices on several others for experiment. Then, as I left shallow frames on one hive last winter, and that colony commenced work in the spring earlier than those with the Hill devices on, I left two with shallow frames on this winter. Then I put a large empty super on each hive, including the two that I had already put on shallow supers of frames. I took a gunny-sack for each super, and put enough dry leaves into it so that when it was prest down in the deep super it would fill it about half full. Then I put on the covers.

My hives are on the summer stands, fronting south, all in a straight row. For outside protection I laid corn-fodder down straight on the ground behind them, piling it up about to the tops of the supers; then I took a six-inch fence-board and nailed sharpened stakes near each end, and drove the stakes into the ground, so that the board came against the front ends of the hive-bodies, covering a large portion of the upper part of them. I then filled the spaces between the hives with old hay. With the corn-fodder behind and the board in front, I could pack the hay in very nicely, and filled it in nearly to the tops of the supers. For ventilation I left the entrance entirely open, full width of the hive.

I wish to know which of the ways I pack the cushions over the tops of the bees is the best; or is there some way better than either of them?

I wish also to know what you think of my method of out

side packing. Does it pay? or would the bees do well enough without any? My latitude is a little less than 40°. Chaff hives are highly recommended, but they are not advisable for me.

The American Bee Journal is a great help to me. I would not think of continuing the business without it.

KANSAS.

ANSWERS.—1. It isn't easy to say how often it is best to open hives. Some, who may perhaps be considered extremists in that direction, say they don't need to open a hive more than once in three years. Others may open a hive once in a week or ten days, but certainly not commencing in February. If the bees have been properly supplied with stores the preceding fall, there can hardly be any excuse for opening them before May, and a colony should not be disturbed unless there is some good reason for it. All depends on the kind of management, and yet both ways may be good. It is very probable that those who open their hives once a week lose more queens by it than they suppose (hardly as many as you lost, tho), and yet the advantage gained by opening may pay for all the losses of queens. Few, however, would think of opening a hive as often as once a week, and it's a good rule to open a hive no oftener than is necessary.

2. Your packing over the bees ought to be good, and most likely they will be better off for the outside packing. If I understand you correctly, there is nothing to hinder the rain from soaking your outside packing, and it is important that it should be kept dry. There is also danger that your bees may not have enough stores, especially if winter should hold late into spring. It's better always to be on the safe side, and too much is always just about enough in the case of winter stores for bees.

I don't know which of the three ways of your inside packing is best, but believe I'd just as soon not have the empty frames over. The closer down to the frames the cushion is the better, providing there is chance enough for the bees to cross from one frame to the other.

In all this matter of out-door wintering much depends upon surroundings that are not taken into account. Buildings, trees or hills surrounding an apiary may make a success where the same preparation would be a failure in an open location with the winds having full sweep.

Wintering—Increase—Supers and Separators.

1. I have 13 colonies of Italians in 12-frame "New Model" hives. I put them in a good cellar with the temperature ranging from 38° to 45°, Nov. 25, with plenty of stores. I raised the hives in front $\frac{1}{2}$ inch from the bottom-board, the cap being glued down tight. Are they all right?

2. I desire to increase 25 colonies—would it be best to divide in the spring, or let them swarm?

3. As I am obliged to make new supers, would you advise me to make them for the $3\frac{1}{2} \times 5\frac{1}{2}$ sections, or the $4\frac{1}{4} \times 4\frac{1}{4}$ sections?

4. What kind of separators are best and cheapest?

SUBSCRIBER.

ANSWERS.—1. If your thermometer is reliable it might be better to have the temperature higher. It is not well to have the temperature down as low as 38°, especially for any extended period. But note at what temperature the bees are most quiet, and try to keep them near that point. If the entrance is only $\frac{1}{2}$ inch, that is not nearly so well as an inch, and two inches may be still better.

2. In any case don't divide till regular time of swarming, then perhaps you will do well to allow what will to swarm once, and divide any that are too lazy about swarming.

3. I don't know. The new size is as yet on trial, and you might do well to try both.

4. The probability is that you mean the material of which the separator is made. If separators are nailed on, tin is perhaps the best of all, and cheapest in the long run. If separators are to be used loose, then wood.

Using Unfinished Sections—Two-Pound Sections.

1. I notice you produce nearly all section honey, and I want to produce the same. Last fall I took about 400 sections off, and the comb is all right, but no honey in them. If I put them on next spring, will the bees work on them? I have them put away in boxes, and are all right as far as I can see.

2. Do you use the 2-pound section? If you do, and think

they are any better, I will get them. I don't want to produce any extracted honey. I would rather part with the bees than have the people think I am selling something not honey.

I see a good deal is said about the bee-moth. I have a neighbor who keeps a grocery store, and he had some molasses that was spoiled; he put it into a jug and said I might take it to the bees. I did not like to say I would not, when he had been so good to keep it. I took it and put it away where the bees could not get at it, and it soured. I happened to set it out one night, and in the morning it was covered with bee-moth. I let it stand, and the bees never bothered it, but I had to take the bee-moth off. It lookt as if it would be a good trap for them.

SUBSCRIBER.

ANSWERS.—1. The bees will work on them all right enough, probably preferring them to fresh sections. Whether they will be as good for you depends on whether all honey was thoroughly cleaned out of them by the bees last fall. If any was left in, no matter how little, it will be granulated, and that will affect the honey the bees store in them.

2. Two-pound sections have given way almost entirely to the one-pounds, and in the general market will not bring as much per pound. It is hardly advisable for you to try them.

Bees Buried Under Snowdrifts.

I am wintering 35 colonies in winter-cases on the summer stands, and they are not protected so but what the snow drifts over them so that some are completely buried.

1. Would it be best to leave them thus, or shovel away from the entrances? I shoveled the snow away once in January, and it came off a bright day so that the bees (being disturbed) came out in quite large numbers and fell blinded to the snow, where they perished.

2. Would it do any harm to lightly scatter some straw over the entrances?

3. Will they be in any danger of smothering where the hive is covered with snow?

MICHIGAN.

ANSWERS.—1. Wintering under snow is a somewhat mixt business. Some say they want nothing better, and probably as a rule it's good. But it may also be very bad. If I remember correctly, Doolittle says he had some colonies completely buried that were ruined thereby. The snow kept them so warm that they started breeding largely, and finisht their existence with a severe case of diarrhea. The later in the winter it should happen that a colony was completely buried, the later the danger therefrom, not only because there would be likelihood that they would be the sooner thawed out, but because excitement and brood-rearing is not so bad toward spring as early in winter.

2. You are right that there is danger that bees will fly out on the snow and be lost when the sun shines brightly, and your plan of throwing straw over the entrance, or darkening it in any way is good. Some throw straw or carpets on the ground in front of the hives on top of the snow, and let the bees fly.

3. There is probably not much danger of suffocating when deeply buried. Enough air goes through the snow to supply the bees. There is more danger of suffocation when the entrance is not covered very deep, especially if the entrance be small. The snow melts, fills up the entrance, then freezes solid, keeping out all air.

No. 2.—DEACON JOHNSING—"I wondah how many feddahs dey am on dis heah roost."

OLDEST BEE-PAPER IN AMERICA

GEORGE W. YORK, - Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., - CHICAGO, ILL.

\$1.00 a Year—Sample Copy Sent Free.

[Entered at the Post-Office at Chicago as Second-Class Mail-Matter.]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—W. Z. HUTCHINSON.
SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT. E. WHITCOMB. E. T. ABBOTT.
W. Z. HUTCHINSON. DR. C. C. MILLER. C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Vol. XXXVIII. CHICAGO, ILL., FEB. 17, 1898. No. 7.

A Sad Year for bee-keepers seems to be the general report from all over Europe with regard to the year 1897, some saying it will be long remembered as the worst year of the century.

Cheap Hives.—"Hives that may be bought for \$25 a hundred in the flat, are good enough for any bees. . . . when painted two coats of good paint," says George Appleton in the Wisconsin Agriculturist. Yes, and kegs costing less than 5 cents may be good enough for bees, but the question is whether it is good enough for an intelligent bee-keeper. Will Mr. Appleton tell us where he can get hives at anything like \$25 a hundred with which he would be satisfied?

The Langstroth Monument Fund.—Mr. N. Cameron, of Douglas Co., Kans., sends us the following on this important subject:

EDITOR BEE JOURNAL:—I see there has been an effort made to raise a monument fund for the late Rev. L. L. Langstroth. I do not know just what has been done, as I have not been taking the bee-papers for some time, but it is my opinion, if a proper effort was made, we could raise a respectable fund. We ought to be ashamed of ourselves if we do not make that fund at least \$500 or \$1,000. I was always an admirer of Langstroth, so much that I named one of my boys Huber Langstroth.

Now, I have this suggestion to make: I will be one of 500 that will give one dollar each, or I will be one of 100 that will give five dollars each. I believe that every bee-

keeper who uses the movable frame is indebted to Langstroth more than one dollar, and many of us more than a hundred times that.

I was going to suggest that subscription blanks be sent to every bee-keeper in the United States that can be reached—several to each one—with a request to get as many subscriptions as possible, no money to be called for till at least \$500 is subscribed. I would be sorry to believe that the bee-keepers of America are so poor, or so penurious, that they will not do something respectable, to the memory of one who did so much for them.

Yours truly, N. CAMERON.

Well, what do you think of Mr. Cameron's suggestions, reader? It is for you to say, if you have not already contributed to the fund.

Since our last report we have received \$1.00 from Wm. Stolley, of Nebraska; 50 cents from A. Suideman, of Colorado; and 25 cents from A. L. Barner, of Washington. We are ready to receive more, and then to turn it over to the proper authorities.

A Troublesome Conundrum is propounded in the Pacific Bee Journal by W. A. H. Gilstrap, who inquires: "If the production of honey is as profitable as some claim it to be, why do nearly all who own bees remain in moderate circumstances?" But there's the fun, Mr. Gilstrap. Besides, can you name a business in which fewer men have gone into bankruptcy?

Bean-Honey.—One accustomed to seeing only a few beans raised in a garden is hardly inclined to think that bean honey can amount to such a great deal. But C. A. Hatch, in Gleanings, explains that in California whole farms, and large farms at that, are devoted to raising Lima beans. He says:

"One ranch near Ventura has 1,900 acres, mostly in beans. The crop of this ranch was 19 carloads one year. I saw 10 two-horse teams cutting, and 25 men shocking beans on their ranch this year, at one time."

No wonder bean-honey amounts to something! It is white and of fine quality, but not positive in flavor, like clover or linden. It never gets as thick as sage honey, and is prone to candy quickly.

Wisconsin Favors Amalgamation.—We have received the following from Pres. N. E. France, of the Wisconsin bee-association, which shows the trend of opinions in that State on the amalgamation of the two Unions:

These resolutions were adopted at the meeting held in Madison, Feb. 3:

Resolved, That the Wisconsin State Bee-Keepers' Association do hereby endorse the United States Bee-Keepers' Union, and recommend Wisconsin bee-keepers to send \$1.00 each to its General Manager, Hon. Eugene Secor, Forest City, Iowa, for membership. Also,

Resolved, That we will rejoice over the amalgamation of the two Unions under one management.

Mr. France, with the foregoing, sent the membership fee of \$1.00 for the firm of E. France & Son, and added:

"We have been members of the old Union ever since its birth, but believe the time has come for the two Unions to unite."

No Klondike in Bee-Papers.—A goodly number of bee-papers have been started at one time and another which proclaimed that they were getting on swimmingly—"had come to stay"—subscriptions were coming in rapidly, etc.; but in a little while they were gone where the woodbine twineth, leaving some chance for doubts as to their proclaimed prosperity. After so many of that sort it is somewhat refreshing to find one which frankly comes out and says it isn't a howling success. "The Bee-Master," of Sheffield, England, has reached its 5th number, and says: "At present we are losing \$50 per month, without charging anything for our own work of booking, addressing wrappers, etc.," that there

are 200 subscribers, and it would require 1,000 to pay expenses out of pocket.

But we needn't go to England for that sort of honesty. It can be found in the columns of the Progressive Bee-Keeper, which has entered its eighth year, and whose publisher says: "Friends, do you know the Progressive has never made a dollar for me yet? It is a fact. It has never paid more than expenses." And yet the Progressive is worth a dozen of those papers that flourish such long lists of subscribers, and then mysteriously faded out of existence. It has worked hard for success, but it seems clear that a bee-paper is not generally a Klondike.

A Honey Syndicate is proposed in Belgium to meet the crisis that is upon them by which the price of extracted honey has fallen till it will not bring in some cases more than 11 to 15 cents a pound. A. Gustin has formulated a constitution and by-laws for such an organization, which occupies nearly five pages of the Belgium bee-journal, *Le Rucher Belge*. According to the proposed plan each member agrees to deliver all his honey to the syndicate except enough for his own household, to furnish only pure honey, and not to get honey of a third party to furnish to the syndicate. The matter is being warmly discussed, pro and con, but all in the best spirit.

Progress in Bee-Culture.—A. I. Root tells about it in *New York Tribune*. It makes one green with envy to hear him tell about getting 25 cents a pound for 6,000 pounds of *extracted* honey years ago. He also tells about a man he lately visited in Arizona who had about 300 colonies in one apiary, and averaged more than 200 pounds per colony! But Mr. Root thinks bee-keeping is a most risky business. By a little carelessness or bad management a man can in a short time lose all. But he can pick up again with marvelous rapidity. A hundred colonies may be cut down to half a dozen in wintering; but if a man is informed and full of grit he may also have his empty hives refilled in one season.

This is a Good Time to attend to the payment of subscriptions to the *Bee Journal*—before the busy time of spring comes on. This is a matter that we dislike very much to refer to in public print, and yet if the financial end of the business of publishing this paper is not carefully looked after, the whole thing would soon come to a finish. So we trust those whom we have patiently waited on will at once pay up, and also send the dollar due for this year. How many will during February send in their remittances, and thus again be square on our books?

HON. EUGENE SECOR, General Manager of the United States Bee-Keepers' Union, was also President of the Farmers' Institute held at Forest City, Iowa, Feb. 8, 9 and 10. At that meeting Mr. Secor was down on the program for a talk or paper on "The Ideal Farm Home." Of course it was a *homely* subject, but no doubt it was treated in a handsome and satisfactory manner.

MR. A. I. ROOT is nothing if not accommodating, so seeing that Mr. and Mrs. Boyden (his newly-wedded daughter and her husband) could not take an extended wedding-trip on account of their being needed in the office, he (A. I. R.) kindly consents to take it for them—going to the Bermuda Islands, where he will incidentally learn about onions, potatoes and things.

MR. JACOB DICKMAN, of Defiance Co., Ohio, who is a regular reader of the *American Bee Journal*, sent his report for 1897 to the *Ohio Farmer*, and it appeared in that paper for Jan. 6. Two paragraphs of his report read as follows, his honey being extracted:

"The yield of our scale hive the past summer has been somewhat marvelous. At least we have heard of none better. The entire yield was 396 pounds, besides enough for winter. The daily increase during part of the best flow was from 18 to 23 pounds.

"The flow the past summer continued a longer time than we ever knew of before, and our entire yield from 50 colonies, spring count, gave us 10,175 pounds, an average of 203½ pounds, and we increased to 103 colonies. Counting the new colonies worth \$2 each—and they are certainly worth more—and the honey worth 10 cents per pound, the profits for the season would be equal to a crop of 6,391 bushels of corn, or a crop of over 225 tons of hay. Whether the business pays or not, let the reader decide."

MR. W. H. PRIDGEN is a "queenly" deceiver. You know how angry you feel when you are beguiled into reading an advertisement when you expected something else, and you know how common the trick is. Well, this man Pridgen has gotten up a pamphlet of a dozen pages, and the title page reads, "Pridgen's Catalog and Price-List of Queens, together with combined and improved methods of Queen-Rearing." Then you look through the pamphlet expecting to see a page or less of stale matter about rearing queens, and all the rest of it advertising matter. That's where you're fooled. Just one page is all he takes to blow his own horn, and the rest is interesting, useful matter about queen-rearing. If he fools his customers the same way when sending out queens, he'll work up a big trade.

MR. S. M. BROOKS has been keeping bees for several years five miles directly west of the Chicago court-house. Last season, with 28 colonies in the spring, Mr. B. increased to 54 colonies, and took 2,000 pounds of comb honey, and 200 of extracted. It is right in the midst of any quantity of sweet clover, but being built up so fast Mr. Brooks will now remove to Stark county, Ind., where he has traded his Chicago property for a 126-acre farm, expecting to go into bee-keeping more extensively there.

MR. JOHN DENYER, formerly of Middlesex Co., N. J., has removed to Northampton Co., Pa., where he purchased a home-stead, and will run the bee and chicken business. Mr. Denyer has been managing several apiaries, but will now combine them at his new place. His partner, A. C. Ramsey, is an experienced apiarist and poultryman. Mr. D. is also a railroad signal inspector.

HON. GEO. E. HILTON, of Newaygo Co., Mich., gave us a very pleasant call Feb. 8. Mr. Hilton has recently been appointed postmaster for his town, and will enter upon his duties April 1. He is not only a honey-producer, a bee-supply dealer, and a busy churchman, but also a good deal of a politician. He has some 300 colonies of bees, and will have them in three apiaries the coming season.

MR. JOSEPH A. SHONE, a bee-keeper in Benton Co., Miss., died at the age of 68, Sept. 20, 1897, leaving 93 colonies of bees, but his wife, unfortunately, is not able to care for them. She writes that there is no other apiary in that vicinity, that their bees have done well, and that they can sell all the surplus honey in the home market. Mr. Shone was for years a reader of the *Bee Journal*, which Mrs. Shone says they "liked so much."

DR. WM. F. McDONALD, of Essex Co., Mass., is a bee-keeper as well as a tooth-doctor. He has sent us a newspaper account of a lively experience he had last July in having a swarm in the city where he lives. He keeps his bees on the roof of a three-story brick building, and says that in his family they have consumed about 400 pounds of honey in less than two years. That ought to be, and doubtless is, a very sweet family.

CATALOGS FOR 1898 have been received at this office from the following who advertise in the *American Bee Journal*: G. B. Lewis & Co., Watertown, Wis.—Bee-Keepers' Supplies.

Geo. E. Hilton, Fremont, Mich.—Bee-Keepers' Supplies.
J. D. Givens, Lisbon, Tex.—Queen-Bees.
Geo. H. Stahl, Quincy, Ill.—Incubators.
Leahy Mfg. Co., Higginsville, Mo.—Bee-Keepers' Supplies.

The Price of Success.—"I never saw a successful bee-keeper who was not, in all kinds of weather, thinking about his bees."—C. P. Dadant, in *Busy Bee*.

Saving Sweet Clover Seed.—"I once gathered a bushel in two hours by pushing an inverted umbrella up close to the stalk, and an assistant bent the stalks over it and beat off the seed with a stick."—J. B. Hains, in *Gleanings*.

Ups and Downs.—In 1896 Dr. Stell was reported in Southland Queen as producing in Mexico from 10 colonies 1,500 pounds of honey that he sold at a dollar a pound. In 1897 the case is reversed. From 18 colonies increased to 40, he got only 22 pounds of honey after paying out \$240 for supplies.

Extracting in Parts.—Hasty in Review thinks it might be a good plan to avoid extracting unripe honey to have two extracting-supers on at a time, extracting alternately, or else having only one super and extracting alternately the two halves, thus giving a chance for better ripening to the part to be extracted.

Wax in Bee-Glue.—M. Bertrand, editor *Revue*, sent to Dr. de Planta a sample of the material used by bees to construct the entrance of a straw hive. The analysis showed: Beeswax, 76.27; resin (propolis), 22.15; water and volatile oils, 1.58; total, 100. Probably many bee-keepers would be surprised to find the large amount of wax they could secure by melting up what they may think pure propolis.

Are Drones a Help to Workers?—Some think that workers are more energetic if drones are present in the colony. Editor Hutchinson thinks that even if the presence of drones is an encouragement to the workers, there's no need of a big lot. He says: "Two or three hundred in each colony, if they are anyways smart drones at all, ought to be able to give the workers all of the 'patting on the back' that is necessary."

The Bee Not Cold-Blooded.—Karl Gruendig, in *deutsche Imker*, combats the assertion of Dzierzon that the bee has no heat of its own, but takes the heat of surrounding objects. Because a bee becomes chilled and apparently lifeless when separated from its companions, it is subjected to a temperature of 40°, and it is not safe to assume that it has no heat of its own, no more than it would be right to say a man is cold-blooded because when the temperature is low enough he freezes.

Peep-Holes and Plain Sections.—A strong point claimed for plain sections with fences is the lack of peep-holes in the corners. S. A. Niver asks *Gleanings* not to put that point too strong, continuing, "There are peep-holes in every box of honey Morton has ever produced. Danzenbaker had one section with nary a peep-hole—the only one I ever saw. To be sure, the fence helps to reduce the size of 'em, but they are there all the same." But W. D. Soper says L. A. Aspinwall has 3,000 pounds in plain sections worth seeing, "square as a piece of plank, and no holes in corners at all." Niver's sharp eyes are pretty reliable.

Plain and Old-Style Sections.—Over the title, "An Object-Lesson in Comb-Building," the Review gives a delightful full-page half-tone picture of four plain sections beautifully filled with four old-style sections placed over them, decidedly to the disadvantage of the latter. The old-style sections lack very much of being filled out as well as the others. The editor says "it is a fair representation of such honey that I have seen produced in the two classes of sections." It would be much more to the point if he could have said, "These sections were produced by the same bees at the same time in the same super."

Profits of Bee-Keeping.—The editor of *Gleanings* has been trying to get Dr. Miller to tell what his 1897 crop of 17,000 pounds of honey cost in labor. "After some thinking, estimating and guessing," the Doctor makes out about

293 days at 10 hours each as the amount of time occupied with the bees for the year, supposing that one person had done everything. As a matter of fact, the work was mainly done by two persons, making the time for each less than half the working days of the year. Three-fourths of the work came between May 1 and Oct. 1. Then the editor makes an estimate after deducting expenses for supplies, interest, etc., and counts that if the Doctor got 10 cents for his honey it would leave \$5.00 per day for the labor. But fairness obliges him to admit that such results are not attainable every year.

A New Theory.—Herr Ludwig has evolved a theory that is considered of sufficient importance to allow A. Bohnenstengel to occupy more than four pages of *Imker aus Boehmen* in refuting it. Instead of a worker or a queen proceeding from the same germ, according to the food given, the theory is that every fertilized egg contains two different germs, one capable of producing a queen, the other a worker. Under ordinary circumstances the worker is developed, and under extraordinary circumstances the queen, and a nurse-bee has three different glands by which it can at will give food that will awaken the latent drone, worker or queen germ. The theory will hardly gain general credence.

"Hybrid Bees are not, as a rule, so pleasant to handle as are the pure Italians," says Editor Hutchinson in the Review. "Mr. Whitcomb, of Nebraska, explains this on the ground that it takes longer to subdue the hybrids. We can give the Italians a few whiffs of smoke and then go right to work handling them. Not so the hybrids. First give them some smoke and then busy yourself with something else for a few minutes; then give them some more and wait a little before opening the hive. The point is that it takes longer to subdue them, but once they are subdued Mr. Whitcomb says they are as easily handled as the pure Italians."

Preventing After-Swarms.—The favorite way with many is to set the swarm in the place of the old colony, putting the old colony at the time, or a week later, in a new place, thus weakening the old colony so it will give up swarming. But L. Stachelhausen objects to this plan in Texas, as he wants the mother colony to remain strong enough to yield a surplus. Cutting out cells immediately after swarming will not do, as the bees may start new ones. So he gives a virgin queen to the old colony as soon as it casts a swarm, lifting a corner of the enamel cloth and letting the queen run down with as little disturbance as possible, and in nine cases out of ten the young queen is accepted—Southland Queen.

NO. 3—DEACON JOHNSING—"Lawd! Lawd! Dat roost mus' be on fish!"

Spelling Reform Again.—In the *Chicago Post* of recent date we find the following:

"The editor of a leading London daily newspaper has received a number of urgent protests against his recent adoption of the American omission of the 'u' in words labor, and the cutting off of the final 'me' in programme. The protests argue that the best American writers and publishers themselves are showing a desire to abandon this, as they think it a butchery of the English tongue."

We wonder if some of our conservative friends who object to spelling "stopt" instead of "stopped" are willing to join the backward reform to write "labour," "honour," etc. Then if that is done, they can hardly stop logically of going back to earlier forms still, giving a language that people now living couldn't read at all. Fact is, some good people can't stand any reform, however good, if it's different from what they were brot up to.

GENERAL ITEMS

Good Honey Crop.

My crop of honey was extra large, the best I have had in years, and the quality was fair. We had no basswood flow.
Oakland Co., Mich. HOMER SCOTT.

Wintering Nicely.

I have 39 colonies of bees which seem to be wintering nicely in the cellar. I am a farmer, but have no trouble selling my honey at home at 10 cents per pound.
Trempeleau Co., Wis. L. STABOSKI.

Report for 1897.

I could not get along without the American Bee Journal. My 1897 report is as follows: From 52 colonies I secured very nearly a ton of honey, and I have sold about half already at a good figure.
HENRY K. GRESH.
Elk Co., Pa., Dec. 11.

Results of the Past Season.

I had 5 colonies, spring count, increase to 8, and got 480 pounds of comb honey. I believe I have gotten more experience in one year from the American Bee Journal than I could have gotten without it in 10 years. I don't see how anybody can keep bees without it.
J. W. HENRY.
Warren Co., Pa., Jan. 8.

Good Year with the Bees.

I have had the American Bee Journal four months, and now feel that I could not do without it.
I have had a very good year with the bees, securing about 450 pounds of honey (both comb and extracted) from six colonies, and increase to 11.
GEORGE DALES, JR.
Summit Co., Ohio, Jan. 10.

Results of the Past Season.

I started in the spring of 1897 with 15 colonies, worked on the Doolittle plan. I had 5 swarms, caught and bought 10, and went into winter quarters with 30 colonies, all in good condition. I got about 740 pounds of honey, all in one-pound sections. Now I might have gotten the 40 pounds alone, but I think the 700 due to the help of the American Bee Journal.
SAMUEL RICKEL.
Fulton Co., Ind.

A Reasonably Good Year.

I keep all the copies of the Bee Journal, and they are of more value to me than many times its cost.
I had a reasonably good year in 1897 with the bees. I had 11 colonies, spring count, secured 500 pounds of comb honey, and increase to 25 colonies. I would have done better but we had a terrible hail storm June 19, which cut the white clover all down, and it took about two weeks for it to bloom again.
S. H. STOFFER.
Blair Co., Pa.

Wintering and Other Experiences.

It was a clear, sunshiny day here yesterday, and I found a number of drones on the snow in front of one of my colonies, and the bees show signs of dysentery badly. All others are all right. I had a swarm issue October, 1897, that had only bees enough to cover one frame. I put them into the cellar. There is a steam furnace 10 feet from the hive. I look into the hive last night, and the bees cover three frames now. The thermometer stands at 50 degrees steadily; in a warm day it goes up to

This Very Remarkable Social Story,

The thought of which is the application to all life of the test question, "What would Jesus do?" has had an extraordinary sale, even during the "dull times" of summer. In the guise of a dramatic story, the book makes a powerful appeal to the public conscience in the lines in which interest is now so deeply aroused, namely, the social conditions affecting the relations of employer and employe, rich and poor, the Christian and the world, the saloon and the voter, etc. The author believes his test—"What would Jesus do?"—to be nothing less than revolutionary, and applies it with searching directness, not only to commercial and social, but also to religious life. The deep interest which the story has awakened is indicated by the thousands that have been sold, and the many voluntary testimonials, among them being the following:

"The reading of the book will search many a heart, and ought to lead to a simpler, holier, and more fully consecrated Christian life."—Sunday-School Times.
"Singularity impressive.... It is a sermon in action, and one that cannot fail to touch the heart."—New York Christian Advocate.
"Mr. Sheldon's book makes a strong impression as a plea for more simplicity of living, for more economy and more principle in the matter of personal expenditure, and for the application of the laws of righteousness and justice to the methods of business administration."—New York Independent.

Size 5x7 1/4—nearly 300 pages.

Price, in paper cover, 25 cts., postpaid; bound in cloth, 75 cts. Or, we will mail a copy of the paper-covered edition for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00, or for sending us two NEW subscribers we will mail you a copy of the cloth-bound edition. We will send the paper-covered book and the Bee Journal one year—both together for \$1.10; or the cloth-bound book and the Bee Journal one year—both for \$1.50. Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ills.

THE HATCHING HEN

HAS LOST HER OCCUPATION and in the production and brooding of chicks she has been supplanted by the better and every way RELIABLE INCUBATORS AND BROODERS. They Hatch and Brood when you are ready. They don't get lousy. They grow the strongest chicks and the most of them. It takes a 224 page book to tell about these machines and our Mammoth Reliable Poultry Farms. Sent by mail on receipt of 10 cents. Send for it now. Reliable Incubator and Brooder Co., Quincy, Illinois. 37D17t Please mention the American Bee Journal.

\$300. for Six Potatoes!

We shall introduce this year for the first time the wonderful new MORTGAGE LIFTER POTATO and shall pay the above sum in prizes for the best six potatoes grown from one seed potato. THE EARLIEST POTATO IN THE WORLD. Tested 4 years. It is white, of excellent quality and A MAMMOTH YIELDER. Be the first in your neighborhood to try it; next year you can sell it to others. Price this year, 50 cents for single potato. First in the Market Cabbage is the earliest to head; beat your neighbors by weeks. Sure Head Cabbage, all head and sure to head large size, good quality and good keeper. Single heads have weighed up to 60 lbs. Climbing Cucumber, entirely new—a perfect wonder. Climbs any trellis or support 6 to 8 feet high; prolific yearly fruiter. Six Week's Turnip; earliest grower, easy grown, good size and white as snow. EARLIEST TOMATO IN THE WORLD—greatest success for earliness, smoothness and quality. Has fruited in 50 days. Big Prizes Awarded for ripe tomatoes grown in least number of days. Instructions with seed. One whole potato by mail (packed from frost) instructions for prizes and a packet each of the five early vegetables and catalog of "SEEDS THAT GROW" for 25c. Fairview Seed Farm, Box 88 Rose Hill, N.Y.

WHERE OTHERS FAIL

the SUCCESSFUL INCUBATORS succeed, why? because they are properly constructed and the correct methods for operating them are plainly set forth in our 72 page Direction Book. Our machines will please you. Prices reasonable. All sold under a positive guarantee which we ask you to compare with others. Send 6c stamps for 128 page catalog and poultry book combined. It will pay you. Address DES MOINES INCUBATOR CO., Box 78, Des Moines, Iowa.

ENNOR'S POULTRY POWDER

Andrew Keiser, Kieler, Wis. says:—"I have used Ennor's Poultry Powder for the past 4 years. Can recommend it for curing Chicken Cholera. It keeps the chickens healthy, and it is the greatest egg-producer in use." By mail, 65 cts. Agents wanted. Address, W. P. Ennor, E. Dubuque, Ill. Please mention Bee Journal when writing.

FIRST PRIZE WINNERS

Our 1898 Mammoth Poultry Guide of 100 pages mailed FREE. Something entirely new, tells all about poultry, how to be a winner, how to MAKE BIG MONEY. Contains beautiful lithograph plate of fowls in their natural colors. Send 15 cts. for JOHN BAUSCHER, Jr. postage. Box 91 FREEPORT, ILL. 44A26t Please mention the Bee Journal.

Bee-keeper's Guide—see page 92.

60 degrees, then I open the windows on two sides of the cellar. The bees hum like boiling water. Before putting into the cellar I tacked wire screen on the bottom of the hive, and two-inch pieces under the hives on the sides and back, on top of the bottom-boards. I put the front side next to the wall, because the cellar is light. I put an empty super on top, and a loose cover on that. The hive sets on a frame 16 inches from the ground, with six frames nearly full of honey, and two empty combs. I hope they will come out all right.

Last season I kept a queen-cage on one hive to keep the bees from swarming, and got 108 pounds of comb honey from that colony. I got 90 pounds from two others that did swarm. I have 20 colonies now. In September I took two colonies from be-trees. I could find no queen, so I gave them full frames of foundation, and they went into winter quarters all right.

C. G. ASCHA.
Berkshire Co., Mass., Jan. 9.

Experience with Bees.

In the fall of 1894 I started with one colony, which I had to feed in 1895 to keep it and two others from starving, and they came out all right in the spring of 1896. I got about 175 pounds of honey, and increased to 11. They wintered all right, and came out in good condition last spring. The past season was pretty good. I secured something like 500 pounds of honey, and increased to 20 colonies, which I have now in winter quarters in fair condition.

C. H. VOIGT.
Manitowoc Co., Wis., Dec. 28.

Not Very Enthusiastic.

I am not very enthusiastic. I have over 100 colonies of bees, and my honey costs me 50 cents per pound. The bees did well for about three weeks, filled up the brood-chamber and some surplus, then the drouth came on, and they stopt breeding, and gained no weight afterward. The bees that went into winter quarters were old ones that work in the field the forepart of the season.

I am almost an octogenarian, and hardly feel able to take care of so many bees, but people here don't want to buy bees—they prefer that I take care of them and let them have the honey for 5 or 10 cents per pound.

Franklin Co., Iowa.

A Little Discouraged.

The honey crop was so light and price of honey so low that some of our numbers have become discouraged, and will quit the business. I have been in the business 30 years, and have a good location, but the past was the poorest season I ever knew, in all respects. I have known seasons when there was less honey gathered, but I never saw such poor quality. Whether the bees will winter on the honey remains to be seen, and makes but little difference—it will be the easiest way to get rid of them. To sell them would be almost impossible. I feel a little discouraged. But send on the Bee Journal all the same.

H. Root.
Onondaga Co., N. Y., Dec. 18.

Large-Entrance Advice Criticised.

The big heads of the fraternity are recommending large entrances to hives; according to them, $\frac{3}{4}$ inch or 1 inch, back and front of the hive, is none too large. It seems to me that such advice is misleading, and may cause serious losses to beginners. That the entrance should be very large during winter in the cellar-wintering, and during the big honey-flow (that is, from June 15 to Aug. 15, or thereabout, in my locality—Montreal), that sounds all right. But I should think that in the spring and fall the entrance should be regulated in such a way as not to entice robber-bees.

But, you will say, What about ventilation? Well, I think that both ample ven-

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

THE PROGRESSIVE BEE-KEEPER

Is a 28-page monthly bee-journal published at Higginville, Mo.—price 50 cts. a year. With the year of 1898, we begin the eighth volume, hence it is past the experimental stage. **R. B. Leahy** and **G. M. Doolittle**, editors. Some of the features of 1898 will be a continuation of "Wayside Fragments," by **Sonnambulist**. "Experience and Its Lessons," by **R. C. Aikin**. This series of articles will be reviewed by Mr. Doolittle, which is practically giving his experience with its lessons. "Experience and Its Lessons," as reviewed, will be a gold-mine for beginners and advantageous to those more advanced in bee-culture. The sonnambulist articles are written in a pleasing style, as none but "Sommy" could write them. They are highly entertaining and instructive. **Dr. C. C. Miller** and other popular writers also contribute to its columns. The PROGRESSIVE is a popular journal at a popular price. Printed in the highest art, on beautiful paper. Fearless in its character, newsy in its contents, and artistic in its make-up. Remember the PROGRESSIVE BEE-KEEPER is but 50c. a year. The PROGRESSIVE and that "one only" book for beginners, the **Amateur Bee-keeper**, by **Prof. J. W. Rouse**, both for 65c. A sample copy of the PROGRESSIVE for your name, and a beautiful, illustrated catalog of apian supplies for the asking. Address,

LEAHY MFG. CO., Higginville, Mo.

tilation and proper entrance may be combined, viz.: by using wire-cloth or perforated zinc applied to the entrance.

I would say, give all the time ample ventilation, but regulate the entrance according to the time of the year, or strength of the colony.

Now you may, if you please, criticise my criticism. H. DUPRET.
Province of Quebec, Canada.

Bees in Good Condition.

Bees went into winter in good condition in our part of Indiana, altho bees are scarce. Nearly all dying last winter.

Noble Co., Ind., Jan. 24. S. Black.

Good Year with the Bees.

The past was a good year with me. I averaged 100 pounds of comb honey to the colony, spring count, and increase to 11 colonies.

Hancock Co., Ind., Jan. 13. J. C. SMALL.

Bees Were in Good Condition.

Our bees were put into the cellar Nov. 22, in good condition. The hives were well filled with good, well-ripened honey, and as they went in with a good force of young bees, I expect them to winter well. The weather is mild.

F. A. SNELL.
Carroll Co., Ill., Jan. 18.

Bees Did Well Last Year.

My bees did very well last year, as I started with 18 colonies and increased to 22, extracted about 2,200 pounds of honey, and got 300 pounds of comb honey from three colonies. I winter my bees in cases packed with straw.

Erie Co., N. Y. M. M. RICKARD.

Poor Year for Honey.

Last year was very poor for honey in this part of the State, altho last spring there was big promise for white clover—I never saw it thicker. Basswood was a complete failure, also willow-herb, but the bees filled their brood-chambers and gave a few finished sections of honey from golden-rod.

What has become of E. J. Cronkleton with his bee-escape?

By the way, I have invented something, too, in the shape of a bee-hunting box, that works like a charm. I may tell about it sometime.

GEO. W. BLAIR.
Mason Co., Mich.

[We do not know what Mr. Cronkleton did with his invention. Perhaps he will tell us.—EDITOR.]

Prospect for an Early Crop.

The "Old Reliable" arrives weekly on Monday evening, and every number brings something new and interesting to a beginner. I am so much pleased with it; could not keep bees without it now.

Bees did not do very well last season, but they are wintering well so far, and the prospects are good for an early spring, which means a good flow of nectar. Long life to the editor of the Bee Journal!

J. T. HEWETT.
Whatcom Co., Wash., Jan. 22.

Supporting the Unions.

I am one of the old members of the National Bee-keepers' Union, and as such I still stick to it. The old Union has done a great deal of good for the bee-keepers, and I am frank to say that I am somewhat partial in its favor, and see no reason why its name should be changed.

It is my opinion that a division of our forces could have, and ought to have, been avoided. In unity there is strength; divided we can do but little.

A true and faithful servant should under all circumstances receive considerate treat-

Large New Maps of KLONDIKE—ALASKA—CUBA FREE

To all who order the People's Atlas of us now we will send free maps of Cuba and Alaska, newly engraved from the latest governmental surveys and official information. Size of each map, 14 by 22 inches. The Alaska map accurately locates the Klondike country and other great gold-fields in that far-off land, and the routes by which they are reached. A brief history of each country accompanies the maps. See our offer below:

OVER 200 MAPS AND ILLUSTRATIONS

THE PEOPLE'S ATLAS contains over 200 large Maps and Illustrations, and 132 Pages, each page 11 by 14 inches. It gives the Population of each State and Territory, of All Counties of the United States, of American Cities, by Last U. S. Census.

HANDSOME MAPS.—The handsome Maps of all the States and Territories in the Union are large, full page, with a number of double-page maps to represent the most important States of our own country. All Countries on the Face of the Earth are shown. Rivers and Lakes, the Large Cities of the World, the Railroads, Towns and Villages of the United States are accurately located.

SPLENDID PICTURES embellish nearly every page of the reading matter, and faithfully depict scenes in almost every part of the world. It contains a vast amount of historical, physical, educational, political and statistical matters, comprising a General Description of the World.

EACH STATE.—This Atlas gives about each State the Population for the Past 50 Years, History, Miles of Railroad, Soil, Climate, Productions, Industries, Educational and Religious Interests, Interest Laws, Etc., Etc.

THE UNITED STATES.—This Atlas gives the Popular and Electoral Votes for President in the years 1892 and 1896, by States. List of All the Presidents, Agricultural Productions, Mineral Products, Homestead Laws and Civil Service Rules, Statistics of Immigration, Public Debt for the Past 100 Years, Gold and Silver Statistics, Postal Information, and Other Information that should be in every Home, Store, Office and School-room.

Miniature Cut of Atlas. Actual Size, 11 by 14 inches.

OUR BARGAIN PREMIUM OFFER

We will mail this great Atlas for only 50 cts.; or for \$1.40 we will send it with the BEE JOURNAL for one year; or we will mail the Atlas FREE as a premium for sending us **one new subscriber** (at \$1.00) to the BEE JOURNAL for 1 year.

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

A sample of the honey will be mailed to an intending purchaser, for 5 cents, to cover postage, packing, etc. We guarantee purity.

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the

Best Goods at the Lowest Prices.

We want

EVERY BEE-KEEPER

.....To have a copy of.....

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy.

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

ment. I cannot help but feel kindly towards Mr. Thomas G. Newman. At the same time, the common good requires that both Unions should combine and become "one." I may, or I may never, require the help or support of either of the Unions, but I will do my share in helping matters along as best I can.

WM. STOLLEY.

Hall Co., Nebr.

Bees Snowed Under.

One-fourth of my bees are completely covered with snow drifts; the other ¾ are snowed under about two feet. They are all packed in sawdust, and will not feel the snow. I shall let them remain as they are till the snow settles some, if soon, and then shovel some of them out, and see how they stand it.

T. F. BINGHAM.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Feb. 11.—Fancy white is plentiful, and sells at 11c.; good No. 1, or grade of that character is abundant, and sells at 7 to 9c.; amber and dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

Much of the comb honey is candying this season, especially if any sweet clover is in it.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply, and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Milwaukee, Wis., Jan. 24.—Fancy white 1-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

St. Louis, Mo., Feb. 9.—Fancy hite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a thin supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3½c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Kansas City, Mo., Feb. 9.—Fancy white comb, 1-lbs., 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5 to 5½c.; amber, 4 to 4½c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

Cincinnati, Ohio, Feb. 8.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 to 4c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

San Francisco, Calif., Feb. 2.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 5c.; light amber, 3½ to 4c.; dark, 1½ to 2½c. Beeswax, fair to choice, 22 to 24c.

Buffalo, N. Y., Feb. 11.—Strictly fancy 1-pound combs are in quite good demand from the fact that it has been so scarce and closely cleaned up, and 11c is quite easily obtained. Other grades do not sell much better, possibly a little, ranging from 9 to 6c., as to grade, etc. Extracted ranges from 4 to 6c., and is in light demand. We can recommend shipping strictly fancy and nothing else, unless you cannot do better.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c.; light amber, 5c.; white clover and basswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Minneapolis, Minn., Jan. 31.—Market is in an overland condition on comb honey. Good chance for fancy white extracted at 5½ to 6c., but comb is at a standstill, particularly

if other than fancy white. Best price available on fancy white combs 10½c., and buyers are slow at that. Darker grades or broken lots are unsalable. If shippers would send in their extracted when it is wanted, and not push undesired comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

Golden's Super for Plain Sections and Fence. — (See page 115.)

CONTRIBUTED ARTICLES

The New No-Bee-Way Section and Double-Cleated Slat Separator or Fence.

These two articles seem to be making quite a stir among some of our cotemporaries; and as there seems to be some inquiry in regard to them among the readers of the American Bee Journal, perhaps a brief description and discussion of them may not come amiss.

Fifteen years ago sections having top and bottom of equal width with the sides were manufactured and sold by Mr. G. B. Lewis, of the G. B. Lewis Co. Just how these sections were

used at that time by bee-keepers who bought them is not definitely known; but in all probability they were spaced apart without separators. This would cause the combs to be bulged unevenly, and, as a result, such combs would be uncratable.

A few years later Oliver Foster, then of Iowa, conceived the idea of making double-cleated slat separators. With these separators he used plain sections—that is, those having top and bottom equal in width to the sides. A row of sections was set on a flat board, and up against them was placed a cleated separator; then another row and another separator, and so on. These were firmly clamped together and put on the hive. On the under side of the cleats was fastened a little strip of tin that projected out far enough to catch the corners of the sections. This was in 1888. The illustration herewith

The B. Taylor Slotted Separator.

given will show the separator as he used it, and is very like those now manufactured and styled "fences," the last name being used, we suppose, because it was short and descriptive.

But for some reason or other these did not attract a great deal of attention at the time, altho we are informed that several bee-keepers throughout the United States began using them, and have been using them ever since. But no one seems to have said very much about them till along in 1895, when the late B. Taylor wrote up and described his double-cleated separators and 4x5 no-bee-way section. At that time he claimed he had been using them some four years; that they gave him perfect sections weighing a scant pound; that "the honey on both sides of the sections comes within $\frac{1}{2}$ inch of the section, and is never broken in moving the separator, and the surfaces are $\frac{1}{4}$ inch apart in crating. In crating sections filled between common flat separators, the surfaces of the combs are $\frac{1}{2}$ inch apart, and requires a larger crate for the same number of pounds." Mr. Taylor further claimed that he not only secured better-filled sections, but that their appearance was very much better.

Altho it appears that Mr. Taylor called Mr. Root's attention to this style of separator and section, the latter did not at the time enthuse very much over it.

Later on Mr. Danzenbaker began to talk of the merits of the plain section; and altho he tried to get the Root people to see their advantages when used in connection with cleated separators, they could not be made to "see." How blind some people can be when they want to be, and how wide awake they can be when they want to see. How is this, Mr. Root?

During the greater part of this time there were others who were using sections without insets or openings; but for some reason they said little or nothing about it in print; but it now turns out that Mr. L. A. Aspinwall, of Michigan, had

been using plain sections in connection with the double-cleated tin separator for a number of years with a great deal of satisfaction. Aspinwall separators differ materially in construction from the "fences" that are now being talked about. In each tin separator there were transverse slots stamped out of the metal, and coming directly opposite the uprights of the sections. Just above and below these slots are fastened short cleats that space and hold the separator a scant bee-space between the sections.

Mr. Aspinwall secures, in effect, sections open all around; and Mr. W. D. Soper writes of Mr. Aspinwall's honey that it was the finest he ever saw. The combs were filled clear out to the wood, and there were no peep-holes or openings in the corners of the sections. Mr. Aspinwall, however, says this statement is a little overdrawn, and that while the openings are small and scarce, there are occasionally some to be found.

Along in October last, Mr. Root, of Gleanings, suddenly became very much awake over plain sections and fences. When he saw them in use at the home and apiary of Mr. Miles Morton, of New York State, he says he did not entirely get hold of their advantages; but later, when he came home and saw Mr. Danzenbaker's beautiful honey, his enthusiasm for this kind of section and fences quite ran away with him. Mr. Root, you know, is a hobby-rider, and sometimes his hobby runs away with him. Whether the section-fence hobby will run away with him now remains to be seen. Among other things he claims as advantages for the plain sections and fence the following:

1. These fences are made entirely of scrap, and, consequently, will cost but little more than the old-style separator, which, after being used a year or so, had to be discarded.
2. Prettier and better filled comb honey can be secured with a fence, for the reason that the bees can crawl all through the slats, affording them easy and direct passage-ways from one honey-box to another. One great objection to the old-style super with its separators is that it shut off each section-box into a compartment or room by itself; and, as every one knows, it was much harder to get bees to enter comb-honey supers than supers of the extracting sort.

The Tall and the Square Section.

3. The peculiar construction of the fence will, we believe, largely do away with the passage-holes in the corners of the ordinary section honey-boxes.

4. The fact that the fence is made up of several different slats, bound by transverse strips on each side, and grooved cleats on each end, has a tendency to very materially stiffen and strengthen the section-holder. In case of the old-style super, the bottom-bar of the section-holder would sometimes sag; but the new fence is so much stiffer than the separator that we believe it will do away largely with the sagging of the bottom-bars.

5. The new section, when filled with honey, will bring a higher price, because they appear to be, and, in fact, are better filled out, and the surfaces of the combs themselves are more even—at least this seems to be the experience of those who have used such sections with a cleated separator or fence.

6. Facility in scraping these sections with their plain straight edges is quite an important feature. It is not an easy matter to clean out the insets of the ordinary old-style sections, and practically impossible to remove the stain. A case-knife or a piece of steel having sharp square edges will, with one sweep, clean almost the whole four edges of the new section at once.

7. The new section and fence greatly simplify the construction of the section-holder. The bottom instead of being scored out to correspond with the openings in the bottoms of the sections, is one straight piece, and of the same width as the section itself. The end-bars are also of equal width with the bottom-bar.

8. The new section is only $1\frac{1}{2}$ inches wide, and yet will hold

as much honey as the old $1\frac{1}{4}$ section with its openings when used with plain separators; and consequently the ordinary shipping-case will hold from 15 to 25 per cent. more honey, thus effecting a substantial saving in cases to the bee-keeper.

The fence and section that the Root people have fixt on are shown in the accompanying illustrations. The slats are $\frac{1}{2}$ -inch wide, and spaced $2\frac{1}{12}$ of an inch apart. The cleats are $\frac{1}{2}$ -inch wide by $2\frac{1}{12}$ thick. But some have asked, "Why $2\frac{1}{12}$?" Mr. Root says that is because, when the space is wider, say $\frac{1}{4}$ or $5\frac{1}{16}$, the bees are liable to ridge

The Fence or Cleated Separator.

the honey opposite the openings. If these spaces are confined to the width of the perforated zinc, which are, in round numbers, $2\frac{1}{12}$ inch, he claims there will be no ridges.

If plain sections ever come into general use, it will greatly simplify the present method of cleaning propolis off the sections, because there are no insets or openings in the sections to clean; and as these openings cannot be cut quite so smooth as the rest of the section, they are apt to be covered more with propolis and stain than other parts of the section. Mr. Aspinwall makes use of a wooden cylinder covered with sand-paper. While this is revolving at a high rate of speed the edges of the sections are drawn across it, cleaning the wood at one sweep, and this makes it look as fresh, so Mr. Aspinwall says, and as nice as when it originally came from the factory. Mr. Golden, whose section-cleaner was illustrated on page 33, in-

Dovetailed Super with Plain Section and Fence.

stead of using a sanded cylinder, makes use of a belt made of sand-paper. The section is laid against the face of this rapidly-traveling belt, and, presto! the whole face of the section is cleaned in the twinkling of an eye.

We understand that the Root people are figuring on a smaller and cheaper machine for sand-papering the surfaces of the sections after they are filled with honey, that can be used by the mass of bee-keepers.

GOLDEN'S PLAIN SECTION SUPER AND FENCE.

In Gleanings for Feb. 1, Mr. J. A. Golden gives full directions for making the fence or slat separator, which we reproduce, with the illustration on the first page, which Gleanings has kindly loaned to us. Here is what Mr. Golden says:

"I send a photo of my arrangement of super for the no-bee-space section, and how I manage to change my leveled-down-comb bee-space sections to the no-bee-space; also how I arrange the section-holder for the no-bee-space section with slatted separator.

"I want to say to all who want to try the no-bee-space sections and slatted separator that they will find this arrangement far the handiest and most accurate of any plan—at least that I can suggest.

"First, I make a mold to make the slatted separator in—see No. 1 in cut; it is made by tacking on a smooth true board some ribs lengthwise just where you want spaces between the slats and the width of the opening. Transversely in the board, grooves should be cut to receive the cross-cleats. The cut will show (of course, make this pattern accurate and true). Cut the old or new separator strips straight the width you desire, and the exact length of inside section-holder. Having the

little cleats cut, and one chooses to tack them together, drop a cleat into each groove, then lay the slats in their proper spaces, placing another set of cleats on top over the under cleats; drive three tacks through each set of cleats, and lift separator out; clinch the small points, and your separator is complete.

"But if one prefers to glue them, it is but a child's play. Having cleats and slats and a pot of hot glue, swipe one side of the little cleats, and put them in the transverse grooves, glue side up, then lay the slats on the glued cleats, and on the slats over the cleats lay another set of cleats, and over all a smooth board, and press one or two minutes; take out the fence and stack up, and keep weighted down for a few hours. It takes Flody just two minutes to glue a one-fence separator.

"Number 2 is the section-holder. It is made solid by nailing the section-slats to two end-boards, just so that four sections will fit between neatly; then nail on one side a cleated board to correspond with cleated separator, and one loose cleated side-board, No. 4, completes the section-holder. The cut shows Flody filling a holder.

"Number 3 shows one of my bee-way supers, filled with the no-bee-space sections; and holder No. 5, showing how they are held in place. No. 4, a loose side-board, is slipt in, and wedges pushed down between the holder and side, and the body of the super holds them permanent, and clamps sections bee-glue tight.

"Number 6 shows three sections of honey with the projecting edges clipped off by a circular saw."

Answer to Questions on the "Golden" Method of Comb Honey Production.

BY J. A. GOLDEN.

On page 66, Mr. McNeal has given us quite an interesting article, and I am very glad to read his comments, yet it is a fact that bee-keepers are more given to theorizing upon the subject of apiculture, so it seems to me, than on any other industry. Theories not practiced figure nothing in apiculture.

But to answer Mr. McNeal's questions and intimations as to my method, I will say:

First, how do I keep pollen out of the supers during the five days? By placing the parent colony over the supers in which the queen and swarm have been hived on starters or full sheets of comb foundation (*not drawn comb*), and providing side-entrances so that when the field-bees come in loaded with pollen they go directly to the brood-combs and deposit their pollen.

Now, I don't know whether they (bees of the swarm), during the five days, return after depositing pollen and deposit their little mite of nectar below or not, but I do know that I have never seen, to the best of my knowledge, one cell of pollen in section honey produced by this method, and I have letters from quite a number of bee-keepers during the past season who claim the same success.

Now, I don't think it ought to be much of a wrinkle if one will properly test as recommended. That's the way I usually do with any manipulation that comes up, and in so doing many theoretical ideas I had trumped up wither away. So I hope Mr. McNeal will fulfill his promises the coming season.

There is much in Mr. McNeal's article I would like to notice, but it would require too much space in this article. I will just say, however, that I use both 8 and 10 frame hives, and I think if he could see them during the season he would think they ought to be able to pile up the nectar.

Before closing, I want to say amen to C. B. Elliott's closing paragraphs on page 68. *It is a fact.* Who will be the next? Let's have them all. Continue that practice, Mr. Elliott, and I don't believe your bees will ever have paralysis or foul brood.

Morgan Co., Ohio.

Questions on Extracted Honey Production.

BY C. P. DADANT.

I have received the following questions with the request that I reply to them in the American Bee Journal:

MR. C. P. DADANT:—In running for extracted honey do you use the narrow frames altogether? and do you use full sheets of foundation in such frames as you do use?

Do you extract during the honey-flow, or leave all out until the end of the season?

How do you care for the empty combs during the winter? and how are they cleaned after extracting?

Any additional information along these lines which you may be able to give will be highly appreciated. CHUCKLEHEAD.

In running for extracted honey, which has been our specialty for some 25 years, we use what is called a half-story frame, but the name is somewhat misleading, for these frames are more than an exact half story in depth. The end-bar is just six inches long, making the frame in the clear about 6½ deep. The length of these frames is the same as of the frames below. With a deeper frame than this, which we tried on about a hundred hives, some ten years ago, and which we kept in use for a few years, we find that if the hive is not very populous, and the weather cool, it gives the bees too much room at one time, and, on the other hand, if the weather is warm and the crop not very heavy, the queen is more apt to go up into a deep frame to lay, especially as there is often more room than needed for the honey at one time. We therefore prefer a shallow frame and, if needed, we put on two supers or more on one hive.

The shallow super, just half the depth of the Langstroth frame, which is used by many is, in our opinion, too much to the other extreme. Its size is so small that with our large hives we would have to use several supers on the majority of the hives, and it increases the labor by giving too many frames to handle. The only advantage that we can see in this 4½ super is its permitting the producing of either comb or extracted honey with the same outer shell. But the outlay of money on supers and hives nowadays is so insignificant when the results are taken into consideration that we would never advise any one to stint on this point. As well might a farmer buy a cradle instead of a harvester, as one of our bee-men buy an implement of inferior grade. The farmer who understands his business not only buys a harvester instead of a cradle, but he buys the best, even if it costs more, for he knows that time is money. With us, time and honey are both money. An extra super, with the frames, costs but a few cents, and if not in use may be put away with the combs in it. There need be no danger from the moth, even if the super and the combs are kept through the summer, provided they have been put away in a cold room (the honey-house is usually cold), and the room carefully guarded against the introduction of any suspected combs during the summer.

Here let me stray from my subject only long enough to recommend the use of a sun wax-extractor. When you have "chips" or broken combs during the summer, instead of putting them away in the honey-house waiting for enough to be gathered to melt up into beeswax, and thereby running the risk of introducing into that house moth-eggs or larvae, it is a much safer and more agreeable method to put them right into the sun extractor, where, at the first warm rays of the sun, these combs are rendered into very good beeswax, and the parasites they may contain are killed.

Do we use the narrow frame altogether? Yes, by all means. We have no earthly use for either the Hoffman close-fitting frame or the Heddon frame. They may be good, and perhaps if we were used to them we would like them, but what little experience we have had with them does not recommend them, in our mind. We want the narrow, free-fitting frame both in hives and extracting-supers, and the name of "rattle-box" that has been given to these hives by some noted bee-keepers has no more effect on our opinion than the epithet of "useless toy" that was hurled at the honey-extractor by a so-called experienced European bee-keeper, when this useful machine was first invented.

If we expected to travel over the country with our bees, taking the hives along like so many trunks, we might like the close-fitting frames, as they would stand the racket best, but when we set a hive down in one spot we expect to leave it there, and when the frames are once placed in proper order, there is no fear of their "rattling about" before the bees glue them fast. When the extracting-combs are well built, we like to space them a little farther apart than the brood-combs, and in a super that is originally made for 11 frames, we usually put only 10, and if the combs get very thick, sometimes only 9.

We do not extract during the honey-flow, unless we have absolutely no room left, and there is a prospect of a continuation of the crop. To be sure, it is much pleasanter to take out the honey while there is still nectar in the field, as we are not annoyed by robber bees, but with a little care robbing is avoided, and the honey extracted after the crop is usually best. Yet, we find very little objection to extracting the fall crop from knot-weed and Spanish-needle as fast as harvested, for this honey is usually pretty ripe when brought in by the bees. For some reason there is much less danger of fermentation in the fall honey than in any other, unless apple or grape juice has been added to it.

The combs are cleaned by the bees after extracting. We usually put the supers back on the hive in the evening just before sunset, so that the uproar caused by the daubed combs may subside without trouble.

We have already said in this article that we keep our supers in the honey-house when not in use. The only requirements in this cold climate to keep those combs safely for years are, to have them in well-closed boxes safe from the depredations of mice, and to let the temperature of the room fall, during the winter, to 10° Fahr., or less. We have never known such combs to be damaged by the moth, unless the latter was carelessly introduced in the room during the summer.

We use full sheets of worker-comb or foundation in our extracting supers. Our reason for doing this is to avoid the building of drone-comb in the frames, and the consequent occasional rearing of drones in the extracting-supers.

Wintering in a Barn—Packing Bees, Etc.

BY WM. H. EAERTY.

I see that some are asking about wintering bees in a barn. I have thus wintered them, and tho they used up considerable honey they wintered very well. I placed the hives so that they were along the south wall of the building, and about six inches from the wall, with the hives about six inches apart. The space between the hives and the wall was packed with chaff and straw. I made a box for the hives to stand on, by taking 2x4's and nailing boards to both edges and also to the ends. The box made a dead-air space under the hives. I had the front of the hives face into the barn instead of outward, and the winter being cold I had no trouble from the bees in the way of coming out of the hives.

PACKING BEES PROPERLY FOR WINTER.

I see that a bee-keeper in Cedar county, Iowa, has fixt up his bees for winter by packing the super with straw, and also packing in straw between the hives, then putting on a cover of leaves and straw over the hives, and covering all with boards. It would be better to put the leaves in the super, and leave the straw for the outside packing. They should be oak leaves, as they are tough and leathery, and they should be gathered on a sunny afternoon, so that they might be both dry and warm when put into the super.

A very good covering for bee-hives on the summer stands is slough-hay or rye-straw tied in bundles and stood around the hives, all the bundles being tied together at the tops. This covering requires no lumber, the bundles standing straight enough to shed rain. If used in a windy country a little dirt can be thrown upon the butts of the bundles of hay or straw to hold them in place.

HOW BEES FLY TO AND FROM THE HIVES.

A late correspondent speaks of the flight of the honey-bee, and of the bee-line. My apiary is located on a gentle swell of land near a creek bottom, and just high enough to give me a good view of my bees as they come and go when at work during the busy season of the year. From what I have seen I am led to believe that the bee flies in a very straight line from one object to another, but those objects are not so far apart as some might be led to believe. I have seen the bees, when coming home with their loads, nearly all make for a tall apple-tree, and from there to the hives. Having found their line, I have gone along it to see how they operated further along the line, with the result as above stated.

My best chance to see the flight was when the bees were going from the hive to the fields to get their loads, and I saw that they moved a little sidewise with each stroke of the large wings, going first to one side than to the other, something as a skater moves when skating on the ice, going first with one foot than with the other, but keeping a true line in the main. A single bee seemed to fly as if in a tube with a diameter of about 1½ inches, moving not only sidewise but also up and down, to something like the same extent, and, like the skater, they seem to gather more force with each side movement.

I stay in the bee-yard about all the time from early spring until late in the fall, and I watch the insects quite closely. In this country changes of the weather are quite frequent and very sudden, and it is fun to watch the bees when they come home to escape a summer shower. The showers are driven before a strong wind, and they make the bees "hustle their boots" to reach the hive in time to escape a wetting.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 102.)

FIRST DAY—EVENING SESSION.

CLIPPING WINGS OF VIRGIN QUEENS.

"Is it advisable to clip the wings of virgin queens?"

Mr. Wheeler—I have had it tried on one virgin queen, and know of the wings of another being clipped; results not favorable.

Mr. Baldrige—Mr. Aspinwall, of Michigan, is in the habit of clipping the wings of virgin queens an eighth of an inch, or about a sixteenth, so they will not fly very far from home for the purpose of mating, and he has succeeded in getting them mated in a way that he would not have otherwise done.

Dr. Besse—I ask that question. I also recollect reading that Mr. Aspinwall recommended clipping. I should like to keep my queens pure. I should advise some of these young men to experiment in it. I believe in clipping old queen's wings to keep them from going very far when they swarm.

Pres. Miller—I do consider it as a thing we need to watch very closely. As has been said, an eighth of an inch has been reported as having been taken off; this was reported as an exceptional case, but it resulted favorably, and Mr. Aspinwall reports that the number of mismatched queens with the wings clipped is not more than one-third of those that were left unclipped, so that those who have pure stock of their own and want to refrain from mixing them with other stock, will probably find a very great advantage in practicing that very thing.

Mr. Baxter—That will do for those who produce comb honey, but not extracted, for there is no trouble, and you ought not to be bothered with any swarming at all.

Pres. Miller—That does not have any reference to swarming, because you will have to have your queens whether they swarm or not; your queens will be replaced perhaps once in three or four years anyhow. Of course, there will be some trouble, but you have to attend to it if you consider the matter of controlling fertilization of sufficient importance for you to take the trouble.

Mr. Baxter—Some one said that he clipped the old queen's wings to prevent her from flying very far when the bees swarmed.

Pres. Miller—That is another question altogether; this is with reference to clipping virgin queens.

Mr. Wheeler—Would that be practical with you when you were producing your honey? Could you practice anything of that kind.

Pres. Miller—I will answer that for myself, that it would be quite a little trouble for me, but if it made enough difference in the result I would do it, because every one of my queens I know about, and see the virgin queens before they are laying; there will be trouble, of course; the only question is, will it pay for the trouble?

IN-BREEDING FOR TEN GENERATIONS.

"Supposing a pure Italian queen is mated with a pure black drone, and in-breeding practiced for 10 generations, what will the stock be?"

Pres. Miller—Will it be Italian stock, or black stock, or what will it be?

Mr. Green—I suppose the one who asked the question referred to the belief that some hold and have advocated that such bees would incline toward yellow stock, and in time become yellow bees; but in my experience I should say not. I should think they would remain hybrids. They might be very dark yellow, possibly; they would be more even than the first cross.

Pres. Miller—The question is not as to the appearance of bees, but as to the amount of Italian blood in the stock.

Mr. Green—There should not be any change.

Dr. Besse—It would be impossible to have them mated

that way with the amount of Italian-blacks in the country now.

Pres. Miller—This is a fair question to ask. You know this, that in some cases crosses are considered valuable; there are some who think very highly of crosses, and some who want pure-blood Italian-blacks. Now the question is, What will your stock be? In that case, what proportion of Italian blood and black blood will you have?

Mr. Schaper—If the drone from the Italian queen fertilizes the next generation, I should think it would cause the third generation to be three-fourths Italian; of course, in breeding you should consider that the drone from the same colony would fertilize the young queen that would be reared from the parent colony. Would that not have a tendency to produce three-fourths blood?

Pres. Miller—It would.

Mr. Schaper—And would remain the same, three-fourths blood all the way through; the third year the drone progeny would not be Italian, it would be three-fourths, so would be the queen.

Mr. Green—It might work either way.

Mr. Kartch—It seems to me the first cross will produce half-breeds, of course, and if you follow up mating with black drones, you will have the queens blacker all the time, and by the time 10 years expire you will have a perfect black bee; you have very little Italian left at the end of 10 years.

Mr. Schaper—By having the first queen full-blood Italian, and mated with a black drone, the next year if the swarm issued and the young queens reared, the queen will be half blood, the drone will, as is generally supposed, be full-blood from that colony, consequently the third generation will be three-fourths, and if they are inbred from the same colony for 10 years, they will remain about the same as they were the third generation.

Pres. Miller—If they keep changing from the first, second and third, why do they stop at the third? Why not change at the fourth?

Mr. Schaper—Because there is no change of stock or blood, it is the same blood.

Mr. Baxter—The third generation the drone will be $\frac{1}{2}$ and the queen $\frac{3}{4}$, and it will finally become perfectly black.

Pres. Miller—I will risk my reputation on figures and give you my answer to it: When you get to the fifth generation you will practically have $\frac{1}{8}$ Italian stock; you can continue at that, and you will be constantly approaching and never quite reaching $\frac{1}{2}$; that is what your stock will be, $\frac{1}{8}$ Italian blood; it will be $\frac{1}{8}$ stock as nearly as you can get to it. The first generation you have a pure Italian queen; you start with that pure queen; the next generation your first cross is half blood, isn't it? Now we have gone from one right down to $\frac{1}{4}$; what will your next queen be? $\frac{3}{4}$; pure Italian queen, pure black drone, result, the progeny is half-blood queen Italian, and the pure Italian drone; now with that half-blood queen Italian and a pure drone, you will have a $\frac{3}{4}$ queen; now your stock rises that time, and it will be between $\frac{3}{4}$ and $\frac{1}{2}$; it will be $\frac{5}{8}$ Italian; it was first $\frac{1}{2}$ Italian, then $\frac{3}{4}$ Italian, then $\frac{5}{8}$; next time $11/16$, and so it will keep going up and down each time getting nearer and nearer to $\frac{1}{2}$, and if you keep on to infinity you will get $\frac{1}{2}$ stock.

Mr. Wheeler—It is quite an important question to me right there. What do you think would be the color of those bees after 10 generations, after that process?

Dr. Besse—I don't think they would have more than one ring around them, anyhow!

Pres. Miller—From my experience I should expect two bands.

Mr. Wheeler—My experience is they would go back to black blood in color. I have most of the bees in my part of the country, and I declare it is almost impossible to keep their color. I buy queens and keep selecting all the time, and my stock runs back.

Pres. Miller—Just upon this line I have had a good deal of experience. For years and years the tendency seemed to be that there was no holding toward the yellow blood at all, and almost every year I would get imported queens from Italy, and it seemed black stock was all I could have. Of late years, it seems to be working the other way, and I account for it in this way: In the first place there was black stock all around me, and my stock was continuously mixing with that stock, but gradually hybrids were about me, more or less pure stock, and that has made a change in that direction. There is another thing that comes in to make me think the tendency is no more to black than yellow, if as much. What is the tendency to change when Italians are brought into this country? What have you found, when you have reared queens? Have you had lighter or darker queens? If your experience has been the same as mine, you will get lighter queens than pure-

stock Italian. You know, further, that we have had what they don't have in Italy—we have the 5-banded stock, the pure yellow all over. I am inclined to think there is more or less a tendency towards a lighter color. That is not disputing Mr. Wheeler's statement, that the tendency of his bees was towards black stock; that was my experience, but I think it was because of the mixing of surrounding bees. I do not think, if you had the same stock all around you, there would be a tendency towards dark, but rather lighter.

Mr. Baxter—In my neighborhood I don't know of any one else who has any bees now within four or five miles of my place, but I have got to keep changing every year, so as to get Italians.

FINDING DARK QUEENS.

Mr. Norris—I am comparatively a novice in the bee-business; my efforts have been hindered a good deal about being able to find queens, particularly dark queens.

Pres. Miller—That is a very proper question to ask. How do you find queens, especially dark ones? Tell us, Mr. Norris, if you please, something about the condition of affairs when you want to find the queen.

Mr. Norris—I can tell my method of looking for them. I smoke them as long as I reasonably can, and use an extra brood-chamber to set out the combs carefully, and look them over carefully as I take them out and put them in, and find it difficult to find queens.

Mr. Baldrige—I think I should put a cover on the hive about two inches deep, something similar to the Simplicity cover, and as you blow the smoke at the entrance, rap on the hive. I find that the queens are generally in the cover, and in a very few moments, without taking the comb out of the hive, I find them frequently on the cover. It is a very easy matter to rap on the hive, and if you take that cover off at the proper time, you will find, almost invariably, the queen in the cover.

Dr. Besse—Black queens are very shy; they don't stay on the hives; they will slip around and hide in the corners; my experience is when I want to find them, the same as Mr. Baldrige's—drum them out, and if you can't see them then, shake them on the alighting-board in front of the hive; then take out one frame and shake them on, and the next one, and so on; they are a trouble to find, sometimes.

Mr. Norris—Once I was bound I would find the queen, so I shook the bees out of the frames on a large sheet of paper in front of the hives. I got all the bees out and watch them carefully as they went in, and could not find any queen until they were nearly all in, and about made up my mind there was no queen. I then raised up the paper, and the only bee under it was the queen!

Mr. Green—I once had to find queens in a large lot of hives in which the combs were hard to handle, and the queens very shy. A great many of them were dark bees. I found that when rapping on the hive and smoking I could find them in that way much quicker than any other. I could almost always find the queen that way within five minutes. In my work in the apiary in finding queens I generally use the plan of shaking the queen out. To make operations easier I have a large alighting-board made of perforated zinc, and shake the bees on that.

Mr. Wheeler—In using Mr. Baldrige's plan, I wish to mention that you should lift the cover carefully, and not take it off with a snap; the queen is likely to knock down if the cover is taken off with a snap or jar.

USING BAIT SECTIONS.

"How many think it necessary to put bait sections in the super?"

Pres. Miller—I think you can have two questions of this. Suppose I say I can get work done without any bait sections at all, but on the whole I think it is better to have them. It would be advisable in that case but not necessary. Let us take the question as it is given. How many think it necessary to put bait sections in the super? [Six.]

How many think it unnecessary? [Five.]

How many think it advisable to put bait sections in the super? [Twelve.]

Mr. Wheeler—There is an "if." It depends entirely upon the kind of hive you use, and what you are doing. If I use a Heddon hive and queen-excluder I don't want any bait sections. My queen is quite apt to come up and lay in bait sections. If I use a Langstroth hive then I want to use bait sections.

Dr. Besse—Have a $\frac{1}{4}$ inch space between the supers and the upper side of the frames; there is no danger of the queen getting up; that is my experience.

Mr. Norris—It depends more upon the honey-flow, if they are necessary, than on any other one thing. If there is a large flow, you don't need any baits.

Mr. Baxter—I don't think it is necessary. If the bees are going to work at all, they will work sometime—if not this year, next.

The convention then adjourned until 9:30 a.m. the next day.

[To be continued.]

Report of the Illinois State Convention.

BY JAS. A. STONE.

The Illinois State Bee-Keepers' Association met in Springfield, Nov. 18, 1897, for a two days' session, and was called to order at 10:30 a.m. by 1st Vice-Pres. J. Q. Smith. The minutes of the last annual meeting were read and approved.

The committee on State Fair reported, and recommended that, tho their work had met with general approval, still some changes were needed in the premium list, as well as in the code of rules. The committee reported that the State Board of Agriculture gave us a good liberal premium list, and some of the members of our Association did very well in trying to make a creditable display.

Since the State Board, and especially Supt. Cater, have done so well by bee-keepers, in offering so liberal a premium list, it should be the object of bee-keepers everywhere to see that a grand display is made—one that will not only be gratifying to the State Board of Agriculture, but a credit to the bee-industry of the State and of the whole country. Not only did they deal liberally with us in our premium list, but Secretary Garrard kindly gave us our score cards in such a good shape that if there was anything wanting it was our own fault. Then Mr. Cater selected a good judge in Mr. George W. York, of the American Bee Journal, and everything was past upon in such a way that no right-minded person had any room for complaint. If the State Board, and Supt. Cater, are as liberal with us in the future as at the last Fair, we recommend that the members of our Association especially guard with zealous care to see that the exhibit is such that no premium be carried off which shall not have well deserved the same. If we make a fine showing we can expect good premiums, and if our showing is inferior we will be only treated right in getting small premiums.

The report was approved, and discussions followed, as to what changes ought to be made in the premium list, and, finally on a motion by Mr. Black, it was left to be settled by the new committee on State Fair, which was named as follows: Jas. A. Stone, chairman, Chas. Becker and S. N. Black. It was the decision of the meeting that in recommending a premium list for Illinois bee-keepers only, that they should not be compelled to be the producers, but that they ought to be apiarists, and their honey the product of this State.

Mr. Robbins thought that in the exhibit open to the world the amount of comb honey ought to be limited to 250 or 300 pounds.

Mr. Becker thought it was only those who went the rounds of the fairs, who demanded such a change, and it was a question whether they were a benefit to the State Fair, or to the cause of bee-keepers. The subject was well considered, and argued on both sides, but seemed to be the prevailing opinion that any changes to be made in the premium list should be made to favor those who are showing in the interests of the cause, rather than those who are making the rounds of the fairs.

AFTERNOON SESSION.

The first on the program taken up was the question-box.

GETTING BEES OUT OF COMB HONEY SUPERS.

How can we with the least trouble get the bees out of our comb honey?

Pres. Smith—I put about six section-cases into a tight box with small strips of wood between the cases so the bees can pass between, and have holes in the box, covered on the outside with cones of wire screen for the bees to pass out.

Sec. Stone—For several years I have used only the Porter bee-escape, and find it takes great care to see that no spaces are left anywhere, or the bees will get back as fast as they go out.

COMMON FARMERS KEEPING BEES.

Mr. Becker asked, "Should bee-keepers encourage the common farmer to keep bees?"

Pres. Smith thought not; that every extra-good year brought everybody into bee-keeping, and as the years grew bad they all went out of the business, with no good result to any one. Others thought about the same.

Mr. Black—It is no profit to themselves and an injury to bee-keepers.

On motion of the Secretary, Messrs. Black, Smith, and Poindexter were appointed a committee to interview the Governor and present the following petition:

WHEREAS, The Northwestern Bee-Keepers' Association, at their annual meeting held in Chicago, Nov. 10 and 11, ask that the Illinois State Bee-Keepers' Association at its next (this) session take proper steps to secure help from the State, to make a creditable exhibit of honey, beeswax, etc., at the Trans-Mississippi International Exposition; therefore, the Illinois State Bee-Keepers' Association in session have appointed a committee consisting of S. N. Black, J. Q. Smith, and Geo. Poindexter, to wait on the Governor, as to his pleasure, and ask, if it be consistent with his will, and for the good of the State of Illinois, that one of the commissioners to have the care of the appropriation from this State to the above-named Exposition, be a bee-keeper, or a man who will favor a good display of the apian products of the State of Illinois at the Omaha Exposition; and, also, ask his Excellency, the Governor, to favor our request if he consider the same proper.

COMB OR EXTRACTED HONEY—WHICH?

"What are the best results for which to work—comb or extracted honey, or both?"

Mr. Black—I think there is more money in extracted, take it year after year. I don't like to use sections the second time. In producing extracted honey we do not have to use so many fixtures, tho I favor working for both. Extracted is always ready for the market, while comb has to be "just so" or there is no sale for it. I think comb honey is the healthier.

Mr. Poindexter would work for half of each. We ought to have some comb honey always on hand.

Mr. Smith—It pays to work for both. I expect to do so in the future, and sell both at the same price—12½ cents. I put my extracted into stone jars, and tie it up with muslin cloth.

Mr. Black would heat the extracted honey while extracting in wet seasons.

DRONES FROM LAYING WORKERS.

"Are drones from laying workers potent to fertilize queens?"

Mr. Black—I have never seen anything that would settle this question in my mind.

All had something to say on this question, but no one could give any light on it.

The Secretary announced that arrangements had been made with the American Bee Journal, the same as last year—one dollar for membership in the Association also giving credit for one year for the American Bee Journal, from any date desired.

The election of officers for the ensuing year resulted as follows:

President, J. Q. Smith, of Lincoln; Vice-Presidents—1st, C. P. Dadant; 2nd, A. N. Draper; 3rd, S. N. Black; 4th, Geo. Poindexter; and 5th, George W. York. Treasurer, Chas. Becker; Secretary, Jas. A. Stone, of Bradfordton.

INCREASING THE DEMAND FOR HONEY.

"How can bee-keepers increase the demand for honey?"

Mr. Black—If you can't sell it, give it away. Keep your trade by buying, to sell them (your customers) when you have none of your own production.

Mr. Smith—Leave a case and tell them you will call again for it if they find they do not want it after investigation. Don't come down on the price in order to sell it.

Sec. Stone—Let people know you have honey, by giving them a chance in some way to see it. I never have any trouble in selling all the honey I can produce, and a good deal more.

SWARMING AND WINTERING.

"Will bees swarm sooner when wintered in the cellar than on the summer stands?"

Mr. Black—It depends upon the winter.

Sec. Stone—If the winter is severe and the spring late, I believe the bees kept in the cellar will come out away ahead in their brood, and it follows they will first be ready for work, and consequently swarm earlier.

Other questions were handed in that for lack of time were not answered, and we will send them to Editor York to be put to his question answerer, in the American Bee Journal, for the querists to watch for.

JAS. A. STONE, Sec.

Plain Sections.—"The past season I used the no-bee-way sections with barred separators, and learned that better comb honey, and more of it, can be produced with them, and it can be cleaned of propolis and packed in half the time that slotted sections can.—E. A. Morgan, in Southland Queen.

A Lubricant for foundation machines given by Alois Alfonsus, in Bienen-Vater, is nine parts skim-milk and one part alcohol. He says it works well, and it has nothing objectionable in it. Another writer in Rhein-Bztg, says one part alcohol and three parts of the watery portion left when cheese is made of skim-milk.

Chilled Bees.—Gravenhorst says in Deutsche Illustrierte Bztg, that chilled bees found on the hives or bee-house after a cleansing flight, may be warmed and returned to other colonies as they have become chilled, because some change in appearance has hindered their prompt return to their own hives; but those found on the ground in front of the hives are not worth minding, for altho they may be revived they are death-candidates, and will not last long.

Tall Sections 14 Years Ago.—The editor of Busy Bee says, when he went to Missouri, 14 years ago, the Crown hive was the principal one in use, with which tall sections were used, having no bee-space in them, the bee-space being in the separator. The arrangement was good, the sections when filled very attractive, and not hard to clean. But the hive was too expensive, and so went out of use. But he thinks, for the average bee-keeper, the ordinary 4¼ section is best.

A Dishonest Lot, is what Aaron Snyder considers bee-keepers who produce comb honey and crate and market the same. If there are any exceptions he doesn't take the trouble to mention it. The special charge is "facing" a shipping-case with nice sections, and the middle of the case filled up with inferior quality. The editor of Gleanings thinks Mr. Snyder seems a little severe in his arraignment. But, really, ought a man to call all comb-honey men aside when he himself is Snyder?

Carbonyle has been recommended in foreign journals as a preservative of hives, for some time. In L'Apiculteur, A. Bassalar reports that in March he put under part of his hives floor-boards painted, five or six months previously, with carbonyle. April 20, on examination, he was stupefied to find 60 out of his 89 colonies gone up. Plenty honey left, but not a bee live or dead. And the 60 colonies were just the ones that had been placed over the carbonyle, the remaining 29 having their old floors.

Creolin for Foul Brood.—Henry Otto, having seen creolin recommended in a German paper as a remedy for foul brood, gave it a trial. He sprayed the bees at the entrance of the hive, commencing the last of October, taking the warmest time of the day, repeating the spraying five or six times for two or three days. Also used an atomizer to spray the frames and inside of hive. The next spring the bees were healthy, and he has had little trouble ever since by applying the remedy on each appearance of the disease.—Pacific Bee Journal.

Handling Plain Sections has been mentioned as a rather ticklish affair on account of the danger of sticking the fingers into comb so near the edge of the wood. In Review, J. E. Crane says his experience has been that they require more careful handling than others, or they will be marred and set to leaking, especially when put in paper cartons. T. F.ingham says, "The very thought of such a section is a thought of danger," but from what he says it appears to be with him only a matter of thought without experience, while Mr. Crane speaks from actual experience. Editor Hutchinson, speaking also from experience, thinks the danger has been overdrawn. He had three cases of such sections filled with honey, and at five fairs they were opened, the sections taken out, pulled about and handled and exhibited and then put back, and not a scratch made on the combs.

Vol. XXXVIII. CHICAGO, ILL., FEB. 24, 1898. No. 8.

California Bee-Keepers' Exchange.—The Los Angeles Fruit World for Jan. 15, reported that C. H. Clayton, secretary and business manager of the Exchange, on Jan. 14 sold three carloads of amber extracted honey at 4 cents per pound, for shipment to Chicago and Boston. An offer of the same price was declined for 36,000 pounds of amber honey later in the day. It was said in the same paper that the market was firm, demand plentiful, and supply somewhat scant.

It is no doubt that the Exchange, when properly working, and supported as it should be by the bee-keepers of California, will prove of great advantage to all concerned.

A German Sees American Bee-Keeping.

—In Luxemburgischen Bleneuzeitung an account is given of observations in America, in which especially the differences between Germany and America are noticed. In America no bee-houses as in Germany, but each hive out in the open air. All movable combs instead of box or straw hives. Frames lifted out above instead of at the back, so any frame can be lifted out separately instead of taking out all the frames to get at the last. One cannot help wondering, however, in what part of America he has been traveling to make the statement that bee-keeping is to be found in America at every farm-house, that the farmer living 20 to 30 miles from the nearest town must depend on the bees for his sweetening; that in America almost all fruit that is boiled down is boiled

down in honey; and that farmers come and offer honey at 4 to 5 cents a pound, and often not being taken at that, they finally offer it at 2 or 3 cents to get rid of it!

New Things are being constantly brought out in all lines of the world's work. Bee-keeping is no exception. In this number we illustrate and describe two of the new apiarian things—the plain section and slat separator, or fence. Now it would be very foolish for bee-keepers to at once throw away all the fixtures they have on hand, and get a big supply of the new. There would be neither sense nor reason in so doing. The proper thing to do is to get some of the new goods for trial, and then if you find them superior to what you have been using, adopt them; if found no better, then you can go on with the former things.

We believe in showing to our readers every new and useful invention that may be brought out in the line of bee-culture, but we hope that no one will conclude that because we do this, we at the same time advise them to throw away or burn up all the old things now in use. No, no; test the new, and then "hold fast to that which is good."

A Few Kicks and Growls.—Mr. J. M. Jenkins, of Elmore Co., Ala., "kicks and growls" in the following (perhaps latest) fashion:

I've got a little kick or two on my mind for the American Bee Journal, and here goes. Of course, the people that don't run papers and railroads know all about how they ought to be run.

1. I don't like that new-fangled way you have of spelling. Can't get used to it. Get to reading an interesting advertisement, editorial or communication, and all at once meet one of those things face to face, and it surprises me—actually, some of 'em "shox" me. (That's a good 'un—shox.) Then I rather lose the subject and catch myself looking ahead to see what next. May be silly, but it's so. I wish you'd quit it, but you needn't stop my subscription, even if you don't.

2. Speaking of advertisements, I wonder how many folks, on receiving a bee-paper or magazine, begin at the back, look over the advertisements from back to front first thing. I always do. I may, for want of time, leave some things unread, but not the pages of business propositions.

3. Another thing, I like to see the full name and post-office of contributors. Why not? Of course, everybody knows I am in the city where the State Penitentiary is, and where I am liable to spend the rest of my natural life, but how many of your readers, do you suppose, know where such little side-lights as Dr. C. C. Miller or G. M. Doolittle live and vote, and have their bees? I am sure the next number of the American Bee Journal will conform to these preferences o'mine—but don't stop my paper.

4. I also growl about the way in which you and Gleanings, and perhaps other bee-papers and correspondents, sometimes hint at or tell on dishonest commission-men. If a commission-man does a crooked piece of business, and it is published without giving his name, what good is done the unsophisticated country sucker that buys your paper, and also swallows the plausible buncombe and flattering testimonials of Wheadon, Horrie, et. al., except to make him suspicious of all commission-men? What's the use of putting us onto 'em after the police have chased 'em out of town and closed up their business?

5. Expose swindlers by all means; but please tell us who they are. You wrong no one by publishing the facts about a transaction, with names and addresses of parties concerned. You can still further help bee-keepers, and, incidentally, the commission-men, by the favorable mention of a commission house that you know is honest and reliable, and deserving of patronage.

That's all. I wish you a happy, prosperous New Year.
Elmore Co., Ala., Jan. 14. J. M. JENKINS.

We will try to reply to some of Mr. Jenkins' questions and objections, tho our answers may not be satisfactory to him and a few others like him (who are outside of the penitentiary, and yet so near to it!):

1. Many people don't like "new-fangled" things and ways, but all of the old ideas and things that have contributed to progress in any line were once thought by some to be "new

fangled." We believe in progress, hence we are trying to help it on a little by uniting with some 300 other publishers, editors, etc., to simplify and shorten our way of spelling the English language by taking a certain class of words first. "Shipt" certainly is simpler than "shipped." "Shox" is your own idea, not ours, Mr. Jenkins. But we prefer it to "shocks," tho "shoks" would be better, and we hope the day may come when it will be in good form to so use it. Two or three of our subscribers stopt their subscriptions because we were trying to help on what we considered a good thing in the way of an improved spelling. But the Bee Journal was not entirely dependent upon such unprogressive folks, so it has just kept right on in its weekly appearance, and likely will continue to do so. We may not be very large in size ourselves, but we are not easily frightened, particularly when we know we are on the right track.

2. This is a matter wherein our readers may do exactly as they please. We would have no objections if they, like the old colored brother, should prefer to read the Bee Journal bottomsides up, "so as to get the bottom facts first!"

3. Here is a thing that seems to bother one or two others besides Mr. Jenkins. But when you subscribe for *any* paper, it is no part of the contract that you shall have the post-office address of *any* of its correspondents. We agree to furnish you a first-class paper for a year. Our contract is confined to the paper. It doesn't go outside. Hundreds seek free advertising in this way, and if we give one address we are bound, in some degree, to give all. We are constantly annoyed by this class of correspondents. We save no manuscripts, and a week following we may not remember the address of any particular correspondent. Our mailing list is arranged by post-offices, not names of individuals. If one asks for the post-office of a particular correspondent, we often can't give it unless it happens to be one we know, and we can't find it on the list without going through the whole of it—like looking for a needle in a haystack. The proper way for a publisher is to give the county and State; that gives the location of the writer, and beyond that no subscriber has any legal demands. If any one has any advertising to do in our paper, to make any money out of it, he must pay for it. It would be wrong for us to charge one man regular rates and admit another man's advertisement free—and in the best and most expensive locations, in pure reading matter. No man wants his post-office address published unless he has some object in view that has no connection with the paper. All proper inquiries can be made through the columns of the Bee Journal, and all replies of general interest, also. By giving the county and State, we give all that any reader has any right to demand; by suppressing the post-office we save writers, who have no advertising in view, an endless amount of trouble and annoyance, and checkmate the free-advertising fiend. One of our correspondents once received 50 letters in reply to an article he wrote for the Bee Journal, and he hadn't paid one cent for advertising! Right is right. We believe in justice to all, hence we *stopt* the free-advertising business for one person and charging another man for the same thing. We don't propose to give one person any advantage over another in the columns of the Bee Journal, however others may do.

4. Experienced publishers, and honorable ones, too, have some respect for libel laws, as well as for other good laws. We cannot publish all that we would, some times.

5. By consulting the advertising columns you will find the names and addresses of commission-men and other dealers who are regarded as "honest and reliable," else they wouldn't be found there. It will hardly do to boom commission-men in a miscellaneous or particular fashion, for you can't tell how soon some of them may be found doing a crooked business. Of course, just as soon as we discover such we drop them, as we have done in several instances the past few years.

Now, we want to say that we are glad Mr. Jenkins sent

In his "kicks and growls," for it has given us a chance to 'give a reason for the faith that is in us.' We want all our readers to know just *why* we do such and such things, so that they may see that it is not because we wish to be whimsical, or to annoy or "discomfuddle" them, but to simply carry out our idea of doing or showing justice to all and impartiality to none. We want to be and do right, but do our best we cannot hope to please all. In fact, you wouldn't read a paper three months that was edited by a man who tried to please all, and had no backbone, or mind of his own. We are simply trying to make the old American Bee Journal as nearly as we know how, just what it ought to be. We sometimes fondly hope that we are succeeding. Then again, like Dr. Miller, we "don't know" about it.

REV. A. B. METTLER, of Will Co., Ill., called on us when in Chicago, Feb. 16. Mr. Mettler is a bee-keeper of three years' experience, and is making a success of it. He finds that preaching and bee-keeping go well together.

SIMPSON HONEY-PLANT SEED, or Figwort, we have been out of for a long time. As we are not able to fill any more orders for it at present, we trust no more requests will be sent in for it until we again announce that we have a supply of the seed. Just now we do not expect to have any more.

MR. CHAS. A. HOLMES, of Suffolk Co., Mass., makes an exclusive business of furnishing strong colonies of bees for use in greenhouses, preferring that those who may need them should give their orders the fall previous. No doubt the greenhouse people will be after Mr. Holmes, when they once learn that he is ready to supply them with the busy bees. They are put into the greenhouses on or about March 10, to work on cucumber blossoms.

MR. JAS. A. STONE, of Sangamon Co., Ill., Secretary of the Illinois State Bee-Keepers' Association, reports Feb. 9, that his bees were wintering nicely—so quiet that they could hardly be heard. Mr. Stone also sent us the report of the late convention at Springfield, which will be found in this number. Referring to it, Mr. S. says: "It is not long; but if any wanted to hear more of it, tell them they ought to have attended the meeting."

CATALOGS FOR 1898 are on our desk from the following who patronize our advertising columns:

John Nebel & Son, High Hill, Mo.—Bee-Keepers' Supplies.
 Page Woven Wire Fence Co., Adrian, Mich.—Wire Fences.
 F. A. Crowell, Granger, Minn.—Bees and Queens.
 F. Danzenbaker, Washington, D. C.—Danzenbaker Hive.
 John Bauscher, Jr., Freeport, Ill.—Poultry.
 Geo. H. Stahl, Quincy, Ill.—Incubators.
 Geo. W. Hufstедler, Beeville, Tex.—Bees and Queens.
 August Weiss, Hortonville, Wis.—Bee-Keepers' Supplies.
 E. Kretschmer, Red Oak, Iowa—Bee-Keepers' Supplies.

MR. A. W. HART, of Stephenson Co., Ill., judging from the following, is almost glad we made a few errors in his first communication, as the correction seems to have afforded some fun:

"EDITOR BEE JOURNAL:—Permit me to say thanks for the frank correction on page 73. I hardly knew which to admire most, the hearty correction or the happy play on the words. When my humorous bee-friend, the ex-secretary, remarked on the 'errors,' he said:

'The editor knows Joliet [with its penitentiary] is in Will county, and he probably thought you were there—or ought to be; and you can't send any more articles as long as you are there, and may be that is what the editor means.'

"He thought he had a good joke on me, and we had a good laugh."

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Wire-Screen Comb Foundation.

Could one successfully use window-screen wire, and cover the mesh with hot wax for brood-frame foundation? □ NEW YORK.

ANSWER.—If you put the wax on so as to cover the wire-cloth entirely, the bees will probably use it, but it will take a good deal of wax, and would fail of being satisfactory in the most important respect, for the bees would make just as much drone-comb as without anything. Don't try it with more than one frame to begin with.

Swarms Clustering Together.

Should two or more swarms having clipped queens cluster together, would they each return to their respective hives? or would they go to some hive together, if left to their choice?

HOT SPUR.

ANSWER.—I don't like to answer, for the very first time you have two swarms of that kind left to their own sweet will, they'll be just about sure to do some other way than the way I say. Perhaps in the majority of cases, each swarm will go back to its own hive. That's on the supposition that each one clusters independently, or goes back to its own hive without clustering. They may cluster together and then each one go back to its own hive. They may cluster together and the united cluster go to one of the hives. They may go together or separately to some other hive from which a swarm had lately issued, and where a lot of returning bees are making a loud call. They may break all up and go all sorts of ways. You see I put in that "all sorts of ways" to cover some new way that your bees will invent.

Loss in Weight in Wintering.

I have 25 colonies of bees. I weighed them Sept. 27, 1897, and part of them again Jan. 8, 1898, and I would like very much to know where part of the weight has gone. Below I give the weights of two lots in pounds—weight given being of the bees and combs:

| | Sept. 27th. | Jan. 8th. | Loss. |
|-------------|------------------|------------------|-----------------|
| No. 2..... | 5 $\frac{3}{4}$ | 4 $\frac{7}{8}$ | 6 $\frac{1}{4}$ |
| No. 3..... | 55 $\frac{3}{4}$ | 49 | 6 $\frac{3}{4}$ |
| No. 7..... | 26 $\frac{1}{2}$ | 20 $\frac{1}{2}$ | 6 |
| No. 17..... | 37 | 30 $\frac{1}{2}$ | 6 $\frac{1}{2}$ |
| No. 19..... | 34 $\frac{1}{2}$ | 27 | 7 $\frac{1}{2}$ |

Average
Total loss, 33 loss, 6 3-5

This lot had all natural stores. In the following lot the figures in the third column represent the amount of syrup fed during two weeks in October:

| | Wt. Sept. 27. | Amt. Fed. | Wt. Jan. 8. | Loss. |
|-------------|------------------|------------------|------------------|------------------|
| No. 4..... | 12 | 17 $\frac{3}{4}$ | 12 $\frac{1}{4}$ | 17 $\frac{1}{2}$ |
| No. 8..... | 18 | 12 | 16 | 14 |
| No. 13..... | 12 | 20 | 7 $\frac{1}{2}$ | 24 $\frac{1}{2}$ |
| No. 16..... | 24 | 8 | 20 $\frac{1}{2}$ | 11 $\frac{1}{2}$ |
| No. 20..... | 15 $\frac{3}{4}$ | 15 | 18 $\frac{1}{4}$ | 12 $\frac{1}{2}$ |
| No. 21..... | 23 | 7 $\frac{1}{2}$ | 25 $\frac{1}{2}$ | 5 |
| No. 22..... | 16 $\frac{1}{2}$ | 15 | 21 | 10 $\frac{1}{4}$ |
| No. 23..... | 22 | 8 | 16 $\frac{1}{2}$ | 13 $\frac{3}{4}$ |
| No. 24..... | 24 | 6 | 19 $\frac{1}{4}$ | 10 $\frac{3}{4}$ |
| No. 25..... | 24 | 7 | 21 $\frac{1}{4}$ | 9 $\frac{3}{4}$ |

Total loss, 129 $\frac{3}{4}$ Av. loss, 13

The syrup fed was made by stirring granulated sugar in boiling water, equal parts of each by weight, and adding three pounds of honey to each gallon. Each colony was given the full allowance at one time in a Miller feeder, late in the evening.

They are all on the summer stands, with a cushion filled with oats four inches thick on top. Part of those fed are contracted to five frames. They are in Simplicity and Danzenbaker hives. Can you give any reason why those fed have lost nearly twice as much as those not fed?

I watch pretty closely, and do not think there was much robbing done. They are all strong in bees, as I took 13 colonies out of a neighbor's box-hives (he was going to brimstone them) in September, and gave plenty of bees to all that were at all weak.

IOWA.

ANSWER.—Your problem is a very interesting one, and you are entitled to no little credit for taking such accurate observations. I am not sure how much satisfaction I can give by way of an answer. Suppose we consider the case of No. 13—the one to which most was fed, and the one that suffered the largest loss, apparently disproportionately large. It lost about 18 pounds more than those that were fed. The supposition is that the bees evaporated the

syrup till it was as thick as honey. The amount of water in honey varies very much, some honey having only about 12 per cent. of water, while other samples contain as much as 25 per cent. It is likely the syrup was reduced till it contained 18 or 20 per cent. of water, say 20 per cent. That would make 1.5 of the syrup when evaporated, water, or $\frac{1}{4}$ as much water as sugar. The 20 pounds of feed you gave contained eight pounds of sugar, eight pounds of water and four pounds of honey. That eight pounds of sugar would only need two pounds of water, six of the eight pounds being evaporated. That 6 pounds taken from the 18 pounds of extra loss leaves 12 pounds unaccounted for. I can only hint at some of the ways in which it may have gone. Extra labor was done by the bees in storing and evaporating the syrup, calling for an expenditure of force with a corresponding loss in weight. It is quite possible that feeding so much thin syrup may have excited a good deal more brood-rearing than took place in the colonies not fed, and this would make considerable loss in weight. And it is also possible that some wax was secreted, causing a large loss in weight compared with the weight of the wax. You have only confirmed what many others have noted, that in feeding bees there is always an apparently large loss not easily accounted for in exact figures.

Keeping Bees on Shares.

I have an opportunity to take 14 colonies of black bees on shares. What would be a proper share? Is one-half of increase of both honey and swarms fair? One party owns hives and bees, the other does all the work, furnishing the best of pasturage. Who should furnish hives, or should each furnish his own? Should the original colonies be kept good in case of death by moths or foul brood, etc.? When is the proper time to count the colonies good, now or in the spring? PENN.

ANSWER.—Be sure to have every particular agreed upon and put down in writing. That's not answering your questions at all, but it's the most important answer you can get, for there's pretty sure to be some misunderstanding about bees on shares. There's no fixt rule as to shares, and it's all as you agree. Much depends on the man who takes care of the bees. If I were putting out bees on shares, I'd be willing to give five times as big a share to some bee-keepers as to others. Depends on what they know, what they can do, and what they will do. Perhaps the most common way is to have each furnish half hives for increase, and take half the increase and half the honey, counting out the original number as belonging the original owner. You can tell better about the colonies by counting in spring, but that's just as you agree.

Hive Dimensions—Running Out-Apiaries.

1. Please give a description of the hive you use. Give length and depth of frames, how many and what style.

2. Can an out-Apiary be run for comb honey without an attendant during the swarming period? Or in other words, can one person manage two apiaries, they being several miles apart? SUBSCRIBER.

ANSWER.—1. The majority of hives are 8-frame, having frames 18x9 inches. But I would not advise any one to use a frame of this size, for altho it varies not more than $\frac{1}{8}$ of an inch from regular size, and is perhaps just as good, still it is an odd size, and on that account not so good. My later hives, and the ones I am getting as fast as I need new ones, are the regular 8-frame dovetailed hives, with frames of what may be called standard size, 17 $\frac{1}{2}$ x9 $\frac{1}{2}$, outside measure. Top-bars of frames are 1 $\frac{1}{2}$ x $\frac{1}{2}$.

2. Yes, if the apiaries are small enough, one person can run several. Of course he must manage to have some kind of control of natural swarming.

Building Combs on Wired Frames, Etc.

I have two colonies, one a prime or first and large swarm, and the other a second swarm (which was small) from the parent hive. I bought two chaff hives and a lot of other things of a lady who once had bees. The frames were not wired, and I was told to wire them. I did so. I did not know how many frames ought to go into the hive, so I put in one eight and the other nine. They were from $\frac{1}{2}$ to $\frac{3}{4}$ inches apart at the top. Now, I was told to wire these frames by crossing the wire diagonally in the center, in order to support the comb and honey. When the bees went to work they made comb on each side of the wire, one piece of comb interlacing another, and one frame also interlacing the other. Some frames had as many as three different pieces of comb, one piece on one side of the wire and two on the other, and so mixt up that it was impossible to take out a frame without breaking and tearing the comb. I took some of them off, also a few pieces that were made from the quilt down in between the frames. What was the trouble? Was the wire put in wrong, or was it too thick? It was common annealed wire, such as is used for picture-hanging.

I straightened out the combs as best I could, as I was anxious to save the bees and let them go at that, so they could gather enough for winter stores. I think they are all right so far as stores are concerned. What course to pursue in the spring is just what I want to know. Some of the frames were not wired; these were built pretty straight, tho somewhat bulgy. I had some foundation with the hives, which I think is the thin kind for sections; this I used in the frames, putting a strip all along the top-bar; it hung down about four inches from the top-bar; some of it sagged, and

some dropt off, which I removed from the hive. Was this comb that was built in chunks (so to speak) what is called burr-comb? How can I best prevent it in the future?

I am a subscriber to the American Bee Journal. I want to make my bees pay, and I want to learn all I can. I am going to get "A B C of Bee-Culture" this winter. Can you recommend me to anything better for a beginner?

MICHIGAN.

ANSWER—You are very wise in planning to get Root's "A B C of Bee-Culture." With that and the American Bee Journal you will be well equipt. If only you had had the book a year sooner it would have saved you a lot of trouble.

The bees have surely made a bad mess for you, but they're not much to blame. You had the frames badly spaced, and used the wrong kind of wire, and probably the wrong kind of foundation. The frames should have been spaced that they would measure $1\frac{3}{4}$ from center to center, altho $1\frac{1}{2}$ from center to center would work all right, and some of the best bee-keepers prefer it. Much finer wire should be used. No. 30, tinned wire is about right. Brood-foundation should be used, and the wire should be imbedded in the foundation, but all this you will learn about in the book you propose getting.

It's a little bit hard to say what is the best thing to be done in the spring. In any case, leave the frames just as they are till time of fruit-bloom. In the meantime, study up the matter of transferring, which you will find fully treated in your book. Then if you can find a frame that you can lift out, you can gradually get others out by cutting away some of the attachments, then the combs can be properly fastened in the frames just as you are instructed to fasten combs taken from a box-hive.

If it's a bad case, probably it may be as well to wait till about three weeks after it casts a swarm, then there will be no brood in the way.

Foreign Queen-Breeders—Hive-Ventilating Wedges—Gluing Cleated Separators.

1. May I ask you to be good enough to give me, or to obtain for me, the address of a good, reliable queen-breeder in Caruola or Italy?

2. Mr. Pettit's idea of ventilating wedges seems good; there is good reason for their use as against corner blocks. But don't you think the ventilation would be more thorough, if, instead of cutting the wedges to a feather-point, they were left $\frac{1}{4}$ inch or so thick at the smaller end? As it is they afford a bigger opening. There is really no draft through the hive.

3. And don't you think, Doctor, that editor Root makes a mistake in *gluing* the cleats on his cleated separators? I began this easy way of putting them on once, but speedily desisted upon a neighbor laughing at what he was pleased to call my folly, assuring me that the moist heat of the hive would loosen them in no time. Thinking it best to be on the safe side, I substituted wee wire-nails, even nailing over those I had already glued; yet I have never felt certain that said neighbor's surmises were correct. Kindly tell us what *you* know or think about glue in the interior of hives, for per-
adventure you have had some experience thereanent.

SOUTH AFRICA.

ANSWERS.—1. Sorry to say I don't know of a single address. Italian breeders used to advertise more than now.

[Owing to unsatisfactory dealings of some foreign queen-bee advertisers in former years, we have not cared to encourage their patronage of our columns.—EDITOR.]

2. Which is best may depend upon the time. Very decidedly it seems better to have the hive level, giving the slant to the floor alone. In spring or early summer, no doubt the sharp edge to the wedge is better—don't want ventilation clear through then. Later on, your plan would suit me better, and in the height of the honey-flow I'm just radical enough to believe that there's nothing quite so good as four blocks under the corners. The only objection I remember to have seen urged against this, is that the bees have only the four corners to climb up. That's bad in theory, and quite a hindrance to the bees, but as in actual practice my bees seem never to be delayed or worried by it, it doesn't worry me.

3. I think I never had anything glued in my hives. But Miles Morton says he has had glued "fences" for I think 10 years or more, and they never have failed. Are you sure that your neighbor is correct in considering the heat of the hive "moist heat"? It surely doesn't look much like it when honey is evaporated in it.

T Supers or Section-Holder—Carniolans and Cyprians.

I got my start of bees only two years ago, and we have had two excessively dry years, and next to no honey-flow at all, so I have had but little surplus honey, and that last September. Now, I make my own hives and have simply increast the stock of bees. I have now 23 colonies in hives that hold 12 Langstroth frames. All have plenty of honey, and have been carrying pollen lively the last four days from maple. I have increast from six, and had only three natural swarms in two years. Now for the questions:

1. Which is preferable in working for comb honey, supers with T tins, or section-holders? I have $1\frac{1}{4}$ inch sections. I have but few supers, and no inside filling for them, and desire to buy only that which is the better of the two ways. Which is the better, and give the best results with least expense and labor?

2. Have you had any experience with Carniolan or Cyprian

bees? I have all three and five-banded Italians, gentle and good workers, but they gather lots of sweet gum for propolis, and stick things up "for keeps." If either of the above are as good or better workers, and not so much on propolis, I thought of making a change. Mine are all rustlers.

Last spring I saved two colonies that run out of stores, and chilled so that nearly half were dead when I noticed them, by setting a Mason fruit-jar full of hot water close to the combs, and when they were warmed up I poured warm sugar syrup among them, and in an hour they were at work storing it in the combs. They came through all right.

ARKANSAS.

ANSWERS.—1. Some prefer one and some the other. Probably a good deal depends upon being familiar with them. My own preference is decidedly for the T super. The A. I. Root Co. have something they have just gotten up that they think better than either, but I have not had a chance to try it yet. Perhaps the chief advantage claimed for the section-holder is, that when the central frame of sections is finished or nearly so, it can be exchanged for the outside frame. I would not make use of that advantage, so I don't value it. An advantage that the T super has, is that it will take sections of any width whatever, whereas a section-holder made for a $1\frac{3}{4}$ section can't be used for any other width.

2. I have had no experience with Carniolans and very little with Cyprians. I have had bees that were a good deal worse than Italians about gluing, but none that glued less. Probably one reason that you have so much trouble with propolis is, that there is so much material ready for their use in the line of propolis. I doubt whether you will gain anything in that direction by changing your bees.

Loose or Tight Hive-Bottom—Honey-Room.

1. I am about to make about one dozen Langstroth hives for myself, and I would like to know which is the better way to make them, with a loose or tight bottom-board or floor. My old hives have a tight floor.

2. I would like to build a small honey-room in my work-shop. Please give instructions as to how to build it.

OHIO.

ANSWERS.—1. Very decidedly I'd have the bottoms loose. Then you can storify when you want to do so, and you can block up your hives from the floor when you want to give more ventilation. Sometimes, however, it is desirable to have the floor fast to the hive, as in hauling. At such time you can fasten the floor to the hive by means of tobacco-staples. If your floor is loose you can fasten it temporarily, but if it's permanently fastened you can't have it loose when you want.

2. Much depends, of course, on circumstances, the size of your shop, position, etc. If you can have it on the south side it will be well, so as to have the heat of the sun. Painted a dark color, it will better absorb the sun's rays. For comb honey you will need things a little different from that which is best for extracted. Without being on the spot it's pretty hard to give specific directions. Partition off what you can spare from your work-room, then plan according to your needs. If you don't have everything planned just right at the start, it doesn't matter so much. The main thing is to have the room, and then you can use it as needed.

Bees Stinging Each Other—How Bees Breathe.

It has long been a question with me why, when one bee stung another, it did not lose its sting, and if it did, what consolation there was to those bees which defended their hive from robbers, if they by so doing finally lost their own lives through the loss of their stings; hence I desire a fuller explanation, as I do not understand about the "breathing holes," as mentioned on page 53, in your answer to "Mass." We have just had a snow-storm of 24 hours duration, which is blowing into drifts. We had over a foot of solid snow before, as a foundation.

IGNORANCE.

ANSWER.—By "breathing holes" I mean the spiracles. Now you know all about it, don't you? If you have a minute's leisure let me tell you a little more about it. Bees don't have a system of bones inside as we do, but a bony covering outside. A bony substance called "chitine" covers the outside. That's so hard that I don't believe a sting could be made to penetrate it. The abdomen or hinder part of a worker has six bands or belts of chitine, each band being formed of two plates, one upper and one lower. If you watch a bee when standing still, especially after active exercise, you will see its abdomen alternately expand and contract—get longer and shorter. The different bands telescope into each other, being joined together by a very thin membrane.

Your blood needs oxygen, and it goes regularly to the lungs for it, and you are constantly drawing air into the lungs and then breathing it out again, so as to supply the oxygen. The bee must have oxygen, too, but it works on a different plan. It has no system of blood vessels to carry the blood where it can get oxygen, so it has a system of air-vessels that ramify and ramify, and carry air to every muscle, gland and organ, even to the wings. The spiracles, or places where the air enters, are 14 in number, five on each side of the abdomen between the bands, and one at the base of each of the four wings. You can see that while the sting cannot pierce the horny chitine, it will readily slide into one of the spiracles, from whence the poison will be promptly distributed to all parts of its ramifications. Once in a great while the sting may get into the thin membrane that unites the bands, and then it will stay in the wound, just as it does when the bee stings you. Now you understand, I hope, a little better about the "breathing holes."

GENERAL ITEMS

Bees in Splendid Condition.

Bees had a splendid flight last Thursday (Jan. 13), so they are now in fine condition to go through the winter.

GEO. SPITLER,
Crawford Co., Pa., Jan. 18.

Too Dry for the Bees.

It is impossible for me to do without the American Bee Journal. The last season was too dry here in this locality for the bees to gather much honey, but what I did get was fine—all comb honey. I have 35 colonies of 5-banded Italians and hybrids, in dovetailed hives. **GEORGE E. ULRICH,** Dauphin Co., Pa.

Good Year for Bees.

I started bee-keeping four years ago with one colony, and last spring (1897) I had eight; from them I had 45 gallons of extracted, and 100 pounds of comb honey, besides eight swarms. I now have 16 strong colonies, and winter them on the summer stands, in Langstroth 2-story 10-frame hives. We had a good year—white clover plentiful, and honey very nice. **Summit Co., Ohio. HIRAM BRADLEY.**

Deep Snow and Storm.

The winter was very mild and pleasant until about one week ago when we were blest with a good foot of "the beautiful," making a good 15 inches of snow on the level, and this morning we awoke to find a terrible storm in progress, with snowdrifts of enormous size, and all double-walled hives outside of the bee-house literally buried beneath the snow. It is one of the worst storms that this section of the country has witnessed in 10 years. I hope it has not reached as far south as Chicago. From a "snowed in" bee-keeper.

CHAS. E. CRAWFORD,
Oscoda Co., Mich., Jan. 23.

[Yes, we got it here, too.—EDITOR.]

Bee-Keeping in Mexico.

We had a very nice year in 1897. The rainy season kept on for a long time, with a sufficient amount of water. Everything did grow splendidly. Just now I am cleaning my coffee, which came out very nice, and is of good quality. Lately we had some quite exceptional cold spells. The temperature came right down to the freezing point, but did not do any harm.

My bees did not do so well as in the seasons before, and I cannot explain why. They had all the year around 3 to 5 frames full of honey in the brood-nest, but did not do much in the supers. I hardly had enough honey to supply my regular customers. The orange season is beginning now, and I am full of hope for the year 1898. **F. BUSSLER.**
Old Mexico, Jan. 20.

Red Clover with Short Corollas.

Again and again we hear and read of the hope, and trials, to lengthen the tongue of the bee so that the nectar from the corollas of the red clover can be gathered. All admit the fact that red clover is one of the richest honey-plants we have, but all deplore the fact that the corollas are so deep and long that the bee cannot get at the nectar. "If the bee only had a longer tongue!" Yes, or if the corollas of the red clover only were shorter!

It is surely praiseworthy if bee-keepers try to experiment to stretch the tongue of the bee, for the nature of animals is changeable. Look at the different kinds of cattle

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |

BEE-KEEPERS! Let me send you my 64-page Catalog for 1898.

J. M. Jenkins, Wetumpka, Ala.
Please mention Bee Journal when writing.

—some good for milk, some for butter, some for beef. Horses—long legs, short legs. Dogs—long heads, short heads. But not only the nature of animals is changeable, but that of the plants is, too. That's why we have so many kinds, and some times very different kinds of one and the same species. Think of apples, cherries, and the garden stuff.

Now, I think it would be a move in the right direction if we try to find or propagate a variety of red clover that has shorter corollas and of just as good, if not better, qualities than the old one. What a picture for the bee-keeper! Let us try! Gardeners, be up and doing! This is something for you! Man has accomplisht much. Why not this?

(REV.) H. ROHRB.
Rock Co., Wis.

Wintering Nicely—Mild Winter.

Bees are wintering nicely up to date. Those on the summer stands get a flight about twice a week. The winter has been unusually mild. Sweet clover seed that dropt from the stalks last fall is sprouting now, fully a month earlier than other years. Fruit-buds, too, are far advanced; no doubt they will get damaged by frost later on.

JOHN NEBEL & SON.

Montgomery Co., Mo., Feb. 14.

Lack of Pollen Cause of Bee-Paralysis.

According to a German bee-keeper quoted in l'Apiculteur for January, 1898, that mysterious bee-disease called "May-disease," paralysis, etc., is mainly due to scarcity of pollen in the hive. Pollen, he says, being a stronger restorer of lost vitality than even honey, larvae and bees fed with a too meager supply of pollen will be lacking in energy and strength, which will cause the colony to behave as has often been described.

This fact, he goes on to say, would explain why the stronger colonies (short of pollen stores) seem to be more liable to show the symptoms of the malady, and why the malady disappears as soon as pollen becomes abundant.

Bee-paralysis has also been traced to sugar syrup feeding. Very likely the same cause lies at the bottom of such an assumption—absence of pollen in the sugar syrup; hence the advisability of mixing with the feed some substitute for pollen.

Here is a hint for our apicultural experiment stations.

H. DUPRET.

Province of Quebec, Canada.

In Favor of One Big Union.

In the Bee Journal of Jan. 20, under the heading, "The New Union's Membership," the editor asks: "Are you a member? If not, you should join at once, and lend your aid in carrying out the important objects of the new Union." With the editor's permission, I would like to state why I have not renewed my membership. I fail to see the use or benefit of being a member of three separate bee-keepers' organizations, when one could accomplish all the objects desired infinitely better than any number can do separately. If we as bee-keepers mean business, we must get together and present a united front to our enemies. If adulteration and the other evils of which we complain are going to be put down, we must have a strong organization with a fighting man at the head of it. Judging from present conditions, it is not likely that more than a small proportion of those who keep bees will ever become members of any union that may be formed, but we have already material enough to make a strong society, and it is no compliment to our intelligence, as bee-keepers, that it has not been done sooner.

There are two bee-keepers' associations in Minnesota, and many States in the Union have one or more, which, if all united, would be a power that would soon make itself felt for good. Let us quit our petty jealousies, if that is what is keeping us apart, and have only one bee-keepers' union in the United States. Can't the constitu-

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

Or, the Queen-Clipping Device will be sent postpaid for 30 cts. But why not get it as a Premium by the above offer? You can't earn 30 cts. any easier. Almost every bee-keeper will want this Device.

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

tion of the "New Union" be made wide enough to take us all in, without having to pay two membership fees? "Would that some Moses would arise and lead us out of the wilderness." **Wm. RUSSELL.**
 Hennepin Co., Minn.

[All right, Mr. Russell. But suppose you just set a good example of "how to do it," by getting in your own membership fee to the New Union just as quick as you can. Unions become large and powerful by reason of those who join its ranks, and not by people staying out of them.—EDITOR.]

A Beginner's Report.

Last year was my first with bees. In March I bought at a sale 10 colonies, a lot of hives and frames, all costing me \$15.00. I moved the bees the next day, moving about half a mile. A few days after moving, one colony left me. The reason, old bee-keepers tell me, was for want of beebread, as they had none, but plenty of honey. All went well for some time, until in August I found that one old colony had whipt and almost robbed another old colony. I had quite a time with my third new swarm. The first two I hived without any veil; the third became cross; they began to sting, and I got a veil, then I hived them all right. I don't bother them any more without protection, for it swells so on me. I got about 400 pounds of comb honey, and 200 of extracted. I sold the most around home, and I could have sold several hundred pounds more of extracted if I had had it. I increase to 18 colonies, which I have in a good, dry cellar in good condition.

I think every bee-keeper should set out a few turnips for the bees to work on early, for the bees work on them and get lots of pollen before much else is in blossom.

Linn Co., Iowa, Jan. 19. **G. H. FREY.**

Historical Recollections.

My attention is called to the following statement in Dr. Gallup's "Recollections of an Old Bee-Keeper," on page 68:

"Mr. Langstroth had the misfortune to have many agents who did not fairly represent him, and one in particular who cheated him out of a large percentage of his just dues. I had the supreme satisfaction of balking him in at least two of his schemes."

As Dr. Gallup is recording in the Bee Journal historical as well as auto-biographical facts, I, for one, would be pleased to have him state who that agent was, who was so mean and so dishonest as to cheat Father Langstroth "out of a large percentage of his just dues." Of course Dr. Gallup knows who that agent was, because he says he "had the supreme satisfaction of balking him in at least two of his schemes."

I would also be pleased to have the Doctor give the details of the swindle to which he refers, as historical facts, if reliable, are sometimes very important. This matter to which the Doctor refers may be the means of explaining to the readers of the Bee Journal why Father Langstroth, during his life, especially the latter part of it, was so embarrassed financially. So let us have the facts, Doctor, no matter whether the agent you mention be dead or alive.

HONEY and BEESWAX MARKET QUOTATIONS.

Chicago, Ill., Feb. 21.—Fancy white is not plentiful, and sells at 11c.; good No. 1, or grade of that character is abundant, and sells at 7 to 9c.; amber and dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

Much of the comb honey is granulating this season.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Milwaukee, Wis., Jan. 24.—Fancy white 1-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

Cleveland, Ohio, Dec. 15.—Fancy white, 12 to 12½c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 7c.; amber, 4 to 5c. Beeswax, 22 to 25c.

St. Louis, Mo., Feb. 9.—Fancy hite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3½c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Kansas City, Mo., Feb. 19.—Fancy white comb, 1-lbs., 10c.; No. 1, 9 to 10c.; amber, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 5½c.; amber, 4½ to 5c.; dark, 4c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

Cincinnati, Ohio, Feb. 8.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 1-2 to 6c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

San Francisco, Calif., Feb. 2.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 5c.; light amber, 3½ to 4c.; dark tulle, 1½ to 2½c. Beeswax, fair to choice, 22 to 24c.

Buffalo, N. Y., Feb. 11.—Strictly fancy 1-pound combs are in quite good demand from the fact that it has been so scarce and closely cleaned up, and 11c is quite easily obtained. Other grades do not sell much better, possibly a little, ranging from 9 to 6c., as to grade, etc. Extracted ranges from 4 to 6c., and is in light demand. We can recommend shipping strictly fancy and nothing else, unless you cannot do better.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c; light amber, 5c.; white clover and haaswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Minneapolis, Minn., Jan. 31.—Market is in an overcloud condition on comb honey. Good chance for fancy white extracted at 5½ to 6c., but comb is at a standstill, particularly

if other than fancy white. Best price available on fancy white comb is 10½c., and buyers are slow at that. Darker grades or broken lots are unobtainable. If shippers would send in their extracted when it is wanted, and not push undesired comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

CONTRIBUTED ARTICLES

Hive Entrances—Co-operation for Bee-Keepers

BY DR. O. C. MASTIN.

The advantage of large entrances has been referred to in the bee-papers several times lately. A report of my experience the past season may be of value to others.

I began the season with six colonies, in movable-frame hives, the entrances of which were very small—not more than $\frac{3}{8}$ the width of the hives, and about $\frac{1}{8}$ of an inch deep. Having decided to give the Danzenbaker hive a trial, I purchased 11 of them, and as the season advanced, looked anxiously for the appearance of swarms to put into them. But severe frosts destroyed most of the early bloom, and only two swarms came out—one June 5, the other July 9.

High winds throughout the season interfered with their flight, and hot winds during August greatly injured the golden-rod, so that, altogether, the season was a very poor one. Bee-keepers in the neighborhood agreed that it was the worst they had seen here.

Now for results: The swarms were hived on $\frac{1}{2}$ -inch starters of foundation. They built out the combs in the brood-frames nicely, and both swarms had abundant stores for winter in the brood-chamber at the close of the season. The first swarm gave 40 well-filled sections, and 10 partly filled; the other gave 20 filled sections, and 12 partly filled. From the other six colonies I secured 12 filled sections and about 20 partly filled.

I attribute the result largely to the difference in size of entrances, the Danzenbaker being $\frac{1}{2}$ -inch deep, and the full width of the hive. The bees in them never loaf, while at the other hives they hung out by the peck, day after day, when the weather was hot, altho all were well shaded by box-elder trees.

SOMETHING ABOUT CO-OPERATION AMONG BEE-KEEPERS.

I notice some very suggestive items in the American Bee Journal of Dec. 9, 1897. In George W. York's paper (page 770), appears the following:

"It [honey] should be found upon the plain, but neat and wholesome, tables of the *toiling masses*, as well as on the sumptuous boards of the *rich and royal classes*. The price of the article can no longer be urged as a barrier to its universal demand. . . . But how shall honey-producers proceed to create a more general use of their delicious and health-giving sweet, and consequently increase the demand? Education of the public is the great necessity. . . . It is little encouragement to have produced a big crop of beautiful honey, and then find that there is no established market for the same—no organized *co-operative system* through which the large crops can be distributed, or placed upon the market so as to yield the *best financial returns*. It has been discovered, I think, that it will not do to rely wholly upon *commission-men*. . . . Bee-keepers must some day be organized so as to handle and dispose of their honey *themselves*. They can do it. Then good-bye to the flowery-tongued *commission-man*, who is a veritable *leech* upon his fellow-men, and should long ago have been everlastingly retired to the robbers' cave whence he came."

Why are not all profit-takers leeches and robbers? Do they belong to the "*toiling-masses*," or the "*rich and royal classes*?" If some are more greedy than others, their crime is only different in degree, not in kind.

On page 771 (1897) Mr. R. C. Alkin says: "Competition, it is said, is the life of trade, tho in fact it is the death of it."

On page 773 (1897) Mrs. Harrison says:

"There was a wide field open to the ingenuity of our grandmothers. They spun wool, cotton and flax, dyed and wove, cut and made garments [reapt the full result of their toil], but now the inventive genius of man has superseded this with nimble-fingered machinery. . . . Their [the bees] law is like that of the Medes and Persians, which changes not—the greatest good to the greatest number."

On the same page Dr. Miller says: "In the old countries *rates are so low* that bees are sent to new pastures and returned by rail. We cannot do that in this country."

On page 777 Mr. York speaks of "eternally destroying our common foe—the abominable adulterators of earth's

S. N. Black—See page 132.

purest natural sweet." A natural result of competition and the profit-grabbing system. I notice also reports of very low prices for honey in California and elsewhere.

The above items are from some of the brightest lights in bee-culture (and I have been forcibly impressed with the fact, judging from their written articles, that bee-keepers as a class are far from being dull people).

Such remarks are thought-provoking. They show that there are some "screws loose" somewhere. Now, would it not be a good plan to discover just what the cause is, or causes

of the trouble are? The first thing to do in the cure of a disease is to remove the cause; and if the disease were a cancer it would be a poor doctor that would apply poultices as a remedy when it was possible to remove it completely by other means.

The causes are mentioned, and the remedy hinted at in the items quoted. The causes are "leeches," "competition," and "nimble-fingered machinery." The remedy—co-operation.

The leeches are profit-takers of various kinds. Consumers are generally obliged to pay several times as much as the producer receives for his labor, or the products of his labor; the profit-takers get the rest. As the profit-takers are a comparatively small portion of the population, and the producers are also the immense majority of the consumers, it is impossible for them to purchase the equivalent of the products of their labor with what they receive for it. And the profit-takers, being comparatively few in number, are unable to consume the balance. This condition is aggravated by "nimble-fingered" machines, which produce without being consumers; and the usury system, rent, etc., which the "toiling masses," as the great body of consumers, are obliged to support, further lessen their ability to purchase the products of labor. It leads to what demagogues call "over-production."

All classes of producers suffer from the same causes, and you may "educate the public" as to the food values of honey till the crack of doom, and, unless their ability to purchase is increased, the trouble will not be remedied. Immense numbers are thoroughly satisfied as to the food value of roast beef, who are not able to gratify their longing for this staple article of food.

Labor-"saving" machines are here to stay; the only question is, how to make a Christian use of them. (The producers should own and operate them, and divide the product equitably.) For a few to enjoy the products of the work of machinery which formerly went to partly satisfy the needs of human beings, can scarcely be called a Christian (Christlike) act.

"Competition is said to be the life of trade, tho in fact it is the death of it," says Mr. Aikin. "Perzactly." Competition is the opposite to co-operation.

There are estimated to be 300,000 bee-keepers in the United States. Under a competitive "system" (?) of industry necessity will compel a large number of them to dispose of their crop as soon as it is produced, and honey-dealers and commission-men will continue to largely regulate the price. Commercial fruit-growers are generally more "well-to-do," and fewer in numbers, and they can come nearer co-operating in the sale of their products. But why, in suggesting co-operation, should bee-keepers exclude other classes of producers? Not until all producers unite and adopt a system of production and exchange which will largely or altogether eliminate the profit, will they improve present conditions to any considerable extent.

I would urge all who are interested, to procure and help extend the circulation of Edward Bellamy's book, "Equality," recently published. Price, \$1.25. Holt Co., Nebr.

[We can furnish the book referred to above, by Dr. Mastin, upon receipt of the price named.—EDITOR.]

Selling Honey Produced in Frames Holding 4 or 5 Pounds Each, Etc.

BY W. W. M'NEAL.

The pound section, when properly filled with nice, white honey, aside from being so very convenient for retailing purposes, certainly looks temptingly good. But now let me tell how I managed to dispose of several hundred pounds of very nice honey I secured last season in frames holding about four or five pounds.

Well, there was nothing wrong with this honey, more than that there was too much of it to the frame for the grocery trade. I got a number of bright, new tin pans that were just large enough to fit in my regular honey-cases, cross-wise, putting in four to the case. This honey was cut into blocks of something near a pound, so that a given number would fit the pan snugly. The comb was first laid on a framework with a wire covering so that the drippings would run through into a pan placed below. Then each piece was taken and neatly folded in paper, the same that the creamery-men use for their butter. This paper is entirely different from that usually found in the groceries.

Take a cake of this honey in your hand, turn back the corners of the clean, white paper, and take a look at the edge

of the rich, sparkling thing inclosed, and if, it doesn't make you want to lick it, it's all because you haven't got a natural taste.

QUEEN STINGING A WORKER—WORKER-BEE IN A QUEEN-CELL.

Here are two things I witness the past summer: The stinging of a worker-bee by a virgin queen; and a dead worker-bee in a capt queen-cell. The queen was the largest virgin I ever saw, and had been caged two or three days in the hive. When I turned her loose on the comb she seized a worker and quickly stung it to death. But this did not pacify her, for she immediately caught two more, and tho she did not kill these she handled them so roughly that when released they showed plainly they did appreciate her action.

The worker-bee in a queen-cell was evidently due to its having crawled into the cell for a final inspection when it was being constructed, the cell being capt over by others. The young queen was also dead. Scioto Co., Ohio.

Buying High or Low Priced Queens—Which?

BY O. M. DOOLITTLE.

I am led to write a few words on the above subject, because many, apparently, do not seem to understand how to discriminate a long line of buying queens, especially those just entering the enchanted field of apiculture. Why I say "enchanted field" is because many go wild over the pursuit before they are hardly initiated therein, thus causing them to pay out money unwisely (money earned through sweat and toil in other pursuits that is often actually needed in the family), for high-priced queens, when such queens are of little if any more value to them than would be queens costing not over one-fifth as much.

The wonderful traffic which we have of late years in queens, has sprung up for two reasons, the first of which is a desire for the improvement of stock; and the second, the call for queens by those who do not wish to rear their own, but wish queens to keep as a reserve force, ready to use in case of queenless colonies, or in giving to the queenless part of a divided colony, whether divided by the apiarist or by natural swarming.

This latter class have in view only one object, that of procuring fairly-good queens at a minimum cost, expecting no more of them than that they will produce plenty of fairly-good worker-bees to secure the honey which their field supplies, and preside over their colonies as all good queens do.

The first or other class buy queens, or should do so, with a different object in view; that is, they want queens which have other value beyond being fairly-good queens in producing bees for the only purpose of honey-gathering, as they wish them for "breeding purposes," with a view to the improvement of the stock they already have. The greater the improvement which can be obtained by rearing young queens from the one purchased, and crossing them with drones from the bees we already have in our apiaries, the greater the value of the purchased queen; for therein lies nearly all of the extra value there is in a selected imported queen, or one from the apiary of the best breeder in the world, above a queen reared in your own apiary, without painstaking on your part.

Mr. Alley surprised the world a few years ago by telling that he had a queen worth \$100, and others have told us about queens whose bees work on red clover. Still others have spoken of queens of extra value as giving bees with longer tongues, giving bees that were hardy for wintering, bees that capt their combs so as to present a snowy whiteness, etc. But had you askt any of these if they considered there was \$100, \$50, \$25, \$10, or even \$5 worth in such queens to place in a box-hive, or in a frame hive that was workt only for the honey which could be obtained, they would have told you at once that their worth did not consist in the amount of honey the bees from this individual queen would produce, but in the good qualities she possess as a breeder, which good qualities were expected to be perpetuated in her queen offspring, and in this way, when multiplied by 25, 50, 100, 1,000, 10,000 or 50,000 times—just in accord with the number of queens reared from her—would the real value become apparent. No one queen can be worth even five dollars for what extra honey her bees will produce over the ordinary average of queens; hence it comes about that a costly queen should be procured for only one purpose, which is for the improvement of stock. That all do not buy for this purpose is often very apparent. To illustrate:

Two parties in one of the Western States ordered queens of a \$5.00 class, one ordered three, and the other a single queen. Supposing that each knew what he was about the breeder sent on the queens without questioning in the matter.

About a year afterward he received a letter from each, one writing that he had kept the queen that was sent him, in a two-frame nucleus during the breeding season, thus allowing her to lay but few eggs during the breeding season, that her life might be prolonged so as to cover several years, this showing that he was more wise than many of our old queen-breeders, who allow some specially good queens for breeding purposes to wear themselves out in egg-laying in a year or two. He further wrote that he had reared over 500 queens from this mother, and expected to rear thousands before she died of old age, to be used in his own and his neighbors apiaries, as the daughters were the best queens for business of any ever had in that locality. He wrote that he was satisfied that the amount paid for the mother was the best investment he ever made.

The other person wrote that he thought the queen-breeder was unreasonable in charging \$5.00 each for such queens as had been sent him; that he had tested them beside the queens which he already had, and that he could not see that they produced enough honey above what his own queens gave to compensate for the large price he paid for them. Further writing brought out that he had not reared a single queen from either of the three, and as one of them did not seem very prolific, he thought he would not breed from any of them, for he believed that no advantage would come to him from so doing.

Again, a party in Australia ordered four such queens, taking all the risk on the same, and then allowed the only one which reached him alive to die some months afterward without trying to rear a single queen from her.

I might give many other instances of like character, but as they would only illustrate the same thing, it would be only a waste of space and time. If bee-keepers do not purchase queens with the expectation of using them to breed from, then the low-priced queens are just as good as any, and the purchasing of those of the costly grade is simply throwing away their money. "A word to the wise is sufficient."

Onondaga, Co., N. Y.

Bees Moving Eggs—Questions to Think About.

BY D. H. WELCH.

There are some things taught by the masters of bee-lore, and published in our bee-literature, concerning which I think we need better evidence before we accept as true. The bee, "*Apis Mellifica*," is so liable to do unexpected things, that it is easy to make an assertion based on practical observation, that under different conditions will result in work so diverse from the first that one is apt to say, "I don't know," unless we jump to this, that or the other conclusion and rush it off to be printed as the most important discovery of the age. And being so important, it is likely to be copied by other journals and publications, and, after one or two such transcriptions, come to be given as facts taught by Mr. D. or E., or O., or Dr. M. or T.

One of these is the common statement that bees move eggs and larvæ from cell to cell, and possibly from hive to hive. We often read statements regarding the truth of this matter. Of course, positive evidence, if valid, counts for everything. To the entomologist or student of natural history, or even to one who has observed and studied the egg of the bee, it would seem a pretty delicate operation to remove it from one cell and place it in another, much less from one hive into another; nor do we find worker-bees possess of any such delicate, tactile organs, such as we would think requisite to this removal. But the close observer of natural economy constantly comes in contact with so many strange things, that he does not place much stress on any seeming impossibility, surely not in the face of positive evidence that the thing is done. Every day we see examples of egg-carrying insects (ants, for instance)—why not bees?

About five years ago I purchased a number of colonies about June 10. They were in box-hives heavy with brood and honey, therefore not in the best condition for moving, but the neighbor of whom I purchased wanted the "holy terrors" moved away at once. In the transfer a comb was broken loose, so after the hives were placed in position, this comb being full of brood, was placed against the outside of the hive, and a board placed over it, to protect it from sun and rain, thinking that, possibly, the bees would care for the brood and then abandon the comb. They did care for the brood, but did not abandon the comb—instead, it was occupied and used until Sept. 1 for brood, cells being occupied as regularly as if a queen had been in possession. I did not see bees carrying eggs, nor did I see a queen on the comb. I know only the

fact—it was done—but how? The mere assertion of the fact is no proof, and doesn't solve the problem.

Another fact for the masters of the profession to discuss occurred during the season of 1897. A small box-hive colony, presumably crowded, proceeded to build comb under the alighting-board, and it, too, was used as a brood comb throughout the season. Why? How? The closest observation failed to reveal the secret of the mystery.

Harrison Co., Ohio.

A New Self-Hiver, Queen and Drone Trap.

BY GEG. W. WILLIAMS.

[Mr. Williams shows herewith a new and improved drone and queen trap that can be used as a self-hiving arrangement. The illustrations are so plain that perhaps no further description is needed, so we publish herewith the directions which Mr. W. has prepared, and which explain pretty fully the trap and its varied uses.—EDITOR.]

See that the center or cone slide is pushed so that the cones are open, and the door in the end is closed; place the trap and fasten on the hive as shown in Fig. 1. When the swarm issues the bees will pass out through the perforations in the

Fig. 1.

Fig. 1.—Front view when in place; also manner of attaching to the hive.

zinc, but the queen being larger cannot get through, but in trying to get out she will find one of the cone holes and run up into the upper part—she will usually do this by the time the swarm is all out, and can be easily seen up there in front trying to work through the zinc.

Take the trap off the hive, and while holding it in an upright position, reach in behind and close the cones by pushing the tin slide as far as it will go, thus completely caging her. Set the hive you wish to have the swarm in *by the side* of the one they issue from, throwing some old cloth or covering over

Fig. 2.

Fig. 2.—Back view of the trap bottom slide up, and showing cone slide partly slipped over the openings in cones, which, when entirely slipped up shuts off communication from one story to the other; also shows back slide partly drawn out, which, when the trap is in position to receive or have the swarm, opens communication between trap and hive.

the *old* one to hide it from the bees; place the trap *bottom up* on the new hive, draw out the back slide which opens communication with that part of the trap the queen is in and the hive, and—well, the bees will do the rest. As soon as they miss the queen from the swarm, they will return to the hive they issued from, and will find her and go into the hive together—thus hiving themselves.

If it is preferred—as many bee-keepers practice—to move the old hive to a new place and set the new hive on the old stand after the queen is trapped, and while the bees are swarming around hunting for her, set the old hive to one side, and the new one on the old stand, placing the trap on as before. In this plan there is no need of covering the old hive, as it is away from where it was when the bees went out.

Occasionally a swarm will cluster (settle) before they miss

their queen, but if you have her in the trap, fix your hives as before and go about your business; they will break cluster and come back and hive themselves.

After they are hived, if you are afraid they will become dissatisfied and leave—as they sometimes do—leave the trap on as it is; if they undertake to go away they cannot get the queen out, neither can she trap herself for the cones are inverted and closed; when they go to work remove the trap.

When the swarm issues, if it is desirable to use the queen for any other purpose, when she is seen in the upper story remove the trap, close the center slide and take the trap where the bees cannot find it (the swarm will return to the old hive), roll an old cloth around the trap to darken it, and open the little door in the end, holding a wire queen-cage over the hole. The queen will be attracted by the light and run in.

To keep the bees from swarming, put the trap on the hive bottom up, with the cones and end door closed, and with the back slide drawn out. When the swarm issues the queen cannot get out nor trap herself, the bees will miss her and return; this they may do several times, or until the young queen hatches out, when the old queen will usually kill the young one, and the bees will usually tear down all remaining queen-cells, which breaks up the swarming-fever in that colony.

In working it as a non-swarm, the drones that accumulate in the trap should be let out every evening by opening the little door in the end, and they will fly out, and not being able to get back will be found the next morning on the alighting-board, cold and chilled, when they can be raked up and destroyed—a thing much to be desired when we do not want increase. I find this works more satisfactory to me than trying to keep all queen-cells cut out, and requires much less labor.

To simply destroy undesirable drones, set the trap on the hive as for catching the queen; when they come out to take their afternoon flight they cannot go through the zinc, but will find their way into the upper story, and late in the evening or early next morning they can be destroyed. A good way to do this is to immerse trap and all under water for a few minutes.

To stop robbing place the trap on the hive being robbed, and if they have not surrendered they will keep out what few robbers that are bold enough to venture into such close quarters.

Polk Co., Mo.

Ontario Convention and Foul Brood Inspector.

BY EX-PRES. J. K. DARLING.

As this is the season of conventions, I send a few lines about the meeting of the Ontario Bee-Keepers' Association, held in Hamilton, Ont., last December. The weather was very mild, and as there was some rain there was a little mud, but we had to get off the pavement if it gave us much annoyance. Hotel accommodations were good, and we had a good attendance. There were several other meetings held that week at Brantford and Guelph, and still the unanimous verdict was that the Hamilton one was the best convention we have had for years. The papers were good, and the discussions brought out by them must prove very profitable. As the stenographer's report will be published in the Canadian Bee Journal, and perhaps some portions of it in other papers as well, I shall not attempt to give a synopsis at this time.

I would like, however, to notice one little episode, and perhaps in doing so I may correct any erroneous impressions it might have left on the minds of some of those who were present.

A discussion having arisen about the manner in which our efficient inspector of apiaries had managed the business entrusted to him, it was stated by some that he had not "fired" as many colonies as he ought to have done, and the impression was left on the minds of some who were present that the speakers wish it understood that the inspector had not seen that foul-broody apiaries were properly cleaned up. I do not know as that was the impression the speakers wish to make, but that was the way it was understood by some of those present. I wish to say that the facts in the case are just the reverse.

It is rather unfair to strike a man between the eyes when his hands are tied behind his back. Some of those speakers know, or ought to know, that the inspector is gagged, if not by statute he is by order of the association, and yet these insinuations are thrown out when the inspector cannot open his mouth in self-defense, or call on persons who are in a position to testify to his thorough work. At the time this discussion took place, there were nearly a dozen bee-keepers present who could have done so, and one or two did stand up for him, but as a general rule bee-keepers do not want it known that they

ever had foul brood in their yards, especially if they are selling bees or queens.

During the past year I have been in a position to know something of what I am writing about, but like the inspector, I must tell no tales. What I want to say is, that his work is well done; first, by making a success of the curing and building up of apiaries instead of burning, and so put the owners in a position to secure a good crop of honey if it was to be had; second, by getting cases settled in a friendly manner, that might have developed into ugly lawsuits through parties having disposed of colonies that were diseased; and third, by doing this in such a quiet and disinterested manner that no harm would result to the business of either party because of their having their bees diseased, and I have yet to learn of the first case that ever went to court after being placed in his hands.

Mr. McEvoy is in a very difficult position, and if he could please everybody we would expect to find him something more than human. I will make a few quotations to show that I am not the only person who takes this view of the matter. When the Foul Brood Bill was before Parliament, and before any inspector was appointed, the late Allen Pringle wrote: "If we can get a suitable man for inspector, with the whole Province to choose from, we will do well." And as proof that time and circumstances had not changed his opinion of our first choice, he stated at the meeting of the North American, in Toronto, that it would be a "mistake" for those having foul brood in their apiaries not to get the "foul brood inspector" there at once.

Mr. R. F. Holtermann, of the Canadian Bee Journal, in summing up the good, if not the bad, qualities of the various officers of the Ontario Bee-Keepers' Association, in a former number of his journal, said:

"There is no man who has met as many bee-keepers face to face in Ontario as has our foul brood inspector, Mr. McEvoy. There are many men qualified to fill the position of every officer in the Association, but only one man can fill the position of inspector, and that man is Wm. McEvoy."

Once more: When that successful and practical apiarist, J. B. Hall, was president of the Ontario Bee-Keepers' Association, he said:

"I feel that as bee-keepers and as an Association, we are greatly indebted to our representatives in the legislature of Ontario, for their generous and kindly feeling to the apiarists of Ontario, and especially for giving the Province an efficient foul brood inspector, whose services are put at our command. I am also pleased that the bee-keepers throughout the Province, excepting one or two would-be scientists, have cheerfully, willingly, and thoroughly, followed the inspector's instructions, and made a clean job by so doing, now have clean and healthy apiaries, and will be in a position to reap a bountiful harvest, if the Ruler of all causes the nectar to secrete in the flowers."

Mr. Hall knew what he was talking about, for as president of the Association the work of the inspector had to pass under his supervision.

I trust the above is sufficient to correct any false impressions that may have been made by the discussion above referred to.

Ontario, Canada.

S. N. BLACK.

Mr. S. N. Black, of Adams Co., Ill., whose picture we show on the first page this week, is one of the oldest bee-keepers we know, hence we are pleased to be permitted to show his honest face, and give a few facts regarding his busy life, in the American Bee Journal. Here is what he has to say:

I have a shadowy recollection of coming from Tennessee to this place a little over 64 years ago. The country at that time was nearly a wilderness. Our nearest neighbor was a Presbyterian preacher, and lookt enough like Father Langstroth to have been his brother, and, like him, was well posted

In bee-keeping. His yard was filled with "bee-gums," as they were then called.

Very soon I was installed as chief assistant in the beeyard, taught how to find the queen and to clip the wing to keep the bees from leaving; that I must not clip the wing of a virgin queen, etc. When I was perhaps seven years old I was running a threshing machine—I was riding one horse and leading two more, treading out oats, the fastest we had of threshing grain! A swarm of bees past, and I left my "threshing" and followed the bees till they settled. I got a "gum" and hived them, and I have owned bees from that day till this, and possibly I have their descendants now.

I had never seen a moth. They had not made their appearance yet, and how horror-stricken I was when I found my pet "gum" that had swarmed four times, one solid mass of worms! I thought if the moth could kill one "gum" they could kill all; but my teacher told me the bees were doubtless queenless, and if I kept the bees strong and lookt after them a little there was not much danger.

I took care of my father's and my own bees till 1855, when I found my "queen-bee" in Miss Sallie E. Crippen. Following the custom, I "swarmed," and set up a new apiary. The old way to get honey was to kill the bees as soon as the frost killed the flowers, but I never killed any bees. I had the tops of the "gums" so they could be taken off, and the honey taken out, often cutting out the top several times in a season, and I dare not tell how much honey I have taken in one season from one colony, spring count—and I am ashamed to tell how little some seasons!

I think it was about 1857, while working with the bees, a man drove up with a movable-comb hive, and as I did not buy at once, he made me a present of a "right," if I would buy or make a hive. I used King's for awhile, then adopted the Langstroth 9-frame. Like many others, I "invented" (?) hives of my own, and very nearly struck a good thing in making the hive taller and using two small frames in the top for surplus honey, getting near the section of later days.

The seasons here have been very irregular—some extra good, others equally poor, with the poor seasons in the majority. Three good seasons left me with over 100 colonies of bees, and enough money in pocket to induce me to give the bees more attention; but the extra-poor seasons came on—one, two, three, four and five, all together—and I about decided that this was a good place to "not keep bees," so I gave away bees, and some died, till last spring I had 8 weak colonies. Late in the spring came warm showers, and such breeding of bees I never saw—every comb was full of young bees, even to the outside, and last fall I had 30 strong colonies and 400 pounds of honey.

Twenty-five years ago nearly every farmer had bees; today I know of four or five persons with bees within four miles of me. The moth is very scarce now. I think they must fly quite a distance, for when bees were plenty within one and two miles, any comb left exposed was soon filled with worms; but comb left out last summer was not molested.

In the many years' experience I think I have gathered a great deal of wisdom, especially in the line of what I don't know—in fact, I think I surpass Dr. Miller in *not knowing*.

S. N. BLACK.

Success is the title of the finest monthly magazine of inspiration, encouragement, progress and self-help for young people that is published to-day. The price is \$1.00 a year. We can club it with the Bee Journal, both together for \$1.80. If you wish to see a sample copy of Success before subscribing, send 10 cents to The Success Co., Cooper Union, New York, N. Y., asking that a late copy be mailed you. We hope to receive a large number of subscriptions for Success. You can't do a better thing than to order it for a year as a gift to some young person of your acquaintance. We have examined the magazine carefully, and know whereof we speak.

A New Binder for holding a year's numbers of the American Bee Journal, we propose to mail, postpaid, to every subscriber who sends us 20 cents. It is called "The Wood Binder," is patented, and is an entirely new and very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See offers on page 91.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 118.)

SECOND DAY—FORENOON SESSION.

The convention was called to order by Pres. Miller at 9:30 o'clock, and the first question taken up read as follows:

BEST BEES FOR HONEY AND PREMIUMS.

"What class of bees are the best honey-gatherers, or premium-takers at our fairs?"

Mr. Whitcomb—Having been in charge of the apiarian department of Nebraska the past 14 years, I have taken pains to follow this matter up pretty thoroughly. We offer in that State a premium for the largest amount of honey stored by a colony during a year, \$25, \$15, \$10, and \$5, making four premiums. This is verified under oath, showing how the colony was wintered, what kind of a colony it was, how it was built up, what the bees were, etc., and then a detailed account of the amount of honey taken. These, together with the premiums awarded on comb honey, etc., I have followed up, and I find that in 99 cases out of 100 they have been taken by the hybrid bees. We talk Italians in our apiaries and at home all the year round, and then when we go to our State fairs we find that the mixt blood has taken off the premium, producing the better honey, storing more of it, etc. These matters are really significant. While the Italian bee is nicer to handle, is less easily alarmed, etc., and less pugnacious, at the same time we find that something else is doing the work everywhere. At every turn we run across the hybrid bee.

Pres. Miller—Would you advise, then, Mr. Whitcomb, that we should try to keep none but hybrids?

Mr. Whitcomb—No, sir. I think that we must have Italians in order to get the good hybrids, that we must keep mixing. If you let them run into hybrids, they will run out, and get to be a small bee. I find no more trouble in handling the hybrid bee than I do the Italian, only I find I need to take a little more time for it.

Pres. Miller—Don't you think that the man who tries to keep up Italian blood will have all the hybrids he wants?

Mr. Whitcomb—Yes, sir.

Pres. Miller—Isn't this true, too—you say that 99 out of every 100 of the colonies are hybrids—

Mr. Whitcomb—99 per cent. of the premiums are taken by hybrid colonies.

Pres. Miller—Isn't it true that the hybrids so far outnumber the pure stock, that we ought to expect them to take a larger number of premiums?

Mr. Whitcomb—With me they don't. In the 30 I have, but two colonies are hybrids.

Pres. Miller—I am not talking about you, but about bee-keepers in general.

Mr. Whitcomb—Among farmers and small bee-keepers you find more hybrids than anything else. In Pennsylvania this fall I found no pure Italians—what might be called pure Italians—and I found them so cross that they would come out in the road, before I got to the apiary, and meet me.

Mr. Thompson—From your experience, do you get more honey from your hybrids than from your Italians?

Mr. Whitcomb—Yes, sir; I get more honey, and a more salable quality.

Mr. Green—I wouldn't agree entirely with Mr. Whitcomb. While I would admit that the hybrids are generally very good workers, indeed, the largest yields I have ever had were from pure Italians.

Mr. Baxter—It depends on what you mean by quality. If you are talking of comb honey, why, there might be the possibility that the comb honey produced by the bright black bee looks a little nicer than the honey produced by the Italian, but when you come to the quality of the honey, I beg to differ there. The quality of the honey produced by the Italian, if anything, is better than that produced by the black bee. That is, the honey itself. The reason it looks better is, that the

Italian puts the capping right close to the honey, and it has the color of the honey, while the black leaves an air-space between, and it looks whiter. I have been buying bees for 20 years, and experimenting with them. I have received queens direct from Italy, and from the Isle of Cyprus, have tried different strains in this country, and I make it a rule to breed up my bees, and I can say, beyond any chance of being contradicted, that the pure Italian is the best honey-gatherer; and I don't breed for size, either. I have some large bees that are not worth anything, and I have some little bits of things that will gather more honey than any large bees I ever saw. I look for the most gentle bees—bees that I can take up in the frames and carry into the house and not a bee move, and I have done it very often without a veil. The pure Italian bee you can hardly alarm, while a black bee, the blacker it is the more fussy it is. That is an experience everybody finds. In the fall of the year, after a right dry season—like this fall, for instance—I go to a hive, look in front, and I will say, "Hello, these look pretty black; I will bet they have no bouey." Open the hive, and sure enough, they have hardly any honey. It is scattered all through the hive. There isn't a frame that is full half way down to the bottom. Go to the next hive, and—"These are pretty quiet, they look pretty nice." Open the hive, and it is a fact, I can tell almost by looking at the front what the inside of the hive will be. Year after year my experience is, that we should do away with the hybrids as much as possible; get your stock as pure as you can. I don't care how much you work with them, there will be hybrids all the time. I will have a nice Italian colony here to-day, and probably two years from now it will be almost black. I say, take pure Italians, the purer the better, every time.

Dr. Besse—My experience is that the full-blooded Italians are very pleasant to work with. Almost all of mine are full-blooded Italians. I have some hybrids, and I must say that they build whiter honey, when it is first finished up, than the others, but if you keep it a few months the cappings will settle down on the honey, and then you can see no difference at all; that is, if you keep it in a warm temperature, the cappings will soon settle down and leave it the same color that the Italian honey is. But when it is first taken out it is beautiful. I have four or five colonies that are almost black, and I must say I took from them this year the handsomest honey I ever saw. It was almost as white as snow; but I noticed, before I left home, that what I had not sold was changing and getting darker in color. I think the black bees store just as good honey as the Italians. And I must say this, that I got from a hybrid colony more honey than I ever did before from any colony, altho at least $\frac{1}{2}$ of my bees are full-blooded Italians. The Italians are much pleasanter to handle, but I think if you will smoke the black bees enough you can conquer them. I have blacks you can handle without any smoker at all. I never use a bee-veil, and it is very seldom I get stung. But, in order to be safe, I generally give them a little puff of smoke before I go to work.

Mr. Thompson—Which give you the most honey?

Dr. Besse—The most I ever got was from hybrids. The most I got this year was from hybrids. I took from one colony of hybrids 224 one-pound sections, all well filled, and the whitest honey I ever saw.

Mr. Thompson—It must have been a stronger colony than the others.

Dr. Besse—A stronger colony, and they didn't swarm. I kept piling on the section-boxes. May be others, if I had watcht them as closely, would have done as well. But they got a start.

Mr. Baxter—I would ask if Dr. Besse has noticed that Italians will travel much farther for stores than the blacks.

Dr. Besse—I think they will. I would see them further from home. I don't know about the black bees. I don't keep many blacks. My opinion is, from what I have heard and read, that the Italians will go farther than the blacks will.

Mr. Baxter related an instance which led him to believe that the Italians traveled farther than the blacks.

Mr. Baldrige—I understood Mr. Baxter to say that the blacks cap their honey so that it looks whiter right over the honey. Is it true that all black bees do that?

Mr. Baxter—That has been my observation. I don't know whether it is generally so.

Mr. Baldrige—That is not my experience. I think I have seen lots and lots of honey that was capt by the Italians almost as nicely as the blacks. The Oatmans changed their bees to Cyprians the time that idea was prevailing, and they had a serious loss in the sale of their honey. They told me they lost one or more cents a pound, and they got rid of that blood as fast as they could.

Mr. Green—This matter of the quality or, rather, the appearance of the honey, is a very serious matter. But I will

agree with Mr. Baldrige, that it is not all strains of Italians that will produce this watery-looking honey. Pure black bees will cap their honey so that it has a chalky-white appearance, and that continues with some of the darker hybrids, but we can get the pure Italians that will cap honey almost the same as the black bees, not to that chalky-whiteness, but practically just as nice. There are only a few strains of Italians, and possibly none of the pure Italians, but those mixt with Cyprians and Syrians, that put the capping down on the honey and make this watery appearance. I had a strain of bees I had neglected breeding up for several years, and they got badly mixt, but they produced practically just as nice honey as the black bees. They were originally from Dojittle's strain. There are other breeders in the country that have the same strain, and they can be obtained, or almost any body, I think, could breed it up.

Pres. Miller—Doesn't the flower that the honey is gathered from have considerable to do with that watery-appearance of the honey?

Mr. Thompson—No.

Pres. Miller—It may have something to do with it, but then the watery-appearance depends mainly on the fullness of the cell, and the different bees make that. I may say that I hear and read with some degree of surprise, the so commonly exprest opinion, that the Italians make so much darker combs than the others. It comes from so many quarters I can't dispute it, and yet thousands and thousands of pounds of honey I have produced, with pure Italians and hybrids of all sorts, and I have never had that fault to lay at the door of the Italians. I don't think they are all alike. I believe, if you are trying to keep pure Italian stock, you will have fresh crosses all the time; and the more distinct the cross, perhaps the better will be the result. I think the best workers I have had within the past two years are of that much despised stock, the Punic; and this is because, I think, there was a very distinct cross—they were not the pure stock. But they're bad about gluing. If you want to sell propolis, get Punic bees.

Mr. Baxter—I believe you practice moving your bees around to different yards, do you not?

Pres. Miller—Yes, I take them out in the spring, and back in the fall.

Mr. Baxter—Have you ever noticed that that makes a big difference in the amount of honey produced?

Pres. Miller—Decidedly.

Mr. Baxter—I move an apiary to a certain place, and that apiary will produce more honey than the same amount of bees elsewhere. It isn't always in the bees alone. There are other things to take into consideration.

Pres. Miller—I have supposed that it was the pasturage.

Mr. Baxter—I can't account for it in that way.

Pres. Miller—I can hardly believe that the moving itself would do it, because that is simply the shaking up. If that would do it, all that you would need to do would be to go and kick all of your hives.

Mr. Baxter—I don't know but what that would be a good idea.

Mr. Baldrige—Do not bees get in the habit, if permanently located, of going certain directions, and continuing to go in certain directions, whereas, if moved to a new location, they have to hunt their pasturage more, and find a greater variety of pasturage? Don't they follow each other, to a great extent, in the old locations, and neglect some fields that may be within reach of them?

Dr. Besse—My experience is, they find forage wherever it is close by. Mr. Baxter says the Italians store richer and better honey than the hybrids. I think the reason is, they work very industriously on the common red clover, and you won't see the hybrids or black bees working on the red clover at all; and the red clover makes very fine honey, a rich-flavored honey, and a little darker than the other grade of honey.

[Continued next week.]

Report of the Maryland Bee-Convention.

BY W. J. VALENTINE.

The bee-keepers met in Hagerstown, Md., to organize a bee-keepers' association. The meeting was called to order by S. Valentine, who was elected chairman of the meeting, and W. J. Valentine was elected Recording Secretary.

S. Valentine stated the object of the meeting. In his opinion the time had come for the bee-keepers to have a union as much as any other industry; that apiculture is no longer a secondary business, but that it had grown to be a industry of itself; that bee-keeping of to-day is not what it was 50 or 25 years ago; apiculture had developed into a science. He who expects to be a successful bee-keeper must

become familiar with the habits of the bees, and work his ap-
 ary scientifically, thus the necessity of a union that we may
 exchange opinions and further the cause of bee-culture, and
 to add to our mutual benefits.

It was also stated that the product of the honey-bee has
 been shamefully abused by adulteration, at the expense of the
 apiarist, and needs protection by legislation as much as any
 other industry.

It was decided to organize temporarily at present, and defer
 the permanent organization until the next meeting, and
 then draft a constitution and by-laws.

A committee was appointed to confer in regard to the
 adulteration of honey, composed of Chas. H. Lake and L. A.
 Hammond.

The convention meets again in Hagerstown, March 8,
 1898, for the purpose of organizing permanently.

Chas. H. Lake, of the Maryland Agricultural College, was
 requested to prepare a paper on "Adulteration of Honey," to
 be read at the next meeting. W. J. VALENTINE, Sec.

Borage for Smoker-Fuel.—Borage is an excellent honey-
 plant, and it is recommended, in *Le Rucher Belge*, to dry its
 leaves, which contain much nitre, and mix them with rags to
 burn in the smoker.

The Finest Honey in the World has been discovered.
 According to an item in the *Pacific Bee Journal*, it is found in
 the Carbiere mountains of Madagascar. But somehow a dim
 recollection comes up that the finest honey in the world has
 been located in sundry other places.

Mixt.—N. Genn has no entrance in hive or floor-board,
 but raises his hives on lath. A man asks, in *Gleanings*, how
 Genn does in winter? The editor replies that Dr. Miller uses
 a reversible bottom-board, and heads the item, "Hiving
 Swarms on Poles." And his father is such a strong temperance
 man!

The Life of a Worker-Bee is about 45 days of actual
 working time, or about 80 days from the time the egg is laid
 until the bee has died from overwork, if there has been a flow
 of nectar.—Geo. W. Williams, in *Progressive Bee-Keeper*.—
 Maybe Doolittle better let up on Aikin for awhile, and
 straighten this out.

Reversing Sections in the Super, for the sake of having
 them finish to the bottom-bar, seems to have died out. R. C.
 Aikin says, in *Progressive Bee-Keeper*, the plan was a failure
 with him, because some sections would not be far enough
 advanced for the comb to stand alone on its head, while other
 sections were already completed.

Doesn't Like the Fence.—Editor Leahy, of the *Pro-
 gressive Bee-Keeper*, thinks fence separators are not durable,
 too many sharp corners to get knocked off, plain sections will
 look too much like something with its ears cut off, and bees
 won't make any even work than in the old section. But he
 hopes they'll be a success, as they can be sold cheaper.

Honey the Cheapest Bee-Food.—A writer in the *British
 Bee Journal* says: Years ago we bee-keepers used to turn all
 the honey into money we possibly could, and any deficiency in
 winter stores was made up with sugar-syrup. This was
 thought to be a good stroke of business; but I for one have
 lived to learn that honey is not only the best, but all things
 counted, by far the cheapest bee-food.

Hauling Bees to the Bean-Fields in California is not
 such a little business. M. H. Mendleson tells, in *Gleanings*,
 about using a six-ton set of springs, and driving with a 24-
 mule team over roads with curves so short the driver couldn't
 see the leaders—"this, too, on one of the most dangerous
 passes, where the least bad driving out of the track would land
 all hundreds of feet down, none living to tell the story." In
 six days from landing in the bean-fields, he has generally had
 his hives filled with honey and the queens crowded.

Bees Breaking Rules.—It having been fairly well settled
 that bees do not thin the base of foundation, L. L. Skaggs
 comes forward in *Southland Queen* and says he has a hundred
 combs in which the base is thinner than the base of the foun-
 dation given. He also has known bees to seal queen-cells when
 the larvæ were not over two days old, and says: "I have torn
 them open and the bees have fed them for several days and
 sealed them again, and it hatch out a good queen; so it is
 with all fixt rules with bees—they delight in breaking them."

Virgin Queen with Prime Swarm.—Editor Lehzen says
 when a prime swarm is delayed by unfavorable weather until
 a young queen is piping in a cell, the swarm is sure to issue on
 the advent of fine weather, the young queen slips out of the
 cell in the confusion, and accompanies the swarm. Usually in
 such case the laying queen is stung, and the colony not being
 satisfied with the virgin queen, returns to the hive. In a few
 days the prime swarm issues with the young queen. He had
 one case the past season when seven young queens issued with
 a prime swarm!

Eggs that Would'n't Hatch.—To the few instances of
 eggs not hatching is added another reported in *Southland
 Queen*, by J. S. Worley. Eggs were placed by the queen in
 the cells, food sometimes placed around the eggs, but in a few
 days all would be cleaned out. A frame of brood in all stages
 was given from another hive, and this was taken care of all
 right. A frame of the defective eggs was given to another
 colony, which gave food to the eggs, but they would not hatch.
 The queen was kept a month, but in that time not more than
 half a dozen cells were capt.

May Sickness—a trouble of bees in Europe, and thought
 by some to be the same as bee-paralysis—has at least this in
 common with the American disease, that neither its cause nor
 its cure is well understood. Of late, in different quarters, the
 lack of pollen has been assigned as the cause of the disease.
 M. Bertrand, editor *Revue Internationale*, thinks that if pol-
 len figures at all in the case, it is rather because of the bad
 quality than of its entire absence. The few cases that he has
 noticed in his four apiaries could not certainly be due to pen-
 ury in that respect, as pollen was plenty and in excess.

Honey-Tea.—Julius Steigel relates in *Bienen-Vater* that
 he used to smile when he read of Pastor Kneipp's patients
 taking a glass of honey-tea after each noon-day meal, and now
 he does the same thing himself, only he takes his before break-
 fast. Bronchitis had become so bad he couldn't speak above
 a whisper. Used up his means doctoring, tried all sorts of
 remedies, finally tried a teaspoonful of honey in half cup warm
 water in the morning. Little by little he improved till no trace
 of the disease remained. But he continues the daily practice
 of the morning allowance to the benefit of his digestive as well
 as breathing apparatus.

Plain Sections made from Old-Style have been put up
 by the ton by J. E. Crane, and his plan will, no doubt, com-
 mend itself to many. He has arranged an arbor for a saw-
 table so he can put on two saws 19-16 inches apart, and
 coming up just 1/8 inch above the table. He runs the four sides
 of the sections through, and the edges are left clean and
 white, much neater than by hand scraping. Thinks a strong
 man could saw down as many in a day as he would clean of
 propolis, perhaps more. The sections look undeniably neater,
 and while he has received no higher price, his honey has sold
more promptly, which on a falling market might amount to a
 cent a pound.—Review.

No-Wall Foundation.—While many have been experi-
 menting with drawn foundation with its high walls, Michigan
 bee-keepers have been experimenting with foundation having
 no walls, members of the State Association having had a mill
 made producing an article without any walls whatever, run-
 ning 16 square feet to the pound. The editor of the *Review*,
 after seeing samples from Mr. Bingham, who produced a nice
 little crop in 1897, using no-wall foundation exclusively,
 thinks it worthy of a most thorough trial. L. A. Aspinwall,
 after using 3 or 4 pounds of the foundation, reports very
 favorably in *Review*. He says it requires an expert to detect
 any difference between the finish product and the natural
 comb. He thinks it possible that in a poorer season results
 might not be so satisfactory. The tendency to warp he con-
 siders quite an objection, but thinks it may be overcome by
 fastening the foundation on three sides. On the other hand,
 Mr. Bingham had no trouble of this kind, as is plainly shown
 by a beautiful picture showing 13 of the unfinished sections.

OLDEST BEE PAPER
-IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan Street, CHICAGO, ILL.

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1 00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

MARCH 3, 1898.

NO. 9.

(NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Much Excellent Reading-Matter now in our hands must wait its turn for insertion. It seems to us we never had such an abundance of good contributions and of such varied character. Especially is this true of matter for the departments of "Questions and Answers," "General Items," and "Convention Proceedings." Of the latter we have reports of these meetings: Colorado, Michigan, Vermont, Wisconsin, Central Texas, and the Northeastern Ohio, Western New York, and Northwestern Pennsylvania, besides the balance of the Northwestern's report, which is now appearing in weekly installments.

We trust no one will get impatient with us, for we are doing the very best we can to crowd in reading-matter as fast as possible. We would like to add extra pages for awhile, in order to get caught up, but to do so would cost more than we can afford at the price the Bee Journal is published weekly. But we really believe that we could fill, with good reading matter, a 32-page paper the size of these pages, and not half try. Perhaps some day we can reach that. In the meantime, please don't be too hard on us if we fail to print your contributions as promptly as you think we should.

Bees Taxable in Iowa.—Hon. Eugene Secor, of Forest City, Iowa, the General Manager of the United States Bee-Keepers' Union, has kindly sent us the following regarding the taxing of bees in the State where he resides:

For the benefit of Iowa bee-keepers who may not happen to be informed on the subject, allow me to say that under the present law bees are taxable in excess of 10 colonies.

Heretofore bees have not been taxable in this State. The change in the law may be a bit of news to some. I have already received personal enquiries from friends in regard to it, hence this statement.

It can no longer be said that bee-keepers in Iowa are enjoying special privileges. EUGENE SECOR.

The New Union Delegates to the Pure Food and Drug Congress, now in session in Washington, D. C., are General Manager Eugene Secor, Rev. Emerson T. Abbott, a member of the Union's Board of Directors, and Secretary Dr. A. B. Mason. Mr. F. Danzenbaker was selected as an alternate, so that if, at the last moment, any one of the regular delegates were unable to attend, he would be right there on the ground to step into the work.

We feel that the United States Bee-Keepers' Union will be ably represented, and that the whole bee-keeping industry will thus have their wants made known in an effective manner.

We shall look for some interesting reports from the New Union delegates upon their return from Washington. We trust that the work done by this congress may result in great good to producers of pure honey, as well as to all other industries that are so vitally interested in the enactment and enforcement of a rigid national pure food law.

We do not know who are the delegates from the National Bee-Keepers' Union, but we presume they were duly appointed, and are in attendance upon the sessions of the pure food congress.

The National Bee-Keepers' Union election of officers held in January, resulted in the practically unanimous re-election of the following who have for years managed its affairs:

President—Hon. R. L. Taylor; Vice-Presidents—G. M. Doolittle, Dr. C. C. Miller, Prof. A. J. Cook, Hon. Eugene Secor, and A. I. Root.

General Manager, Secretary and Treasurer—Thomas G. Newman.

There were 129 votes cast, out of a membership of about 300.

General Manager Newman, when announcing the results of the election, said that some who were elected "state that their time is too much occupied with other duties to fill the office for 1898; this, however, is the business of the Advisory Board to attend to, as well as to fill vacancies, should any occur." We do not know who have declined to serve, but doubtless they will be known when their successors are named.

Bee-Keepers' Rights in Germany.—At Weinhelm, Germany, there is a patent-leather factory, whose skins when spread out were covered with spots supposed to be dropt by the passing over of bees from a neighboring apiary. Suit was brought to have the bees removed. It was not proven that the bees were the culprits, and, besides, bee-culture was necessary for the sake of fertilizing fruit. If this case should go against the bees, numerous other factories would follow suit, and bee-culture as well as fruit-culture suffer great damage. Fruit-culture was in Weinhelm before the leather factory, and in this case the weak must be protected against the strong. The case was dismissed.

Subscribers Criticising the Bee-Papers.—Editor Hutchinson made a call for the views of his readers as to the Bee-Keepers' Review, asking them freely to mention faults as well as merits. As was natural, few of them mentioned faults (unless it were the faults of rival bee-papers), but a collection of extracts from the letters makes very interesting reading. One man is brave enough to say he doesn't like to see advertisements of a free bottle of medicine, awakening a desire for more at a high price, because of the temporary effect of the alcohol in it. Another thinks it would be an improvement if the writers would limber up as if talking to their fellows, instead of being so very staid with the burden of their dignity and responsibility. It might be a good thing for the writers of the American Bee Journal to take to heart this last criticism. The man that has a good idea, and can

tell it in the plainest language, just as if talking quietly with a friend, is the writer who will be read with the most pleasure and profit.

We have often invited our own readers to feel free to criticize the American Bee Journal, and whenever they think they have a suggestion that they believe might help in improving it, to feel free to send it to us. We are not perfect, by any means—neither is the Bee Journal—but we are endeavoring to give as good a bee-paper as we can for the money we have to expend upon it. Of course it is not, by a long ways, up to our ideal of what a perfect bee-paper should be, but just give us about 10,000 regular, prompt-paying subscribers, and we will begin to show you a bee-paper something like the one we have in mind. This "Barkis is willin'" to do his part as soon as the bee-keepers of this country will give him the opportunity. Until then, the Bee Journal will be made just as good as we can make it under existing circumstances.

Wisconsin Farmers' Institutes.—Mr. N. E. France, Wisconsin's Foul Brood Inspector, has sent us a copy of the 300-page Bulletin No. 11, or "Wisconsin Farmers' Institutes," edited by Supt. George McKerrow; 60,000 copies are published. It contains an article on "Keeping Bees for Profit," by Mr. Jacob Huffman, and "Foul Brood Among Wisconsin Bees," by Mr. France. Very good pictures of Messrs. Huffman and France appear in connection with their contributions.

In Mr. France's article we find a report that he was enabled to make in connection with his work in 1896 in Wisconsin. It shows 51,709 colonies of bees, valued at \$258,545; 2,585,450 pounds of honey sold for \$180,981; and beeswax and queens to the value of \$9,500, making a grand total of nearly half a million dollars. If all the figures were known for the whole State, it would total nearer one million dollars, we believe.

We do not know how the book referred to is to be circulated, but by addressing Supt. Geo. McKerrow, Madison, Wis., no doubt a copy can be secured.

Honey Snow-Cream.—Mr. C. J. Baldridge, of New York, thinks the following combination is superior to ordinary ice-cream:

One cup rich sweet cream; $\frac{1}{2}$ cup extracted honey of decided flavor; mix and cool thoroughly, then stir in fresh, light, feathery snow till it crumbles, and serve at once. This will be enough for four good dishes.—Gleanings.

Better not wait until next summer to try the above—it's wholly a *winter* dish, apparently.

Mr. ALBERT UNTERKICHER, of Riverside Co., Calif., writing Feb. 12, says:

"The outlook at this writing for a crop of honey for 1898 is very thin for California, unless we get abundant rains."

Mr. GEO. WALKER, of Ontario Canada, says of our pamphlet, "Honey as Food:" "It is the best little thing I have seen in years. I am sure it will sell the honey." Better send us 50 cents and get a trial lot of 50. Every family ought to read it.

Mr. A. P. REED, of Merced Co., Calif., sends the following testimony concerning the American Bee Journal:

"I enjoy reading the Bee Journal very much. Its weekly visits are looked forward to with fond anticipation, and I am always realizing—have not yet been disappointed."

KEEPING THE HONEY DEMAND SUPPLIED, after once working it up, should be the constant endeavor of every bee-keeper. Of course your own crop will run out—perhaps it did long ago. Then, why not buy honey to furnish your customers, and not compel them to wait until another season? We have a large quantity of both pure extracted alfalfa clover honey and basswood, the former in 60-pound cans, and the latter in small barrels holding 280 pounds net. Quite a number of bee-keepers in various parts of the country have had honey from us, and say it gives most excellent satisfaction. One-barrel orders of the basswood, or 4 cans of the alfalfa, we ship f. o. b. Chicago at 6 cents per pound. Or for 8 cents in stamps we will mail you a small sample first. Get a trial shipment, and see how it goes. You should be able to make good wages at selling honey from now until next summer, as the canned fruits and other things put up last fall by the thrifty housewives will be running short now, and they will be more likely to want honey to take the place of fruits, etc.

Mr. FRANCIS DANZENBAKER, Editor Root says in Gleanings, "is one of the most progressive bee-keepers he ever met." In proof of the statement Mr. Root acknowledges that to Mr. Danzenbaker belongs the credit of a number of the apian improvements in recent years. He says:

"I believe in giving credit where credit is due, and I will say that Mr. Danzenbaker was the first one to show us the advantage of the dovetailed or lock corner; improved construction in hive-covers; improved construction in bottom-boards; the D. case—this letter D. simply representing Danzenbaker; improved method of crating hives; and last, but not least, directly and indirectly the advantages of fences and plain sections."

That sounds pretty good for Mr. Danzenbaker, and yet, just think of the blame that will be given him for causing so many changes in apian fixtures! Changes cost money to every bee-keeper who indulges.

Mrs. A. J. BARBER, of Montezuma Co., Colo., when sending us her renewal subscription, also included with it a dollar for her membership fee in the United States Bee-Keepers' Union, and also one dollar for the Langstroth monument fund. Regarding this fund, Mrs. Barber said:

"I think if we bee-keepers don't raise at least \$200 for the monument, we are an ungrateful set, and I shall feel ashamed of our selfishness."

Just so. Bee-keepers should do the generous and just thing to the memory of the lamented Father Langstroth. We hope that due gratitude will be shown in the erection of a monument that will reflect credit upon the living, and be a proper mark of honor to the dead.

THE MONTREAL WITNESS is one of the strong kind of weekly newspapers. Its principles and convictions are not for sale. Here is what one of the best Canadian religious weeklies thinks of the Witness:

"Nowhere, we think, is there a press of higher moral tone than that of our beloved country. It possesses, we think, the unique distinction of having a leading journal in its largest city which for over 50 years has been a moral crusader, a champion of reform. In all that time it has not published one liquor, or tobacco, or theatrical advertisement. At the sacrifice of much money it has stood true to its high principle, and stands foursquare, a tower of strength, against all the winds that blow."

Mr. H. E. HILL, of Pennsylvania and Florida, has been engaged to edit the American Bee-Keeper, beginning with the February number. For a year or so back that paper has been running some 16 pages (or half of its contents) in "plate matter," composed of a miscellaneous assortment of short stories, anecdotes, etc. This is all omitted now, and the size reduced to 16 pages, filled with strictly bee-reading. Quite an improvement. We hope Mr. Hill will not find that he has undertaken an "up-Hill" job.

Mr. W. R. GRAHAM, of Hunt Co., Tex., wrote as follows] Jan. 31:

"I have been taking the American Bee Journal regularly for over 20 years, and am not tired of it yet. It is always a welcome visitor. I have been a bee-keeper from boyhood, and am now over 70 years old. I have been learning all the time—not all learned yet."

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

A Case of Ignorance.

O. O. Poppleton says (page 92) that I was wrong in thinking that one glass in a wax extractor would make as hot work as two. That shows he can tell a good deal better by trying a thing than I can by guessing at it.

Edwin Bevins is troubled to understand (page 83) why I should misunderstand "Iowa" (page 39), and thinks there was an open space between the brood-frames and the cushions. The guess Mr. Bevins makes as to what misled me is partly correct, but not the whole of it. The "empty supers" mentioned had something to do with it, and also the fear that the bees might starve. It didn't occur to me that any one would think of bees starving right on top of sealed combs.

I'm much obliged to these good friends for correcting me, and glad to know such sharp eyes are upon me, for many is the time when answering so many questions that a fear comes over me lest I may mislead in my answers. I'm not sure, however, that some of the rest of you wouldn't make mistakes both in understanding and answering if you were in my place. Questions of so many different kinds, sometimes needing answer when I've hardly time to study over them; sometimes spelt in such way that it is a serious problem to make anything out of them (for example, "woushe" in a letter this week meant "wish"); sometimes spelling all correct but writing so illegible that I can't tell what the spelling is; sometimes having an overstock of ignorance on the subject inquired about—say, friends, if you'd spell me a spell you'd wonder I don't get more things twisted.

C. C. MILLER.

Leaving Bees Packed till Putting on Sections— Workers Going with the Queen when Mating.

1. Will it be right to leave my bees all packed as in winter, on the summer stands, leaving all the packing till time to put on sections? The hives are 8 to 10 inches apart. Most of them are as they were in the fall.

2. Do any worker-bees accompany the queen when she goes on her wedding-tour? They are never quiet till she comes home to the hive.

IOWA.

ANSWERS—1. Yes, providing they are well supplied with stores.
2. I don't know. Perhaps they do.

Telling from Which Hive a Swarm Issued.

Suppose I have 30 colonies of bees, and I go out some day and find a swarm clustered on a tree. How am I to tell from which colonies it issued?

NOVA SCOTIA.

ANSWER—The nicest way is to have the wings of the queen clipped, then watch what hive the swarm returns to. If your queen is not clipped, hive the swarm or get it in some kind of a box and take it away from where it is clustered (it will make it a little surer if you put it in a cellar for the time being), then take a handful of bees from the swarm, dust them well with flour, and watch what hive has the powdered "ladies" return to it.

Getting Increase and Other Questions.

1. I started last spring with four two-frame nuclei, which developed into four apparently strong colonies. They are in 8-frame dovetailed hives, in winter-cases, packed with chaff. If they come through the winter in good condition, I want to increase as much as I can consistently, regardless of honey. What method shall I pursue? I have eight acres of orchard for them to commence on.

2. As the days here during the summer are quite warm, and the nights cool, I kept the hives in the winter-cases during the summer. Would bees kept thus be liable to need further ventilation?

3. Will it be advisable during the heat of the day, in the early spring, to remove the cover of the winter-case for an hour or so, to warm up the hive, previous to removing the packing?

4. If so, about what should the temperature in the sun be?

5. Are there any external indications when they are getting short of feed?

EASTERN WASHINGTON.

ANSWERS—1. The first thing to do is to thoroughly inform yourself on the general principles of bee-keeping, if you have not already done so, by thoroughly studying a good text-book. For there are so many changing conditions to meet, that it is not easy to put down any cast-iron rule of procedure. Moreover, the text-

books will give you plans for increasing, which you can use separately, or more or less in combination, according to the exigencies of the case. Possibly for the largest safe increase without caring for a crop of honey, nothing is better than the nucleus plan. By that means you can always keep your colonies strong without running the risk of having the season close with a lot of weaklings on hand.

2. Probably they would. The opinion seems to be gaining ground that it is decidedly advantageous to have very free entrance below, for ventilation during the honey harvest.

3-4. When the thermometer goes up to 50 degrees in the shade, not cloudy, and the air still, if a colony fails to start flying, it may be well to give it a hint to do so, either by doing as you suggest, or by pounding on the hive.

5. Hardly any that you ought to wait for. The carrying out of young brood, that is, the white skins or pieces of skins, is a good sign that starvation is approaching, but you ought not to wait for that.

Laying Worker-Bees.

On page 2 Mrs. L. C. Axtell writes of "laying workers." I am perplexed to know what she meant by "laying workers."

CONN.

ANSWER—A laying worker is just what its name implies—a worker-bee that lays eggs. When a colony is queenless and has no means of rearing another queen, it is likely to happen that eggs will still be laid. Formerly it was supposed that a single bee did the laying, but closer investigation shows that a number of workers, if not a majority in the colony, engage in the unusual occupation of laying eggs, which eggs produce living bees, but in no case anything but drones. Get a good text-book and read up all about them.

Changing Brood-Frames—Self-Spacing Frames.

1. My bees are on frames 12 inches deep by 19 long. Would you change to the Standard Langstroth frame?

2. Is the 10-frame Langstroth hive better for wintering than the 8-frame?

3. Do you like self-spacing frames better than the common?

WISCONSIN.

ANSWERS.—1. That's a very difficult question to answer. It's a very troublesome thing to have two kinds of frames, and if you have had good success with the ones you have, and if you have nearly as many hives as you think you will want, I should do a good deal of thinking before making a change. If you have only a few, and you think you can do about as well with the standard frame, then you may be wise to change, if for no other reason than that you can more readily and more cheaply get what's in fashion. Moreover, if you want to buy or sell colonies of bees, it will be better to have the regular frame.

2. Yes and no. Left to themselves, a colony in a 10-frame hive is safer for wintering in most cases than in the 8-framer. The two additional frames make it almost a sure thing that there will be more honey in the hive, consequently less danger of starvation. With sufficient care and proper management the 8-frame hive may be as good or better. Given two colonies equal in every respect, one in an 8 frame hive, the other in a 10-frame, each with the same amount of stores, and I'd rather risk the smaller hive for wintering, if for no other reason than that there is less room to keep warm.

3. After a few years' trial with the self-spacers, I must say I give them the preference decidedly. If there were no other reason, the quickness and exactness of spacing would turn the scale in their favor.

Preventing After-Swarms—Getting Bees Out of Supers, Etc.

1. What is the best, quickest and surest way to prevent all after-swarms?

2. If a person wishes to get as much honey as he can from his bees, would it help to prevent after-swarming?

3. When you pile several supers of honey on top of each other for the purpose of getting the bees out, what escapes do you use above and below, how many supers do you put together, and how long does it generally take to empty them?

4. I would like to know if you think my bees are all right. I winter them in the cellar where vegetables and tobacco (not very much of the latter) are kept. The thermometer is never under 33 degrees, and hardly ever over 42 degrees. I open the window once every week to let in fresh air. The bees are in the Heddon hives with the cover and bottom-board tight, but the entrance is open full width. I clean out the dead bees about twice a week with a wire hook. As yet very few have died. When I go into the cellar I cannot hear the bees, but when I put my ear close to the hive I can hear them just faintly humming, but sometimes they hum pretty loud when they are disturbed a little. I wintered four colonies in the same way last winter, successfully, except in one weak colony the unoccupied combs were a little mouldy.

IOWA.

ANSWERS—1. When the colony swarms, set the swarm on the old stand, putting the old hive close beside it. Six or seven days later take the old hive away and set it on a new stand. The field-bees will all go back to the swarm after returning from the field,

weakening the old colony so much that it will give up the notion of swarming. In most cases it would be sufficient to move the old hive to a new location at time of hiving the swarm, but it will weaken it a good deal more to wait a week, for lots of bees are hatching out every day.

2. That depends. With you in Iowa, probably you will get more surplus to throw all the strength possible into the swarm, (unless, indeed, the bees are satisfied not to swarm.) If, however, the bees should swarm very early, (in some places they swarm in April), and the main honey-flow comes late enough so the swarms could not take advantage of it, then it might be that more surplus could be got from the old hive, prime-swarm and after-swarm than if the after-swarm was prevented. But in Iowa, it's pretty safe to say, that every after-swarm you hive cuts down your honey crop.

3. The supers are piled 10 or 15 high, altho 8 is much better than 15; a Lareese escape is put under the pile with free chance for the bees to get out under the escape, and a Lareese escape is put on top, unless, better still, a large cone escape is put on top. If piled early in the day on a bright day when bees fly well, an hour or two may empty them, otherwise a few may stay in all day. Of course a high pile will not be cleared so rapidly as a small one.

4. As a rule, 38 to 42 degrees is too cold for a cellar. But there is no little difference in thermometers, and it is just possible that an exact thermometer would show that your cellar never gets below 40 degrees. At any rate, no matter what the thermometer says, if the bees say its all right it is all right. That is, if they keep as quiet as yours are. But isn't it a good deal of care to go down twice a week to clean out the dead bees? Possibly its only fun for you, but its not so certain that the bees like it. Better raise the hives half an inch or an inch higher from the bottom boards at front, so as to give more room, and then you needn't trouble cleaning them out so often. My bees have now been in the cellar more than nine weeks and the hives don't seem to need cleaning out yet, and probably will not be cleaned out till they are taken out in the spring.

Cleated or Fence Separator.

Please describe a cleated separator. Is a cleated and a fenced separator one and the same? I have been using a frame (of my own make) with a no-bee-entrance section for 14 years, but if there is anything better I want to know it. WISCONSIN.

ANSWER.—Fence, fence separator and cleated separator are all one and the same thing. Instead of the separator being all in one piece, it is in several pieces, perhaps four, the pieces being $\frac{1}{4}$ inch or less apart, and fastened together by cross-cleats on each side, these cleats being $\frac{1}{2}$ inch or less wide, and about $\frac{1}{2}$ thick, altho these figures might vary. Perhaps yours may be the same thing, and at any rate it might be useful if you would report about yours.

Wintering Out-Doors—Chaff Hives—T Supers.

1. I want to keep quite a number of bees, and want to winter them on the summer stand. What is the best and the cheapest way?

2. Please give me your opinion as to which are the best two and simplest chaff hives that are manufactured, or the best in every respect for comb honey.

3. Is the T super better, or as good, as others?

NEW JERSEY.

ANSWERS.—1. That's a very difficult thing to answer. Locations vary, and even in the same location one man will winter bees better in one, and another in another way. Perhaps as cheap a way as any good way is to have the hives close together, well protected beneath and on all sides except perhaps the front with leaves, planer shavings or something of the sort. But to give full minutiae would take more room than can be given here, and you will do well to study up the whole subject in a good bee-book.

2. There is nothing impossible about there being a dozen different kinds of chaff hives, and yet as I don't remember ever to have heard of more than one, I'm not able to give an intelligent reply to your question.

3. Opinions differ very much as to what is the best surplus arrangement. After trying wide frames and T supers on a large scale, and a number of other surplus arrangements on a smaller scale, I have never been able to find anything that suits me so well as the T super. Of course, something depends on knowing just how to use a surplus arrangement in the best way.

Wintering Bees in Tennessee.

I began keeping bees last April (1897). I have been a constant reader of the American Bee Journal since that time, and owe what success I have had in the bee-business to it, and the failures I charge to myself. I am in trouble now, and look to you, through the American Bee Journal, to help me out. Our winter here has been very warm, and bees have been able to fly almost every day up to 10 days ago. In the fall I contracted the entrance to about 4 inches, and left all the supers on the hives. I thought this would be a good plan here to winter on the summer stands. Yesterday (Feb. 4) I opened the hives (it being warm enough for the bees to fly), and found water on the top of frames and in the super, and the bees seemed to be buzzing as if hot (in fact they were). One colony had died. The combs and sections in the supers were damp

and moldy. I opened the entrance the full length. Was this right? Should I take off the supers? I have told you the condition they are in, now please tell me the remedy, and to save the other colonies. I have 18, all Italian, and two imported queens, which I purchast direct from Italy. TENNESSEE.

ANSWER.—What made you leave sections on your hives over winter? Please don't do that again. Just as soon as the bees stop storing, take off all sections so they will be fresh and nice to use another season. There may be no objection to leaving a super on without sections, but you can fill it up with leaves, planer shavings, or something of the sort, and not spoil the sections. The trouble is that your hives were too close, the moisture from the bees not having a chance to escape. You did the wise thing to open the entrance full width. That will give the hives a chance to dry out. If the winter continues as warm as it has been, it may be well to open up a very little on top, so as to allow the moisture to escape in that direction.

Question on Packing Bees for Winter.

I have packt the super with dry sawdust and chaff, with two passage-ways in each frame about $\frac{1}{2}$ way from the top of the frames, and about 2 inches space over the brood-frames. The bee-entrance to each hive is one inch deep and 5 inches long, with wire-screen covering, with a bee-passage at the bottom to keep mice out, which gives good ventilation. I have a shade-board in front of the hive, and have the hive cracks, etc., all filled with clay, also top and back of the hive covered with boards, with good, tight covers on the hives. The hives are about 8 inches from the ground, with plenty of ripe honey, and at this time the hives are covered with about 2 feet of snow. Now, what changes would you make to winter bees out-doors? MAINE.

ANSWER.—Possibly you might make an improvement on the sawdust (which some consider a little heavy). Dry leaves are well liked, and whether because better or more convenient, planer shavings are popular. If you mean there are 2 inches of empty space directly over the brood-frames, I should say that it might be an improvement to have barely enough space for bees to cross over from one frame to another. If I understand correctly the entrance is covered with wire-cloth, all but enough at the bottom to allow a bee to pass through, the wire-cloth having meshes too fine for a bee to pass. Possibly that could not be improved, and possibly it would be better to have the whole entrance covered with wire-cloth having about three meshes to the inch. That would allow a bee to pass through at any point while effectually excluding mice. But if your bees winter perfectly it will be pretty good evidence that even such slight changes are not needed.

The remainder of your questions, relating to the culture of fruit-trees, belong to a horticultural rather than an apicultural journal.

The T Super vs. Pattern-Slats.

What advantages do you find in T supers over pattern-slats?

I am much troubled with the slats, and if the T supers are no better, somebody should get up one that is. Some of the slats sag a little, other supers sag a good deal. When they are tiered up two may be so far apart the bees put comb between them, while others come so close they stick them together with bee-glue. Hold forth regarding this. ILLINOIS.

ANSWER.—I'm not sure what you mean by pattern-slats, but suppose you mean what are called "section-holders," consisting of a wide frame without any top-bar, the bottom-bar being scored out to fit the sections. My experience with this sort of surplus arrangement is very limited compared with the T super, having used the latter in large numbers for years. The editor of Gleanings cannot understand how I can prefer the T super. Possibly if he were as familiar as I am with it, he could understand it better. There's a good deal in being used to a thing, and learning to take advantage of all the little points. Possibly if I should use section-holders as many years as I have T supers, I should find more good in them. But to answer your question.

First, I may mention one thing in which the T super has not an advantage over the section-holder. When the central sections are about finished the outside row of sections can be jumped into the middle of the section-holders, and this cannot easily be done with the T super. This is the great point claimed for the section-holder, but as I do not consider it the best practice so to shift the sections, the advantage does not count with me. The T super is more easily filled than the section-holder, for the sections can be put in the T super as rapidly as they can be set in a row on a table. It is much easier to empty a T super than a section-holder. The T super has T tins which are so firm that there is not the least tendency to sag, whereas the sagging of the section holder may make trouble. But go slow about changing to the T super until you find they are better in your hands. There are some little kinks in using them that must be learned to get the most benefit from them.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

Publishing Honey Crop Prospects.

Query 69.—Is it wise for the bee-papers to publish reports as to the honey-crop, or crop prospects, as reported by bee-keepers from various parts of the country? Some think that to do so is apt to injure the market price of honey.—OHIO.

E. France—In my opinion, yes.

Prof. A. J. Cook—Always let on the light. So I say, yes.

G. M. Doolittle—Possibly there is something in it; but I like to read the reports, all the same.

W. G. Larrabee—I like to hear the honey crop reports, but I hardly think it wise to publish them.

A. F. Brown—I do not know. I like to read what others are doing, their failures as well as successes.

Chas. Dadant & Son—You might as well withhold the crop reports of wheat, hogs, etc. Don't keep the light under the bushel.

R. L. Taylor—Yes. It may sometimes injure the market price, and sometimes improve it, and will always aid in fixing the price where it ought to be.

J. M. Hambaugh—On the theory of "Where ignorance is bliss, 'tis folly to be wise," the reports might be unwise. Let us have the reports, however.

Dr. J. P. H. Brown—I am liberal enough to believe that correct reports do no injury to the producer; but, on the contrary, he can work such reports to his benefit.

C. H. Dibbern—1. Yes, general information is what we all need to conduct our business on intelligent principles. 2. No, it only adapts the market to prevailing conditions.

Wm. McEvoy—When any bee-keeper sends in an honest and very fair report of the honey crop in his locality, I believe that the editors of all bee-papers are in duty bound to publish such reports, and should.

Rev. M. Mahin—It is as wise to publish reports of the honey crop as of the corn or wheat crops. In case the reports are not favorable the tendency will be to increase the price. I think the truth should be publish.

Emerson T. Abbott—I can see no special objections if bee-keepers are disposed to report the result of their season's work. As for myself, I am not in the habit of saying much about my private business in public print.

Dr. C. C. Miller—That's a troublesome question. Harm is sometimes done by rose-colored reports, but it's more the fault of bee-keepers than bee-papers. It would hardly do for the papers to suppress information. We want to know, you know.

J. A. Green—If we could have regular reports from reliable men in the various honey-producing localities, they would be of great value. Ordinary correspon-

Sweet Clover

And Several Other Clover Seeds.

dents seldom mention anything but good yields. This is misleading, and often has a very injurious effect. I think this was particularly the case during the past season.

Eugene Secor—If bee-papers do not publish reports of the honey crop, how are we to know what the crop is? It is the prospective honey crop that injures the business, especially when great things are published that do not come to pass.

Jas. A. Stone—Decidedly, yes! It is the only way we have of knowing what our honey is worth. I have often seen bee-men who do not read the bee-papers, sell their honey (because they had a large crop) for 10 cents per pound, when it was worth 15 cents in Chicago.

G. W. Demaree—Wise or unwise, our bee-periodicals would be awfully "dry" if they for any cause failed to give us the news from the honey-fields. The consuming world do not see the bee-papers. Besides all this, some of us despise the tendency of the times to "sail under cover," that is, hide facts. Few apiarists now living believe in "over-production" of honey.

J. E. Pond—In my opinion it is advisable for bee-papers to give items of news that affect the honey interest in any wise. I do not see how any one can be injured by their so doing, and the honey crop is so varied in various sections that I cannot see how the market price can be injured thereby. It is not the news that raises or lowers the price, but the actual question of supply and demand, a rule of political economy that is inflexible.

Mrs. L. Harrison—I think that it is an injury to the pursuit. No one can tell what the harvest will be, until it is removed from the hive. As an example, a man came into this city in the early autumn with choice white section honey, which he offered for 8 cents per pound. A groceryman who purchased said at the time it was "worth 12 cents, but that was his own figure." He had read of the great crop, and being a poor salesman, wanted to sell before it came to market freely.

Poor Prospects for California

I think we are in for another poor season, if not a dry year. All rains have been followed by hard north and east winds, which have dried out the soil again, and this section of the State looks dry and barren. This time in the year we should have a nice green growth of vegetation. Many people are worried, and stockmen are losing from starvation on the ranges. Hay is nearly double its usual price, and those having hay for sale are holding for exorbitant prices.
M. H. MENDLESON.

was looking out for his bees, and they did not sow any.

Now, I wish to tell how I workt it. Last spring I ordered of George W. York & Co. 50 Alsike clover leaflets, and made a list of about 20 farmers around me, took the list and the leaflets to the postmaster (he being an intimate friend of mine), told him what they were and my object, and those that had not gotten their mail that day we slept one in their box, and those that had received theirs were left until the next day, so each of these men received a leaflet, and didn't know where it came from, and in a few days they were talking about Alsike clover, and all could talk intelligently.

One man came to me and said he had received a circular on Alsike clover (I told him I had one, too), and that he was going to get some seed when he got his other to sow the farm that joins our place.

I think I am safe in saying that there were 50 or more acres of Alsike clover sown mixt with other seed. I shall do the same thing again this spring. J. W. P.

Reports for Several Years.

I brought to this place 26 colonies in the fall of 1893. I lost 25 in the cellar, and in 1894 I started with one colony, bought two nuclei, and increased to eight. In 1895 I started with eight, increased to 26, and sold 1,000 pounds of comb honey. I then wintered 24, and in 1896 increased them to 52, sold 2,600 pounds of comb honey, and wintered 50. In 1897 I increased from 50 to 100, reared 70 young queens, and sold about 900 pounds of honey, all told. In 1897 I had to depend upon others to look after the bees; this shows that all of us do not work the same.

The last was a very poor year for me, at least in the way of gathering honey, tho' most of my neighbors did not get one pound of honey of any kind. C. CRANK.

Oscoda Co., Mich., Jan. 24.

Wiring Frames—Report.

I wish to give my way of wiring frames. Instead of punching holes in the end-bars for the wires, I use 3/8-inch blind staples. My frames are 8 inches deep inside, and it takes four staples in each end-bar. One is placed one inch from the top-bar, and one the same distance from the bottom-bar; the other two 2 inches apart between the end staples, all on the inside of the frames. I drive the staples about two-thirds their length, and crosswise of the bar, then weave the wire through the staples and fasten the end of the wire with a small tack, then tighten up the wire and fasten the other end; then if I find the wire too slack, I can tighten it to a nicety by driving the staples to any depth that is called for.

The staples are inexpensive, as one pound will be plenty for 25 hives, 10 frames to the hive.

My honey crop last season was 2,000 pounds from 85 colonies, spring count. The honey sold for \$200. I can't put an estimate on the fun I had with the bees.

WM. M. BARNES.

Richland Co., Wis.

The Season of 1897.

The last season was not a very successful one, yet much better than the three preceding years. I started last spring with seven colonies, increased to 15, and secured 100 pounds of choice comb honey, and 200 pounds of extracted, of No. 1 quality. The bees built up well on apple-bloom. Later, white clover was very plenty, yet it did not yield much nectar on account of wet weather. In July Alsike clover was in full bloom, and the bees made up for lost time in gathering honey and in swarming. The honey was the best I have ever secured. The extracted candied as early as the middle of October. The latter part of October we had very hard frosts, which killed all of the fall flowers, so the bees could work no more, yet they swarmed with nice, large queens with them. Something I never saw before, bees swarming with no chance of

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Feb. 21.—Fancy white is plentiful, and sells at 11c.; good No. 1, or grade of that character is abundant, and sells at 7 to 9c.; amber and dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

Much of the comb honey is granulating this season.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Milwaukee, Wis., Jan. 24.—Fancy white 1-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

St. Louis, Mo., Feb. 9.—Fancy bite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3½c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Kansas City, Mo., Feb. 19.—Fancy white comb, 1-lbs., 10c.; No. 1, 9 to 10c.; amber, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 5½c.; amber, 4½ to 5c.; dark, 4c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

Buffalo, N. Y., Feb. 11.—Strictly fancy 1-pound combs are in quite good demand from the fact that it has been so scarce and closely cleaned up, and 11c is quite easily obtained. Other grades do not sell much better, possibly a little, ranging from 9 to 6c., as to grade, etc. Extracted ranges from 4 to 6c., and is in light demand. We can recommend shipping strictly fancy and nothing else, unless you cannot do better.

San Francisco, Calif., Feb. 16.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 5c.; light amber, 3½ to 4c.; dark tulle, 1½ to 2½c. Beeswax, fair to choice, 24 to 27c.

Market is ruling steady for choice to select qualities of both comb and extracted, but more especially for the latter, owing to light stocks and a fair demand, both on local accounts and for shipment. Increase quantities are expected to be consumed in the course of a few weeks, owing to observance of Jewish holidays. Dark grades are not readily salable, and where custom is secured for this sort, very low prices have to be accepted. Not much beeswax on market, and there does not appear to be the slightest possibility of there being any excess of stock during the balance of the season.

Minneapolis, Minn., Jan. 31.—Market is in an overloaded condition on comb honey. Good chance for fancy white extracted at 5½ to 6c., but comb is at a standstill, particularly if other than fancy white. Best price available on fancy white combs 10½c., and buyers are slow at that. Darker grades or broken lots are unsalable. If shippers would send in their extracted when it is wanted, and not push undesired comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey at late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c.; light amber, 5c.; white clover and basswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cincinnati, Ohio, Feb. 21.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 1-2 to 6c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

Cleveland, Ohio, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6½c.; amber, 4 to 5c. Beeswax, 22 to 25c.

“Golden’s” Disk Whirling-Belt Section-Cleaner.

BY MISS FLORA FITCH.

DEAR MR. YORK:—We get letters every now and then wanting to know who this “Flody” is. My name is Flora Fitch. Having always lived next door to Mr. Golden, since a mere child, he has always playfully called me his girl, and I have more or less assisted him with his bees, and in the gallery. Through Mr. Golden’s kindness I have learned something of the nature and habits of the little honey-bee, as well as some of the mysteries of photography. My father having gone to his long home, my mother, little sister, and myself, make up our family.

And now, Mr. York, as I promised to write for you a description of Mr. Golden’s disk whirling-belt section-cleaner, I will now proceed:

The pictures will perhaps tell more than I can explain on paper. The gearing is metal, and revolves on an upright shaft, upon which a disk is set, or taken off, having a mortise on the under side. This disk consists first of a wooden wheel $\frac{3}{4}$ inch thick by 14 inches in diameter. A hoop $1\frac{1}{2}$ inches wide is tacked around the outside rim, and extends one inch over the disk-board. A piece of good drilling or canvas is wet with starch-water, then ironed smooth. Take a compass and a card-board, make a circle $\frac{1}{8}$ inch less than the disk wheel, then make a circle $3\frac{1}{2}$ inches smaller than the previous circle; cut out, and you have a pattern. Take two or three sheets of wadding and fold as often as the pattern will cover. Lay on the pattern, and with a sharp penknife cut around outside and inside the circle. Lay the batten on the canvas, and over the batten put a piece of muslin, then baste around the inner circle, after cutting the muslin like X.

Then baste around the out circle and stitch with sewing machine. Trim, dampen, and run a hot smoothing-iron over, cut the pattern in four pieces, and cut out four pieces of No. 2 $\frac{1}{2}$ or 3 sand-paper, glue one at a time, and lay on the cushion belt. Lay on a wood separator. Then with a moderately hot iron, press for two or three minutes, and so on until finished.

Having another hoop, something like a bucket-hoop, spread the canvas over the disk-board, put over the small hoop, pressing it down over the disk-hoop, pulling the edge of the canvas and stretching it tight like a drumhead. Trim, and you have without doubt one of the safest and most common-sense belt section-cleaners yet presented for inspection by bee-keepers.

In testing this machine, we have taken sections having had the combs cut out, and placed over this belt, and quickly made bright and clean, and not breaking a joint. We have taken sections of partly-drawn comb from right out-of-doors in the cold and cleaned them bright, and not a crack could be observed.

You see this belt “gives” under the least pressure, and

there cannot be the least jar, no difference at what speed you run the belt, and it is just the same with the other belt machine. Besides, one can work much the speedier, at least that is our experience.

We send you two views, one showing a plain view of the cleaner, and one showing how the arm may rest while holding a section, as the arm becomes pretty tired when working all day. Place the machine near a table, and with a stool high enough to give nearly a standing position is best. I find it much the easiest to take a section in the right hand, and as I place my wrist on the rest (which turns either way on its upright), and as I bring the section in contact with the whirling sand-belt, I take hold with the left hand, thus the section is

The Golden Disk Section-Honey Cleaner.

guided backward and forward, and turned around, until the four sides are cleaned, and then the edges.

But, dear me, Mr. York, don’t hold the section on the sand-belt very long, for if you do you will have a lump of honey all in your “two little hands.”

So now, Mr. York, when you commence to clean section honey, “do be careful.”

Mr. Root said in Gleanings that he had a disk machine in his mind’s-eye. (We don’t know whether he will have the whirling-belt or solid disk). If a solid, or even a raised, sur-

face on a solid substance, he will undoubtedly find some breakage in his honey. Of course, nice work can be done, for we have had enough experience to know, and also know something about a belt machine, and that is what Mr. Golden, and I, too, want the bee-keepers to know, which is the best and safest.

There is another thing we learned. A light machine somehow, even fastened to the floor, jars more than a heavier one. Now, Mr. Editor, I have told you about the Golden disk whirling-belt daisy section-cleaver. Morgan Co., Ohio.

Honey for the Alaskan Gold-Seekers.

BY L. G. CLARK.

The various articles and controversies that appear in the American Bee Journal have had my close attention, and tho there is some conflict of ideas and methods of obtaining the same results, there is one proposition upon which all are well agreed, and that is the necessity of extension and building up of the market for honey. The veterans have all made their suggestions, all of which have merit and would obtain good results if properly followed out, and now I wish to propose a plan of extension of market territory which has not yet, to my knowledge, been advanced.

The mining regions of Alaska have, during the past season, taken thousands of tons of California evaporated fruits and vegetables, beans, bacon, etc. The opening of spring will see hundreds of vessels laden with these commodities going northward, and their cargoes will sell for fabulous prices among the famishing Klondikers. Thousands of prospectors will be rushing in, and the amount of provisions necessary to supply that vast region will be enormous. One of the principal articles in every prospector's outfit is syrup. Every company that contracts to take up and supply men agrees to furnish a given amount of syrup. Fat and fat-producing foods are the most necessary articles of diet in that cold region; hence the heavy demand for sweets.

Syrup, as well as all other articles of food and equipment, sell for many times their actual value, and there is no gainsaying the fact that in a country where gold is the cheapest commodity, honey would in every instance be given the preference over the cheap syrups and trash now supplied them. The transportation and commercial companies now controlling that trade are furnishing the cheapest grades of syrup and imitation honey in order that they may gain the greatest possible profits.

There is some talk of necessary legislation by the present Congress on behalf of Alaska, and if a pure food law—a most decidedly necessary one—could be past for the benefit of that country, it would do much towards relieving the honey market. True, California would get the bulk of this trade, but that would relieve the Eastern markets accordingly.

I have read much of late about the United States Bee-Keepers' Union, and there are some who seem to doubt its possible usefulness. Let the Union present the above proposition regarding an Alaskan pure food law, to Congress, and secure its passage. The result would be far reaching and beneficial, and he who could then doubt the wisdom of "Union"-ism would be unworthy of consideration.

Napa Co., Calif.

The "Lampman" Section-Comb Cutter.

BY H. LAMPMAN.

I am one of those engaged in the keeping of bees for the profits I derive therefrom. I take the American Bee Journal, and of course have seen a good deal said about leveling-down combs in sections. As I have received a good many good things out of the American Bee Journal, I will show its readers what I have invented for the purpose of cutting or leveling down combs in sections of the previous year. I have used it the last three or four years with the greatest of satisfaction. I have tried everything that I ever heard of, besides a great many devices of my own, and to me they were not satisfactory, until I hit upon this device, and it does it so nicely and completely that I thought it would be of benefit to the fraternity.

For some reason or another, at the end of the season I usually have a great many unfinished sections, so it is quite an object for me to be able to utilize them the next season. I can get more uniform combs, and just as white appearing. It will be seen by the construction of the cutter that whatever residue of propolis there may be, is entirely separated from the comb, leaving it perfectly clean. After one has a little practice, he can cut down a great many in a day; I never

tried to see just how many, but I should judge that 1,000 would be a very easy day's work. Before cutting the combs down they must be perfectly dry, and entirely free from honey. I have no difficulty in producing No. 1 honey from such combs, besides the advantage of getting the bees started in the surplus cases.

The cutter is made altogether of tin, and one bolt. The size, of course, each one will have to regulate according to the size of the section used. The size for a $4\frac{1}{2} \times 4\frac{1}{2}$ section is $4 \times 10 \times 2$ inside the box, with a flange at each side to form the gauge. Cut a hole 2 inches in diameter, 4 inches from one end, and in the center. Put a rim one inch high around the hole inside. Take a piece of XXX tin, 4 inches wide, fold it together, and draw to an edge, using a file to finish up with. Cut a piece like the end of the cutter-knife with a slot hole near the top of this end-piece, so you can raise or lower it, and form the knife around it. Put a hole on each side a little below the gauge on the box. Put the knife in, then a $\frac{1}{2}$ -inch bolt through all, with a thumb-nut to clamp all together.

To use it, get a box that will be about right for you to sit at comfortably in a chair; cut a hole in the end about 4

The Lampman Section-Comb Cutter.

inches in diameter, place the cutter on so the hole in the center will come in the center of the one in the box; fasten with a screw at each end. Now put water in the box about $\frac{1}{2}$ inch deep. Always be sure to keep water in the box. Adjust a shelf in the wooden box for a lamp to rest on; have the lamp so it will come close up to the hole in the cutter-box. Let it get quite hot. Now sit down with this box directly in front of you, take a section in your two hands, have the knife face from you, place the end farthest from you in the gauge, then lower the other so it will come on top of the knife, then

Sectional Drawing

steadily pull toward you, letting it slide off the top of the knife on the gauge. When the section strikes the knife, directly raise that end slowly in such a way as to scrape off any comb that may be there, all the time keeping the other end in the gauge. Reverse, and perform the same act.

It takes nowhere nearly the time to do it, that it does for me to explain it. When the wax box gets about half full, let it cool and remove the wax. If the residue collects on the underside of the knife, take an old case-knife and remove it.

All are at liberty to make and use this cutter-box.

Winnebago Co., Ill.

Instructions for Moving Bees Long Distances.

BY C. P. DADANT.

I have received the following questions which I will answer in the American Bee Journal, as it may help others:

MR. DADANT—I have a small apiary of 27 colonies of Italian bees which I wish to ship from this place (Geauga Co., Ohio) to Kankakee Co., Ill., as early in the spring as possible; and while the books give general instructions but differ somewhat in detail, there are some points I am in doubt about, never having had experience in this branch of the business.

My bees are in two-story chaff hives, and of course tight bottoms. How early in April would it be safe to move them? Would it be wise to put screen cloth over the entire brood-chamber? Would there not be danger in case the weather turned cold (but not freezing) of chilling the brood? Would box cars be as good as stock cars? I notice some advocate stock cars to ship bees, but I presume they have in mind shipping in hot weather.

WM. M. WHITNEY.

It is very difficult to give instructions on a subject of this kind and make them fit all cases, but I will try to give, from my past experience, as explicit instructions as possible. There was a time when bees brought a good price and we were selling from 50 to 150 colonies of bees each season, shipping them

to all parts of the country. We have shipt bees in closed hives, with only a 4x4-inch opening covered with wire-cloth in the bottom-board, from April 1 till May 15, without loss. On the other hand, we have had great losses from shipping bees with the entire top replaced with wire-cloth, in May, simply from their having too much fresh honey in the hive.

One of the most indispensable requirements in shipping bees great distances is to have but little if any fresh honey. We would, therefore, be sure to ship the bees before fruit-bloom, unless the season was very backward and cold. After a good winter, with populous hives, we would try to ship about the last of March or beginning of April. With two-story chaff hives, all in one piece, as we understand, we would if the colonies were strong, remove the cap or cover and tack a piece of wire-cloth over the upper story. The cap could then be put on or left off, at will, according to the weather. We would use box cars, for there would be but little danger of overheating the bees, and darkness keeps them from fretting if the hive is otherwise uncovered.

If the colonies were only of middling strength, and the time early, say the last of March, we think they might be riskt without any air but the crevices in the cover, provided they had sufficient empty room in the upper story to enable them to cluster away from the brood-combs, if they felt ill at ease. Stock cars are not good to ship bees because they admit too much light. In a closed car, if some of the bees happen to find an opening, they will be compelled, by the absence of light, to remain in the car, and many of them may return to the hive. In an open car, they will be lost at once, the minute they emerge from the hive.

We do not like to ship bees without an opening at the bottom of the hive. As a matter of course, in a double-bottom hive, it is out of the question to give them air in this way. But this may be remedied by a larger opening at the top. We never put wire-cloth over the entrance, because we have often noticed that the bees, being accustomed to flying out at that spot, will fret themselves to death, and their dead bodies will soon obstruct that entrance, so that it might as well be closed. When the air comes from the bottom there is more chance for a circulation. In warm May weather, with single-wall hives, we have often shipt bees by covering the entire brood-chamber with wire-cloth, protected by a board raised two inches above it and cleated on the hive. The cap or cover, which accompanies the hive, is then shipt separately.

We have shipt bees in the hottest weather, in July, by removing half of the brood-combs and replacing them with dry combs, alternating them with the others. In hot weather it is also well to leave a part of the old bees behind. In this way a man may readily leave a small swarm on the spot from which the bees are removed, without injury to the colony removed but rather for its benefit, for a very populous colony will find difficulty in a trip of several hundred miles. If they are confined in too small a space, in hot weather, suffocation will soon take place, the bees seemingly being drenched with perspiration, and the combs breaking down from the temperature being raised above the normal degree of blood heat.

To recapitulate the above remarks, we will say: Ship the bees when the hives are the lightest, but as early in spring as practicable. In cold weather give but little ventilation. If the weather is fair and the colony strong, have an opening either at the top or the bottom. If at the top, shelter this opening with a board cleated above. In hot weather open both top and bottom and remove a part of the brood-combs, or space them so they will not be all together.

Mr. Paul L. Viallon, of Louisiana, who used to ship large quantities of bees from the South to the North every spring, at the time when we were also shipping, told us that he was in the habit of fastening the combs with cleats placed between them so as to avoid breakage. This precaution, which is advisable in shipping single colonies by express, is rendered unnecessary, as in the present instance, when the apiarist loads and unloads his bees himself.

Mr. J. M. Hambaugh, late of Illinois, but now of California, has devised a very good contrivance to give air to colonies when transporting them from place to place. Mr. H. was in the habit of moving his bees to the hills in the spring for the clover and basswood crop, and moving them back to the low lands of the Illinois River in the fall. This contrivance consisted of a light frame taking the place of the super, but only three inches high. This frame which was fitted over the brood-chamber and under the cover or cap, in the same way as a super, was perforated in about two-thirds of its length, on all four sides, with an opening about an inch wide. This was covered with wire-cloth, and a perfect system of ventilation was thereby established right over the brood-combs, without the rays of the sun being permitted to interfere in any way with the comfort of the bees.

In transporting bees, the apiarist must use his own judgment, but it is better to give rather too much air than not enough. Yet it is well not to carry the thing far enough to chill the brood, but when the hive is populous the bees are not likely to allow the brood to remain uncovered if there is any danger of its being chilled. They will be sure to do their best to keep it warm.

Let it be remembered, also, that obscurity is best. The rays of the sun are injurious, therefore we object to box cars, except in case of exceedingly hot weather, which is not to be feared in this latitude, even in the month of May.

Haucock Co., Ill.

Some Notes from Western Iowa.

BY E. S. MILES.

We have had a nice winter up to the present time (Jan. 15), enough snow for sleighing, and no bad storms or very low temperature. The snow has protected the clover, which notwithstanding a very dry fall now looks as if it would come through in fair condition.

Bees seem to be wintering all right, as they have plenty of good, thick honey to live on. I often read articles condemning the practice of taking the early honey away, and

Another View of the Golden Disk Section Cleaner.

leaving the late-gathered honey for winter stores, but our fall honey is thicker and heavier than clover or basswood honey, and bees have always wintered well on it for me.

LARGE VS. SMALL HIVES AND SWARMING.

Out of 25 colonies in S-frame hives run for comb honey, there were 7 that did not swarm; while out of 4 colonies in 10-frame hives treated the same, 3 swarmed, and the other one was run for extracted honey. So it does not seem to me that the 10-frame hive has any advantage over the S-frame as a non-swarmmer. I have a neighbor who has a colony in a dry goods box, size about 1½x2x3 feet, and they invariably swarm.

I remember last year they were the first to swarm of any in the neighborhood. There is no hive large enough to prevent swarming in this country in good seasons.

MOTH-TRAPS AND CARELESS MANAGEMENT.

I have a neighbor who told me lately that he had a colony of bees with two cases of comb honey entirely eaten by the

"worms" last fall; that is, the honey and comb were eaten, and the bees killed. Another neighbor who has had bees more or less for 20 years or more refused the dovetailed hive because it had no moth-trap attachment. It is needless to say that the competition for the home market, or any other market, does not come from such as these.

Another neighbor, whom I was helping at threshing, a couple of years since, wanted me to look at his bees. On raising the cap to the hive we saw the combs were attached to the cover, as there were no sections on, and they had begun at the top and built their comb box-hive fashion. On seeing the combs which were filled mostly with brood, the owner exclaimed, "There, they are at it again—rearing young ones. I just tore the young ones out the other day, and now they are at it again! Whatever shall I do to make 'em quit rearing young ones and go to storing honey?"

It was with difficulty I restrained him from tearing out the combs of brood as he had done shortly before, as I saw them lying around on the ground, for the "old" ones to "lick up."

COLONY ROARING OUT-DOORS IN WINTER.

I would like to ask Dr. Gallup if he hasn't made a mistake about that colony in the crackt hive roaring so loud in such cold weather. He referred to this in one of his recent articles. I never heard of a colony of bees roaring in cold weather so as to be heard a rod or more. I'll leave it to Dr. Miller if it is not a good indication of safe wintering, for bees to remain quiet. Dr. G., I'll bet you've got that crackt hive, and that loud roar, and one of those old-time northern basswood honey-flows mixt a little, somehow or another.

I was puzzled when I first saw those drones. Has our good old tested "queen" of apicultural journals turned drone-layer? Hardly; she has just "boomed" the colony till they are so strong and prosperous they must have a few drones, I suppose. Now, if she doesn't "swarm," won't she make a record? I hope so. Crawford Co., Iowa, Jan. 14.

CONVENTION PROCEEDINGS

Report of the Michigan State Convention.

BY W. Z. HUTCHINSON.

The bee-keepers of Michigan met in Mt. Pleasant, Dec. 31 and Jan. 1. The meeting was called to order on the evening of the 31st, with Pres. T. F. Bingham in the chair, who address the convention briefly as follows:

PRESIDENT BINGHAM'S ADDRESS.

I trust I shall be pardoned for not occupying your time with a lengthy address. It has been my pleasure to read the addresses of other presidents during the past year, and I have found them a pleasure and a profit. But in reviewing the season's trend no marked improvements have been tested sufficiently to merit especial attention except in foundation. The so-called drawn foundation has not developed such qualities and experiments as to exclude discussion of them in our convention. The reports and experiments on the no-wall or Michigan foundation I trust will be fully made and discussed. No other body has taken such a stand, and it is to be hoped that doubts regarding it will be eliminated, and that it may be reported as a positive success or failure.

One danger threatens our industry, which it will be well to consider, namely, foul brood. It has made its appearance in the East as also in the West. To avoid it is most desirable, and if already existing in this State, we need to know it that we may all guard against its further diffusion.

It would be desirable further to know how this peculiar honey season has averaged in results.

The supposed-to-be-new section without borders may justly and profitably come under your special care.

T. F. BINGHAM.

H. S. Wheeler—I used a few pieces of the deep-cell foundation, but saw nothing about it that was desirable. I think that more tests are needed.

Pres. Bingham—Bees are not satisfied with any foundation that we can give them. The more walls that we give them the more tinkering is needed to make it over to suit

them. If we give them foundation with no walls, there is less still of the tinkering. No one can make the cell-bottoms perfect, so that the bees will not change them over, but the less change that is necessary to suit the bees the better.

Mr. Bingham here showed a super of sections containing partly-finished combs. One object of its exhibition was to show how straight were the combs—no curling—and the other was to show that the foundation had been drawn out and utilized as soon as a section of partly-drawn comb that had been placed in the super.

W. Z. Hutchinson—Even with the no-wall foundation the bees make a change in the base. First, they change it over to a rounding base, then back to a lozenge-shape, as the side-walls are started.

Mr. Wheeler—Is it not true that the bees first make the rounding shape to the base when building comb naturally?

Mr. Hutchinson—I believe it is. I suppose that if we wish to make foundation that will require the least change we should make foundation with cells having a rounding base.

Pres. Bingham—The flat-bottom foundation can be changed to the natural-shaped base, and it is so changed, but the deep-cell foundation cannot be so changed. The Dunham foundation was fine for use in the brood-chamber. The cells were sound, and the bases very thin, but there was plenty of wax in the side-walls. In the days of the Dunham, wax was low in price and honey was high, and the saving of honey in secreting wax for comb-building was of importance. Now the reverse is true. But the Michigan, or no-wall, foundation will not answer for brood-combs, as it is too light.

The Secretary now read a paper from Mr. L. A. Aspinwall, on the subject of

Comb Foundation—Some Advantages and Disadvantages of the No-Wall Kind.

The changed condition of wax after being subjected to a melting heat, rendering it tough and leathery, becomes an objectional feature in comb foundation; and only through precaution in maintaining the limit of heat necessary in melting is the objection minimized. In addition to this objection, and coupled with it, is impurity. This latter, however, is chiefly propolis, and can be almost entirely eliminated in rendering by using the solar extractor.

Its being soluble in hot water at once commends to us the superiority of sun-rendering over either water or steam; the latter, however, is less objectionable, altho the high temperature (212° at least), together with the attendant condensation, naturally tends to dissolve the propolis and contaminate the wax. Being soluble in hot water, particles infinitely small become incorporated with the wax, the presence of which may be recognized by the greenish shade, which also is proportionate with the amount it contains. The contrast is wonderful when compared with the beautiful yellow product of the sun extractor, as is also its texture, which is rendered hard and brittle in the same ratio.

Inasmuch as wax melts at a temperature varying from 150° to 160°, according to its purity, I would caution all against excessive heat, even in sun rendering. With a temperature over 212° the tendency to soften propolis whereby it becomes more or less incorporated with the wax is much increased. Instead of painting the extractor black, which is a severe strain upon the wood, being subjected as it is to extreme expansion and the consequent contraction, I use white paint both inside and out, obtaining the most satisfactory results.

Altho other impurities, such as pollen and that which naturally results from old brood-combs are found, their elimination is comparatively easy. However, in justice to the manufacturers of comb foundation, I will state that the use of sulphuric acid serves a useful purpose in separating the impurities from wax; still, a means of prevention is always preferable to a cure. Then, again, cleanliness in all the work of sun-rendering is a matter worthy of our consideration; and, being done outside, saves much inconvenience to the inmates of our homes.

The changed condition of wax, to say nothing of impurities, has necessitated much effort on the part of foundation-makers, not only to restore its original color, but the softness of its texture. While much progress has been made in this respect, far more satisfactory results have been obtained by reducing the quantity of wax in each lineal foot of foundation.

Altho foundation as first made was heavy, with but little projection or cell-walls above the base, and, in many instances none, Mr. T. F. Bingham suggested to the Michigan bee-keepers, in session last year at Mt. Pleasant, the possibility of producing a very light foundation without the cell-walls. Of course, the changed condition of wax after being melted, whereby it is rendered hard, was duly considered as being ob-

jectionable, and the use of a minimum quantity advised, hence, a return to the primitive design.

But the state of the art had advanced—the methods of manufacture had been improved, as well as the foundation itself. An exceedingly thin septum being the result of continued experimenting for years seemed an opportune time for the aforesaid change—not unlike the development of our improved section, in which the plain style, altho first made, is only now being popularized.

The members of the Michigan convention being willing to try the experiment suggested by Mr. Bingham, unitedly paid the amount necessary to procure a mill engraved expressly for the purpose.

In due time Mr. Bingham announced that the mill had been completed, and those desirous of testing the product could do so by procuring the foundation through him; whereupon I ordered some three or four pounds. Upon receiving and examining the foundation I was agreeably surprised to find the product so thin and delicate. However, owing to its smooth angular surface, which was minus the cell-walls, I was somewhat skeptical as to its acceptance by the bees. I expected to see much of it torn down, or transformed into drone-comb. In this respect I was agreeably surprised, it being readily accepted by the bees, and not a single section was found to contain drone-comb.

But the finished product was far more interesting and satisfactory. The daily test by both Mrs. Asplwall and myself led us to give it the preference. It requires an expert to detect any difference between it and natural comb. Altho I remarkt to Mr. Hutchinson, when at our home, that it was about equal to the natural product, I also mentioned the tendency to warp, which is quite an objection. In some instances the foundation warpt to such an extent that little or no cell-room was left between the septum and separator at the lower edge or bottom of the section, necessitating elongated cells on the opposite side. Altho the objection is apparently slight, still such combs are never fastened to the bottom of the sections; consequently they lack the plump, well-filled appearance, as well as the requisite strength necessary in transportation.

If we carefully examine the process of comb-building, the added knowledge will enable us to understand why a foundation without cell-walls so closely approximates natural comb in the finished product.

During comb-building small particles of wax are constantly being welded to the edges of new comb, which is also true of foundation with rudimentary cell-walls. Bees invariably attach the plastic material to the edges, previously reduced to a like condition, in order that the work may be homogeneous throughout. As a natural consequence, the base or septum is scarcely toucht during a good honey-yield. With foundation having no cell-walls, the angular bases must first be operated upon by the bees, and rendered sufficiently plastic to restrain the new particles of wax. This process practically renews the entire base, inasmuch as the angles of both sides necessitate much closer work than we would naturally expect.

While this process of renewal or rendering the angular surface plastic is productive of comb equaled only by the natural, it also causes the warping already alluded to, especially when the sides are operated upon unequally.

In all lines of progress, however, with a point gained we are likely to encounter a corresponding evil. But inventors wear them away. By fastening the foundation on three sides, the objection would be overcome, altho a lesser one (that of fastening) would present itself.

Altho I do not like divided sections, which, by clamping, secures the foundation, still I think some method should be devised to supersede the use of hot plates or melted wax, if possible.

In all probability we shall not experience a honey-yield for some time which will fully equal that of last season. Under the circumstances of a poor yield, the Michigan foundation might prove a failure. Certainly, 1897 was exceptionally favorable to the acceptance of any artificial base. During times of failure bees, like individuals, are wont to be employed, and will tear down the artifice of men's hands rather than remain idle.

L. A. ASPINWALL.

Mr. Bingham had used the no-wall foundation quite extensively, and, as already mentioned, had a super on exhibition. The super was not a selected one, and was taken right from the hive, as shown by the propolis. It was necessary to use a knife in prying the sections loose. A Mr. Robinson had used about 10 pounds of this style of foundation. It workt very well until the flow of honey slackt up, then the bees gnawed down the foundation.

Mr. Wheeler—I had trouble last year with the bees gnawing out the Van Deusen foundation.

Pres. Bingham—I used the no-wall foundation altogether last year. It runs from 17 to 18 feet to the pound. We were all delighted with the honey. Not only this, but there was a saving of some \$7.00 or \$8.00 in the cost of foundation, over what it would have cost to use ordinary foundation.

After dinner of the second day the convention took up that part of the President's address relating to

FOUL BROOD.

Mr. John N. Rankin, who has charge of the Michigan Experiment Apiary at the Agricultural College, read the Michigan foul brood law, which appeared on page 633 of the American Bee Journal for 1897.

Pres. Bingham—Foul brood is spreading, and something ought to be done to prevent its spread.

Mr. Hutchinson—That law that Mr. Rankin has just read was drawn up by Prof. Cook a good many years ago. At that time it was probably a good law. Foul brood and the methods of getting rid of it were not then so well understood as they are now. A person of ordinary intelligence, who will be careful and thorough, can get rid of foul brood without much loss, and it is an injustice to compel a man to burn up his colonies when the hives, bees and wax, yes, and the honey, may be saved. I do not know the text of the law in Ontario, Canada, but it allows the owner or the inspector to get rid of the disease.

Pres. Bingham—There are a great many careless, incompetent bee-keepers, and if we allow one to attempt a cure, we must allow all the same privilege.

Mr. Rankin—I think that we ought to be allowed to cure it.

R. B. Oldt—Foul brood can be easily gotten rid of. A swarm hived in an empty hive will be free from the disease. A colony or swarm driven out can be hived the same way, and will be free from disease. The old colonies can be united, and when the bees have all hatcht they can be driven out and treated as a swarm. The old combs can be melted into wax.

At this point Mr. Rankin read a paper showing

What Has Been Done at the Michigan Experiment Apiary.

When I consented to give a paper on the work at the Michigan experiment apiary, I did not at the time realize how little had been done.

The bees were taken from the cars May 19—21 colonies in all. As soon as these were examined they were united down to 12 fair colonies.

Every bee-keeper knows of the time, labor and expense required to start an apiary, and how little chance there is to do any practical work the first year. We requeneed the 12 colonies, and at present have 17 tested Italian queens in our yard, as well as several pure home-bred ones.

There are certainly many difficulties in the path of the Michigan experiment apiary. Finance is perhaps the greatest one of them all. The old bee-house has been turned into a dwelling, and is now occupied by one of the professors, so another house had to be fitted up. We will hope, however, that this is only temporary, and will soon be replaced by a better one.

The only equipment that was on the grounds was a lot of old-style hives of different makes, so new fixtures had to be bought. The stock is not complete yet, but will be when next season opens.

The director of the station has certainly been very fair with the apiary department, and has given it as much attention as he does the other departments. He has granted everything that I have insisted was a necessity. He is interested in the department, and wishes to see it prosper.

Of course, we can't expect to get a whole outfit together in one year, but the future certainly looks good.

It would be a great step towards success if practical bee-men took more interest in the work of the station. If you are interested, let the director know about it. We have had a great many letters from farmer bee-keepers, and they are very much interested.

An experiment was made to test the drawn and thin foundation the past summer, and it was certainly a very interesting one. It was too late to test them in the honey-flow, so we fed back. They proved to be of about equal merit. A result of this experiment can be had by applying to the apiary department of the station.

An effort was made to unravel bee-paralysis. We procured two queens from the apiary of T. S. Ford, of Mississippi, from colonies that were affected with the disease, and introduced them to healthy colonies. These are $\frac{1}{2}$ of a mile from the apiary. Through the first part of November one of them showed slight traces of the disease, and when spring opens we

may find that we have the desired results. However, there is nothing certain about it as yet. We are wintering these two colonies on the summer stands packed in chaff. The remainder are in the cellar.

We have had many inquiries about foul brood, from farmer bee-keepers, asking how it looks, how to get rid of it, etc., and what laws there are for their protection. There is only one law in Michigan for the protection of bee-keepers, and this one is in the Public Acts of 1881, page 125. It provides for a foul brood inspector. It does seem a pity that a disease as well known as foul brood should be constantly gaining ground, as it certainly is in some parts of Michigan.

It has always been one of my desires to breed a strain of bees with a tongue long enough to reach red clover, and we began this systematically the past season. The average length of bees' tongues in our vicinity are: Black, 4.2 m. m.; hybrid, 4.9 m. m.; and the Italians, 5.3 m. m. The ordinary bumble-bee has a tongue 8.3 m. m.

We made one direct cross, or an in-cross of one colony, and the bees from this cross have a tongue 5.5 m. m., an increase in length of 1 m. m. over the parent colony. I have not told you about the unsuccessful attempts—there were very many, more than our successes. If we could control the mating of queens we would, I think, be certain of success.

We have tried clipping the ends of the queens' wings, and in every case the queens were not fertilized. The ordinary red clover corolla-tube is from 9 to 10 m. m. long, so we still have a tongue 4 m. m. too short. When the tube fills with nectar up to 4 or 5 m. m. from the bottom, as it sometimes does, our bees work on it quite freely.

We have had no encouragement in this line. Some of the men with whom I have talked shake their heads and say, "Impossible." But we are going to stick to it, as I think it is worth trying.

Follow up the history of any live stock—swine breeding, we will say—the old Chinese and Siamese hog of 1750 does not resemble very closely the neat, well-fleshed Chinas or Berkshires of to-day, and yet they are descended from them. To be sure, their tongues have grown shorter, but they have been bred that way.

I would say in conclusion that the outlook for the Michigan experiment apiary is good. What we need most of all is the hearty co-operation of bee-keepers to educate the State Board to know that ours is an important industry, and that it needs and deserves a good, well-equipped apiary for experimental purposes.

JOHN M. RANKIN.

Following the reading of the foregoing paper was an informal talk which showed that there was a feeling that there is a need for a change in the Michigan foul brood law. Mr. Hutchinson suggested that possibly the treatment of foul brood might come under the jurisdiction of the Live Stock Commission, but, of course, a change of law is needed. Too many preliminary steps are now necessary. There is also another point, altho a minor one, viz: If one makes complaint of there being foul brood in a certain apiary, and it turns out otherwise, the expense of the examination falls on the complainant, and some will hesitate on this account about making a complaint. A resolution was finally passed empowering the Secretary to see what steps were necessary to secure a revision of the law, or to have the matter of foul brood looked after by the Live Stock Commission.

Mr. Oldt here gave his plan of wintering bees. He first had hives with straw around them. The bees were dry and warm, and bred up well in the spring. Then he changed and used chaff on the outside and packed the hives, two in a box. He noticed that the bees crowded up on the side of the hive that was next to the other hive in the box. They did this in both hives. Then he thought that if two are benefited in this way, more would be better yet, so he put 10 hives in one box. Now he puts all of his hives in one long row on the north side of his apiary, surrounding them with boards and chaff. He sets the hives two deep; that is, there is one row above another. He packs heavily at the sides and back, but not more than four or five inches in front. There is one objection to this style of wintering, and that is, if the bees fly in winter there is likely to be some mixing up of the bees from one colony to another. He says that with this method of wintering, the bees consume as little honey as with cellar-wintering. He puts a two-inch rim under each hive.

Mr. Mead—I winter the bees the same, only I pile straw in front of the entrances.

Reed City was chosen as the place for holding the next convention; and Hon. Geo. E. Hilton was chosen President; L. A. Aspinwall Vice-President; W. Z. Hutchinson Secretary, and John M. Rankin, Treasurer.

W. Z. HUTCHINSON, Sec.

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 134.)

SECOND DAY—FORENOON SESSION.

SOME SWEET CLOVER QUESTIONS.

"What is the average yield of sweet clover seed per acre?"

Mr. Baldrige—I never knew so definitely till this year. I gathered several hundred pounds of seed myself this year, to have it perfectly free from weeds. On $\frac{3}{5}$ of an acre we got 202 pounds of seed in the hull. This seed was cut in the city of St. Charles, Kane Co., Ill., on some vacant lots, and the ground was thoroughly covered, and it was a good, fair crop.

Pres. Miller—The next question is, "Ought it be hulled?" The imported seed is all hulled; the domestic is all unhulled.

Mr. Baldrige—For home use I think it ought not be hulled. If it were used for coloring purposes, as it is in Germany, I understand, or for oil, then of course it should be hulled.

Pres. Miller—For seed, unhulled.

Mr. Whitcomb—I bought some that was not hulled, and I don't think that one seed in a hundred grew; and since then we have been sowing the hulled seed, with very great success.

"What does a bushel of unhulled seed weigh?"

Mr. Baldrige—35 pounds is what is allowed for a bushel of unhulled seed, but it won't weigh over that unless it is very plump and very clean.

Pres. Miller—Will you tell us the best time to harvest the crop for seed?

Mr. Baldrige—The best time I have found to harvest it is before it will scatter any, and that would of course be in the dough state. It should be cut green. If it gets to be dead ripe, the seed will not be as plump, and not weigh near as much, and will not be as good. If you cut it green put it in little piles, and let it remain at least a week, until it is thoroughly cured, and put it in the piles so that if it rains you will not have to turn the piles over—about as large as a sheaf of wheat—and then thresh it where you cut it, and don't undertake to haul it. Put it on a sheet or a large blanket—I use sheeting. Put it on and strike it a few blows with a stick. You don't need a flail. I had one made on purpose, and I don't need it. A broom-stick is just as good to thresh it as the best flail ever made. A few strokes will drop out all the seed. That is the simplest and best way I know of to gather it. Cut it with a corn-knife, so as to pile it straight as you cut it. If you cut it green you will lose no seed. If you cut it in the dough state it won't shell any. I generally use a sickle. It is slow work to gather it. It is worth more than some ask for it, to gather it properly.

BEE-KEEPERS' UNION AND SWEET CLOVER.

"Should the Bee-Keepers' Union assist any of its members in a litigation in regard to sweet clover, in a case of trespass and damages simply? If so, why?"

Sec. York—What Bee-Keepers' Union does the questioner mean, the National or the United States, or any bee-keepers' association? It seems to me if the Bee-Keepers' Union is organized to defend or protect its members that it should help a bee-keeper who is prosecuted, or persecuted, in that way. I should say that it ought to help the member.

Mr. Baxter—I believe the National Bee-Keepers' Union was organized to protect the bee-keepers in their rights, and it doesn't seem to me, whether it is removing bees outside of the city limits, or whether it is cutting down the flowers on which they feed, it makes no difference—it is always of national interest—of interest to everybody. I believe it is just as vital a question as removing bees outside of the city limits, or anything similar.

Mr. Baldrige—In a case of trespass a man might come upon my premises and harvest my potatoes or my corn, or anything else, and I am a bee-keeper, I am a member of the Union. Is it the duty of the Bee-Keepers' Union to assist me in protecting my corn crop against the doings of some officials? I think not. If the question was to decide whether a man had a right to grow sweet clover upon his premises, that is another question. This is simply a case of trespass.

Mr. Baxter—The State of Ohio passed a law prohibiting the growing of noxious weeds on premises, and appointed the highway commissioners to see that all such weeds were destroyed, and I understand that sweet clover was included as one of the noxious weeds, and, such being the fact, the high-

way commissioners entered upon certain land and destroyed sweet clover; and the gentleman whose clover was destroyed turns around and sues those gentlemen for trespass. Such being the case, the question arises: Is sweet clover a noxious weed? And if so, has the State a right to pass such a law as that? If it has, then there is no trespass. If it has not, then the trespass will stand.

Mr. Baldrige—I notice that Mr. Baxter is misinformed. That is where the gist of the matter comes in. The law was repealed before the sweet clover was touched.

Mr. Whitcomb—It seems to me that our Savior settled that question when he said, "Help ye one another." I understand that the United States Bee-Keepers' Union is not prosecuting this case, but that individual bee-keepers are giving their testimony in this case at the suggestion of Dr. Besse, and it has been rather more a pleasure to me than a duty, to help him out with what I have known about sweet clover, and about its not being a noxious weed or anything of the kind. We find farmers all over the country, not bee-keepers, who assert that this is a noxious weed; and I have for four or five years made in my State a public offer of a hundred dollars to any man that would furnish authentic evidence that sweet clover has ever encroached on well-cultivated land anywhere. If any of you Illinois people want that \$100, furnish evidence and you can have it. It is simply an impossibility. The nature of sweet clover is foreign to its encroaching on cultivated land. It simply cannot stand it. If you can run a mower over your sweet clover plants you will kill it all. It cannot stand pulling up. It does not grow like other weeds. It is not a weed. It is a grass, and belongs to the alfalfa family. You will find it valuable as a honey-producer, as a forage-plant, relished by hogs, cattle and horses, and by everything. It is true that in the spring of the year stock not accustomed to it do not take to it readily. I would like to help Dr. Besse in this matter. I think he has been wronged, and ought to have justice, and if I could do anything personally to help him or any one else in that position I would like to do it. It is a pleasure and not a duty, and it has been my nature all along through life to have a little sympathy for the under dog in the fight; I can't help it, and I think it will always be so.

Mr. Stone—I believe the time will come, and it has in every neighborhood where sweet clover is an old plant and understood, when we will be entirely let alone. The trouble with sweet clover is, it springs up so suddenly that the farmers are all alarmed. In my neighborhood I have had almost every farmer that I know ask me what that awful weed was, and when I tell them it is a species of clover, it seems to satisfy them a little while; and one man that asked me about it said to me, "Why, that is an awful weed, and I am told it will go 20 feet into the ground." That is not so at all. But still I let him believe it was, and I said, "I don't care if it goes clear down to China; it will bring fertility from the other side of the world; it dies in a year, and then I will have a hole clear through to the other side of the earth"—and we laughed it off. The next spring I saw him digging up plants along the roads to take home and set out. We have only got to stand it for two or three years, and the sweet clover will be in, and they will forget what a thing it is. If it were an awful thing they will forget what it is, but when they find it is beneficial they will want it. I don't look for any trouble at all.

(Continued next week.)

Lots of Brood-Chamber Room.—The editor of *Gleanings* says he will again, this year, as he did last, use two-story, eight-frame hives in his out-apiary, even for comb honey.

Kind of Bees.—Have your queens mate with drones as distantly related as possible; use queens closely related to imported Italian stock for extracted honey, and Golden Italians for white cappings, is the advice of G. M. Doolittle, in *Gleanings*.

Is a Colony an Organism?—Editor Lehzen, of *Centralblatt*, considers the controversy that has been going on with some heat in Germany as to whether a colony of bees is an organism or not, as needless. He seems to think time and ink can be better spent in matters of practical importance.

Who Shall Keep Bees?—This question is discussed by Dr. Miller in *Canadian Bee Journal*, and he seems to have difficulty in coming to a conclusion. A publisher of a bee-journal will want bee-keeping in the hands of those who keep enough, say 20 colonies, so they will want a journal specially devoted to bee-keeping. The bee-keeper with a hundred colonies thinks it a bad thing to have half a dozen colonies scattered here and there—knocks the bottom out of the market with poor honey and low prices. But considering the farmers whose flowers are to be fertilized, and general public whose tables are to be supplied, in the final analysis the question comes, "What is the best way to get bees evenly distributed all over the land, and to have an abundant supply of honey at so low a price that it may be an article of daily consumption on the tables of the great middle class, and that it may even be many times enjoyed by the poor?" Prof. Cook, a fair man and a friend to farmers, advises a return to the old plan of having a few bees on every farm. But how can that be done? What stops the farmers? And if there were no large apiaries now, would any more farmers keep bees? If they will not, then it may be a good thing to encourage some one person in every few miles to keep a number, and leave the matter largely in the hands of the specialist. A still better way may be to instruct the coming farmers so that they may desire to make bees a part of their farm stock.

Puts Bees Out Early.—N. D. West, a New York man who owns 500 colonies, cellars his bees. They had a flight Nov. 18, he relates in *Gleanings*, and he got them in as soon as possible after that. He will put them out the last of March or by April 1. He doesn't wait for a warm day, but has some anxiety about the weather the day of their first flight. If a soft snow should be on the ground many will be lost. After the first flight the queen will supply all the eggs the bees can care for, and there will be young bees on hand before time for much pollen-gathering. When taken out on a fine day he finds many bees will get into the wrong hives, filling some to overflowing and depleting others. Some successful bee-keepers, however, leave their bees in till fairly warm weather comes in April.

Disturbing Bees in Winter is vigorously objected to by C. P. Dadant, in *Busy Bee*. Bees leave the cluster to learn the danger and are chilled. The trouble is worse in the cellar, bees being more alert in temperate atmosphere, hundreds roaming about and leaving the hive, the least ray of light attracting them. But there's a time for all things, so he thinks there's a time for disturbing bees. It's when a warm day comes, and the bees haven't found it out because in a shady place, in a hive with thick walls, or for some other reason. At such times they must be waked up to get the benefit of a flight. His bees in chaff hives remain quiet till he wakes them up, when other bees are having a good flight.

Moisture of the Atmosphere in its effect upon hives should be considered in weighing, if false conclusions are to be avoided. An empty hive that had stood out with other hives till Oct. 15 was then put into the cellar, and in 5½ months it gained in weight 2¼ pounds. Set in the open air, it lost more than a pound in two days. There is possibility of deception in another way, when weighing colonies in hives. A hive is weighed on a certain date, then a long cold-spell comes, at the close of which there is found no falling off in weight. Yet there has been a heavy consumption of stores, the loss of weight in honey being now partly shown by the matter loaded in the intestines of the bees.

Getting Bees Out of Box-Hives.—The opinion seems to be gaining ground that it is not best to transfer before swarming-time. The *British Bee Journal* has strongly advocated the idea, and the *Busy Bee* seems of the same mind. It advises: "Wait till box-hive colonies swarm; put the swarm on the old stand, set the old hive 10 feet back with entrance reversed, next evening set old hive close to swarm, facing same way, and a week later set in new place. Let the old hive alone till another swarm comes out, and then treat it in the same way again." But please, B. B., in how many cases would that old colony swarm again?

Winter Loss of Bees.—M. Devanchelle says: "I often smile when I hear bee-keepers say that, on a visit to their bees in March, they found only a small loss in bees—those on the bottom-board. They take no account of the bees that have been carried out dead each fine day, nor of the many bees lost in their flights. A colony will do well, if in March it has lost only a fifth, a fourth, or even a third of the bees it had at the beginning of winter."—L'Apiculteur.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1 00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. H. Root; E. Whitcomb; E. T. Abbott; C. P. Dadaut; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. MARCH 10, 1898. NO. 10.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Pure Food Congress Delegates, Hon. Eugene Secor and Rev. E. T. Abbott, past through Chicago Monday, Feb. 28, on their way to Washington, D. C. We were able to spend a few hours with them before they took the 3:30 p.m. train leaving for the East. We shall look for some interesting reports from the New Union's delegates, upon the completion of the work of the Pure Food and Drug Congress. With the enactment of a strong national anti-adulteration law, the New Union can begin to make it uncomfortably warm for honey-mixers. In the meantime bee-keepers should continue to become members, so that a well-backed organization will be ready to push the battle to the gates.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

Bees and Peach-Trees.—The Florida experiment station isolated two peach-trees, exposing one to a colony of bees during flowering-time, and preventing all access by bees to the other. Both trees set their fruit properly, but the one to which bees had no access dropt its fruit when the stone was forming, while the other retained and matured it. Score another one for the bees.

Color and Taste of Some Sorts of Honey.

—Tony Keller, in Luxembourg Bztg., gives description of a number of sorts of honey. Linden varies greatly in color—water-clear, clear yellow, quite green, even dark green, greenish gray, or greenish yellow; very solid when granulated, sometimes almost snow-white. Locust varies from water-clear to deep green, of delightful flavor and odor, thick, and granulating very solid. Apple blossom, clear yellow, pleasantly aromatic. Cherry, clear golden yellow, pleasant odor. Horse-chestnut, thin, transparent, generally colorless, sometimes yellowish. Sweet chestnut, dark, and almost offensive in taste. Asparagus, greenish and unpleasant. Rape, mostly a strong aroma, reminding of the blossoms; varies in color, mostly intense yellow; very sweet, many times without odor or flavor, but commonly aromatic, and tasting of the combs, thick, granulating rapidly in cold or light, when it is solid and yellowish white. Mustard, many times completely resembles rape, and is easily recognized by the sharp taste and aroma of this flower. Onion and fennel honey easily remind one of their origin. Heather is reddish, of powerful flavor, with the strongest aroma of all honeys, very thick, granulates slowly, distinguishing itself from all other honeys by its jelly-like character.

Section-Honey Cleaners are attracting much attention now. Several have already been illustrated and described in the bee-papers. And this week we show another—the second one gotten up by Mr. J. A. Golden. Doubtless by the time they will be needed for use this year, several more designs will be evolved by various inventive genuses.

Miss "Flora" has done well in her description on another page. What a mercy it is to her that we don't publish post-office addresses in full in the Bee Journal. Why, if we did, after giving her latest photograph, as we have on page 145, she would have to sit up nights to read all the letters that young bee-keepers would be writing her! But she has told in a very nice way who she is, and how she and her Golden friend work together.

Referring to Amalgamation of the two Unions, Editor Hutchinson, of the Review, said in his February issue:

"I feel sure that if the matter could now be put to vote, that amalgamation would be carried unanimously. What is there to hinder such a vote being taken?"

We presume a vote could be taken at any time that five or more members of the Old Union requested it, and provided the request met with the approval of the Advisory Board. We doubt not it would carry all right were nothing further said to prejudice or unduly influence the membership against consolidating the two organizations.

The California Bee-Keepers' Exchange includes 200 honey-producers as members, and handles about one-fourth of the honey-product of the State. So we learn by a report. We should say that is a fine showing for its age. Doubtless in a very few years the Exchange will easily control the annual total output of California honey. Bee-keepers should co-operate with it in every possible way, for its success means greater success for all its membership.

For Sore Eyes.—Thoroughly dissolve in a teaspoonful of warm water a few drops of extracted honey. Four or five times a day drop three or four drops of this in the eye. If some remains on the eye-lid, remove it after a few minutes, without rubbing or wiping hard. A few days will cure.

Exports of Beeswax.—During the year 1897 it is reported that the exports of beeswax from New York amounted to \$80,262, or about 120,000 pounds, at 25 cents per pound.

BIOGRAPHICAL

WILLIAM JAMES CULLINAN.

It becomes my painful duty to chronicle the demise of another able and well known member of the bee-keeping industry, W. J. Cullinan, who died at Quincy, Ill., Jan. 17, 1898. He was born in Mt. Sterling, Ill., and at about the age of four years his parents moved into the country nearly eight miles north of the city, where young William attended the district school near by. Here he gained distinction as a leader in all oratorical and literary contests. He was the sixth child of eight, three of whom have preceded him to the Other Shore.

When William was but 11 years of age, he lost his father, and had to assume the burden in a large degree of the farm and consequent work, taking from him the advantages of a more thorough education.

About the year 1885 the farm was sold, and Mr. Cullinan, with his mother and family, again removed to Mt. Ster-

W. J. Cullinan.

ling, where he embarked in the harness business, and bee-keeping as a side-issue. About this time he was married to Miss Myra Moran.

Mr. Cullinan will be remembered as a frequent contributor to the bee-periodicals during the years 1885 to 1895, his articles being terse and to the point, showing him to be a man of culture and a deep thinker. Bee-keeping was his favorite occupation, but a chain of adversities darkened the horizon of his future, and held in check the realization of his ardent hopes. He was frail from his boyhood, having heart-trouble, which threatened his life at times.

In the course of a few years three children were born to Mr. and Mrs. Cullinan, a daughter and two sons. In the spring of 1892 Mr. Cullinan's mother died, and in 1894 his youngest son, Louis, a bright, winsome baby, nearly one year old, was taken, leaving a desolate home and aching hearts; and in the winter of 1895, Georlie, the only remaining son, nearly four years of age, passed from earth. It seemed that Mr. Cullinan and his companion in sorrow had their cup filled to the brim. Their brightest star had set, and all seemed a

blank. Their Christian fortitude, however, came to their rescue, as it always does to those who put their trust in Him, and they were content to know there were two shining lights across the way to guide them to that better world.

Nearly eight years ago Mr. Cullinan became a resident of Quincy, where he resided thereafter. There, under many difficulties he resumed his favorite avocation of bee-keeping, his apiary being a model one, and the not numbering above 40 colonies, they were equipt in the highest standard of excellence, both as to quality of bees and improved appliances. His articles were mostly written from there.

Mr. Cullinan's health had been on the decline for many months, hence his final departure was not without warning. He was a devout member of the Catholic church, and early in his sickness he set his house in order. He was surrounded at the last with many kind, sympathetic friends, two sisters, a loving wife and only daughter. His bereaved wife and only remaining child have the heartfelt sympathy of all who know them. A kind and loving husband and father has been called, but with the blessed assurance that all things needful were given him, his spirit being cleansed in the blood of an atoning Redeemer, he awaits with outstretched arms for the blessed union that can never separate, on the banks of the eternal river. His body was taken to Mt. Sterling, where it was tenderly laid in the silent tomb beside his little boys, who preceded him to the spirit land.

J. M. HAMBAUGH.

MR. LEWIS SYLVESTER, of Kane Co., Ill., called on us last week. He reports for 1897 a spring count of 14 colonies, increased to 35, and a crop of 1,600 pounds of comb honey and 300 of extracted, mostly from white clover.

MESSRS R. H. SCHMIDT & Co., of Wisconsin, writing us Feb. 28, had this to say about their bee-supply trade:

"Business is rushing. We have just completed our new factory, which covers 4,000 square feet of floor space."

MR. C. THELMANN, of Wabasha Co., Minn., wrote us Feb. 24:

"Bees seem to be all right; no signs of diarrhea as yet. We have about one foot of snow and fair sleighing. Snow drifted badly. Temperature is moderate."

MR. FRANK RAUCHFUSS, Secretary of the Colorado State Bee-Keepers' Association, reports that they have now 60 members, and expect soon to have 125. That will then be the largest State bee-keepers' organization in existence, we believe.

MR. T. F. BINGHAM, of Bingham bee-smoker and honey-knife fame, writing us Feb. 23, reported that they could hardly keep up with their orders for smokers and knives. Bingham's goods are known the world over for their honest worth to bee-keepers.

MR. EUGENE BELDEN, a gentleman who for two seasons has been in the employ of the Inter-State Manufacturing Co., of Wisconsin, called on us last week. Mr. W. H. Putnam is the President of the company, and they are prepared to do a large business in bee-keepers' supplies. Of course, their advertisement runs regularly in the Bee Journal.

MR. W. NORMAN, of Shawano Co., Wis., dropt in to see us March 1. He is getting on nicely with his bee-keeping, tho having begun only two years ago. He will succeed. Mr. Norman had the misfortune to lose his grist-mill by fire recently, causing a net loss of about \$4,000. Fire uncontrolled is a fearful destroyer.

MR. J. S. SCOTT, of Utah, referring to the Langstroth Monument Fund, wrote us Feb. 20:

"I arise to second Mr. N. Cameron's motion (page 104), and will guarantee for myself and one other to make two of Mr. C.'s 100 or 500, as the case be. Like Mr. Cameron, I do not wish to buy a cheap stone to mark the resting-place of our beloved Langstroth."

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Bee-Cave too Close and Cold.

I have nine colonies wintering in a cave. On entering the bees are quiet but soon raise quite a hum. The cave is moldy; what is the cause, and what is best to do about it? There is nothing in the cave but the bees. The thermometer stands between 30 and 40 degrees.

NEBRASKA.

ANSWER.—Probably the cave is a little too close, and very likely a little too cold. When you open the door you let in fresh air, and the bees make a stir to get their share of it. The thing to do is to let them have more air and more heat. Much easier said than done. If you could have a stove it would be good, but don't use a stove of any kind that will allow smoke or gas to escape in the cave. Making the cave warmer will of itself help change the air without doing anything else, but if that doesn't seem sufficient, you can leave a crack somewhere for more ventilation. The great trouble is to get enough ventilation without making the cave too cold. If your thermometer is correct, it ought to stand at about 45 degrees. If you can't have a stove, hot stones, jugs of hot water, or something of the kind might be used. Even a temporary warming up will help. But don't use hot water unless cork tight.

Using Hives in Which Bees Died—Foul Brood.

1. During a long spell of very cold weather this winter, three or four of my colonies of bees in dovetailed hives died, leaving considerable honey in the brood-frames. Will it be all right to have new swarms in those hives after cleaning out all dead bees, or would it be better to take out the comb and make the new swarm commence new?

2. What is "foul brood"? What causes it, and how could I detect it in my bees?

CALIFORNIA.

ANSWER.—1. Those combs will probably be a great help to a new colony, and will be all right to use.

2. Foul brood is a disease caused by a microbe or bacillus (bacillus alvei), the disease affecting the larvae. The most prominent feature depended on, perhaps, in detecting the disease, is theropy character of the rotten larva when a tooth-pick is thrust into it and withdrawn. The first intimation you are likely to have is the bad smell, holes in the center of the capping of the brood, and the coffee-color of the dead larvae lying not at the bottom of the cell, but at the bottom-side of the cell. It may be worth your while to get Dr. Howard's book on foul brood.

[We mail this book for 25 cents.—EDITOR.]

Cleaning Hives—Moving Bees—Taking Bees Out of the Cellar—Mice and Bees.

1. Would you advise transferring bees, in the spring, from one hive to another, and so on until all are changed, in order to clean the hives? My hives have the fast bottom-boards.

2. I had my bees on the north side of a slope facing the south in the sun. I am thinking of moving them a few rods north in a small orchard, and face them to the east. What do you think about it?

3. Do you think it best to take bees out of the cellar quite early, or wait until it warms up well?

4. Do mice bother bees in the cellar enough to hurt them much? There are a few mice in my cellar. I have a trap set for them.

IOWA.

ANSWERS.—1. An excellent plan.

2. Probably it will be better, but you can't always tell till you try, and sometimes it's hard to tell after you try.

3. I think I wouldn't take them out till soft maples are in bloom, and not then if it didn't promise good weather. Some, however, favor taking out early as possible, and I wouldn't like to be too positive about it.

4. When you open your hives in the spring and find great holes gnawed in the nice brood-combs, you'll think mice are a good deal worse than you supposed. Next winter have the entrances closed with wire-cloth, three meshes to the inch.

Melting Comb Honey by Steam—Crushing Comb Honey.

1. Would it be practical, without injury to quality of honey, to melt honey-combs in a large tank by a steam-pipe? Bee-keepers here have frequently a large amount of candied honey in the spring from colonies that died the previous winter, that they wish to melt up, and frequently use the sun extractor, which injures the color

of the honey for selling. Steam would reduce it quickly without doubt, but whether the honey would be discolored or otherwise injured, is what I wish to know.

2. Mr. Aikin writes about the feasibility of crushing honey by running it through wooden rollers. Now, could honey be run through rollers successfully, and has it ever been tried? A party here has some 50 box-hives for transferring, and after the brood is disposed of, he wishes to crush the combs in the easiest manner possible in order to save the honey, and not be so long as it would take him in using sun-extractors; and at the same time he does not wish to discolor the honey.

"OUT WEST."

ANSWERS.—1. I'll resign the floor to any one who has tried it, giving my guess that great care must be taken or the honey would be spoiled by overheating.

2. So far as I know, Mr. Aikin's plan is yet in the theoretical stage. But I think he contemplates using only virgin combs, and old brood-combs might be a very different thing. Pollen and the old combs would likely discolor and flavor the honey.

Amount Consumed by Drones.

Are drones large consumers of honey?

B.

ANSWER.—It takes a good deal of honey to rear them in the first place, for a drone is a good bit larger than a worker. I should hardly suppose the mature drone will consume as much in proportion to its size as a worker, for it is not so active, still it must take no small allowance to support it.

Lessening the Quantity of Drones.

Is it profitable to use a drone-trap to lessen the quantity of drones, or can the trap be used for queens to mate with drones from select colonies?

B.

ANSWER.—If there are many drones in a colony it will take a good deal to support them, and it will pay to trap them out. As prevention is better than cure, it will be still better to avoid the expense of rearing them by removing nearly all the drone-comb. You can do a good deal toward improving your stock by encouraging drones from your best colonies and repressing the rest. But if bad drones surround you on all sides in your neighbors' colonies, the problem becomes much more difficult.

Transferring Bees—Swarming Management.

1. As I have 12 colonies that I wish to transfer from a cheap frame to a Hoffman frame of the same size, what would be my best way of doing it?

2. My plan for swarming next season is as follows: I must have one empty hive to begin with. Now suppose No. 1 swarms June 2, I will give the swarm in the empty hive and put it on a new stand. Now June 6 No. 2 swarms, or within one week of No. 1. I will take No. 2's swarm into No. 1, and so on through the whole apiary. Do you think my plan will work to good advantage?

NEW YORK.

ANSWERS.—That's easy, the frames being the same size. Wait till fruit-bloom, then with a thin-bladed knife cut out the comb from a frame (it will help if the knife is hot.) Have the frame lying on a board a little larger than the frame. Lift the frame off the comb and put over it the new frame. Have four or five strings of common wrapping-twine long enough to go around and tie. Place these strings at intervals across the frame and comb. Have another board like the first, and place it over frame and all. Now with one hand under and one on top, turn the whole business upside down. Take off what is now the top-board, tie the strings, lift up the board with the frame to an upright position, take away the board and hang the frame in the hive.

2. I think I've read of the same thing years ago. Very pretty in theory, and sometimes successful in practice. But won't you do a good deal better to set the swarm always on the old stand, putting the mother colony on a new stand?

Some Wintering Questions.

1. What will be the result of wire-screen in front of winter hives? Bees fly out when too cold and drop on the ground and die.

2. My 56 colonies of bees are all in winter hives, about 2-inch space all around filled out with dry sawdust, and cover sealed. I find them moist, and it appears that there is mold inside. What will be the outcome?

3. I opened one hive, found half of the bees dead and honey very moldy. I took out four frames, put them into a new hive, and one frame with honey and pollen that I had from the past summer. I put in the follower, sealed up the cover, and put the hive in a dark room. The temperature runs from 42 to 50 degrees; the room is 6x9x9 feet high, ventilated. Will the bees come out all right?

4. I have to feed them. Will it be right to set partly-filled sections in front of the hive? How much will I have to give them?

MICHIGAN.

ANSWERS.—I suppose your idea is to put wire-cloth before the entrance, so the bees would have all the air they want without being able to leave the hive. You could hardly do a worse thing,

for the bees that try to get out will raise a great commotion, stirring up others that will then try to get out, and when they find they can't get out they will become quite excited, and you'll have a lot of dead bees clogging the entrance, losing more than would have died on the snow. A good many of those bees that die on the snow are ready to die anyhow, so the loss is not so great as you probably suppose. The right thing is to put up a board or boards to shade the entrance so the light will not shine in the hive to entice out the bees when it is too cool.

2. Probably not very good. Better give a little vent at the top through the sawdust, or if there is no sawdust on top, you must try to help the matter in some way. One way will be to put on top a lot of packing of some kind, carpets, rags, planer-shavings or something, and allow the moisture to pass up through. Perhaps it may do to leave the hives sealed up, pile on packing on top, and give air at the entrance. In any case don't have the entrance too small, but if there is no chance for upward ventilation, a larger entrance is needed. An entrance $\frac{1}{2}$ -inch high the width of the hive is probably none too much if all is tight on top.

3. Hard to tell, but chances are fair if room is entirely dark. If there's a little streak of light coming in somewhere, your bees will likely make for that.

4. It isn't certain it will be successful. If it's too cold, bees won't touch it. If warm enough for bees to come out of the entrance to take it, there's danger of robbing. That might be managed by giving it on a warm enough night, and taking away any that might be left before time for bees to fly next morning. Probably you'll need to feed all you can get them to take, hoping that spring may come early enough so they'll pull through. August or September is a much better time to feed bees than February.

Making a Range for Bee-Pasturage.

Won't we have to make a range for bee-pasturage if we make a success of bee-keeping? ILLINOIS.

ANSWER.—We cannot make a success of bee-keeping without a range of good pasturage, but if we lack that I don't feel so very sanguine about our being able to make the range.

Perforating Wood Separators.

Would it be advisable to bore holes large enough to admit the passage of bees through the wood separators, opposite the center of each section? MINNESOTA.

ANSWER.—Decidedly a good thing. They will probably be all right if the holes are not larger than $\frac{3}{8}$ inch, and the more holes the better.

Keeping Bees in Town—Looking at Bees in Winter.

1. I thought of keeping a few colonies of bees, but as I live in town, I don't know if it's allowed in a city. I have two lots planted to peaches, plums and cherries. I thought it would be a nice place, but I don't want to get into trouble.

2. If bees swarm are they apt to sting any one living near by? How could I keep boys from pelting the bees?

3. Again, I have one colony in the cellar; do you think I could lift off the top of the hive and look in to see if they have plenty of honey? Do you think they would come out if I bored three inches on top of the hive to give them air? MICHIGAN.

ANSWERS.—1. It is not likely that there is any objection to your keeping bees, but you can easily find out by asking the mayor.

2. Bees are not apt to sting any one living near by when they swarm. They would be more likely to make trouble when not swarming, if they should be placed near the street where people were passing by. It would be a help against this, and also be some security against the boys pelting them, if you have a high fence between them and the street.

3. If the top is not nailed on I think you could lift it off without the bees coming out. Move very gently at it, and if the bees get stirred up too much, wait till they settle down again. Of course the cellar must be kept entirely dark, but you can have a light in it long enough to look at them.

Getting a Colony Out of a Tree.

Last fall I was hunting bees and found a tree on another man's land about six miles from my home. The man that owned the land would not let me cut the tree, on account of its being a shade-tree, but told me if I could take the bees out and not damage the tree I could do so. I would like to get them out in the spring, as soon as it would do. How can I proceed to get them and save them? At what time can I do so in the spring? WISCONSIN.

ANSWER.—Probably the first thing would be to see whether you couldn't buy the tree and then cut it down. If the tree couldn't be bought, then a little special prospecting and engineering on the spot would help decide what should be done. Try to find out about where the upper part of the hollow is, and where it terminates below. If the entrance-hole is away at the upper end, then bore a hole at the lowest part of the hollow. Most likely, however, the

entrance is toward the lower part of the hollow, in which case bore a hole clear at the lower end. Then with a well loaded smoker pour continuously smoke into the lower hole until the bees file out at the upper hole. If it is so you can, have a hive located at the hole where the bees come out, so they will run right into the hive. If that cannot be done, then smoke the bees out without the hive, and closely plug both holes so not a bee can get back. Then treat the bees as you would a swarm, taking the cluster as soon as it settles and putting it in a hive. It is possible that you might drive the bees out without making any extra hole, by dropping in some very strong-smelling substance such as naphthalene, or perhaps carbolic acid.

Characteristics of a Bee-Keepers' Wife.

On page 22 you say: "If you want to know the kind of a woman to select for a bee-keeper's wife, I have some good advice on tap." Well, let us have it. YOUNGSTER.

ANSWER.—Just a few points may be sufficient as a guide. A bee-keeper's wife should be willing, on occasion, to take a few stings for the sake of being helpful. Considering the price of honey, she must be willing to do without many hundred dollar dresses. She should be able to wash, iron, bake, and give a few swarms between times. She should have so much good sense that she wouldn't be willing to marry a millionaire if he used whisky or tobacco, or if he were not clean and pure in his speech and life. She should be one whose highest happiness consists in living for others, and who will remain single all her days rather than marry one who is not of the same mind. When you find one to come up to these requirements, you may do well to begin to save up something to start housekeeping, if—you're good enough for her.

A Bachelor Information-Sécker.

On page 22 you say you have some good advice on tap as to the selection of a wife for a bee-keeper. Now give me the best you can. TENNESSEE. ()

ANSWER.—I refer you to answer already given to your question, as asked by "Youngster," and would say in addition, give the preference to a girl that is willing to have her pretty white hands soiled rather than to have her mother wash all the dishes.

Feeding Bees in Winter—Transferring.

1. I have five colonies that are short of honey. They haven't enough to last till Spring. They are in 10-frame hives, and seem to be all right otherwise. What would be the best to feed? How can I feed at this time of the year?

2. I want a book on transferring bees. ILLINOIS.

ANSWERS.—1. Nothing can be better than combs of sealed honey, and it's a good plan always to have a stock of these on hand. Quietly and carefully take out a comb the side where there are the most combs without bees, and remove the frames till you come to the cluster of bees. Then put in your frame or frames of honey, and put back enough of the empty combs to fill up the hive. If you haven't any combs of honey turn to page 83 of this Journal, and you will find instructions from Edwin Bevins for making candy, which is the next best thing after combs of honey.

2. You will find instructions for transferring in any one of the leading text-books on bee-culture. Perhaps you will like better to wait till the bees swarm before transferring.

[We mail Prof. Cook's 460-page "Bee-Keepers' Guide" for \$1.25—or club it with the Bee Journal for one year—both together for \$1.75.—EDITOR.]

Using the Dadant Hive—Separators.

1. As I wish to keep only 40 or 50 colonies, could I use the Dadant hive for comb honey, and yet prevent swarming successfully?

2. Would it do to use the Dadant hive with dummy or division-board reduced to eight frames till I have about as many as I want, then take out the dummy and use it for extracting honey?

3. What kind of separators is the best to use in the super for comb honey? Would tin ones do as well as wood? I am using the 8-frame Langstroth hive now. IOWA.

ANSWERS.—1. The Dadants have used their hive successfully for comb honey, and altho they now work entirely for extracted honey, if they were to change to comb honey they would probably not change their hive. But you would hardly be wise to change with the expectation of being as free as they from swarming without first trying it on a small scale.

2. You can contract to any desired number of frames, but 8 Dadant frames would be a good deal more than 8 Langstroth frames. You could fill up with frames and extract from them, but it would hardly be as satisfactory as to have your extracting-frames in a super, for you'd be likely to be troubled with more or less brood.

3. Separators are generally made either of tin or wood. If the separators are loose, wood is generally used. A loose tin separator might bend in and out and make bad work, while the stiffness of the wood prevents this. If the separators are nailed on, tin is used, the tin being stretch tight when being nailed.

GENERAL ITEMS

Cold Weather in Colorado.

We are having cold, cold winter weather here now, 8 and 10 degrees below zero most of the time. I guess the bees are all right; they were when last I lookt at them.

Otero Co., Colo., Jan. 27. W. BISHOP.

Open Winter So Far.

We have quite an open winter here, the roads and fields are dusty. Bees did very poorly here during 1897. I secured about 50 pounds of surplus honey from 30 colonies, spring count. Those that secured enough stores for winter are in good condition at present in the cellar, dry and quiet.

I must have the Bee Journal, honey or no honey.

JOHN M. SEILER.
Carver Co., Minn., Jan. 31.

Bee-Keeping in W. North Carolina.

I am wintering 54 colonies of bees here at home on the summer stands, without any protection except a single-walled hive. I don't expect to lose more than 2 per cent. I did not get any surplus honey last year of any importance. There has been a general failure in the honey crop for the last two years in these mountains. Bees actually starved to death in August here, but when September came, they got enough to carry them through the winter safely, so that was very good, for I began to get scared for fear I would have to feed, as I don't like that sort of bee-keeping. I hope we will all have a prosperous season this year.

A. J. MCBRIDE.

Watauga Co., N. C.

Bees Get More Interesting.

If I had never seen the American Bee Journal I might have gotten along without it, but the sample copy received in September induced me to try it for three months, and now I don't see how I can get along without it.

I have been in the bee-business for eight years, and the deeper I get the more interesting it becomes. Last summer I did considerable transferring. It was a tolerably good season for honey, and the prospect is good for being considerably better this year. I produced about 1,200 pounds of honey from 82 colonies, spring count. Altho a man of average truthfulness, there are some of the box-hive bee-keepers who come to see me, hinting as much as if I had over-estimated the capacity of my bees, but when I show what I have on hand, and my safe book, and estimate what has been used in my family, they are pretty well satisfied as to the truthfulness of my assertions, and it also has a tendency to create a fever.

VAN BUREN CO., IOWA. JAMES COE.

Bee-Keeping in Dixie.

I am a novice in bee-keeping. Altho I have had bees before, I did not know of the improved methods until last year, too late for honey, but I divided and have six colonies instead of two. With hybrids, Italians, and Carniolan bees, I have a variety of bees, but all in dovetailed hives.

I have a good deal of theory gathered from bee-literature. If I can put part of it into practice, I think I can make a success of it. I know it would not do to try to put all in practice we learn from books. I notice the questions askt in the Bee Journal of experienced bee-keepers, and after reading the answers, and finding them so different, I wonder what an inexperienced man is to do, but go ahead and learn for himself.

I am amused reading about the chaff hives, and all other appliances they have for keeping bees warm in winter in the

North and West. All I have done to my hives is to take the supers off, and let the hives remain on the summer stands. There has not been 10 days all told this winter that the bees did not fly; they are bringing in pollen now. We have no great flow of honey from any one plant, but we have wild and cultivated flowers from March until November. Our nearest bee-supply house is 200 miles away, therefore the box-hives, log-gums, and black bees predominate in this part of the country. January 12. ALABAMA.

Bees Were in Good Condition.

My bees went into winter quarters in fine condition. Some of them that were in 12-frame hives had over 100 pounds of honey. I have a swarm that came off Oct. 10, and stored some honey, but I am feeding them; they have brood in the hive now. They are in the sitting-room where it is very warm.

I see there is some difference of opinion as to hives. I like the large hives best, as the swarms are so much larger, and do better. I cut 23 bee-trees last summer, and I noticed that when they had lots of room they had enough bees to fill it with honey. Where the cavity was small, they usually didn't have it full for want of comb to breed in. H. GILBERT.

Jasper Co., Iowa.

Better Than the Dailies.

I would not do without the American Bee Journal for the money, for there is more news in it than half of the daily papers that cost four or five dollars a year. Cass Co., Nebr. C. C. BRUSH.

Bees Wintering Well.

Bees (135 colonies) are wintering well. We had a good crop of honey, and all is sold, with calls for more. Success to the "Old Reliable." R. H. ABBOTT, Loudon Co., Tenn., Jan. 29.

Bees Helpt Him Out.

I am very much interested in the American Bee Journal, and if I had a little more room for my bees I would go right into the business. I had only 8 colonies last spring, got about 700 pounds of comb honey, and increased to 13 colonies, and that was a help during a 7-months' strike. Bureau Co., Ill. PETER RUNLUND.

Wintering Well—Cold in Tennessee.

Bees have stood the winter well so far, and are in fine condition. I have run an apiary for the past 20 years, and have not had bees winter better. It is cold at this writing—dowd to zero this morning. G. D. HAWK.

Sullivan Co., Tenn., Feb. 3.

Bees Wintering Well.

I am wintering 110 colonies of bees this winter. They are doing well. They produced last summer about 5,000 pounds of comb honey; they didn't swarm much last summer. I have had bees here about 30 years. I used to keep them in the box-bive. WILLIAM FLEMING, St. Croix Co., Wis., Feb. 4.

Hope for Good Season.

The bees seem to be wintering all right so far. I put an even 100 colonies in the cellar this winter. There was not much honey produced in this county last season. I had only about 400 pounds of surplus honey from 70 colonies, spring count, all dark or fall honey, no light honey. There are a few bee-keepers that did a little better than that in localities where there are but few bees kept, but through the county generally there was but very little surplus honey gathered, tho nearly all gathered enough for winter stores late in the season, mostly after about Aug. 20. But perhaps what

made last season a poor season for honey will make next season a good one. I can see no reason now why it should not be. There was plenty of young white clover last fall, and basswood. Where it does not bloom one year it usually blossoms very profusely the next. So we are hoping for a good honey-flow next season. (What a glorious thing it is to be filled with hope!)

And then if the New Union only gets in a little good, hard work on the glucose mixers, and the American Bee Journal knocks out a few more of the dishonest commission-house rascals so we can hope for good prices for our honey (if we get any honey), we shall have a good deal to feel thankful for along those lines.

S. LAMONT.
Wabasha Co., Minn., Jan. 18.

Report for 1897.

I commenced the spring of 1897 with 24 colonies, and got some over 700 pounds of honey, mostly comb, and increased to 44 colonies. All are in good condition. My honey is all sold in the home market at 7 to 8 cents for extracted, and 10 to 14 cents per pound for comb honey. The winter is fine here, good sleighing, and not severely cold so far.

THEO. REHORST.
Fond du Lac Co., Wis., Jan. 29.

A Beginner's Report.

The information that I got out of a sample copy of the American Bee Journal has been worth one year's subscription to me. I am new in the business. I went to a friend's house early last spring; he was looking at his bees, and showed me the interior of the hives, and I got the bee-fever, altho that was the first time I had ever seen the inside of a hive. Three days later I had purchast six colonies, and I managed to get through the summer very successfully; out of the 6 only 4 stored any surplus honey, and from them I got 150 pounds of salable honey in sections; and I think that they have a good store for the winter.

CHAS. S. COCHRAN.
Baltimore Co., Md., Jan. 30.

Co-operation—Big Honey-Eater.

I am suprised that the American Bee Journal does not teach, preach, print and shout co-operation in some form or other for "bee-men." Is it not a fact that co-operation, well, you see my drift.

I have boycotted sugar. I use from 5 to 6 pounds of the best extracted honey per week. How much should I use, that I may be the champion honey-eater?

The weather continues dry.
Riverside Co., Calif. A. F. SEWARD.

[Yes, we believe in co-operation, and in honey-eating. Perhaps you are now the champion eater of honey, as you are putting nearly a pound a day out of sight. May your tribe increase, and earnestly practice "co-operation" in the consumption of honey!—EDITOR.]

And Still They Come.

Now I thought there were too many writing in the Bee Journal, so I would keep mum, but there are things that hit too hard. The last one is Thomas Chantry's report, on page 40. I read it with the book right side up, and then turned it all other ways, but can't make anything out but 1.371 one-pound sections filled from one divided colony. Now, South Dakota is not a warm country in winter, and if that was pure honey, I must throw up the sponge; 114 pounds for each month in the year—is it done by handling the bees or the type?

In 1896 I got 240 pounds, average, and in 1897 190 pounds, average, all extracted, and I thought I did well; but O my! that's nothing to our South Dakota man.

I have 70 colonies, but owing to my poor health they are in bad condition, but "Gip," my hired boy, is getting them in shipshape again.

I have been in the bee-business off and

on (mostly on) for 45 years, yet I know but little about bees. The American Bee Journal is a great help to me.

I will keep still if something doesn't hit me again. H. F. BAKER. Liberty Co., Fla., Jan. 25.

[Mr. Chantry must have meant the colony and its divisions, and likely had a good fall flow. But if that is not it, Mr. C. can arise and explain.—EDITOR.]

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Feb. 21.—Fancy white is plentiful, and sells at 11c.; good No. 1, or grade of that character is abundant, and sells at 7 to 9c.; amber and dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c.; dark, 4c. Beeswax, 26 to 27c.

Much of the comb honey is granulating this season.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Milwaukee, Wis., Jan. 24.—Fancy white 1-lbs., 11 to 12c.; A No. 1, 11 to 11½c.; No. 1, 10 to 11c.; No. 2, 8 to 9c.; No. 1 dark, 8 to 9c. Extracted, in barrels, kegs and cans, white, 5½ to 6c.; dark, 5 to 5½c.

The supply of honey is good and the quality very nice as a general thing. The demand is not up to our desires, yet we are hopeful it will improve and all will be wanted at fair value. We feel like sustaining prices, and continue to quote as above.

St. Louis, Mo., Feb. 9.—Fancy hite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12½ to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3½c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Kansas City, Mo., Feb. 19.—Fancy white comb, 1-lbs., 10c.; No. 1, 9 to 10c.; amber, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 5 1-2c.; amber, 4 1-2 to 5c.; dark, 4c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

Buffalo, N. Y., Feb. 11.—Strictly fancy 1-pound combs are in quite good demand from the fact that it has been so scarce and closely cleaned up, and 11c is quite easily obtained. Other grades do not sell much better, possibly a little, ranging from 9 to 6c., as to grade, etc. Extracted ranges from 4 to 6c., and is in light demand. We can recommend shipping strictly fancy and nothing else, unless you cannot do better.

San Francisco, Calif., Feb. 16.—White comb, 1-lbs., 7½ to 9½c.; amber, 4 to 6c. Extracted, white, 4½ to 5c.; light amber, 3½ to 4c.; dark, 1½ to 2½c. Beeswax, fair to choice, 24 to 27c.

Market is ruling steady for choice to select qualities of both comb and extracted, but more especially for the latter, owing to light stocks and a fair demand, both on local account and for shipment. Increase quantities are expected to be consumed in the course of a few weeks, owing to observance of Jewish holidays. Dark grades are not readily salable, and where custom is secured for this sort, very low prices have to be accepted. Not much beeswax on market, and there does not appear to be the slightest possibility of there being any excess of stock during the balance of the season.

Minneapolis, Minn., Jan. 31.—Market is in an overloaded condition on comb honey. Good chance for fancy white extracted at 5½ to 6c., but comb is at a standstill, particularly if other than fancy white. Best price available on fancy white comb is 10½c., and buyers are slow at that. Darker grades or broken lots are unsalable. If shippers would send in their extracted comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c.; light amber, 5c.; white clover and basswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cincinnati, Ohio, Feb. 21.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 1-2 to 3c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

Cleveland, Ohio, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6½c.; amber, 4 to 5c. Beeswax, 22 to 25c.

Cash PAID FOR Beeswax

For all the Good, Pure Yellow Beeswax delivered to our office till further notice, we will pay 25 cents per pound, CASH. No commission. Now if you want cash, promptly, for your Beeswax, send it on at once. Impure wax not taken at any price. Address as follows, very plainly,

GEO. W. YORK & CO. 118 Michigan st., CHICAGO, ILL.

\$100

Given as Bounties to purchasers of the improved Danz. Hives and Sections. See schedule in my bee-book "Facts About Bees." Tells

how to produce honey that sells for the most money. Free for 2c in stamps. Address THE A. I. ROOT CO., Medina, Ohio.

CONTRIBUTED ARTICLES

Improving the Race of Honey-Bees.

BY REV. L. J. TEMPLIN.

It seems to be the consensus of opinion among bee-keepers that improvement in the honey-bee is a consummation devoutly to be wished. That this is practicable admits of little doubt. Indeed, there have already been such improvements in modern times as to give lively hopes of still greater advance along these lines in the near future. In order that time and effort be not thrown away, it is important that all such efforts in this direction shall be based on intelligent, scientific principles.

Two general laws lie at the foundation of all propagation of organic beings. These are, first, the tendency of all offspring to resemble, in all essential qualities, their parents. This law is embraced in the axiom, "Like begets like." The second law referred to consists in the well-known fact that there is a tendency in every individual to vary in slight particulars from all other beings of the same species.

By the first of these laws we know with a certainty, within certain limits, what the result of the mating of two animals will be. We know that the offspring will resemble, in all essential characters, the parents from which it sprang. Any violent departure from the specific type is considered a monstrosity, and is rigorously destroyed—in nature, by the uncongenial environment, and in domestication, by the will of the breeder. It is to the second law mentioned above that we must look for the means for improving any race of domestic animals. It is only to a very limited extent that we can control or influence these variations. Yet, by food, shelter, etc., we may do something towards improvement. But it is by careful observation and grasping and fixing the variations that are continually arising from the operation of occult laws, of which we know nothing, that the breeder may make progress towards the goal that he seeks. It is by seizing these slight variations and adding them up in certain directions that progress may be made.

To become an eminent breeder of improved stock of any kind requires a nicety of discrimination, and a correctness of judgment possessed by comparatively few. What may be accomplished by this method, of the accumulation of slight variations, is seen in the different races of domestic animals. There is little doubt but that the different breeds of horses, cattle, sheep, swine, poultry and dogs originated in a single source for each species respectively. It is perhaps somewhat difficult to conceive that the difference between the extremes of some of these races, as that of the Shetland pony and the Percheron or Clydesdale horse, or between the grayhound, the Newfoundland and the spitz or poodle dogs could be the result of breeding and selection along different lines of variation. But these differences are great they do not amount to specific value. Indeed, divergences greater than these may exist without exceeding specific limitations. Mr. Darwin says:

"Altogether at least a score of pigeons might be chosen,

which, if shown to an ornithologist, and he were told that they were wild birds, would certainly be ranked by him as well-defined species. Moreover, I do not believe that any ornithologist would in this case place the English carrier, the short-faced tumbler, the runt, the barb, pouter, and fantail, in the same genus; more especially as in each of these breeds several truly-inherited sub-breeds, or species, as he would call them, could be shown him. Great as are the differences between the breeds of the pigeon, I am fully convinced.... that all are descended from the rock-pigeon (*Columbia livia*)."

All these differences, wide as they are, have been produced by the selection of those individuals that varied in the direction of the chosen standard, while those that varied in the wrong direction, or that failed to vary in any perceptible degree were rigorously excluded. Now it seems probable that the different races of hive-bees were produced by this same process of selection, aided by the influences of environment. Some have regarded the differences existing among the bees

Rev. L. J. Templin—See page 169.

of Europe and western Asia as of specific value, but there seems to be no good reason to consider them so. These differences consist in variations in size, form and color, but they are but little greater than are found to exist between individuals of the same race; and certainly not to be compared with the differences existing among the races of higher animals. The fact that such marked variations should have been produced by the art of man in the past shows the plasticity

of the nature of these insects, and is a guarantee of the success of intelligent, persevering efforts for their improvement in the future.

The first thing for the man who would strive for the improvement of our common races of bees should be to determine along what lines his efforts are to be put forth. Second, he should have a clearly-defined idea of the end he wishes to attain. Third, he should have a settled, definite plan by means of which he expects to reach the desired end.

Suppose he wishes to improve his bees along the line of honey-gathering qualities. This end he hopes to reach by developing a strain of bees with longer tongues than ordinary bees have, that they may gather nectar from flowers with corollas too deep for ordinary bees to reach. There is doubtless a minute difference in the length of the tongues of different strains or colonies of bees. Our breeder would naturally select for the beginning of his experiment the colony with the longest ligula that could be secured.

Now the bee-keeper finds himself at a disadvantage as compared with the breeder of common races of farm stock. It is quite probable that in their efforts to reach to the bottom of deep flower-tubes the tongues of worker-bees often become more or less elongated. Now, if these same workers could propagate their species this lengthened ligula would probably in some cases be transmitted to their offspring, as is often the case with acquired properties. But the worker is sterile, so we must go back to the mother-bee, that probably never makes any effort to increase the length of her tongue. Any progress along this line must be sought in the drone and queen progeny, and can result only from such slight variations as are spontaneously or naturally produced by the operation of unseen and unknown forces influencing the systems of the parent bees. When a queen is found whose worker progeny show superiority over other bees she is to be used for rearing other queens, some of which we may expect will give workers with still longer tongues.

By continuing this process of breeding and selection it is reasonable to suppose that in a few generations a strain of bees may be developed that will readily work on red clover and other deep-celled flowers, to the great benefit of the bee-keeper. Selection may be made by measuring the tongues of the workers or by observing those bees that work on the longest-tubed flowers, and finding the hive to which they belong, and choose it for a starting point in improvement. Improvement in any other direction may be secured by pursuing the same course towards any other desired end.

San Diego Co., Calif.

A Few Comments "Pro Bono Publico."

BY "COMMON-SENSE BEE-KEEPING."

I am not employed to answer questions nor to criticise articles, but I feel constrained to make a few remarks, and with the clemency of the editor, here they are:

THAT GRAFTING-WAX RECIPE on page 22 seems wide of the mark, compared with what I learned from a grafter about 40 years ago, and I have also seen it published in nursery recipes, and have also talked about it with nursery-men and grafters at various times, and supposed it was the universal rule. The proportions are (whether taken in pounds or ounces) four of rosin, four of beeswax, and one of tallow. Too much tallow will make it melt easily by the sun, and drip off from the tree.

TRANSFERRING BEES.—In that new way of transferring, given on page 5, the danger is that when the box-hive was set in the ground, full depth, to stay for several weeks, bottom end up, with the new hive over it, a big rain storm might come along and fill the hole and old hive itself full of water, and drown everything therein that couldn't climb for the new hive. That would be "drowning out," and not transferring. The delusion lies in supposing that the bees decamp from the old hive, and went to the new one on account of the way they were fixed. It will be noticed that Mr. Delmott's job was put up right in the height of the swarming season, and more than likely the old colony was about to cast a swarm, and it did, and the swarm went to the new hive rather than to a tree, just as they might have done if the old hive had not been disturbed. Then in 25 days, when the young brood would all be hatched, the old hive could be shaken out clean, and the bees put into a new one or united with the other swarm with less than half the labor that was consumed in fussing with the other way.

BEES FREEZING—It is a great mistake to say that "bees can't freeze to death." Many thousands could testify to the

loss of weak colonies in cold winters with no visible cause but that *they perished by reason of the cold*. In such cases they creep into the cells as close together as possible, like persons covering their heads in a cold sleeping-room. It may be said that "bees hibernate," but the proof is all on the other side, and every living creature that does not hibernate may be killed easily by the frost below their powers of endurance. Stiffness and numbness of the cold does not prove hibernation with the bee any more than it does with man.

THE SECTION DEPARTMENT.—Mr. Hutchinson, important changes are needed in the section department of the bee-hive. When the right thing comes before the public the bees will fill the sections as readily as they now seek to put their honey above the brood and at the sides of the hive. If the near future confirms what the past has proven, the rightly constructed "anti-bee-space hive" will figure largely in the reform.

Pennsylvania.

Feeding Bees—When, What and How to Feed.

BY C. P. DADANT.

I once sold a colony of bees to a friend in the month of May. The apple-bloom was just over, and the weather had been cold and disagreeable most of the time. (By the way, take notice that when the weather is unpleasant during fruit-bloom, there is much less quantity of fruit than when the weather has been warm and the bees and insects have helped the fertilization.) This colony of bees was strong and full of brood, but had very few stores. After delivering the hive and placing it in a selected spot in this man's orchard, the bees were liberated, and I gave the beginner a few instructions. Among other things I said:

The season is a little backward, the weather cool, and between now and clover bloom you will perhaps have to feed these bees. This remark came like a cloud in a fair sky: "Feed them! What? Feed them now? In May? If they can't feed themselves in the month of flowers, what will they do in winter?"

Friend novice, every old bee-keeper will tell you that the most dangerous time for the bees to starve is just at the eve of a big harvest. An indifferent observer may readily believe that there are plenty of blossoms in the fields from the beginning of spring till the drouth of July without any intermissions. This is not correct. Our gardens may be sparkling with blooms of all colors, and roses without end, but the business-blossoms, those on which the honey-flow depends, do not always or in all places follow one another in close rotation. After the willow, the maple and the hazel, there is an interruption. There is another after fruit-bloom. These different plants furnish the colonies just about enough nectar to induce them to rear brood to their utmost capacity, and more honey is consumed than at any other season. Hives that were rich in the fall may have been examined in February and found still heavy with stores, but in March the hive is already much lighter, and by May 1 it often happens that the last drops of old honey reach scarcely to the fresh nectar. A difference of a few degrees in latitude will only change the time of breeding, and the time of blossoms, by a few days or a few weeks, but the result is similar. There is a scarcity just when the colony is most in need of a plenty, and if the queen is very prolific, and the winter supply has not been very great, more attention is needed at the time when it would seem that care was superfluous.

Between fruit-bloom and clover-bloom, in this latitude, we often see three or four weeks when very little is to be had. In favored locations the locust, the gooseberry, the raspberry, and some other shrubs may keep up the larder of the bees, but a few rainy days, when the hive is full of bees, will often cause them to use up their last drop, and, if no succor is at hand, they may be compelled to throw out the brood. Tho the drones are still in the larval state, they seem already to know that they will be useless and fit only to eat the surplus, for they methodically begin by casting these out first. Whenever you notice them carrying out these white drone-grubs, you may know something is wrong, and if nothing is done, and the weather continues unpleasant, or the bloom continues scarce the worker larvæ will go next. Even tho I am an enemy of drones, as my readers have surely perceived ere this, I do not think it well to advise any one to let this hecatomb continue, for while they are destroying the drones, they are stunting themselves, and their queen is likely to relax or perhaps discontinue her laying at a time when her eggs are worth three times more to the colony than all the honey they will need. Bees are *not* wasteful creatures, and if too much is

fed to them at this season it is not at all lost, tho it would be an error to crowd them with a surplus at a time when the crop is so near.

Let us watch our bees at all times, but mostly when they are the highest to a bountiful crop. If a fair allowance has been left for winter, they will still have plenty when the snow disappears. But for awhile after that you will see them carrying in pollen and water, and so little honey that it is a wonder that their stores do not diminish more rapidly.

There are plenty of seasons, tho, when instead of being short they increase their surplus out of every bloom. If the winter is fair, the weather propitious in the spring, they may begin to put honey in the supers even out of fruit-bloom. But such seasons are exceptional.

Strange as it may seem we have lost more bees from starvation in June, within a week of the opening of a good flow of clover, than at any other season, winter included. But in June, as in winter, if the bees starve it is the apiarist's fault. Rainy, cloudy weather, if protracted for four or five days, will often reduce the very finest colonies to the verge of starvation.

WHAT TO FEED TO BEES.

In the fall when the bees have to be put into winter quarters, and they need a supply, our aim is to give them this food as fast as possible, so they may not consume too much of it in breeding. The food is also wanted to be as compact as possible. If first-class honey is not at hand, the very best possible feed may be prepared with granulated sugar diluted with half of its weight of hot water and mixt with about one-fourth or one-third of the quantity of good honey to keep it from crystallizing in the cells. This feed is even better for the bees than average honey, and some of our over-zealous theorists at one time advised the removal of all the honey from the hives and replacing it with this feed. But it is bad enough to have to feed when your bees are short without giving yourself the trouble of removing the honey for the problematic and uncertain gain that might be realized from feeding back sugar syrup.

Bees wintered in the cellar may very well be fed through the winter with cakes of ordinary sugar-candy laid over the cluster. But the most important feeding is at this season of the year, between spring and clover bloom, for on it a great part of the success depends. If our colonies are rich in stores it is well, but they should breed plentifully, and we must urge them to this. A spoonful of warm feed is often very stimulating. The feed should be thinner than in the fall, for water is needed to rear brood, and they can use much thinner honey than in the winter. The nectar that they harvest from the blossoms is often thin enough to run like water from the combs when they are handled, and the feed given to them may well be as watery as this.

In the spring feed little, but feed often. It is better to keep them breeding by repeated feeding, but the quantity should be small, so they may not fill their cells with food that should be occupied with brood. Do not overfeed your bees, but be sure they have enough to keep on breeding all spring.

HOW TO FEED THE BEES.

We use the Hill atmospheric feeder. It is simple and good. An inverted can with a cover pierced with little holes is placed right over the brood-combs. The bees do not have to displace themselves to reach their food, and can get it in any kind of weather. Much or little can be given, and it is away from the entrance where robbers are prone to lurk.

The worst feeder of all is an out-door feeder in which you feed your bees and anybody's bees that may be about. The next worst is an entrance-feeder. Hancock Co., Ill.

Working Up an Appetite for Honey.

BY A. F. FOOTE.

I am a farmer, and began keeping bees about 15 years ago with only the idea of supplying my own table with that most exquisite of all sweet—honey. Without the aid of any bee-literature, I have been successful beyond my most sanguine expectations; and now, that I have arrived at an age when physical labor, on the farm, is practically out of the question, I find easy, pleasant and quite remunerative employment with my bees. Having noticed several articles on "marketing honey," I would like to give my method, which has always exhausted the supply ahead of the demand.

In the first place, I keep a "guide-board" by the roadside, informing the passer-by (who, by the way, on account of it, does not always pass by) that I have honey to sell, sometimes giving the price and sometimes not, as I think best.

This brings a good many customers outside the immediate neighborhood, and for whom, of course, it is intended. With this class, and my neighbors, I always let the scales tip in favor of the customer, who is always sure of good weight.

We have a good deal of company, and the very best honey is *always* on the table at meal-time. I will not say that there is not a little "policy" in this, too, as a visitor frequently says before leaving: "I think I will have to take a dollar's worth of that honey; it is very fine."

I keep two or three stores in as many villages supplied, taking goods in exchange, the merchants buying it outright, and sell it for the same price they allow me, making their profit on the goods I take.

Again, I work a little advertising scheme once or twice a year with the church socials, in which I am not the loser at least. It is given out as extensively as possible, that a certain evening "There will be a 'Honey Social' at the residence of Mrs. ——. Supper, 10 cents. Warm biscuits and honey 5 cents extra." I furnish the honey, and the proceeds all go to help pay the minister.

My aim from the start has been to "work up an appetite" for my honey, even if I have to *give away* a section or two here and there. The result is that I am not able to supply the home demand, notwithstanding there are four or five other quite extensive apiaries within a few miles.

Mitchell Co., Iowa, Jan. 18.

The Bees, Not the Queen, Order the "Walk-Out"—Stores for Winter.

BY B. T. STONE.

In 1894 a bee-keeper in Florida asked the following questions in the American Bee Journal:

"When bees swarm, which order the walk-out, the queen or the workers?"

I was not one of the many that answered this question, but I can now answer it to the complete satisfaction of any person. July 19, 1897, I opened a 10-frame hive to examine it for a disease that closely resembled foul brood, and I removed three of the middle frames, placing these in an empty hive fully 4 feet from the hive that I was going to examine, and after I had them nicely placed in the empty hive, I then commenced to examine the remaining seven frames, and to my great surprise a swarm commenced to issue from the three frames in the empty hive, and while the bees were swarming from the three frames, the bees on the seven frames, fully 4 feet away, remained quiet; but after they had all swarmed from the three frames, the bees on the seven frames caught the excitement, and they rolled out of the hive by the thousand.

Now, I am positively certain that the bees on the three frames ordered the walk-out, and I am equally certain that the queen was not on either of the three frames, for I examined them carefully before I placed them in the empty hive, and after the swarm was in the air I again examined the three frames, and not a queen was to be seen. I quickly returned the three frames to the hive and closed it, but I did not get it more than closed when the swarm returned to the hive. As quick as the swarm returned, I opened the hive, this time to look for the queen, and I found her on the outside frame. This experience will forever convince me that the bees order the walk-out, and not the queen.

In 1896 I had a colony to cast a prime swarm at 4:30 a.m. It was so dark and cloudy the swarm could not be seen 100 feet away. I have been a bee-keeper eight years, and I have only lost five colonies during the winter. I know now how to winter bees without the loss of a single colony. Bees will winter far better on good, thick syrup, made of granulated sugar, than they will on the best of honey. I have had colonies in October robbed of the last drop of honey, and would feed them good, thick syrup, and these colonies would come out in the spring and do better in every way than colonies wintered on the best of honey. Preston Co., W. Va.

Complete Volumes of 1897.—We have on hand about 30 complete volumes of the American Bee Journal for 1897, which we will mail to any one upon receipt of 60 cents. We also have about the same number of the first six months' copies of 1897, which we will mail for 30 cents. As there were 832 pages of the Bee Journal last year, here is a chance for our new subscribers to get a good deal of valuable reading-matter for a very little money. Better order at once, before they are all gone.

CONVENTION PROCEEDINGS

Report of the Northeastern Ohio, Western New York, and Northwestern Pennsylvania Bee-Keepers' Convention.

BY ED JOLLEY.

This Association convened at Corry, Pa., Jan. 12 and 13, 1898. The usual business preliminaries disposed of, a general informal talk on bees was in order.

FOUL BROOD.

Mr. Spittler started the mill with the question, "Does any one know of a foul brood law in the State of Pennsylvania?" No one knew of any such a law, but all were agreed that there should be such a law in every State.

President Dewey asked if any one knew of foul brood in his vicinity. No one knew of it at the present time. Mr. Edgett's bees had had foul brood a few years ago. "It was caused," he said, "by the bees in some hives being accidentally smothered. Having brood in all stages it chilled and rotted in the combs. These combs were given to other colonies, thinking they would clean them properly, but the brood that was subsequently reared in these combs developed into foul brood."

Mr. Nichols thought foul brood might be caused by the injudicious spreading of brood, allowing it to become chilled and rot in the combs.

Mr. Sutton thought that the spraying of fruit-trees while in bloom often killed off the bees to such an extent that the brood was chilled and subsequently caused foul brood. All present, however, did not concur in the opinion that foul brood could be spontaneously germinated, and thought that in a locality entirely free from the disease chilled brood could not possibly cause it.

BROOD-FRAME COVERING IN WINTER.

"What is the best covering for over the brood-frames in winter?"

The majority used burlap or other cloth that would permit moisture to escape. Mr. Sutton used enameled cloth, the enameled side toward the bees. Mr. Nichols had the best results by using a board over the frames, putting it on and allowing the bees to seal it thoroughly. Messrs. Sutton and Nichols both used a heavy packing on top of their sealed covers. Mr. Dewey used a rim covered with cloth, over which he laid felt wrapping, such as is used for covering steam and water pipes, it being a non-conductor of heat and cold. Mr. Peck used a box larger than the hive; setting the hive in the box, he packed the space between the hive and the box with chaff, and also put six inches to a foot of chaff on top of the hive.

EXAMINING COLONIES WITH SEALED COVERS.

The question arose as to how those using sealed covers examined their bees during the winter.

Mr. Nichols always tried to be sure that his bees had honey enough to carry them through, and then trusted to luck.

Mr. Sutton could tell about all he wanted to know in winter by putting his ear to the outside of the hive. If the bees were quiet, or he heard a low, even hum, he felt reasonably sure they were all right. But if every now and then he heard a sharp, plaintive note, he was apprehensive.

Mr. Edgett examined his bees at any time during the winter or summer that he wanted to know how they were getting along.

Mr. Peck would not disturb his bees during the winter, not even by walking through his apiary, if there was a frozen crust on the snow. In fact, if he caught a person walking through his apiary at such a time he would order him out.

The President's annual address was now delivered by Pres. Dewey, in which he expressed his pleasure at meeting those present, and extended his best wishes that success might crown our future efforts.

Mr. Spittler next read a paper on

Spring Management of Bees.

If the conditions necessary for successful wintering of the bees was complied with the fall previous, spring management will be, as a general thing, a very simple matter. Of course,

bees must have the needed attention at the right time, even if they come through the winter in the best possible condition.

Some of the colonies will have consumed double the stores that other colonies have by consuming stores in brood-rearing or some other cause or causes. They will have to be attended to—perhaps fed—while other colonies will have abundant stores, too much perhaps, and will need frames of honey taken to be replaced by empty ones so as to give the queen plenty of room for depositing eggs. Without this precaution early and small swarms may be the result, but often the hive is too short of stores, even with strong colonies.

In no case should bees have more combs than they can well cover in the spring, if it is desired to build up colonies for the early honey-flow, whatever that may come from. So in most cases contraction of the brood-nest will have to be practiced for best results. But, says one, "That will be fussing too much." Perhaps it will, but as heat is one of the necessary conditions for brood-rearing, heat must be provided; this can only be done by contracting, especially in small colonies. A weak colony with a good queen can be built up to a strong colony if taken in hand in time.

When bees are examined—overhauled—in March, if the weather is warm enough to contract the brood-nest so that brood-rearing can commence, a weak colony should have but three frames at first, and one of these should be full of honey. If the cappings next to the center are broken a little to start up business, all the better. The next time you handle break some more cappings, perhaps on the outside of the comb this time would be best, especially if more than two weeks since first handled.

Then follows expanding the brood-nest, which must be practiced with great caution, and in weak colonies it should not be done until young bees hatch out in pretty large numbers so as to be sure that chilled brood will not result. By adding combs from time to time, and feeding all that will be necessary to keep the queen busy, the very weakest colony can be built up, but better not have weak colonies.

By providing water in abundance in a warm location—in a sunny place protected from west winds—much may be done to prevent spring dwindling. By not giving more combs to the bees than they can cover, the wax-moth, so much dreaded by many bee-keepers, can do no harm. GEO. SPITTLER.

Mr. Dewey had some dark honey which he wished to utilize in the spring to the best advantage. He queried as to whether it was best to feed for stimulating brood-rearing to colonies that had an abundance of honey in their hives, or whether it would be better to feed it so as to fill the brood-combs just before the white honey-flow. The majority thought the stimulative feeding would pay the best. Mr. Peck thought that if he filled the combs with the dark honey just before the white honey-flow, the bees would carry it up into the supers where it would do more harm than good.

The prevention of swarming was next considered. Mr. Nichols' plan was to give plenty of super room in time. He practiced clipping the queens; the first year he clipped one wing, the second the other, and the third he superseded the queen. Mr. Sutton gave room underneath the brood-nest to prevent swarming.

The next on the program was a paper by Mr. L. K. Edgett, on

Management of Swarms.

This subject is one prolific of discussion, and I can do no more than give the method, as it has been a success with me and others who have used it in this locality.

It may be well to give my reasons for its use. With black bees I found the Heddon plan would prevent all after-swarms, but with Italian, Syrian and Carniolan in many instances it only delayed them a few days, and if I cut out all queen-cells but one, left the hive crowded with young bees that had no work, as there was no brood to nurse or comb to build, they would hang out until the young queen began to lay, or they were old enough to go to the fields, and this time was lost.

Here we have a short honey-flow, generally, and not very heavy. Colonies that swarm store very little or none after swarming in the June honey-flow. I do not advise the use of this method in May or August, but on swarms that come at the beginning or during the June flow. When a swarm issues during this time, I hive it in a hive contracted one-fourth, and set it in the place of the old colony, leaving the colony beside it turned at right angles or moved in any way to throw the working-force into the new swarm. The third day after, put the supers from the old hive on the new swarm, and move the old hive so that the entrance comes close to that of the new swarm. This can be done a little at a time, or all at once, as best suits the operator. Leave the hives in this position until

the seventh day, then take the frames from the old hive. Shake nearly all the bees down in front of the new swarm, and cut out all the queen-cells but one. Then move the old colony to a new stand to build up for buckwheat. You then have a colony that will store surplus if there is any to be gathered.

I have used hives containing eight frames $8\frac{1}{2} \times 11\frac{1}{2}$, and from that up, and I find this works best with large hives.

L. K. EDGETT.

THE MARKETING PROBLEM

was next considered. All present were agreed that the prevailing low price of honey was not due to over-production, but to a class of slovenly, careless bee-keepers, whose chief success was in spoiling the market. Their honey was not worth more than they got for it; but the price paid for it was the ruling price for the season. The only remedy suggested that seemed feasible was by co-operation, and have a bee-keeper in each neighborhood to buy up all this honey and then keep the market supplied, but not overstocked.

HOUSE-APIARIES.

Mr. Dewey next gave a talk on house-apiarles. His house-apiry is built after the plan of Mr. Langdon's, as described in the Bee Journal for 1895, except that Mr. Dewey made his wider than the Langdon plan, having room for his supplies and fixtures inside. He likes it better than an out-door apiry for several reasons. The operator is protected from the hot sun; he can open a hive without fear of robbing; can feed a colony at any time without other bees having access to it; and can lock the door, thus making it safe from prowlers. Its most serious drawback is the loss of young queens at mating time, the hive-entrances being so close together and so much alike.

The Secretary next read a paper written by Mr. N. T. Phelps, on

Progress of Bee-Keeping.

It was probably a mistake to put me down for a paper on the progress of bee-keeping, as I am no writer, and am also one of those who believe it better to put forth one's energies to keep up with the present than to begrim one's hands with the musty records of the past. This places me a little out of my element, but as the task has been assigned me I will do the best I can. The old-time methods of bee-keeping will be mentioned not because they will be new to any members present, but to recall those things and place them in comparison with the present methods, and thereby provoke discussion in practical things that concern the present day.

I now recall no pursuit that has made the advancement that bee-keeping has in so short a time. A few years ago the ordinary bee-keeper knew very little of the natural history of the bee, and almost nothing about proper hives and appliances. Perhaps I can mention no *old* thing or any *new* thing that is not known to every member present, but let me compare a few things used and believed then, with a few things used and believed in now.

When I was young I lived very near one of the best old-time bee-keepers in all the country. He kept a large number of colonies, and it was believed that his would rob and carry home all the bees in the neighborhood. It was of no use for any one else to try to keep bees near him, because his family lived together in greater peace and happiness than any one else, therefore his bees were more loyal to him than to any one in the neighborhood. To-day we know that a good, strong colony in a normal condition will hold their fort against all comers. Give them plenty of honey to gather from the fields, and they don't care if a man does quarrel a little with his wife or mother-in-law. This old bee-keeper's hives were made of rough board boxes or hollow logs sawed off, and two cross sticks put through them, and he never saw the inside of one of them from the day the swarm was shaken off the branch in front of them until they died from some cause that the modern bee-keeper with his movable-frame hive ought to be able to prevent.

The bees themselves seem to have made a great deal of advancement, too. Then they were ruled by a "king." They had to do everything as he commanded, some were soldiers at his command, some stored honey at his command, some gathered bee-bread to live on at his command, others made wax at his command, and when he died they mourned themselves to death for him. Now the colony has no government at all. Every bee is so good and patriotic that each bee does just exactly right every time—does just exactly what is best for the colony under all circumstances.

My neighbor bee-keeper used for surplus honey a box 6x6x12 inches, also made of rough boards, sometimes with a

hole in one end covered with a piece of broken glass. Auger-holes were bored in the top of the hive to match, and the box was then set on top of the hive. When the bees got ready—if the family were real good—they would fill this box with honey. The honey was gotten out by prying off one side of the box, usually the bottom, and then cutting it out with a knife. When the honey was sold to a neighbor this box was saved and sent back to the bee-keeper. Quite a contrast with the present method of using one-piece sections. Then that honey sold in those boxes for 25 cents per pound—sometimes as high as 30 cents per pound. Now a net price of 12 cents is quite up to expectation. I don't quite see the progress in that, do you?

The first attempt to make any kind of a comb-gulde that I know of, was by pouring melted wax through one or two of the holes in this box and letting it run lengthwise of the box, making a little ridge of wax along the top of the box, when it was then set on the top of the hive. Contrast this with the foundation we use to-day, and the attempt at drawn comb. We know the foundation we have been using is a great success. It is to be proven whether drawn comb will be as much of a success in the hands of the average bee-keeper. This much, however, we do know, that it is one of the greatest mechanical achievements of the present day.

About the year 1856 the "old bee-keeper," before mentioned, had 170 colonies around three sides of a yard, on benches. The next spring he had not *one* live bee left. His neighbors surmised that he and his wife had quarreled, therefore the bees had left. But along in the next summer when the benches were moved so as to mow the weeds, the remarkable discovery was made that the worms had driven the bees out of the hive. He also remembered that he had seen a good many bees coming out of the hives along in the latter part of the winter, but he never thought to blame the worms for it at the time.

Now every up-to-date bee-keeper *knows* whether his bees have enough stores to winter on, and if short of stores supplies them with enough to last them until more can be gathered. Then the "king" ruled his lifetime; *now* the queen is removed whenever her usefulness begins to wane.

Many more things could be mentioned, but this is enough for one convention. Mention of some things might be made that I am afraid are not progress in bee-keeping. One of them is the Hoffman frame. While I believe in a distance-keeper or spacer, I want the frame so movable that *any* frame can be readily taken out. We owe almost all of this advancement in bee-keeping to a readily movable frame. When the frame is less movable bee-keeping will not be as scientifically attended to.

Another thing is the "fence" and no-inset section. I have had experience enough to know that many more sections of honey will be damaged in handling and shipping without insets than with.

N. T. PHELPS.

The following officers were elected for the ensuing year: President, George Spitzer; Vice-President, H. S. Sutton; Secretary and Treasurer, Ed Jolley, of Franklin, Pa.

Franklin was chosen as the next place of meeting, and the time selected is Jan. 11 and 12, 1899.

ED JOLLEY, Sec.

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 151.)

SECOND DAY—FORENOON SESSION.

SWEET CLOVER DISCUSSION CONTINUED.

A Member—Is the National Bee-Keepers' Union helping Dr. Besse in his lawsuit?

Pres. Miller—I am one of the Advisory Board of the National Bee-Keepers' Union, and if they have offered any help to Dr. Besse I don't remember anything about it. I don't think that is the case. Dr. Besse, has the National Bee-Keepers' Union promised to do anything in the case?

Dr. Besse—They have promised to stand by me. Mr. Newmau and I corresponded, and he said they would assist me.—[In the annual report of the National Bee-Keepers' Union, it states that Dr. Besse has received \$75 toward the expense of pushing his suit.—EDITOR.]

Mr. Baxter—I sympathize with Dr. Besse, and I think it would be proper to help him under certain conditions, but I

maintain that the National Bee-Keepers' Union, or any other Union, as far as that is concerned, cannot do anything unless he has been attacked under color of law. Then it is their duty; otherwise, not.

Mr. Stone—I do not believe that it is any of our business to interfere unless it is a State law, and then I would like to see the Union go in and contest that law, and see whether it could stand, to make sweet clover a noxious weed. I wouldn't care if it cost \$5 to every member of the Association, as far as I was concerned.

A Member—Sweet clover has been grown in our county (Kendall) for 25 years. It was sowed there on the streets and on the roads by a man for his bees. And from that day to this I believe that the farmers in the neighborhood have been fighting it, and I believe they are fighting it stronger today than ever before. The people for miles around my town believe that sweet clover is equal to Canada thistle. Nothing that has ever been written or said seems to affect it.

Mr. Karch—There has been something said about sweet clover which I do not agree with. It doesn't act the same in our locality—Will county. I remember in my boyhood days it was very seldom we saw a plant anywhere. I remember seeing the first one in our garden; it was there for a curiosity. The roads in our locality now are covered in some places, and you can notice the difference, year by year, where it extends further and further. I won't allow sweet clover to grow on my farm any more, not much more than I would Canada thistle. I hate to have anything spread on my farm which is not under my control. The highway commissioners are very careful in cutting sweet clover on the roadsides, and you ought to see what a beautiful blossom there is; the bees as much as two weeks ago were working on that sweet clover on the roads. It is in fine blossom to-day, and I don't believe there is any more killing sweet clover by cutting than there is by pulling the bloom off with a rake.

Pres. Miller—Localities differ. I have a little place of about 40 acres. I sowed over I think about 25 acres with sweet clover, sowed it on grass and everything as it was, simply scattering the seed over the ground. That was perhaps 15 years ago. I tried to encourage its growth all I knew how during that time. This year perhaps on that 20 or 25 acres there may have been half an acre of sweet clover. So you see it doesn't spread so very fast on my place. I have had it die out entirely where I sowed it and tried to keep it—just gave it the same treatment that I would red clover, had a stand come up and have every appearance of being good, except a rather weak growth, yet next spring there wasn't a plant of it there, not one. Yet it flourishes on the roadside.

Mr. Whitcomb—Three or four years ago I noticed all over the northern part of this State, when the pastures were entirely gone, that the farmers were maintaining their stock on the sweet clover on the roadsides. And during those dry years out about Grand Island, Nebr., had it not been for the sweet clover growing on the roadside poor people would have had to sell their cows. Isn't a plant that is so hardy valuable? Isn't it of some value to cultivate as a forage-plant and as a bee-plant? Ought we not to turn in and foster it, and take care of it, and sow it, and put it in a position where it would be of some value? Anything else that came up the farmer community would take hold of and be using as a forage-plant. Something is going to grow along the roadsides, in Illinois and Nebraska, and everywhere there is fertile land in a prairie country. If it is not sweet clover it will be rag-weed or sunflowers. A patch of sweet clover along the road looks a great deal nicer to me than a patch of wild sunflowers. People will pass through sunflowers week after week and never say a word about it, but if they strike a patch of sweet clover they are horrified. Ignorance and superstition are two of the worst evils this country has to deal with. And I have traveled over long stretches of your Illinois country, where if you went a foot your clothing was covered with the pollen from the rag-weed; and it is a villainous weed.

Mr. Baxter—Poisoning the air with its pollen.

Mr. Whitcomb—You sow a little sweet clover there and the whole country is horrified. The nature of sweet clover is not such that it will encroach upon your cultivated land. It may encroach on your pasture a little bit. If it does, you have one of the best pasture plants you ever saw. Let a little patch of sweet clover appear out in your pasture, and you drop your work and go and pull it up and carry it away! Why? Simply because you have not studied the nature of sweet clover, and don't understand that you are destroying one of the most valuable plants that ever grew on your farm, and one that will furnish you pasturage before anything else comes up, and after everything else has been killed by frost.

Mr. Baxter—The Dadants have been growing it for about years; and, as a pasture plant, there is one objection to it.

The cattle eat it so close to the ground that it dies out through the winter, very often!

Mr. Baldrige—Mr. Karch says it is so difficult to get rid of. I gathered seed this year from perhaps two acres of ground, and I doubt very much whether you can find a solitary root alive to-day where I cut. In fact, I have a standing proposition where I live, that if they will let the seed get in the dough state, or cut it in full bloom, that there won't be one solitary root alive the next spring. I will give a dollar apiece for every root that will be alive.

Pres. Miller—Would they be alive if they were not cut?

Mr. Baldrige—No, but the seed would drop. If you want to get rid of it, you cut it at that stage and you get rid of both seed and root. It is the easiest plant in the world to destroy if you once really understand its habits.

Mr. Karch—I will say that our stock in Will county must be educated to the use of sweet clover as a fodder. I have failed to see any cattle in our neighborhood ever touch any sweet clover, consequently they never kill it by eating it close. That is my experience.

Mr. Green—Sweet clover is no new thing with us. Thirty years or more ago at least there was a patch of it in our garden, and for at least 10 years it didn't get 10 feet away from that spot. Within the last 15 years, and especially within the last 8 or 10, it has grown very rapidly, and spreads all through the highways and waste lands of the neighborhood, and the highway commissioners in most of the townships cut it down very religiously; but I am not at all alarmed. I would just as leave they would do it as not, and perhaps a little rather, because they do not understand the nature of the plant, and they either cut it down at such a time that it grows up and makes late pasturage for the bees, or they cut it so that it gives the young plant a chance to grow. So they are not getting rid of it. Within the last year or two I have noticed it encroaching considerably upon hay or pasture land, but of course it does not stand cultivation. In regard to stock eating it, I have a horse that has never been educated to eat sweet clover at all, but if she can get out of the gate at all, she will attack that clover the first thing.

Mr. Schrier—I can remember about six years ago a family came from Michigan, sowed some sweet clover seed, and it spread out in the road, and I think it spread from our town clear down to Cairo, and all the cattle come from town and keep it down from spring till fall. The roads are well supplied with the sweet clover. My stock had no chance to get at it, so I can't speak for my stock. They don't get out in the road, and inside cultivated land I have none there. On meadow it will grow a little so long as it is not cultivated. So I think sweet clover is a good thing for honey, altho I would call it a nuisance on the highway, the way you see it in some places, as high as a horse where it is not cut down, and it looks ugly. But if the stock are around they will keep it down.

Mr. Thompson—I have a neighbor who has pastured two cows with the sweet clover on the roadside all summer long. The pastures were dry, and if he hadn't had that sweet clover they would have starved, or else he would have had to sell them. With regard to the benefits to bee-keepers I know this: In Kane county for the last two or three years it has been so dry that if we had not had an abundance of sweet clover our bees would have starved.

Pres. Miller—I am very anxious that the highway commissioners shall cut it down on the roadside. It is an objectionable plant, because it grows tall and strong for the roadside. It is worse than most plants in that way. Before it gets to that height cut it down, so that it will not leave a very objectionable stubble, which will be still disagreeable after it is cut down, but cut it down before it blossoms, and then you have it out of the way, and I feel very certain it will blossom afterwards just when I want it to. With me its blossoms are worthless during the blooming of white clover, because there is so much white clover I don't care for it. But if it can be cut down and bloom a little later than it is of value as a honey-plant.

Mr. Whitcomb—I can agree with Mr. Karch's statement, that stock won't touch it. Stock must be cultivated to it, in general. There may be an exceptional case when a cow or horse getting it for the first time will eat it. Texas cattle, I am told, must be educated to eat corn. Moreover, cattle must be educated to eat alfalfa.

Mr. Cooley—Can sweet clover be grown for forage and also for the blossom for the bees?

Pres. Miller—Yes, and no. Cut it before the first blossom shows, and it will give you a crop of forage, and will not interfere in the least with it as a honey-plant.

Mr. Whitcomb—In cutting for forage it is necessary to be careful not to cut it low. You must not cut it as low as tim-

othy. If you run your mower right down to the ground the chances are you will kill it entirely.

Mr. Lyman—I would ask if any one knows in regard to the present law in this State, in regard to commissioners cutting the weeds along the roads?

Pres. Miller—I think the law is that they may cut the weeds on the road.

Mr. Lyman—Doesn't it give farmers until Aug. 20 to cut those weeds? I think it does.

Pres. Miller—Perhaps that is true.

Mr. Schrier—They have time till the last of September.

Pres. Miller—Do I understand this, that if you say to the commissioners on your land, Don't touch this until a certain date, that they must concede that?

Mr. Lyman—The farmer, as I understand it, has until Aug. 20, or about that time, to cut the weeds along the roadside, and if he does that he is allowed \$1.25 a day, which is applied on his taxes. If the commissioners cut the weeds after that, the cost of the cutting is charged to him.

Mr. Baldrige—I have heard of such a law before, and a great many farmers where I live availed themselves of its provisions. They would be allowed so much on their taxes the coming year. But I understand that the law did not pass the legislature. It was an act before the legislature, but never became a law. A great many will find that out when they come to pay their taxes—they won't be allowed anything.

Mr. Stone—I don't think there is anything of that kind in the law.

Mr. Green—I think Mr. Baldrige is correct in regard to that law. I remember seeing it in the newspapers a report that such a law had been past, and farmers were notified and advised that they could obtain a rebate on their taxes in that way, but a week or two after that the papers informed that the law had not been past.

Pres. Miller—I think it will be well for us to have a little rest, allowing a chance for those not yet members to become so, and I believe Mr. Cooley has brought a sample section of honey built on the drawn foundation.

Mr. Stone—I would like to say that I have samples of the heads of two kinds of clover that I would like to have the members see. They were sent to me by a gentleman in Australia.

Pres. Miller—What kind of clover?

Mr. Stone—One of them is strawberry clover, and one he called creeping clover. The creeping clover has a seed that is a perfect rosette, and looks as if it were made out of brown paper.

Pres. Miller—It looks almost exactly like the alfalfa seed, only on a larger scale.

Mr. Stone—In those pods there are about five seeds, and for fear I would run out of the seed I planted three seeds out of the five. They are three or four times as large as a red clover seed. They grow very rapidly. Out of the three seeds three plants came, and something killed one, and I got a large teacup of these little pods from the two plants. The strawberry clover has a head just like a strawberry. They have little spots of fuzz on them that look like a strawberry.

(Continued next week.)

Bucket Honey was slow sale at 8 cents per pound this season, while that put up in pint Mason jars brought almost twice as much. Compliments on the good sense of the consumer are in order.—Somrambulist, in Progressive Bee-Keeper.

Bees Adapted to the Climate.—The best bee for any place must be one that comes from somewhere in nearly the same latitude, according to J. O. Grimsley, in Busy Bee. Carniolans coming from latitude 46° are all right for the North, but breed too much in the mild winters of the South. Italians come from latitude 44°, Cyprians from 35°, and Holy-Lands from 31°, so he would choose accordingly.

Bring up the Grade of Extracted Honey, is what Dan White makes a strong plea for, in Gleanings. He says: "Every fellow has been extracting and grading to his own notion, without saying a word to the other fellows. I believe we have just

as good a right to agitate the grading of our product as have the comb-honey producers. While they are polishing and sandpapering their sections, say we put such a finish on our extracted honey that we can draw a little attention. You see they are trying to attract the eye, and we will try to attract the palate."

Prevention of After-Swarms.—Put a cone escape at the entrance of the old hive, having previously set the swarm in place of the old hive, putting the old hive close beside it. No bees entering the old hive, only one queen will be left, and when that is ready for fertilization, remove the old hive to a new stand, or dispose of as seems best. F. A. Gemmill says, in Review, he has practiced this for five or six years, and J. B. Hall longer.

Bees Select Best Queen-Cells.—M. Jukos says in Meheszeti Kozlony, that, after careful observation, he finds that bees destroy purposely such larvæ in queen-cells as will not mature good queens, reserving only the best. Acting on this hint, instead of taking cells from a colony immediately after the issuing of a first swarm, he waits until four or five days later, and finds he has not only more beautiful queens, but decidedly better ones.

Don't Heat Wax too Much.—L. A. Aspinwall, in Review, thinks there is danger of getting too great a heat in melting wax, even in a sun-extractor. Over 212° the tendency to soften propolis so it mixes with wax is much increased. For this reason he paints his extractor white, outside and in. This is better for the wood, too, than black. A. C. Miller says many a lot of fine wax has been spoiled, or very much darkened, by allowing the water in which it is melted to boil together with the wax.

Telescoping Hive-Caps over sections are valued by Doolittle. "On cool mornings where there is only the one thickness of lumber between the outside air and the sections, we will find that the bees have stopt work in the sections and very largely gone below, while with the telescoping cap, the bees are enabled to keep up sufficient heat so that comb-building is going on the same as it was the evening before." And nearly the same thing on extremely hot afternoons.—Progressive Bee-Keeper.

Wintering Nuclei.—In reply to a call from G. M. Doolittle for some plan by which queens may be carried over winter, Dr. Miller tells, in Gleanings, how he has wintered in the same hive two colonies or nuclei. A bee-tight division-board separates the two parts, and the two nuclei clustered up against the division-board, forming a single cluster with the division-board in the middle. Editor Root says that before they sold off queens in the fall, they wintered nuclei in this way successfully.

Untimely Brood-Rearing in early spring or late winter, its causes and consequences, are dwelt upon in Sweizerische Bztg., also in Preussische Bztg. The brood-nest is unduly extended, bees fly much and are lost in the chill season, and too often a cold spell comes on, obliging the bees to shrink to a small cluster, leaving a large amount of brood to perish. Some strains are specially given to this fault, and breeding from these should be avoided. Winter warmly, but not too warmly; avoid too much bright sunshine on the hives; be sure to have abundant stores in the hive in the fall, so there will be no need to excite the bees by too early feeding; allow plenty of ventilation and avoid all disturbance; these are the means advised to avoid the evil results of this unseasonable and exaggerated brood-rearing.

Shipping Bees in Cars.—Frank McNay prefers a stock-car as being cooler in warm weather than a box-car. He says in Gleanings: "My plan was to load the hives firmly, yet apart, so as to secure a circulation of air around each hive. This was done by placing a row of hives across the end of the car, a few inches apart, then securing them in place by laying two rows of lath crosswise on top of the hives, letting the ends of the lath press firmly against the sides of the car, and nailing lath to each hive with 1-inch wire-nails. Then we placed another row over the other, resting on the lath, with space between the hives over the center of the hives in the lower row, then we nailed on two rows of lath, the same as before. This plan worked nicely, as there was not a hive moved from its position en route, and as they had to be loaded two tiers deep, this break-joint plan not only served to facilitate ventilation, but also afforded an excellent opportunity to sprinkle water in the top of the lower as well as upper tier of hives, which was done several times, as they were three or four days on the road."

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B. Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott, C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. MARCH 17, 1898. NO. 11.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Next National Convention of bee-keepers ought to be even larger and better than that of 1897, if that be possible. But whether or not that will be attained depends much upon *where* it will be held. Editor E. R. Root and Rev. E. T. Abbott are whooping it up for Omaha, some time during the great Trans-Mississippi Exposition to be held there from June 1 to Nov. 1, 1898.

The Executive Committee, who have to decide as to where the convention is held, want to be assured of as low railroad rates to Omaha as will obtain to Cincinnati where the Grand Army meets early next September. This assurance the Omaha Exposition people so far seem to be unable to make. So there we are.

In all probability the rate to Cincinnati will be one cent a mile each way, as it was to Buffalo. Personally, we should like very much to go to Omaha, and it seems to us that all the railroads on this continent could well afford to make a straight rate of one cent a mile to Omaha during the months of the Exposition.

The Executive Committee of the United States Bee-keepers' Union feels that it ought to know something *definite* about rates before it decides to hold the meeting anywhere.

Honey Market of Belgium.—The United States supplies Belgium with more honey than any other, and the trade is well established. France is her chief competitor. Out of more than 2,000,000 pounds imported into Belgium in a recent year, the United States supplied 915,000 pounds. So reports the Orange Judd Farmer. We believe a large general foreign trade in United States honey could be developed if the right men could be found to undertake it and work it up.

Foul Brood and Drones.—We have received the following letter from Mr. A. F. Fluckiger, of Oregon, who says:

As I am a reader of the American Bee Journal, I would like to know your opinion about the article written by Mr. Poppleton, on foul brood, as per the enclosed clipping, as it differs much from Mr. McEvoy's statement. Also the facts about apiculture, from Mrs. Jessie Thornton; I find all a little strange, as I never before read in a bee-journal that the drones are useful for ripening the honey.

A. F. FLUCKIGER.

The articles to which Mr. Fluckiger refers are clipped from the Webfoot Planter, an agricultural paper which seems to be published in Portland, Ore. Mr. E. R. Poppleton says:

"I do not agree with Dr. Chase (nor do our best bee-journals), as to his statement regarding foul brood. You can no more start foul brood in a hive of bees than you can start a herd of cattle without a male and female. The disease is caused by a small insect or spora, and must be taken into the hive, where it multiplies very rapidly. It takes from 6 to 12 months to kill a hive—according to the amount of spora taken into it. . . . If bees become weak from the middle of June to October, moths will frequently fill the hives so full of web that the bees cannot get in to contract the disease. . . . As for the bee-moth, I believe they save ten hives to where they kill one—if they ever do kill any, which I very much doubt. In the 8,000 or 10,000 hives I have transferred during my 20 years' work throughout the Willamette valley, I have never found one good hive that I thought the moths could have killed. . . . The reason moths will save bees is because they fill the foul brood hive so full of web the bees cannot get in to carry off the honey. Foul brood hives that die in the winter are the worst to deal with, as there are then no moths to keep the other bees out, and these are sure to smell it in the spring."

It would be somewhat interesting to know what Dr. Chase could have said that would neither agree with Mr. Poppleton nor our best bee-papers. For certainly the bee-papers would not entirely agree with Mr. Poppleton in some of his statements. There must be something peculiar about Mr. Poppleton's locality, for he says you can't start foul brood in a hive full of bees, while elsewhere you cannot find a better place. With him "the disease is caused by a small insect or spora," while elsewhere, instead of belonging to the animal kingdom it belongs to the vegetable kingdom, the whole trouble being laid to a minute plant called "bacillus alvei." In other localities the bee-moth will hardly be considered such a benefactor as to save ten hives to where they kill one!

Then, the idea of moths trying to kill "hives" made of wood! Of course they couldn't. But they have often destroyed colonies of bees.

Mrs. Jessie W. Thornton, who has been engaged in bee-keeping for 20 years, gives "a few facts relative to the honey or section rack." She says:

"A good colony should consist of from 9 to 12 frames of honey and brood, one good queen, and 20,000 workers. Granting that the operator has a good colony ready for the production of comb honey, he will now place his honey-rack on top of the frames, directly over the brood-chamber. If the weather is fine and there are plenty of flowers for the production of honey the section-rack will be full of unripe honey in from four to six days. Now comes the process of ripening—quite essential—for bees will not cap unripe honey. In the ripening process is where the drones come into use, and therefore they should never be killed off. With their large wings they fan the air, keeping it in motion, and thus causing the water to evaporate from the honey. It will take about four days for the honey to ripen if the weather is fair; if cloudy it will take longer. Ten days is long enough in any case, so in ten days from the time you put on the rack you can take it off and it will be nicely filled with white, ripe honey."

Mrs. Thornton lives quite a distance south of Mr. Poppleton, and if possible has a still more peculiar locality. With 20,000 workers the section-rack will be filled with honey in four to six days, and with fair weather ripened in four days more, so you are always safe to take it off in ten days! In other localities, with twice as many bees, the bee-keeper will

think he is doing pretty well if he can have all his sections ready to take off in twice ten days. Possibly, however, it is not so much the locality as the management. While others try to limit the number of drones, Mrs. Thornton kindly fosters them, and they repay this fostering kindness by fanning the air to ripen the honey. But has she not a different strain of drones? for probably no one else has ever known drones to fan the air while in the hive.

BIOGRAPHICAL NOTES.

REV. L. J. TEMPLIN.

L. J. Templin was born at Danville, Hendricks Co., Ind., Dec. 20, 1834. He grew to manhood in Delaware and Henry counties of that State. He got his education in the public schools and by close reading and study at home. At the age of 20 he began teaching in the Indiana common schools. In the spring of 1856 he was married to Miss Mary A. Lerner, of Howard Co., Ind. Two years later he entered the ministry of the Methodist Episcopal church, in the North Indiana Conference. After four years of labor in this field, during which he was much of the time in the midst of great revivals, hundreds being converted and added to the church under his labors, his health failed, and he has been a great sufferer from asthma.

After the failure of his health, Mr. Templin located at Kokomo, Ind., and engaged in the nursery business. Dr. J. M. Hicks, of Indianapolis, became a member of the firm, adding a bee-department. It was here that Mr. T. became interested in bee-keeping. His health proving too bad for the business, he sold out, and after traveling two years as emigrant agent for the Santa Fe Railroad Co., he moved to Hutchinson, Kans. Here he engaged in teaching the common schools, and also had charge of the scientific department of the Teachers' Normal Institute of his county for several years. His health continuing to decline, and his wife's health having utterly broken down before leaving Indiana, their next move was to Canon City, Colo. Here he engaged in fruit-raising and bee-keeping, in both of which branches he was quite successful.

On account of several attacks of la grippe, the health of both Mr. and Mrs. Templin became so impaired again that another change seemed imperative. This time Southern California was chosen. On arriving there Mr. T. purchased a ranch at the foot of the San Miguel mountains, fronting on the noted Sweetwater reservoir, near a station and post-office, about ten miles east of San Diego. Here he is engaged in the bee and poultry business, to which he is adding the raising of Belgian hares. For many years Mr. Templin was a very ardent Republican, but becoming disgusted with the subserviency of that party to the liquor power, in 1884 he became a working, voting Prohibitionist. In this work he has been very active, having served five years as chairman of the county central committee of his party while in Colorado. He also served one term as chairman of the Colorado Prohibition State Central Committee; and canvast that State quite extensively in the interest of prohibition and The Challenge, the organ of the party in that State.

Mr. Templin has been a rather prolific writer for the public press; dealing largely with rural and scientific topics. Political and religious subjects have also engaged his pen to a considerable extent. Some of his writings have commanded considerable attention, being reproduced in leading publications in both America and Europe.

A FRIEND.

□ MR. THOS. GLANCY, of Hardin Co., Iowa, gave this office a call March 10, when in Chicago with stock. He sells his honey crop in the home market, having about 30 colonies.

MR. GEO. C. LEWIS, son of G. B. Lewis, of the G. B. Lewis Co., called at this office March 5. He reported a busy time at their bee-supply factory. They are preparing for a large trade this season.

"NO BUSINESS DONE ON SUNDAY" is a prominent line in the bee-supply catalog of M. H. Hunt, of Michigan. We were pleased to note it. There are too many who reserve their bee-work or bee-business until Sunday. If a man cannot keep bees without doing the work on Sunday, he would better let bee-keeping alone. We believe in resting on Sunday, in getting our mind off of week-day business cares and work. Six days labor out of seven is enough. All the world would be better off did it rest a seventh of the time. And as the great majority have agreed on Sunday as that "seventh," all should unite in seeing that everybody may rest on that day, and that no secular work be done.

MR. ALLEN LATHAM, of Norfolk Co., Mass., has this to say of the Bee Journal of last year:

"I consider that the 1897 American Bee Journal is the best of all years for at least 10 years."

Well, we have some complete sets of last years numbers still on hand, which we will mail to any one ordering, at 60 cents each. There are 832 pages in the volume—pretty cheap at 60 cents.

Mr. Latham has kindly sent us a sample of aster-goldenrod extracted honey, which is of a rich, golden color, and most excellent flavor. For a fall honey we do not know of better.

MR. T. S. FORD, of Scranton, Miss., the February Bee-Keepers' Review reports, died last November. Mr. Ford for several years wrote excellently for the Bee Journal as well as some other bee-papers, especially on the subject of bee-paralysis, with which he had considerable experience. He was one of the two or three that preferred to do without the American Bee Journal rather than see its reformed spelling. We regretted that so evidently intelligent a man should take such a stand, but he did, and we doubt not, had he lived, in a few years he would have been surprised that he ever could have looked at the subject as he did.

MR. JOHN DETWILER, a Florida bee-keeper, is also interested in oyster and clam culture. In a local newspaper he has two articles, one on "Experimental Oyster Culture," and the other on "The Propagation of the Soft Clam." About all we know about oysters is that we like to eat them; and as to clams—well, like a clam, we're softly mum.

PRES. E. S. LOVESY, of the Utah Bee-Keepers' Association, sent us this testimonial, Feb. 17:

"I am well pleased with the grand old American Bee Journal. It seems that there is some new feature, or something new and interesting, every week, for the benefit of bee-keepers."

CATALOGS FOR 1898 are on our desk from the following who are among those patronizing the advertising columns of the American Bee Journal:

Marilla Incubator Co., Marilla, N. Y.—Incubators.
M. H. Hunt, Bell Branch, Mich.—Bee-Keepers' Supplies.
Northrup, King & Co., Minneapolis, Minn.—Seeds of all kinds.
W. T. Falconer Mfg. Co., Jamestown, N. Y.—Bee-Keepers' Supplies.
Reliable Incubator and Brooder Co., Quincy, Ill.—Incubators and Brooders.
Gus Dittmer, Augusta, Wis.—Bee-Keepers' Supplies.
Electric Wheel Co., Quincy, Ill.—Wide Tire Wagon-Wheels.

MR. S. T. PETTIT, of Canada, writing us lately said:

"I enjoyed the 'kicks and growls' sent in by Mr. Jenkins, on page 120, tho I don't agree with him in kicking at your improved way of spelling. My wife and I rather like the short cuts—it never 'shox' us a bit. But, soberly, I am getting used to it, and like it."

In a few years we expect to find plenty more people commending us for our stand on spelling reform, who now look upon it with disfavor. Many unpopular things of the past are now "right in style." Before the first locomotive was invented, some people said it never could be made to run; then when they saw it running at about 10 miles an hour, they said it couldn't be made to stop! Of course, if some people want to go on writing *six* letters where *four* will do better, that's their privilege. See a few of them: Capt for capped, ript for ripped, nipt for nipped; then five in place of seven: dropt for dropped, shipt for shipped, stoip for stopped, etc.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Building a Bee-House.

If a bee-house is built with drop-siding and building-paper on the outside of the studding, and shiplap and building-paper on the inside of the studding, with building-paper between the roof-board and shingles, ceiling boarded with shiplap and building-paper, with ventilator on top, will it winter bees all right? WISCONSIN.

ANSWER.—So far as the house is concerned, it's probably all right. But you can't depend upon a house alone. Some kind of proper packing must be used, at least over the hives. The house will not keep the bees as warm as in a cellar.

Putting Bees Out of the Cellar.

My bees in the cellar are doing well. Would it be advisable to take them out when sap flows from soft maple? I have quite a grove of maples, and could tap and let the bees work on it if it were prudent. I know bees work on the maples, but I am at a loss as to when would be best to turn them out. I am experimenting with top ventilation of hives instead of bottom. IOWA.

ANSWER.—Better not take them out till your soft maples bloom, according to some, and according to others take them out about the first of April whether maples bloom or not.

Tell us how you come out about your ventilation. You'll likely find that in the cellar your bees will be all right if other things are right, whether the ventilation be at the top, bottom or middle.

Wintering in a Bee-Shed—Black Drones.

1. I have a bee-shed 16 feet long, three feet at the back and four feet at the front. I have a trap door to let down on the south side, and it is fastened up by strap hinges. I have my bees in dovetailed hives, and they are all packed in the shed with fine straw two inches thick. A part of my bees have plenty to go on. The hives will weigh all the way from 50 to 60 pounds. Where is it best to winter bees, in a shed or out in the open air?

2. What would you do with the drones from black bees if you were to give them Italian queens—trap them, or not? IOWA.

ANSWERS.—1. It isn't easy to tell without trying, but very likely they'll winter all right in the shed. Look out that the entrances don't get clogged.

2. What is best to do with the black drones depends on circumstances. If there are plenty of black drones within half a mile or a mile of you, it isn't worth while to do very much about your own. If you have only your own to contend with, then it will be well to trap them. But in this case prevention is better than cure, and it will be well to get as nearly as possible all drone-comb out of the black colonies.

Candied Honey for Honey-Vinegar.

I have some brood-frames full of candied honey. Will it be fit to make into honey-vinegar? COLO.

ANSWER.—It will be excellent for that purpose if the combs are clean.

Hives Under Apple-Trees—Unfinished Sections.

1. I have no bee-shed, so I set my hives under the shade of apple-trees, where the apples, in falling, hit the hives. Will this disturb the bees enough to make it advisable moving them out in sun? Apple-trees are all the shade I have.

2. What would be the best way to dispose of partly-filled sections? Would it be advisable to put them where the bees could clean them up—I mean out-doors? If so, when would be the best time? The bees have plenty of stores and could do without any feeding, but I would much rather the sections be cleaned up if it would be advisable. KENTUCKY.

ANSWERS.—1. I have had bees under apple-trees for years, and while I'd a little rather the apples wouldn't thump the hives, yet I don't believe it does much harm, and I expect to continue using apple-trees for shade.

2. It is quite possible that the best thing you can do with those sections, if there isn't enough honey in them for table use, is to melt them up, taking pains to melt them very slowly, no matter if it takes two or three days for it; then when melted and cooled, take off the cake of wax. For the honey is probably more or less granulated, and if it is, the bees are not likely to clean it out so clean

that not a particle of the grains of honey will be left, and any grains of honey will be a damage to the new honey stored in them. Of course it will be all right to feed them to the bees before melting, if you like, in which case it will be well to have something placed under to catch the chips of wax and grains of honey. If you had allowed the bees to clean them out last summer or fall, then the sections would be good to use this summer again.

Italianizing—Carrying Out Bits of Comb.

1. I want to Italianize my apiary next season. Not desiring any increase, how would it do to remove the black queens when they begin making preparations for swarming, and give the queenless colonies queen-cells in a day or two afterward?

2. Could as much comb honey be produced in this method as by waiting till the honey harvest is over and then requeen?

3. My bees are wintering on the summer stands. Some of them seem to be carrying bits of comb or wax out upon the alighting-boards. Are those that are carrying out the comb doing as well as those that are not? There is no moth. BEGINNER.

ANSWERS.—1. It will do all right if you're sure to give them good cells and not have them swarm.

2. Keeping the force together in this way ought to give good results in honey, perhaps better than if you let them swarm and requeened after harvest.

3. That's nothing against them if it's the bits of capping and refuse from the bottom of the hive. If it's pieces of comb broken from the cell-walls, there is danger that mice may be troubling. It's a good plan to have the entrances closed with wire-cloth having three meshes to the inch; this will allow free passage for the bees, but bar the mice.

Foul-Broody Combs.

I sent to Arkansas for a queen and introduced her all right. This was the beginning of June. I put a second story on with drawn combs, that I got from a neighbor. The bees cleaned them up and fixt them ready to fill with honey. That was all they ever did. I took off the second story to examine them, and I found four frames with a great number of cells not hatcht out, and all brood dead. I stuck a splinter into it to see if it was ropy; it did not draw out much; the cell-cappings were shrunk a little. I think it was foul brood. I got a clean hive with starters and shook the bees off in front, and after the bees had quit flying they seemed to work a couple of days, then the next time I lookt the bees had fled. I lookt over the orchard expecting to see them, but that was the last of them. I was not a bit sorry.

Would it be safe to use those combs that the bees cleaned up? They did not put a particle of honey into them, and they are nice and clean. I would not like to melt them up. How would carbolic acid and water do? ONTARIO.

ANSWER.—If I had those combs I wouldn't be a day older till I'd cut them out, and use the frames for fuel to melt the combs. Too much risk to fool with any kind of drugs in a case of that kind.

Using Combs on Which Bees Died.

1. My first winter with bees, I find one colony as "dead as a door-nail," as Dickens puts it. It was well covered with pine needles, except the front of the hive; had two frames of honey left; bees were clustered on top and near the top of three empty frames, and in each cell under the cluster is a bee wedged clear into the cell. I tried to cut them out, but couldn't cut across the top as the top row was full, and the pressure would make the foul contents of bees squirt all around. Are those combs of any use?

2. Can the bees be gotten out?

3. The colony was not a very strong one. What caused them to die? MASS.

ANSWERS.—1. If the combs were good before the bees died, they are still of value.

2. Yes. Some say mice will clean them out. If you keep the combs in a good, dry place, the bees may be pickt out with a pin after they are well dried, and some of them may even shake out. Or the bees themselves will make a pretty good job cleaning them out after they are dry.

3. Perhaps diarrhea. Possibly they starved. Even with plenty of honey left in the hive, they could make no use of it during a cold spell if it was out of their reach.

Nucleus Method of Increase.

I have one colony of bees, and want to increase them as many times as can be done with safety, next season. I do not want honey, but increase. NEBRASKA.

ANSWER.—In the matter of trying to make increase there are things to be taken into account that are all the time coming up, general principles that should be fully understood, or there's a chance to make a mess of it in a hundred different ways. As you mention the matter of "safety"—a thing often too little considered—perhaps the best way will be to work on the nucleus plan. The supposition is that your colony is in a frame hive. If the season is not a good one, you must count on feeding whenever it is

needed. If your colony will be accommodating enough to swarm in good season, all right. If not, you must take the matter into your own hands. Take two frames of brood with the adhering bees and the queen, and put them in another hive on a new stand. That leaves the old colony queenless, but very strong, for you must not think of doing anything until the colony has become very strong. And it's so important to have good queens that you must not think of a nucleus having anything to do with a queen-cell till it's sealed. In about a week you may take the old hive from its stand and put in its place the hive that has contained and still contains the queen, filling up this hive with foundation if you haven't done so before. You may now divide the contents of the old hive into nuclei. Put one of them on the stand from which you have just taken the queen, and the others in new places. Each nucleus should contain two or three combs with adhering bees. One comb well filled with brood may do for one of the combs, or if the combs are not so well filled, it may need two or even three frames with brood. Of course each nucleus must have a sealed cell. You now have the old queen on the old stand with a fair supply of bees, for many of the field-bees will go back to the old stand, and you will have, perhaps, three nuclei. As soon as the old colony gets as strong as it was before, you may repeat the operation, and in course of time the nuclei first made may become strong enough so they can be used to strengthen. Remember that "safety" is your motto, and you're not to be fool enough to get a whole lot of weak nuclei started, and have none of them strong enough to amount to anything. Work your nuclei up into strong colonies as fast as you can, and don't draw from any of them till they have at least five or six frames of brood. You can go on making two or three nuclei at a time if you have a long, good season, and you can do something toward making a good season by feeding. If you have an 8-frame hive to begin with, it may be worth your while, before doing anything in the way of dividing, to give it a second story and try to have 10, 12 or more frames of brood.

A Case of Bee-Diarrhea.

A beginner in bee-keeping who is a neighbor of mine is in trouble. His bees have the dysentery, and he knowing me to take the Bee Journal, has requested me to write for advice as to what is best to do.

IOWA.

ANSWER.—The disease called formerly dysentery, and now generally called diarrhea, is perhaps hardly a disease at all, in the strict sense of the word. It is a painful condition caused by the overloading of the intestines of the bee, and that being the case, the plain cure is to give the bees a chance to empty themselves. That's the only cure. As soon as a warm day comes, the bees will fly and empty themselves, for they are neat creatures and unwilling to soil their hives as long as it can possibly be avoided. Some have thought to hurry up matters when the weather was too slow, by taking the bees in a warm room and giving them a chance to fly. I'm not sure that it was ever a great success. But I have some little faith in warming them up thoroughly. When bees are in the cellar, it may be heated to 60 or 80 degrees, and then allowed to cool down again. If they are out-doors they can be brought in at night into a warm room, and the room allowed to cool down before daylight next morning, when they must be set back. But be sure the room is perfectly dark when they are warmed up. Your great hope will be in a warm day coming so they can fly.

The Solar Wax-Extractor.

Is the solar wax-extractor patented? If not, what is the size, and how is it made?

ILLINOIS.

ANSWER.—I know of no patent on the solar wax extractor. There are various sizes, and you can make them almost any way, so you keep the main principle in mind. That is, to have an enclosure covered with glass into which the sun can shine, with opportunity for the melted wax to separate from the slum gum or debris. A simple way is to have a box with a cover hinged on, a large pane of glass in the top of the cover, in the box a pan with a perforated bottom, in which to put the combs or scraps to be melted, and underneath this a pan to hold the melted wax.

Transferring and Dividing Colonies—Two-Story vs. One-Story Hives.

1. I have five box-hives with bees which I want to transfer in the spring to Champion chaff hives. Could I make an artificial swarm out of each colony at the same time when I transfer the bees? If so, please let me know how, and when would be the best time?

2. Is the Champion chaff hive a good hive?

3. Is a two-story hive as good or better than a one-story hive?

NEW JERSEY.

ANSWERS.—1. You could divide a colony into two or more at the time of transferring, but it would hardly be advisable. You may, however, reach the same end in a better manner. Wait till the colony swarms, and hive the swarm in the new hive. Set the swarm in place of the old hive, putting the old hive close beside it. A week later, remove the old hive to a new place. Two weeks later still, or three weeks from the time of swarming, all the worker-brood will be batched out in the old hive, when it can be transferred

to a new hive. The first one will be strong, and will give a good account in surplus honey if the season is favorable, the other one ought to satisfy you if it gets in proper condition for winter. Of course in a remarkable season it might yield surplus, and in a poor season it might have to be fed.

2. I have no practical acquaintance with the Champion hive, but I suppose it is a good chaff hive.

3. It all depends upon circumstances whether one story is as good as two. If only eight frames are in a hive, there are times when it will be much better to have two stories. With 10 or 12 frames in a hive, there is no great need of a second story, unless it be for surplus honey. Of course, if surplus receptacles are counted as second stories, then no one would think of doing with only one story, unless the long-idea hives are used, having perhaps 20 frames in one story.

Transferring—Cyprian Bees.

I have five colonies of black bees in box hives, and I want to transfer them as soon as possible into 8-frame dovetailed hives.

1. When is the best time to do it?

2. What time after transferring can queens be introduced?

3. Would you recommend Cyprian queens? SUBSCRIBER.

ANSWERS.—1. The time usually considered best is in fruit-bloom, but the belief is constantly gaining ground that it is better to wait till the colony swarms.

2. Any time.

3. I should not prefer them, but some like them.

Gathering Pollen Early—Perforated Zinc.

I purchase two colonies of hybrids in January, weighing about 50 pounds each, and moved them home, a distance of about 400 yards, the weather being brisk for about a week, then it moderated. They came out, and in a day or two they began bringing in pollen in large quantities. What were they gathering it from, as trees had no chance to bud or sprout? Or did they rob other bees? At the same time I found young brood which they had carried out, one of them matured only a crippled wing, showing they were rearing brood some time before.

2. I want to transfer them into movable-frame hives in the spring, and am making excluding-boards of perforated zinc-strips and wood-slats, alternately, the strips perforated with one row of square-cornered holes 17-100 x 9-16. Are they as good as two rows and round ends? MISSOURI.

ANSWERS.—1. The pollen carried in could not be from robbing other bees. When they rob it's honey they're after, not pollen, and the pollen that's in the hive they couldn't pack on their legs. It isn't easy to say what the pollen was gathered from without knowing the resources of your neighborhood. Pollen may be had from some plants and trees when you would think not a bud has started. Willows and hazels blossom and yield much pollen when the leaf-buds show no sign of starting. In some places skunk-cabbage is the first thing to yield pollen.

2. I doubt if you can detect any difference between one row and two rows, or between holes with round and square ends.

Management of Transferring.

1. I have 20 strong colonies of bees in large box-hives where I want to start an out-apiary. I have 8-frame dovetailed hives on hand to transfer them in next summer. I don't want them to swarm, as I could not be there to care for them. When would you transfer?

2. Can I "drive" them just before the swarming-season, and get nearly or quite as good results as by natural swarming?

3. Would you wait three weeks before making the next "drive," or drive out a few every week for three weeks?

4. Hived on starters, how many days would you wait before putting on the boxes, not using any excluders?

5. Do you think they would swarm during a honey-flow of about six weeks?

6. Can you suggest a better plan to get a crop of honey and keep down swarming? CONN.

ANSWERS.—1. Transfer in fruit-bloom.

2. In most cases probably not quite as good, but nearly so.

3. You were talking in the first place about transferring, but this is a different thing. It will be simpler to wait three weeks instead of making several "drives," and perhaps better.

4. Perhaps two.

5. Hardly, after being thrown on starters.

6. That's a hard question, to know how best to keep down swarming and get the most honey if you're running for comb honey. Study thoroughly your text-books, and have the general principles as familiar as A B C, and then you'll be better able to know just what will suit your case. If you are running for extracted honey it's much easier. In that case a plan highly commended by some, is to put one comb of brood with queen and adhering bees in the lower story, filling up with frames of foundation, and putting the remaining brood and bees in a second story with an excluder between.

GENERAL ITEMS

How to Sell Honey.

I have sold over 5,000 pounds of honey at retail, and have calls every day for more. My method of selling is to put 10 pounds in a tall gallon crock, and sell it for 90 cents, jar and all. Let every bee-keeper do the same, and less honey would go begging for a market in the large cities.

Lenawee Co., Mich.

C. A. HUFF

[Mr. Huff evidently practices what he preaches. Others could go and do likewise in the way of selling honey. When your own crop runs out, send for some of the alfalfa and basswood honey we offer in these columns. A small sample of either by mail, for 8 cents, to cover postage and packing.—EDITOR.]

High or Low Elevation for an Apiary.

In the answer to Maine on the above question, on page 54, Dr. Miller says he will yield the floor to any one who can throw light on the subject. I am unable to fully answer the question, but my experience may throw on a little light.

Last spring I placed two colonies of bees on the roof of an eight-story factory in Brooklyn, near the East river, and they gathered for me 150 pounds of nice comb honey, and I do not think they would have done better if they had been on the ground. I am wintering them on the roof, well protected. They are in good condition, and all right now—Feb. 7.

BROOKLYN.

A Report for 1897.

I commenced in the spring of 1897 with 15 colonies; I had six swarms, increasing to 21, and got about 46 pounds of surplus honey from most of them, tho I didn't get more than 25 or 30 pounds from some. They gathered honey very fast in the forepart of the season, tho it was too dry in the fall at the time that we get our best honey. We have a fine fall honey weed here, tho I don't know the name of it. It yields the finest honey that I ever saw. It grows very tall and has a fine bloom. It is a little like the boueset.

Hurrah for the American Bee Journal! I don't see how I can do without it. We have been taking six regular papers for a long time, and when they get here the Bee Journal is the first and the last one that I read.

Calloway Co., Ky.

W. W. BUCK.

Results of the Last Season.

I like the Bee Journal better every year, and always look forward to the night it arrives with pleasure. I have learned all I know from it, and would like to see more of my bee-keeping friends subscribe for it. Last season was the best I have had; from two colonies of Italians I took 252 pounds of extracted and 28 of the whitest and best-filled sections I have ever seen. After taking off the sections I put on a second story with ten frames half filled with foundation; eight days after I extracted nearly 60 pounds, making a total of 96. Another colony built their combs, and I extracted 156 pounds from them. I averaged 56 pounds of comb honey per colony. My bees are all Italians, in 10-frame Langstroth hives. I am making a few 12-frame hives. Mine are all double-walled, packed with two inches of chaff. I believe in large hives.

Ontario, Canada.

JAMES LATDLAW.

Bee-Keeping in South America.

I read the Bee Journal with the greatest interest, but sometimes it is difficult for me to understand how old, settled questions, as about the necessity of comb foundation,

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

The Honey that Suits All Who Buy It.

We can furnish **White Alfalfa** Extracted Honey, in 60-pound tin cans, on board cars in Chicago, at these prices: 1 can, in a case, 7 cents per pound; 2 cans in one case, 6½ cents; 4 cans (2 cases) or more, 6 cents. The Cash must accompany each order.

can be ventilated again. I cannot understand how bee-keepers can do without foundation. I have about 300 colonies, and make a business of them, and would really not know how to manage them alone with my daughter without comb foundation.

Bees are very cross here in summer-time. We have black bees. I believe the Spaniards brought them into this country.

People who dream about the stingless bee should know that those bees are not really bees (*Apis mellifica*), but *meliponas*. There are many classes. One I know does not sting, but crawls in one's hair and heard, gives very little honey (in small pots like a tumble), and the wax is soft and different from beeswax. I have heard about the other classes, too. Some of them fight and bite terribly, much worse than honey-bees. They live altogether in hot climates, and it would never pay to domesticate them, as they produce very little honey. J. NOELTING.

Buenos Aires, South America.

Early Spring and Fruit-Bloom.

We are having a very early spring, and if this weather lasts 10 days longer, bees will swarm before. Plum and peach trees are in full bloom here now, and the weather is like the month of May. I have 13 colonies, and they are in good condition, and storing honey every day. I examined them today. C. R. West.

Ellis Co., Tex., March 8.

A Bee-Keeper in Trouble.

Last October we had a big rain, but since then we have had hardly any. It has been dry until now (Jan. 12). We have just had a good rain, about 1 1/2 inches, which gives us in Southern California hope for a good honey-year if it keeps on raining occasionally.

I have now 200 good colonies of bees. Last winter I lost a good many by neighbors who went on my land in my apiary and tipped over my hives. Now they have sued me as a criminal for keeping bees on my own land from where the bees fly off to others' land. I am right in the foothills, and the mountains back of them; there are other bees and apiaries around me, but they don't say anything about them. I have my case appealed to the superior court. I'd like to know how I can be a criminal when legally holding property—bees and land—and make an honest living from my bees and pay taxes on them. But the neighbors wanted to destroy my bees and my living. I shall fight for my rights.

Last spring I had about 60 colonies left; 36 were very strong in March, so I took bees from them and made the weak ones stronger. I got 13,000 pounds of extracted honey, all light amber, and increase my bees to 200 colonies. Most of them are now in good condition, but the price of honey is discouraging—3 1/2 cents per pound.

FRANK S. BUCHHEIM,
Orange Co., Calif.

Sowing and Growing Alfalfa.

I have noticed of late that there have been a number of enquiries in regard to this plant, as its virtues as a honey and fodder crop are unsurpassed in any locality where it will grow as a honey-plant. It needs a moderately-dry climate, and in a dry, irrigated district where there is an abundance of water that can be poured over the surface of the soil. This supplies the roots with sufficient moisture, and produces a vigorous growth, then if there is no rain to wash the nectar out of the blossoms—under those conditions I believe it is at the top of the list as a honey-plant.

In reply to enquiries as to when and how to plant: Where there is no danger of frost, sow in the fall; where that danger exists, preparing the ground in the fall is best. The next best is as early as possible in the spring. The soil should be as fine as it can be reasonably made, and I believe the earlier it can be sown, within reason, the better. It can be sown alone or with

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|----------------------|-----|--------|--------|--------|
| Sweet Clover (white) | .60 | \$1.00 | \$2.25 | \$1.00 |
| Alsike Clover | .70 | 1.25 | 3.00 | 5.75 |
| White Clover | .80 | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover | .60 | 1.00 | 2.25 | 4.00 |
| Crimson Clover | .55 | .90 | 2.00 | 3.50 |

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight.

wheat or oats. If sown early so as to catch the spring rains, I would sow about 18 to 20 pounds to the acre; if sown late or with other crops, I would put on 23 pounds; for if it is sown with grain, and it should happen to be a very thick stand, it may smother some of the alfalfa. It needs more moisture the first season than afterwards. A rain after the grain is taken off will give a vigorous start. With us, if we sow it with grain, as soon as the grain is off, we turn the water on for a few hours, and the result is that we soon have a green field.

Nearly all farm animals will eat alfalfa and grow fat on it, either in its green or dry state; thus, if it does not pay as a honey-plant where it will grow, it will pay as a fodder crop. Its only danger is bloat when fed in its green and wet state.

Salt Lake Co., Utah. E. S. LOVESY.

The Nickel Plate Road

changed time and also depots March 6, 1898. All trains now arrive and depart from Van Buren Street Station, near Clark St., Chicago. All trains on "L" loop stop at Nickel Plate Depot. City Ticket Offices, 111 Adams Street, and Auditorium Annex. Telephone Main 3389. (5) 11A2t

Convention Notices.

Texas.—The Texas State Bee-Keepers' Association will hold its annual convention at W. K. Graham & Son's, Greenville, Texas, the first Wednesday and Thursday in April, 1898. All interested are invited.

W. H. WHITE, Sec.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, April 5, 1898, at 10 a.m. A full program in the interest of the industry will be presented. It is very desirable to have all parts of the State represented. Among other things to be considered is the transportation and marketing of our products, and also the adoption of the best plan to represent our State at the Trans-Mississippi Exposition, and to get our new foul brood law into active operation. Every bee-keeper should be interested in these matters. All are cordially invited. In case there may be any that cannot attend, we would be pleased to have their address, and have them send in questions on general topics. Several members of the Association have desired us to again call the attention of our bee-keepers to the Langstroth monument fund. Any who feel able should throw in their mite to mark the last resting-place of this the greatest of all American bee-keepers. No one will feel as if it was labor in vain, who takes a fraternal interest in this desirable object.

JOHN B. FAGG Sec., East Mill Creek, Utah. E. S. LOVESY, Pres., Salt Lake City, Utah.

Chicago's Favorite Passenger Station.

Reasonable success seems to have followed the efforts of the management of the Nickel Plate Road to make it popular as a passenger line for travel East. It is regarded as a favorite by many in making the journey from Chicago to Eastern points.

Patrons of that line will be gratified to learn that arrangements have been made, effective Sunday, March 6, for all passenger trains of the Nickel Plate Road to arrive at and depart from the Van Buren St. Station in Chicago.

The many advantages afforded by this Great Union Depot, located in the heart of the business portion of Chicago, and the continued advantage afforded by lower rates than over other lines, having three Express Trains daily, with through Sleeping Cars to New York and Boston, and the advantage of superior Dining Car Service, when all considered, should show increase travel over the Nickel Plate Road. HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Mar. 8.—A little fancy white sells at 11c. if free from any indication of graining, but the majority of white honey sells at 10c., with off grades at 8 to 9c.; amber is not selling readily at 8c.; dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 1/2 to 5c.; dark, 4c. Beeswax, 26 to 27c., and in active demand. The weather is now suitable for shipments of comb.

Milwaukee, Wis., Mar. 8.—Fancy, 11 to 12c.; A No 1, 10 to 11c.; No. 1, 10 to 10 1/2c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4 1/2 to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the BEST. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better

Buffalo, N. Y., Mar. 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5 1/2c.; light amber, 5c.; white clover and basswood, 4 1/2 to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cincinnati, Ohio, Feb. 21.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 1-2 to 6c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

Cleveland, Ohio, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6 1/2c.; amber, 4 to 5c. Beeswax, 22 to 25c.

Kansas City, Mo., Feb. 19.—Fancy white comb, 1-lbs., 10c.; No. 1, 9 to 10c.; amber, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 5 1-2c.; amber, 4 1-2 to 5c.; dark, 4c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

St. Louis, Mo., Feb. 9.—Fancy hite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c.

Detroit, Mich., Feb. 1.—Fancy white, 11 or 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply, and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12 1/2 to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3 1/2c. Beeswax, 28c. Late arrivals of California honey have demoralized our market.

Minneapolis, Minn., Jan. 31.—Market is in an overloaded condition on comb honey. Good chance for fancy white extracted at 5 1/2 to 6c., but comb is at a standstill, particularly if other than fancy white. Best price available on fancy white comb is 10 1/2c., and buyers are slow at that. Darker grades or broken lots are unsalable. If shippers would send in their extracted when it is wanted, and not push undesired comb [and vice versa] the stuff would move more advantageously to all concerned. The trouble is, when a fair price is obtainable some shippers hold out for more and in the end lose by it.

\$100

Given as Bounties to purchasers of the improved Danz Hives and Sections. See schedule in my bee-book "Facts About Bees." Tells

how to produce honey that sells for the most money. Free for 2c in stamps. Address: THE A. I. ROOT CO., Medina, Ohio, or F. DANZENHAKER, Box 466, Washington, D. C.

Something About the No-Wall Comb Foundation

Since so much has been said in regard to the possibility of producing foundation with deep walls, there has been considerable discussion of the advisability of using such foundation, and very plausible arguments have been brought forward in support of it, but also of the opposite, or of a foundation without side-walls at all for the honey-sections. The greatest objection to high-wall foundation is the possible production of comb honey in which the septum would be heavy. As a matter of course, if the foundation was made as thin as the bees produce it naturally, the objectionable feature would be avoided, but it is yet a problem whether this kind of foundation may be produced in merchantable quantities. Meanwhile, I have noticed that the advocates of no-wall foundation

I will say first that there is no doubt that the very lightest foundation that can be made by machinery will be sufficient, and will carry the weight of bees, if it is allowed to cool or temper long enough before it is put into the hive. The aim that will be attained by using an exceedingly light grade will be the avoidance of the well-known "fish-bone." A foundation with little or no cell-wall will be much more readily modeled by the bees even if it did not come out of the hands of the manufacturer in thinner sheets than other grades. Hence the result reported that the comb built on a no-wall foundation seemed about as thin as natural comb.

Now as to the warping of this foundation, it comes from a very simple fact. When the sheet of wax comes out from between the rolls of the mill, there is nothing to draw it to either roller, the result being that it sticks alternately to each and "warps" as it comes out. We have long ago noticed that foundation which sticks unevenly to the rollers as it is milled, sticking partly to one and partly to the other, or first to one and then to the other, does not prove satisfactory in the hive. As we were both apiarists and manufacturers of foundation, and making a specialty of both, this was one of the first things we ascertained years ago. No matter how you may smooth it down, the sheet which has warped in the mill will warp in the same way in the bee-hive. The deeper the cell-wall the more damage to the sheet if it is warped as it comes out. In our

Unfinished Combs Built from No-Wall Foundation.

are out-spoken, and show a desire of further experiments in this line.

In the last January Bee-Keepers' Review, two different persons report on this foundation which was tried last year. The greatest objection seems to come from the foundation curling or warping when given to the bees. As this experimental no-wall foundation was made in our shops, I believe that we can throw some light upon the subject, and show how the difficulty above-mentioned may be avoided.

practice we never allowed a single sheet which did not stick uniformly to one roller to go to the shelf, but all such sheets were mercilessly re-melted. With the no-wall foundation, if we were to remelt the sheets that warp in coming out, tho they do not warp to a great degree, we would not produce a single sheet.

The remedy for this is not difficult to find. Let one of the rolls of the mill have a rudiment of cell-wall, just enough to make the sheet fasten to this roll more than to the other,

and you will have sheets of foundation which will not so readily warp in milling, and which will therefore warp but little if any in the hive. The sheet of foundation without cell-wall at all can hardly be handled in warm weather without warping. It is, to use the expression of Mr. Vandervort, "like a rag" in your hands. With a little cell-wall, be it ever so little, it will have more firmness, and will stand handling. But let it be remembered, if you handle a sheet of foundation and get it slightly out of shape, no matter what you may do, it will return to that shape when hung freely in the hive.

If foundation with such a cell-wall as above-mentioned was found acceptable and desirable, it could be produced thin enough to fill about 135 sections to the pound, and do good work.

Hancock Co., Ill.

[Mr. T. F. Bingham, who was instrumental in bringing out the no-wall comb foundation, sends us the following regarding his experiments with it in 1897.—EDITOR.]

The Michigan No-Wall Comb Foundation.

The various efforts to produce a foundation which would be acceptable to the bees as well as those who use honey, demonstrates beyond belief the great value of foundation in a general sense. But as neither the bees nor consumers hitherto have been entirely satisfied, the experiments go on. The Michigan convention last year took the no-wall idea and carried it to a conclusion. The convention had a no-wall machine adapted to the Weed process, constructed and supplied such foundation to the members who wish to experiment with it. Several availed themselves of the opportunity, and used sufficient amounts to fully demonstrate that the bees did not gnaw it down, and that they did accept it promptly. As these two points were the only ones bee-keepers regarded as dangerous, the experiments may be justly regarded as a success.

While such results were to a certain extent satisfactory, they did not cover the ground or explain why obtained. One fact was perhaps more clearly demonstrated than any other. Among the hundreds of sections filled, not one had the patches of drone-size cells, showing conclusively that the foundation, however thin, was not gnawed or cut.

Another fact demonstrated was, that in sections of ordinary size the foundation, neither the half-filled combs, stretch nor sagged. They remained as put in, except that the foundation, having as it did sharp corners, was before the side-walls were put on made to appear less angular and more downy; that is, the shiny appearance vanished, as did also the yellow color. Nothing could have been more complete than the transformation in color and texture. It was so perfect that no one could have realized that only three hours before the beautiful white, downy, perfectly-formed combs were thin, corrugated sheets of yellow beeswax.

Experiments in brood-frames filled with the same foundation, 5x12 inches, did not sag or stretch, tho as white and transparent as natural combs until about half full of honey, when they began to settle, and the cells to assume a rectangular form. This experiment furnishes one more evidence that it is not the walls of foundation that prevents its settling, but its general thickness.

During a good flow of honey, with cool weather, no sagging in foundation 5x12 inches took place, but in the same flow a few hot days developed the fact that no-wall foundation, the lightest ever made in pieces 5x12 inches, with no support, would not do for brood-frames, tho none did worse than to settle. It was a great pleasure to me to realize that I could now produce comb honey in sections 4x5 inches that I could put on my own table without apology—no yellow, hard strip in the center to prevent its being served to expert visitors.

Clare Co., Mich.

T. F. BINGHAM.

[In the Bee-Keepers' Review for January, Editor Hutchinson had this to say about the no-wall foundation, which was accompanied by the illustration appearing on our first page this week, kindly loaned us by Mr. Hutchinson.—EDITOR.]

The No-Wall Foundation.

Some of my readers will remember that at the meeting of the Michigan State Bee-Keepers' Association, held in 1896, Mr. Bingham so strongly advocated what he considered the advantages of a very thin foundation having no side-walls; that sufficient money was contributed to pay for the expense of making a mill upon which such foundation could be manufactured. Some of this foundation, running about 16 feet to the pound, was sent out to the different members; some of them using as much as 10 pounds of it. Unfortunately, how-

ever, so far as a report was concerned, Mr. Bingham was about the only one present who had given the foundation much of a test. I produced no comb honey in my own apiary last year, and Mr. Aspinwall was detained at home by company.

It will be remembered that Mr. Aspinwall had previously reported in the Review that he was pleased with it so far as the eating quality of the honey was concerned, but that it curled too much to suit him. His only objection is that of curling. To show how little trouble *he* had from curling, Mr. Bingham brought along to the convention a super full of partly-finished sections just as they came from the hive. The foundation had been brought out, or partly drawn out, and filled with honey, and, as this was at the end of the season, when, as all experienced bee-keepers know, there will be curled combs if at any time, the exhibition of that super, just as it came from the hive, was a pretty good proof that foundation will not curl in *some* place where it might be expected that it would. Of course, no one doubts that it *did* curl with Mr. Aspinwall, but, of course, there must have been some reason for it—something in his management, locality, or *something*.

Mr. Bingham's supers are small; I think that two are required to cover the top of his hive, and that one super holds 15 sections. Some boys got hold of two of the best-filled sections, and "gouged" them so badly that they were valueless for pictorial purposes, but I rescued the other baker's dozen, and brought them home, and had them photographed, first taking one side from all but two of them. From the photograph I had a half-tone made which is shown herewith. I did this to show how straight are the combs that are built under circumstances where curled combs would be expected. Mr. Bingham says that this was not a selected super, and to show that the sections were not selected, he brought the super just as taken from the hive, with the sections all stuck together with propolis, so that it was necessary to pry them loose with a knife in order to get them out.

I honestly believe that this thin, no-wall foundation is worthy of a most thorough trial. The fault of curling has been urged against it, and some complaints were made that the bees were more inclined to gnaw it down when no honey was coming in than they were other kinds; but, as in many other things, actual experiment under various conditions is needed. The quality of the finished product is certainly very fine; the nearest approach to that of natural comb of anything I have seen.

In working out the ordinary flat-bottom foundation the bees do change over the base to the lozenge-shaped style. There are no side-walls on the way, and it is possible for them to make this change. With the deep-cell or Weed style of foundation the bottoms of the cells are so securely braced by the three deep walls that center upon each cell-bottom, that it is impossible for the bees to "budge" the bottoms of the cells. Not only this, but the side-walls are in the bees' way, and prevent their getting at the bottoms of the cells to make changes. Even with the ordinary or lozenge-shaped base, the bees make some changes in working out the foundation. Mr. Bingham had with him a piece of the no-wall foundation which had been partly drawn out in a strip down through the center. Some of the cells were, perhaps, one-fourth of an inch in depth, and shaded off until there could be seen only a few "scratches" that the bees had made on the surface of the wax. About the first thing that bees do, judging from the appearance of this specimen, is to make the bottom of a cell rounding, like the bottom of a prest-tin wash-basin. Then, as the side-walls are started the lozenge-shaped character begins to appear in the base. It is much the same in natural comb-building. Get a piece of natural-built comb having a wedge-shaped edge of cells that are not complete. Look right down close to the edge, where the bases and side-walls are being started. You will see that there is a stage in the proceedings when each base or bottom of a cell is rounding instead of being formed of lozenge-shaped pieces. As the side-walls are laid out and started, the lozenge-shaped base appears.

What is the point to all this? Well, it is probably that we will never be able to make such foundation that the bees will accept it without change, and be satisfied with it any more than we can make a nest that would suit the robin, but let us get just as near to it as we can.

Mr. Bingham has brought out the best style of smoker, and the best style of honey-knife, and it is possible that he has struck upon the best style of foundation for use in the sections.

Genesee Co., Mich.

W. Z. HUTCHINSON.

Injurious Honey-Crop Reports—Ripening Honey.

BY C. DAVENPORT.

In my last I promised to show that reports of very large or expected large crops actually do injure the market for our product. A year ago the past season I went to Minneapolis and took samples of white clover comb honey which was strictly fancy in every respect, and altho there are dealers there who handle honey by the carload, I could not sell them even 1,000 pounds, for from the reports in the bee-papers they said there was the largest crop of honey ever known or heard of, and they expected very low prices later. Soon afterwards, I was in Chicago on other business, and found it was the same there—the dealers all thought there was an immense crop, and refused to buy outright, except at a price below the cost of production.

Now, as in both instances, this was early in the season, before they had received any shipments to amount to anything, their only way of forming an estimate of the crop was through the bee-papers, for practical bee-keepers do not send private accounts of large crops to dealers, notwithstanding what they may say to the contrary.

Probably some who read this will think that the price at which honey sells in the cities does not, or cannot, affect them, as they sell in their home market, where they obtain fair, and in some cases, large prices. But in a short time there may be more honey produced in their locality than the home market can produce. Take my own locality, for instance. But a short time ago here clover and basswood comb honey sold for 15 and 18 cents per pound; the last two years it has sold for 7 and 8 cents per pound, by the case, and some bee-keepers have scoured the country retailing it for this, and in some instances even less.

Now, in my opinion, another reason why honey has declined in price in the city markets is the inferiority of most of it, to what it used to be. I think without exception all producers now remove the sections as soon as possible after the honey in them is captured, and while this results in whiter, nicer-looking honey, it is greatly inferior to what honey was years ago, when it was left on the hives for a month or more after it was finished, and when consumers paid from 25 to 40 cents a pound for it. While I believe that honey can be removed as soon as captured, and handled so that it will be nearly if not quite as good as that left on the hives for sometime, I do not think there is more than one bee-keeper in five thousand, as they average, who does, or tries to do, any more with comb honey after it is removed from the hive than to keep it so it will look all right until it is sold; when, if it is shipped to some city market it is probably stored in a cool room, and by the time the consumers get it they know that if honey is not now manufactured without the aid of bees it is not what it used to be, and many decide that they can buy other things for the same money that they would rather have. I believe a mistake has been made in paying so much attention to the appearance rather than quality.

In order to show that this is not theory, I will say that my own crop is thoroughly and properly cured after it is removed from the hives, and on this account I have customers who take and pay two to three cents more per pound for it than they can buy elsewhere that which looks fully as good. Two years ago my crop was unusually large, and I had to find a new market for a few thousand pounds of it, and these new customers were so pleased with the quality of it that if I had had it the past season I could have sold a good deal more than my previous large crop without any soliciting.

CURING-HOUSE FOR COMB HONEY.

I will briefly describe my curing-house, and the method I pursue in curing the crop. The house itself is a small wooden building double-boarded on the sides, with double floors, and two thicknesses of heavy building-paper between the boarding and under the shingles on the roof. Being constructed in this way it is an easy matter to keep a high temperature inside with but a small amount of artificial heat.

When the filled supers are removed from the hives they are stacked up in this room, with the under ones raised about a foot from the floor, and inch strips placed between them all, so the air can circulate freely between them. The temperature is then kept as nearly 95° as possible for from 4 to 6 weeks, depending upon the condition of the honey, for the thickness or body of the same kinds of honey varies greatly with different seasons. In a dry season honey is usually thicker when sealed than it is in a wet one. The past season white clover honey was very thin and hard to cure in this locality.

Some who removed sections as soon as they were sealed

lost part of it on account of its souring in the combs. Until one has eaten it they would not believe the difference there is in favor of honey that is thoroughly cured or ripened, and such honey will seldom sour or caudly inside of a year if it is kept in an unfavorable place afterwards. It is also much safer to ship. I ship some honey thousands of miles every season, and so far as known there has never been a dollar's worth broken in transit. Southern Minnesota.

Again the Evolution of the Honey-Bee.

BY L. W. BECKWITH.

If the editor will permit, I will say a few words on the above subject, in reply to Mr. Doolittle's article on page 530 (1897), and then drop the subject.

In his first article, Mr. Doolittle declares that bees can learn *nothing*; and makes six other assertions neither of which is generally admitted, and when I express a doubt he tells me that the proof devolves on me and not on him. If Mr. D. had ever been present when any point in law, politics, religion, or any other question was being discussed pro and con, he would have learned that the affirmative proved the proposition or lost its case. I showed that bees do learn, and he admits it, but claims that they were capable of learning just as much at the beginning; and in so doing he admits that his first statement—that bees can learn nothing—is false.

He tells us that he knows that bees cannot be improved, because God at the beginning pronounced all his work "good," and he is willing to take God at his word. He understands that as God said it was good, therefore it could not be improved, or made better; so we may reasonably infer that when Mr. Doolittle advertises an improved strain of bees he intends to deceive and swindle his patrons.

I do not doubt but he is every day making use of vegetables, fruits and animals which he knows to be improvements on those in the natural or wild state—"just as they came from the hand of the Creator, six thousand years ago."

Yes, I do believe that bees may be educated and improved within certain limits, and that in so educating them they will not necessarily "become a curse instead of a blessing."

Weld Co., Colo.

[In order that a final utterance on this subject from both Mr. Beckwith and Mr. Doolittle might appear in the same number of the Bee Journal, we forwarded the foregoing to Mr. Doolittle, who thus responds:—EDITOR.]

The following paragraph appeared from my pen in the Progressive Bee-Keeper for March, 1897, and I reproduce it here so the readers of the American Bee Journal may see the item which has caused Mr. Beckwith and others to write much uninteresting matter to practical bee-keepers, in order that it may appear that Doolittle "intends to deceive and swindle his patrons:—"

"INTELLIGENCE IN BEES."

"Noticing an item in one of the papers, trying to prove that bees were intelligent creatures and reasoned, I am led to say that bees have the same habits now as they did at their creation, as permanent and unvarying as the attraction of gravitation, or any law of Nature. They still act alike under like circumstances. They are incapable of education. They learn nothing. By taking advantage of these habits, we can control their actions and make them subservient to us, just as we take advantage of any law of Nature, and, by proper machinery and manipulation, cause them to produce desired results. If bees possess the intelligence of the higher order of animals, and could learn tricks like dogs and horses, we could not manipulate them as we do now, and they would become a curse instead of a blessing."

I believe what I wrote in the Progressive, when taken in a broad, general sense (as practical bee-keepers take the statement that drones from an Italian mother when fertilized by a black drone are pure) is true. In a technical, narrow way, it may not be strictly true. However, it is evident that the trouble does not lie in any fear that the item appearing in the Progressive will harm anything pertaining to apicultural pursuits, but that, unwittingly on my part, this ran counter to a certain evolution theory, that away back in the dim vista of the past, thousands or millions of years, there was an infinitesimal "mite" which evolved into a tadpole, then into a monkey, and finally into the intelligent man of to-day; hence "a man of straw" was set up, which they proceeded to knock down, wondering why Doolittle did not enter into the combat.

Gentlemen, I prefer to take the practical side, which allows the Bible account of how man came on the earth to stand, and that bees have *not* "learned" so but what they

are subject to man. Further than this explanation would be out of place in a journal devoted to the best interests of bee-culture. I am aware of my liability to error, but to abuse me because I do not think as you do, when I accord you the right to think as you please, will only show that you are not infallible, and will do me no harm. G. M. DOOLITTLE.

[Again we must say that those who wish to make a display of their deep (?) knowledge of evolutionary and philosophical subjects will have to go outside of the columns of the American Bee Journal to do it. Life is too short, and there is too much of practical importance in bee-culture, to waste valuable space in a discussion of extraneous and theoretical matters having scarcely any bearing on apiculture.—EDITOR.]

The Two Bee-Keepers' Unions—Co-operation.

BY W. D. FRENCH.

The United States Bee-Keepers' Union and the National Bee-Keepers' Union are nearly the same in name, and both are inadequate to meet the demands or actual necessities of bee-keepers.

Now, if petty differences are at rest, and tranquillity predominates over personal bickering, we may feel more at liberty to express ourselves in regard to our desires relative to co-operation, amalgamation, or mingling together all bee-keepers. We must be mindful of the fact that both Unions have labored to perform what is indispensable; the old one, by its able management, has performed a wondrous task, and still is moving on the same plane of action, showering volleys of hot shot upon the enemies' breastworks. The new Union, starting on its mission to do good, undoubtedly will succeed, and its duties, as portrayed, no one can gainsay.

Should both be blended or made one its utility undoubtedly would be increased, and yet the most important feature, and that which is most vital to honey-producers, is not incorporated in either Union, viz:

THE MANIPULATION OF THE HONEY MARKET.

I am opposed to trusts and combinations in a sense where they have originated for the sole purpose of heaping additional burdens upon the general public, by enhancing the price of food or other products, or to place a restraint upon any one physically, morally or mentally, but the consolidation of bee-keepers is not to be classed in the category of such vile institutions.

Profits arising from the sale of honey should not be distributed except to bee-keepers themselves, but to maintain a proposition of this character bee-people must certainly act together, disposing of the honey-product of the United States under one general management.

I have many times insisted upon a proposition of this kind, and urged bee-keepers to unite under one organization, not designing to burden the consumer by any additional expense, but to stimulate the price to the producer.

I would respectfully call the attention of bee-people to the proposition submitted to the Buffalo convention in 1897, from the able pen of Geo. W. Brodbeck, of California, who plainly set forth his views upon this subject, and who very forcibly vented the minds of many. While I am not fully in accord with this proposition *in toto*, it brings to bear the main object which all apiarists should consider.

Every State should have its organizations not unlike the California Bee-Keepers' Exchange, which has now been established (beyond a shadow of a doubt), and has become a reality surpassing all anticipations of its founders.

If every State were as thoroughly organized there would be little difficulty to establish a Union that would not only benefit the fraternity, but would place the pursuit in the category of one of the leading industries of the United States.

A Union established in the interest of bee-keepers must necessarily embrace the marketing problem, together with the protection of bee-keepers in their lawful rights, the prosecution of adulterators, and any other question which might involve the promotion of the honey-industry of our country.

Agitation of a pure food law, to be passed by the general Government and by each State Legislature would certainly bring action, and we would then be fully prepared to meet the enemy, and stamp that nefarious swindle in the mud of oblivion.

Now, bee-keepers, will you consider this proposition? Will you act in harmony, unite forces, blend all elements by burying the tomahawk of opposition, and become united in

one grand and noble Union for the benefit and uplifting of a demoralized pursuit in which we are all interested?

I am sure I hear some one speak, in which he tells us that such a proposition could never be materialized, for the reason that a sufficient amount of cash could not be realized to transact business in its infancy. To overcome this feeling, which would seemingly be a stumbling-stone, I will offer (after we get the next honey crop in California) as a starter \$20, and if 100 men will do the same thing, by putting in an equal amount, we would have the snug little sum of \$2,000 to start with, besides all revenues which might be derived from membership fees.

Now, gentlemen, brace up and tell what you think.

San Diego Co., Calif.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 183.)

SECOND DAY—FORENOON SESSION.

After a few minutes rest, during which the members examined the specimen of honey built on the drawn foundation, as exhibited by Mr. Cooley, and the seeds of clovers shown by Mr. Stone, the President said:

THE NEW DRAWN OR DEEP CELL FOUNDATION.

Pres. Miller—How many have used the drawn foundation this season? I count four. We will be glad to hear from those four.

Mr. Baxter—I claim that I have used drawn foundation, but I have not used this foundation spoken of here to day. I consider that this is a misnomer, altogether. It is not drawn foundation at all. It is what I would call deep-cell foundation, or deep-wall foundation. That is what such foundation was called years ago, when some one in Kentucky invented two machines for making it. It is not drawn. It is no more drawn than the other foundation is. It is done by pressure, and not by being drawn, and I think it is generally understood among bee-keepers, when you speak of drawn foundation, it is the old foundation drawn out by the bees. I have some of that foundation at home now, and partly worked upon by the bees. That is drawn foundation. I would not advocate the using of this, for the reason that it looks too artificial. It is too much as it was when it was first given to the bees. It is very well to give them a start. Give them the base of the cell, that is sufficient.

Mr. Moore—I am chock-full of the effect on the consumer of this sort of thing. I have been six years on this ground, and am simply chock-full of ideas as to what consumers have said to me on this very point. I am thoroughly convinced that this whole matter of foundation, when you use anything more than the merest beginning, is bad, and that is one of the things I use in talking to them. My customers tell me they buy three or four times as much of me, because I say it is pure. My brother produces lots of it, and it is just as the bees build it, and they ask me every day a dozen or twenty of them, "Did you build that, a full, complete comb as I have here?" "Did you build that?" or, "How did they build that?" And my answer is, "They can't build that. It takes 400 bees a whole summer to gather a pound of honey, and there is no man, not even a Chinaman, that can." I tell you now, if I offer this foundation honey-comb to our customers at 10 cents a pound, and say, "Here is some the bees built themselves," for 25 cents a pound, nine out of them take that. They jump to conclusions. They don't look at these things through the eyes of the bee-men. They think if you cell a little deeper you can cell a little deeper. That is the way it is published by the newspapers who want to do us an injury. I have had grocery men insist upon it, and say, "Why, they make it," and they have even named the A. J. Root Company to me as people who made comb honey complete. You can see what the public thinks of it. When you go to making the cell deeper they jump to the conclusion you can make it full depth, and put

something else in besides honey, and they don't want it. There sits in this room a gentleman who represents one of the largest wholesale dry goods houses in Chicago, and he knows that a week of explanation cannot wipe it out. This ray of distrust is the idea that honey can be got without the aid of the bee at all, or it may be that you do half the work; and I have stood for an hour and explained to four or five men, who askt me, "Did you make this?" or, "Where did they make it?" or, "What did they make it out of?" or, "How did they cap them over?" and, "What do they put in it?" I tell you it is a damage to you as bee-keepers to use anything more than the merest bottom, aside from the question of economy to you as bee-keepers in your hives. It is the distrust the people have of anything the bee doesn't make. They know that man is awfully smart. They have confidence that the bee is as disingenuous as she was thousands of years ago: and if you leave the bee alone it will treat you nicely. I would like to have Mr. Everett speak to you.

Mr. Everett—This is my first experience in a bee-convention. I haven't nearly as many bees as a lot of you people here, probably. I went into bee-keeping as an amusement, really. I had them when I was a boy, and when I located in Oak Park I sent over to Michigan and got a couple of colonies of bees. I had 80 this summer. And I used the foundation such as the gentleman has exhibited to you here. I found it to work perfectly satisfactorily. And I believe, as he says, that anything beyond this foundation would be a detriment, altho I must say this, that I have never had any experience with what you term the drawn foundation. I have used the latest that I could get, in all the honey that I have produced, and I do not find any trouble whatever in disposing of it. As Mr. Moore says, the people are suspicious. I had a groceryman tell me the other day that a person brought back a section of honey that I had sold to him, with six or eight cases, and said it was not genuine honey. But the person didn't know what he was talking about. It was from this thin foundation. I am not able to give you any light on this question, because all I know is what I have pickt up in my own bee-yard.

Mr. Stone—I have had men by the score that were handling comb honey tell me that they were selling that for manufactured honey, and when I would look at it I would tell them just the facts in the case, and what I believed about it. And there were samples sent from a neighboring city where a lady I had known all my life lived, and she said she sent them to Springfield to have me see them; she said if Mr. Stone said that was manufactured honey she would believe. Her husband had bought it of a groceryman for manufactured honey. There were two good samples of white clover honey and Spanish-needle honey; and I showed them the card of Mr. Root, which he publishes, offering a reward of a thousand dollars. They said they would go back to their groceryman and enlighten him. I hope that nobody will ever send any out to Springfield, and that they will never enlighten the people there in regard to the raised cell. I don't want it around. It gets just to the point where Mr. Moore speaks of, it gets it so that people say if they can do that much they can do more, they can fill it, and they can cap it. I hope it will never go any farther.

Pres. Miller—I want to just say this, as Mr. Whitcomb said awhile ago, he always felt like doing something for the under dog in the fight. Now, there is nobody on the other side at all.

Mr. Wheeler—Here is one.

Pres. Miller—I want to say that I do believe we ought to be entirely fair, at least. When foundation was introduced there was objection made to it in the first place, but that has died away, and everybody has said it is all right to use foundation, and not many object to filling the section all full of foundation, and using it altogether, and yet if you go just a little beyond that then there is something terrible about it, and if all of this talk gets to the public no heavier blow has been made to the sale of comb honey than has been made just by the objections of bee-keepers themselves. It is not the public that is objecting to this; it is the bee-keepers. It is said, "Up to a certain point it is all right." Now, if that is true, if the public will commence objecting at a certain point, won't they object just a little before that, to that same material being put in? If it is to bad material they object, won't they object before that? Now, why is it, if it is a right thing to put in that sheet of foundation, that it is so much worse when you increase the amount of material that you put in by 50 per cent., or 100 per cent.? It is the same material exactly. If it is good in one case, why isn't it in the other? Some have called attention to the yellow part that is there, and state that with ordinary foundation that would be white. My bees don't make it white, and some of you know your bees don't make white septum out of yellow foundation, and I be-

lieve if any of you watch closely you will see it is left yellow. But your attention is very closely called to this sample. You will see flaws you haven't seen before. You are looking for something wrong about it. Now, as the final outcome of this, I believe if bee-keepers keep quiet, and don't bring up objections that don't exist, that no harm will ever come from it. I want to say candidly to you, that I doubt very much if many of you will ever use a pound of it. I don't believe, in the first place, you can afford to. In the second place, it will not always be found to be an advantage for you as bee-keepers. I will say to you that in my own case I did not see any advantage in using it, and as it is more expensive, I am not likely to use it. Now, don't let us raise suspicions in the mind of the public ourselves, where there is no cause for it. If you quietly try this, and find it is not profitable, you are not going to use it, and there is no use in your saying that this is such a bad thing, when you are all the time using a part of the same thing, and the most important part, too. You say, "If it can be made as thin." They have made the walls of it as thin as the natural product. That is all I am going to say; and you can go on now and fight it.

Mr. Baxter—I beg to differ with you radically. I know that bee-keepers are not finding fault with it, but the public is. With my own experience all over the country—and I go around a great deal—when I take up a piece of this foundation, I tell them I am using only this much. You see that doesn't look like the natural comb at all; there isn't a particle of resemblance. "Well, I don't like it. It tastes bad when I bite into it. I want the natural comb honey; but if you haven't got that I will take this." But when I show them the other they say, "If you can come that near to the comb you can make a natural comb." That is the difference between this and the natural comb, while there isn't so much between the other. When you go to using things like that you can take one and say, that is all right, I use that. But they shake their heads and don't believe you. I do object most emphatically to the other, not because I think that it is not a good thing, but because I believe that it will arouse the suspicions of the public a great deal more than this ever did, or anything else that the bee-keepers could use.

Pres. Miller—Let's have a report from the others who have tried it.

Mr. Wheeler—I believe I tried 18 sections of the drawn foundation, filling with full sheets, and I had a little different experience than these gentlemen about the bees working on it. I think there will be a little misapprehension in regard to that. My bees went to work, and they seemed to begin at the bottom, and sort of fixt the comb over. They didn't put honey right into it. The honey-flow was all right, but they left it for a few hours or for a day or two empty. I would take that out, and the edges would be kind of whitened over, and no honey there. It wasn't like the comb, if I had put a section with partly drawn comb in it. They would have begun to put honey in it as soon as it was put in. That led me to think that they fixt it over, and within six hours from the time I put in one lot of sections the bees were whitening it and working on it. And the foundation put in at the same time they hadn't toucht. After those sections were filled we all ate of it, and I let my neighbors taste of it by the side of the honey built on the old-fashioned foundation, and I could not detect one particle of difference, nor could any one else. I used Mr. Root's extra-thin foundation, the Weed process, and I would like to show you the two foundations side by side to-day. I have 18 of those sections nicely filled, and from the outside appearance you cannot detect a particle of difference. I believe it would be impossible for you to. I think 15 or 20 people tried it. This year I could not see that it was very much advantage. It seemed as if this year the bees would commence promptly on the old foundation that I had on the hives for four or five years, while in other years, in a poor honey-flow, they would not have toucht it. So it was hard to tell whether this was an advantage or not this year, because they began and workt on that right along, filled the super up with bees, and I couldn't see that they workt on the old-fashioned process any less quickly, but these sections started were finisht sooner.

(Continued next week.)

Beeswax Wanted.—Until further notice we will pay 26 cents *cash* for all the good yellow beeswax delivered to us. We accept only that which is absolutely pure. If you want cash, and want it *at once*, send us your beeswax now. Be sure to put your own name and address on each package, when shipping. Then mark it very plainly—George W. York & Co., 118 Michigan St., Chicago, Ill.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Fastening Foundation in Brood-Frames— Changing Location of Hives.

1. I am just a beginner at bee-keeping, and would like to know what is the best way to fasten foundation in brood-frames?
2. Would it be all right if I moved my bees about 100 feet away from the place where the hives stood last summer? I am keeping them in a cellar this winter.

ANSWERS.—I have never found anything that suited me so well as to have a saw-kerf in the underside of the top-bar, said kerf being $\frac{1}{4}$ inch deep and 5-32 inch wide. Slip the edge of the foundation into the kerf, then a drop of melted beeswax here and there will hold it till the bees fasten it. An easy way to drop the melted wax, is to make a wax-candle by roughly squeezing pieces of wax or scraps of foundation about a string hardly as coarse as common wrapping-twine, then when the "candle" is lighted, you can hold it to one side and let the drip fall where you want it.

2. When you put them out of the cellar you can put them in an entirely new place without any risk whatever.

A Supposed Curious Experience.

A curious thing happened to one of my colonies this winter. Some time in November I examined this particular colony as I was suspicious something was the matter, because there was so little life about the hive compared with the rest, and I found a very small handful of bees in a 9-frame chaff-hive full of honey. The first of December the weather grew cold and there was quite a snow-storm, so my husband helped me move that hive with others to a more sheltered locality, he lifting one side and I the other (and it was all I could possibly lift). Stepping backward my foot slipped, and down I went, hive and all! My first thought was that the colony was ruined.

With my husband's help I was extricated from the unpleasant situation, and the hive placed on the stand. I found, on examination, that no combs had fallen down, but the weather was cold and I feared the scattered bees would die, so I heated a large soap-stone, wrapt it in several thicknesses of flannel, and put it among the chaff cushions just over the brood-frames.

From that time until Feb. 11 there seemed but little stir. That was a warm day and the bees all had a fine flight, but I wish you could have seen that hive! There were thousands and thousands of the bees, and the alighting-board, front and top of the hive, was first covered with bees and the air full of them. They look like young bees out for the first time. Do you suppose that putting that soap-stone among the cushions caused brood-rearing in mid-winter? It certainly looks as if it might be so.

My 14 colonies seem in good condition at present. N. Y.

ANSWER.—I'm sorry to offer any words of discouragement, but I'm very much afraid if you look into that hive again you'll find the colony not so very strong. Indeed, you will probably risk nothing by looking into the hive any day, for it is very doubtful if there is a living bee in it. Those bees that were having such a lively time about it on that warm day, were most likely robbers from the other hives.

Clipping Queens' Wings—Candied Colorado Comb Honey.

1. Is it well to cut the wings off of what queens you can in an apiary where at least a third of the hives have their brood-frames so crusted with the honey and brood that you cannot raise them? I have bought a good many of my 250 colonies is the reason why they are in such a condition. I lost a good many queens last year from the old hive. I wondered if turning them so many times, and then carrying them to a way-off stand might not confuse them so that they would take the young queen to the wrong hive?

2. Don't you think it mean for Eastern honey-men to say Colorado honey is not as good as their home honey? We have all kinds of honey just as they do back East—white clover as well as alfalfa, etc. Pure alfalfa honey does not candy. Last season, very early, the mesas here were covered with a blue flower that I think was *argeratum*, but it made such fragrant honey that the people here called it wild heliotrope. And by the middle of June we were taking off this lovely white honey, but alas, it candied in a very short time. I melted mine up and sold it in tin cans. But I might just as well have saved the trouble, for the Chicago commission men I, with a few others, sent a carload of honey to, got me only five cents per pound for the whole lot of mine, and four cents for one man's 550 cases of beautiful comb honey. He said it arrived in only fair condition, most of the cases leaking, but when honey is not broken down, don't you think the cases can be cleaned and

all be made right? The most of the carload of honey was white as snow. I said when I packed it that it looked like angel-cake—the most delicate honey I ever had. COLORADO.

ANSWERS.—1. Decidedly, if I could get at only part of the queens I would clip them.

2. It seems to be the common thing for bee-keepers to think that the product of their locality excels. If you will note the mention made at different times in bee-papers, you will find that every little while some one speaks of the honey from his region being the finest in the world. I am quite inclined to the opinion that good honey can be found in very many parts of the world, and that people are likely to like better the honey with which they are best acquainted. There are inherent differences in honey, however, and there are differences in taste. The alfalfa honey I have eaten from Colorado I should rate very high indeed.

You don't say whether the honey you sent to Chicago was comb or extracted, but from your speaking of its not being broken down, I suppose it was comb. If cases of honey are leaking, that must affect the value a little, and the worse the leaking the more the price is affected, but it does seem that it ought to have brought more than five cents a pound, if combs were not broken down. Not knowing exactly the condition of the honey, of course no one could say exactly what it should have brought, but I would want to know pretty surely a commission man was all right before shipping, as he has matters all in his own hands.

[We are quite sure that this same honey was sold as the questioner states, at a low price, and was retailed at one of the city meat markets here at two sections for 15 cents. We bought 10 cases of this same lot of honey from the commission man who had it in stock, and when we came to open it we found it candied solid. This was in December. We returned eight of the 10 cases, selling the other two at cost, 10 cents per pound.—EDITOR.]

Preventing Swarming—Drone-Comb.

1. Would this be a good way to prevent swarming? At swarming-time take all the combs with brood, honey and adhering bees, except the one with the queen on should be hung in the upper story, and the brood-chamber filled up with frames, starters and a queen-excluder on top.

2. Or, at swarming-time, take a swarming-box and shake all the bees and queen from the brood-chamber into the swarming-box and carry them into the cellar till the next day, then hive them as a natural swarm, and let the old colony rear a young queen.

3. I have a good deal of drone-comb in my brood-frames. Can I, in the spring, remove the drone-comb and place the rest of the frames on one side of the hive and a division-board next to them, then when honey is coming in, put empty frames in the middle?

MINN.

ANSWERS.—1. If I understand you correctly, you mean to have one frame of brood with the queen and adhering bees in the lower story, filling up the story with frames and starters, and putting the balance of the combs in a second story, a queen-excluder being between the two stories. This is the plan recommended by G. W. Demaree, and has been successful with him, only you will be likely to have a good deal of drone-comb if you use only starters. Full sheets of foundation will be safer.

2. If you mean literally to take all the bees, the likelihood would be that you would lose a lot of brood by cold and starvation. If you leave enough bees in the hive to take care of the brood the plan may be all right.

3. That's a good plan if you're anxious for more drone-comb. For those empty frames will probably have more drone-comb built in them than the ones you remove. You can make a sure thing of it, however, by giving full sheets of foundation. Of course, when you take away the combs with drone-comb you must look out that the queen shall not be cramped for room.

Dark Combs—Worms in Hives.

What makes honey-comb black, or nearly so? We took about 20 pounds of honey from the long frames in the lower part of three or four hives, last fall, it being our first year with bees in this part of the country, and the comb was dark—some of it almost black—thick and heavy. The honey was also darker and richer and of stronger flavor than I had ever known honey to be. They had plenty of white and red clover within a mile, and in some respects did well; the exception was that we had to burn one hive, as it contained nothing but a mass of comb and white worms, large, thick and soft. I shall be glad to be informed of the cause of those worms and their prevention and cure. MASS.

ANSWER.—Before I forget it, let me advise you to get a good text-book on bee-culture, and if you do I feel sure you'll thank me for the advice. That will inform you fully about wax-worms and a great many other things. If next summer you should kill a hen and leave her lying somewhere where dogs and cats would not get her, you would probably find her some days later filled with worms or maggots. It would not be right to conclude that the worms had killed her. Neither did the worms ruin your colony. Bee-moths haunt all apiaries, trying to get in the hives to lay their eggs, and succeed to some extent in doing so, but the bees are alert to clean out the young worms that hatch out of the moths' eggs, especially if the colony is strong, and still more especially if the bees are Italian. But if a colony becomes weak and queenless then the moths take possession, and in course of time the combs will be filled with wax-worms.

I don't know what makes comb black. I might say age, but that's only dodging the question. Whenever comb is used for rearing brood it commences to grow dark, and every generation of brood reared makes it darker until it is nearly black. It has been said that the dirty feet of the bees are responsible. It has been said that it is caused by the first discharge of the feces of the young bees. It's all right for brood-combs, and bees prefer the blackest combs, either for brood or honey. But people don't. The whiter the comb is the better it is liked for the table, and indeed it is not merely a matter of looks, for old, black comb doesn't taste so well. The darkness of the honey, however, was not caused by the comb, but by the flowers from which it was gathered. If the combs had been snow-white, the honey would still have been dark. Fall honey is generally dark.

Perhaps from Skunk-Cabbage.

How can you account for two days after four degrees below zero, the bees carrying in yellow pollen; not many, but even a few? The whole bee is covered with yellow dust, like in the spring or summer. Where can they get it? NEW JERSEY.

ANSWER.—I should guess from skunk-cabbage, but will yield the floor to any one who can tell without guessing.

Getting a Tree-Colony—Bees in a Room.

1. I have a bee-tree standing on another man's land that I found last fall, and the man who owns the land would not allow me to cut it, but told me if I could take the bees out in the spring I could do so. Can they be taken out? If so, how and when would be the best time to do so?

2. Also, I have a colony of bees in the "gum" that I cut and brought home last December, and not having any room anywhere else, I put them in an unoccupied room where it was dark, but I can't give them ventilation enough as the weather warms up outside. Will it do any hurt to set them up out-doors? And would they need anything covered over them? WISCONSIN.

ANSWERS.—1. Each case of this kind is a problem by itself; the position of the colony in the tree and other differing circumstances making one case quite different from another. If there is a hole below the colony and another above, or if you can make holes, you might succeed in smoking out the bees, and perhaps as good a time to try it would be in fruit-bloom. But you'd have only the bare bees, and if you can get a fair price for sawing cord-wood perhaps you'd do as well to buy a colony.

2. Probably you'd better set them out. It can do no harm to cover them, but of course you must leave the entrance free.

Transferring Bees—Getting Bee-Supplies—Bees and Fruit—Gluing Sections.

1. When would be the best time to transfer to get as much comb honey as possible?

2. About what time ought I to get my bee supplies?

3. I have a fruit-grower about 200 yards from my bees. Is it any better for the bees, or not?

4. Is it better to glue the one-piece sections and the joints? VIRGINIA.

ANSWERS.—1. Probably you'll do as well to wait till the colony swarms, hive the swarm in the new hive, placing it on the old stand and putting the old hive close beside it. Then in about a week take the old hive away and set it in a new place perhaps a rod away. That will throw all the flying force into the swarm, and it will do good work in supers if the season allows. If the box-hive has top boxes, take them off and shut up the holes so the bees can't get up, for it may hinder them about swarming if they have extra room.

2. It depends somewhat on circumstances when is the best time to get bee-supplies. If you want only a small amount, you can wait till about the time you need to use them. Even then, however, it is much better to order ahead. If you wait till about the time you need the goods, it sometimes happens that dealers and manufacturers are behind with orders, and you have to wait. Sometimes there is delay in freight trains or goods are miscarried, making a delay of two weeks or more. You can generally tell in December what you will want for the next season, and may as well order then. But if you haven't ordered before March, better order right away.

3. A fruit-plantation near by is an advantage to your bees, and perhaps the bees are a still greater advantage to the fruit-grower.

4. The one-piece sections don't need gluing at all. Generally it isn't necessary to wet the joints, but if they have become at all dry it is better. You can easily tell; if the joints don't break, don't wet them; if they break, wet them.

Wintering Bees in a House in North Dakota.

I came to North Dakota in 1878, but the severity of the climate kept me from trying bee-keeping. Last spring I got one colony and increased to four, putting them in winter quarters in fair condition Nov. 1.

Some of your answers to questions begin to give me some con-

cern. You are doubtful of bees confined from Nov. 1 to April 1. I built a frame house 8x10x8 feet, double-boarded and tar-papered outside, and lined and papered inside; shingle-roof, double-doored; the house is close, still it will stoop down to zero or lower. I set hives side by side, packed them all around with wheat chaff, gave a little top ventilation, set the hive on a tray two inches deep, with a spout 3x3 inches, leading out one foot through the chaff.

1. Will the bees not stand it five months?

2. Would I better take them out, if living, in March, and run the chances of being chilled in the hive?

3. Would it do to take them out for a flight in March, and take them back in again?

4. Will there be any danger of some frames of honey I kept over, candying, so I cannot give them in the spring to the bees? Parts are not sealed. I keep them in the bee-house, at zero heat.

N. DAK.

ANSWERS.—1. If I understand you correctly, a spout leads directly to the outer air from the entrance of each hive, so that there is nothing to hinder the bees flying if a day comes warm enough. That makes a big difference, for I think the cases we were talking about where it was considered doubtful about five month's confinement, was where there was no outlet so the bees could fly. The chief question is, if a day comes warm enough for the bees to fly, will they feel the heat enough through their thick packing to start them to flying? If they get a flight, they'll probably stand it all right.

2. If there comes a warm day, and they don't seem inclined to wake up at all, it will certainly be better to take them out for a flight than to let them stay where they are and not fly at all. If you can get at the hives inside to pound on them so as to stir up the bees on a warm day, it might be a good thing to do so. I'm not sure but it might do some good to blow air into the entrance with a strong bellows. That might be done after the outside air gets warmed up.

3. If you can't get them to fly without taking them out, perhaps you may as well leave them out, seeing it ought soon to be warm weather.

4. Very likely the honey will be more or less granulated or candied, for unsealed honey would hardly go through the winter without candying, unless kept in a warm place. When you give the combs to the bees, if you have some receptacle beneath so the granules can be caught that they throw out, you can melt these up and then feed.

Remedy for Moth-Worms.

During the year 1897 I had 13 colonies, and out of that number the moths have left me 5. My bees were wild, and seem to be a cross with the Italians and blacks. All who have bees in this country lost a great many from the ravages of the moth during the last summer and fall. For a while the honey-flow was very strong. Besides the wild flowers we have the mesquite which yields very fine honey. Can you give us a remedy for the moth-worms? It would be of inestimable value to this country.

TEXAS.

ANSWER.—Let me first tell you how to encourage the production of moths. Allow plenty of pieces of comb to lie around for breeding places, where the moth can lay her eggs. If a colony dies in winter, be sure to let the empty hive with its combs stand out where the moths can get at it. They will be delighted with this arrangement. Be sure to increase rapidly, so as to have a lot of little colonies so weak they can't fight their way against the moths and worms. If they can't be queenless, that will help greatly, and it will be still better if they have no Italian blood.

If you don't care to have your combs eaten up with worms, then you can just do the opposite. Keep strong colonies. Don't allow queenless colonies. Break 'em up, or unite with something else if they're not strong enough to re-queen. Get as much Italian blood into your bees as you can. If you have some empty combs in which the worms have started, give them a treat of brimstone smoke. But you'll never be greatly troubled with moths if you'll follow just one rule—KEEP ALL COLONIES STRONG.

Rearing Queens—Italianizing.

What is the best way to rear queens? I have Italian bees at home and black bees at one of my son's, and wish to rear queens to Italianize them. In 1896 I paid \$1.50 a colony to have them Italianized, and they failed to change. He claims the bees superseded the queen he put in, and reared a queen of their own. Is such a thing possible, when there are no bees nearer than two miles, and the nearest being bees that he had Italianized? ILLINOIS.

ANSWER.—If you want to do very much at rearing queens, it may pay you to get Doolittle's excellent book on queen-rearing; at any rate, a good text-book, if you haven't one. If you look through the answers in this department for the past three or four weeks, you will find an answer to your question which hardly need be repeated here, those answers having been published since your question was written. [We mail Doolittle's book for \$1.00, or club it with the Bee Journal for one year, both together for \$1.75.—EDITOR.]

It certainly was a very unusual thing for all the queens to be superseded, if there was any considerable number, and doesn't speak the most for the character of the queens. Even if the queens were superseded, if all were Italianized, the resulting stock ought to be pretty good Italians.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY
GEORGE W. YORK & COMPANY
 118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott, C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Engene Secor, Forest City, Iowa.

VOL. 38. MARCH 24, 1898. NO. 12.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "c" when so pronounced, except when the "e" affects a preceding sound.

Impatient Subscribers.—Several evidently nervous readers who have asked questions to be answered by Dr. Miller, in the "Question and Answer" department, threatened to stop their subscriptions because we didn't get in their questions with the answers as soon as they thought we ought. Now, any one who writes to us that way is very thoughtless. Here we have been giving two full pages of that department every week for several weeks, and even set it in a smaller size type so as to get more in, and still we have on hand a stack of questions with Dr. Miller's answers. It seems impossible to get caught up, but we are doing all we possibly can to do full justice to all.

Here is one way that many can help out themselves and us: Get a good bee-book, read it carefully, and thus find the answers to a thousand and one questions without asking us to print over and over again replies to the same simple questions every week or so. Of course, there will be plenty of questions to ask after reading the best book. Prof. Cook's "Bee-keeper's Guide" is a good book; has 460 pages, and we mail it for \$1.25; or club it with the Bee Journal one year—both together for \$1.75. Get a copy of it and read it.

Money and Beeswax of Kansas.—Secretary Coburn, of the State Board of Agriculture estimates the 1897 product of honey and beeswax in Kansas at 540,000 pounds, valued at \$81,000. We believe that is a low estimate. As Kansas knows better than to waste any of her hard-earned money in saloons, she has more to spend for honey and other good things. Her inhabitants ought to be a clean, sweet people. Those that we have seen from there speak well for Kansas.

New Subscribers—Room for More.—Yes, we have room for quite a good many more new subscribers, and this is a good time of the year to invite them to begin to read the American Bee Journal. It is not that we are anxious to increase the number of honey-producers, but we do feel that every one, even if he has only one colony, ought to take and read the Bee Journal. We trust our present subscribers will aid in placing it in every bee-keeper's home. Many have already done splendid work in the line of securing new subscribers, and we appreciate it greatly.

We are constantly offering desirable premiums for the work of getting new subscribers, but as there may be some who prefer to have a cash commission, we will say that any present reader who sends a new subscriber for the balance of this year (worth 75 cents), may forward to us 50 cents with the new name and address, and keep the other 25 cents as pay for their effort. There is many a boy or girl that can easily earn some spending money in this way. Let there be some good work put in on this during the next month. You will thereby be helping yourself, the new subscriber, and us.

Talking in His Sleep.—Somnambulist, of the Progressive Bee-keeper, altho he may be a sleep-walker, has always talkt as if wide awake. This time he has snrely been talking in his sleep, and when he wakes up he'll take it all back.

The American Bee-keeper complains because in the Ladies' World Lena Thatcher had given an excellent article on "Honey as an Article of Food," said article having been taken almost verbatim from the writings of Thomas G. Newman, but without any credit therefor. Sommy asks who of the 400,000 readers of the World would ever have seen Mr. Newman's writings, and thinks it a case where "the end justifies the means." Oh, Sommy! your conscience hasn't gone to sleep, has it? You would hardly be justified in stealing a few millions from Rockefeller just because you made a good use of it by distributing it among the poor! Besides, just as many would have read it if Lena had had the common honesty to say she had taken it from Thomas G.

Bee-keepers in the United States.—The Progressive Bee-keeper estimates that there are 12,000 people who keep bees in the State of Missonri alone; and that if 40 other States have as many, there would be about 500,000 in this country. That may, and may not, be a high estimate. But if it is even nearly correct, it seems strange that it is almost impossible to get only some 20,000—about 1 in 25—to subscribe for a bee-paper. It must be that the great majority do not realize the value and help a good bee-paper would be to them. With possibly one or two exceptions, there isn't a bee-paper published to-day but what deserves at least five times the circulation it now has. Here is a big field to cultivate—a field filled with hundreds of thousands, and yet only a few thousands who as yet comprehend the real value of a bee-paper to them in their work with bees.

Honey for a Cough and for Erysipelas.—Mrs. Julia D. Chandler, of Chicago, hands us the following recipes, which no doubt will be found useful:

HONEY COUGH SYRUP.—The druggist cut spruce-gum with alcohol, stirring after—it is not very easy; and then added extracted honey. I do not know the proportions, however, as the bottle was sent to me as a simple remedy, to use for a child with a delicate throat.

HONEY FOR ERYSIPELAS.—Dr. Hayward (in the Medical Record) calls attention to honey as a remedy for erysipelas. It is used locally by spreading on a suitable cloth, and applying to the parts. The application is renewed every three or four hours. In all cases in which the remedy has been employed entire relief from the pain followed immediately, and convalescence was brought about in three or four days.

Manufacturing Bee-Supplies.—As illustrating the difficulty of getting supplies made at home, G. C. Greiner tells in *Gleanings* about going to a planing-mill where they readily agreed to plane lumber exactly to any required thickness. But the first board was too thick or too thin, sometimes 1/16 out of the way. Then change of planer, followed by one edge of the board thicker than the other, or the middle thicker than the edges. The same thing occurred at other mills. What they had always considered exact work wouldn't be considered so in bee-supplies. He found the only satisfactory way was to get supplies from those who made it a special business, and were provided for the exacting requirements of matters pertaining to bee-hives. Home-made work hardly pays.

Asking Questions is all right. We want our readers to feel free to ask for information, but we will have to draw the line for awhile on asking and answering over and over the same questions, week after week. We think the trouble is that beginners are not careful enough to read every question and every answer found in Dr. Miller's department of the Bee Journal each week. Hence it is that they keep on asking about "transferring," "what to do with unfinished sections," etc.—questions that Dr. Miller has answered "forty-seven" times (more or less) the past three months. We think, in order to save space, and also to get caught up, we will have to ask Dr. Miller to simply give the previous page numbers where can be found replies to repeated questions.

Alfalfa for Hay.—Mr. E. S. Lovesy, who lives in the great alfalfa region of Utah, refers thus to Prof. Cook's statement about alfalfa, as found on page 97:

I agree with Prof. Cook when he says that our lucern secretes honey liberally in dry weather; but when he says that it is better for hay to cut it just before it blooms, I can say that my experience is the opposite. I believe there is in it much more virtue, nutriment or strength when cut after it has been in bloom a week; some here claim to have tested this. As I have always agreed with Prof. Cook in all else, I would like to ask him if he has tested this matter, or does he give it as common custom or belief? Sometimes this proves a common error.

E. S. LOVESY.

He Never Smokes.—A supply-dealer was in his store with a bee-keeping customer, and when passing a shelf on which were piled bee-smokers, the following short conversation took place:

SUPPLY-DEALER—Wouldn't you like a smoker?
CUSTOMER—No, thank you. I never smoke.

This smoker anecdote we donate to Mr. Bingham, of bee-smoker notoriety. We know when and where it really occurred. We only wish that every bee-keeper could honestly make as good reply, and still use a (bee)-"smoker."

Bee-Literature (?).—E. E. Hasty will be sad. Not long ago he mentioned the departure of a certain order of literature from bee-journals, fondly hoping it might never return. Now has Rambler in *Gleanings* rambled clear out of sight and sound of bee-keeping, and discourses upon the difficulties of pleasing an alling wife in the proper selection of a chicken to be killed for Thanksgiving. Fortunately it doesn't come in the busiest time of the year.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

MR. B. FRANK HOOVER, of Whiteside Co., Ill., wrote us recently:

"I'm glad you have adopted reform spelling. Continue, and if anything become even more radical, and adopt even a greater reform. Our reforms come thru our papers."

MR. W. W. WHIPPLE, of Arapahoe Co., Colo., wrote Feb. 14:

"I think after reading five numbers of the American Bee Journal for 1898, that it is worth its weight in Gold, with a big G."

MR. CLAUDE STERT, of Uvalde Co., Tex., writing us March 7, said:

"We are shortly expecting a fine crop of honey from a shrub abounding on these low hills, called 'gwahilla;' but some times that dread enemy, "a late frost," puts an end to our expectations."

MR. F. G. HERMAN, of Bergen Co., N. J., wrote us March 7, when sending \$1.00 for the Langstroth Monument Fund;

"Bees commenced carrying pollen to-day, just two weeks earlier than any previous year. We are having an early spring. I trust we shall be smothered in honey this year."

MR. O. O. POPPLETON, of Dade Co., Fla., wrote us as follows, March 8:

"The honey-flow so far this winter is not so good as usual, but yet enough so that nearly every warm day I do a little fooling with the extractor. I have out about 1,000 pounds only. Prospects are good for a strong flow from saw palmetto in April and May."

THE CANADIAN BEE JOURNAL publishers had a fire to break out in their establishment, March 3, which ran through the entire main building of their works, and practically totally destroyed their bee-goods, and otherwise did great damage. The fire caused a slight delay in getting out the March number of the Canadian Bee Journal, but everything is running again on extra time.

THE CARLETON FAMILY, of Anoka Co., Minn., are well represented in the Langstroth Monument Fund. Here they are: Mrs. J. A. Carleton, 50 cents; Will Carleton, \$1.00; Rose E. Carleton, 50 cents; and D. L. Carleton, 50 cents. Also the first two of this quartet of Carletons have become members of the New Union. That's the way to support good causes. There is room for plenty more people like the Carletons, both in the Langstroth Monument Fund and in the New Union. And we are ready at all times to receive their money, and turn it all over to the proper authorities.

MR. E. S. LOVESY, of Utah, writes thus in reference to the Langstroth Monument Fund:

"I read with some encouragement what Mr. Cameron has to say on this subject, on page 104. I agree to Mr. C.'s suggestion, to be one of 100 to give \$5.00 each. I have agitated this matter considerable, because I believe it to be a laudable object. As bee-keepers, let us not procrastinate in this any longer, but let us have 'a long pull, a strong pull, and a pull all together.' This will be a credit to ourselves and an honor to our dear departed Langstroth."

THE LEAHY MFG. CO., like others, are on the jump to fill their orders for supplies. Here is what they wrote us March 11:

"This is a great year for trade. We have been running our factory 22 hours a day for over a month now. If bee-keepers would take bee-journals like they buy bee-supplies, there would be fun in running a journal."

Yes, that's so. There would be fun as well as money in running a bee-paper if all who ought to subscribe would do so. Wonder what can be done to induce them to see their duty and need. Here's a problem to solve for any one who wants to earn some good money.

Marks-Hoffman Metal-Spaced Frames—A plate of metal let into a saw-kerf in the end-bar as a space—having been commended in Gleanings, F. Boomhower, after having tried them, says they are death-traps, not to be compared with staples as spacers.

Golden Italians are generally supposed to be of comparatively recent origin, yet in a letter written by Baron Berlepsch in 1854, and lately published in Gerstung's Bienenzucht, he says: "I have a queen which looks exactly as if chiseled out of ducat gold. Her progeny excel all others."

The See-Saw Section-Cleaner has been in editor Root's head for some time, and now he has got it so far out of the whirl and bustle of that busy location as to get it on paper. Works a little like an old-fashioned turning-lathe, having a foot-treadle, and a coil-spring above, so it can be whirled back and forth.

"Covers are Apt to Shrink," says the Australian Bee-Bulletin "thus becoming narrower than the top of the hive, their efficacy in resisting heat and damp is to that extent impaired. Covers should be made at least an inch wider than the top of the hive." But why not shrink that inch before the covers are made?

Management of Swarms.—Here's the plan of Thos. W. Odle, as related in Gleanings, by which he says he gets good crops of honey: When a colony swarms he kills the queen, reserving extra-good ones in nuclei, then at the proper time removes all queen-cells but one, and in about 20 days has a young laying queen that he thinks worth two old ones.

Tall Sections of Light Weight Sold Best.—Thos. V. B. Neece sold sections running 15 to 16 ounces each at 16 cents a pound, 15 to 16 cents a section. A competitor sold at the same price, per pound, plain and tall sections $1\frac{1}{4}$ or $1\frac{3}{8}$ -inch thick, but this made them 10 and 12 cents each. The tall, thin sections went off rapidly and the others dragged. Now Neece wants to adopt tall, thin sections weighing 10 to 12 ounces.

The Crane Fence.—Besides the Root and the Aspinwall fence, there is now the Crane. Gleanings describes it as consisting of four pieces with no cleats only at the two ends. This makes a rather weak fence, but has the advantage of freer communication. Where the three inside cleats usually are, wooden pegs about $1\frac{1}{8}$ -inch thick, $\frac{1}{4}$ -inch wide and 5-12 long are driven through the four slats, so as to abut against the uprights of the sections.

The New No-Bee-Way Section in England.—Somewhat strangely, when a new thing comes up in either England or America, interest in it does not usually cross the water. Plain sections and cleated separators seem to be an exception. The British Bee Journal says that already two forms of separator are patented, and a third just ready. It thinks, however, that the bee-way section is not in immediate danger of being forever swept out of sight.

To Separate Swarms Clustered Together.—Have ready a very large tub. Take it where the united swarms are, and sprinkle it lightly inside. Arrange several branches of trees in the tub so they shall not touch each other. Dump in the swarms in a single cluster, cover the tub with boards, leaving free entrance for bees still in the air. Each queen will take a separate branch, and in half an hour the separate swarms can be hived. It is well to sprinkle the branches with sweetened water.—*Apiculteur.*

Identifying Laying-Workers.—D. W. Heise, who from starting out in Canadian Bee Journal as a "picker up of unconsidered trifles," has developed into a full-fledged boiler himself, is desirous of a chance to crack the knuckles of this boiler. Well, if it is a matter of necessity that the knuckles must be cracked, there is probably no one who will administer the cracking in a more judicious manner, or with fuller consideration for the benefit of the crackee than the same man Heise. So here's the chance, D. W.: Quoting from American

Bee Journal, page 806, you aid and abet the promulgation of the idea that a laying-worker can be "seen and told by her looks." Now you may get from W. W. McNeal full instructions for the identification of laying-workers, said instructions duly certified before the proper officer of the law, and neither you nor any other bee-keeper on that side the line can pick out for sure a laying-worker, even if one-fourth the workers are engaged in that interesting occupation, unless you surprise them in the act. This assertion failing to prove true, you are at liberty to administer such knuckle-cracking as the merits of the case and your sympathy for the culprit may dictate.

Not Safe to Trust to a Single Queen-Cell.—A. Maujean asks in *Le Rucher Belge* whether you are sure you will have a good queen when you have, to all appearance, the very best queen-cell. Sometimes queens are dead in cells, even dying after they are sealed. In his experience he has had a cell perfectly formed and sealed, but with no queen whatever in it; the cell containing only a little royal jelly, the larva having probably died when very small and shrunk to nothing, leaving no trace.

Deep Hive-Entrances.—Deep entrances prevented entirely lying-out the past summer for James L. Montgomery (Gleanings), but Mr. Doolittle says it is about the same whether bees lie out in idle clusters, or in idle clusters in room made for them by deep entrances under the hive. But Mr. Montgomery scores a point for deep entrances when he says that colonies in 8-frame hives with deep entrances swarmed very little, "while those without the deep entrance have all swarmed, some of them twice."

How Field-Bees Unload.—Doolittle says in *Progressive Bee-Keeper* that after having watched hour after hour he believes that not one bee in a thousand returning with a load of honey ever enters the sections till it has given up its load to a young bee an inch to six inches from the entrance. The field-bee rests a few moments to half an hour, then goes fieldward again. The young bee evaporates the nectar, and if the yield of nectar is too big to be evaporated by the young bees they deposit some of the nectar in the cells, and at night all hands turn to evaporate.

Scale Colonies.—The practice of having a colony on scales to note daily gain or loss is commended by R. C. Alkin, in Gleanings. But he thinks it unwise to depend on a single colony as an index of what all are doing, for it may be that such colony may be working in a different quarter from most others, and this is one of the ways perhaps in which may be explained the difference in results of two colonies apparently alike in all respects getting such different yields in the same apiary. To get satisfactory results, he thinks there should be two or more colonies noted.

Simmins' Direct Introduction of Queens.—In *Bee-Chat*, the new English quarterly bee-paper, edited by S. Simmins, he gives the following rules to be observed in his plan of direct introduction of queens. 1. Keep the queen *quite alone* for not less than 30 minutes, without food, but warm. 2. Insert after dark, under quilt, first driving the bees back with smoke. 3. No further examination is to be made until after 48 hours has expired. 4. Make no division of, or nucleus from, the hive within three days prior to insertion, unless the original queen is then left on her own stand.

Points in Using Plain Sections.—L. A. Aspinwall is one of the men who have successfully used plain sections, and he gives a valuable article in *Review*, especially valuable as it points out some of the troubles to be avoided. Accurate measurements must be used, and the space above and at the sides, where vertical passages are used, must not be more than $\frac{1}{4}$ inch, and at bottom $\frac{3}{16}$. Even then there will be bulging if bees are crowded for room, and burr-combs will be built throughout the hive, so supers must be promptly removed when filled. Parenthetically he remarks that bees will put burr-combs in $\frac{1}{4}$ -inch spaces between and above top-bars if there is a scarcity of room. Greater care is required in handling and crating, putting not more than one or two sections with bulged edges in a crate if there are such sections. He thinks no-drip cases are not needed with plain sections, for even with veneers the plain sections come together so close that drip will not get through. He uses tin separators of peculiar construction, and scores a point in favor of tin by saying: "To scrape propolis from a thousand separators is no small task. But with a large kettle of boiling water, a thousand or more made of tin may be cleaned in 15 or 20 minutes."

GENERAL ITEMS

Mr. Pettit and His Divider.

I would like to ask Mr. S. T. Pettit, of Canada, the following question: After quoting what he says in his article, on page 51, he says, "Here is a point I must call attention to.... There must be no passage-ways for the bees outside the followers; the bees must be kept and obliged to do their coming right against the divider," etc.

Why is it that the bees must be compelled to enter thus? I ask the question because his recommendation seems to be very imperative as to this. Then following he says: "I have thought a good deal about it, and can hardly tell why.... I like to have space between the divider and the super wall." Now I suspect he has been reading of my method of producing comb honey, for that's just where I permit the bees to enter, even from the bottom of the hive on up to the topmost super, having provision made to enter each super if they wish, or go from the bottom of the hive to the top super direct, and I am thinking that after he tries the space 5-16, 1/4, 3/8, or 1/2 inch, he will feel like saying, "I wish I hadn't said there must be no bee-space." Any way, such positive directions are misleading, but unintentionally given in writing, especially on bees and their habits, I think, very frequently. J. A. GOLDEN.
Morgan Co., Ohio.

Wintering Well—Season's Report.

My 64 colonies in the home apiary seem to be wintering pretty well, all packed in chaff on the summer stands. I have 28 colonies 2 1/2 miles away, 16 of which having only a cushion on top; they don't seem to be wintering as well so far, altho the winter has been quite mild up to this time.

My bees did quite well last season. I began the season with 87 colonies, closed with 92, and took 6,000 pounds of honey of fine quality, about 1,200 pounds being comb in pound sections, which is all sold at 7 and 8 cents per pound for extracted, and 10 to 12 1/2 for comb honey. Our home market is in a fair way to be ruined with cheap honey.

I began bee-keeping 18 years ago with one colony in a box-bive. I had the genuine bee-fever, and I've got the same disease yet. I feel that if I should happen to live the allotted life of man, my bee-keeping experience has just begun, as I am now only 33 years old. I have been a constant reader of the American Bee Journal for about 16 years, and it has been of great value to me. B. W. PECK.
Ashtabula Co., Ohio, Feb. 1.

Experience with Bees.

I have had many years' experience with the bees, and could not look for success in the business without the American Bee Journal. I was a subscriber away back in the early '60's, when it was published by Samuel Wagner, in Washington, D. C. We are never too old or too wise to learn. In those years I considered myself well up in bee-lore, tho I made no claim to being an expert. But failing health compelled me to drop out of the business for 15 years. On the partial recovery of my health the old passion for bees revived, and I have been trying to do a little at the business for the last three years; a trifle over a year ago I subscribed again for the "Old Reliable," and the first number received revealed the fact that the procession had moved on and I was left a long distance in the rear. I have recovered some of the lost distance in the last year. I recollect no season in my experience when we obtained more satisfactory results from our labors with the bees (except prices) than the last.

I commenced last spring with 10 colonies

GEO. W. YORK & CO. 118 Michigan st., CHICAGO, ILL.

in the 8-frame dovetailed hive, one queenless, and increase them to 19. I cut off all second swarming by following Mr. Heddon's plan, that is, by setting the young swarm on the old stand, leaving the old hive by its side for a week, then removing it to a new stand. This plan proved successful, and less trouble than any I have ever tried. My plan has usually been to hive all after-swarms in an empty hive, cap, or convenient box, let them stand until evening, then shake them down in front of the parent hive and let them run in. I don't remember a swarm treated in this way issuing the second time. This plan requires more care and labor, and a greater risk of loss.

I obtained 1,050 one-pound sections of honey. The best colony stored 167 sections. I have been a little slow in using separators in the supers; the reason was, I believed the bees would not accept it as readily, and do as good work in the supers with as without them; but after using them one season, and taking into account the perfect shape, uniformity of combs, and ease in handling and packing, I could not be induced to abandon their use.

Bees went into winter quarters in fine condition, packed in chaff on the summer stands, and are doing well up to date. I am patiently and anxiously waiting for the time when I can again hear their busy hum. L. JONES.

Floyd Co., Iowa, Feb. 2.

A Report—Bee-Management.

I commenced the season of 1897 with 15 colonies, got 1,160 pounds of honey, and increased to 24 colonies, all going into the cellar in good condition. I sold all of my honey on the home market at from 10 to 14 cents.

I got my best yields from prime swarms, from colonies in 10-frame hives, hived on the old stands in 8-frame hives. The 8-frame hive isn't large enough to cast the kind of swarms I want, so I will use 10-frame hives the coming season, and contract to 6 or 8 frames for the new swarms, and hive on the old stands; then give the balance of the 10 frames after the basswood and clover harvest is over, and extract any surplus then, and the parent colonies may gather in the fall. I will leave the 10 frames in to get large prime swarms from the next season.

White clover yielded immensely here for a short period last season. The basswood was an entire failure. Wire-weed and golden-rod yielded well in the fall, considering the drought.

I clip all queens as soon as fertilized, and supersede all queens at three years old, or rather I intend to from this time on. I don't want to be bothered with old queens playing out in the pinch of the game.

RUFUS WILLIAMS.

Lawrence Co., Ind.

Several Notes and Comments.

I was sorry to hear that Dr. Besse had lost in his sweet clover lawsuit, for I was real interested in watching the reports concerning it, and hoped that he would win.

As will probably be remembered, along last July several fellows used adulterated means for getting some honey out of my storehouse. I reported the same at the time, and Editor York hoped that an example would be made of them, as I caught them and landed them behind the bars. Well, one of them broke jail and got away, while the other fellow is putting in time at the "Pen," on a two years and six months' sentence.

Now, the above fellow used adulterated means to get honey, while some others used adulterated honey to get means. What is the difference twixt the two? [One is mean enough to adulterate, and the other is adulterated enough in himself to be mean.—Ed.]

Yesterday was a nice, sunny day, and all my bees were out; thus far every colony that was put into winter quarters has responded to the roll call of "Old Sol." My bees are mostly the yellow strain. I also

have some leather-colored; all seem to winter alike. They are outside, packed in chaff. I have a few colonies of common bees, and one peculiarity I have noticed is, that on the bottom-board of the common bees there are quite a few tiny white wax-scales, while I find none among the Italians.

By the way, the American Bee Journal appears to be getting better and better, every issue seems to be an improvement on the former one. Dr. Gallup's recollections are just excellent. H. G. QUIRIN.

Huron Co., Ohio, Feb. 9.

Wintering in Canada.

Lots of snow, and wind and weather nowadays here. I have just 80 colonies of bees in the cellar, and only 2 out-doors, and I believe there is more pain and suffering in those two than in the 80 that are so snug and nice in the cellar.

S. T. PETTIT.

Ontario, Canada, Feb. 3.

New Union—Question for Mr. Russell.

On page 125, Wm. Russell asks whether the constitution of the new Union cannot be made wide enough to take all in without having to pay two membership fees. Will he kindly tell what there is in the new constitution to hinder exactly what he wants? Also, how he would go to work in any different way than the new Union has done, to get all united in one strong organization? What does he want the new Union to do before he joins?

INQUIRER.

Success in Bee-Keeping.

I have been a bee-keeper five years, and have made a success. I have not lost a full colony in any way, and with the exception of 1894 I have had a good crop of honey. When I began people told me that bees did not pay any more, and some of them had kept bees for several years without getting any honey to speak of. In 1895 I harvested 50 pounds per colony; in 1896, 82 pounds per colony; and in 1897, 80 pounds. By 1896 people began to enquire how I managed, and last year they adopted my plans, taken mostly from the American Bee Journal, and they are getting to be bee-keepers. Big hives with plenty of honey, and reasonable care in winter, will solve the problem for the farmer, as nearly as it will ever be solved. W. S. DONER.

Pottawattamie Co., Iowa, Feb. 8.

A Report for 1897.

I commenced the spring of 1897 with three colonies of black bees, also bought one two-framed nucleus of Italians, for which I paid \$1.85. I increased to 12 colonies, and took 170 pounds of comb honey. The Italians did not swarm until July 16, when I hived the swarm and placed them on the old stand, removing the parent hive to a new stand. The next day I was about to put a super on from the parent hive; I took the cover off, and there the first thing I saw was a young queen on top of the sections. I put her into a glass, went back to the hive and found another queen; I caught her also, took the super off, and found two young queens in the body of the hive. I then divided the colony, and left a queen in each part, making three from one nucleus, and two queens over. July 26 the two young queens were laying, and made good colonies, with plenty of honey for winter. D. PATTERSON.

Decatur Co., Iowa, Feb. 9.

Figwort—Viper's-Bugloss—Bloodroot.

I want to enter a mild protest against what has been said lately in favor of the Simpson honey-plant (Scrophularia nodosa or figwort). The honey is abundant in each little cup, and may be all right for feeding back to the bees; but in my opinion unfit for table use. The "A B C of Bee-Culture" describes it as a little dark. It is, in fact, as dark as charcoal, and of repul-

sive taste and smell as the plant itself. Seeing it recommended, I bought some seed few years ago to try the honey. I am done with it now.

About the same time I tried another honey-plant be viper's-bugloss, called also "blue thistle" (Echium vulgare); it is a biennial, and a good fertilizer if we judge from its large, long taproot. "A B C of Bee-Culture" says that "it produces a beautiful white honey;" now this is not exactly the case with the plant I have had. The honey is rather dark, like that of buck-wheat, but the flavor is all right. Each plant in a good soil will produce 8 to 10 long stalks, and, each of these, hundreds of nice blue, reddish flowers, from July to October in my place. Animals will not touch it on account of its prickly leaves. It is also a medicinal plant, as the borage.

I have also had quite an experience with the blood-root (Sanguinaria canadensis), of which there is an abundance here. Bees in early spring revel on its white flower to gather the reddish pollen—one of the earliest flowers here. It is a sight to see three or four bees trying at the same time to get a load of its pollen. The plant is a perennial, and most easily propagated from the root; and since it blooms before any leaves are out, may be spread under shady spots.

H. DUPRET.

Province of Quebec, Canada.

The Prospects in California, Etc.

I was very fortunate the past year in securing a good crop of honey, part comb and part extracted. The former I disposed of at an average of 10 cents, and I hold the latter for better prices, and judging from present prospects the coming season is destined to score another failure. As a rule, the greater portion of our rainfall comes previous to Feb. 1, but up to this time the precipitation has been in small quantities and at long intervals, and never before during my 10 years' residence in this State have I witness such discouraging prospects for those who are dependent upon grain-production, as the present; and then this has a special bearing on our own industry, for they, as a rule, succeed in securing a crop when we fail.

Those who were present at the State convention enjoyed a rare treat in meeting and listening to Thos. W. Cowan, and I desire to say that there is plenty of room for such as he, at all times and on all occasions, in this, the Golden State.

GEO. W. BRODBECK.

Los Angeles Co., Calif., Feb. 2.

Bees in Fine Condition.

My bees are in fine condition at present in the cellar, with the temperature at 40 degrees above zero.

We are having some cold weather now, with plenty of snow, which I think is a good thing for clover, which was in fine condition last fall. We almost always get a good crop of honey when we have plenty of snow.

I have taken the American Bee Journal for about 15 years, and I had it stopt at New Years because I thought I was going to leave the bees, and go at something else, but as long as I keep bees I want the Bee Journal. I was away and saw William Anderson, who lives about 12 miles from my place; he has about 100 colonies, and has never read any bee-paper, so I got him to let me send and get the American Bee Journal for him. He takes great interest in bees, and winters them in a cellar. His bees were in good condition when I was there. J. F. WIRTH.

Henry Co., Ill., Feb. 3.

Looking Ahead—Season of 1897.

The winter is rapidly drawing to a close, and I presume all bee-men are directing their thoughts an planning for the coming honey harvest, which of course we expect.

Bees in this locality went into winter quarters strong in stores and in numbers, and up to date have wintered well. We

have had an unusually mild winter thus far; bees could have wintered on the summer stands with little protection without any loss. Most of mine are on the summer stands.

The honey year of 1897 ended quite well. The forepart of the summer was unpropitious for honey-gathering; there was an abundance of white clover bloom, and other honey-producing shrubs and trees, but owing to the cold and wet we got but very little honey, but later on the weather grew warmer, and bees did fairly well in gathering honey from Alsike clover, buckwheat, golden-rod and asters. I think I am safe in saying that the average per colony in these parts would be 50 pounds.

The "Old Reliable" comes regularly to my table—a most welcome guest.

Convention Notices.

Texas.—The Texas State Bee-Keepers' Association will hold its annual convention at W. R. Graham & Son's, Greenville, Texas, the first Wednesday and Thursday in April, 1898. All interested are invited.
W. H. WHITE, Sec.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, April 5, 1898, at 10 a. m. A full program in the interest of the industry will be presented. It is very desirable to have all parts of the State represented. Among other things to be considered is the transportation and marketing of our products and also the adoption of the best plan to represent our state at the Trans-Mississippi Exposition, and to get our new foul proof law into active operation. Every bee-keeper should be interested in these matters. All are cordially invited. In case there may be any that cannot attend, we would be pleased to have their address, and have them send in questions on general topics. Several members of the Association have desired us to again call the attention of our bee keepers to the Langstroth monument fund. Any who feel able should throw in their mite to mark the last resting-place of this the greatest of all American bee-keepers. No one will feel as if it was labor in vain, who takes a fraternal interest in this desirable object.

JOHN B. FAGG Sec., East Mill Creek, Utah.
E. S. LOVESY, Pres., Salt Lake City, Utah.

"The Wooden Hen."—The little illustration shown herewith is small only in size, but really large in magnitude, when we consider that the "Wooden Hen" is no larger than a live hen, yet has double the capacity. It weighs only 15 pounds, has a capacity of 28 eggs, and while not a toy, is just as amusing, besides being instructive as well. We doubt

If a more acceptable or more valuable present could be made to the farmer boy or girl, and we suggest that every one of them who read the American Bee Journal write Mr. Geo. H. Stahl, Quincy, Ill., and ask him for a copy of his handsome little booklet describing the "Wooden Hen"; also his large catalog of the Model Excelsior Incubator. Tell him you write at the suggestion of the American Bee Journal.

Bee-keeper's Guide—see page 189.

TREE PLANTING

may be a way to wealth or a waste of money—depends on the kind of trees. All trees, plants, vines, from the Reid Nurseries are No. 1 stock, true to name. You gain by buying now. Prices were never so low. Write for illustrated catalogue, suggestions, estimates. Try Star Strawberry, Eldorado Blackberry for profit.

The Bee-keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also the most well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the 'hoo' as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

A Good Bicycle Free

Now, then, young men and young ladies, also boys and girls, take advantage of this offer and get a Wheel (A THOROUGHLY GOOD ONE) with a little work. To increase our circulation we have made arrangements with a first-class concern in this city to furnish us with their well-known

ALAMO WHEELS

at a price which enables us to give one **FREE** as a premium for sending us **50 New Subscriptions** to the Bee Journal at \$1.00 each. You can send them in as taken, and when your list of 50 is complete, we will ship your beautiful wheel, freight paid, to your nearest depot. This wheel retails in the ordinary way at \$50.00—and it concerns nobody but ourselves how we managed to get in on the inside cut price. For 40 Subscriptions we will ship a Juvenile of the same make. Below we give specifications:

Frame—Shelby Seamless Tubing. 1½ Main Frame. Connections—Steel (selected.) Fork Crown—Oval (drop forged.) Handle Bars—Steel or wood, drop or upright; cork grips. Wheels—28 inch. Pedals—rat trap. Rims—best elm. Tires—Morgan & Wright or Vim. Spokes—selected piano wire. Bearings—Tool steel (turned by experts.) Gear—64 to 80. Saddle—leather (rubber or felt neck.) Weight—23 to 25 pounds. Color—black, maroon, nicely striped. Special color by arrangement. Furnishings—Tool bag, oiler, wrench, air pump, etc.

Ladies' model built on same lines with the usual difference between sexes, such as rubber pedals, etc.

Address: **GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.**

\$100

Given as Bounties to purchasers of the improved Danz. Hives and Sections See schedule in my bee-book "Facts About Bees." Tells

how to produce honey that sells for the most money. Free for 2c in stamps. Address: **THE A. I. ROOT CO., Medina, Ohio, or F. DANZENBAKER, Box 466, Washington, D. C.**

The Kitzelman Up-to-Date Fence.—The fence here shown is made of a high grade of Galvanized Colled Spring Wire, with the Duplex Automatic Ball Bearing Woven Wire Fence Machine, which is made entirely of iron and steel, and is so simple and easily operated that any one who knows how to turn a grindstone can take it right into the field or any place and make 50 to 80 rods a day of the best fence on earth, horse-high, bull strong, pig, chicken or rabbit tight, at a cost for the wire of only 12 to 20 cents a rod. Messrs. Kitzel-

man Bros., Ridgeville, Indiana, whose advertisement appears elsewhere in this paper, claim the Duplex Automatic Ball Bearing Machine is the result of their 10 year's experience in the manufacture of woven wire fence machines, and is Perfection Itself. Send for their illustrated catalog which fully describes 24 different designs of fence, not forgetting to say you saw their advertisement in the American Bee Journal.

Get Your Money's Worth.—If there is one thing above another that produces comfort and pleasure in the conduct of business, it is the absolute certainty that you get full value for your money when you make a purchase. We do not wonder, therefore, that people turn to those individuals or companies who offer a positive guarantee of quality to the purchaser. A good many manufacturers are now sending out their goods on trial with the proviso that if not satisfactory in every way, they may be returned. This is true of our advertising patrons, The Marilla Incubator Company, of Marilla, N. Y., who manufacture the incubators and brooders of that name. That these people make good machines and deal fairly with the public cannot be doubted if we consider their own business proposition in which they say—"Our only argument: we ship a machine that will give satisfaction or it is not a sale." Write these people for catalog, prices, etc., and mention the American Bee Journal.

The Page Woven Wire Fence.—The Page Woven Wire Fence Company's Illustrated Catalog will be sent FREE to any person asking for it: it shows many styles of their fences and contains much valuable information about setting end and anchor posts. The Lithograph of the Manufactory at Adrian, Michigan, exhibits something of its magnitude. It is claimed that they manufacture more Woven Wire Fence than all others combined. Their fence is used in almost every country on the face of the earth. They have, within the last five years, manufactured enough fence to entirely encircle the earth, and average 12 horizontal wires high, and used about 500,000 miles of wire. Address the Page Woven Wire Fence Company, Adrian, Mich., for a catalog, and be sure to mention that you saw their advertisement in the American Bee Journal.

NO DIRT LEFT
 In clothes washed with the "BUSY BEE WASHER," 100 pieces in one hour and no hard work done. That's the record. **AGENTS WANTED.** Exclusive sale. Write for terms. **Lake Erie Mfg. Co., 147 E. 13 St., Erie, Pa. 44E26t** Please mention the Bee Journal.

Wide-Tired Wagon Wheels.—Elaborate tests of the draft of wide and narrow-tired wagons have just been completed by the Missouri Agricultural College Experiment Station, Columbia, extending over a period of a year and a half. These tests have been made on macadam, gravel and dirt roads in all conditions, and also on the meadows and plowed fields of the experimental farm. Contrary to public expectation, in nearly all cases draft was materially lighter when tires six inches wide were used, than with tires of standard width. The load hauled was in all cases the same, and the draft was most carefully determined by means of self-recording dynamometer. The beneficial effect of the wide tire on dirt roads is strikingly shown in some recent tests at the station. A clay road, badly cut into ruts by the narrow tires, was selected for the test, as presenting conditions least favorable to the broad tire. A number of tests of the draft of the narrow tire were made in these open ruts, and immediately followed by the broad tires running in the same ruts. The first run of the broad tires over the narrow ruts was accompanied by an increase draft; the second by a draft materially less than the original narrow tire, third by a still greater decline, and in the fourth trip the rut was practically obliterated and filled. In another trial, when a clay road was so badly cut into ruts as to be almost impassable for light vehicles and pleasure carriages, after running the six inch tires over this road 12 times the ruts were completely filled, and a first-class bicycle path made.—Columbia Herald.

Put wide tires on your wagon. You can buy wheels of steel or wood to fit your wagons with these wide tires at reasonable prices, and the Electric Wheel Co., of Quincy, Ill., have a book called "Preservation of Farm Profits," which they send free to any one upon application, which is full of information on this subject. Write them for it, and tell them you saw the notice in the American Bee Journal.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Ill., Mar. 8.—A little fancy white sells at 11c. If free from any indication of graining, but the majority of white honey sells at 10c., with off grades at 8 to 9c.; amber is not selling readily at 8c.; dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 1/2 to 5c.; dark, 3c. Beeswax, 26 to 27c., and in active demand. The weather is now suitable for shipments of comb.

Milwaukee, Wis., Mar. 8.—Fancy, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 10 to 10 1/2c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4 1/2 to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the best. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better

Buffalo, N. Y., Mar. 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.

New York, N. Y., Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5 1/2c.; light amber, 5c.; white clover and basswood, 4 1/2 to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cincinnati, Ohio, Feb. 21.—There is a slow demand for all kinds of honey. We quote 10 to 13c. for best white comb honey, and 3 1-2 to 6c. for extracted. Beeswax is in fair demand at 20 to 25c. for good to choice yellow, with a fair supply.

Cleveland, Ohio, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6 1/2c.; amber, 4 to 5c. Beeswax, 22 to 23c.

Kansas City, Mo., Feb. 19.—Fancy white comb, 1-lbs., 10c.; No. 1, 9 to 10c.; amber, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 5 1-2c.; amber, 4 1-2 to 5c.; dark, 4c. Beeswax, 20 to 22c.

The supply of honey is large and the demand light.

St. Louis, Mo., Feb. 9.—Fancy hite comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c.

Detroit, Mich., Feb. 1.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c.; No. 1, 8 to 9c. Darker grades are selling lower and in better supply, and can be bought at 6 to 7c. Extracted, white, 5 to 6c.; darker grades, 4 to 5c. Beeswax is in good demand at 26 to 27c.

Indianapolis, Ind., Jan. 15.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

Boston, Mass., Jan. 18.—Fancy, in cartons, 12 1/2 to 13c.; in glass, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 9c.; No. 2, 8c.; No. 3, no sale. Beeswax, 27c.

The demand for honey is light on all grades, with a full supply. Pure beeswax is in good demand, but supply is light.

Philadelphia, Pa., Jan. 18.—Fancy white, 10c.; No. 1, 9c.; amber, 8c. Extracted, white, 5c.; amber, 4c.; dark, 3 1/2c. Beeswax, 28c.

Late arrivals of California honey have demoralized our market.

Chicago's Favorite Passenger Station.

Reasonable success seems to have followed the efforts of the management of the Nickel Plate Road to make it popular as a passenger line for travel East. It is regarded as a favorite by many in making the journey from Chicago to Eastern points.

Patrons of that line will be gratified to learn that arrangements have been made, effective Sunday, March 6, for all passenger trains of the Nickel Plate Road to arrive at and depart from the Van Buren St. Station in Chicago.

The many advantages afforded by this Great Union Depot, located in the heart of the business portion of Chicago, and the continued advantage afforded by lower rates than over other lines, having three Express Trains daily, with through Sleeping Cars to New York and Boston, and the advantage of superior Dining Car Service, when all considered, should show increase travel over the Nickel Plate Road. (S) 11A2

 Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.

CONTRIBUTED ARTICLES

Taking the Bees Out of the Cellar.

BY DR. C. C. MILLER.

Having received a letter from Mr. M. M. Baldrige, a part of which is of such general interest, I send it for publication, as follows:

FRIEND MILLER:—My 31 colonies of bees in the cellar were taken out to fly, and to remain out, on March 8. It was warm enough on March 7, but there was too much snow on

the ground. On March 8 I waited till the afternoon, so as to have as little snow as possible when the bees would begin to fly. I began at 1 p. m. to carry the bees out, and had them all out by 2:30. They had a very good flight, but a much better one on March 9. It was 54° in the shade at 1 p. m. March 8, and 56° at 2:30. The next day it was up to 64° in shade. I am glad to have the bees out-doors now, and that they had such a good flight.

I had one colony out-doors all winter, packed in planer-shavings. I rather think it has wintered all right, but the bees did not fly therefrom until March 8, and not then until it was over 50° in the shade!

As I do not touch my bees for at least a month or six weeks after they are put out to fly, I cannot tell very well till then how well they have wintered. I may then be able to determine whether the packed colony out-doors has wintered better than those in the cellar. I am at present inclined to think that a less number of bees have died in that colony than in any of the others. My cellar is pretty warm, but none

Apiary of F. J. R. Davenport, in Ellis County, Texas.

too warm to suit me. The temperature runs from 45° to 60° when the bees are in the cellar. It is a small room, partitioned off from the main cellar, has a board floor, and is lined on three sides with boards and leaves.

My bees were taken to the cellar in November, 1897—the 21st, I think. They had a nice flight the day before, when the temperature was 66° in the shade. It would have been just as well to have left the bees out till about the first of December, or later. I like to put bees in *late* and take them out *early*, as nearly as possible to the first of March. In 1897 I got them out the latter part of February. It was an ideal day for bees to fly, being over 60° in the shade, and no wind.

I prefer to watch the temperature and other conditions, and take out the bees in the daytime, and when they can fly *at once*. To make them do this I use smoke in the cellar. I puff some into the entrance of each hive when ready to be taken out. This drives the bees back among the combs and stirs up the entire colony. I can now take the colony out-doors with no danger of stings, and as soon as the bees are on the stand they are ready to begin to fly. I want all the bees to fly that wish to at once, and I pay no attention to the stand, or part of the yard the hives were on in the fall. It matters not to me whether the bees get back to their own hives or not. There will be no fighting when first put out, and the bees will be in the apiary somewhere. If some colonies get more than their proper share of the bees this can be remedied six weeks or two months later, by simply exchanging strong colonies with weak ones. I find this the best way possible to equalize an apiary and make all colonies of nearly equal strength. If the exchange be made when the bees are flying freely, and bringing in honey, there will be no fighting nor no loss of queens. Try this plan by and by, as indicated, and satisfy yourself. When honey is as cheap as it is to-day, it won't pay to equalize the strength of an apiary by the slow-poke way of exchanging combs of brood. Truly yours,

Kane Co., Ill., March 11. M. M. BALDRIDGE.

The question as to the right time to take bees in the cellar, and the right time to take them out, is one of great interest to Northerners. Mr. Baldrige wants to get his bees in late and out early. A strong argument for that is the fact that in such case the time of confinement is shorter, and cold and long confinement are the two factors leading to diarrhea. Cold alone will not produce diarrhea. Confinement alone will, if the confinement be long enough. The more severe the cold the shorter the confinement they can bear. So if all other things are equal, the later the bees are taken into the cellar and the earlier they are taken out the better for the bees. The trouble is that other things are *not* always equal, and you don't know enough ahead to guess how other things will be.

Quite a number who cellar bees are now advocating taking them out earlier than has been generally considered advisable. So many are they, and men of such good repute, that I have been led to question whether I may not have been in error in keeping mine in so late as I have been in the habit of doing, so this year, as an experiment, I have taken out 20 colonies before the usual time. N. D. West, of New York, some of the Canadians, Mr. Baldrige, and others in his vicinity, are among the advocates of taking out early.

First, as to taking in. Mr. Baldrige lives less than 30 miles from me in a bee-line, and yet I suspect that the lay of the land is such that he has a somewhat milder place than I to winter bees. He says Nov. 20 gave him a fine flight-day at 66°. Only 2° less with me, and my bees also had a fine flight, and we both hustled them into the cellar immediately after. He says it would have been just as well to have left the bees out till about the first of December, or later. Then why didn't he leave them out later? I know that it would have been not only "just as well," but a good deal better, to have left them out till Dec. 9, for on that day, at 52°, they would have had a good flight. Why didn't I leave them out till that time? Just because we *didn't know* beforehand that they could have a flight as late as Dec. 9. Indeed, I drew a long breath of relief when they had the flight Nov. 20, for I was just a bit afraid they wouldn't have a flight again before spring. I have known such a thing as there being no flight after the first of November.

I am in entire accord with Mr. B. in wanting to put bees in *late*, if by that he means as late as possible and yet let them have a flight immediately before cellaring—that is, within a day or two. But it's always a matter of watching and guessing. When it begins to seem like settled weather I am always uneasy for fear it may stay cold, and I have a strong feeling that when cold weather sets in every day they are left out is as bad as five days' confinement in the cellar.

Suppose, then, they have a good flight Nov. 15. I know that they can stand the confinement from that time, and I don't

know that they will have a chance for another flight. If Dec. 10 is a warm day then I've given them 25 days unnecessary confinement in the cellar, and they would be better without it. But suppose I wait for a flight Dec. 10, and it doesn't come—doesn't come till spring. Instead of 25 days in the cellar they've had 25 days out in the cold, which has filled their intestines very much more, and done them vastly more harm than if they had been in the cellar. So I'd rather do the smaller harm than take the risk of killing outright a number of colonies.

Now, as to taking out. I think I know just when is the best time to take bees into the cellar, if I could tell beforehand all about the weather, but I'm not so sure about the taking out, even if I had a full chart of the weather six months ahead. For years I've watched a certain soft-maple tree for its first blooming. Not time to take out till it blooms, and try to judge then what the weather is likely to be. Sometimes it blooms, or at least partly blooms, and then comes a long, cold spell. Nothing so very definite, you see. Watch for the maple to bloom, then guess whether the maple knows what it's about. Something like weighing pork by putting it on one end of a plank across the fence, balancing with stones at the other end, then guessing at the weight of the stones.

March 8 Mr. Baldrige took out his bees, there being too much snow the day before. If I had put mine out March 8, it would have been in a snowbank. But I got 20 colonies out March 14. The question is whether those 20 will be better off or worse than the others which remain in the cellar till later. Will the cold weather after they've had their flight do them as much harm as the longer confinement in the cellar will do to the balance? I don't know. Possibly I can tell something about it after all are out, and possible not. I think I've never had any spring drowsing when bees were taken out late. I have had it when they were taken out early.

Last year Mr. Baldrige took out the last of February; I not till a month later. Mine did well, could hardly have done much better if taken out earlier, but then I can't be sure about it. In 1873 mine were taken out Feb. 22. Two survived out of 50! Do you wonder I'm shy of taking out early? But they were not strong. Sometimes I wonder whether there may not be quite a difference in locations, even tho not many miles apart. Possibly the difference in the shelter of an apiary may make a difference. It is also possible that very strong colonies are better out early, and weak ones not so early. But so long as mine do well when taken out late, I'll go rather slow about pushing them out in the cold till I've tried it first on a few. C. C. MILLER.

McHenry Co., Ill., March 15.

Suggestions on Rendering Beeswax.

BY C. P. DADANT.

It occurs to me that I might give some indications to many of our bee-keepers that would enable them to render their beeswax without that greenish, grayish, grainy residue so often found at the bottom of the cakes. I have heard no end of assertions made about this residue. One of our brightest bee-keepers assured me that it was propolis; another said it was grains of pollen, and that there was a great deal of pollen in all the beeswax that is produced. Gentlemen, it is all a mistake. It is beeswax badly rendered, mixt with impurities, of course, but spoilt by water. Smell it, taste, burn it, and you will make sure of this.

In the January Review, one of the contributors, speaking of beeswax spoilt by water, suggests that this is caused by some chemical change. It is *not* a chemical change, but simply a mechanical mixture. Take the white of an egg, which is a viscous, ropy, clammy, adhesive substance; beat it awhile with a fork, and its condition will change entirely. You will then have a light, white foam without adhesiveness or viscosity, yet there has not been any chemical change. The white of the egg is simply mixt with air and its capillary attraction is broken or lessened. Beeswax overheated and beaten by steam is in the same fix. Its tenacity is broken, its color is changed, and it may be made to contain as much water mixt with it, and yet not actually apparent, that it will lose 25 per cent. of its weight when returned to its proper condition. I once had a half barrel of cappings which had been neglected till midnight, and I tried to render these cappings by simply turning a steam-pipe into the barrel among the cappings. Not an ounce of this made good beeswax till I had melted it with the sun extractor. Therefore, I strongly urge those who render beeswax to heat their wax slowly with water, of course, but boil it a little. You can boil beeswax till there is nothing left but this fine, grainy residue.

Some of our leading bee-keepers seem much occupied with the thought that beeswax when rendered is made more tough and less fit for foundation because of its becoming mixt with propolis. I believe there is nothing in this. Propolis is much softer than beeswax at a high temperature. You and I have all had our fingers soiled with it when handling the bees in warm weather, and if it was mixt with the beeswax in rendering, instead of making it tougher it would make it softer. But very little if any of the propolis mixes with the wax when it is properly rendered, and what does mix cannot injure it. There is much more danger to the wax from the water than from anything else, and the water only makes it brittle, and apparently rotten. I say "apparently," for I believe there is no such thing as actually rotten beeswax under any conditions.

Hancock Co., Ill.

The Bee-Space and Size of Hives.

BY W. S. DONER.

I have been reading the comments on the bee-space as a cause of poor wintering, but I must say I do not agree with those that condemn the bee-space as a bee-killer. If it is the bee-space, will Mr. Greiner please tell us if the bee-space was not in 8 and 10 frame Langstroth hives, as they are the poorest hives to keep bees in that I know of, for any one that is not an expert, as the bees, especially blacks, will put all the honey into the surplus department in the summer honey-flow, and if there is not a fall honey-flow along comes the farmer and takes all the honey, and leaves the bees to starve (or to be killed by the bee-space). The Langstroth shallow-frame system of forcing all the honey into the surplus apartment is too much like killing the hen to get the egg.

The farmer wants a hive with as much comb as a 12-frame Langstroth hive, and with frames not less than 12 inches deep, and some people that are bee-specialists, myself included. I would rather have 20 pounds of honey to a colony in the spring for results than to have the increase from 30 pounds fed to them. With me, the large hives give the best results for honey.

Some people will tell you that bees will not put as much honey over a frame 12 inches deep as over an 8 inch, but I have found that the deep, large hives have the strongest colonies, and the largest yields of honey. I have 8-frame dovetailed hives, and hives of my own construction that hold the equal of 12½ Langstroth frames, and they are in two sections, each 7¼ inches deep, and the hive for a colony I wish to winter is 16x16 square by 14½ deep. They are lock-jointed at the corners, and have Hoffman self-spacing frames. Colonies in the small or 8-frame Langstroth hives stored an average of about 60 pounds to the colony; and the large ones about 90 pounds of comb honey a colony. The large colony that put up the most has a record of 120 pounds of comb honey; and the best 8-frame colony, 80 pounds.

This county is covered with ex-bee-keepers whose bees have starved to death by being bled to death for the last drop of honey, as the bees need all the brood apartment in an 8-frame hive to rear brood, so up above goes the honey, and if the man has an extractor he has the key to the situation. He can practically take all the honey, and about four times out of five he does not know that he is leaving his bees to starve.

When properly managed (in a country that has a fall honey-flow, as this part of the country usually has), the 10-frame Langstroth hive is all right, but the 8-frame takes too much watching to suit me.

Give each colony of bees the equal of 10 Quinby frames, and about 40 to 50 pounds of good honey, and you need have no more fear of the bee-space than you would if they were in a box without any bee-space. Plenty of good honey for the colony, summer or winter, is better than money at interest—it is the bee's bank account, and will pay you every time.

The apiaries of 8-frame hives in times of prosperity would put one in mind of mushroom towns in western Kansas, which in time of adversity depart like the passing of a shadow. The large hives do not increase the apiary so fast, and it pays as it goes along. If the manufacturers of apiarian supplies would put out a hive suitable for the farmer, in a few years they would be able to sell more hives than they do at present, and it would put the bee-business into the hands of the farmer in a more "stayable" shape.

CONVENTION PROCEEDINGS

Report of the Wisconsin Convention.

BY N. E. FRANCE.

The Wisconsin State Bee-Keepers' Association met in Madison Feb. 2, 1898. As the Secretary and Treasurer were expected on the noon train, a motion was carried to have a social meeting until after dinner.

The convention was called to order at 1:30 p.m. by Pres. F. Wilcox. G. W. Wilson, of Readstown, exhibited a large piece of very thin beeswax, rendered by his solar extractor, which he described and is so easily handled.

FOUL BROOD INSPECTOR'S REPORT.

The State Inspector of apiaries for 1897, N. E. France, reported that as it was left to his judgment how best to apply the \$500 appropriated by the Legislature to be used in suppressing foul brood, and finding that no transportation would be granted by the railroads, as requested by our State Association and recommended by the Governor, he decided that the first thing to do was to buy a quantity of Dr. Howard's books on the history and treatment of foul brood, and to distribute them among the Wisconsin bee-keepers as called for. In the forepart of the summer the inspector was called upon to visit various apiaries of diseased bees, and found in many places the colonies affected with dead brood, much resembling what Dr. Howard describes as pickled brood. In some places it was quite serious, and seemed to be contagious. In describing it the inspector said that this dead brood was mostly confined to brood either sealed over or about to be sealed; the larval bee was of dark color, head black, hard, and dried to a sharp point. The larva was easily drawn from the cell, and had a very tough skin from which, on being punctured, a clear fluid would run out as thin as water, and free from the smell so peculiar to real foul brood; in no case thus affected was there any indication of the ropiness found in foul brood.

In some parts of the State there was lack of fraternal love—the owners claiming that their bees were all right, but that their neighbors' bees were diseased, and he was requested to call on them and burn up their entire bee-keeping outfit. The inspector boarded with bee-keepers when possible, and had often secured the use of their teams free of charge, thereby saving the using of railroad mileage books, and lessening the total expense. He said that as other State officers were allowed transportation in the State while on State work, this office ought also to be entitled to it. The Governor had requested our State Association to present such a petition to him, which they did; he endorsed it and sent it to the General Passenger Agent last May, but he refused to grant the request at that time.

At the close of the above report, a motion was made and carried that the Executive Board be a committee to take such steps as would be necessary to secure transportation of the State inspector of apiaries in Wisconsin.

A lengthy discussion of foul brood followed.

SHIPPING COMB HONEY—WHITE CLOVER SEED.

QUES.—"What is the best way to ship comb honey?" Pres. Wilcox thought in single cases with lath over the front glass, or in quantity lots of six or eight 24-pound cases, crated, with convenient handles.

Mr. France reported having seen white clover seed harvested in Washington and Dodge counties. It is easily saved, and is profitable work, one firm last season paying \$74,000 for white clover seed from these two counties. In many parts of the State he examined large fields of clover fully as rich in seed, which had been allowed to go to waste.

Mr. Lathrop said that drone-larvæ are good chicken feed, and that if sections were well cleaned as soon as taken from the hive, there would be no danger of wax-moths.

J. Hoffman asked how to get the best results for comb honey. Pres. Wilcox replied that one should have abundant brood up to the honey-flow, then contract the brood-chamber and give supers as occasion demands.

INCREASING THE DEMAND FOR HONEY.

QUES.—"What shall we do to increase the demand for honey?" "Rev. Winter said, "Keep talking of the many uses

of honey." H. Lathrop called attention to the great value of Dr. Miller's leaflets, and thought that bee-keepers should set the example by using it at home for domestic purposes. Pres. Wilcox spoke of having a printed sign, "Honey for Sale Here;" another advised bee-keepers not to crowd to large city commission houses, but sell direct to consumers. Mr. France spoke of having all honey in neat packages, with name and address of producer on each package; also to keep a book list of those sold to, so that at any time it can be referred to.

The question, "Will honey be affected by moisture after being taken from the bees?" was asked. Several replied from experience that it would gather moisture, and if stored in damp cellars either comb or extracted would be likely to sour.

Mr. Lathrop was appointed a committee of one to secure reduced freight rates on bees in less than car lots, and report at the next meeting.

SECOND DAY'S PROCEEDINGS.

The meeting was called to order by the President; the minutes of the previous meeting were read, and the Treasurer's report was given. It was decided that as the Association's expenses had been paid by Secretary France, all the funds now in the treasury should be turned over to him to pay all bills, and apply the balance upon shortage in legislative expenses.

QUES.—"Shall our Association make a State honey exhibit at the Omaha Exposition?" Mr. France said that he had attended the meeting of the Wisconsin Commission at Milwaukee, and as there was no State aid, and all money would have to be raised by subscriptions, he recommended that we make no honey exhibit, and that the supply dealers take such space as they desire at their own expense.

QUES.—"Should our State Association have semi-annual meetings?" ANS.—No.

AMALGAMATION OF THE TWO UNIONS.

QUES.—"Should the two Bee-Keepers' Unions be amalgamated?" This was answered by resolutions as follows:

Resolved, That the Wisconsin State Bee-Keepers' Association do hereby endorse the United States Bee-Keepers' Union, and recommend Wisconsin bee-keepers to send \$1.00 to the General Manager, Hon. Eugene Secor, of Forest City, Iowa, for membership in said Union. Be it further

Resolved, That we will rejoice at the amalgamation of the two Unions under one management.

HONEY ADULTERATION—SWEET CLOVER.

The adulteration of honey in our markets was discussed at length, and the new food law on adulterated honey was read by Mr. France.

The subject of sweet clover came up, with its great worth to bee-keepers as a honey-plant, and excellent stock pasture if kept cropped close. Mr. France called attention to the wrong idea of many bee-keepers as to their lawful rights, many having the idea now that they had no right to its free use in the highways, whereas, anything in the highway, be it trees, weeds, or anything that is obstructing or hindering in the highway, the authorities having a right to remove for the good of the road, but that this law applied to sweet clover no longer as being a noxious weed upon the farm; that a person has a right to raise it for his own use.

QUES.—"Is the quality of honey of any given plant affected by difference of soil or climate?" ANS.—Yes.

The election of officers resulted as follows: President, F. Wilcox; Vice-President, J. Hoffman; Secretary, N. E. France, of Platteville; Treasurer, H. Lathrop.

PREVENTING HONEY GRANULATION—FEEDING BEES, ETC.

The question arose as to how the granulation of honey could be prevented, the most satisfactory answer being to heat the honey, care being taken not to overheat and discolor it, and to use hot water in the outside vessel to prevent the honey from burning.

QUES.—"What is the best feeder for the fall feeding of bees?" ANS.—Mr. G. W. Wilson uses a 2-quart basin covered with floating screen; others preferred to save during the honey-flow some choicest full combs of best sealed honey, and when a colony needed feed to exchange for the empty combs in the hive.

QUES.—"What is the best direction to face the entrance of hives?" ANS.—If to east or south often in the spring the sun warms so as to induce the bees out when the weather is too cool; it is better to have shade-boards or double-walled hives.

QUES.—"What is the most convenient vehicle in the apiary?" ANS.—Daisy wheelbarrow. N. E. FRANCE, Sec.

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 181.)

SECOND DAY—AFTERNOON SESSION.

In the absence of Dr. Miller for a short time, Mr. Whitcomb occupied the chair, and read the following question:

STING OF THE HONEY-BEE.

"Is the sting of the honey-bee poisonous?"

Mr. Whitcomb—No, I do not think that the sting is poisonous. It is the formic acid that is injected into the circulation that is poisonous. It is not only poisonous in the circulation, but in the stomach, and it is the most deadly poison known. That is one reason why honey makes some people sick. There are people all over the country that cannot take any honey. We have made some experiments on that lately, with people who had never previously been able to eat honey, giving them honey in which we knew there was no formic acid, and without a single exception they have reported that it failed to make them sick. This honey was taken off by the Porter-escape process. But by the old-fashioned robbing process, going to the hives and robbing the bees, the instinct of the bee is to save its honey, and in stinging small particles fall off on the honey, and that makes people sick.

Mr. Karch—My wife was stung right on the forehead. She said she was feeling very queer, that something pretty near like that happened to her some years before when she thought she was overcome by the heat—a sort of sun-stroke, and she said, "I feel just the same as I did that time we thought I was sun-struck." But this was no sun-stroke, it was a bee-sting. Another time she was stung on the wrist. It wasn't but a few minutes till she fainted away; it just went through her system, starting from where she was stung, and turned kind of purple, and she said she could taste it when it got to her mouth, a very disagreeable taste. She fainted away, and I thought she was dying, and sent for a physician as fast as I could, but not finding him at home, we did the best we could, and after awhile this fever past away, this heat, this hot wave, and she began to swell some, and turned pale and cold, with severe pain in the stomach, apparently about the same symptoms as poison would cause, and I thought she was going to die. We tried hot baths and warm applications, and she got over it. The next day the neighbor's wife told me, "I didn't say anything to you yesterday, but I thought your wife was about to die. We didn't expect her to live a half hour." I said, "You needn't have told me, that was what I expected."

Mr. Heffron—I saw in a French journal awhile ago that a man had been stung very largely, had 150 stings around his neck at one time; they were extracted afterwards, and the injurious effects were prevented by making a plaster of ipecacuanha powder. They just wet it up with water, and put it on around his neck, and it hardly swelled at all, and produced no injurious effects. I have used it this summer in perhaps a dozen cases. I haven't guarded myself very much against the sting of bees because I learnt I could prevent any evil effects. I took a little ipecacuanha powder and wet it and put it on the place, whether on my face or on the front or on the side of my neck, front or back, as I had been stung in all those places. It didn't swell at all, and I used to swell badly.

M. S. Miller—My father was stung on one of the main blood-vessels on the back of the hand. He described the feeling as if there had been a whole lot of ants starting from that point and crawling all over his body. It made him very sick, and in about a half hour he had to "throw up," probably in 20 minutes, and after that he began to get better. The doctor he had declared he could not have lived over half an hour if he had not done that.

Mr. Heffron—The stings of bees have been kept dried for six months, and then have the same effect that they would when fresh. So the poison is not something that is not necessarily connected with what little fluid there may be.

Mr. Karch—The doctor said of my wife that if it had not been for "throwing up," she would have been dead.

Mr. Smith—I would like to know if it makes any difference how the sting is removed.

Mr. Green—Decidedly. That is one of the principal things in preventing pain and swelling. One should not pinch it out, nor try to dig it out, but scrape it off as quickly as possible.

DO BEES HEAR?

Mr. Whitcomb—I wanted to ask one question: Do bees hear? If so, how?

Mr. M. S. Miller—Is it not a recognized fact in medical science that there is such a thing as transmitting sound to the sense commonly known as hearing outside of the ear, and if that is so with man, why not also with bees?

Mr. Whitcomb—Four or five years ago, while attending a farmer's institute, Prof. Bruner, of the Nebraska State University, made the assertion that bees had no ears and could not hear. Nobody over there cares to contradict Prof. Bruner very much, but I did "call him down" at once, and the Professor qualified it by saying that if they had any means of hearing he could not find it. Since then I have investigated the matter considerably. I am not a scientist, but nobody has ever handled bees for any length of time without being satisfied they could hear. There is the hum of fear and anger, and of satisfaction that seem to be understood by every bee in the colony at once. If I take a colony of bees in this room and make it dark, and scatter the frames here and there, the minute the hum of satisfaction has started up on the comb where the queen is, they will all leave the other frames and go to the queen, going across the floor. And the peculiar noise the queen makes, in case of starvation or of abject fear, seems to be understood entirely by the bees at once. On investigation I have come to this conclusion, that bees hear entirely through the nervous system, the nerves coming to the surface along the abdomen of the bees, and they operate the same as our ears, and they understand that way. The nervous system of the bee is very finely constructed. After a friendly controversy Prof. Bruner has agreed with this idea. I say they hear, and hear as distinctly as we can through our ears.

ALFALFA IN THE NORTHWEST.

Pres. Miller then resumed the chair, and read the following question:

"Will alfalfa stand the winter in the Northwest?"

Pres. Miller—There is a field of it about seven miles from me (northern Illinois) that has stood for several years.

Mr. Karch—Some of my neighbors have had it for years, and it seems to stand first-rate in that country.

Mr. Stone—I can't understand why it is that the University at Champaign, when they made a test of alfalfa, reported that it was a failure in Illinois, and that it was not a valuable plant in this State. I have a small patch of it myself, in the neighborhood of Springfield, and it has done very well. I am going to sow more of it. I know a man that has 20 acres of it, and he has cut it two or three times a year, and it is very fine. I have cut mine four times a year for two summers.

Pres. Miller—The general understanding is, it doesn't belong to this climate—won't do here; yet, if it is anything like as good a plant with us as it is elsewhere, it is worth the while of the bee-keepers to inquire into it.

Mr. Stone—I sowed last spring 20 acres of alfalfa with my Alsike, with oats, and on one side, finishing up, I sowed an acre of alfalfa.

Pres. Miller—Did you sow alfalfa with the oats or alone?

Mr. Stone—I sowed it after I sowed the oats. I always sow my oats and cultivate them in well, and then sow the alfalfa, and run over it with the drag or some light harrow. I sow clover seed that way, never sow it without covering it. When I went over it on the morning of the day I came here, I found a very fine stand in the stubble on most of it. For some cause it died out on one end, and I can't understand why, unless it was because the ground was too rich and too loose for it to take to the soil. The seed I have in my garden—a small patch, probably 10 square rods—I sowed about the time of sowing red clover, and it was up in about three or four days. Red clover sometimes lies for two or three weeks before you can see it is up. It is very tender, and I understand that everywhere they grow it they have to cut the first crop, cut the weeds to keep it from choking out the alfalfa, and after that you have no trouble. This year we have had one or two hogs penned up, and have cut alfalfa every day for them, and with half the corn that they would eat to keep them alive, they have thrived with that alfalfa till I never saw hogs in better condition than they, and they are just as greedy for it as anything else you could feed them.

Pres. Miller—Turn the hogs on it, or cut it, in summer?

Mr. Stone—Cut it.

Mr. Whitcomb—You can turn them on it. I brought perhaps the first stalk of alfalfa that was brought east of Salt Lake, in the spring of 1877. It is a very hardy plant after it is established. The ground, to sow alfalfa, should be prepared as carefully as though you were going to plant onions, in the richest land you have. The most successful growers of

it in our State put it in with a plow. Then cover it in. Get it into the moist ground. It won't stand heavy frosts in the fall. The best alfalfa growers in our State do not put any crop in with it at all. They mow the weeds down. After it is established there is no trouble about a stand, where there is moisture within ten feet of the top. I had trouble last year because it was wet all through the spring of the year. This year it has done nicely, and we have harvested four crops. It is not only an excellent thing for feed while it is fresh, but stock eat it with a great relish in the hay. I once opened up some bales of alfalfa hay, and found it was more than half sweet clover. The stalks were so large in many cases that they had to double them over. I thought I was "sold," but when I came to feed it I found the stock went for the sweet clover first. It is an excellent plant. Instances are on record where the roots have been found 30 feet below the surface. But on a lime subsoil, where the lime is near the top, I would say it is not a good alfalfa country; but anywhere that you have water within ten feet of the top it will do. It is a little peculiar about harvesting. It should be raked up right after the mower, and allowed to cure in the shock, and then hauled in from there. I regard it as one of the best forage plants for all this northwest country. But it is very tender in the spring of the year. It cannot stand frosts, and it cannot stand too much wet in the spring. I sow 20 to 30 pounds to the acre, so that the alfalfa takes the place of weeds as quickly as possible.

Mr. Stone—Wouldn't it do to cut the hay down when there is no dew on it, and then put it up as soon as it is withered?

Mr. Whitcomb—I am afraid it would be a failure then. I did a little of that one year, and it all had to be taken out.

Mr. Stone—You are sure you didn't have any dew or moisture?

Mr. Whitcomb—I am not sure of that. I don't cure it in the windrow, but in the shock. It cures nicely there. Then haul it in. You will not lose the leaves that way, but if you allow it to dry on the surface of the ground there will be no leaves left. In Colorado we find hogs are raised and fattened alone on alfalfa, and they are good hogs, too. Of course, they are not corn-fed hogs. Nothing fattens hogs like corn. Horses can be carried through the winter without a bit of grain if you have plenty of alfalfa hay. There is but one thing that I regard better as forage, and that is sorghum.

Mr. Stone—There is only one thing I don't like about alfalfa—it doesn't produce much honey here with us, I believe. I never can find half a dozen bees on my whole patch at one time. It might be if we had more of it so the bees would go to work on it, it might be used, because I find millers and other insects working busily on it.

Mr. Whitcomb—I haven't been able to get any alfalfa honey at all. The nectar in the alfalfa doesn't seem to have any attraction for honey-bees, except where there is nothing else for them to work on. Alfalfa honey has no flavor or taste.

Mr. Baxter—One day last July a gentleman said, "Your bees are making a lot of honey." I said, "Not now." He replied, "My neighbor has a little patch of alfalfa, and they are just literally covered with bees." I never went there to examine, but it appears they must have been on it, or else he would not have told me so, because he is a man of honesty.

Mr. Stone—I would like to ask him if he is sure that the man was not mistaken. People with us get alfalfa and Alsike and sweet clover all mixed up, and don't know what they are talking about.

Mr. Baxter—If he were not an intelligent German, who had seen it growing in the old country, I might have believed that he didn't know. He said he had seen it growing, and was sure this was alfalfa. I would say that I have seen fields literally white with white clover, and not a bee on it. I have seen it when the bees were starving. I have seen the same with buckwheat. I have seen the same with heart's-ease. The trouble is we probably did not look at it at the right time. You may look at buckwheat about 10 or 11 o'clock and not find a bee, but from daylight until that time it was probably literally swarming with them. With other plants it depends a great deal on the season and atmospheric conditions.

ALSIKE CLOVER AS A HONEY-PLANT.

Mr. Karch—How is the Alsike for a honey-plant?

Pres. Miller—That is certainly one of the very best honey-plants.

Mr. Whitcomb—I agree with you there. I don't think we have anything better, and nothing better for hay.

Mr. Stone—I do not believe it ever fails to yield honey. I will just state what I learned at the World's Fair. A man there said he kept a dairy at Elgin, and that his cows pro-

duced more milk than any other dairy in the country. I askt him the cause, and he said that he ascribed it to his having Alsike clover for pasture. I askt him if his cows were not a better milking strain than his neighbors' were. He said no, that the same cows were now doing much better than before they had Alsike pasture. I then askt if he kept bees, to see if there was a motive behind it, and he said he did not. He said his neighbors' bees just swarmed on it. On a 10-acre strip of Alsike I cut a crop of hay, the second crop came up, and it was all headed out, and so was the red clover along the other part of the meadow; and every day when I would come to the field for my milk cows in the evening, they would always be on that Alsike clover, and they ate it down so closely, the cows and the sheep together, I was afraid they would kill it; and the red clover, to look across it, didn't appear to have been toucht.

(Concluded next week.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Tarred Paper in Honey-House Walls.

Will tarred paper used on the walls of a honey-house impart its tarry odor to the honey kept therein? I have just purchased some for that purpose. N. MEX.

ANSWER.—I think there has been some complaint in that direction, but if the paper is put on early this spring, it will probably not be troublesome by the time honey is stored in it. If any one has actual experience in the matter, will he please rise?

Putting Bees Out—Early Feeding.

My bees are alive yet. How soon had I better move them to the summer stands? Will it hurt to examine them now, and take out the straw above the brood and put in sections of honey in the super to feed them? IOWA.

ANSWER.—Unless you are very much afraid the bees will suffer for lack of stores, better not open up a hive till weather is warmer, say in fruit-bloom. Of course it is better to disturb them than to let them starve. But putting on a super to feed them makes a good bit of empty room for them to keep warm. On account of changing place and losing their bearings, the sooner the bees are put on their summer stands the better.

Transferring to New Combs and Hives.

I have five colonies of bees in box-hives. I wish to transfer in spring to movable-frame hives. Can I do away with all contents of the old hives after the bees are transferred in the new? My reasons are, I want to start my apiary with good, clean material, and I think the old combs may be so old as to be unfit for use. All five hives are as full of bees as they can hold, and have plenty stores left. So far they are doing nicely, and are gathering pollen every day that the sun shines, and it is not too cold. LA.

ANSWER.—Yes. Perhaps the most economical way will be to wait till the bees swarm, then hive on full sheets of foundation, and three weeks later, when all worker-brood has emerged, drive out all bees and unite with the swarm, unless you want to increase.

Wagon-Rack for Hauling Bees.

Please describe the wagon-rack you use in hauling your bees to and from the out-apiary. MICH.

ANSWER.—My wagon-rack is quite a simple affair. A common farm-wagon box rests on heavy springs that are detachable, and I can't tell what the springs are called. It's a pair I borrowed from a fruit-dealer who hauls on it heavy loads of melons, etc., and all that's necessary is to raise up the wagon-box and set the spring on the bolster. The wagon-box itself is filled with hives, so the rack must be high enough to accommodate that. The width of the boards used for the sides and ends of the rack of course determines its height. For side pieces use boards long enough to project back farther than the end of the wagon-box, for you may as well have two or four hives on the rack back of the box. These side pieces sit edgewise on the sides of the wagon-box, a board of the same width being nailed on the front end, also at the back end, and for greater security one at the middle. Short boards 12x6 inches are nailed on the sides projecting down on the wagon-box, so there's

no possibility of this frame-work slipping off. Strap or band-iron is nailed on at the joints where the end pieces are nailed to the sides, for fear the nails might work loose. Now boards six inches wide are nailed across the top to support the hives. These are long enough to take two hives, the hives standing back to back, but not near enough to touch, the entrances of the hives facing toward each side of the wagon. Nail the first board on the front end, and nail on the front edge of the board a strip $\frac{3}{4}$ or an inch square to prevent the hive slipping forward. Now lay on loosely the second board about where you think it ought to be. Before putting on the second board, nail upon the middle of it, that is about $2\frac{1}{2}$ inches from each edge, two strips about $\frac{3}{4}$ -inch square, these strips not meeting at the middle by perhaps six inches. Lay this second board loosely about where you think it ought to go, and then put on two empty hives. Push the board up to place, and that will show you just where you ought to nail it, only it would be too tight a fit, so have a little strip of $\frac{1}{4}$ -inch to lay beside the hive so as to allow $\frac{1}{4}$ -inch play. Now fasten the second board and go on with the third, and the rest in the same way, only the last board will have its strip at one side instead of the middle.

From end to end is now put on each side a strip perhaps an inch or more wide, and in the middle a board wide enough to keep the backs of the hives from touching. If you are to drive over a very rough road, it might be necessary to have the strips that hold the hives from sliding off, more than an inch thick.

The wagon-box I use holds nine eight-frame hives, and the rack 22, making 31 hives at a load. This is much less than some others haul at a load. It would be an easy matter to have made my load 42 instead of 31 by making the cross boards longer, so as to take three hives abreast instead of two.

Getting Increase—Alternating Shallow Brood-Chambers.

1. Which is the best way to increase, from one to about four colonies?
2. Will the bees rear brood extensively, alternating two six-inch deep brood-chambers once in ten days? WIS.

ANSWERS.—1. Sometimes there is no "best," only a worst way, unless you want to do a lot of feeding. Even with feeding, it's a pretty hard matter to do much if honey doesn't yield. With a good season there ought not to be much trouble about it. As you can't tell for certain what the season will be, it's a good plan to keep on the safe side and work on the nucleus plan as described in the text books and in late numbers in this department.

2. It's a little doubtful whether you can gain anything by alternating. With a good strain of bees and a good queen, you're likely to have all the brood reared the bees can care for, if you give them combs enough. Breaking up their arrangements by alternating the two stories might in some cases induce more brood, but it might, as well, make less.

Out-Apiary Questions—Full Sheets of Starters in Sections—Number of Colonies in an Apiary.

1. What can I run an apiary of 35 colonies, spring count, for?
2. The bees are $\frac{1}{2}$ mile from my apiary. Do you think I can run that yard and my own myself?
3. Are full sheets of foundation in the sections better than one-inch starters?
4. How many colonies do you think can be kept in one apiary in Virginia? VA.

ANSWERS.—1. You can run them for extracted or comb, or for part of each, or you can run them entirely or partly for increase. The size of the apiary really makes very little difference about it.

2. If you have sufficient experience there ought to be no trouble about your running both apiaries yourself. If the out-apiary is only $\frac{1}{2}$ mile away, however, it would be almost as well to have the bees all in the home apiary, and it would be a good deal more convenient.

3. I very much prefer full sheets.

4. If the location is an average one, probably from 75 to 100.

Figwort—Managing Sunday Swarming.

1. I would like to know something about Simpson honey-plant or figwort—how to grow it, what time to plant it, and what the seed costs. Does it kill out in winter? Do early frosts hurt it? Will it grow well on light, sandy soil?
2. What would be the best way to manage bees in swarming-time, so that the bee-keeper would not have to do anything with them on Sunday, and not lose any swarms? MICH.

ANSWERS.—1. When the interest in figwort was at its height, I sent to another State and bought plants enough to set out about an acre, and had probably as nice a plantation of it as was ever seen. My advice to you, as a friend, is to let it entirely alone and not plant a seed of it. I don't believe it will pay you to fuss with it. If there is any one who had a plantation of it 10 years ago and has not given it up, I should be glad to hear of it. Not long ago the editor of *Gleanings* said he thought a plant of it might give as much honey as (I think it was) 10 of sweet clover. And yet he does not deny that they have given up growing it—a pretty strong proof that it isn't considered of profit enough to grow. Answering

your questions, however, I should say your quickest way would be to set out the plants. If you could see one plant in blossom or seed you could then recognize it, and very likely you might find a good deal of it growing wild right about you. It seems rather inclined to grow in fence-corners and shady places when growing wild, and is not inclined to increase rapidly. In such positions it stands the winter well, but in the open ground is inclined to winter-kill, at least in this locality. I think it will not do so well in sandy as in stronger soil, but I may be mistaken about this. Now, if the experience of others is different, and they have found figwort worth cultivating, by all means let us hear from them, but let it be those who have had it under cultivation 10 years or more, as a great many, I think, started with it years ago.

2. One way is to have a queen-trap at the entrance, then take a look at the cage Monday morning.

Rearing Queens--Queenless Colonies.

1. How soon can queens be reared with safety of mating with drones?

2. I have two queenless colonies on top of other strong colonies with plenty of combs, honey and bees for each hive. What time should I set them off to themselves to rear them a new queen? Or would it be best to leave them where they are?

My bees have been bringing in pollen and honey on warm days for some time. Combs were $\frac{2}{3}$ full of brood Feb. 19. Miss.

ANSWERS.—1. When you find drone-brood sealed, you may then begin to rear queens, so far as concerns drones being ready.

2. You don't say whether these colonies on top have communication with colonies below, or are entirely separate. If there is communication, probably they are by this time part and parcel of the colony below, and may be considered as all one colony. If separate and queenless they will not rear a queen, either where they are or anywhere else, without having young brood given them. If you want them to rear a queen by giving them brood, you can move them at once or leave them till the young queen lays.

A Non-Swarming Colony.

1. I have a colony of bees that have not swarmed for 8 years. I bought the queen from a breeder in Illinois. During these years they have not changed color, which is remarkable, as I am surrounded by black and hybrid bees. Can it be possible that the original queen is still in the hive?

2. I am anxious to introduce some of this stock into my other colonies. How should I go about it and not interfere with my honey crop? I have 50 colonies, all at this time in good condition. We have had a very open winter, very little snow, and just enough cold weather to let us fill our ice-houses. VA.

ANSWERS.—1. I haven't the slightest idea the same old queen is there. It's probably not so very often a queen lives half that time, altho there have been cases recorded where a queen was six years old.

2. Hard to tell just what may be the best way, so much may depend on circumstances. One way may be to have queen-cells ready, and when a colony swarms cut out all queen-cells in the old hive and give a cell of the choice stock. If you want to change the queens of the other colonies, you can do it toward the close of the honey harvest without interference.

Increase by Dividing—Dummies—10-Frame Hives—Changing from Blacks to Italians.

1. I wish to increase the number of colonies by dividing. They are in 8-frame dovetailed hives. Can I successfully make three out of one by supplying queens, and have them in good condition when clover bloom comes? How would you proceed? How without giving queens?

2. In using dummies, is it necessary to use chaff or plain board? Must the empty space be filled with them or not?

3. I am just a beginner and have only a few hives. I have thought of changing to 10-frame hives, as I think I would like them better. Do you think it advisable in my locality (Trumbull Co.)?

4. Would you advise me to change from black to Italian stock? My bees are a little mixt, and are hard to handle. They are good workers. Are the yellow as good? OHIO.

ANSWERS.—1. I'm afraid you're rather wild in your expectations. If I could each season make sure of making three colonies of each one, taking the entire season for it, without getting a drop of honey, I think I'd stop fooling with a honey crop and raise an annual crop of bees. Some years I might do it, but other years I couldn't. But I wouldn't dream of starting in the spring, the best season I ever knew, with 30 colonies, and have 30 colonies ready for the clover harvest. If I wanted to have the advantage of the clover crop, I wouldn't think of increase until the beginning of harvest at the earliest, and I'd study carefully all that's said in the text-books about increasing, and then take the plan that seemed best adapted to my circumstances. In any case, I'd keep most of my colonies, what might be called fairly strong colonies, all the time. By supplying queens, you would probably do well to follow the nucleus plan as lately mentioned and described in this department, and you could hasten matters considerably by furnishing queens, instead of waiting for the bees to rear their own.

2. Either one will do. It isn't necessary to have the space filled solid. For example, if you want to fill the space usually filled by two brood-combs, you can have a single dummy measuring $2\frac{1}{2}$ inches through, or you can have two dummies an inch thick, or three dummies of $\frac{3}{4}$ -inch stuff, or a single one of these last will do if you're not afraid the bees will build in the space.

3. If you don't expect to give them very much attention, the 10-frames will be safer for winter, and possibly may be best in any case, but I think likely, if you give them closest attention, it may be better to have the 8-frame hives and use two stories, whenever needed.

4. You will probably find the Italians better workers, and gain by the change.

Transferring—Putting in Frames of Foundation.

1. I have two good colonies in box-hives. I would like to transfer them in the spring into new hives. I also would like to get one natural swarm from each. How can I best succeed? How would it do to put in full frames of foundation (say five) in a 10-frame hive, then after the first swarm comes out place the new hive where the old one stood, place the old one in front of the new hive, make a bee-pass between each opening, of screen wire, then open a hole in the top of the old hive, smoke by spells, and compel them to vacate. After smoking down well, take old hive away. Would this plan work? If not, tell me why, and a way that is better.

2. I am putting in two full frames of brood-foundation for all my natural swarms this year. Should I put them in together, or put an empty frame between them?

3. I have a colony that has been in an old hive for a number of years. Last summer it cast two fine swarms in June. A month after it seemed that the old hive had nothing but drones. The first of August I killed most of them. What was the cause of so many drones? Did the drones come back from the young swarms cast, or was the queen dead? or was it the fault of the old comb in the old hive? I introduced a new queen, after which the bees seemed to feel better. Is there any use to molest the old comb in that hive this spring? The bees are in good condition now. IND.

ANSWERS.—1. Better leave the bees in the box-hives till they swarm, and hive the swarm in a frame hive. Set the swarm in place of the old hive, putting the old hive beside the swarm. A week after swarming set the old hive in a new place. Two weeks later transfer the old colony, at which time there will be no chance to injure any brood.

2. Perhaps it will be as well to put an empty one between.

3. It is possible that there is an unusual amount of drone comb in the hive. Possibly the colony was queenless, and a queenless colony will welcome all drones that may come from other colonies. If there was never trouble before or since as to a superabundance of drones, the comb is not likely to be at fault, and need not be disturbed.

Working for Both Comb and Extracted Honey.

I am thinking of running an out-yard the coming season, and would like to work it partly for comb honey. Do you think the following plan would be likely to work?

Work the colonies for extracted honey until they get well at work in the surplus, then place a super of sections filled with foundation under the extracting-super. Do you think it would be likely to cause swarming as much as it would if the sections were placed on at first? Would they be likely to complete the extracting-super before beginning the sections? Please tell what you think about this plan. NEW YORK.

ANSWER.—If you use full-sized combs in the extracting-super, unless there is a pretty heavy harvest, there would be danger that your super of sections would not be finished in good time. With shallow extracting-combs the matter will be helped. You probably would be troubled less with swarming than to put on the sections at the start with no extracting-combs. If the extracting-super is large and the colony not strong, or the harvest poor, the sections would be little worked, and vice versa.

The "Golden" Comb-Honey Management.

What is your opinion of Mr. Golden's method of producing comb honey? Do you think it superior in any degree to the ordinary method of treating a swarm and the colony it issues from? Should you approve of it, please say what you think of adopting the same tactics with colonies that do not swarm. Seems to me if it will do under one set of conditions, it ought to do under the other. Don't you think it would result in pollen in the sections? or is that which a friend tells me true, viz: That when the queen is confined the bees cease to carry in pollen; as, during her confinement, and unlike queens of our own species under like conditions, she is producing no progeny that would require feeding. SOUTH AFRICA.

ANSWER.—I have no experimental knowledge on the subject, and could hardly give an opinion that would be of value. But I may say that the popular notion that a colony with a caged queen carries in no pollen is somewhat out of the way. If you should see the many combs loaded down with pollen that I have seen in such cases, you would feel very sure that caging a queen does not stop the gathering of pollen, altho it lessens its consumption.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. MARCH 31, 1898. NO. 13.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

New Use for Honey-Leaflets.—That bright noter and picker of the Canadian Bee Journal, D. W. Heise, suggests that instead of the Canadian societies continuing bee-journals as premiums to members, they should furnish a supply of our honey-leaflets—"Honey as Food." Why not? They would help to make an outlet for the honey of the members—the very object desired.

Some Original Ideas.—In the Southland Queen, Mr. Madley is reported as saying you don't need comb foundation to secure straight combs if your hives front south, but if they front north or east foundation must be given to prevent crooked combs. He "never saw a bee-tree that the bees went in on the north or east side." Rev. T. C. Thedford says bees measure cells when making them by the length of their legs. He forgot to say which legs. "Madford" and "Thedley" have truly "original ideas!"

Plain Sections and Fences.—Editor E. R. Root, in Gleanings for March 15, replies as follows to the article which appeared on pages 114 and 115, on the no-bee-way or plain sections, and fences or cleated-slat separators:

THAT BLIND EDITOR.—Some chap in the American Bee Journal, referring to my early disapproval and subsequent approval of the plain section, accuses me of being *blind* when I want to be blind, and of being able to see when I want to see. I take it that this is a polite insinuation that, when it is to the interest of our supply trade to recognize the merits of a good thing, I am loud in my praise of the thing in question; and that, when it is not to the interest of the supply business, then I am very *mum*. Naughty York, not to put on his name and address! I wish I could just catch that fellow without a

name. I would show him that even *he* looks through a glass darkly, for it is very evident he fails to see that I have not been as naughty as he thinks. However, I will forgive him, for, tho not committing himself directly, he apparently thinks the plain section and fence a good thing.

We want to say that the "chap" Mr. Root refers to knew exactly what he was talking about when he made the accusations and insinuations that seem to have opened the eyes of a certain "blind editor." We wouldn't think of disclosing our contributor's name and address, for no telling what calamity might befall him should he ever cross Editor Root's pathway, even if the latter does say he'll "forgive him." That's all right. He may "forgive," but to forget—that's another matter.

The California Bee-Keepers' Exchange.

—We have received the following regarding the Exchange, from a Californian who knows whereof he speaks:

"MR. EDITOR:—I notice that on page 152 you have an 'editorial comment' that is a trifle misleading in relation to the business of the Exchange. The best of our dealers estimate that the honey crop in this section of the State is about 200 carloads; the Exchange has handled about 25 car lots; therefore, instead of handling one-fourth of the crop, it is only one-eighth, which makes quite a difference.

"The time to know how the Exchange is going to succeed is after the settlement for the year is made. If the bee-keepers have realized as much for the sales as they would to have sold to dealers, then there will be no cause for complaint. But if the net price falls short of that, then look out. The Exchange idea is all right, but the trouble just now is the lack of confidence in its workings.

"We do not anticipate much of a honey crop this year, as the rains are few and light."

The Pure Food and Drug Congress

was held in Washington, D. C., March 2, as per announcement, and the United States Bee-Keepers' Union was represented by General Manager Eugene Secor and Rev. Emerson T. Abbott, as we have previously mentioned in these columns. In the Busy Bee for March, Mr. Abbott gives this report of the doings of the Congress:

THE PURE FOOD CONGRESS.

There was held in Washington, D. C., beginning March 2, one of the most important meetings ever convened on this continent. I refer to the National Pure Food and Drug Congress. It was called together by a local committee made up of public-spirited and enterprising gentlemen who live in and adjacent to the city of Washington. There was a general response to the call from all over the country, and representatives of the various industries interested were there from as far west as California, and as far east as Maine.

There were nearly 300 people in attendance, and almost every leading productive industry of the land was represented. The writer and General Manager Secor went as delegates to represent the United States Bee-Keepers' Union. As there was considerable expense attach to such a long trip, I had some doubts at first about the propriety of sending delegates, but the moment I reached Washington and saw the class of men there present, and the industries which were represented, all doubt was dispelled. One of the leading ideas of our Union is to "prevent the adulteration of honey," and more was done at Washington in co-operation with other industries in two days than we could do in years working alone. What we want and need is a National Pure Food Law covering every article of human consumption for either food or medicine, and we seem now to be in a fair way to get it, and the members of the United States Bee-Keepers' Union can feel that they have had a hand in the making of it.

Your delegates received the fullest recognition on the floor of the Congress, and bee-keeping at once took its place along by the side of other trades and industries, and was recognized as a part of the great movement for pure food and common honesty, which is sweeping over the country from Maine to California. Mr. Secor was placed on the Committee on Credentials, and the writer was made a member of the Committee on Permanent Organization, and was subsequently elected chairman. Later Mr. Secor was appointed a member of the Committee on Resolutions, and myself a member of the Legislative Committee of 25 to consider the "Brosius Bill,"

and report to the United States Congress. We were also made Vice-Presidents for our respective States. I do not mention these things to bring myself and Mr. Secor into prominence, but to let the bee-keepers know that our Union received full recognition by the other industries.

The Congress elected Mr. Blackburn, the present Food Commissioner of Ohio (and a gentleman of sterling worth and wide experience in pure-food legislation), its permanent President, and I take pride in saying that as a member of the Committee on Permanent Organization, I had a hand in presenting his name to the Congress. He proved to be the right man in the right place.

I have not the space to give a full account of the meeting, but will say that the unanimity of sentiment and feeling manifested by the representatives of the various industries of the country on the subject of pure food points to the fact that a powerful influence will be brought to bear on the Congress of the United States when the Bill comes before it, for its immediate passage. The reader can help to swell this influence by writing to his congressman and the members of the Senate, saying that their constituents ask that when the Bill recommended by the Pure Food Congress comes up for passage that they give it their hearty support.

This is not a political measure, but a movement in the interest of common honesty and the health and prosperity of the people, and all good men and women who believe in fair play can unite in urging its passage without regard to their political affiliations, or "previous condition of servitude," if you please. *Do it at once!* EMERSON TAYLOR ABBOTT.

We believe with Mr. Abbott that the United States Bee-Keepers' Union could not have done a wiser thing than to send its delegates to the National Pure Food and Drug Congress, just as it did do. It was a most notable gathering, and we understand not only from the foregoing, but from personal conversation with Messrs. Secor and Abbott, that they as representatives of the bee-keeping industry of this country were both honored and appreciated by the Pure Food Congress. We were glad that the New Union could have so large a hand in so important a matter. We trust that the Brosius Bill may soon be past by the United States Congress, and be speedily and rigidly enforced. Nothing else could possibly aid honey-producers so much as would the enactment and enforcement of such a law.

Innovations in Printing.—The American Bee Journal has shocked some of the conservatives by its clipped and condensed spelling, but it is not alone in innovations. The Progressive Bee-Keeper eschews italics and substitutes capitals, giving an unusual look to the page. The Southland Queen and the Pacific Bee Journal think it is all right to shorten "all right" into "alright." Of course it's alright.

Glueing Fence Separators.—Some one raised the question as to whether glued fences might not melt apart in the heat of the hive. Mr. T. T. Barrows, of New York, has this to say about that point:

"You need not be afraid to glue your fence separators, for if the glue is good they will stay. I have used them glued for 8 or 10 years, and they are as good to-day as when first made."

The Colorado Convention meets April 13. Executive committee meeting the 12th.

A New Binder for holding a year's numbers of the American Bee Journal, we propose to mail, postpaid, to every subscriber who sends us 20 cents. It is called "The Wood Binder," is patented, and is an entirely new and very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

See "Bee-Keeper's Guide" offer on page 205.

FARM BEE-KEEPING is what Mr. Abbott will hereafter call his paper—the Busy Bee. Good change.

MR. ISRAEL OVERHOLT, of Ontario, Canada, wrote us March 21: "Bees have wintered well in this locality."

DR. C. C. MILLER, located in McHenry Co., Ill., writing us March 21, said:

"Finish taking out bees to-day. Earliest for years. Earliest season for many years. Bees are in fine condition."

MR. C. A. BILLINGS, of Wayne Co., N. Y., wrote us March 15:

"My nine colonies wintered on the summer stands have come out in good condition—were out in good shape Sunday."

MR. E. P. RICHARDSON, of Salt Lake Co., Utah, when renewing his subscription recently, said:

"The Bee Journal is a good bee-paper, and worth several \$ more a year than you ask for it. Lots of good information in each number."

MR. JOHN S. FRANKS, of Perry Co., Ind., tells how he appreciates the Bee Journal in the following words:

"I like the Bee Journal very much, and am anxious every Thursday evening to see it. I read everything it contains with great interest, and when a number fails to reach me I am disappointed. I could not well get along without it."

TOBACCO-DUST and A. I. Root. Whew, what a combination! Wouldn't have believed it if we hadn't seen it in Gleanings. But the tobacco-dust is not to be smoked or chewed, so don't get excited. It is simply a remedy for "almost all sorts of noxious insects," and also "an excellent fertilizer." We wish that all the tobacco grown could be turned into dust and used as mentioned, instead of much of it being used by people who seem to be anxious to die with "tobacco cancers," "tobacco hearts," or insanity caused by excessive smoking. Tobacco is a most excellent thing—to keep out of your mouth.

MR. P. E. SHEAR, of Ulster Co., N. Y., sent 50 cents on the Langstroth Monument Fund. We are inclined to think that before bee-keepers will be satisfied to let this matter rest, they will want to see at least \$1,000 put into a monument to mark the resting-place of their beloved Langstroth. Why wouldn't it be a good plan for the large manufacturers of hives to contribute—oh, say about a couple hundred dollars each? Their prosperous business is practically the result of Langstroth's invention. And as bee-keepers are helping to support the manufacturers, indirectly it would be the bee-keepers' tribute to the memory of Langstroth.

SPELLING REFORM is coming. Gleanings is going to adopt it, too—sometime. Here is what Editor Root said recently: "But if even half of the printers and publishers would flop over, I guarantee you I could adapt myself to the change." That's a good deal like saying: When even half the people of this country have the backbone to vote out the saloon, why, I'll be with them. Or, suppose the great Wendell Phillips had said before 1861: "When even half the people are ready to strangle slavery, I'll be ready to help." Not much; but instead he all the time worked to hasten the coming of the day when the curse of human slavery should be no more on this continent. Say, Editor Root, why not you help lead off in some of the grand present-day reforms, as you have led off in many advances along the upward way of apiculture?

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

BIOGRAPHICAL NOTES.

F. J. R. DAVENPORT.

The Progressive Bee-Keeper has kindly loaned us the two engravings showing Mr. Davenport and his apiary in this number of the American Bee Journal. From that paper for November we take the following interesting notes concerning our Texas bee-keeping friend:

F. J. R. Davenport, the subject of this sketch, was born March 18, 1849, near Beaver Dam, in Ohio county, Ky., where he remained until he was about 26 years of age.

From his earliest youth he has been an admirer of bees and bee-hives, for his father, Robert Davenport, who was born in Ohio county, Ky., May 16, 1823, has always been an enthusiastic admirer of the busy little creatures. The old gentleman states that he dropt corn for 10 cents per day, when he was only 8 years of age, and earned enough money to purchase one colony of bees, and has never been without them since. He moved to Texas in 1873, where he still re-

F. J. R. Davenport.

sides. In the '80's he owned and superintended three apiaries, consisting of more than 1,000 colonies. In 1883 he extracted 22,000 pounds of honey, and, by the way, he invented his own extracting machine, which answers every purpose that the patent extractors do.

From the above it is natural to suppose that the son inherited his enthusiasm for bees from his father.

In December, 1873, F. J. R. Davenport was married to Miss Josie Austin, daughter of Rev. James F. and Crinna Austin, of Cool Springs, Ky. In October, 1875, he moved with his family to Texas, and for 18 years has resided in Ellis county. His education is limited, and he states that while his advantages for an education were not very good, he was nevertheless favored with better opportunities than he improved. From childhood, as before stated, he admired bees, but his limited finances forbade him making any attempt at the business until 1886, when he purchased two colonies. For four years he accommodated himself with nail-kegs and rude boxes of his own construction, and such other things as were inexpensive and possibly convenient. In 1890 he secured his first patent hives, and from that time dates his bee-keeping on modern methods. He bought books, subscribed for bee-journals, and, as fortune favored him, he soon had all of his bees transferred to frame hives, and has been improving them ever since by introducing good queens of different varieties, principally Italians, Cyprians and Holy Lands. He has studied the nature and workings of bees, and, together with his experience, has acquired quite an efficient knowledge of them. He has acquired the art of queen-rearing, and in fact can do almost anything with them that any one else can. He mani-

festes great interest in the bee-keepers' associations, and attends the conventions when possibly convenient. His apiary, consisting of 176 colonies, is in a shady hackberry grove, and presents an attractive scene.

Besides being an enthusiastic bee-keeper, Mr. Davenport is also a prosperous, energetic farmer. He owns a large farm of the best quality, black, waxy land, and has it well improved. He has two windmills with hydrant attachments, which convey the water to his house, garden and lots. He also has good stock, Jersey cattle, Berkshire and Poland China hogs, and even fine poultry, such as Brahma, Langshan and Brown Leghorn. To use the expression, "He lives at home, and boards at the same place." He has almost retired from farm work, as his bees require most of his time, but he superintends everything, and his four industrious boys execute his plans. By his industry and managerial qualities, together with the assistance of a noble companion, he has accumulated an estate valued at \$10,000. He and his family are members of the Methodist church. He is of quite a jovial disposition, and his avoirdupois tips the beam at 210 pounds.

May he and his family enjoy many more years of health, prosperity and happiness.

Five-Sixteenths End-Bars are preferred by their largest customers, says Editor Leahy, so hereafter they will make them 5-16 instead of $\frac{1}{4}$ thick.—Progressive Bee-Keeper.

A Superstition in Oldenburg, Germany, is that no swarms will leave throughout the following season, and that all swarms will settle low, if bees are fed before sunrise on Holy Thursday.

Pop-Holes in Section Honey.—Editor Hutchinson thinks the whole secret of getting corners in sections all filled out without any pop-holes, lies in giving the bees free communication on all sides of the section.

Needs Much Salt.—D. W. Heise thinks that average of 250 pounds per colony from J. McArthur's bees, as reported in the British Bee Journal, should be taken with a little salt. The editor of the Canadian Bee Journal thinks it would better be all salt without the dose.

Laying First on Outside of Comb.—A Stray Straw in Gleanings mentioned that frequently, in enlarging the brood-nest, the queen first lays on the outer side of a new comb, and wondered why. G. M. Doolittle says it's because on the inner side of the comb the cells are largely filled with pollen.

The Composition of Honey, according to Dr. Oscar Haenle, is in general as follows: Dextrose (grape sugar, crystallizable) 42; Levulose (fruit sugar, uncrystallizable) 35; Saccharose (cane or beet sugar) 2; total sugar, 79 per cent. Water, 20; nitrogenous matter, 10; mineral matter, 0.2; phosphoric acid, 0.02.

Best Way to Ship Comb Honey.—This topic was discussed at the South Texas Convention, and E. J. Atchley said, "Comb honey cans, with large screw-caps, is by far the best in this climate." Do they cut the honey out of the section before putting it in the can, or has the printer of the Southland Queen been taking liberties with the report?

Effect of Cold on Brood.—Editor Rauschenfels says nymphs, larvæ and eggs perish in about an hour if subjected to a freezing temperature. Brood subjected to a falling temperature ceases to eat at 41°, and falls into a lethargic state if the temperature continues to fall, which terminates in death if the temperature is not raised.

Better Get Standard Goods.—Fred S. Thorington is asked by a correspondent whether the correspondent better get dove-tailed hives or some more like the ones he now has. Mr. Thorington says, "When goods are ordered, they should be of some standard patent." (Quite likely he said "pattern," and Leahy's devil "patented" the word.) He further says: "If hives and

supplies are not in general use, that are ordered at the factory, there is always an extra charge for setting the machinery; so the standard, if not the best, is the cheapest." Besides, the probability is that standard goods have become standard generally just because they are the best.—Progressive Bee-Keeper.

Italian vs. Black Bees.—J. E. Crane started out an enthusiast for Italians, but in an experience of years found that in some cases blacks were ahead. In Review he says he believes that in localities where dark honey abounds, dark bees will beat, even if this is true for only part of the season, while in sections where clover and linden abounds with rarely much dark honey, Italians are the thing.

Preparing for a Dry Year.—Californians seem to be rather looking for a year of failure for lack of rain. J. James, in the Pacific Bee Journal, advises saving the expense of having to feed a big lot of bees by confining the queen on four frames by a division-board with a piece of excluder-zinc 4x6 inches. Then if the outlook is good next season, take away the division-board Feb. 1 and feed freely.

Wants Some Drones.—Hasty, the Reviewer, thinks the workers will not be satisfied without some drones, and it isn't best to cross them in this too sharply, if there's no drone-comb in brood-chamber the queen will lay in sections unless excluder or full sheets of foundation in sections are used, neither of which he wants to be forced to, so he wants in the two outside combs quite a bit more than Doolittle's 4 to 6 square inches.

Double Duty on Half Rations.—Editor Bennett, of the Pacific Bee Journal, seems to be starting out in good shape to meet the failure of the honey harvest, if failure it is. He eats only dinner and supper, no tea, coffee, sugar, pie or cake, plain food with lots of honey, doing twice the work on half he formerly ate. But Hasty is warned that a novelette will start in again. Takes an unfair advantage of Hasty by saying a lady will write it.

Numbers of Bees Rather than Colonies seem to be preferred by D. W. Heise (Canadian Bee Journal.) In his locality a man started with 35 weak colonies and got 900 pounds of surplus. Two miles from this man another started with 20 strong colonies and got 2,000 pounds—26 pounds per colony in one case, 100 in the other. Such a result might generally be expected, altho sometimes a distance of two miles makes a big difference in the harvest.

Bees Necessary for Growing Crops.—Albert Gale, in Agricultural Gazette, as quoted in Australian Bee-Bulletin, makes the vigorous assertion that if the native flora are wholly, or nearly wholly, cleared from the land to the extent of giving insufficient storage for the bees, so as to decimate them to the extent of their numerical inability to carry on the necessary work of fertilization, "the result will be more disastrous than drouths or floods, because our fruit trees, etc., would cease to yield their crops."

No-Bee-Way Section.—The South Texas Convention decided "that the said section was no improvement over the old section." The Southland queen is down on them hard. Doesn't like them—wouldn't like plain bedsteads without scallops—honey doesn't look so well in plain sections and won't sell as well—but wants to hear more about them. Is going to make something better than fence-separators—sawed wood-separators with perforations seven inches long. Evidently fences and plain sections don't suit that "locality."

Space Under Hives.—The question has been asked whether the bees are not hindered about getting to the combs by having a hive raised. Doolittle says, in Progressive Bee-Keeper, that this can make no difference, for the cluster comes down to the bottom. That swarming is overcome by raising the hive was proved a myth years ago, when there was plenty of swarming with all hives raised. After having tried that and various other bottom-boards, however, he strongly favors the Dr. Miller bottom-board with a shallow side for summer, and the other side, two inches deep, for winter.

Controlling Swarming at Out-Yards.—The editor of Gleanings says the question of preventing swarming in out-yards run for comb honey is a poser, but he tells how he managed last year, having few swarms, altho some honey went into extracting-combs. All queens were clipped, or entrances covered with queen-traps. Toward the swarming season he

put on a second story with one or two frames of brood from below, filling up with empty combs or frames of foundation. After the upper story was pretty well filled with brood or honey, in some cases he put a super of sections on top of the whole, while in other cases he took off the upper story and put two section supers in its place, crowding all the brood possible into the lower story, and reserving the frames of honey for winter stores or extracting.

Paint for Hives.—R. C. Aikin says he has tried paint of all colors, and a hive painted *straight black* was the worst he ever had for swarming. Has had many dark red, and thinks they get too hot and cause swarming. Prefers light shades. Doolittle thinks hives should stand in shade from 8:30 to 4:30 o'clock, in which case color will make no difference. But he thinks bees do much the best in hives not painted at all, if the hives have single walls. If there's any *good* reason for paint other than looks, he has never seen it advanced. He wouldn't let any one paint his single-walled hives for \$1.00 each. It would lose him \$2.00 in honey, because it would hinder early breeding.—Progressive Bee-Keeping.

Thinks Hasty Has Fears.—Dr. Miller having said in Gleanings that when a new queen was given to a cross colony there seemed to be a change in the temper of the bees, so soon, that it must have been the presence of the queen that made the difference, and Hasty having commented thereon in Review, the Progressive Bee-Keeper's Somnambulist thus comments on Hasty's comments:

"One more fragment that I espied along the way was this, from that Bachelor Hasty, or hasty Bachelor, of the Review:

"May it not be that all bees, immediately after re-queening, haul in their horns a bit, and feel as if home were hardly worth fighting for?"

"Now, where did he get that notion? No question of its originality; and if *that's* the way *he feels*, small wonder there's no queen to his establishment."

W. L. Coggshall's Bee-Keeping.—E. R. Root, in Gleanings, tells something of a visit to this man, who, he says, "runs over 1,000 colonies." (A wicked friend suggests that they can hardly be his own bees, or he wouldn't stir them all up by running over them.) Rapidity of manipulation seems to be the order of the day, and stings! A hand-cart holding four extracting-supers with an empty super on it is taken to a hive, hive-cover removed, quilt lifted a little way, smoke blown under, quilt flopt up and down sucklog the smoke down into the hive; when $\frac{2}{3}$ the bees have gone down the first frame is lifted from super, shaken in front of hive, and if any bees are left on the comb, a sweep or two of Coggshall's broom removes them, then the remaining frames are shaken into the super. When the super is emptied it is not pried off the hive, but jerked or kicked off, making the bees mad, of course, but they take the stings and save the time. Then a second, third and fourth hive is visited, and the load taken to the extractor. The editor, while looking on, kept poking his hands deeper into his pockets, and the stings kept going deeper in his clothes, but the men worked away as if it was an every-day matter to work in a cloud of stings.

Two Bad Men—Too Bad.—"So shines a good deed in a naughty world," runs the quotation, but that very shining makes the shiner a conspicuous target for the evil-minded. Just because this Boiler shows such startling *originality* in the items given in this department, thus giving to the world ideas that otherwise never would have been born, D. W. Heise, of the Canadian Bee Journal, and Hasty, of the Bee-Keeper's Review—a man that has to eat 12 ounces of honey a day to keep him sweet—with fiendish malignity sorely wound the tender feelings of the Boiler. The Kanuck gets mad and calls names because some choice morsel he was gloating over is scooped and brought to light in a weekly, some two or three weeks ahead of its intended advent in a monthly. But say, Heise, what's a body to do when he's overloaded with original ideas? Would you have him hold on to them and "bust his boiler?"

Instead of standing off at an admiring distance, Hasty has the audacity to come close up and measure his own little height, saying he is "getting jealous." Yet he seems to have sense enough left to fear he will be accused of egotism, as he expresses it, "for even putting my [his] head up that high." The idea of such a man as Hasty, who can never clearly express what he has to say, and whose style is so dull that it must be a second-hand affair that some one has thrown away, comparing his prosy platitudes with the brilliant scintillations of this deponent! Perish the thought!

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order—

| | 5lb | 10lb | 25lb | 50lb |

GENERAL ITEMS

Favorable Weather for Bees.

Plums and peaches are in bloom. The weather is very favorable for the bees.

JOHN M. RYAN.

Marshall Co., Ala., March 19.

Did Nothing Last Year.

Bees did nothing here last year. I had to feed to keep them through the winter.

C. R. GARDNER.

King Co., Wash., March 16.

Had a Good Flight.

My bees have wintered well so far. I have 34 colonies, and they all had a good flight the other day.

JNO. HERBERT.

Kane Co., Ill., Feb. 12.

Severe Winter for Bees.

Our bees have had quite a hard time here, as the winter so far was exceptionally severe, with no rain to speak of. If rain will not set in soon and plentiful, we are sure to go through another season worse than last.

P. A. SIOLI.

Sonoma Co., Calif., Jan. 31.

Had to Feed for Winter.

Last year I got a fraction over 50 pounds of honey per colony, but I had to feed for winter about 70 pounds of sugar, without cooking. This I did the latter part of October and the first of November. The bees are doing well on it. I have 15 colonies.

A. J. MILEY.

Rockbridge Co., Va., Feb. 14.

An Old Subscriber.

Having the "Old Reliable" from No. 1, Vol. 1, to the present, I have not yet found the place to say "stop," and probably will not while I am able to hear the hum of the busy bees. I have 16 volumes bound, and probably would have had more bound volumes had not Mr. Newman given one volume in "blanket form."

Warren Co., Pa. W. J. DAVIS, 1st.

Foul Brood Treatment in England.

In my report of Mr. Cowan's address before the California Bee-Keepers' Association, published on page 85, the idea might be conveyed that the bee-keeper in England, in treating foul brood, resorted in all cases to extermination. The discussion at the meeting had a tendency to that effect, and the error might have crept in from that source. To place the matter right, I will quote from the "British Bee-Keepers' Guide," the English method of treatment:

"If the colony is weak, destruction of bees, combs, frames and quilts, together with thorough disinfection of hives, is far the best course to pursue. We thus destroy the spores and remove the source of infection. If, on the contrary, the colony be strong in bees the latter may be preserved by making an artificial swarm of them. They are then confined in a straw skep and fed on syrup medicated with naphthol beta. The frames, combs, and quilts, must be burned, and the hives disinfected by being either steamed or scrubbed with boiling water and soap; then painted over with a solution of carbolic acid (one part of Calvert's No. 5 to two parts of water); when the smell has disappeared the solution is ready for use. The bees are kept confined to the skep for 48 hours, by which time all honey they may have taken with them will have been consumed, and such of the bees as are diseased will have died off. Those remaining are shaken from the skep into a clean frame hive furnished with six frames

Cash PAID FOR Beeswax

For all the Good, Pure Yellow Beeswax delivered to our office till further notice, we will pay 26 cents per pound, CASH. No commission. Now if you want cash, promptly, for your Beeswax, send it on at once. Impure wax not taken at any price. Address as follows, very plainly,

GEO. W. YORK & CO.

118 Michigan st., CHICAGO, ILL.

fitted with full sheets of comb foundation, and are fed with medicated syrup a few days longer. The skep used as their temporary home must then be burned. All such work as is here described, should be done in the evening, when the bees have ceased flying for the day, to avoid chance of robbing."

Recipe for naphthol beta solution: "Naphthol beta was introduced after exhaustive experiments by Dr. Loret, and subsequent experience here has proved its efficacy. To make the solution proceed as follows:

"For convenience of measuring, procure from a chemist an 8-ounce bottle, marked with 16 divisions of half an ounce. Thus each division will be equal to one tablespoonful. Put an ounce naphthol beta into the bottle and half fill with pure methylated spirit. Shake until the crystals are dissolved. Then add spirit until the liquid reaches the 14th line on the bottle. The solution is then ready for use. Each division will contain one tablespoonful, which is just the right quantity for 10 pounds of sugar. The solution should be stirred into the syrup while the latter is hot."

Los Angeles Co., Calif. J. H. MARTIN.

Favorable Winter for Bees.

The winter has been favorable for bees. As the fall honey was "nifty" on account of severe drouth, bees went into winter under unfavorable conditions, no young bees having been reared to amount to anything.

The Bee Journal meets my approval. I always read the editorial page first.
Cass Co., Mo., Feb. 17. W. D. HURT.

Report for 1897.

My report for the year 1897 is 7,000 pounds of comb honey of good quality from 60 colonies, spring count, increase to 100. December 10 I put 50 colonies into the cellar, leaving 10 on the summer stands. I had to move my bees out Feb. 10, as they commenced to spot the hive inside. I have had bees eight years. I always put them in a row and cover them with straw, so it is dark for them.
Bureau Co., Ill., Feb. 15. C. W. ANDERSON.

Honey Crop Prospect Fine.

The prospect now is fine for a honey crop. The bees are at work on the peach and plum bloom, turraips, mustard, etc.

I could get along, I think, without the Bee Journal, now that I know a little about bee-keeping, but it would be like the Irishman who had a coat made, and when he went for it, he found the sleeves sewed to the pocket-holes. The maker asked him "if it would do." "Yes," replied the Irishman, "but it's a poor do." I could do without the Bee Journal, but it would be "a poor do."
DeKalb Co., Ga., March 19. M. V. ESTES.

Mild Winter—Wintering Well.

We here in northeastern Pennsylvania have had a very mild winter so far, only a little snow, and about two weeks of real cold weather. Last week my bees were flying strong every day. There are 65 colonies all on the summer stands, and every one alive yet. I expect to move my entire apiary sometime between now and April 1, about 1/2 mile to a No. 1 place for bees, a southeast slope where the morning sun strikes them better. We have lots of young white clover yet, and the prospects are good for another crop this year.
Luzerne Co., Pa., Feb. 15. PAUL WHITENREAD.

New York State Association.

In pursuance of a call issued by a committee from several bee-keepers' societies, asking that delegates be sent to Geneva, N. Y., March 16, to organize a State bee-keepers' association, the representatives from the different local societies met and decided to organize a society to be called "The New

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apiarian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polisht, snowy-white Sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

York State Association of Bee-Keepers' Societies."

The following officers were elected for the ensuing year: W. F. Marks, President; F. S. Emms, Vice-President; and H. S. Howe, Secretary-Treasurer.

The next meeting will be held at Geneva, N. Y., the second Wednesday in January, 1899.

The active members are to be delegates from the county societies, but any bee-keeper will be made welcome at the meetings.
HARRY S. HOWE, Sec-Treas.

Utah.—The Utah State Bee-Keepers' Association will hold its semi-annual convention in the City and County Building, Salt Lake City, April 5, 1898, at 10 a. m. A full program in the interest of the industry will be presented. It is very desirable to have all parts of the State represented. Among other things to be considered is the transportation and marketing of our products, and also the adoption of the best plan to represent our state at the Trans-Mississippi Exposition, and to get our new fowl road law into active operation. Every bee-keeper should be interested in these matters. All are cordially invited. In case there may be any that cannot attend, we would be pleased to have their address, and have them send in questions on general topics. Several members of the Association have desired us to again call the attention of our bee-keepers to the Langstroth monument fund. Any who feel able should throw in their mite to mark the last resting-place of this the greatest of all American bee-keepers. No one will feel as if it was labor in vain, who takes a fraternal interest in this desirable object.

JOHN B. FAOG Sec., East Mill Creek, Utah.
E. S. LOVESY, Pres., Salt Lake City, Utah.

A Good Bicycle Free

Now, then, young men and young ladies, also boys and girls, take advantage of this offer and get a Wheel (A THOROUGHLY GOOD ONE) with a little work. To increase our circulation we have made arrangements with a first-class concern in this city to furnish us with their well-known

ALAMO WHEELS

at a price which enables us to give one **FREE** as a premium for sending us **50 New Subscriptions** to the Bee Journal at \$1.00 each. You can send them in as taken, and when your list of 50 is complete, we will ship your beautiful wheel, *freight paid*, to your nearest depot. This wheel retails in the ordinary way at \$50.00—and it concerns nobody but ourselves how we managed to get in on the inside cut price. For 40 Subscriptions we will ship a Juvenile of the same make. Below we give specifications:

Frame—Shelby Seamless Tubing. 1½ Main Frame. Connections—Steel (selected.) Fork Crown—Oval (drop forged.) Handle Bars—Steel or wood, drop or upright; cork grips. Wheels—28 inch. Pedals—rat trap. Rims—best elm. Tires—Morgan & Wright or Vim. Spokes—selected piano wire. Bearings—Tool steel (turned by experts.) Gear—64 to 80. Saddle—leather (rubber or felt deck.) Weight—23 to 25 pounds. Color—black, maroon, nicely striped. Special color by arrangement. Furnishings—Tool bag, oiler, wrench, air pump, etc.

Ladies' model built on same lines with the usual difference between sexes, such as rubber pedals, etc. Address.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4 inch Smoke Engine too large.

January 27, 1897. Truly, W. H. EAGERTY, Cuba, Kansas.

Mr. Bingham, Dear Sir:—Please send per mail a 4-inch Smoke Engine. I have one of your Smokers; it is too small in time of trouble.

February 21, 1898. A. F. SEWARD, Riverside, Calif.

9A9t **T. F. BINGHAM, Farwell, Michigan.**

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the

Best Goods at the Lowest Prices.

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginville, Mo.; or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden strain, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898.

W. Z. HUTCHINSON.

FLINT, MICH.

WOVEN WIRE FENCE

With our Duplex Automatic Machine you can make a genuine Rabbit-Proof fence, and one that is also Horse-high and Bull-strong for 16c A ROD and a Hog fence for 12c. HONEY and BEESWAX MARKET QUOTATIONS.

Chicago, Mar. 23.—Very little demand for honey in the comb, the season being about over for its sale in any quantity beyond a case or so at a time, many retailers refusing to carry it in stock owing to sales being infrequent. Prices askt are 10c for best grade of white, 8@9c for No. 1 or fair grade of white; ambers, 7@8c; dark, same. Extracted, 5@6c white; amber, 4@5c; and 4c for dark and buckwheat. Beeswax, 27c.

R. A. BURNETT & CO.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax in good demand at 26@27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season.

M. H. HUNT.

Kansas City, March 21.—Fancy white 1 lbs., 9@10c; No. 1, white, 9c; amber, 8@9c. Extracted, white, 5@5½c; amber, 4@4½c; dark, 4c. Beeswax, 20@22c.

Supply of comb honey is large; demand fair.

C. O. CLEMONS & CO.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging.

S. H. HALL & CO.

Cincinnati, Mar. 21.—Demand fair for extracted, with insufficient supplies. Prices range from 4@6c, according to quality. Demand for comb is slow at 10@13c for best white. Beeswax in good demand at 20@25c for good to choice yellow.

CHAS. F. MUTH & SON.

Indianapolis, March 24.—Fancy white, 11 to 13c; No. 1, 10 to 11c; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

WALTER S. POWDER.

San Francisco, Mar. 16.—White comb, 8@9½c; amber 5@6c; extracted, white, 4¼@5c; light amber, 4¼@4½c. Beeswax, 24@27c.

The firm tone last noted as prevailing in the market for extracted honey continues to be experienced, with light stocks of all grades. The same condition is reported as existing in the East and in Europe. Comb honey is still in more than ample supply for current requirements, having to depend wholly on local customs.

Milwaukee, March 8.—Fancy, 11 to 12c; A No 1, 10 to 11c; No. 1, 10 to 10½c; No. 2, 9 to 10c; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c; dark, 4¼ to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the BEST. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better.

A. V. BISHOP & Co.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.

BATTERSON & Co.

New York, Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5¼c; light amber, 5c.; white clover and basswood, 4¾ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cleveland, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6½c.; amber, 4 to 5c. Beeswax, 22 to 25c.

A. B. WILLIAMS & Co.

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

CONTRIBUTED ARTICLES

An Uncapping-Box and Apiary Apron.

BY MRS. EFFIE BROWN.

Hitherto I have never ventured far out into the fields of bee-literature, for, somehow, there are so many able and experienced hands there that, when I do find out something which I think is good, just as I get all ready to publish the facts somebody is sure he knew all about it years ago.

Last summer I made myself an uncapping-box, and this spring I am making some apiary aprons which I am going to describe without trying to find out how many other bee-keepers already have just such articles.

My uncapping-box first came from the grocer—only a common soap-box, but by taking from and adding to it became a very handy thing to have in extracting-time.

The first thing I did with it was to clean it, and then wax it well so that it would not leak where I did not want it to.

cappings. When I had the screen tacked on, I turned the box bottom upward and nailed a top-bar of a frame across the edge of the bottom I had just sawed; then another across the bottom of the end of the box, from which I had just knocked the strip. These two strips, when nailed, were about two inches apart, and each being nearly an inch wide, I nailed a piece of half-inch stuff (four inches wide and five inches longer than the width of the box) down solidly onto the two pieces of frame just nailed on. I then had a trough under the screen, and projecting far enough away from the box to run the honey into a pail.

A narrow strip on the back end of the trough, and one on each side of the projecting end, was all that was needed except the legs.

Now, I can't tell you much about the legs, only that they were made of good, stout strips of wood, with no two of the same length. But, anyway, after I had them nailed on, the corner from which the honey was to drip was the lowest. The whole box stands tilted slightly cornerwise, with the end of the trough high enough to set a pail under.

When I am going to extract I tack a narrow strip across the top of the box to rest the frames on, and then shave away. The cappings fall into the box, and the honey seeks the lowest corner where it passes through the screen down into the pail. The box should be large enough to hold all the cappings of

Mr. Paul Whitebread and His Apiary, in Luzerne County, Pennsylvania.—See page 217.

Then I turned it over and sawed off a strip of the bottom about three inches wide and the whole width of the box. Over this, inside of the box, I tacked a double thickness of common window-screen through which the honey could drain free from

one day's extracting. If allowed to drain all night they will be about dry in the morning.

After the box is completed it should have another coat of wax so that all the cracks will be well filled.

I know some of you men who read this will smile at this description, but I don't care much if you do. I made the box all myself, and if it isn't a thing of beauty I am sure it will be a joy for a long time.

And now about my aprons. There isn't much to be said about them which is commendable, except the pockets, and they are, I am sure, superior to any man's pocket, for I can carry my dishcloth in them if I want to. That's more than a man can do with his pocket, especially if he uses tobacco! [Oh, no, Mrs. Brown. Unless you mean the dishcloth would be the sufferer. Surely, a dishcloth is far cleaner than any tobacco we ever saw.—EDITOR.]

I used a common butcher's apron for a pattern, and cut a slit in each side to put the pockets in. These were made of good oilcloth, and when sewed up each was 8 inches wide and 10 inches deep. I did not set them on the outside, but put them in like a trouser's pocket. May be you think you would not like to carry a wet dishcloth in your pocket, but I do. I take a nice new one that never has washed any dishes yet, and wet it, then wring it out and put into my pocket. When working extracting I often feel quite "stuck up," and if I happen to be out among the bees in the hot sun, the damp "dishcloth" becomes very acceptable.

The only other things I need in my pockets are a screw-driver and a cheap jack-knife. If these do get wet and rust they are not a great loss. If the pockets become sticky, I turn them inside out, and wipe them off. The aprons should be made of good dark cloth, and soaked more than rubbed in washing.

And now if the men cannot understand the uncapping-box, I hope they will tell the women about the apron.

Eau Claire Co., Wis.

Cabbage Palmetto Honey—Buckwheat Bloom.

BY O. O. POPPLETON.

On page 749 of the Bee Journal for 1897, Mr. Harris asks me some questions about proper handling of cabbage palmetto honey when it shows fermentation under the cappings. I have never had the trouble Mr. Harris speaks of with that kind of honey, but have twice seen the trouble with a very dark, strong grade of honey that was gathered in May. This honey was full of air-bubbles under the cappings, and, after being extracted a little while, it had to be handled very carefully or it would blow bungs out of barrels, etc. I have seen it so bad that it was impossible to get more than a half gallon of honey in a gallon jug, without its foaming so as to run out of jug and waste. It makes no difference with this kind whether it is extracted before or after being sealed. The fault seems to be inherent with this kind of honey, and not because of lack of ripening. I know of no method of handling this honey that will correct the trouble, unless it might be by use of the sun evaporator. Mr. Mitchell and Mr. Hart (of Volusia Co., Fla.) have both had much experience with evaporators, and I presume have had enough of this kind of honey to test their value in such cases.

No, I don't think that extracting before being sealed over will remedy this evil. Handling honey in deep cans as I described, is an advantage with all kinds of honey, and should always be practiced, but that is not thorough enough to entirely cure the evil when honey is bad enough to ferment under the cappings. Fortunately, that kind of honey is not very common. I have had to contend with it only twice, and not in large quantities then.

BUCKWHEAT BLOOM—BEES WORKING NEAR HOME.

On page 743 (1897) Mr. Hutchinson is quoted as follows:

"Forty acres of buckwheat were once sowed early in the season, three miles from my little apiary. . . . It bloomed two or three weeks before any other buckwheat, and my bees worked upon it and secured a little more than enough for their immediate needs, but when the buckwheat bloomed near home, the combs filled up with a rush."

This was said as proof that bees do not work profitably except near home, but it proves nothing, owing to a peculiar habit of buckwheat bloom. I never knew extra-early-blooming buckwheat to yield any quantity of honey, altho bees seem to work on it the same as they do after the yield sets in. This was probably the real reason for the facts Mr. H. quotes.

CYPRESS LUMBER FOR HIVES.

On page 745 (1897) the question is asked whether cypress lumber can be used for bee-hives. Yes, I prefer cypress to any other kind of lumber I have ever used.

BROOD-REARING IN WINTER.

On page 70 Mr. Doolittle says that "Quinby was correct in saying that brood-rearing would commence in all good colonies about Christmas, but that means in colonies wintered outside." For some reason or other my bees in Iowa didn't follow this rule. Fully nine-tenths of my colonies, as a rule, would commence brood-rearing between March 15 and April 5. The only reason for this difference that I can think of is that mine being in chaff hives may have caused the bees to act differently.

MOVING BEES FROM ONE LOCATION TO ANOTHER.

On page 134 the point is brought out in discussion that bees that are removed from one location to another in the spring will usually do better work than will those colonies not moved. I noticed this fact when first beginning bee-keeping, nearly 30 years ago, and repeated observations since then have confirmed me in my opinion that such is a fact. I am not able to give any theory why it is so—I can simply say that all my experiences in moving bees seem to uphold that opinion.

PACKING FOR WINTERING BEES.

On page 139, in answering a question about packing bees for wintering, Dr. Miller says: "Dry leaves are well liked, but sawdust is considered too heavy." He is correct, but my experience taught me that very fine chaff—that from timothy—is best of all; and next to that, I liked, not common sawdust, but such as is made by very fine saws while working in dry pine—such, in fact, as our bee-hive factories make in large quantities. I think this will be found better than planer-shavings. But beware of coarse sawdust, that isn't thoroughly dry. This last is probably what Dr. M. referred to.

Dade Co., Fla.

What to Do With Queenless Colonies in Spring.

BY G. M. DOOLITTLE.

A correspondent wishes me to tell in the American Bee Journal what to do with queenless colonies in the spring. He writes as follows:

"I find, on this the first flight of my bees, that I have several queenless colonies. What had I better do with them? If it is best to unite them, what is the best method of doing it?"

What to do with these queenless colonies will depend upon two things—first, the wants of the correspondent, and, second, the condition of the queenless colonies. If the colonies are strong in bees, and the correspondent wishes more colonies than he already has, then I should give them a frame of brood from some colony having the same which it can spare, and send South for a queen for them, or let them rear a queen for themselves, just as my means would allow. The colony will become self-sustaining sooner if a queen is procured for them than they will by rearing their own queen; for most likely the first lot of cells built will have to be destroyed on account of not having drones in the apiary thus early. To rear a queen before there are any drones for her to meet, often proves a vexatious thing, as an unfertile queen is hard to find in order to be rid of her; and if not fertilized she will prove to be a drone-layer, or worse than useless.

If the colonies are to rear their own queens, brood must be given them once a week till they have a laying queen, which makes extra work; still, if anxious for bees, this work is not to be shunned, for such colonies with their young queens often prove among the best for honey during the season.

If the colonies are weak, or the owner does not desire increase, the best thing to do is to unite these queenless colonies with those having queens. To do this uniting, I would employ one of two plans at this time of year, and, as far as possible, unite the queenless colonies with the weaker ones having queens.

The first plan I would use is this: Select a time just after the bees have had a flight and become quiet, if the weather is cool, or wait till near evening if the weather is warm, and then carry the colony having the queen to the stand of the queenless one, and shake the bees from the latter off their combs and from their hive in front of the hive having the queen now on their own stand. Previous to shaking the queenless bees off their combs, blow some smoke in at the entrance of the one having the queen, till they set up a loud humming, which shows that the guards are conquered, when the hum will be interrupted as a call by the queenless bees, which will run in immediately, and no fighting will result. After dark take the now united colony to the stand formerly

occupied by the one having the queen, and remove the hive and all pertaining to it from where the queenless colony stood, and no bees of any amount will return to be lost.

The other plan is this, and often works nearly or quite as well as the first: Crowd the bees having the queen upon a few combs as possible with a division-board, having a half-inch hole near the center of the same. Having previously taken the most of the combs away from the queenless colony preparatory to uniting, set the remaining combs with the adhering bees in the space on the opposite side of the division-board, closing the hive. Have the entrance open only on the side occupied with the colony having the queen, and the bees will unite of their own accord in a short time, as they will open up communication through the hole in the division-board soon after the queenless bees are placed in the hive. Use the same precaution about removing the hive, stand, etc., from the situation occupied by the queenless colony, and the work is done. Onondaga Co., N. Y.

Rich Bee-Keepers and Poor Alfalfa—A Reply.

BY W. A. H. GILSTRAP.

I find the following editorial paragraph on page 104:

"If the production of honey is as profitable as some claim it to be, why do nearly all who own bees remain in moderate circumstances?" But there's the fun, Mr. Gilstrap. Besides, can you name a business in which fewer men have gone into bankruptcy?"

Yes, sir, I think so. So far as my information goes, peanut peddlers, tamalla peddlers, and boot-blacks, are examples. Many more might be given. Many banks, ranches, railroads, and stores are past on by bankrupt courts, a few apiaries also, but a boot-black's kit, never!

The article in the January Pacific Bee Journal which you comment on, applies better to this coast than to my native State (Illinois). We run more bees than you, possibly make a bigger pow-wow over it; while you get about as good an average yield, and make more money than we do.

Our climate admits of more winter work of varied nature. It is an unusual occurrence here to have a plow idle till noon because the ground is frozen too much to plow. In our coldest winters plowing can be done from daylight till dark most of the time, thereby enabling the farmer to plow 300 to 600 acres with one team in a season, seeding it to grain with a seeder which is fastened to his plow. Even more might be done. Some grain-raisers in this county are reported as making \$3,000, or even \$5,000, last year. One man can superintend several hands and do a "big business."

One man can manage 40 to 640 acres of orchard or vineyard, or 10,000 sheep. Henry Miller has control of over 13,000,000 acres of land, much of it well improved, besides many stores, hotels, irrigating ditches, slaughter-houses, etc. I don't believe he could successfully manage 3,000 colonies of bees.

Chickens, horses, hogs and mules might be mentioned, but it would be of no use to introduce more witnesses. If we manage to get 100 pounds per colony from 300 colonies, we are told we are doing well. If this honey sells for 2½ to 3¼ cents per pound from 7 to 40 miles from place of production, we feel that it is no wonder that no one accumulates much filthy lucre, while representatives of all occupations that are more prone to bankruptcy get rich.

Just how much hard cash our best bee-keeper has made in the last three years I do not know, but, candidly, I believe Wisconsin, Illinois or New York offers better inducements than California. If Mr. G. M. Doolittle can get 80 or 100 pounds of comb honey on an average, and sell at the New York price, he would better stay there—if he is not afraid of freezing. Dr. Miller can make more money where he is than here, much as I would like him for a neighbor.

ALFALFA FOR HAY AND HONEY.

Prof. Cook's remarks on alfalfa (page 97) do not apply to central California entirely. It is generally regarded as making a heavier crop of more nutritious hay if cut after full bloom is reached. Bee-keepers should not discourage this plan. If left too long it is woody, and not relished by horses. When alfalfa is left for seed it is generally better for honey than any other way.

In the driest season of the last five my bees stored about 20 or 25 pounds per colony, while the next driest year they reached 140 pounds average—my best run. Alfalfa is my main honey source.

This season promises to be very dry, altho spring rains may help us greatly. Fresno Co., Calif., Feb. 23.

SUCCESSFUL WINTERING.

Three Essential Elements Necessary to Winter Bees Successfully in House-Apiaries by the Use of Artificial Heat.

BY JOHN CHRYSOSTOM.

I may remark, by way of preface, that the bees at Notre Dame are kept in three houses, each differing in warmth and structure, and that the hives are kept on the same stands summer and winter.

After removing the surplus honey in the fall, the hives are prepared for winter and left till apple-bloom. Then they may need some attention. This management saves the time and labor that would otherwise be given to packing for outside wintering or removing to cellars. Besides, the latter does not always prove satisfactory. In this article I shall confine my remarks to colonies wintered on the summer stands in the house by artificial heat.

On this head my observations have been especially accurate on two colonies—a strong colony of 5-banded bees on 16 frames in two stories of the Langstroth-Simplicity hive; and a very weak colony of dark Italians. It may be necessary to explain why the latter colony is so weak.

Last August I took three frames partly filled, with brood and adhering bees, and put them into an 8-frame hive, filling it with drawn combs. About the time they had their queen laying, I removed the young queen and replaced her by an old one, which injustice the bees resented by balling her for a day and a night. The following day they put her outside the hive. Tho I several times liberated her, yet the bees would not allow her to re-enter the hive until the next day, when they finally accepted her; but then, she was in bad condition. When winter came, I found that there were scarcely enough bees to cover two frames. To these I added eight other frames containing honey and pollen, making in all 16 frames in two stories. Thus prepared, they went into winter quarters.

Results: In order to ascertain as nearly as possible the number of deaths occurring in each hive, I put a wire screen before each hive so that the bees could not get out. This I removed from time to time to count the dead in the porticos. On Feb. 7 I found 13 dead bees in the portico of the 5-banded bees, and amongst them a young drone. The total number of deaths in this colony since Nov. 1, is 26, and in the weak colony, 36. Most of these died from the effects of cold, as I had neglected to contract the entrance. When wintered on this plan, the entrance should be small and protected from direct winds; and when the mercury falls much below zero, it is advisable to throw loose snow about the entrance.

On Feb. 10 the mercury stood about 60° in the shade. The sun was bright and warm, and the bees were ready for a flight. On removing the screens, it was a pleasure to look at the bees issuing from their hives so strong and frisky. I searched several times during the day, and a dead bee was not to be seen at either hive. Even the weak colony gave me a pleasant surprise by their numbers and healthy appearance. When standing near the hives a sweet odor was perceptible.

The three essential elements necessary to winter bees as above described are *sunshine*, *pure air from the outside*, and *artificial heat*.

That bees should pass through the winter so strong and healthy is certainly very gratifying and productive of good results. As soon as the first pollen and honey appear, there is a strong and vigorous force to collect it, as there are no funerals or house-cleaning to prevent them. Such wintering will do much to confute the idea of bees dying of old age, before they have lived 60 or 90 days. Such a thing is not in harmony with the laws of nature. The children may live as long as their mothers, and we find that the mother-bee lives three or four years, or even longer. The worker, or field-bee, die young, because, like soldiers in active campaigns, their brave little lives are exposed to innumerable dangers.

The successful wintering of bees in house-apiaries with, or without, artificial heat depends apparently upon little things. Some of these I shall enumerate:

Bees cannot be wintered successfully in a house-apiary on the windward. By *windward* I mean the side against which the winter storms blow. In this locality the coldest storms blow from the southwest, west and northwest. The openings in the walls of our house-apiaries are on the north-east, east, and southeast. Our success in wintering bees for four years has been uniform. It is advisable to have good wind-breaks on the north and southwest. The porticos should be protected from direct winds.

During the coldest weather this winter, when the mercury fell eight or ten degrees below zero, and the wind blew a gale from the northwest, the bees in an observation hive

located on the sheltered side of the house were walking over the combs. On another day, when the wind blew directly against the portico of the hive, and the thermometer registered 28° above zero, the bees in the same hive were more compactly clustered than on any other this winter. This fact, I think, is quite significant.

When all the requisites for successful wintering in house-apiaries, with or without artificial heat, are properly understood and intelligently applied, the house-apiarist will become as popular on account of its great convenience as it will be for its giving the best results in wintering bees. A house large enough to winter 30 or 40 colonies will also afford space enough for a honey-room, extracting facilities, a place for storage of hives, etc., and even a work-shop. The noise of the work-shop will not disturb the bees if the hives occupy a separate floor. Those who are interested in this subject may follow St. Paul's advice: "Prove everything, and hold fast to what is good."

If these remarks will be instrumental in making the long, weary hours of winter more comfortable for "our little sisters, the bees," and more profitable to their larger brothers who take care of them, the object of this article will have been accomplished.

St. Joseph Co., Ind.

*House-apiaries should have many small windows about 18x24 inches. It were well to have the sashes on pivots at top and bottom. This is a matter of convenience. The bees that leave the combs when the hive is opened will settle on the window and it is easy to get them out by turning the sash. These windows also admit sunshine on the hives the same as if they were outside, which fact, I think, is in more than one way beneficial. In very hot weather, dark, close-fitting blinds will keep the house cool.

CONVENTION PROCEEDINGS

Report of the Northwestern Bee-Keepers' Convention, Held in Chicago, Nov. 10 and 11, 1897.

REPORTED BY A SPECIAL BEE JOURNAL REPORTER.

(Continued from page 198.)

SECOND DAY—AFTERNOON SESSION.

SIMPSON HONEY-PLANT OR FIGWORT.

Mr. Dunne—I would like to ask if any one has had any experience with the Simpson honey-plant or figwort?

Pres. Miller—The Simpson honey-plant, or figwort, or carpenter's square, or heal-all, is before us. Who has had any experience with it? How many of you have seen it grow? Three. What do you know about it as a honey-plant?

Mr. Green—From my experience I should say that it yielded honey readily enough, but I don't know that it is practicable to raise it. It may be. I have never tried it.

Mr. Stone—I have seen it along the roadsides; in some places a good deal of it, and I have seen bees just swarming on it every day, and it blooms a long time, but I do not think it is fit for anything except for a honey-plant. It is a weed. If we can get a honey-plant that is better I would rather mow down the Simpson honey-plant and kill it out. I think that is just like the spider-plant.

Mr. Whitcomb—I doubt if it is profitable to cultivate anything for honey alone.

Mr. Green—I have seen considerable clumps of it growing. It grows all through the woods in our neighborhood, but it doesn't seem to be a very thriving and robust plant. It doesn't take care of itself very well and establish itself against other weeds as sweet clover does.

Pres. Miller—When the boom was first on for the Simpson honey-plant I sent off and bought plants enough to set out an acre, cultivated it carefully, and had a flourishing field of it. Bees worked on it, and they will wherever it is, but a honey-plant to be of any use must not cost too much, and this field the next year was not good for much. I took care of it as carefully as I would of corn. The plants died out, and I afterward found that there were scattered plants of it in my neighborhood that I could have gone and dug up, but I didn't know the plant in the first place. I think you will find very few succeed with it. I only know of one exception—Mr. Williams, of Missouri. I think every one else has given it up as a bad

job. But they are still going on in the old countries with those things, and across the ocean they are still talking about the Simpson honey-plant, and are distributing seed. But we have got through with it, and they are now in the heat of the disease. I don't think it is worth planting at all.

WHAT TO SOW FOR HONEY ALONE.

"What honey-plant can I profitably sow for honey alone?"

Mr. Green—You can sow sweet clover if you have any waste land to sow it on, but not if you have land that is very valuable for other purposes.

Mr. Stone—I believe that Alsike clover will pay a large rent to just raise it for a honey-plant.

Mr. Duane—Is there a difference between the Alsike clover and other clovers?

Pres. Miller—The Alsike clover, or Swedish clover, is medium in growth, and has smaller stems than the red clover. Perhaps as it ordinarily grows it doesn't grow quite so high, and the blossoms are medium between red clover and white clover, more nearly the size of white clover, and pinkish. If white clover grows rank it will grow as large as Alsike.

CRIMSON CLOVER, CATNIP, ETC.

Pres. Miller—How many are there present that have had any experience with crimson clover? That is one of the new clovers.

Mr. Stone—I have never grown but one crop, and not very much of that. It didn't succeed well through the winter. It grew in little patches and little clusters around, and I re-sowed it with Alsike in the spring, when I saw that it failed to be a stand. I learned from the government report at Washington that a number of animals, both cattle and horses, had been killed by the eating of crimson clover. The little hairs that are on the blossoms would accumulate in their stomachs in balls that were indigestible, and it would cause death. A number of cases that were examined and reported to the government station on examination were found to be caused by the balling of those little hairs.

Pres. Miller—I had supposed that was on the seed.

Mr. Stone—Yes, on the head. And they said that if the head matured until it got brown, that then was when the danger point was; that if it were cut very early it mist that, but there would be some heads in any condition of it almost that would make it possible for the injury to be caused.

Pres. Miller—I had quite a piece of crimson clover, perhaps a quarter of an acre, and while I do not believe that it is likely to be a very successful plant in this climate, not standing the winter, yet in some places it succeeds, and it may be well to have it tried more; but what I want to suggest is that all of you will do well to have a patch of it near your dwellings for the beauty of the flower. When in bloom it is a beautiful sight, well worth planting if the bees didn't touch it at all.

M. S. Miller—I believe Mr. Green spoke of the Simpson honey-plant doing well in a woody district. Is there any plant that could be sown in such a place that would do well; for instance, in a waste piece of woods that would not be fit for cultivation?

Pres. Miller—The Simpson honey-plant would come very well in that category; and another plant that will do tolerably well where it is partially shaded is the common catnip.

Mr. Baxter—I think the aster is better than either one.

M. S. Miller—Can a person cut catnip so that you can sow it?

Pres. Miller—You can get catnip seed, plenty of it.

Mr. Stone—It grows very much in hedges.

Mr. Baxter—I think that is from the protection the hedge gives it; the cattle don't tramp it.

M. S. Miller—In taking a number of old colonies of bees, such as a person finds scattered over the country, that have never been attended to, would it be advisable to try and use those old hives in connection with anything outside or using them for fuel?

Mr. Stone—Use them in the smoker.

Mr. Baxter—They are not good for the smoker, either. Use them for kindling. That is the best use for them.

Pres. Miller—I don't believe they are of any use for anything but kindling.

SPRAYING FRUIT-TREES—ENGLISH SPARROW.

Mr. Whitcomb—I would like to know how many present are troubled by having fruit-trees sprayed in the spring.

No hawks were shown in response to the question.

Mr. Baxter—They don't use the spray with us very extensively. Some years we have used as much as a carload of blue vitriol right near the town in connection with London purple, but our people down that way have been educated to use at the proper time, altho for a short while there were two

or three that thought the only time for the curcullo was to spray right in the blossom, but they have gotten over that. But I think that it would be a wise thing for each State to adopt a law so as to prevent that, because I have known of instances where serious damage occurred by spraying at the wrong time, altho the horticultural societies and newspapers have taken up the subject so thoroughly that almost all that do spray now will spray at the proper time. There are very few, I suppose, that are still of the opinion they must spray right in the blossom.

Mr. Whitcomb—All the books say that the coddling-moth lays its eggs in the calyx of the apple. Some experiments were made at the experiment station of Nebraska, and Prof. Card says that is not the case. They made some discoveries that entirely contradict that.

Mr. Duone—I would like to ask if the English sparrow is injurious to the honey-bee?

Pres. Miller—I have never heard of such a thing.

Mr. Baxter—It would be a very great wonder if it wasn't because it is injurious to almost everything else.

POULTRY OR OTHER BUSINESS WITH BEES.

M. S. Miller—I would ask whether in a small place poultry would interfere with bees. They will not, so far as I know, except in the case of ducks. Will any other kind of poultry eat enough bees to do any damage?

Mr. Whitcomb—No, sir.

Mr. Baxter—Not even ducks. I have ducks running all through my apiary.

Mr. Whitcomb—They will drink out of the same bowl, and not interfere with them. I have known chickens to eat bees, and to follow it up, but it is an acquired habit.

M. S. Miller—We had a few ducks at home, and they appeared to think that bees were the finest pudding ever made.

Mr. Karch—We have a great lot of chickens, ducks, geese and all, and I never noticed that any of the poultry interfered with the bees.

Mr. Baxter—I have chickens that eat bees—just follow up one hive after another, and eat them. I have watcht those chickens, and they invariably take the drones.

Pres. Miller—A question closely connected with that is the question as to what other business can most conveniently and properly be workt along with bee-keeping, and some have answered that the poultry business was one of the best for combining with bee-keeping.

Mr. Whitcomb—I should say horticulture.

Mr. Stone—I would say the same.

Pres. Miller—What kind of horticulture?

Mr. Whitcomb—Fruit and gardening.

Pres. Miller—How many of you know anything about the combination? Here are a number. Now tell us the advantages and disadvantages.

Mr. Karch—I think it would depend largely upon the location, whether horticulture would pay—the nature of the soil. In some places it is perhaps too cold.

Mr. Whitcomb—The honey-bee is one of the greatest friends of the horticulturist. I have always advocated that friends stand close together.

Mr. Stone—Mr. Becker, one of the members of our State Association, keeps a number of colonies, and in the neighborhood is a man who keeps three or four acres of raspberries, besides fruit, grapes, apples, peaches, and nearly everything of the kind. Mr. Becker has often had a flow of honey, a good flow from those raspberries of his neighbors when the rest of us didn't have anything that our bees could go upon. He would have a number of hundred pounds of honey from those raspberries alone. My bees have workt very strong through the apple-bloom season. I have a great many apple-trees. Other fruits I haven't raised very extensively. But I know that my bees get a great benefit from those apple-trees, and his bees get a great benefit from those raspberries.

Mr. Baxter—We raised this year and shipt 25 carloads of strawberries, 6 carloads of blackberries, and 34 carloads of grapes. It is true that two of my brothers are in partnership with me in the fruit business, but they are not in the bee-business—that belongs to me exclusively. I have 250 colonies of bees, and altho during the month of June I devoted as much time to the gathering and shipping of strawberries as my brothers, it did not interfere to prevent my producing some 30 barrels of white clover honey in connection with the fruit. And I think it would pay well. Besides that, those big fields of strawberries were a great item in building up my colonies in the spring. I have seen it said that bees do not gather anything from strawberries. I know better than that, for I have tried it very extensively. We have something over 80 acres of strawberries, and we have been in that business now up-

wards of 10 years. The grape business—I can't remember when we didn't work in that, because it was my father's, and we grew up into it. The same with apples. We raised apples, grapes, strawberries, blackberries, and some currants, and we used to raise a great many raspberries, but it is difficult to ship them, and of course we have no home market, and have to ship them away to Minneapolis, St. Paul, Grand Forks and Denver, and all through the Northwest, and of course we have to raise such things as we can ship.

Dr. Besse—I don't know what a younger man than I would do, but for a year like this a man wouldn't want to do anything more than attend to his bees; with 125 or 150 colonies he doesn't want anything else to do. It takes a great deal of time to get supers ready, taking off honey and sell it; he finds it is about all he wants to do the year around—at least I do. On a small scale a man might keep a few bees and follow gardening or fruit-raising, or something of that kind. I think the orchard business, especially for the fruits, would go well together.

Pres. Miller—That one item should be considered. While all that is said may be true, it is also true that the busiest time in the small-fruit business comes at the busiest time in bee-keeping. I had a number of acres in raspberries and strawberries, and I found that at the very time when I was busiest with the berries I was busiest with the bees. So today, while I believe with Mr. Whitcomb that fruit-raisers and bee-keepers should be close friends and neighbors, I want them on the opposite side of the fence, so far as it works in my locality. At least I don't want to be the fruit-raiser if I am the bee-keeper, just on account of its coming that way. The probability is Mr. Baxter is of such executive ability he can oversee the two trades, but if he does much at directly overseeing, and doesn't delegate that overseeing to any one else at the busy time of picking berries, it will take about all his time, but he probably has some one to help in both departments.

Mr. Baxter—I don't oversee, Mr. President. I do the work myself. I work for extracted honey. If I workt for comb honey it would make a big difference. My supers go on the hive before the strawberries are ripe. I put enough on so that I don't have to put on more during the season.

Pres. Miller—So the bees don't keep you busy at the time of the berries?

Mr. Baxter—No, sir.

Mr. Whitcomb—The year 1892 was very wet with us, very wet and cold. I had 300 bearing cherry-trees adjacent to my apiaries, and during the time that the cherries were in full bloom there were two days in which the colonies workt profusely on the cherry blossoms. As a result of that we harvested upwards of 200 bushels of cherries, while my neighbors who had no bees got no cherries, and had to buy their cherries of me. Their trees were in just as good condition.

Pres. Miller—How far apart?

Mr. Whitcomb—A mile or two off. Their trees blossomed as profusely as mine, and I could not attribute it to anything else than the bees pollenizing the cherry blossoms.

ADULTERATION OF HONEY AND OTHER FOODS.

Miss Kate Will, a lecturer on "Science of Health and Pure-Food," address the meeting as follows:

"I read with great pleasure and interest yesterday in the newspapers about your resolution to Congress against the adulteration of honey. I lecture on health foods, and honey is something I am very much interested in, for I consider it a health food, and I have contended for quite awhile that it is useless to get up State laws on adulteration of foods, that we must go before Congress. We are having a series of meetings here on the subject of health, and we talk on different lines, and I talk on health food. We had a meeting of that kind yesterday. I brought it up. I told them there that we would have to go before Congress for a national law against the adulteration of foods. Of course you know better than I do how honey is adulterated, and with such a valuable health food as it is, I do wish something could be done about it to keep it pure and healthy. I am so glad you have taken it up, and I wish you success. Anything I could do through the woman's organizations I would be glad indeed to do."

Mr. Whitcomb—I don't think there is one-half of the adulteration of honey that the honey is given credit for. I don't believe there is a gentleman in this room that adulterates honey. I don't know anything about it. I couldn't tell anything about it. I would like to know how many present adulterate honey.

Pres. Miller—All those present who adulterate honey please hold up their hands. (Laughter.)

No one responded, and Pres. Miller said, "We now stand adjourned."

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

To Several Inquirers.

One of the unpleasant things for me is to receive a letter containing a postage stamp or a stamped envelope. When I see one on opening a letter, I'm pretty sure that some one wants an answer by mail. A number have written me of late asking replies by mail. Now just stop a half minute and think of the time it has taken to write the replies you see on this page, and remember that it has to be done 52 times in the year, and if I answer all of the questions by mail, it would use up a good many weeks of the year. Probably there is not one question in twenty asked whose answer the correspondent would not rather receive at once by mail. If I answer at once by mail in one case I'd have to do so in all. See? You wouldn't like it if all the others were answered by mail, for in that case this department would cease to exist, and I've been led to believe that several of the readers of this paper were interested in reading the answers given. Now, if you were in my place, could you do other than to treat all alike?

Another thing. Be sure to say *always* that you want the answer in this journal, if that's where you want it, no matter if you've sent questions twenty times before. For altho I may be familiar with you and your writing, I may not remember whether I replied in this or some other paper.

C. C. MILLER.

Acacia and Acantha as Honey-Trees.

What kind of a honey-plant is the acacia tree in California? also the acanthus, which is of Japanese origin. Last year we had a good flow from them. Do you know if they secrete honey every year?

CALIF.

ANSWER.—Not being familiar with these trees, it will be a favor if some Californian will help us out.

Management of Weak Colonies.

I have two weak colonies of bees now, and to judge from appearances I should say they each contained about 8,000 workers and a queen. Our honey-flow will be here in about six weeks. Would I get more bees in time for it, by (1) uniting the colonies now, or (2) by leaving them as separate colonies until just before the commencement of the honey-flow, and then uniting?

TEXAS.

ANSWER.—Perhaps you'd get more honey by uniting now than by uniting at harvest time, that is, if the colonies are so weak that they will need uniting at harvest. Possibly a compromise wouldn't be a bad thing. Take from one of the colonies brood and bees from time to time, and give to the other till it becomes very strong. Then if it becomes very strong, a week or two before harvest you can repay the favor and possibly have the one strong and the other in fair condition for the harvest, and get more from the two than from a united one. If, however, you find that can't be done, you can then give from the weak to the strong at harvest, and make sure of one strong one.

Suspected Honey—Dividing Colonies Early.

Last fall I put into winter quarters in our home yard eight colonies, and to-day but three are living—they being weak. I suspect that dread disease (foul brood) from the appearance of the combs and cappings, and wish to convert the combs into wax and honey, and the frames to ashes. Now, I do not know what to do with the honey after the operation of rendering.

1. What use would you advise me to make of it?

2. I have about 50 chaff hives, in some of which the suspected colonies have been; would you risk putting other colonies into them? If not, in their present condition, how can I make them fit for use?

3. I have 15 colonies in an apiary a few miles from home. When, without much risk, can I divide (I expect to send for queens and give queens at once) without risk of chilling the brood?

I went to a hive this forenoon and cut from one of the combs, which I suspect infected, a piece of comb which I send you in this mail. You perceive that it lacks the "ropiness" and the "glue-pot" smell; therefore I can scarcely believe that it is foul brood.

ILLINOIS.

ANSWERS.—1. If the honey is of good flavor there is no objection to using it for table use. Of course not if it is foul and dirty, but there is no harm comes to the human stomach from swallowing some of the minute plants that are so deadly to the larva of the bee. If scalded it might be used for feeding, but you better not use it for feeding except early in the season, for it wouldn't be nice to get any of the scalded honey into the surplus combs, and it

wouldn't be wholesome for wintering. Perhaps the best thing would be to sell it for what it is, and have it used for printers' rollers or some such manufacturing purpose.

2. Opinions are divided as to whether it's safe to use a hive in which foul brood has been, but you'll do well to be on the safe side and not use anything in the least suspicious. Boiling-heat kills the foul brood germs, altho freezing does not. If you can have a boiler large enough to take in half the hive, scald that, then the other half. Another plan is to wet the surface of the hive with kerosene, set it on fire, then before it has time to burn the wood itself, cover it up so as to smother the fire. Of course you'll take out the chaff and burn it.

I doubt whether yours is foul brood, but there's no harm in being somewhat suspicious.

3. Lots of harm done by dividing too early. Not merely chilling brood, but dividing the force when much more rapid gain would be made by leaving the force together. You'll hardly gain anything before about swarming-time—at least not till the colony gets to its fullest strength.

Sweet Clover.

1. I send a sample of clover. Is it the sweet clover of the North? Is bokhara clover the sweet clover?

2. Where can I get seed of the sweet clover?

My bees are doing finely. Fruit-trees are in full bloom here, now (March 18.)

IND. TER.

ANSWERS.—1. As nearly as can be told from the crushed condition in which it came, the specimen sent is the common sweet clover of the North. Bokhara clover, sweet clover and mellot are all one and the same thing.

2. [See the advertising columns of the Bee Journal.—EDITOR.]

Feeding in the Spring.

1. I have a good colony of bees which I have to feed. How much sugar syrup must I feed them till they can gather enough honey to live on. This is March 24.

2. Would you encourage brood-rearing this early?

3. I got a colony of bees of a man late last fall. The bees came to his orchard and settled in a hive with a few frames. They filled the hive full of honey, leaving no room for brood. Now the hive is four-fifths full of honey, with combs crosswise and every other way, and I want to give them room for brood. Would the following do? Put a new hive filled with frames of foundation on the old stand, put an escape on top of the new one, then turn the old hive upside down on top of the new one, and drum on the old hive. If this will not do, what can I do? Of course the hives are the same kind, and I will feed the bees afterwards.

IOWA.

ANSWERS.—1. Hard to tell just what they'll need, but you'll be safe to give anywhere from five to ten pounds, then give more later if they need it.

2. Yes, at least so far as to see there were plenty of stores, and keep the bees snug and warm.

3. Your plan would be likely to lose a lot of brood when brood is very valuable. Better set the new hive right under the old one, and if they're at all crowded for room for brood, there will be no doubt about their building down and rearing brood. The only trouble might be in case your hives have fast bottoms, but in that case you could split the bottom off the old hive.

T Super—Contraction When Hiving Swarms—Candied Unfinished Sections—Use of Queen-Trap.

1. If you were to fit out a new apiary, would you use the T super, or some other one? Why?

2. When hiving swarms in a contracted brood-chamber, do you use the super the full size of the hive, or contract it also? or do you practice contraction in hiving swarms?

3. I have a nice lot of half or two-thirds filled sections that are uncapped, that have a few cells of fall honey in them that has candied. I want them for bait sections in the spring. Should they be cleaned out, or should they be used as they are, and let the bees take care of the candied part?

4. Will a heated plate answer to thin down combs in unfinished sections?

5. How about the use of the queen-trap when one can be present only at noon and evenings? Will the swarm return and remain clustered on the trap, or will they enter the hive again? Should they remain on the trap, would it not be necessary to give ventilation from some other source while using the trap? Or would you, under the conditions named above, cage the queen as recommended by some, or practice Doolittle's plan for preventing swarming in out-apiaries?

SOUTHERN OHIO.

ANSWERS.—1. With my present knowledge, I should use the T super, because with it I can get nice sections of honey with less labor than with any other I've tried. It is entirely possible, however, that some new arrangement may come up that may be better than the T super, and if it were possible to wait, I would not fully stock up till I had pretty fully investigated.

2. I have never practiced contracting a super except in case of a prolonged and very slow harvest. If I hived a swarm on less

than the full number of frames, I'm inclined to think I should use a full super, but I do so little at hiving swarms that I really don't know what I would do.

3. I very much doubt whether you can use those sections in any possible way to produce first-class comb honey. Certainly it wouldn't be first-class if you leave candied honey in them—and the bees will not uncandy it—and you probably can't get the sections emptied in any way so there will not be granules left, and the least trace of that kind will affect the fresh honey stored in them. If you think best to use one of them as a bait in each super, be sure to keep it out of any honey you may sell as first-class.

4. Excellently. Indeed, that's just what the B. Taylor Handy leveler is, with the very important addition that it automatically stops the melting when it gets to a certain depth.

5. In most cases the swarm will return, whether the bees remain altogether with the queen, or all go into the hive, or compromise the matter by dividing up and going both places. Ventilation is important, and additional ventilation will be well unless the trap be made very large and open. I think it might be well to give Doolittle's plan a fair trial. It must be remembered, however, that what seems to work all right at one time may fail another. Also that a plan may be entirely successful in Doolittle's hands, and in some other person's hands a failure, just because some little kink is not followed up in one case as in the other, and the kink may be so little that Doolittle himself would hardly suspect it would make any difference. For instance, Doolittle said to put sealed queen-cells in supers and the young queen would hatch out, kill the old queen and take the reins of government into her own hands. I tried it on a pretty large scale. The young queens hatch out all right, and in at least one case that I watcht closely the young queen was found on the combs in the brood-chamber a day or two after emerging from the cell. A day or so later she was gone. In every single case the old queen remained and the young queen was removed. I learned later, what perhaps I might have known in the first place if I had more carefully read instructions, that the work should be done at or near the close of the honey harvest. I had done it much earlier. So in trying any new thing we must not condemn the plan as a failure unless we know to a dead certainty that we have fulfilled every condition.

Spring Feeding—Smartweed Honey.

1. I had four colonies wintering on the summer stands, and have lost the strongest one from dysentery. They filled the brood-combs and 20 one-pound section-boxes of just such honey as I send you a sample taken from a section. Now, as I have these sections and the eight frames, of which the outside ones are solid, and the others more or less filled with this black honey, I would like to know if it would be safe or advisable to feed it when the weather permits the bees to work every day. I would like very much to use the brood-combs, as they are straight and almost free from drone-comb. They were drawn last season from full sheets of foundation. My bees are within one-half mile of the city; possibly they got into an old molasses barrel.

2. What kind of honey does smartweed yield? We have quite a lot of it here.

This honey was gathered in September. My three remaining colonies seem strong, and are flying now almost every day.

NEW HAMPSHIRE.

ANSWERS.—1. It is safe to feed almost anything bees will take when they have frequent flights and are not storing in supers, unless it be honey from a foul-broody colony. I should not hesitate to use such as you have sent.

2. There is a difference in what is called smartweed. What is perhaps properly called smartweed has an exceedingly acrid taste when the leaves are chewed. The plant, however, which yields the most of what is called smartweed honey, if I am rightly informed, has no smarting taste at all, altho the two plants look very much alike. Its right name is heart's-ease. Heart's-ease honey, altho dark, is very much liked, generally, where it abounds, as in the Mississippi bottoms. The sample you send is probably a mixture of fall flowers and molasses, as there seems to be present quite a strong odor of the latter.

Starting in Bee-Keeping.

We expect to be novices in the bee-business this spring. We want to start in right. We are located a little south of the center of the State of Minnesota. Please tell us in plain English what kind of a hive to get, how made, how many frames, size of frames, how many stories, etc. Any other information about hives that would help a beginner would be thankfully received. Now having the hive all complete, what kind of bees shall we stock up with? We want the standard, the very best for this section. A thumb-nail full of your experience as a starter.

BROTHERS.

ANSWER.—First and foremost, and by all means get a good text-book. May be you better get two, so you needn't quarrel about which shall have it first, for it isn't pretty for brothers to quarrel. There's no harm in having different kinds of books, but whatever you do, don't have more than one kind of frame. At least only one size of frame, and probably the nearest to a standard size is what is called the Langstroth or Simplicity-Langstroth size (in reality every movable frame is a Langstroth) 17 $\frac{1}{2}$ inches long and 9 $\frac{1}{2}$ deep, outside measure. It doesn't matter so much just what the hive is if you're all right on the frame. Perhaps the dovetailed is as good as any.

You say, "how made," darkly hinting that you want instruc-

tions how to make the hive yourselves. Now I'm a good deal of a coward, and dare not tell you, for if I should, one of you brothers might sometime meet me with a gun in a lonely place, and a jury would hardly convict you for shooting any one who should give you encouragement to build a hive yourself without any experience, when you can get one all ready to nail together for little more than the lumber costs, and everything about it made with more exactness than any good mechanic could make it for double the money. Even if you think you must make your own hives, get one for a pattern.

Number of frames—that's a puzzler. I'd like a chart of the bumps on your heads first. If the bees are not to have very much intelligent attention, not less than 10 frames, and then they're not so likely to starve in winter. Even with the best attention it's possible 10 frames or more are best, certainly for extracted honey. But if your intention is to put all the brains you can into the business (don't forget a good book) perhaps an 8-frame hive run two stories part or all of the time may be best. With more than eight frames to the hive, you will hardly want more than one story for comb honey, and perhaps not more than one story for brood if you run for extracted.

Now, as a matter of important advice, I must not forget to mention a good text-book on bees as the very first thing. If you can't get one in any other way, sell out your right to the American Bee Journal and invest the money in a book, and then I'm sure you'll find some way to get the journal afterward, but get the book in some way, and then study it thoroughly. You'll find some things then that you'd like to ask questions about, and this department is always open for people like you.

Nearly forgot to answer what kind of bees. I can only answer for myself. If it was as easy to get one kind as another, I'd have pure Italian. If there were no other bees within five miles of me, I'd have pure Italians anyhow. But if common blacks are within a mile, it doesn't matter so much how you start, for your stock will be mixt more or less anyhow, and you can get fresh blood after you start. Expressage on bees costs so much, that in the latter case you might do well to start with whatever kind you can easily get right near you, and then you can get a pure queen afterward. Better start with the wrong kind of bees than the wrong kind of frames. You can change the bees better than the frames. Don't forget the book.

Questions on Size of Brood-Chamber.

1. How does G. M. Doolittle's article on page 49, favoring a 10-frame hive, correspond with your experience in using two 8-frame bodies for one brood-chamber?

2. What is the greatest number of frames you have had occupied with brood when the white clover flow began, where the queen had access to 16 frames?

3. Suppose we have 12 frames in one body, and reduce to eight frames at the opening of white clover, as per Mr. Doolittle (removing 1 brood if necessary), and put on a 32-section super, would you consider such a colony in good condition to gather the greatest possible amount of surplus? If not, why?

4. If a 10-frame body will give the queen all the room needed, would it not be economy both of time and money to use the 10-frame instead of two 8-frame bodies?

5. Would you recommend other than the 8-frame hive, (one or two story for the brood-nest) where white and alsike clover gives the main surplus, and heart's-ease, Spanish-needle and other fall flowers generally yield until frost?

IOWA.

ANSWERS.—1. Mr. G. M. Doolittle is well informed, a careful observer and a conscientious adviser, and you're quite safe in trusting him. My experience corresponds in the main with his; whatever of difference there may be you will find in replies to your other questions and in summing up.

2. I may have had more than 14 frames with brood in them, but I hardly think I've had more than what would be called 14 frames of brood.

3. One thing I should not like about it is, that a fourth of the sections would be without any brood-combs under them, and I never could get bees to work as well in such sections.

4. Decidedly yes, if there is room for the queen and the necessary stores.

5. I don't know.

And now I may say on this whole subject of deciding as to the size of a hive, if I had to choose and start all afresh, I would have some difficulty to decide. Many things are to be considered. I certainly would not think of using an 8-frame hive and confining a colony to that the year round. In some cases a 10-frame hive wouldn't be big enough, and then it would be convenient to enlarge to 14 or 16 frames. Having a space under sections filled with dummies doesn't work satisfactorily, and on that account the 8-frame hive would have the preference. Other things being equal, a strong man would choose a 10-frame hive, and a weak one the smaller. Having two stories is more trouble than having a larger hive in one story. It's less trouble to have a large hive well stored for winter than a small one. The man who uses two stories must count on giving his bees close attention at the right time. His bees will take care of themselves better in a large hive. But if I were obliged to use only one story the year round, I suspect I'd want it larger than 10 frames.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See offers on page 223.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

APRIL 7, 1898.

NO. 14.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "di" or "ed" final to "ti" when so pronounced, except when the "e" affects a preceding sound.

The Pure Food Congress.—Last week we gave a short report from Rev. E. T. Abbott, who, with Hon. Eugene Secor, was a delegate to the Pure Food and Drug Congress which met last month in Washington, D. C. Now we have the privilege of presenting an interesting report by Mr. Secor, General Manager of the United States Bee-Keepers' Union. It will be read with interest, and is as follows:

REPORT OF DELEGATE TO THE PURE FOOD CONGRESS.

The "Pure Food and Drug Congress" which held a three-days' session in Washington, beginning March 2, was a notable and important gathering. Notable in its personnel, notable in the earnestness exhibited by its members, and notable in the fact that not a suspicious breath was detected on any delegate during the life of the body. This fact alone marks its lofty purpose and its fealty to a high ideal. Reformers need no stimulant to action except a noble aim. The delegates and visitors were of such character and ability as to impress one with the idea that some important object was behind the motive which brought them together.

Altho this was the first national gathering of the kind, 21 States and about 15 organizations were represented by regularly appointed delegates. From those States which have the best and most efficient pure food laws—notably Ohio, Pennsylvania, and New York—the largest delegations were present. These States, having had the most experience in trying to enforce State laws against adulteration and misbranding, feel the necessity of national legislation along the same lines.

Leading chemists, celebrated physicians, and earnest educators, were in attendance. Dr. H. W. Wiley, who is at the head of the Division of Chemistry of the United States Department of Agriculture, gave a very instructive lecture before the Congress, illustrated by samples of food products most generally adulterated. Secretary Wilson was present and address the body, as well as Congressmen.

The object of this congress was to unite all food and drug

interests on a uniform plan of operation before the Congress of the United States. Heretofore every specialized interest was pressing its own claims independent of all other interests. The M. D.'s thought only of drugs, the dairymen only of butter, the bee-keepers only of honey, etc. If all these and all other organizations representing people who demand honesty in the preparation, branding and marketing of all products, especially those intended for human consumption, could unite on a common ground, and unitedly present to the Congress of the United States their combined influence in the interest of the unprotected consumer, a long stride forward would be accomplished.

Competition in business is now so intense that the honest manufacturer or dealer in food products or medicines has no show in the market of the country. Adulteration, misbranding, and imitations, are carried on to such an extent and produced with such skill, and are prest upon the public with such persistency and adroitness that the conscientious manufacturer of food or drug preparations cannot compete and prosper. Therefore, in the promotion of the pure-food idea we have not only the consumer with us, but also all dealers and manufacturers who would prefer honesty to fraud if they can be protected in their business.

State laws alone are insufficient. Decisions of the United States Supreme Court touching the interstate feature of our commerce renders it necessary to reinforce State laws by national enactment.

The aim of this convention was to agree on a Bill to present to Congress. The Brosius Pure Food Bill, which had already been introduced in the House, was taken up and carefully considered by a committee of 25, representing every food and drug interest. Mr. Abbott was placed on this committee. He and I first went over the Bill very carefully, keeping in mind the industry which we represented, and when it had been considered in committee I noticed it was reported back endorsing the suggestions made.

Thus the Bill ran the gauntlet of every interest represented in the convention. When reported back it was taken up section by section in committee of the whole, and almost unanimously endorsed. It will therefore go through Congress with the united influence of nearly all the Pure Food organizations; all manufacturers of foods, medicines and condiments who are honest; all dealers who would rather sell a pure preparation than an adulterated one, and all consumers for it goes without saying, that the great mass of people want honest dealing—they want to pay for what they buy, and not pay a high price for a cheap article.

I said that heretofore there has been a great diversity of opinion regarding the ideal pure-food law. Some wanted imitation butters *prohibited*. Some wanted glucose *taxed* out of competition. Some thought that all combinations and mixtures should be outlawed. But the sober, second thought of all the interests brought together at this convention was to allow the greatest freedom to manufacturer and consumer consistent with honesty.

If the people prefer glucose to extracted honey, let them buy it; but they have a right to know *what* they get, and ought not to pay for the former when they get the latter. The bottler has no right to label pure glucose, or any package containing any portion of it, "Pure White Clover Honey." This is what they are doing now, and this is what the producer of honey has to compete against.

Now let every bee-keeper write a personal letter to his Representative and Senator, asking them in the interest of fairness to every honest industry to vote and urge the early consideration and adoption of the Brosius Bill, H. R. No. 5441. Something like the following might do, in writing to your representative in Congress, if nothing better can be said:

TO THE HON.

Washington, D. C.,

Dear Sir:—As one of your constituents who is interested in the subject of food adulteration, and anxious that all preparations of food and drugs shall be put on the market for exactly what they are, I write to ask your support and influence for the Brosius Pure Food Bill, H. R. No. 5441, now before Congress, which I understand to be in the interest of honest branding of all preparations consumed by man.

I represent an industry which is suffering from the unjust and dishonest competition of a cheap and inferior adulterant, but I ask your support of this Bill because I believe it will protect all honest producers and dealers, and discourage fraud and deceit in the preparation of everything intended for human food, and will aid in the enforcement of State laws enacted in the interest of pure food.

Respectfully yours,

_____, Bee-Keeper.

I have only to add that the delegates of the United States Bee-Keepers' Union received full recognition at the convention, being placed on the most important committees, and

granted equal rank and honor with other organized industries. They were able to correct some false impressions, and to place the industry of honey-production on an equal footing with other rural occupations before the promoters of Pure Food legislation.

EUGENE SECOR,

Delegate to the National Pure Food and Drug Congress.

Forest City, Iowa, March 29, 1898.

We give nearly all our editorial space this week to the above subject, because we believe it is an exceedingly important one. We trust that bee-keepers will at once act upon the suggestion made by Mr. Secor, so that their Congressmen may be prepared to vote intelligently when the Brosius Bill comes before them for action.

Judging from the reports made by Messrs. Abbott and Secor, we believe that it was one of the wisest things possible for the United States Bee-Keepers' Union to send its delegates to the Pure Food Congress. They did their work well, and as Mr. Secor says in his last paragraph, "placed the industry of honey-production on an equal footing with other rural occupations before the promoters of Pure Food legislation."

Paul Whitebread and His Apiary.—Mr. Whitebread, whose apiary is shown on the first page this week, writes us as follows about himself and his apiary:

I was born Oct. 31, 1869, in Luzerne Co., Pa., where I have ever since had my home. In 1892 I became interested in bees and bought a colony in a box-hive at a public sale. The next spring I sent to Ohio for a colony of Italians in an S-frame dovetailed hive, then I subscribed for a bee-paper and bought all the best bee-books I could find, and increased my bees by artificial and natural swarming. I never lost a swarm by absconding (going to the woods at swarming, or any other time), but I had heavy winter losses till I filled the upper stories with chaff, and laid something across the top of the frames for the bees to pass from one comb to another.

Last spring (1897) I started with 45 colonies, and increased by natural swarming to 65. I got 1,100 pounds of comb honey. I produce no extracted.

A few years ago but very few bees were kept around here, but now there are lots of them, and nearly all Italians or hybrids, and in improved hives. I have tried the different races of bees, and have settled on the 3-banded leather-colored Italians; and in hives I find the S-frame dovetail with Hoffman frames my choice, but I was thinking the hive and frames might be a little deeper, so I built 16 hives 2½ inches deeper than the regular dovetail, and had them filled with swarms. They winter bees most excellently, and I have had some in use now two seasons, and I could find no difference in the amount of honey gathered per colony between the standard and the deep frames.

I have in my apiary 65 colonies—45 in regular dovetailed hives, 16 in deeper hives, but same width and length as the regular dovetail, two in hives with frames 13x9, one American, and one box-hive. The hives stand in rows 6 feet apart, and 3 feet apart in the rows. All the hives face the south, and are on stands 4 to 6 inches high.

On the corner of the hive with the cover off, is my "smoke engine;" and the frame I hold in my hands is a Hoffman. It was rather cold, and the bees were clustered on the center of the combs when the photographer came, it being Nov. 17, 1897, almost too late to open a hive.

They were nearly all packed for winter, with chaff in the upper story or super. (Myself you can see in the picture, but my wife you cannot, for I have none.)

PAUL WHITEBREAD.

Perhaps by the time Mr. W. has another picture of his apiary taken, he will have it a little more complete, showing his wife, who, no doubt, whether or not she is a good baker, will ever after be sure of having good "White bread" in her house.

A Convention in Wisconsin.—Mr. N. E. France, the hustling State Inspector of apiaries for Wisconsin, expects to hold a meeting of bee-keepers at Ft. Atkinson, April 11. He has already promised an attendance of 60. This will be a fine opportunity for bee-keepers in Jefferson Co., Wis., to meet Inspector France, and also to have a good bee-convention. Go if you can, and help in the meeting.

To Preserve Combs of Pollen, take them when they are fresh from the hive; with a dredging-box, powder them with fine sugar, lightly knock off the superfluous sugar, and then put them away in a suitably dry place.—Noerdl. Bztg.

Selling Honey—Producing honey is one thing, and selling it another, in the judgment of Friedemann Greiner (Gleanings, page 169), and he thinks it might be well if New York bee-men had something like a honey-exchange, with some one like S. A. Niver for salesman.

Slant of Cells.—E. R. Jones says in Southland Queen, that in transferring brood-combs it doesn't matter which side up the combs are that were used for brood-rearing when first built, but those first used for storing honey are built with an upward slant, and are better right side up.

The Holtermann Hive-Cover, as described in Canadian Bee Journal, is one which telescopes half an inch, has two end-pieces, two side-pieces, a bottom-board, galvanized iron top, with packing of ashes, sand or loam between the boards and iron. Claims to be cheap—doesn't say how cheap—water-tight, and a good protection against heat and cold. Surely aiming in the right direction.

A Longing for Better Spelling crops out in a foot-note in Gleanings. The editor says: "I wish both precedent and custom would permit us to spell by the phonetic method; that we might even go as far as Bro. York, in the American Bee Journal; but as we do so much printing for other parties, our printers and proof-readers would be in a snarl of confusion if we attempted to carry on the two systems—can't do it."

Score One for Full Sheets.—American Bee-Keeper quotes J. A. Green at the Chicago convention, on the use of comb foundation in section honey: "If you have a small strip in the top the consumer can tell it; if not, nine times out of ten he can't detect it;" and adds that if there is a difference in the foundation and natural septum, to associate the two in one section is to invite the attention of the consumer to the contrast.

Breeding from Good Stock.—Of late considerable has been said about breeding to improve stock. The editor of Gleanings has seemed just a wee bit inclined to throw cold water on some phases of it, but the editor of American Bee-Keeper says, "Too much cannot be said regarding the improvement of our stock." J. B. Case gives a strong illustration of gain in amount of crops, simply by rearing queens from colonies that gave largest yields.

Cause of Low Honey Prices.—Ed Jolley, in American Bee-Keeper, thinks one reason for low price of honey is the fact that producers rush off the crop to commission-men, and they being overloaded, each one tries to put the price a little lower than others to give their shippers first chance, and this honest effort results in low prices for all. Another factor is competition with sugar and syrups. Thinks unity among producers and thorough organization the desideratum.

Working Up the Honey-Trade—J. H. Martin is backed up by the editor of Review in saying the permanent results of honey exhibitions at fairs are by no means as great as generally supposed. People see so much of everything and look so fast that few permanent customers are made. Much more efficacious are exhibitions for a day or more at groceries, explaining to customers and distributing honey-leaflets. The California Exchange has been doing a good thing by keeping two hustling agents on the road to drum up trade.

Effects of Different Honey-Flows.—In Gleanings, R. C. Aikin gives some of the results of his observations from scale-colonies. He thinks something like a third of the ingathered nectar is lost in evaporation. With a daily average of 1½ pounds, even strong colonies could scarcely be induced to do anything in sections, the tendency being to lengthen the cells

in the brood-chamber and crowd the honey in there, rather than to build comb in a new place. In 1894 he got more extracted than comb, but a lot of the extracted-honey colonies starved in winter and the rest had to be fed in spring, making the advantage over comb honey more apparent than real. Bait sections were filled, no matter where they were put in the super, being usually the only ones filled. For good work in sections, especially in the hands of any but an expert, he thinks a flow of three to four pounds per day is needed.

A Robber-Stopper.—A simple and ingenious instrument to stop robbing is given by M. Pirson, in *Rucher Belge*. Take a cigar-box (any similar box will answer, even a paste-board box); remove the lid and one of the sides. At one end make a hole about $\frac{1}{8}$ inch square, so that one bee at a time can pass, and cut out of the bottom a strip perhaps 4 inches by $\frac{1}{2}$. Place it at the entrance of the hive, closing any part of the entrance not closed by the robber-stopper, and the robbers are afloat to go in the large hole. If a single one enters the small hole it will be dispatched.

Disturbing Bees in Winter.—Editor Hutchinson copies C. P. Dadant's article from the *Busy Bee*, in which he strongly argues the damage arising from winter disturbance, then calls up the discussion in the first number of the *Review* published, in which were given many instances where bees had been disturbed during the winter repeatedly, moved from one part of the country to another, hives opened in cellar, bees fed, etc., and no harm done. Well, it's some comfort to know that one doesn't really need to kick 'em around much in winter, anyhow.

Sweet Clover.—Prof. Cook is taken to task in *Gleanings* for his sweet clover views. The editor says: "My, oh my! where has Prof. Cook been these years?" Mr. Boardman and a dozen others can show him that stock prefer it to other fodder; the Ohio Experiment Station that were once down on it, favors now its introduction, and in some parts of the West hundreds of acres of it are grown, and hundreds of tons of it cut for fodder. He ends up by saying: "Where nothing else grows it is a Godsend. I should almost as soon expect to hear Prof. Cook say the honey is not round as to argue against sweet clover."

Cleats vs. Handholes for Hives.—The Straw man of *Gleanings* gloats over the fact that two such men as Mr. Boardman and Mr. Doolittle agree with him in preferring cleats to handholes for handling hives, to which the editor replies: "I am half inclined to believe that you and Mr. Boardman are right; but keep this to yourself. We make the handholes because they are cheaper, take less room in crating, and because bee-keepers generally are satisfied with them. I suppose the fact is, the average bee-man does not lug his bees in and out of the cellar as much as you and Mr. Boardman do, and that is why he doesn't complain."

Variation in Bees.—J. E. Crane, in an interesting article in *Review*, declares that variation in bees as to their different characteristics, is fully as great as among other domestic animals, and as valuable. He instances differences in temper, comb-building, promptness in working in supers, daubing with propolis, gathering pollen, swarming, etc. He instances one colony that had the peculiar trait of tearing down their brood-combs in spring apparently out of pure cussedness, and after they had done so for the third spring he knocked out the trait by changing the queen. The moral of it all is that there is a fine field for intelligent and progressive bee-keepers to greatly improve their stock by proper selection.

Somewhat Voracious Mosquito-Hawks.—The voraciousness of mosquito-hawks or dragon-flies that fill the air by tens of thousands around apiaries in localities near the sea in the South, catching and devouring bees by wholesale is something frightful according to the editor of the *American Bee-Keeper*. On several occasions he caught two that were eating bees, allowed one to eat all that was eatable of the other; "then turning the long, slender posterior of the still eager gourmand to its head, it would immediately proceed to consume its own body with the same apparent avidity and relish that it had shown for its earlier victims, the bees." So those Florida fellows are not without their own troubles.

Plain and Tall Sections are not favorably considered in the *Canadian Bee Journal*. The editor says go slow and look on for a season. He says "it is unreasonable to suppose that the bee-space, secured through an attachment to the separator instead of the section, would give a better-filled section."

Thinks bee-keepers who adopt this style of section will be disappointed and lose money. S. T. Pettit calls the plain section "a silly fad." If the bees are crowded as he usually crowds his to get well-finished sections, the cappings would be fastened to the fence. "This talk about less peep-holes and better-finished sections is all nonsense." He objects to a tall section that the foundation is more liable to sag and curl out of shape than in a square one; may look a little better, but there will be no more money in it in the end.

Bee-Keeping for Farmers.—D. N. Ritchey is very emphatic in the belief that every farmer should keep bees, and says a farmer who hasn't one or more colonies is not up to the times, which is a little rough on T. B. Terry and other leading agriculturists. He thinks not five per cent. of the farmers have honey on the table as food, and he probably might have made the percentage much smaller without distressing the truth. A notable statement is this: "I can show you farmers living by me who had not had a crop of clover seed for 20 years, until I moved here and bred my bees to such a size that they can work on the red clover; and now they are getting large yields of the very best of seed."—*Busy Bee*.

Plain Sections are somewhat disesteemed by Hasty in the *Review*. Apparently taking it for granted that they will be filled out more plumply than the others, with almost certainly no collusion with Doolittle he falls into the same line of argument, picturing the not-over-skillful Bridget as with case-knife in hand, she cuts out the honey. "Half the time the knife wanders away from the wood. Besides the main square, several thin slices of comb have to be stacked on one side of the plate, to the serious detriment of looks." Where the outside row of cells is not sealed, even a child can see where to cut. The edges of the cake are all nicely rounded off to start with, and will remain so. He concludes that plain sections will look best at grocer's and the other kind on the table, and "good looks on the table are all our customers are willing to pay for when once their minds are directed to the matter. And those of us who sell largely to consumers are likely to do some missionary work right in that spot."

Plain Sections.—A little set-to in *Review* between Doolittle and the editor. Referring to that beautiful picture in the *Review* of the four plain and four old-style sections, in which the plain ones were so much better filled out next the wood, Doolittle says he decided at once he preferred for his own use one of the old-style sections because it would cut out more easily, look better on the plate, and not drip so much. He thinks also that the two lots of sections were not built by the same strain of bees. Hutchinson doesn't know about the bees that built the two lots, and admits he'd choose for his own use same as Doolittle, but gets back at him in good style by saying, "the time when we, as producers and sellers of honey, wish a section to look the most attractive, is when it sits on the counter and there is a man with 15 cents in his pocket standing in front of it and trying to decide whether it is best to have the money and the honey change places." He also considers it very important that the comb should be well filled to the wood to secure safety in shipping, and even in handling after it reaches the grocer.

Cleome Pungens, or Giant Spider-Plant.—Rarely does one see any notice taken of bee-keepers' interests in seed catalogs, but here is a notice of one of the novelties in flower seeds of several years ago, in the catalog of R. Scott & Son:

"This is one of our native annuals, but little known and yet well worthy of general cultivation. It is a robust plant, growing vigorously four to five feet high, unaffected by wind or weather, and flowering profusely and continuously for months. In fact, it is a *perpetual bloomer*; it begins to flower when only a small plant, the spikes continuing to increase in size as the plant grows, until they reach upward of two feet in length. The flowers are very showy, with long, slender stamens; single petals measuring an inch across, and of a bright rose color. As the spikes grow and the lower flowers drop off, the curious seed-pods are formed—the plant maturing ripe seed while still in full bloom. These long, slender seed-pods, reaching out in every direction, are carried upon still longer stipules, giving the effect of a *many-legged spider*, with the bright bunch of flowers as the head. As a background, in a group or scattered among shrubbery, *Cleome Pungens* is very effective; it grows freely from seed sown in the open ground, thrives luxuriantly, and blooms all summer, no matter how unfavorable the season may be. It is also one of the very best honey-producing plants. The bees delight in it, and cluster about it constantly while the flowers are open, which is after 5 o'clock in the afternoon and before 10 a. m.

GENERAL ITEMS

Gathering Pollen.

My bees are doing very well here. They have been gathering pollen since Feb. 5, and will soon work on tree blossoms.

Oscar Gessner.
DeKalb Co., Ga., Feb. 25.

Two Seasons' Report.

I started with 5 colonies of bees two years ago, increase to 13, and lost one. Last year I increase to 32, and removed 700 pounds of nice comb honey in one-pound sections. Success to the American Bee Journal.

John H. Amos.

Not a Good Season.

I have 22 colonies that seem to be all right. Last season was not a very good one with us. I had 14 colonies in the spring, sold 3 swarms, increase to 22, and got 300 pound of comb honey. I sold it at 12 1/2 cents.

Wm. M. Milton.
Franklin Co., Kans., March 5.

The Season of 1897.

My bees did very well in 1897. I started with 17, increase to 31, doubled back to 25 colonies, and got about 500 pounds of honey, about half comb and half extracted. My bees seem to be in good condition so far this winter.

Winchester Rickel.
Kosciusko Co., Ind., Feb. 20.

Seem to be Wintering All Right.

I have taken the American Bee Journal for a good many years, and could not keep bees without it. I am wintering 143 colonies, and they seem to be wintering perfectly. I had about 13,000 pounds of extracted honey last year from 100 colonies, spring count.

F. B. Farrington.
Winnebago Co., Iowa, Feb. 21.

Hopes for a Good Crop.

Bees are all alive. The sun shines and the spots don't show much now. I feel fairly well, and hope for a good honey crop, and a better market. It has been weak the past two years. I have quite a lot of honey on hand, and if I could find ready sale I would be content to stick to it, but I expect to stick without the content, any way, if not any improvement. Swim or sink.

E. H. Sturtevant.
Washington Co., N. Y., March 2.

Several Seasons' Report.

I commenced in 1895 with 2 colonies, and got no honey or swarms that year, but in 1896 I got about 15 pounds of surplus and 3 swarms. I lost one in wintering, in 1897, and had 4 left in the spring. I had 9 swarms, and about 200 pounds of honey, and to-day all my bees are having a good flight—12 colonies in all. I lost one colony last fall. It became queenless. I winter my bees on the summer stands.

B. F. Sturgeon.
Columbiana Co., Ohio, March 7.

That Big Yield of Honey.

I see I have been called up to explain a mistake; also I received a private letter or two "calling me down," something in the same manner as did Mr. H. F. Baker, of Florida, for reporting such a large yield of honey.

In the first place, I did not intend anything should be printed. All I said was to give the editor to understand that I was getting a great deal of satisfaction from the American Bee Journal. I did not have

Sweet & Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

any thought of telling a big story. I only intended to say that we have a little honey in this State, and that I can *divide* and get some honey. I think from the result I did obtain, I could almost or quite obtain the results reported, that is, taking it as the editor explained, by taking the whole increase, as we have a very heavy fall flow.

The statement I intended to make was that, from a colony artificially made, that is, *one artificial swarm hived on only starters*, I took off 137 one-pound sections of honey. Now, how the figure of the 1-pound sections got fastened on to the 137, I cannot understand. But I could tell a story much larger than I intended, but I don't want to get the reputation for big stories.

Clay Co., S. D. THOS. CHANTRY.

[It looks as if we got Mr. Chantry's figures somewhat mixt. We are glad to give the correction.—EDITOR.]

Results of the Past Season.

We had a good flow of white clover honey till July 4, and got some of the finest honey I have seen. But we had dry months of July and August, and the bees stopt short carrying in any honey until the first of September, when we had a good honey-flow again, but it was of a dark color. Our average was 75 pounds per colony. We have had a mild winter so far, and bees are wintering well, both in the cellar and on the summer stands. J. G. RISLOW. Winnebago Co., Iowa, Feb. 21.

First Flight Since Thanksgiving.

The bees had a good flight here Feb. 8—the first since along about Thanksgiving. They are affected with dysentery, and have spotted the hives considerable. I have lost but one colony, that starved with honey on the opposite frame, the weather being so cold that they could not reach it. It was in a single-walled hive. To-day the weather is more springlike, and for the bees favorable, with no bottom to the roads, the mud being so deep that it is almost impossible to get around with a team. J. M. YOUNG. Cass Co., Nebr., Feb. 14.

Anti-Adulteration—Gathering Pollen.

I am deeply interested in the pure food and drug movement. I think it is one of the most important subjects now before the American people. It seems to me that enough poison has gone down the throats of the people in adulterated food. The bees have been confined to the hives but three or four days at a time this winter. They have been gathering pollen from maple and elm for some days. The honey-flow is not affected here by rainfalls in the same way it is in California. For instance, the poplar is the first important flow, and at that time of year we have sudden heavy rains which frequently come when it is in bloom, washing away the nectar.

I could not think of doing without the American Bee Journal. J. S. M. KELLY. Jackson Co., Ala., Feb. 22.

Mild Winter—Manzanita Honey.

I lost one of my colonies last fall by worms, being unable to attend to them, but I have 13 colonies left to start with in the spring. We have had a very mild winter here so far. The bees have been gathering pollen for about two weeks from the willow and hazel. The peach blossoms are beginning to open. I am afraid we will have an early spring, and kill all our fruit if the weather doesn't change. Our coldest nights this winter were about the first two weeks in January. My bees look fine. I am just able to hobble out to my bee-house. I have a bee-house with two rows of hives facing east and west. I do not think we can do without a bee-house here, on account of the long, hot summer.

I have noticed that the manzanita does not bloom every year. I would like to hear from some of the others about manzanita

A Good Bicycle Free

Now, then, young men and young ladies, also boys and girls, take advantage of this offer and get a Wheel (A THOROUGHLY GOOD ONE) with a little work. To increase our circulation we have made arrangements with a first-class concern in this city to furnish us with their well-known 1898 Model

ALAMO WHEELS

at a price which enables us to give one FREE as a premium for sending us 50 New Subscriptions to the Bee Journal at \$1.00 each. You can send them in as taken, and when your list of 50 is complete, we will ship your beautiful wheel, freight paid, to your nearest depot. This wheel retails in the ordinary way at \$50.00—and it concerns nobody but ourselves how we managed to get in on the inside cut price. For 40 Subscriptions we will ship a Juvenile of the same make. Below we give specifications:

Frame—Shelby Seamless Tubing. 1 1/2 Main Frame. Connections—Steel (selected.) Fork Crown—Oval (drop forged.) Handle Bars—Steel or wood, drop or upturn; cork grips. Wheels—28 inch. Pedals—rat trap. Rims—best elm. Tires—Morgan & Wright or Vim. Spokes—selected piano wire. Bearings—Tool steel (turned by experts.) Gear—64 to 80. Saddle—leather (rubber or felt neck.) Weight—23 to 25 pounds. Color—black, maroon, nicely striped. Special color by arrangement. Furnishings—Tool bag, oiler, wrench, air pump, etc.

Ladies' model built on same lines with the usual difference between sexes, such as rubber pedals, etc. Address.

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

honey. Have you ever had a sample of it? I thought I would be able to send you a sample of it this year, but I do not think I can, from the way it is looking. All the cry around here is for manzanita. It is the finest honey we get here.

I wish Prof. A. J. Cook could have seen our cattle eat sweet clover last summer; they would leave everything else for the clover. **W. A. PELLEV.**

Nevada Co., Calif., Feb. 27.

[No, we have never seen any manzanita honey, as we remember. We should be pleased to taste it.—EDITOR.]

Wintering in Sheds.

I placed in winter quarters, in December, 1896, 15 colonies. I lost two in wintering, and to the 13 I added 4 colonies by purchase, making 17 in all. These I increast to 38, and produced 2,300 pounds of first-class comb honey. Not having a suitable cellar, I have wintered my bees in common board sheds with double horizontal doors opening toward the south. In warm days I open the doors and let the bees fly. At present they seem to be in good condition.

C. A. STEWART.

Kane Co., Ill., Feb. 21.

Section-Cleaners—Wintering Well.

Referring to page 147, why does not Mr. Golden use a continuous belt instead of a gear? Gearing always runs harder, and with more jar and noise.

I think the American Bee Journal is all right. We were introduced in January, 1898, and I am always at the post-office Thursday mornings, and have not failed as yet to get it on that date.

My bees are wintering finely. They have had two flights this week, and our prospects here are for an early spring and a good honey-flow. **GEO. O. MORRIS.**

Bureau Co., Ill., March 11.

Another Bachelor Bee-Keeper.

The answer to the question askt by a bachelor information seeker of Tennessee, on page 155, is so good that I think it will stand referring to once more. We have a bright-eyed girl in our neighborhood that soils her slender hands washing dishes. But a bachelor bee-keeper walks 1 3/4 miles nearly every evening in the week to help her, for the sunshine of affection he receives. Would she wash those dishes in less time by herself? **SUBSCRIBER.**

Acton, Calif.

[Certainly, if the bachelor bee-keeper tried to help her wash the dishes, the bright-eyed girl could do it in less time alone. But if he did nothing else but wipe them while she washt them, of course the two ought to get through sooner.—EDITOR.]

Bees Under Snow.

This has been the snowiest winter I have known here, and bees have had fewer flights than in any winter before since I have kept bees. Mine are all on the summer stands, and were flying freely from all hives about Feb. 9 and 10.

It may not be out of the way to give utterance here to a word of caution about leaving entrances to hives clogged with snow. I notice that some bee-keepers are inclined to take considerable risk in this

Bee-Hives, Sections, Shipping-Cases—everything used by bee-keepers. Orders filled promptly. Send for catalog. **MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO.,** Nicollet Island, Minneapolis, Minn.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polisht, snowy-white Sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c., postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.
Address, **Lehay Manufacturing Company,** Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.

direction. I have had to clear the entrances many times this winter. Once when there was a snowfall of two days I cleared them two or three times; and sometimes found the bees of strong colonies crowded against the snow at the opening, as if suffering for want of air.
Decatur Co., Iowa. **EDWIN BEVINS.**

A Correction—Wintered Well.

I want to make a correction: On page 166, where it says six years it should have been 36, when sweet clover was sown in our town and spread out on the roads. I have taken the bees out the cellar. All colonies are good and strong, and have worked two days on the maple blossoms.
Will Co., Ill., March 19. **C. SCHRIER.**

Honey-Dew.

Bees have been working on willows for over 40 days, and as the fruit-trees are commencing to bloom now they ought to be in good condition for a harvest if this year is not too dry. If honey-dew comes from Heaven, it's a pretty small one, for I have watcht it fall and saw that it comes from the aphides. Last summer, on some low willows where I could see them easily, I saw the aphides in small clusters on different limbs, and they exuded (especially if disturbed) small drops of a clear, sweet liquid. Where it fell on the limbs it was turned dark and was gummy. Bees and other insects were working on it at the time. I have seen bees working on oak trees the same as on those willows, but I didn't investigate closely.
Sacramento Co., Calif., Feb. 24.

Money in Doubling-Up Colonies.

Five reasons why I double up.
1. To strengthen the colonies.
2. To get more honey.
3. To do away with old queens.
4. To do away with old combs.
5. To prevent increase.
It is better to double up in a honey-flow. Double up late in the evening when all the bees are at home. To unite No. 2 and No. 4, take the cover off of No. 4, smoke them well, then puff some smoke in at the entrance of No. 2, then pull No. 2 from the bottom-board and set it on No. 4, and puff smoke in at the entrance of No. 4, and they will not fight much. In 5 or 10 minutes give them a little more smoke. You will find this works like a charm. Smoke them well. I do not use any paper between the hives, nor kill one queen. I let the bees manage that, unless I want to save one. No. 2 weak old queen, and old combs; and No. 4 good combs. Unite them, get rid of one old queen, old combs strengthen No. 4, and get 30 pounds of extracted honey to nothing. Good. Or, if No. 2 has good combs, let it stay on until there is a swarm, then smoke all the bees down out of the top hive, take it off and put the swarm in it. The swarm then has combs, brood honey and pollen.
B. A. ARMOR.
Murray Co., Ga.

Wedges vs. Blocks for Raising Hives.

On page 123, answering South Africa, Dr. Miller says: "The only objection I remember to have seen urged against this [setting hives on four blocks, one under each corner], is that the bees have only the four corners to climb up." Well, here is my objection, or rather my objections:
First, I want my bees all to use for going and coming one side or end of each hive only. Then you know where to look for the queen when they swarm; and more, you have three sides of the hive for pleasure and practical everyday operations, and you are out of each other's way, and so may live in peace and harmony together.
Another reason, and a strong one it is in my mind, why I prefer the wedges to blocks, is because the wedges afford *climbers that direct the bees to go just where they are wanted with their loads.* Of course, the bees, to the

hive be set on four blocks, will get up, but my bees so fixt fail to go up just where I want them to go up. There is much in that, that the future will see.

But I cheerfully confess that on very hot days I would like to have a free passage right through under the bees.

Years ago I cut a hole of about 20 inches through the rear end of the floor and covered it with wire-cloth. This I closed when necessary with a slide on the underside of the floor, but the wire-cloth would be so persistently and completely closed with propolis, that I gave up that form of ventilation. All considered, I place a high value upon the use of the wedges. Almost always they afford ample ventilation with my hive.

S. T. PETTIT.

Ontario, Canada.

The "Golden" Management.

I read with much interest the articles by Mr. Golden, but one thing I don't understand, that is, when he hives a swarm in supers and places the parent hive on the supers, does he put a cover on the supers, and place the old hive on that cover, or how? If he uses no cover, what keeps the bees from going back into the brood-frames?

CLINT BACHTEL.

Modoc Co., Calif.

[Mr. Golden sent us the following reply to the above question.—EDITOR.]

No, no, there must not be anything between the swarm and the parent hive. Do not be alarmed about the bees going up to the parent hive; only those that are laden with pollen enter that department, and deposit the pollen where the brood and larvae are, that I have ever discovered. Others seem to have had pollen below, while I have never as yet had a single cell. When bees swarm naturally they know it, and hived in a new house they know it, even if the new and old are joined together they know it, and they know they have had their say in the matter, and are contented if plenty of room is given them; and if the queen-cells are carefully destroyed success is sure to be the result. But side-entrances must be provided, both in the hive and supers.

J. A. GOLDEN.

PRINTED

Envelopes and Letter-Heads.

Our New Press.

We have put in a new small Job Printing Press on which to print our own stationery, circulars, etc., and while being able to do this we may as well do some work for our readers, if they will favor us with their orders. If you want Envelopes or Letter-Head, send 2-cent stamp for samples and prices. We will make right prices for neat, good work. All orders can be filled by express, at small charge, as the weight would not be great.

GEORGE W. YORK & CO., CHICAGO, ILLS

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Mar. 23.—Very little demand for honey in the comb, the season being about over for its sale in any quantity beyond a case or so at a time, many retailers refusing to carry it in stock owing to sales being infrequent. Prices asked are 10c for best grade of white, 8@9c for No. 1 or fair grade of white; ambers, 7@8c; dark, same. Extracted, 5@6c white; amber, 4@5c; and 4c for dark and buckwheat. Beeswax, 27c.

R. A. BURNETT & Co.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax in good demand at 26@27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season.

M. H. HUNT.

Kansas City, March 21.—Fancy white 1 lbs., 9@10c; No. 1, white, 9c; amber, 8@9c. Extracted, white, 5@5½c; amber, 4@4½c; dark, 4c. Beeswax, 20@22c.

Supply of comb honey is large; demand fair.

C. C. CLEMONS & Co.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging.

S. H. HALL & Co.

Cincinnati, Mar. 21.—Demand fair for extracted, with insufficient supplies. Prices range from 4@6c, according to quality. Demand for combs is slow at 10@13c for best white. Beeswax in good demand at 20@25c for good to choice yellow.

CHAS. F. MUTH & SON.

Indianapolis, March 24.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

WALTER S. POWDER.

San Francisco, Mar. 16.—White comb, 8@9½c; amber 5@6c; extracted, white, 4¼@5c; light amber, 4¼@4½c. Beeswax, 24@27c.

The firm tone last noted as prevailing in the market for extracted honey continues to be experienced with light stocks of all grades. The same condition is reported as existing in the East and in Europe. Comb honey is still in more than ample supply for current requirements, having to depend wholly on local customs.

Milwaukee, March 8.—Fancy, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 10 to 10½c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4½ to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the best. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better.

A. V. BISHOP & Co.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.

BATTERSON & Co.

New York, Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and finding ready sale at 10 to 11c; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c; light amber, 5c.; white clover and basswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cleveland, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6½c.; amber, 4 to 5c. Beeswax, 22 to 25c.

A. B. WILLIAMS & Co.

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

WESTCOTT COM. Co.

\$100

Given as Bounties to purchasers of the improved Danz. Hives and Sections See schedule in my bee-book "Facts About Bees." Tells

how to produce honey that sells for the most money. Free for 2c in stamps. Address THE A. I. ROOT Co., Medina, Ohio. or F. DANZENBAKER, Box 466, Washington, D. C.

For Sale Cheap 90 colonies of Bees in lots to suit; in prime condition For particulars address, W. SPENCER, Bunker Hill, Ill. Box 114. 14 A4t

Premium Offers!

Queen-Clipping Device Free

The Monette Queen-Clipping device is a fine thing for use in catching and clipping queens' wings. We mail it for 30 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device.

A \$1.00 Bee-Veil Free.

Globe Bee Veil

By Mail for One Dollar.

Five cross-bars are riveted in the centre at the top. These bend down and button to studs on a neck-band. The bars are best light spring steel. The neck-band is hard spring brass. The netting is white with face piece of black to see through. It is easily put together and folds compactly in a case, 1x8x7 inches, the whole weighing but 5 ounces. It can be worn over an ordinary hat; fits any head; does not obstruct the vision, and can be worn in bed without discomfort. It is a boon to any one whose files bother, mosquitos bite, or bees sting.

For sending us only TWO NEW subscribers to the Bee Journal for one year (at \$1.00 each) we will mail to a regular subscriber one of these Globe Bee-Veils; or, for \$1.75 we will send the Bee Journal one year and the Veil to any address.

Plain Sections—No-Drip Cases—Paraffine Paper.

BY F. L. THOMPSON.

One is tempted to employ emphatic language on observing the various changes being contemplated in bee-supplies; not because they are changes (that would be narrow-minded), but because some of them are expensive. Honey has been steadily going down in price; supplies have not, and will be even more expensive if one wants to keep up with the times. I contend that a legitimate and sorely-needed field of inventive energy is in danger of being overlooked, namely, How to keep the price of supplies in just proportion to the price of honey.

It is stated that a higher price will be obtained for honey produced by the new methods. This is undoubtedly true in some few localities, according to reports. That it is in the majority I am not prepared to admit. From what I have experienced and heard of the Denver market, I should expect to gain nothing whatever by the use of plain sections. Even as far east as Vermont, it appears that plain sections of honey bring no more in the market, according to the testimony of Mr. Crane, in the January Review. We are therefore confronted at the start with the probability that the majority of bee-keepers will gain nothing, in direct cash value, by changing.

Plain sections require less work in their manufacture; therefore, they ought to be sold for less. In fact, Mr. Asplund, in the Review, says his plain sections cost him less than the ordinary kind. But it appears it is not to be so in the general market, according to a catalog of a large supply firm, which quotes them at the same prices as the ordinary kind. This is not right.

Then the "fences" are \$1.00 to \$1.50 a hundred, according to style. Compare such prices with 40 and 60 cents a hundred, the prices of ordinary separators.

Shipping-cases have not followed honey down in price. But why not? As long as the exterior is attractive, *i. e.*, smooth and accurately cut, I think it would really pay me in the long run, taking everything into consideration, to use a case of workmanship and material no superior than should be expected for 10 cents, while acknowledging the excellence of the 15-cent ones.

In regard to shipping-cases, one vital point has been overlooked. Time is money. It takes more time to nail up several hundred no-drip cases than it used to when they were of the old style. The paper has to be cut and inserted, and five little strips nailed in each one. I am not condemning the no-drip style, but would like to have it without so much expenditure. After all, the old style cases are not so bad, when bottom starters are used, and the honey shipped in such quantities as to admit of making a regular pile in one end of a car, with straw all around, and boards in front. It is a question whether under such circumstances it really pays to use the new style at all.

But this is not all. We are now told that progressive bee-keepers use thin strips of veneer between the rows of sections in the shipping-cases. These are \$2.00 a thousand—another expense.

And perhaps still more, it is hinted that shipping-cases, as well as supers, ought to have followers and wedges. Great Scott!!

PARAFFINE PAPER AGAIN.

I don't see why this should be made a subject of controversy. It is a question of facts. My bees deposit propolis on the paper, tho tightly cushioned and warmly packed. If others' bees don't, I congratulate them, and wish mine wouldn't. But they do.

There are two other disadvantages of the paper, not mentioned before. One is, that it makes it so undesirable to inspect the supers from above, to see when it requires tiering up or taking off, that one is forced to resort to the comparatively clumsy and tiresome method of prying it up, inspecting

F. L. Thompson.

from below, then setting it down with the care which the presence of the bees on the edges nearly always necessitates.

The other is, that the advantage it gives of securing sections with tops perfectly bright and fresh, only applies to one super on a hive during the season. The others, having served to tier up, will have the tops of the sections as dingy as by the ordinary plan of a "layer of air."

No doubt it is a neat and effective aid, tho not an indis-

pensable one in small apiaries; but in large apiaries, if one wants to accomplish the same objects, it can be done with a greater saving of time and money by returning to the old plan of wide frames—single-tier ones, of course—with anything one wants on top for warmth. Last season I used one set of double-tier wide frames. The results were all that could be desired, as far as the sections were concerned.

Montrose Co., Colo.

Some Southern California Notes.

BY PROF. A. J. COOK.

DRY SEASON.—Southern California is experiencing an exceptionally dry season. This place, which stands higher than most sections, has had only about eight inches. The season is now so far advanced that little more can be expected. As about 15 inches is necessary for a full honey crop, the outlook is not encouraging. Already the bees have stored some from fruit-bloom, eucalyptus and the early-blooming buckthorns, which will help to feed the bees, tho unless a goodly supply was left in the hives last year, many colonies will surely starve to death.

INTELLIGENCE IN BEES.—Speaking of intelligence among bees—is it possible that bees sense the unfavorable seasons, and are rendered cross by the outlook? Bees are unusually cross this spring. A young lady, who has kept bees for three years with no trouble, finds them so provokingly petulant and irritable this season that she contemplates disposing of them. She says that they are too much for both veil and smoker. She has never had such trouble before; and this notwithstanding that she has secured considerable honey during the last weeks.

COUNTY ASSOCIATIONS.—The Central California Bee-Keepers' Association, consisting of Kern, Kings, Tulare, and Fresno counties, is likely to break up and each county form a separate association. As there are enough bee-keepers in each county for a good association, this seems wise, especially as the railroad fares are very high in that region.

STORING HONEY.—There are reports that considerable honey has been stored already, notwithstanding the limited rainfall. The flowers are out very early this season, and the citrus trees and buckthorns are crowded with bees.

SHIPPING HONEY TO ENGLAND.—It is reported that four carloads of honey were shipped enroute for London, England, from San Diego county last month.

MANZANITA AND BUCKTHORNS—It is reported from San Diego that the black manzanita and buckthorns are in blossom very early this season, and the bees are securing not a little honey from them. The same is also true of the later plants and the wild pea all over Southern California.

Los Angeles Co., Calif., March 29.

Honey from Pine-Needles—Is it New?

BY D. C. LEACH.

About the first of last October, after the honey-gathering season was over, I noticed one morning my bees were busily at work. They came in as heavily laden as when the basswood is yielding its rich treasures in greatest abundance. They would drop on the alighting-board and on the ground, and stand for a minute or two panting as if their strength had been taxed to the utmost in reaching their hives.

I thought it very strange, but as I was very busy I gave the matter but little attention. I found, however, their activity was kept up all day, and renewed early the next morning. I then concluded that some one had cut a bee-tree in the woods not very far off, and my bees were gathering up the broken and wasted honey.

The third morning, however, they were at it as busily as ever. I knew then that my bee-tree explanation was at fault, for 20 strong colonies of bees, working as mine then were, in a few hours would have gathered every drop of honey that could have been thus spread over the ground. I resolved, therefore, to follow the course of the bees, and, if possible, solve the mystery. The rush and roar was so great that they were easily followed.

After going some 50 or 60 rods I became conscious from the motion and numbers of the bees I was nearing the solution

of the mystery. A few rods farther on I entered a grove of young white pines, from 10 to 30 feet high, and then I knew all about it! The needles of those pines were covered with thousands of minute globules of as clear, white, sweet nectar as I ever saw! They glistened in the sunlight like diamonds. All the bee had to do was to alight on a pine-needle and drink her fill!

About four days this unexpected honey harvest continued and then ended as suddenly as it came.

I have kept bees in the immediate vicinity of pines for many years, but never knew a case of this kind before. None of this nectar appeared on the foliage of the Norway or Jack pines in the vicinity. None of the honey gathered from the pines was deposited in the sections, so I cannot speak positively of its quality, but I have no doubt it was as good as the best—if not better! The globules were clear as crystal, in taste the perfection of sweetness, and thicker than first-class syrup.

Is it something new for bees to gather honey from pine-needles? I think I have read of a certain kind of pine on the Pacific Coast that yields a poor quality of honey, but I have never known it to happen in Michigan.

I will add, in conclusion, that I think my bees must have increased their winter stores nearly 200 pounds from that pine grove.

Grand Traverse Co., Mich.

Exhibiting Bees in a Glass Observatory-Hive.

BY A. F. BROWN.

The following bit of experience is called forth by information asked for on page 39, replying to which Dr. Miller advises keeping the observatory hive covered as much as possible. My experience differs. Nine or ten years ago, when working for a railroad company, I kept a 3-frame observatory hive in one of the windows of the passenger waiting-room of the station at Huntington, Fla., for upwards of three years, and never during the whole time had the light excluded from the bees. I put them there to be seen—to study their habits, and for other people to see, and to do this it was necessary that the bees and their work be in sight all the time; consequently I had no cover or shutters to exclude the light, nothing but the glass, and I assure you the bees never "buzzed themselves to death," but after the first week worked on in their normal condition as if in a hive as dark as Egypt.

I used the Langstroth size of frame, the entrance was at the bottom at one end, then through a tube about 8 feet long, slanting upwards so the bees came out about 6 feet above one's head on the outside of the building, there being a platform or wide veranda, as it were, all around on that side of the station.

The exit-tube was made of strips of laths, size inside about $\frac{3}{4} \times 1\frac{1}{4}$ inches. I put a small colony of Italian bees into this hive at first, and later on, by changing the queens, had several different kinds of bees—blacks, hybrids, Carniolans, and Holy Lands; in fact, I did everything with this colony of bees that one would do with a full size colony, and I had them right where I could observe all that took place in the work inside a normal colony.

Often I would have only one full comb in the hive, letting the bees build new comb in the other two frames to give me the opportunity to observe the whole work. If allowed to get strong in bees and brood, which they would soon do, they would swarm like any other colony; or if space was given above (on top) by means of an inch hole, and a tumbler turned upside down over it—first attaching a bit of comb or foundation to the bottom of the tumbler—the bees would go up and fill it with honey, and once we got them to work in a bottle inverted over the hole.

Having no wooden shutter or cloth to cover them up, one could watch everything without disturbing the bees in the least. When all three frames were in the hive, and the queen got the inside one filled with brood, she would come over on the outside comb, and one could watch her in her work of depositing eggs, and see the bees feeding her, etc.

The two glass sides of the hive were hung on hinges the same as a door, and often I would open the hive for various purposes, changing the frames about, removing the frames the queen was on, so as to be next to the glass, or some other operation; in such cases quite a few bees would take wing, the same as when a hive is opened out in any apiary. □

Well, the interesting part I wish to call attention to is, that when the hive was closed up these bees did not hang around buzzing, trying to get in where they came out, but at once flew out one of the open windows or door, and up to their

regular entrance-hole. They knew as well as I did when the glass door was open, or when it was closed.

And now comes more interesting facts. In the three years the bees were kept in the station waiting-room, and the hundreds of times the hive was opened with a dozen or more people looking on, and even handling the bees, only one person, to my knowledge, ever got stung.

A dozen trains a day past within 18 feet of the bees—all the jarring, hustle and life of a regular railroad station, with hundreds of passengers going and coming, and yet the bees lived on peaceably, and increased, prospered, and did well.

At different times, and I might say for the most part of the time, there were all grades of Italian-black hybrids and pure-black bees in that particular observatory hive. But here I should add that with the exception when first putting the bees there, all were reared in the hive, and consequently knew no other life but the one surrounding them. This may also explain why they did not buzz themselves to death on the glass.

I should remark here, that in the case of young bees sometimes starting out for their first flight, they tried at first to get out of the glass, but it did not last long, and they soon learnt the right way, and then always followed it. Also, in case of their throwing off a swarm, which happened several times, the bees always went out the tube, and none stooped buzzing on the glass inside.

I have found that a single-comb observatory hive is not as good or as instructive as one having two or three combs, for the reasons that the number of bees in a single-comb hive are too small to amount to much in the way of building comb and storing honey, etc., and when you do get it just nice and strong, why, it is but a day or so before it is too strong—at least somehow I never got satisfactory results from them, and I have had bees in one for a year, and several times for a few months; but with a two or three frame hive you have something that one can gain much information from.

Then don't have shutters or covering of any kind over the glass. Let the bees be in the light all the while, and then when you wish to examine them or watch their work you don't throw them in an unnatural condition, as you do when you have them in a dark hive, and only give them light when you wish to watch their movements.

Do not put them in a sunny window, unless the hive is well back inside, and the ends of the frames face the window; and this is the proper way they should face, so that one can get to examine both sides of the hive inside the room. I would rather keep them on the north side of the house, or in a room that had a veranda outside, so that the sun could not shine on the combs through the glass.

The ideal spot, in my estimation, for an observatory hive, is on a shady veranda. Then when the hive is opened there are no bees flying around inside the room. The entrance can be through a tube running off near the roof, and thus have the flying bees out of the way; and one can sit and watch the hive for hours. There is much of interest to be noted from a small colony of bees kept thus. Volusia Co., Fla.

Section-Cleaners—Producing Fancy Honey.

BY JAMES COBMAC.

There has been considerable published in the bee-papers on the subject of cleaning sections of propolis stains, and on page 33 is shown a machine offered by J. A. Golden for that purpose. The half-tone is a good one, and the eyes of the operator say, "Now, you see, this works like a charm." The charm of the young lady in the half-tone (to me) is more charming than the machine, because I think I see in the illustration a young lady who is not ashamed to allow her position before the machine to be understood that she is a helper in the affairs of the household and its income, and not given to be waited on, while many others pass their time with yellow-covered novels.

But my admiration does not go far enough to construct a machine for the purpose shown, because I think I know that one can produce comb honey without having it daubed with bee-glue. A bee never ought to be allowed to travel on the upper side of a section. Something ought to intervene between the upper surface of the sections and the hive-cover or another super. I have tried paper, wax, paraffined, etc., which allows the bees to raise the edges thereof, piling up glue superabundantly at their option, which paper prevents a free passage to the super or supers.

Four years ago, with pattern-slats (section-holders) of two inches in width for sections $1\frac{3}{8}$ wide, laid on top of the sections and held in place by a $3/16$ strip $\frac{1}{2}$ inch wide laid across in the center of the super, the super made $\frac{3}{8}$ deeper by

nailing a strip all around the upper edge of the super, would effectually prevent the smearing of sections unless the weight of honey therein bent the lower set of section-holders. To prevent this, another strip the thickness of the space between the lower holders and brood-frames, placed in the center across the frames, kept all level and tight. My brood-frames being $\frac{1}{8}$ thick, would not bend down and allow the heavy sections to settle.

You do not need to scrape the sections; they will come out of the super as clean as put in, except the edges touching the separator and the inset.

In cleaning the edges I use a thumb-plane. A narrow box has a strip four inches wide nailed across it, through which a hole is bored, also directly under this hole one through the bottom of the box $\frac{1}{4}$ inch large. A small box $\frac{1}{4}$ inch larger than the section, and $\frac{1}{8}$ inch lower than the section, with inset cut out $\frac{1}{8}$, as the one in the section. Fasten a wooden pin in the bottom of this last box to go through the hole in the cross piece of the large box and through the bottom of the same. This last box will turn on the pin. Lay the section in, give the plane a curving sweep from the corner of the inset up the straight edge to the corner of the other inset. A thin shaving is removed from the section. Turn the box and use the other side likewise. This removes all soiled wood. A knife with a notch $\frac{1}{8}$ deep on the square end of the blade, drawn across the inset, cleans that.

In using sand-paper the dust of the section would often catch the honey in the uncapped cells and injure the appearance.

The production of fancy honey demands as much fineness as any undertaking I ever engaged in. There are many ways used to accomplish a certain end, and if others give their experience one can cull and be greatly helped.

The "Solomon" of Marengo does the American Bee Journal "proud," as the boys say. It is a grand addition for the beginner—the department of "Questions and Answers."

Our winter's snow lying so long on the ground, after being parched with drouth and heat last fall, gives token of another season favorable to a good yield of nectar from white clover, as it is increasing in rootlets. Should the coming spring be favorable in temperature, with plenty of ozone in the atmosphere, we may expect a good harvest. Polk Co., Iowa.

The Loco-Plant and the Bees.

BY I. W. BECKWITH.

Three years ago I brought several colonies of bees to this vicinity, and the next spring they worked well on the wild flowers, which were abundant till about the middle of May, when they all stooped work entirely, and from that time during the summer I scarcely saw a loaded bee enter a hive.

In the fall I rendered a quantity of comb that I had on hand into wax, and to my astonishment not a single bee came into the house, which I kept open while the wax was cooking. I encouraged breeding that fall and the next spring as much as I could, yet they dwindled away till there were but few left.

In the spring they again worked well till the middle of May, when they "struck" again, taking no notice of exposed honey or melted wax. I told a neighbor, J. L. S. Jackson, how my bees had acted, and he said he thought they were looded by using honey gathered from the loco-plant, which is very abundant in the immediate vicinity where I kept my bees.

For the benefit of those who never heard of the loco, I will say that it is a leguminous plant that grows on the arid plains of the Western States. When an animal eats leaves or roots of the plant—some say the root only—the brain becomes affected so that the animal loses its reason to a greater or less extent, and in severe cases it perishes, apparently because it does not have sufficient reason to go to water and otherwise take care of itself.

I thought Mr. Jackson was mistaken about the cause of my bees' actions, and having lost all my bees, I bought some more about a year ago, and they behaved during the past season just as the others had done—that is, they worked all right in the spring till the loco had been in bloom a short time, when they quit work, were quite irritable, and their conduct was generally different from other bees. The few young that they reared on honey that they already had in store (they quit work before they had stored much loco honey) seem to be all right.

If anybody else has had similar experience I would be very glad to have him report through the American Bee Journal.

Weld Co., Colo.

American Bee Journal and Spelling Reform.

BY C. P. DADANT.

FRIEND YORK:—I wish to digress a little from the bee-talk to-day to have my say in regard to the new way of spelling that you have introduced in the columns of the American Bee Journal, as I notice some comments upon it by your different contributors.

This new spelling is certainly offensive to the eye before we become accustomed to it. In the beginning, I used to do as Mr. Jenkins remarks—it used to detract my attention from the subject in question. But one evidently gets used to this, for I no longer notice it, altho the American Bee Journal is, I believe, the only paper that we take which follows this reform.

The greatest objection to the spelling reforms, such as this, come from people who are good scholars, and who object very often on the ground that if we make reforms on this subject it will become impossible to recognize an educated person from an uneducated one, since every one can write just as he talks. This argument is not well founded. If the reform is brought about in the right way, it will bear only, as with your method, on such parts of speech as will have been agreed upon, and it will require rather more of an education than less for writers to keep informed upon these changes.

I am free to confess that, altho I approve of the change, it would be next to impossible for me to follow this orthography from mere slavery to habit. I would have to drill myself very carefully for quite awhile in order to do away in my handwriting with the old way of spelling. But because we are accustomed to a bad way should we discourage those who are faithfully trying to educate the young generation to better ways? Let the old fogies, like myself, stick to their old ways if they cannot do otherwise, but let not any of them ridicule the progressive man who tries to bring forward something better. Otherwise we might as well go back to the English method of spelling labour, neighbour, and borough instead of neighbor, labor, and boro. "Plow" is surely a progress on "plough," tho it means the same. If we are a progressive nation, why should our progress be all material and not educational and mental? Why should we cling to the old way of spelling any more than to the scythe and the cradle? Is the man who writes his name "Ztschmidztseh" any brighter or more successful than plain "Smith." Perhaps you will think this name is of my own invention, but not so. I believe the man was a Russian, and I have actually received a letter signed as above.

It is not only in spelling that we might help the reform which is so slowly going on in scientific circles for the purpose of making education easier, but in many other lines. We lose sight of the fact that while our children are overcoming the difficulties of the language, they are uselessly losing precious time, which, in this age of progress, might be occupied much more to their benefit. But language is only a small portion of what has to be learnt by a child to acquire an education. What about figures? Why do we so long cling to the ridiculous English system of weights and measures when we have within our reach the most simple system that may be devised—the metric system? Our scientists have long ago decided that the metric system was the only rational system of weights and measures, and as far as they have been able they have drawn us in this direction. But we have too many old fogies who are afraid that a change might disturb their own equilibrium. Better have the rods and the eels, *Flemish* and *English*, and the yards and the feet, carefully divided into 12ths, which are themselves divided into eighths and sixteenths so as to make (so it would seem) computations as difficult as possible! Imagine the United States leaving the decimal dollar to go back to the pound sterling containing 20 shillings, subdivided into 12 pence!!

All these reforms frighten us. Why? Because we make a bugbear of nothing. We have been accustomed to our rut, and the deeper it is the better we like it, for we think the world is all at the bottom of that rut. But with a little effort we will ascend to the top, and with what profound disgust we will then look back into that pit! At any rate, if we have not the courage to climb out we must not try to discourage those who are climbing, or to pull back in those who have got out.

The teacher up-to-date has no hesitancy. He says that the spelling reform is but a trifle. He does not frighten at the half-dozen strange words of the metric system, and soon discovers that those few words contain the key to a method which is simplicity itself. He quickly decides that it is better to have the freezing-point at zero than at 32, and boiling water at 100 than at 212. Progress is made of little things. Then let us try to help it. Hancock Co., Ill.

CONVENTION PROCEEDINGS

Report of Vermont Bee-Keepers' Convention.

BY M. F. CRAM.

The 23rd annual convention of the Vermont Bee-Keepers' Association was held at Burlington, Jan. 26 and 27, 1898.

The meeting was called to order by Pres. H. W. Scott, prayer offered by R. H. Holmes, and then the minutes of last meeting read and approved. The following committees were appointed on Resolutions: J. E. Crane, R. H. Holmes and M. A. Everest; on Nominations, M. F. Cram, H. L. Leonard, and O. J. Lowrey.

The Secretary's and Treasurer's reports were read and approved, the former's report showing a balance of \$5.00 in favor of the Association.

COMPARATIVE VALUE OF RACES OF BEES.

Then came an address by Pres. H. W. Scott, after which R. H. Holmes talkt on the comparative value of the Italian and black races of bees. He thought not many of the original black bees were left in the State—they were now Italians and hybrids; each colony showed different characteristics, as much as horses or cattle. The Italians come out ahead on the following points: Gather honey faster; better to defend the combs from moths; better to defend their stores; fly farther for honey; in fact, were generally at the front.

Mr. Leonard claimed it was the condition of the colony more than in the breed of the bees, but thought the Italians were better for surplus.

Mr. Crane said that in some seasons the Italians outstrip the blacks; in other seasons it was the reverse.

Mr. Holmes then told of the great value of a good queen.

SPRING MANAGEMENT OF BEES.

Mr. Crane gave his method of spring management. First, we must save the heat of the hive by contracting, and seeing that they had plenty of stores; but to begin with we must get the best bees. Bees vary in characteristics, and that is the very best ground we have to make improvements upon, and it could be done the same as in horticulture. He told how the sugar-beet had increased from 6 per cent. to 25 per cent. in productiveness; what is true of plants is also true of the larger animals, fowls and bees. He thought the swarming instinct could be bred out, in a great measure. The large draft horse and the little pony had all sprung from one parent-stock. The dairy cow had been improved, and why not the bee? The Italian had grown much lighter in color since coming to this country in 1860. One point in our favor, we can breed a bee and test its merits in less time than we can our domestic animals, and Mr. Crane thought we could in time breed them up to nearly twice their present productiveness.

A FEW QUESTIONS AND ANSWERS.

QUES.—If bees have been growing better, why do we get less honey than 15 years ago? ANS.—Partly on account of pasturage being cut off, and partly on account of peculiar seasons.

QUES.—Is it any advantage to have hives painted? ANS.—Yes.

QUES.—How can we secure the whitest comb? ANS.—Have your sections on only when honey is coming in.

EVENING SESSION.

Prof. L. R. Jones gave a lecture on the bees and the flowers. He also showed by stereopticon views the pollenization of flowers, and the aid that the bees are to the same, which was very instructive and well illustrated. The question was askt Prof. Jones, if it was any benefit to spray fruit-trees while in bloom. He said no authority in the United States had ever given out that spraying in bloom had ever given as good results as spraying after the bloom had fallen, and many bad results had been obtained from spraying while in bloom.

Cassius R. Peck then gave a report of the work done at the Experiment Apiary. It was a very concise report, but owing to some peculiarities in the season some parts of the work did not reach the desired object, and will be continued next season.

The convention then listened to a recitation by Albert M. Cram, and two songs by Mr. Everest.

THE QUESTION-BOX.

QUES.—What is the value of bee-escapes? They were spoken of favorably by Messrs. Fassett, Lowrey, Leonard, and Holmes.

QUES.—Is there danger of over-stocking?

ANS.—Apiaries should be from 3 to 5 miles apart, or farther. Bees will fly from 5 to 7 miles from home, and in California, where big stories originate, bees have been known to fly much farther.—[We fear this is mostly a "big story."—EDITOR.]

SECOND DAY.

The committee on Nominations reported as follows, which report was approved:

President, R. H. Holmes; Vice-Presidents, J. E. Crane, for Addison Co.; Cassius R. Peck, for Chittenden; Geo. H. Terrell, for Lamoille; P. W. Smith, for Orange; V. N. Forbes, for Rutland.

Secretary, M. F. Cram, of West Brookfield; and Treasurer, H. L. Leonard.

The committee on Resolutions reported as follows, which report was also approved:

Resolved, That we express our thanks to the proprietor of the Van Ness House for the use of a room for our annual meeting; also to the railroads of the State for reduced rates to members attending this meeting.

Resolved, That we tender our thanks to the Board of Control of the Vermont Experiment Station, for the interest they have taken in our pursuit, and also for experiments made at the station.

Resolved, That we express our thanks to Prof. L. R. Jones, for his able and interesting lecture upon the agency of insects in the fertilization of flowers.

WHEREAS, An all-wise Providence has seen fit to remove our associate, J. W. Smith, from this present life, therefore, be it

Resolved, That we recognize amid the busy cares of the world, the frailty of human life, and the necessity of living with a wise reference to the life beyond the present.

Resolved, That we tender our heartfelt sympathy to the family and friends of the deceased in this our loss and their sad bereavement.

J. E. CRANE,
R. H. HOLMES, } Com.
M. A. EVEREST, }

BEE-KEEPERS' EXCHANGE FOR VERMONT.

Would it be practical for Vermont bee-keepers to organize a bee-keepers' exchange?

Mr. Crane said if apiarists would combine they might do so, but he did not know as that could be done in a general way at present. He thought a good trade could be worked up by a canvas with honey; that a good agent could sell large quantities at paying prices.

Mr. Lowrey said if you show the people a nice article they will buy, but the point is to sell in large quantities. He thought Vermont led the world in quality, and we ought to have the best prices. He also thought it could be sent by the carload, send a man with it to sell it, and we would get what it was worth.

Mr. Leonard then spoke of the California Exchange. Mr. Everest mentioned the building up of a trade, which every one had got to do.

The following committee was then appointed to confer with the Board of Control in regard to the work to be done at the Experiment Aply the coming year: O. J. Lowrey, H. L. Leonard, and M. F. Cram.

WEED PROCESS FOUNDATION WINS.

Then came reports of members who had used new kinds of foundation. Mr. Lowrey showed three different specimens which the bees had drawn out and filled with honey, each section having a private mark known to Mr. Lowrey. A committee was then chosen to sample the honey, which they did to their great satisfaction. Weed's new process carried off the honors.

MANAGING SWARMING IN OUT-APIARIES.

QUES.—Can an out-apiary run for comb honey be made profitable with no one to hive swarms? ANS.—Yes, if tended by an experienced man.

Mr. Crane then gave his method. Commence the middle of May, clip all queens' wings, and go over them once in eight or nine days, and if preparing two swarms remove the queen if found, if not cut all queen-cells that would hatch in eight days. Eight days later cut all queen-cells, and introduce a

virgin queen, and eight days later see that she is laying. Cutting just the cells sometimes will stop their swarming.

Mr. Lowrey had used traps, and was successful in keeping the bees from absconding. He had used a double hive and could give ventilation with that. He sometimes took away the brood and let them re-queen themselves on another stand.

The new no-bee-way section and fence were then spoken of by Mr. Leonard, who told of the benefits he thought were in them. He thought he would prefer the fence with holes instead of cleats.

All thought the honey season was a poor one in Vermont last year.

There was a good attendance at the convention, and two of the oldest members of the Association said they thought it was the best meeting they ever attended in the State.

M. F. CRAM, Sec.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. O. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Raising the Hive for Ventilation.

In putting blocks under the four corners of the hive to give ventilation in summer, is there not danger of raising the bottom of the brood-frames too high off the bottom-board, which might be a detriment? or do you think that would do no harm?

INDIANA.

ANSWER.—I have had no trouble from that source. The only trouble likely to happen is that raised too high the bees would build comb to the bottom-bars, which could easily be trimmed off.

Cyprian Bees, Italians and Blacks.

Are the Cyprian bees any better honey-gatherers than the Italians? Will they sting when one goes into the yard, unless their hive is opened? Do you think that black bees are any better honey-gatherers than the Italians? Where can I get a Cyprian queen?

N. H.

ANSWER.—Cyprians have the reputation of being regular savages, stinging with or without provocation. Some claim that a slight admixture of Cyprian blood improves Italians as to working qualities, while others say it's only because of the introduction of fresh blood. The fact that Italians are preferred by nearly all who work chiefly for honey is good evidence that neither blacks nor Cyprians are as good. It is somewhat doubtful if any one has Cyprian queens in this country; at any rate I don't know of any.

Combs Breaking When Extracting.

In my limited experience in extracting I did almost nothing at all because the combs would break down so badly. I finally gave up, and used the honey as "chunk honey." I had full-depth Hoffman frames and wired horizontally medium brood foundation. A bee-keeper 35 miles east of me reports the same trouble. Now then, how can the combs be prevented from breaking down while extracting?

OREGON.

ANSWER.—One way is to let the combs get to be ten years old before extracting from them. Not highly recommended, however. But that's another way of saying that you must be very careful with new and tender combs. The heavier they are the more danger of breaking. So go about it in this way: When you first put a pair of combs in the extractor, turn no faster than is absolutely necessary to set the honey to flying out of the cells. When half or more of the honey is still left in the cells of that side, reverse the combs and empty most of the honey in the other side. Not much more than half of it, however. Now extract pretty closely from the first side, then from the second. In that way you can extract from very tender combs without breaking. It will take less force to extract when the combs are warm from the hive than when the honey has become cool.

Moisture in the Hive—Hive-Entrances, Etc.

1. One of my neighbors has a colony of bees in frames smaller than the Langstroth—and in a box made to fit the frames. This box has a permanent bottom and an entrance not over four inches long. Some time ago he noticed honey running out at the entrance, and called my attention to it. We looked into the hive and

at one side honey seemed to be oozing out of the comb. It did not seem sour, either. What was the cause of it? The bees seem to be wintering all right. I warned him against robber bees.

2. Do you think there is any danger with so small an entrance?

3. Would be not better transfer into a standard frame hive when fruit-bloom comes?

IOWA.

ANSWER.—1. I think it more than likely that what you saw was the moisture from the bees settling on the sealed combs and on the sides of the hive. Sometimes it runs in a stream out of the entrance, especially if the entrance is so small that there is little chance for the vapor to pass out. It is possible, however, that the moisture has settled on the unsealed honey to such an extent as to thin it and make it run out of the combs, and even to work into the sealed honey so as to make it ooze through the cappings.

2. Probably a larger entrance would have been better, but now that activity has commenced, it may be well enough to let the entrance remain small till the weather gets warmer.

3. If he doesn't intend to handle the frames, or intends to handle them very little, it may be well enough to leave things as they are, otherwise he might do well to transfer three weeks after swarming.

Queen in Observatory Hive.

I have saved over a young queen. I have had her in an observatory hive in the house all winter, and given an occasional flight. She has a hundred or so of attendants. If I don't need her for a queenless colony, can I give her more bees by moving a colony and setting a hive with this queen in its place? I mean will they fight her?

NEBRASKA.

ANSWER.—If honey is coming in plentifully it will likely work all right; otherwise not.

Using Combs from a Worm-Killed Colony.

Last fall I lost 2 or 3 weak colonies by starvation, and then worms. After the bees all disappeared I brimstoned the combs and killed the worms. The combs seem to be all right with the exception of the webbing left by the worms. Will it do to give these combs to bees in swarming-time?

SUBSCRIBER.

ANSWER.—Yes, it will be all right, especially if the combs have been where they were frozen, for freezing kills the wax-worms, altho possibly the eggs may stand freezing. At any rate, even if there should be a few worms present, a colony of bees strong and healthy enough to swarm would make short work of cleaning them out. But you better keep a little watch, or the worms may use them up before swarming-time. Either keep them where the moth will not get at them, shut up tight or in a cool cellar, or brimstone them as often as you find signs of worms.

Wants to Increase and Italianize.

I have two good colonies of bees with plenty of honey on Langstroth frames, which I find will fit the dovetailed hives. These two colonies seem to be doing well, and are quite populous, having gone through the winter in the cellar without losing as much as a handful of bees. The stock was said to be Italians, but from what I can learn they are only blacks or hybrids. I would like to increase them, and at the same time Italianize them. Would you advise purchasing Italian queens now for each colony, introduce them at once, and then about swarming-time divide them into about three colonies? If so, from whom can I best purchase good queens at low prices? Or would you prefer to purchase one tested queen and then form nuclei from her colony after she has been in the hive about five or six weeks?

ELMWOOD.

ANSWER.—As there is some danger of failure of introduction, thereby giving a bad set back at a time when it is important to have brood-rearing at its best, perhaps the better plan will be to get the one queen. Those who offer queens in the advertising columns of the Bee Journal are all supposed to be reliable.

A Bunch of Eight Questions.

1. What is the width of the $4\frac{1}{2}$ -inch section that you use? and how much honey does it hold?

2. How do you prevent swarming?

3. About how many years are brood-combs fit for use?

4. Would it be advisable to begin to stimulate bees about April 10, so as to get two lots of brood by June 1?

5. Would you think about 70 colonies too many to put in one yard in the spring?

6. In wintering your bees in the cellar how do you prevent the temperature from rising there when it gets quite warm outside?

7. Keeping a select tested queen that you purchase in a nucleus as some advise, is there any danger of them swarming out when she has filled the combs with eggs?

8. What other substance besides wax do bees use in building combs?

ILLINOIS.

ANSWERS.—1. The sections I've been using for the past two or three years are $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{4}$. The amount of honey contained is a variable quantity, averaging not far from 15 ounces, but some-

times a section will weigh more than a pound and sometimes less than 14 ounces.

2. Bless your heart, who told you I prevented swarming? I try to, and do about everything you've ever read about in the books and papers, but still the bees get the start of me only too often. Abundance of super room seems to be a help, also raising the hive on four blocks nearly an inch. Sometimes queen-cells are carefully cut out, and often that delays swarming. With extracting you can do pretty well at prevention of swarming, but with comb honey it's a tough problem.

3. I don't know. Some of mine must be perhaps 30 years old.

4. Unless you have a good deal of experience you better let stimulative feeding alone, farther than to see that the bees have plenty of stores. Results vary widely, and if you try it at all, better try only part and see how they compare with others.

5. Not in any fairly good region. In some places 10 would be enough and in others 500 might do. Probably few places in your State would stand more than 100.

6. I don't. There isn't any special danger from rise of temperature—the danger is from bad air. At night I open wide the windows and doors, and leave them open as late as I can in the morning.

7. I have never had any trouble in that way. There must be a strong force of bees as well as a crowding of queen to induce swarming.

8. Perhaps little or nothing else in the actual cell-walls, but more or less propolis in making the attachments, and in sealing brood they seem to use bits of pollen and whatever comes handy.

Preventing Second Swarms—Carniolan Bees.

On page 186 we find that Mr. Odle kills the queen when a swarm issues, and at the proper time removes all queen-cells but one, thus securing large crops of honey and a young queen. On the same page we learn that it is not safe to trust to a single queen-cell. Will the following plan work well?

1. When a colony swarms, hive the bees on the old stand, and set the parent colony by its side. Give the new colony two or three frames of brood from the parent hive, and fill up the vacancies in both hives with "dummies." Put on supers and endeavor to get the full force of working-bees to work in them. Before the queen-cells hatch in the parent colony remove it to a new stand, thereby causing the working-bees to go to a new hive, and also preventing a second swarm. After the queen has been fertilized, you may take your choice of the queens and unite into one colony.

2. From what country do we get Carniolan queens?

VIRGINIA.

ANSWERS.—That's practically a very common way of preventing second swarms, and a good way. The after uniting might not be so satisfactory, but it might be tried.

2. From Carniola, in Austria.

Moving Bees.

I have 4 colonies of Italians which I sheltered in an out-house all winter, facing southeast, and the bees could fly at their will, as the entrance was open all winter. I put my ear against the hives and heard the buzz throughout the winter. Now that the weather has been pretty good, I have seen them fly, seemingly very busy and in good health. Very few bees I found dead. But the main point which I wish to know at present is this: I intend to move some 20 miles out, and will have to go by wagon.

1. Can I open the hives without doing any harm, say about April 14 or 15?

2. Shall I take out all frames that are sealed?

3. Can they be transported as they are at the present time, or not? Which will be the safest way?

NEW JERSEY.

ANSWERS.—1. Yes, if it's warm enough so the bees fly freely.

2. It isn't necessary.

3. Unless the roads are very rough they can go all right probably just as they are. This spring I take nearly 200 colonies to two out-apiaries without doing anything to them at all. They have loose-hanging frames, but the bees glued the frames up pretty well in the fall. The frames are not moved at all to loosen them before hauling. The wagon has springs, and on a smooth road one can trot right along, but on a rough road the driving must be careful. They are loaded so the frames run crosswise of the wagon.

Pollen or Bee-Bread.

At last we have warm, spring weather, and I could not resist the temptation to take a peep into some of my hives, and see what was going on. And I saw—and now I do not see as they have—that is, they forcibly impress me with the feeling that they have not such a thing as a lost art. In plain English, I "got it in the neck," also in the eyes, and various other exposed points. I found that they were breeding but very little, and were almost destitute of bee-bread. I could not find enough in some hives to fill 20 cells, but all have an abundance of honey. I found one of my strongest colonies dead, with about 30 pounds of honey and not one cell of bee-bread. Could that have caused their death?

I have noticed that this colony was very uneasy every warm day this winter—would be flying when other bees were perfectly quiet. They were scattered all through the hive. I found the

queen in one of the clusters. I placed a box in the yard with graham flour (I had no rye flour), and before night they were carrying away large quantities of the finest of it on their legs. Will that answer in place of bee-bread or pollen?

Soft maple seems to be about two weeks later than last year. If the bees had been given rye-flour last fall, would they have stored it, and used it this spring for brood-rearing? NEBR.

ANSWER.—I doubt whether the absence of pollen was the cause of death? More likely diarrhoea. Graham flour is a good substitute for pollen. Probably any of the grains ground, will do well, and it is all the better to have bran and all—gives a better foothold for the bees. But nothing seems to suit them quite so well as the natural pollen, and when they can get that you will find them deserting any substitute you may have given them. They probably would have stored rye-flour last fall, and yet they were, perhaps, as well off without it. They still had a little pollen, and some have reported that rye-flour stored in the cells became hard and troublesome.

Gathering Honey by Moonlight.

Is there any authority for the statement that bees have been known to gather honey on moonlight nights? NEW YORKER.

ANSWER.—The testimony on this point is not clear. I have some recollection of reading that when linden is in full play, bees will sometimes remain out over night on the trees. This might, and it might not, be accompanied by night work. Bees certainly work nights in the hive, but it might be difficult to find proof that on a moonlight night, a bee leaves the hive and gets back with a load of plunder before the break of day.

Combs Melted and Broken Down—New Union.

1. I had some combs to fall down from the heat last summer. What would you do with such combs? Would it be better for me to cut them out and put in full sheets of foundation?

2. Is there any bee-association? I want to become a member if there is such a thing. IOWA.

ANSWERS.—1. It's probably a toss-up whether you better use them or cut them out. Where there is less than half the comb left, as is probably generally the case, it may be more satisfactory to start with a full sheet of foundation. If the frame is half full of good comb it may be well to save it. If you don't want the bees to build drone-comb in the vacancy, you can cut comb out of one frame and fill in the other.

2. Yes, there's an association that's just the thing for you—the United States Bee-Keepers' Union. Send a dollar to the editor of this paper—George W. York—and become a member to help put down adulteration and to help bee-keepers' interests in general.

Transferring—Queen-Candy.

1. What would be the best way to transfer bees out of five old hives? I have been advised to wait till the bees swarm, and have the swarm in a new hive. Three weeks later transfer the rest of the bees into another hive. Could I not drive a swarm out of each hive at the swarming season, and get nearly or quite as good results as by waiting till each colony swarms? How do you make queen-candy? NEW JERSEY.

ANSWERS.—1. Of course you can do that way, but in the great majority of cases it will probably not be as well.

2. You probably mean Schulz or Good candy, such as is used when queens are shipt, and sometimes used in feeding bees. Take the very best extracted honey you can get, warm it, but not to any thing like scalding heat, mix with it fine powdered sugar until it makes a stiff dough. Knead in all the sugar you can, working it thoroughly. Let it stand a day or more before using.

A Beginner's Questions.

1. Is there a patent on all the hives that are advertised in the Bee Journal? If so, what is the price of a patent?

2. If there is a patent on the hives, would it be breaking any law to make hives like them for my own use?

3. What is best to do with bees that have worm-nests on the sides of the hives?

4. What is the best plan of handling three or four colonies of bees? BEGINNER.

ANSWERS.—1. A great many hives have been patented, but not many of the hives now in use have patents that are now alive. All movable-comb hives come under the Langstroth patent, but that expired long ago. The price of a patent depends on the seller, and he puts whatever price he pleases on it.

2. If there is a patent on a hive, it would be an infringement for you to make a hive coming under that patent, even for your own use.

3. If the colony is strong it will take care of itself. But it will be a help to scrape off the nests of worms from the side of the hive with a knife or something of the kind.

4. As soon as you are a little accustomed to handling bees you will find it much the best plan to handle them with the bare hands.

Rubber gloves are made for beginners, but they are warm, sticky and uncomfortable. Some use a cheap, white glove, perhaps made of hogskin, which has a very rank smell. You ought to have a good bee-hook. The publishers of this paper will be glad to furnish it if you will write them.

Ventilator in a Bee-Cellar.

I wish to build a bee-cellar to hold 150 colonies, with a stone arch and a work-shop on top. What is the best way to put in a ventilator? WISCONSIN.

ANSWER.—I have a sub-earth ventilator that runs for several rods four feet or so under ground, so as to bring in air somewhat warmed. It got-stopt up, and last winter didn't work at all. The bees (nearly 300 colonies) wintered well without it, and I'm not sure I'll have it opened up again, for I'm just a little bit suspicious of the quality of the air after it has had a chance to take in possible underground gases. The bees wintered finely, and the only chance for air to get in was through the walls, but there was plenty of chance for it to get out through two chimneys that started from the ground. Probably a chimney or a shaft of any kind to carry up the air will be all you will need.

A City Bee-Keeping Beginner.

I want to begin with one colony. I live in the city, within 900 feet of Brooklyn's largest park, near by a large cemetery, and within a half mile of the open country. My idea is to set the hive on a ledge, shaded, and easily reached from an upper window.

1. How early can I start my colony?

2. What book or manual goes more into practical details of bee-keeping than Prof. Cook's book?

3. Is my plan feasible?

4. Later on I shall feel perturbed if the bees swarm, which they doubtless will do. My experiment is for study, observation, and what the future may develop. I am an expert in poultry farming or culture, and expect to make the apiary an adjunct to the business I am planning to begin next year—provided I learn enough about it this year. LONG ISLAND.

ANSWERS.—1. Any time now will do, as there will be early flowers for the bees to work on.

2. I should say Prof. Cook's book goes into practical details, but it's a good thing to have "line upon line," and you will like Root's "A B C of Bee-Culture," also Dadant's "Langstroth on the Honey-Bee."

3. Decidedly yes, and you'll have lots of fun at it.

4. If you don't want the bees to swarm you can get the start of them by dividing.

Transferring—Putting on Sections.

1. Last fall I bought at an auction several colonies of bees in frame hives, which, being hived without the use of foundation, the combs are built crosswise of the frames, making all fast together. The hives, I believe, are called the "Eclectic." The front and back are 3 inches thick, and fast to the bottom-board; both sides can be taken off, leaving two division-boards, one on each side of the frames. I wish to transfer into the light chaff hive. Can it be done? If so, how?

2. Two of the colonies I wish to transfer are weak. Can they be united at the same time they are transferred?

3. How soon can sections be put on after transferring? NEW YORK.

ANSWERS.—1. They can be transferred much as your text-book instructs to transfer from box-hives, but you may have the advantage in this case that possibly one or more of the frames can be first got out, and if no frame can be got out, then with a long-bladed knife you cut away all attachments from the walls of the hive, and then turning the hive upside down dump out the whole of its contents.

2. Yes, if you transfer at a time when honey is yielding there will be little trouble about uniting.

3. Put on sections when clover—if that's your first principal crop—has commenced to yield, or when you see the bees put bits of white wax along the top-bars and upper parts of the brood-combs.

Don't Ask for a Catalog.

Please send your catalog of sections and bee-supplies.

BEE-KEEPER.

ANSWER.—Perhaps this doesn't fairly come under the head of "Questions and Answers," and yet as I get a communication like it quite often, it may save some stationery and postage for me to say here that I'm not in the supply business—have no catalog, no hives to sell, no bees, no honey, no nothing. I'm just an every-day bee-keeper that the editor has hired to stand up and have all sorts of questions fired at him, and then I guess at the answers. The only thing I ever have to sell is honey, and it isn't worth while to ask me about that, for it's generally sold in a lump before it comes off the hives. Ask me anything you like about bees or bee-keeping to be answered in this department, but don't ask me for catalog. C. C. MILLER.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitecomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

APRIL 14, 1898.

NO. 15.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the Joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Farmers and the Price of Honey.—In the Canadian Bee Journal Dr. Miller having referred to the opinion that farmers hurt the honey market by selling at a low price, C. H. Dibbern asks him if he ever knew "a farmer who didn't get all he could for his honey?" Dr. Miller disclaims paternity for the opinion which he calls a tradition, and says:

"But as I understand the tradition, it doesn't matter a bawbee if it should be fully established that every farmer from Cain down, always got the last cent he could for his honey. The point is, that his honey isn't worth a price proper for a good article, but there is such a general feeling that honey is honey, that when a farmer sells a dirty mess at five cents, that does a great deal towards establishing five cents as a proper price for everything that comes under the name of honey. Now, mind you, I don't say that's true. I am only trying to instruct you in the tradition. I never had any practical experience in the matter."

Incidentally the Doctor takes occasion to ventilate his long-mentioned theory—a theory too unpopular to be mentioned on his native soil—that the moral right that a bee-keeper has to a certain territory should be made legally secure.

Eat More Honey.—Mr. F. H. Dow, of New York, has the following excellent recommendation of honey in the Orange Judd Farmer:

"There is no more delicate or wholesome a sweet in existence than the nectar of flowers, so skillfully gathered and stored by the honey-bee. Its use ought to be more general. Indeed, honey should be used as common as butter. Children usually like honey, and they should be allowed to use it freely. It is healthful, and in all cases of colds, sore throat and the like it acts as a medicine. Whenever you purchase a cough medicine, honey is usually one of its principal ingredients. My two children have nearly always had all the honey they

cared to use, and I am confident it has been beneficial to them. On our table we consume large quantities of honey, and I actually believe its free use is conducive to the family health."

It would be a good thing to get your local newspapers to publish such testimonials for the use of honey. Suppose you take the above paragraph, with a sample of your nicest honey, to your local editor, and see if he won't be glad to publish the one and eat the other. And he will likely say, also, that you have the best honey he ever tasted.

The Bee Journal and Spelling Reform is touched on by Mr. C. P. Dadant in his very sensible article on another page. One would conclude, from the way a few of our readers have written to us in opposition to the contemplated reform in spelling, that they were entirely ignorant of the fact that the English spelling of to-day is entirely different from what it was a century or so ago. Just look at the following—the way Shakespeare spelt in the 17th century:

Sunne (sun), cuppe (cup), fysche (fish), musick (music), civill (civil), horrou (horror), duckcoy (decoy).

Say, don't some of the old-fogies want to go back and learn how to spell? We should think they would, or else try to help continue this wise reform in our spelling. Many bee-keepers don't know it, but Dr. C. C. Miller—whom all know, as well as admire—is right with us in trying to have the American Bee Journal do what it can toward simplifying the spelling of English words.

Some people think that the whole thing is simply a *fad*, or the idea of a few crazy-headed, would-be reformers. For all such, as well as for some others, we are glad to reproduce here a portion of an editorial in a recent issue of the New York Voice, with this heading:

IS SIMPLER SPELLING A MERE FAD?

It is amusing always, but sometimes, we confess, a little provoking, to note the dense prejudice, and often downright ignorance, that are encountered by any attempt at the simpler spelling of English words. Is it nothing that men like Benjamin Franklin, Noah Webster, Noah Porter, for years president of Yale College, W. D. Whitney, the editor of the Century Dictionary, Dr. Murray, the editor of the great Oxford Dictionary, now in progress of publication, Prof. Max Muller, Prof. W. W. Skeat, the famous etymologist, Prof. Lounsbury, of Yale, and other leading English philologists of England and America, earnestly advocate this reform, and give very substantial reasons for their faith in it? Is it nothing that William T. Harris, the United States Commissioner of Education, declares that this reform, if carried out fully, would save two years in the school life of every child, telling us that he has demonstrated this by actual experiments; and that Dr. J. H. Gladstone, member of the school board of London, says?

"The average English child spending eight years in school spends 2,320 school hours in spelling, reading, and dictation, and 720 hours of spelling lessons might be dispensed with if our spelling were simplified. The child-life of no other nation is so clouded with the misery of such absurd and antiquated spelling."

And that thereupon Max Muller pertinently asks?—

"Is every English child, as compared with other children, to be mulcted in two or three years of his life to learn it?"

Is it nothing that so level-headed, big-brained a statesman as William E. Gladstone should say?—

"I often think that if I were a foreigner, and had to set about learning English, I should go mad. I honestly can say I cannot conceive how it is that he learns to pronounce English, when I take into account the total absence of rule, method, and system, and all the auxiliaries that people usually get when they have to acquire something difficult of attainment. There is much that may be done with advantage in the reform of spelling as to the English language."

Is it nothing that some of our leading merchants and manufacturers declare that a very serious drawback to the extension of trade into countries of other tongues is the grave and needless complexities of English spelling? Is it nothing that the great matter-of-fact and scholarly German government, by an imperial decree, has ordered the dropping of all silent letters in German words, and that these words be phonetically spelt—"Express every sound you hear in correct and

distinct pronunciation; and that the French Academy has taken steps for the reform of the spelling of many of the French words, and that Italy, "classic Italy," has made her language phonetic; and poor Spain, and nearly all other nations in Europe are moving in the same direction? Are the Anglo-Saxons alone to pay the penalty in orthography of being the great-grandchildren of blundering ancestors?

We might say that the publishers of the New York Voice—Messrs. Funk & Wagnalls Co.—are also the publishers of the great Standard Dictionary. They are the leaders in several reform movements, one of which is the spelling reform.

The New Union still continues to grow. It is getting ready—preparing to fulfill its great mission of usefulness to the pursuit of bee-keeping. Of course not much has yet been done—it has had few opportunities, and less funds. Prof. Cook, in the April Pacific Bee Journal, has a few words on "The Unions," from which we quote the following:

"The New Union promises to combat every evil of any magnitude that attempts the injury of bee-keepers. As yet it has only talkt. People seem doubtful if it will grapple with adulteration, etc., especially the wrongs that the Old Union resisted so effectually. . . . Many hold aloof because of such doubt. I think we should all unite on one Union, and that the one that would fight every enemy to the knife."

Well, what have the General Manager and Board of Directors to say to Prof. Cook's strictures upon the United States Bee-Keepers' Union? They are the fighting part of the organization, and to them bee-keepers must look for the results.

Our own faith in the ultimate value of the work to be done by the New Union is as strong as ever. It needs only the funds, and the opportunities to use them. When the former are ample, the latter will no doubt be found in sufficient abundance.

Here is what a Kentucky bee-keeper has to say about joining the New Union:

GEORGE W. YORK & Co —

Dear Sirs:—Enclosed find \$1.00 for membership fee to the United States Bee-Keepers' Union. I want to put in my mite to help up that grand organization. It should have the hearty co-operation of every bee-keeper in the United States. Why can't we build one of the grandest associations in America? I believe we have the good-will of each other, and a reasonable amount of intelligence. We may be lacking some in financial resources, but it seems to me if all bee-keepers could realize the benefits of a strong and thorough organization, built on the broad platform of the United States Bee-Keepers' Union, they surely would be willing to contribute as much as \$1.00 at least.

I hope the next meeting-place will be at Cincinnati.

W. S. FEEBACK.

MR. JOHN W. WILCOX, of Jo Daviess Co., Ill., writing us March 28, said:

"Bees have wintered well in this vicinity. I did not lose a colony."

MR. ALEX. SCHROEDER, of Austria, writing us March 26, said:

"We had hardly any winter this year, but still the vegetation is very backward, and so are the bees."

MR. JACOB OSWALT, of Stark Co., Ohio, is writing a series of articles on his bee-keeping experience for the Alliance, Ohio, Review—a leading newspaper there. This is a good idea. No doubt every newspaper in the country would be glad to publish a few articles on bees and honey, if written by local bee-keepers. It is a good way to advertise the value of honey as a daily food. Try it.

MR. ARTHUR MILLER, of Windham Co., Vt., when sending the dollar to renew his subscription, added:

"I could not get along without the American Bee Journal."

Now, we were glad to have Mr. Miller say that, for we believe he means it. We also are often inclined to think that there are quite a number that feel the same way—we know there are many that *pay* the same way—*promptly*. But there are, oh, so very many that seem to *like* to get the Bee Journal right along, but who seem to *forget* that we need their subscription dollars in order that we may be able to continue to send the Bee Journal to them so regularly.

Suppose *all* our good people who are in arrears on their subscription just look up the matter *now*, and send in enough to pay to the end of 1898. If about two thousand should do that we'd say—well, we believe the "Mrs. Editor" could say it better than, for *we'd* be "too full for utterance"—full of joy and thankfulness. And we believe those same subscribers would be happier, too.

MR. J. H. MARTIN—the California "Rambler-ing" correspondent of Gleanings for years—seems to have been greatly affected by the pictures of Mr. Golden's section-cleaners—but more impressed, evidently, by the two-handed "cleaner," or operator, than by the machines themselves. Just see how hard he has been "struck:"

"Mr. Editor, I wish to enter a protest against the method Mr. Golden uses to illustrate his machine. I have tried to find the useful points in the machine, but never get farther than the beautiful young lady in the foreground, who is looking right at a fellow. Take her away so I can study the machine. Stop my paper." [Didn't think of it before, but Golden must have had his eye on you. So you've been caught in the trap? Tired of making flap-jacks and keeping bachelor's hall, eh?—Ed.]—Gleanings.

MR. W. F. MARKS, of Ontario Co., N. Y., recently visited The A. I. Root Co. Mr. Marks was instrumental in getting for his State the enactment of the law against spraying fruit-trees while in bloom. He has lately been working up the *Apis dorsata* business—trying to get the Government at Washington to send some one after the big bees of India. He thinks they would be quite an acquisition to this country. But some other very good bee-keepers don't agree with him on that point. We'd like to see that anti-adulteration law pass in Congress first, and thus protect the purity of the honey produced by the bees we already have before getting bigger bees here to gather more honey to compete with glucose and other adulterants.

MR. GEO. W. HUFSTEDLER, of Bee Co., Tex., writing us March 29, said:

"Our bees are gathering honey at a lively pace now, except a day now and then when we have a wind from the north. My advertisement in the Bee Journal brings me lots of business."

Mr. Hufstedler evidently knows how to get his share of business. Some others might do the same who are not now advertising in the Bee Journal. If you have queens or supplies to sell, the bee-paper is the place in which to let it be known. Our advertising columns are open to all honest dealers.

MR. W. L. COOGSHALL, of Tompkins Co., N. Y., called on us, with his young son, April 5, when on their way on business further west. Mr. C. has nearly 1,200 colonies of bees in 13 apiaries. His crop last year was about 50,000 pounds of extracted honey, and 4,000 in the comb. He and his brother "D. H." have been in the bee-business since 1862, so they have had a good opportunity to see how bee-keeping has grown in all these years. We take it that they have made some money in the business, tho' doubtless less to-day than in their earlier years in honey-production.

MR. O. B. BARROWS, of Marshalltown, Iowa, died lately. We do not know the date or particulars of his death. He was once mayor of Marshalltown, and had been a regular reader of the Bee Journal for years.

MR. J. E. BUNKER, of Cook Co., Ill., wrote March 31, when paying his subscription:

"The American Bee Journal contains too many items of interest for one interested in that line to be without."

T Supers.—R. C. Aikin stands with Dr. Miller for T supers in preference to wide frames or section-holders. Doolittle thinks a properly made wide frame is better than either of the others.—Progressive Bee-Keeper.

Storing Honey in Cisterns.—Gleanings says R. Wilkin, of California, has his honey stored in a *fire-proof concrete* reservoir. He is holding his 14 tons of extracted for 5 cents, which he is likely to get if the crop is as poor as anticipated.

Nailed Sections, on account of their solidity, says Doolittle in Progressive Bee-Keeper, are so much better that he wouldn't take one-piece or dovetailed sections as a gift if he could buy material for nailed at three times the price of others.

Another Section-Cleaner.—J. A. Golden comes out in Gleanings with another section-cleaner—his third, is it?—this time the cleaner being a belt running almost horizontally over two wheels. He claims that the belt will jar a comb much less than a solid-surface disk or wheel.

Taking Bees Out Early.—J. B. Hall likes to get bees out of the cellar as early as March 1, so as to start early breeding. R. F. Holtermann has been putting them out earlier and earlier, and wants them out as soon as they can have a good, safe flight.—Canadian Bee Journal.

Enlarging vs. Contracting.—Hasty in Review refers to Doolittle's plan of starting in spring with 10 frames and then at the harvest taking out what the queen doesn't occupy, and says he works the other way. Starts with seven, then at harvest fills up the extra-prolific ones to 10 or more frames.

Big Average Per Colony.—Editor Leahy, in his explorations on Long Island, has discovered a bee-keeper, John Young, who year after year averages 100 pounds per colony from 100 colonies, which he sells at 20 cents, making his average yearly sales \$2,000!—Progressive Bee-Keeper.

Bees on Farms.—The editor of the Busy Bee is pushing with both shoulders to have the time come he would like to see in this country, "when every farmer and fruit-grower will keep a few bees, and the value of the honey-bee to the orchardist, and of honey as a food product, will be generally recognized."

Light Sections Selling Best.—G. M. Doolittle says in Gleanings that last fall he assorted his sections as to weight, making certain cases of 20 sections each weigh 19, 20 and 21 pounds, respectively. The 20-pounders brought a cent a pound more than the 21's, and the 19's 2½¢ more than the 21's. Strong argument for light weight.

Floating Pollen.—Hasty takes Dr. Miller to task for admitting the possibility of pollen enough in honey to set the queen to laying. After a good deal of exploration in that direction himself, he says: "If he will take a microscope and examine different samples of honey until he has found even one grain of pollen, he will thenceforth discontinue that strain of speech."

Moving Bees in Summer.—E. Ruffy reports to Revue Internationale that he moved an apiary of 22 colonies a distance of ¾ of a mile, in the evening, taking no special precaution, and there was no trouble. Again, early in September he moved 92 colonies 1/10 of a mile successfully, taking them early in the morning. But to be successful one must move the whole apiary.

Foul Brood.—F. A. Gemmill sounds a note of warning against putting too much trust in R. L. Taylor's statement, that it is unnecessary to first place the bees on starters for four days or so before allowing them to work out foundation in order to effect a permanent cure. He thinks Mr. Taylor's plan may have worked with him, but would not be wise in all cases and under all circumstances.

Robbing.—F. Chatelain says in L'Abeille that the worst kind of robbing is what is called quiet or slow robbing, in which the robbed colony submits without objecting, there being no fighting in the case, and the robbing going on through the entire season. His plan of curing is to shut up the robbed colony for a day or two, then on opening it stir it up by pounding with a stick so as to make it defend itself. It is to be hoped that such robbing is not very common. Of the ordinary cases of robbing he thinks by far the greatest cause is allowing a colony to become so short of stores that it starts to robbing in sheer desperation.

Bee-Space and Brace-Combs.—Dr. Miller says, in Gleanings, that with the ¼-inch space between top-bars he has more brace-combs than he likes, and wonders whether it would be any improvement to have more or less than ¼. The editor thinks it possible less might be better, and says that bees pass freely through ⅜ that space, altho they "scrooch" a little. He tried it by putting over top-bar cleats 2-12 thick, and plugging glass over. The average bee, when walking full height, stands about ⅜-16-inch high.

Section-Holders vs. T Supers.—The editor of Gleanings and the "stray straw" man are at swords' points with regard to which is better, the latter asking for one case in which one who has tried both preferred the section-holder. Mr. Root and his lieutenants said there were *hundreds* of them, but they couldn't recall names, till I. S. Tilt came to the rescue and said he was the man. Now the editor calls for a show of hands from those who have tried the two arrangements, asking their exact preference.

Temperature of Cellars.—Chas. Dadant says when the temperature in a cellar surpasses 47°, the bees desiring to go out are in continual movement. They leave the hives in great numbers to lose themselves in following up the least ray of light that enters through some crack. Dr. C. C. Miller, while admitting that such experience may be correct, thinks it unnecessary. With pure air in the cellar, his bees remain tranquil in the hives at 50°, altho not quite so quiet as at 45°.—Revue Internationale.

Moving Bees.—The Review says when a colony is to be shipped a long distance it's a good plan to set it on a new stand for a few hours before shipment, so that the old bees that do most of the worrying en route may be eliminated. The buyer might object to getting a less number of bees, but the colony on arrival will be worth more without the old bees. E. A. Wander told him bees could be moved a short distance without stopping the entrance. Just subdue with smoke, then put them on a wagon.

A Boston Yarn.—The Pacific Bee Journal copies it from Boston Transcript. At Yarmouthport they had to stop tearing down an old house because the bees had "made a hive" (doesn't say whether dovetailed) between the walls. "One whole side of the building is solidly packed with the honey, and it is expected that hundreds of pounds will be taken out." Say, Bennett, why didn't you agree to eat (you and Hasty) at seven sittings, all that "whole side of the building" will be likely to yield?

"Strained" Honey is generally spoken of as a somewhat unsavory mess, being mixt with pollen, brood and dead bees. Doolittle comes to its defence in American Bee-Keeper, and says when he was a boy strained honey at their house was all right, and a good deal better than *some* extracted honey, taken from the brood-nest, with disgusting-looking larvæ by the score, together with their food, floating on the surface.

Great Fall in Price of Sections.—When Doolittle commenced bee-keeping, sections cost \$20 a thousand. He got machinery and made them to sell. Soon the price came down to \$15, then \$10, \$8 and \$6. At \$6 he gave up making to sell, but made for his own use till \$3.50 was reached, when he concluded it was cheaper to buy. He says the sections at \$20 didn't compare in any way with the \$3 sections of to-day.

Why Swarms Go West.—Dr. Miller having replied he didn't know why so many swarms went west, Hasty makes the guess that the prevailing winds being from the west, a runaway swarm being in search of better supplies, goes west on account of the smell of abundance coming from that direction. That looks more like a reason than a guess, *if* the west is the chief direction of runaways.

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|---------------------------|-----|--------|--------|--------|
| Sweet Clover (white)..... | .60 | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | .70 | 1.25 | 3.00 | 5.75 |
| White Clover..... | .80 | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | .60 | 1.00 | 2.25 | 4.00 |
| Crimson Clover..... | .55 | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

Experience in Retailing Honey.

Query 70.—1. Have you had any experience in retailing honey?

2. If so, will you name a few of what you consider the needful points to order to make it a success?—**HONEY-MAN.**

R. L. Taylor—1. No.

Eugene Secor—1. No.

Dr. C. C. Miller—I'm no good at it.

Jas. A. Stone—No; only a little at home.

C. H. Dibbern—1. Yes, decidedly. 2. Produce honey that everybody wants.

Prof. A. J. Cook—1 and 2. I have, and give results and suggestions in my "Bee-Keepers' Guide."

W. G. Larrabee—1. Yes. 2. Represent your honey just as it is, sell a good article, and ask the same price from every one.

E. France—1. Yes. 2. Get your crop in first-class marketable shape and neatness. Let it be known that you have such honey to sell.

G. M. Doolittle—1 and 2. Leave a free sample at each house. Then go around a few days later and you will make sales at nearly every place where you left a sample.

J. M. Hambaugh—1. Yes. 2. a. A good salesman. b. A pure and wholesome article. c. Packages of various sizes and attractive forms, both comb and extracted. d. Push the goods.

J. E. Pond—1. Not to any extent, as I have never produced honey to sell. 2. I could give my opinion, but with no experience in the matter such opinion would be simply a "Yankee guess."

Dr. J. P. H. Brown—1. Yes. 2. The nicest and neatest shape. Education of customers as to what is pure and clean honey. Talk up the wholesomeness of your honey, and talk down the adulterated commercial syrups.

A. F. Brown—1 and 2. Yes, extracted honey in glass jars and tumblers; only put it into jars and tumblers about as fast as needed. Use small, plain, neat labels. Don't be "stingy" with sampling to prospective customers—to every one.

Rev. M. Mahlo—1. A little. 2. Have good honey put up in attractive packages. Give away small samples. I have retailed more at my house than anywhere else. When people find that I have a good article at a fair price they come for it.

Emerson T. Abbott—1. Yes. 2. A fine quality of honey and a good live salesman, who is thoroughly posted in the bee-buiness, are two things that are very essential. You cannot tell a man on paper how to sell goods. He must learn this by practical experience.

Mrs. L. Harrison—1. Yes. 2. Never consider an order too small to give it your attention. Show your goods, and

Two Special Offers.

As explained in former ads, publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo., or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a free, TESTED Italian Queen. Purchasers may have either the bright, golden stratu, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. **W. Z. HUTCHINSON,**

FLINT, MICH.

shade prices to suit quality. Keep grocery men continually supplied, and purchase your family supplies in exchange. Favor your customers in every reasonable way.

G. W. Demaree—1. I sell at retail at my apiary store-room. Being located near a little town my sales are fairly good. 2. Be honest, liberal, never misrepresent the quality of honey sold, and give good weight. When the people know you, according to their conclusion will be your success or your failure.

J. A. Green—1. Yes. 2. Intelligence, industry, knowledge of the salesman's art and human nature, courtesy, tact, and a thorough knowledge of honey, are the principal qualifications. There are many little "tricks of the trade" that are hard to explain, and impossible in the limited room of this department.

A Discouraging Prospect.

I feel that I cannot get along without the Bee Journal, altho from every sign this will be one of the worst years California has experienced for a long time. We have had but very little rain thus far, and can hope for little from now on, so it looks as if disaster must result to the bee-industry here this year.

ALBERT ROZELL.
Los Angeles Co., Calif., March.

A Farmer-Bee-Keeper's Report.

I am a farmer and bee-keeper. I commenced the spring of 1897 with 25 colonies. During the summer I increased to 40, by natural swarming, and in July I harvested 1,000 pounds of comb honey and 200 pounds of evaporated honey. I don't use a honey extractor. I separate the honey from uncapt and unfinished sections by evaporation. I have my honey all sold at 12 and 15 cents per pound. I found a market for it in Alliance, Ohio.

I have my bees all in the Falcon chaff hive, with 10 frames. I use the Langstroth frame, and winter the bees on the summer stands. They are all in grand condition—no signs of dysentery. JACOB OSWALT.
Stark Co., Ohio, March 31.

Preventing Swarming—Best Hive.

To prevent swarming, pile on the supers, 5 or 6, before the bees begin to whiten the tops of the combs. If there is a good nectar flow, you will get lots of honey, tho but few or no swarms.

The best hive for central Illinois is the same square as a 10-frame Langstroth, but 12 inches deep. Put the frames crosswise, or short way of the hive. Telescope all caps over the hives. Use frames six inches deep for extracting, and tier up the same as for comb honey. Use brood-frames for sections, inset top and bottom the same depth as sections. Tier up by placing the new super under the old one.

A machine for pushing the full sections out of a wide frame is easily made, tho I have never seen them advertised for sale.

The spring is early. White clover is abundant, and will bloom in April this year. WM. CAMM.

Morgan Co., Ill., March 29.

Plain Section and Tin Separators.

I have been very much interested and amused at remarks made in the American Bee Journal on no-bee-entrance sections and cleated separators. About 14 years ago I saw the advantages of the plain section, so I made and used several wide

GEO. W. YORK & CO.
118 Michigan st., CHICAGO, ILL.

frames and separators to accommodate the plain section, but finally discarded all in favor of the frame I am now using, the cleated separator being among those discarded.

My wide frame is made to accommodate four sections 4 1/4 x 4 1/4 x 1 1/2; the top and bottom bars made of pine strips 1 7/8 long by 1 1/4 wide by 1/4 thick; the end pieces 4 1/4 long by 2 wide by 3/8 thick, with projection of 1/4 inch on one side only. On the side opposite the projection is nailed a tin separator, 3 1/2 inches wide, leaving a bee-entrance of 1/4 inch at the top and bottom of the section, making an unobstructed passage from one end to the other of the case, and does away entirely with the necessity of sections with insets. It also enables the bees to build their combs flush with the front side of the sections, while at the side next to the separator there will be a bee-space, which is a great advantage in crating for market, and the bee-passageways in corners of sections are greatly diminished. I have from 100 to 200 colonies run for comb honey exclusively, and have used nothing but this frame and section since 1885, and will continue to do so, as I am satisfied there is nothing better at present.

Walworth Co., Wis. F. W. TRAVIS.

Bees in Southwest Georgia.

The bee-industry is rather a new business in this section (southwest Georgia) as to Italian bees and movable-frame hives. I have persuaded some of our best farmers to try the new methods, and none regret it.

The galberry honey exhibited at our Fair last fall was pronounced, by competent judges, "the best in the world."

Thomas Co., Ga. THOS. WIGHT.

Wintering Bees in a Cave.

I have had great success in wintering my bees in a cave well ventilated. One year ago I prepared the cave by packing in the bottom about one foot deep of fine flax straw to keep the moisture down and to absorb the moisture from the bees. I put 43 colonies into a cave 6x10 feet, and last spring I took them out all alive and in fine condition. Last fall I put in about the same number, and at this writing they are in fine condition.

Calhoun Co., Iowa, March 7. C. S. BURLEY.

Two Queens in a Hive, Etc.

I see so often that some one blots on the subject of two queens being in the same hive at one time, and it appears that it is doubted by many. Of course it is natural for only one queen to be in a hive, but I have seen two laying queens in one hive—a 10-frame hive. It was a hive that the colony had not yet completely filled the brood-chamber, and one day while looking through it I found a new queen, and on the next frame I found the old queen; both were laying, and so I took the old queen and introduced her to a colony of blacks, and all was well. I am satisfied that two queens are sometimes found in one hive, although it is not natural to find it so.

I have been in the bee-business for 7 or 8 years, and have started several apiaries, one of which I am very proud of.

Bees did fairly well last season. I am with the Dadants on the hive question, as I have tried four different kinds.

P. W. STADLMAN.
Columblana Co., Ohio.

The Spelling Reform Endorst.

Bravo! Mr. Editor. I quite enjoyed the vigor with which you kick back on the spelling question. A man who is able to keep right on when he knows he is right, altho not popular, has little need of outside support, and yet it may be a gratification to you to know that some of your readers—and I am fain to hope they are in the majority—appreciate your course in the matter of spelling.

I sometimes feel that I don't do as much as I ought for the reform, having been

Queen-Rearing...

Brought down to 1898. All new ideas and methods by one who has had 37 years' experience in rearing Queens. Address

HENRY ALLEY, Wenham, Mass.
15Atf Please mention the Bee Journal.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polisht, snowy-white Sections, beautiful, straw-colored transparent Foundation, improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c., postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

brought up to believe in its desirability from childhood, when I took my first lessons in a phonetic reader.

My father, in his younger days, was clerk—"assistant" he was termed at that time when he was the only one—to Isaac Pitman, who gave to the world the most popular system of shorthand, and spent much of his long and useful life in the endeavor to bring about a reform in the spelling of English. That Mr. Pitman was more successful than many in gaining some appreciation during his lifetime was shown by the fact that he was made *Sir Isaac*.

I have written phonography since my tenth year. (Mrs.) A. L. AMOS.
Custer Co., Nebr.

Bees in Good Condition.

My bees are in good condition. I have 30 colonies, and have not lost one in two years. D. E. LANE.
Washtenaw Co., Mich., March 11.

Little Surplus Honey Produced.

Alfalfa is the principal honey source here, but owing to numerous hailstorms and water-spouts but very little surplus honey was produced in this vicinity during the season of 1897. I hope for better times this season, as the bees wintered well, and have been flying daily for about three weeks. Spring is about one month earlier than last year.

We have 50 colonies all active now, and wintered on the summer stands without loss. S. L. PAYNE.
Malheur Co., Oreg., March 10.

All Wintered Well.

Last fall I put 34 colonies of bees into the cellar, all in good condition. March 15 being a fine day I set them out, and all came out in No. 1 condition. They have had several good flights, and all seem strong and ready for business. I intend to purchase 25 to 50 colonies this spring, unless my head trouble returns again. I have never fully recovered from it. Whenever I am out in cold winds my head troubles me. I wish the Bee Journal the greatest success. J. W. VAN ALLEN.
Crawford Co., Wis., March 24.

Bees in Texas.

Bees have been busy at work all during this month, and were doing well, but they are frozen in to-day.

I am glad that the American Bee Journal is taking the stand against fraud and adulteration. Give it to 'em! S. E. FRIEND.
Callahan Co., Tex., March 23.

No Loss in Wintering.

Bees wintered well without any loss, and are in fine condition for spring work, with plenty of stores for quite a spring campaign. A. Y. BALDWIN.
DeKalb Co., March 26.

All Wintered—The Outlook.

Our 162 colonies of bees wintered without the loss of a single colony—100 in the cellar and 62 packed in chaff out-of-doors.

White clover was badly injured last fall by the dry weather, but the snow and timely rains this spring have saved alive what was not killed out, and it is looking quite thrifty, so we are expecting some honey again this year, tho probably not so much as last year. Mrs. L. C. AXTELL.
Warren Co., Ill., March 31.

Bees Wintered All Right.

As a rule the bees in the greater part of this State have come through the winter in good condition. I have bees in four different places, and I have visited three of those places and found them all alive at each place. In all my bee-keeping experience this is only the second time that I have ac-

complisht so desirable a result. The other apary being about 26 miles away, I have not yet gotten around to it. I find that many of our bee-keepers smother their bees, year after year, but owing to the weather this winter being a steady dry cold most of the time, the bees were kept more dry, and thus they came through all right, which is what they never do if it is damp and they sweat badly.
E. S. LOVESTY.
Salt Lake Co., Utah, March 19.

Mild Winter—Crop Reports.

Winter has past, and glad sunshine now welcomes our busy bees. Mine have wintered successfully on the summer stands, without any protection at all. This has been the mildest winter we have had for years. I look for a good honey-yield this season. Basswood failed last year, and so it will be very apt to come in again this year. White clover I think is all right.

By all means do not stop publishing "honey crop prospects," for they are very interesting reading. Success to the "old reliable" American Bee Journal.
Cooper Co., Mo. F. N. BLANK.

Wintered Nicely.

I started in last spring with 14 colonies, inreast to 32, and got 1,000 pounds of comb honey in one-pound sections, which I sold at 18 and 20 cents per pound. My bees have wintered nicely without any loss so far. They have been gathering pollen for the last 10 days. At present everything indicates a good bee-year. The American Bee Journal has been a great help to me during the last year.
HIRAM MESSER.
Greene Co., Pa., March 14.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Mar. 23.—Very little demand for honey in the comb, the season being about over for its sale in any quantity beyond a case or so at a time, many retailers refusing to carry it in stock owing to sales being infrequent. Prices askt are 10c for best grade of white, 8@9c for No. 1 or fair grade of white; ambers, 7@8c; dark, same. Extracted, 5@6c white; amber, 4@5c; and 4c for dark and buckwheat. Beeswax, 27c.
R. A. BURNETT & CO.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@5½c; dark, 4@5c. Beeswax in good demand at 26@27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season.
M. H. HUNT.

Kansas City, April 9.—Fancy white, 1-lbs., 9@10c; No. 1, white, 9c; amber, 8c. Extracted, white, 5@5½c; amber, 4½@5c; dark, 4c. Beeswax, 20@22c.

Demand for both comb and extracted honey is fair.
C. U. CLEMONS & CO.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging.
S. H. HALL & CO.

Cincinnati, Mar. 21.—Demand fair for extracted, with insufficient supplies. Prices range from 4@6c, according to quality. Demand for comb is slow at 10@13c for best white. Beeswax in good demand at 20@25c for good to choice yellow.
CHAS. F. MUTH & SON.

Indianapolis, March 24.—Fancy white, 11 to 13c.; No 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.
WALTER S. POWDER.

San Francisco, Mar. 16.—White comb, 8@9½c; amber 5@6c; extracted, white, 4½@5c; light amber, 4½@4¾c. Beeswax, 24@27c.

The firm tone last noted as prevailing in the market for extracted honey continues to be experienced, with light stocks of all grades. The same condition is reported as existing in the East and in Europe. Comb honey is still in more than ample supply for current requirements, having to depend wholly on local customs.

Milwaukee, March 8.—Fancy, 11 to 12c.; A No 1, 10 to 11c.; No 1, 10 to 10½c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4½ to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the best. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better
A. V. BISHOP & CO.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.
BATTERSON & CO.

New York, Feb. 9.—There has been a fair demand for comb honey of late, and we are gradually reducing our stock. Fancy white is scarce and holding ready sale at 10 to 11c.; off grades white and amber, 8 to 9c.; mixt and buckwheat, 6c. Extracted is in fair demand—California white, 5½c; light amber, 5c.; white clover and basswood, 4½ to 5c.; buckwheat, 4c.; Southern, 50c. a gallon. Beeswax is steady at 26 to 27c.

Cleveland, Feb. 22.—Fancy white, 12 to 13c.; No. 1, 11 to 12c.; No. 1 amber, 9 to 10c. Extracted, white, 6 to 6½c.; amber, 4 to 5c. Beeswax, 22 to 25c.
A. B. WILLIAMS & CO.

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c.

A Book Recommended by Dr. Gallup.

THE NEW METHOD

In Health and Disease.

By W. E Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from Weakness to Strength so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings cannot be sick. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, not a drug treatment.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helpt by some of the "New Methods" given here; even those who have been pronounced Consumptive have been entirely cured. While for Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentary, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy publisht, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

GEORGE W. YORK & CO.,
CHICAGO, ILLS.

Queen-Clipping Device Free

The Monette Queen-Clipping device is a fine thing for use in catching and clipping queens' wings. We mail it for 30 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device.

CONTRIBUTED ARTICLES

SWEET CLOVER.

A Symposium On Its Value as a Forage Plant.

Some time ago we called for testimony from those who had experience with sweet clover as a food for stock, that

SWEET CLOVER—AN EARLY FORAGE-PLANT.

I have read Prof. A. J. Cook's article on sweet clover, published on page 97. I do not wish to enter into a controversy in regard to the use of *melilotus* as a forage-plant—whether it is wise to try to use it for such purpose in all parts of our country can only be settled by fair trial. Sweet clover is not indigenous to our country, but both species have been brought from the Eastern World. These grasses were first placed by early botanists with the true clovers—red and the white. The Greeks establish the genus "trifolium," or the three-leaved plant, under the name "triphullon;" but later, when the Latin language was written, it was called "trifolium." Subsequently the two sweet clovers were separated from the clovers and formed the genus *melilotus*. The Latin word

A Luxurious Growth of Sweet Clover in Genesee County, Michigan.—From Bee-Keeper's Review.

having been called in question. We have received several responses to that request, and herewith give some of them, following them with some extracts from other sources:

"*melilotus*" was formed of the prefix *meli*, honey, and *lotus*, some leguminous plant.—Prof. Asa Gray.

One of the explanations of the use of *lotus* in the Latin is,

a plant serving for fodder, *melilot* (*Trifolium officinalis*). This settles that the yellow sweet clover was early used for forage. As Prof. Cook suggests, it is probably an annual. But if it furnishes a good flow of nectar it may be used to advantage; for the white is known to be a biennial, taking the second year to flower, and after it matures its seed the entire plant dies. To have sweet clover for the bees the next season we have only to sow the seed of the yellow in the fall that the white dies, or early the next spring, and if it is an annual it will flower early in June here in Chicago; a full month before the white comes into bloom. Or bee-men may have a bloom of the white sweet clover every year by sowing its seed every year, and not without.

Cook Co., Ill.

D. S. HEFFRON, M. A.

COWS EAT SWEET CLOVER IN FRANKLIN CO., MO.

It is strange indeed to see how widely men's experiences differ in the same pursuit, with the same thing. Some say that their stock can be educated to eat sweet clover. Mr. Lighton, on page 72 declares emphatically, "But I do know they simply will not eat sweet clover in any form."

Prof. Cook, a bright light who has dispelled the gloom from the field of bee-culture to a great measure, and has illuminated the way, also speaks depreciatively of sweet clover as a forage plant. I have 55 colonies of bees, and have had sweet clover growing on my farm for four years. My experience is that my stock, especially cows, eat it in any form—green or dry. I was somewhat surprised a few weeks after turning a fine Durham milk cow into a pasture where I had grown sweet clover, to find she had eaten the dry stems down to six inches of the ground. She did this in January, when the straw or stems were perfectly dry and apparently void of nutrition.

In making the above statement I don't want it inferred that I am casting any reflections on the statement of Mr. Lighton. I believe he has spoken truly his experience, but altogether the adverse to what I have experienced here in Missouri.

Franklin Co., Mo., Feb. 7.

A. B. BATES.

STOCK WILL NOT EAT SWEET CLOVER IN SALT LAKE CO., UTAH

There seems to be considerable discussion pro and con in regard to the merits of sweet clover as a fodder and honey-plant. Under favorable conditions it is an excellent honey-producer, but as a fodder-plant, if it has any advocates in Utah, I do not know it. In June, when it is young and tender, when one would think stock would relish it, they won't touch it as long as they can get other feed. I have fed it with lucern and other clovers and grasses, and they invariably pick out and eat the other feed. If we do not give them other feed they will pick off a few tender buds and leaves, but under no condition except sheer starvation will they eat the stems. But in August and September, where the stock is allowed to roam among it at will, they appear to eat considerable of it; but some people tell us that even then it is because they have nothing better.

Be that as it may, we find that it causes a profusion of bloom and honey, small shoots not over six inches high being covered with blossoms, and under favorable conditions the bees work on it till frost. But in Utah, to try to make a fodder plant of sweet clover, it would not be worth the cutting and hauling.

Of course, Utah has her lucern or alfalfa, which, we think, is the best fodder and honey plant on earth. I have known nine tons to be cut from one acre in one season, and nearly all living animals will eat it—even pigs and chickens will thrive on it if fed green; and under favorable conditions we think it is one of the finest honey-plants grown. But, like sweet clover and other honey-plants, it is not much good as a honey-plant in a rainy, wet climate. Sometimes we have an abundance of honey from sweet clover, lucern, and Rocky Mountain honey-plant; at other times little or none. It is not because there is no nectar in the blossoms—it is because the rain washes it out.

Salt Lake Co., Utah.

E. S. LOVESY.

STOCK EAT SWEET CLOVER IN WELD CO., COLO.

They are all having a drive at the sweet clover question, and yet I think they have not got the right end of some of the points. As to the question whether stock will eat it and thrive on it, I have seen enough to know that both horses and cattle do, and do it readily. It is simply one of those things that they not like when first tasted, but of which they grow fond with use.

In South Africa, when they wish to fatten a steer, I have heard they feed on sweet potatoes, and nothing else, and the beast won't start on them for about two days, and after hav-

ing them for a time will eat them by preference over anything else.

Right across the road from me there is a large field, part hay land, part rough, with cottonwood and willows; in this there is a quantity of sweet clover. I saw 70 head of cows, young steers and calves turned in there after the cleaner parts were cut last fall, when there was plenty of uncut hay and after grass, and saw the whole bunch eat the sweet clover chiefly and voluntarily the moment they were put in. Some were half Texans from the southern part of Colorado or New Mexico, some were natives.

The seedling sweet clover is very small in the early season, but grows quite heavy in the autumn, but does not flower, and stays soft, and gave in this case great pasture, and the stock flourished. I think it would make a fair crop of hay cut late in the fall, and the next season it would certainly cut an early crop of hay, and flower well afterwards for the bees, and if the land was then cultivated it would be got rid of pretty effectually.

WALTER A. VARIAN.

Weld Co., Colo.

STOCK EAT SWEET CLOVER IN CUMING CO., NEBR.

For the benefit of the American Bee Journal readers I will give my experience in regard to stock eating sweet clover. I have on my 160-acre farm about an acre of sandy land where I never succeeded in getting a satisfactory crop. So about six years ago I concluded I would have a crop of sweet clover there, but my experience told me that it would be a very difficult matter to get a catch by sowing the seed there, but I had a small patch, probably two or three rods, which stood very thick with one-year-old plants five or six inches high in the first part of May. A part of these—probably about 200 plants in all—were dug up and transplanted on that sandhill. They stood quite far apart, but they grew and bloomed that same year. In the fall, when the seeds were ripe, I scattered them all over the ground. The succeeding summer that hill presented a beautiful green spot; the clover grew over a foot high, but did not bloom until the year after, about the first of July. It bloomed the whole summer, and to my surprise the bees worked on it for two weeks after we had the first frost.

As I wanted a new pasture, ten acres adjoining this hill was sown to timothy, orchard grass, and blue grass. The sweet clover patch being almost in the center was fenced in with the rest. I really did not think at the time that my cows would eat the clover—it tasted very bitter. The cows were not put in the pasture until May of last year. The tame grass was then six to eight inches high, but it did not take long before they had found my sweet clover, and they kept it eaten down so low the whole season that only a spray of flowers here and there could be seen. The pasture was not overstocked, as six head of cattle was all that had access to the 10-acre lot.

I now concluded to sow more sweet clover, so 200 pounds was ordered, and 150 pounds was sown last October on 10 acres of wheat-stubble, and nothing more done to it. The balance of 50 pounds will be sown on the same 10 acres the coming fall. This is necessary in order to make it bloom every year.

You will get a catch of sweet clover best on very poor, solid ground, but it will grow equally well or better on good ground, providing that the weeds are cut often the first year. If left to grow they will kill the sweet clover. As it starts very slow, it is necessary to sow in the fall so the seeds can be softened during the winter and start to grow early in the spring. A zero spell will not kill the plants just coming out of the ground, if the ground is covered with stubble or other rubbish and dead weeds. Should the ground be clear or loose, the young plants will heave out and die.

Sweet clover transplants very well, and I have gotten such a high opinion of its merits, that if there was no other way of getting a few acres of it started, I would transplant one-year-old plants about 10 feet apart each way, which would only take a little over 400 plants to the acre. The year after I would plant 400 more between the others, and keep clean around each plant two or three months after they were planted. That would give them a sure start, and a growth of clover that would surprise all beholders.

If any one doubts that stock will eat sweet clover in preference to the best tame grass, he may call at my place in May or June, or any time while it is green, and I will convince him to his entire satisfaction that at least my stock is very fond of it.

J. F. ROSENFELD.

Cuming Co., Nebr.

IS SWEET CLOVER A NOXIOUS WEED?

This question has been up quite often the past few years

and is pretty well settled by this utterance of the Ohio Experiment Station, recently issued in a newspaper bulletin:

HOW SHALL WE RANK SWEET CLOVER?

Many portions of Ohio have the roadsides and other sodden or "out of tith" lands occupied by the white sweet clover plant (*Melilotus alba*, L.). Since it has been regarded as a noxious weed the former Ohio Statute placed it in the same list of proscribed plants with Canada thistle, common thistle, oxeye-daisy, wild parsnip, wild carrot, teasel, burdock, and cockle-burs.

Under the operation of this statute, private lands might be entered upon to destroy the melilotus growing for any purpose as for bee-pastures. The destruction of bee-pastures in this manner actually occurred near Delaware.

Rightly, then, it may be asked, "How shall we rank sweet clover?" To answer this we must consider where sweet clover grows, and what is its character. Sweet clover grows spontaneously along tramped roadsides, even to the wheel-ruts in abandoned roadways, and in tramped or sodden land anywhere. When found in meadow lands it appears not to occur except when the ground has been tramped by stock when wet. It grows by preference in old brick-yards. It may be grown in fields by proper tillage.

The character of sweet clover may now be determined. Viewing it in no other light we thus see that sweet clover grows luxuriantly in places where few or no other plants flourish. But it belongs to the great class of leguminous plants which are capable, by the aid of other organisms, of fixing atmospheric nitrogen, and storing it in the plant-tissues. It belongs with the clovers, and it may thus be used to improve the land upon which it grows, and this appears to be its mission. It occupies lands that have become unfitted for good growth of other forage-plants. Its rank, then, is *as a useful plant*, capable of increasing fertility of land.

How shall sweet clover be treated?

The character determined, the treatment to be accorded this clover plant is really settled. *The plant is the farmer's friend, to be utilized and not to be outlawed.* The plant grows and spreads rapidly. So do red clover, white clover, timothy, blue-grass, and other forage plants; but sweet clover grows where they do not; it indicates lack of condition for the others. Viewed in this way it is to be treated as preparing unfitted lands for other crops.

It may be mown a short time before coming into bloom, and cured for hay. Stock will thrive upon it if confined to it until accustomed to it. The roadsides, if taken when free from dust, may be made almost as profitable as any other area in clover by cutting the sweet clover and curing for hay. If this is regularly attended to while stock is kept from other lands that it invades, sweet clover will be found doing always the good work for which it is adapted.

The italics in the above are ours. We wish that every one who has been against sweet clover could read that strong defense of it.

A MISSISSIPPIAN'S ESTIMATE OF SWEET CLOVER.

The following paragraphs appeared in the Agricultural Epitomist of last January:

At the North, *Melilotus alba* is considered a weed and a pest—not looked upon with any degree of favor except as a valuable plant for bee-pasture. In the South, it is one of the most valuable fertilizing and hay plants we have; also highly appreciated for its early spring and late fall pasturage. Stock are not fond of the plant at first, but soon acquire a taste for it. For dairy cows the hay is specially valuable, very largely increasing the flow of milk and the yield of butter, improving the quality of both, in fact. None of the clovers are superior to it as a fertilizer. It grows satisfactorily only on land well supplied with lime. It is distinctively a lime plant, and if there is but a very small percent of lime in the soil it will not thrive well, and we advise against sowing on such lands. On our lime prairie soils of East Mississippi and Central Alabama this plant is largely grown. It thrives admirably with Johnson grass—in fact, the two supplement each other nicely. The strong, deep-penetrating roots of the melilotus loosen up the hard subsoil, and enable the Johnson grass to grow off to better advantage.

It matters not how severe the drouth or excessive the rainfall, melilotus is a certain crop—a sure crop, independent of any variation of the seasons—a plant that can be depended on.

As a fertilizing crop it cannot be excelled, if equaled, by any of the leguminous soil-recuperating plants. On soils where the highest limit of corn production did not exceed

eight bushels per acre, a few years of melilotus-growing on the land so enrich the soil that 30 bushels of corn per acre was easily raised.

Melilotus is a biennial, and reseeds itself every two years. It stands cold as well as alfalfa and red clover.

We have no seed for sale. We have no personal motive in speaking so highly of the merits of this plant. Recognizing these merits that characterize this plant, having personally witnessed the practical values of the plant on our own farm as a fertilizer, hay, and pasture plant, we feel in a humor to do it justice by giving greater publicity to its virtues.

Is it not strange that a plant that has proven itself so meritorious at the South, and growing steadily and continuously in favor here, has no friends in the North to sing its praises or accord it any worth whatever, save the apatist—the owner and lover of the honey-bee?

Oktibbeha Co., Miss.

EDWIN MONTGOMERY.

After copying Mr. Montgomery's high testimonial to the value of sweet clover, Mr. A. I. Root has this to say in regard to it in Gleanings:

Please notice the writer is not a bee-keeper, does not sell seed, and has no interest in any shape in the matter. I would call special attention to what he says about its value in the South, and I want to add that we very much doubt whether there is a place in the North where cows cannot be taught to eat sweet clover when it is pastured or cut at the right stage of growth. I am sure there is not a locality anywhere where it will not prove to be one of the best plants known to enrich impoverished soil by plowing it under. Our experiment stations are pronounced in its favor wherever a test has been made. Since the matter has been suggested in regard to lime for its growth, I am inclined to think our friend is right about it. This thing, at least, is true: It will grow on ground so poor that no other plant can be made to make a stand. In fact, it grows with rank luxuriance on soil thrown out from deep railroad cuts; and such land can be made productive by plowing under a heavy growth of sweet clover, without adding anything else; and, astonishing as it may seem, where the ground is rich, and will grow all sorts of weeds, we oftentimes fail to get a good stand of sweet clover. A. I. ROOT.

In the April Bee-Keepers' Review appear several articles on sweet clover, and also the beautiful illustration which Editor Hutchinson has very kindly loaned for our use on the first page this week. From the articles in the Review, we copy the following, as it all comes in so nicely with the rest of our symposium on sweet clover:

HOW TO GROW SWEET CLOVER.

In my opinion sweet clover can be made to grow upon any soil by a proper supply of lime applied thereto, artificially. My plan would be to plant the sweet clover in hills, or drills, the same as corn, and then use a cup full, a pint, or possibly a quart of fresh slackt lime to each hill. I would use a hoe to make a depression to receive the seed, then cover with lime, and finish with soil. The seed will come up if covered two inches deep, more or less. No one need be afraid to use even a quart of slackt lime, if thought best, to each hill, for it is my belief that the sweet clover plant will grow and thrive in lime alone, and without a particle of soil! My experience along that line seems to corroborate that statement. Three to five seeds to each hill will be ample, for if but one of them germinates, the plant will make a stool large enough to shade the entire plat of ground; even if not closer than three feet apart each way. M. M. BALDRIDGE.

Kane Co., Ill.

SWEET CLOVER MAKES GOOD PASTURE—EASILY ERADICATED.

I have sowed sweet clover upon pastures and waste-places for the last six years, and can say that it has filled the bill for stock; especially in dry seasons when other clovers and grasses are literally dried up. It is a mistake to say that stock will not eat it; as, after tasting it a few times, they give it a preference. Last summer I saw a pasture of 17 acres in which sweet clover was eaten down close to the ground, while Alsike, timothy, and white clover went to seed in the same lot. Just over the fence, in another lot, the sweet clover grew seven feet high, and so thick that one could scarcely pass through it.

It is called a weed by some, but this is not the case. Of course, if sown upon waste lands, such as swamps, open woodlands, clearings, etc., it will take the place of thistles and ragweed, and hold its own, but, as it dies root and branch the second year, there is no trouble getting rid of it. Not only

this, but it leaves the ground full of richness that it has brought up from the lower depths. A. A. ALVERSON.
Ottawa Co., Mich.

SOWING SWEET CLOVER—COWS EAT IT.

I have had six years' experience with sweet clover, and find that it will flourish in any place where Alsike or white clover will thrive; but it will not grow on "blow-sand."

I begin sowing it in the fall at the time that the seed is ripe, and continue until corn-planting time; sowing on the high land first and finishing up on low swamp-land. I sow it in waste-places, old slashings and pasture lots. In the fall of 1894 I seeded down 10 acres of land that had just been cleared and burned over. I sowed timothy, Alsike, and sweet clover, and went over it lightly with a drag. The following year I turned in seven cows. They did not touch the sweet clover until it was about two feet high, picking out the other grass that grew among it, then, as the hot, dry weather came on, they took to the sweet clover and ate it to the ground, allowing the other grass to grow up and blossom. The cows remained in good health, and gave good messes of rich milk. Ottawa Co., Mich. DAVID BERTSCH.

Well, what more need be said in defense of sweet clover? It seems to us about all that is needed is for farmers to get better acquainted with the various values of sweet clover, and then take full advantage of all that the plant has to recommend itself.

Against the Plain Section and Fence.

BY J. S. SCOTT.

I am a subscriber to the American Bee Journal, and my old partner takes Gleanings. I have read with interest all that has been said about the old no-bee-way section and (misnamed) fence separator. I have been anxiously waiting for something in reference to them from some large honey-producer, such as Capt. Hetherington, C. Davenport, and others.

We were persuaded a few years ago, by the "Sage of Medina," and the "Medicine Man of the Maregoes," that in the 1½ two-bee-way section and tin separator we had reached the acme of our pursuit, and advised to fall in line, which we did, and their praise has ever since been on our lips. But, behold! we are now advised to stop and turn back to the old no-bee-way section. This we could do were it not the demolishing effect on our bank account, for I feel that we could place before our customers just as nice a section of honey as we do now, but no nicer. It would cost—three of us who work together—at least \$700 to make the change, and at the present price of honey we cannot afford to do so.

I believe each individual speaks from his own personal standpoint, and I would like to ask the "Sage of Medina" who is to be benefited by the change. Certainly not the honey-producer, nor yet the consumer, for we now place before our customers a most attractive section of honey, fit for the lips of Jupiter.

I read Gleanings from Genesis to Revelation, and see the change strongly advocated, more so than elsewhere. They quote Aspinwall, in Review, as saying that the cost in shipping-cases and sections alone will be 51 per cent less. It is impossible for me to see how any one can believe this. Do the Roots ask less for the no-bee-way section than for the other? Will a shipping-case cost less with veneering between every two rows of sections together with follower and wedge? I think not. To say nothing of the difference in handling the sections by inexperienced clerks. I am slow to impugn the motive of any one, but I do not think we will be compelled to use a search-light to find the only persons who would be benefited by this change. I also believe that to agitate any change so costly is bad policy, unless it is plainly shown to be a benefit to the producer and consumer. I acknowledge that I can see neither in this.

I could say much more on this subject, but I do not wish to encroach more on your time. Utah Co., Utah.

[We would suggest that Mr. Scott try a few of the new things this year, and then if he likes them, and feels there is enough in the change to pay him and his two friends for making it, they can go ahead and spend that \$700. Otherwise, they'd better hang on to their bank account.]

Be slow to make changes, until you have proven that the new in your hands is superior to the old.—EDITOR.]

COMB FOUNDATION.

How Much to Use in Sections, How to Cut and How to Fasten It.

BY G. M. DOOLITTLE.

I am requested to tell the readers of the American Bee Journal how much foundation I would use in the sections, how I cut the same (without having it stick to the knife, or breaking it), and how I fasten it in the sections.

The amount to use in each section is governed somewhat by the state of the "pocket-book," and whether you are going to give your increase on full sheets of foundation, or only on starters in the frames. If you must rob your family of necessities or comforts that you may buy foundation, then I should use only a triangular piece in each section, each of the three sides being 1½ inches long; or if I were to fill the brood-frames full of foundation for the swarm, then I should use starters in each section as above.

But if I had sufficient money so I could procure the necessary foundation, without a sacrifice to me and mine, then I should fill each section with *extra-thin* foundation to within ½ inch of the bottom, and within ¼ of the sides of the section. This is what is called "filling the sections with foundation." And I should thus fill them if I allowed the swarms issuing from the apiary to build their own comb, which thing very many of our best apiarists consider just the thing to do. Any prime swarm has wax-secretion well under way when they leave the parent hive, it often being seen standing out in little white flakes from the wax-pockets, and if we furnish no place in which these new colonies can build comb, all of this secretion of wax is wasted (or often worse than wasted) by the bees using it in thickening the bases of the cells in the sections, this causing the consumers of our honey to growl about the "fish-bone" in the center of the honey. For this reason many of us think it best to let the bees use this wax in building brood-combs so as to allow no waste, and also because any section which is filled with foundation presents a much nicer appearance after being finished, as a rule, than does the one wherein the comb is nearly or wholly built by the bees. And all know that it is the *nice appearance* of comb honey which causes it to sell at fancy prices. When the bees will no longer build worker-comb below—as many new colonies will not—after being hived two or more weeks, then it is profitable to fill out the rest of the brood-chamber with frames filled with comb or comb foundation.

CUTTING FOUNDATION FOR SECTIONS.

The cutting of foundation was something which used to bother me as much as any one thing I did about the bee-business; after finding out how to do it, it seems very simple. The first requisite is a piece of ¾ lumber a little longer than any foundation which you will ever be likely to have, and as wide as two widths of the foundation, when two sheets are laid on it side by side. A 1¼-inch nail should be driven near each end down through this board into the bench or table, or whatever you use it on, so as to hold it in place, and still allow of its easy removal when not in use. Next get out two strips from the ¾ lumber, two inches wide, and as long as the foundation-board which you have tacked to the table. Stand these by the side of the table or foundation-board, so they will nearly touch each edge of it; when you are to nail to the top of these strips a board from ¼-inch stuff, which is wide enough so as to come out even with the outer edge of each strip, and as long as is the foundation-board, nailed to the bench or table. Upon lifting it off you will have a shallow box without top or ends when turned over.

Now with a lead-pencil mark lines across the top at intervals, the distance between the lines being just the same as the width you wish your foundation after it is out. Now, with clinch nails, of suitable length, nail strips of the ¼-inch stuff across the top between the lines you have drawn, so that your shallow box need not split and fall to pieces after you have sawed through where you have marked the lines. Having these ¼-inch strips all nailed on, next, with a fine saw, cut through where each line appears, allowing the saw to cut down on the side strips to within ⅛ inch of their cut-off, and you have the foundation-cutting form complete, except that I would nail on to one end of the table or bench board a strip three inches high, so that when laying the foundation on the board for cutting, each sheet could be brought up to this strip, thus "evening" the ends so that all might be exactly alike.

Now lay on sheets of foundation till you have from six to ten sheets deep, according as you find most convenient for you to cut, and then lay the same number by the side of the first pile, for you will remember that we are to cut two piles at once.

Having the two piles of foundation all even and nice on

the table or bench board, we now carefully place over it (and out against the guide-strip at the end which evens the foundation) the board having the saw-kerfs through it, when we are ready for the knife.

For a knife I prefer an old table-knife, such as our grandmothers used—one that has been worn till it is very thin, when the edge is made very sharp on an oil-stone.

Now to prevent the wax sticking to the knife was a problem on which I workt a long time. I was told by some to have the knife hot by keeping it in hot water; others advised the use of weak lye, honey, etc., all of which did not please me. Having a rag moistened with kerosene close by, and passing the knife over it before each stroke so as to moisten it with the oil, workt the best of any of these, and this plan was used until one day when I was in a great hurry I drew the knife through the foundation as quickly as possible, without bothering with any oil, when lo, and behold, the whole sticking matter was solved, for the friction caused by the rapid motion of the knife through the wax melted it to a sufficient extent so it did not stick to the knife at all.

To be sure I was right, I quickly drew the knife to the middle of the pile and stopt, allowing a few seconds to pass before I tried to go on again, when I found the knife was fastened and could not well be moved except by tearing the foundation. A later trial of several quick strokes with the knife and then suddenly putting it to the tongue showed that it was almost too hot to be borne without pain. I now have no more fussing with hot water, kerosene-oil, or anything of the kind, but draw the knife through the foundation just as rapidly as possible, when the cut edge of the foundation is left as smooth and shiny as though it had been melted in two. It is best not to bear down too hard in cutting, using two or three light strokes to cut through a pile of eight or ten sheets, rather than trying to cut through the whole at one stroke.

FASTENING FOUNDATION IN SECTIONS.

As to fastening into sections, I formerly used the brush or spoon plan of so applying melted wax that was spread on the foundation and the section at the same time, and in cooling it adhered to both. But of late I have used the heated-plate plan, by way of the "Daisy" foundation fastener, and I am satisfied there is nothing better. Onondaga Co., N. Y.

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

The 18th annual convention of the Colorado State Bee-Keepers' Association was held in Denver, Jan. 17 and 18, 1898.

REPORT ON HONEY ANALYSES.

The Committee on Honey Analyses made their report. Three samples of honey, two put up by a Denver firm, and one by a St. Joseph firm, had been purchast in the market, packt in the presence of two of the members, and sent to the State chemist, who analyzed them, and found that the Denver samples contained a considerable percentage of cane sugar syrup, and the St. Joseph sample was probably a solution of glucose with a piece of comb honey added. As a certain bee-keeper—a member of the Denver Bee-Keepers' Association—had stoutly asserted that the Denver firm was not guilty of the charge of adulteration, the Executive Committee, at a special meeting, decided to purchase a new set of samples and have them analyzed by another chemist. Accordingly the committee went together to the same business house where the previous samples had been purchast, secured another lot of honey put up by the same parties, and had them packt up ready for shipping by the clerk who sold them. The parcel was sent by express to an Eastern honey expert, who analyzed them with practically the same results as the State chemist had found. The agreement of the two analyses was considered sufficient evidence by the committee.

ROOM FOR HOLDING MEETINGS.

The committee on securing a room in the Capitol—E. Milleson—made the following report: "As a committee appointed to secure a room for the meetings of the State Bee-

Associations, I desire to report that the Capitol building still remains under the supervision of the superintendent of the building, and he is disposed to do the best he can in furnishing a meeting-place for the bee-keepers of the State; but we hardly see the way cleared for a room for our exclusive use."

LAW ON SPRAYING FRUIT-TREES.

The committee on securing a spraying law—F. L. Thompson—reported that a law had been formed, and adopted by the last legislature, so that it is now in force. It is to be found in Section 15, page 65, of the Session Laws of Colorado for 1897, and reads as follows:

"It shall be unlawful for any person or persons to spray fruit-trees while in bloom, with any substance injurious to bees. Any person violating the provisions of this section shall on conviction before any Justice of the Peace be liable to a fine of not less than \$5 or more than \$50. . . . The proceedings of the State Bee-Keepers' Annual Convention shall be filed with the Secretary of the Board of Horticulture, who shall edit it and file with the Secretary of State, who shall cause the same to be publisht annually with the report of the Board of Horticulture."

E. Milleson, who is the fruit inspector of Arapahoe county, said he thought there would be a revolution in spraying materials, by the use of insecticides harmless to bees, and also said that the poisons now used were so largely adulterated as to not even harm the larvæ.

S. M. Carlzen stated that a few of the horticulturists on the western slope, whose names he could not give, were making efforts to repeal the spraying law. This was confirmed by a letter from a western-slope bee-inspector, not read before the Association, which will appear later in this account of the proceedings.

SAMPLES OF HONEY-COMBS.

Pres. R. C. Alkin exhibitd three sections containing septa of honey-combs, the rest of the comb and the honey having been removed, all built in the same super. One had been part natural comb, and part comb built on extra-thin foundation. The natural septum lookt much lighter on account of the color of the wax, but the difference in thicknesses was small. But chewing showed a difference in quality, that of natural comb being more brittle. Another section contained a septum resulting from the use of deep-cell foundation. In eating, no difference could be perceived between it and ordinary foundation. The third section had contained very heavy brood foundation. This had been much thinned, and the wax used in building up the side-walls, also some deposited where the cell-wall joins the base.

H. Rauchfuss also exhibited a septum of comb from deep-cell foundation, and some finisht sections in which deep-cell foundation, ordinary foundation, and Given rolled foundation had been used. Altho the Given rolled foundation was clumsy, the septum after completion was not so thick as that of comb from the deep-cell foundation. The latter was commenced sooner, but not finisht sooner than the other.

SUNFLOWERS FOR SHADING HIVES.

Mr. Varian recommended the Russian sunflower as furnishing shade to the hives just when wanted, and not sooner. As the seeds stand the frost, they could be planted in the fall. They will grow on poor soil. About six should be planted about a foot from the hive, on the south side.

Pres. Aikin then read his annual address as follows:

President's Annual Address.

Fellow Bee-Keepers and Friends:—It is a pleasure to me to be with you. A little over one year ago I thought likely I should never meet with you again, much less to serve you as president of this association. I am intensely interested in our pursuit, and as well in the welfare of each of you, financially, morally and spiritually.

I wonder how many of you are here because you love your neighbors. I think we may say that most of us are here through one or both of two general motives—love of self and love for others. I trust that not one is here through selfishness only; at least I hope not. Personally, I feel sure that these annual gatherings cost me more in labor and thought than all I can get out of them as a money consideration.

While it is true that we may get value received on a money basis, there are other ways in which we may get well paid. It is a pleasure to me to see your faces, to shake the hand, to talk of each other's welfare, and to try to help each other. Brethren, try to get all you can that will benefit you financially and morally, but let your getting be of that kind that worketh both ways, charitable and full of love. "Give and it shall be given unto you; prest down, and shaken together

and running over, shall men give into your bosom. For with the same measure ye mete withal it shall be measured to you again."

Let us help each other. I know there is a large element in this world who would laugh at such advice and call it foolishness; but nevertheless the biggest fool of all is he who does not know the value of such advice. We are here to help each other—and ourselves. How can we best do this?

I believe it was two years ago that, in my address, I strongly urged this Association to a more thorough organization and co-operation. I again urge it. Trusts, combines, and monopolistic organizations are multiplying everywhere. Recently a trust representing millions of capital was organized to control one of our worst enemies—glucose. This is not the kind of organization I urge, for such a one is monopolistic, selfish, unkind, "giving that it may receive again." There is another kind of organization which is honorable and kind, that *receiveth that it may give*, and which we may call co-operation. Fellow bee-keepers, are not our hearts as one in this?

What shall be the work of this convention? How have you fared the past year? Tell us what you have produced, where and how you have sold it, and the remuneration. I find the burden of complaint to be "poor markets." We must not rest till something has been done to better the honey market. With laborers unemployed or poorly paid, with farmers and all classes of producers barely making a living, or going behind, there is no use to expect higher prices. Our duties in

sent to you later, I feel that then our organization will be on a more solid footing. It will then be in order for you to reach out to greater usefulness. I recommend that this Association do something toward the support of the United States Bee-Keepers' Union. I wish that every apiarist in the State were members of that association. Of course we want your membership in this Association, too, but you should not neglect the other. An advance of $\frac{1}{2}$ cent per pound on 500 pounds of honey would far more than pay your dues in both organizations, and I believe that a conscientious support of both would benefit you several times over all it would cost you.

In order to advance co-operation a better statistical plan is needed. I therefore recommend that you make arrangements by which our secretary and other officials of the organization may get into communication with apiarists in all parts of the State; and to facilitate this, provision should be made for printing return cards so that all the apiarists would have to do would be to fill blanks and mail, this Association doing the rest. In this and connected directly with it should be a sort of information bureau whereby apiarists may be informed of crop and market conditions.

I believe that our State should be well represented at the Trans-Mississippi Exposition at Omaha. Considering the work that we should do at home, and the very low state of the Association's financial condition, I cannot recommend that our funds be applied in that direction. However, I appeal to

Bee-Supply Factory of E. Kretchmer—One of Our Advertisers.

general as citizens have to do with many of the far-reaching influences that have to do with general conditions influencing morals and money, but as members of the Colorado State Bee-Keepers' Association, and as bee-keepers in general, we have duties toward each other in the pursuit. We may be able to concert our action and better pack and market our product, and thereby help ourselves in some points at least until such time as good-will shall prevail among all classes to the good of all.

I desire to point out in speciality some things this Association should do at this time. We have a constitution. Its limitations and regulations have not been properly observed. We must amend our methods or our constitution—both need amending. The constitution requires us to hold this, our annual convention, the third Monday in January, beginning at 10 o'clock a.m. This is too ironclad to best serve our interests. I recommend that this provision be amended giving us more liberty as to time of meeting, and that it be so modified as to be largely in the power of the executive to call meetings.

Besides this, there are other amendments needed in both constitution and by-laws. Sections 4 and 7 of the constitution need amending. Also sections 3, 5 and 13 of the by-laws. I will not here detail these matters, but so soon as you shall be ready to consider the matter I will point out to you what in my estimation is needed, when you can adopt or reject, as seems best.

Should you see fit to adopt amendments that I shall pre-

the apiarists of the State to do what they can in that direction outside of the Association, and should the bee-keepers rally to the support of the Association, we may also do something as an Association. Our State produces both quantity and quality, and we ought to be represented.

I appeal to the apiarists of the State to stand by your Association in both moral and financial support. Your officials are willing to execute for you at a cost of both time and means if you will but give them the proper backing. Stand by this Association, for in helping it you help yourselves. Co-operative organization is just, proper, and to be desired for the good of all.

Defensive organization is a necessity to protect ourselves against common enemies. Do you not know, fellow apiarists and all classes of producers, that a large element of mankind—perhaps I should call them by a less dignified name—are planning, yes, even deliberately plotting, in many cases, to induce or compel you to divide your earnings with them? There are non-producers—many of them—who are abundantly worthy of our support, they are necessary in the social economy, and we sin if we do not duly support them; but the monopolistic and unfair grabbers, and above all the parasites who feed upon honest productions, must be gotten rid of.

Dear friends, let charity prevail. Do a labor of love, so loving the right and hating the wrong, that no wrong-doer can stay among us and continue to do wrong. May our motto be harmonious and persistent action, *action, ACTION.*

R. C. AIKIN.

The Secretary next read his report, as follows :

THE SECRETARY'S ANNUAL REPORT.

At the last annual meeting your Secretary was instructed to request the publishers of *Gleanings in Bee-Culture* to withdraw the quotations of a certain firm dealing in honey in this city. After considerable correspondence, and even after they were informed of the result of two different analyses, they still preferred to continue their quotations, saying they wanted more analyses made. But as this Association is not in a position to waste any money for this purpose, it was thought best to let the matter rest.

During the last session of the legislature a law had been past to have our report printed with the Horticultural Report. Accordingly I prepared a very complete report of our proceedings, and had the same turned over to the Secretary of the State Board of Horticulture, Mrs. Martha A. Shute, but I have been informed lately that there are no funds available for the printing of the same.

During the past season communications were received from Florida and also from the United States Department of Agriculture for copies of our foul brood law, which were furnished.

As there was a glut in our honey market during the latter part of the summer, I have tried to be of some assistance to my fellow bee-keepers in finding an outlet for this surplus, and have met with fair success.

I have also received communications from the officers of the Trans-Mississippi and International Exposition in Omaha, inviting the Association to make an exhibit at that place.

On account of lack of funds certain lines of work, as the collection of honey statistics, etc., could not be carried out. I hope the past favorable season will revive the interest in Association matters among bee-keepers, and result in a largely increased membership.

FRANK RAUCHFUSS, Sec.

COMMITTEE ON PERMANENT EXHIBITS.

A committee on permanent exhibits, consisting of R. H. Rhodes, J. E. Lyou, H. Rauchfuss, J. B. Adams, and Mrs. M. A. Shute, was appointed, and reported that they had some assurance of having cases furnished to be placed in the Capitol Building.

A letter dated Jan. 11, from Vice-Pres. W. L. Porter, at present in Los Angeles, Calif., was read, which is as follows :

CONDITION OF THE DENVER HONEY MARKET, ETC.

I have been requested to write on the condition of our honey market—its present demand and supply. At the present time the demand for honey in Denver is very slow. Dealers all complain that it is getting very slow. Perhaps this may be on account of Holiday trade, and it may be better soon. The supply seems to be ample. Houses that are dealing in honey say they have ample stock to last through the year. Dealers have told me that in the past week, in order to move honey at all, they were compelled to sell at \$2.00 per case, the same price they paid for the honey.

It is very evident that the demand is too small, or the supply too great, for bee-keepers to secure a living price for the product of their apiaries. Through the joint effort of a few of the leading bee-keepers several carloads of honey have been shipped East, from the Denver markets; and it is evident, if we wish to sustain a fair market, this must be done in the future. As no one bee-keeper produces honey extensively enough to ship alone, co-operation is necessary, and it is to be hoped that the State Association may get in shape to do it for its members. You may depend on my hearty co-operation.

I have been attending the California association. There was a good attendance of wide-awake and energetic bee-keepers. The meeting was a very interesting one. Mr. Cowan was present and gave a talk on bee-keeping in England; the remarks were very instructive. The Association took action on the uniting of the two Unions. The vote was unanimous that the New Union should absorb the Old, and the Old should wind up its business and cease to be. It would seem to me to be wise for our Association to pass a similar resolution. They also past a memorial to Congress to give us a pure food law, and a committee was appointed to draw up a resolution and present the same to the Secretary of Agriculture.

W. L. PORTER.

[Continued next week.]

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See offers on page 255.

Delayed Laying.—M. Gillet says, in *Revue Eclectique* that he had a queen not fecundated till 29 days old, commenced laying three days later, laid only drone-eggs for nine days, then worker-eggs.

Making One's Own Supplies.—*Gleanings'* Strawman says: "Doolittle advises a good workman with the necessary tools to make all his needed wares after starting, except sections. Doolittle! I'm a good workman, and I can borrow what tools I lack, but if I can get a job of sprouting potatoes at 10 cents an hour I believe I can save money to buy my hives and other 'fixins.'"

Spreading Brood, as usually practiced, by inserting an empty comb in the center, is condemned by H. W. Brice, in the *British Bee Journal*. His plan is to wait till the bees completely cover the frames on which they are clustered, then put, only on one side, an empty comb next to the last frame of brood. In a few days put an empty comb on the other side, but in no case put an empty comb between two frames of brood.

Foundation in Sections.—The report of the Ontario experimental apiary says the results of a very thorough and extensive test made with different amounts of foundation in sections, show that it is important that the sections be filled to sides and bottoms, otherwise there will be more pop-holes and the comb will not be fastened firmly to sides and bottom. Foundation running about 12 feet to the pound was most readily accepted by the bees; when thinner, there was greater tendency to pop-holes and gnawing down.

Plain Sections in Canada.—Editor Holtermann bluntly says, "I think that the plain section is a decided humbug." He says, "We are turning out our new sections this year in one piece, with the top and bottom-bar cut clean away in the corners." At the Ontario Convention J. B. Hall objected to the plain section because of the danger of making the combs bleed in handling. F. A. Gemmill replied that when you take hold of a section with a plain top-bar it's all the same as a plain section, and he thinks a nicer looking section can be produced with a cleated, perforated separator. Editor Holtermann thought it might be practicable to have a bee-space on one side and not on the other, but when it comes to having it on either side he predicts failure.

Stimulative Feeding, or "speculative" feeding, as the Germans call it, is discussed by W. Fitzky, in *Centralblatt*. He cites the opinions of various authorities, who are by no means in entire accord. Gravenhorst says with weaklings it does more harm than good, but judiciously managed by the experienced bee-keeper, it produces profitable results with strong colonies. Kilchling says beginners cannot be warned too earnestly against it, for if bad weather comes, the bees, excited by the feeding, fly out in numbers, and instead of being strengthened, the colony is weakened by means of the bees that are lost. "Biene und ihre Zucht" says, under certain conditions of pasturage, the experienced can use it to advantage. Herr Fitzky adds that stimulative feeding is an art to be learned by practice.

Killing Old Bees in the Fall.—Mr. Alpaugh moves a hive in the fall to a new location, sets a top story on the old stand to catch the returning old bees, then destroys them. He thinks the colony winters better for the depletion. The old bees die in the winter, and he thinks some young bees are lost in dragging them out. J. B. Hall is somewhat of the same mind. He doesn't want any more bees in a hive than will take good care of the queen and be ready to make a good start in spring. Beyond that he thinks they only consume honey. If two colonies are to be united in the fall, he just takes the combs from one and lets the bees die.—*Canadian Bee Journal*. This seems just a little on the line of the practice of—was it Hosmer?—a good many years ago, killing off bees so as to have only a pint or a quart to winter. Quite a bit of talk about it at the time, but no one else seemed to succeed at it, and it was given up. Possibly killing off the old bees is the secret of success.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY
118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Engene Secor, Forest City, Iowa.

VOL. 38. APRIL 21, 1898. NO. 16.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

"A Journal that is bright, wide-awake, vigorous, up-to-date, and full of ideas that help arouse the reader to better deeds, can be forgiven almost any failing."—Review.

All right, we feel forgiven, for so many of our readers have told us that they consider the American Bee Journal just that kind of a journal. Next.

Bee-Supply Branches.—It is surprising to note how many of the large manufacturers of bee-keepers' supplies have within a few years established branches in various parts of the country. It seems to be growing as a fad with a firm that has their big headquarters somewhere, to have a whole lot of their smaller hindquarters scattered almost everywhere. We believe the practice will not be so very profitable in the long run. Some day there will likely be a gathering together from "all quarters," to the profit of all concerned.

An Unfortunate Bee-Keeper.—We have received the following from Mr. C. P. Dadant, in regard to a bee-keeper and family who are destitute through the recent awful Shawneetown, Ill., flood:

MR. EDITOR:—Your readers have undoubtedly all read about the terrible disaster at Shawneetown. But, like myself, most of them have probably not thought much farther about it, and altho quite willing to lend a helping hand, they have failed to find the opportunity to subscribe to help the sufferers.

It now appears that one of our brother bee-keepers, and a very deserving one, is among the sufferers, and I take the liberty to present the facts to the bee-keeping fraternity.

Mr. Thos. McDonald, of Shawneetown, was accidentally paralyzed in the hip and legs by falling from a building in 1895. He has since been unable to work, being confined to a

wheel chair, and his apiary of 200 colonies, and a few milk cows that he owned, were managed by his wife and daughters. They were, in this way, making a good living in spite of his position and inability to work.

The flood of Sunday evening, which destroyed the entire town, drowning over 100 people, deprived him of all he had. They lost their home, their cows and their bees, saving only their lives. Friend bee-keeper, is this not a case deserving of our help? The bee-keeping fraternity is a sort of freemasonry, an occupation apart from all others. Let us do as other brotherhoods do, help our suffering ones, remembering that our turn may come to suffer. Let no one hold back because he can give but little. It is the little drops of rain that make the mighty rivers.

If Thos. McDonald can get help enough to buy a few bees he can keep out of the poor-house. Bee-keepers, let us hear from you!
C. P. DADANT.

In a private letter Mr. Dadant suggests that the contributions be sent either to us or to Mr. McDonald direct. But we believe it would be better to forward all to Mr. C. P. Dadant, Hamilton, Hancock Co., Ill., who doubtless will be glad to turn over the total amount, and see that it is properly used, as he vouches for Mr. McDonald's worthiness. We forward our own contribution to Mr. Dadant at once, and trust that all who feel able to do so will send now, so that our suffering brother and family may be able to start with bees again in time to do something this season, which is now at hand. All contributors and their amounts will be published in the American Bee Journal later on.

Let as many as can send \$1.00 each. More if you can do so, or less if not able to send so much.

Grading or Sorting Comb Honey.—How often we have been deceived in honey the past year. We have bought lot after lot, that was very beautiful next to the glass, but back of that—well, it was simply fraudulent putting up, that's all. What good excuse can there be for putting well-filled, white and tempting sections of honey in the outside row, and then filling up with partly-filled, half-sealed sections?

We should like to see the practice come into vogue, of the producer putting his name, county and State, on every case of honey shipped to a city market. It would be infinitely to the credit of the ones who were honest in the putting up of their best grades; and the other fellows would suffer by the practice, as they justly deserve.

There ought to be an advance made this year along the line of a more honest grading or sorting of comb honey for market. Dealer and consumer would alike rejoice.

The Langstroth Monument Fund.—Mr. E. S. Lovesy, President of the Utah Bee-Keepers' Association, sends us the following suggestions on the proposed monument to be erected to the memory of Father Langstroth:

FRIEND YORK:—I have received information that a proposition has been made to erect a Langstroth monument at a cost of about \$75. As a bee-keeper I do most emphatically protest. Shame upon us, if 100,000 or more bee-keepers in the United States cannot do better than this in honor of our beloved friend—the greatest of all American bee-keepers. The trouble is not a lack of generosity on the part of our bee-keepers, but a careless indifference or lack of interest in the matter. We can and must do better. Then let us be up and at it, till the noble work is done.

I move that a committee of five or more bee-keepers be appointed by the officers of the United States and National Bee-Keepers' Unions, to find out where the best and most substantial monument can be had at a cost of about \$500; said committee to also receive inscriptions and select one from among those received to be placed on the monument; and that they also be authorized to agitate the matter until the work is completed in a manner that our bee-keepers will not be ashamed to visit the last resting-place of our long-to-be-remembered friend, L. L. Langstroth.
E. S. LOVESY.

No doubt many said while they were reading the foregoing, "Why, I'll second that motion." We believe that \$1,000

could be raised as easily as \$500, if the matter were pushed by a competent committee.

In order to get it started, we will suggest what we think would be an excellent committee, to be known as "The Langstroth Monument Committee:"

Hon. Eugene Secor, Forest City, Iowa, General Manager of the United States Bee-Keepers' Union, chairman.

Thomas G. Newman, San Francisco, Calif., General Manager of the National Bee-Keepers' Union.

Dr. C. C. Miller, Marengo, Ill.

G. M. Doolittle, Borodino, N. Y.

Mrs. L. Harrison, Peoria, Ill.

Now, why isn't that a fine committee? In it are represented the two Unions, and three of the oldest and best writers on apiculture, one of them to represent the "dear women" bee-keepers. What more do you want?

If this committee shall be the one selected to undertake the work, and provided they accept, we suggest that they at once issue an address to bee-keepers, to be published in all the bee-papers, and that hereafter contributors be requested to forward all moneys to them. Contributions can be sent to any one of the five members, and all be forwarded finally to Chairman Secor, who would be authorized to pay it out when the monument is selected, placed in position, and the work approved.

We believe The A. I. Root Co. have in hand about \$75 that has been contributed toward to Monument Fund, and we have \$10 lately sent to us. If the matter were taken up at once and urged as it deserves, we think that by Oct. 1, 1898, the desired amount could be raised and the monument erected this year.

Provided this matter is taken hold of and worked as it ought to be, our own further contribution of \$5 will be made.

Produce Only the Best Honey.—High aims are always to be encouraged everywhere. Why not in the production of honey, and especially that in the comb? It is our opinion that too much of the inferior grades are put upon the markets, and particularly city markets. We have been greatly surprised at some—yes, a good deal—of the comb honey we have seen in the Chicago market the past year. We truly believe there was but a small percentage that was really fancy honey.

Now it seems to us that with the experience of added years, and with all the present-day improvements in bee-keeping appliances, better-appearing honey ought to result. Bee-keepers should not be satisfied to place before consumers, year after year, inferior looking honey, ragged-edged, and with corduroyed sides, but our aim should be to produce as even and squarely-built sections of honey as we possibly can, trying to improve as the years come and go. We ought to make the effort, at least.

Honey for Burns.—A 4-year old boy was badly scalded, and in despair his parents had recourse to the old domestic remedy—honey. Six pounds of honey were dissolved in warm water, with which the parts were several times bathed. The pain departed at once, and the boy rapidly recovered. This is reported in a German paper. It does not seem to make much difference whether you put honey on the inside or the outside of a person, it is alike beneficial.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Unpainted vs. Painted Hives.

What do you think of unpainted vs. painted hives, as stated by Mr. Doolittle? IOWA.

ANSWER.—Mr. Doolittle says he wouldn't allow his hive-bodies to be painted if any one would give him a dollar a piece for it, for it would make a difference of \$9.00 each in the development of brood in spring. I don't know how exact those figures may be, but I've so much faith in the general principle that I haven't painted a hive for many years, except to paint the covers.

Foul-Brood Treatment.

1. My bees are troubled with foul-brood, and I got Dr. Howard's pamphlet with McEvoy's foul-brood treatment. Is his treatment the best to cure foul-brood, and is it as good or better than the starving plan?

2. Also, could I use the honey that was in the hive where there was foul-brood, to feed the bees, if I boil it well? N. JERSEY.

ANSWERS.—1. You can probably do nothing better than to follow the plan mentioned, which is practically the same as the starving plan, as it uses up all the infected honey before any can be fed to brood.

2. Yes, only such honey will not be fit for winter.

Crimson Clover as a Honey-Yielder.

We have been having ideal spring weather for about a week now, and the bees are working like trojans. They are about a month ahead of what they were last year, and if the weather does not take a change for the worse, I will have honey in the sections within a week, which is something unusual for this section. I would like to know the honey-producing quality of crimson (not red) clover, as compared with white clover. There is about 100 acres of it on all sides of me, and if it yields much nectar, I should have a good crop of honey. There is also a good lot of white clover in my vicinity; saw the first blossoms on it yesterday (March 18.) I have a good stand of sweet clover, planted as an experiment, and will report later how it turns out. Please advise me as to the crimson clover as early as possible. I might mention that the bees work on it very freely. GEORGIA.

ANSWER.—You are the very man to give something definite about crimson clover, and it is to be hoped that you will keep your eyes wide open to tell us all about it as soon as it gets through its principal blooming. Reports so far say it is a great yielder, and there can hardly be any doubt on that score in the mind of any one who has seen the bees at work on it. I do not know whether any one as yet has had so large a quantity of it in one place as to be able to say exactly as to the quality, the supposition being that it is excellent, and on this point you ought to be able to enlighten us. As it comes earlier than the other clovers, with 100 acres you probably ought to be able to have it unmixt with other honey. Be sure to report.

Question on Transferring.

I am a beginner, having only had bees last summer, and getting out of health during the honey-flow and ever since, I have not done them the justice that I might. I got 24 old hives with bees, and some empty in addition, increased to over 40, commencing the winter with 39, which are good now; one was short of "funds," so I today exchanged two empty for two full combs, with another.

1. What I want to know is, your opinion of the best way to change the bees from seven or eight hives of odd patterns, in which the frames are locked and crooked. I wish to get them into standard eight or ten-frame dovetailed hives. I have seen several methods described, and I am not satisfied with any given in books or papers. Could I not set the hives (old and new) one on the other, and drive the bees into the fresh hive until I knew the queen was in the upper new story, then put a queen-excluding zinc between them, and in a few days make the entrance at the upper story and close the lower, and by thus doing induce them to leave the old hive nearly empty of everything but old comb, and make one excessively strong colony? Or, would the bees insist on filling the comb in the old hive full of honey as the brood hatch out? If they would not fill the old story tight full, the combs could be cut out and melted down with little trouble. I judge they would when treated thus, cut out any queen-cells there were in the old story when the new one was added and the queen sent upstairs. If they would not do so, the simplest way, of course, to avoid trouble and

get good results, is to make a "drive," and put the new hive on the old stand, and turn the other and shift it a few times; but that will not turn all the bees into the new hive, so the process will have to be repeated, and if I repeated it after the new queen was hatched. I think the swarm would be too poor to do any good.

2. If they turn to queen-rearing and swarm, which hive would you leave on the old stand, and which will give the best returns in comb honey? COLORADO.

ANSWERS.—1. Your plan might work and it might not. In several instances I have put an excluder over the hive with brood, having the queen in the empty story above, and they sulked a long while—in one case the queen just wouldn't lay at all, altho kept there for weeks. If you put a frame of brood from some other hive in the upper story, you may make the queen lay all right. There is danger that the bees will fill the combs below with honey, but you can help the matter by closing the lower entrance. Then you can gradually increase the opening between the two hives, say after about a week, and when the opening becomes too large to suit the bees, they'll not be likely to want to store anything below, but you must be sure they have abundance of room above. They'll not be very likely to start queen-cells below.

2. Leave the new hive on the old stand and you'll probably get more comb honey, for if you leave the old hive there, they'll be likely to swarm again.

Managing Swarms.

I will tell you how I would like to manage my bees (all that will swarm) and see what you think of it. That is, when a swarm comes out I intend to kill the queen (all clipped) and have the bees come back again to stay. Is this a good way, or not, for comb honey? If so, at what date would you cut queen-cells? In this way of managing, say a queen is extra prolific, I would cage her instead of pinching her head off. Where is it best to keep the caged queen in the hive, and how long? PENN.

ANSWER.—Your plan is a good one if. And a good deal hangs on that if. If you cut out all cells but one before the first one hatches out, and if you miss no cells, and if you select the best one of the lot, and if there is no brood in the hive young enough to be grown into something in the semblance of a queen, you're all right. Perhaps seven days after the issue of the swarm will hit the first and the last conditions, and you'll have to run the risk of leaving the best cell and not missing any. Possibly it might be still better to listen at night for the first piping, which may be in seven or eight days, then in the morning before the bees have time to swarm, cut out all queen-cells. That's safer than to make your choice of cells, so far as the quality of the queen is concerned, and you are not likely at that time to have any unsealed brood. The chief danger is that you may miss a cell.

At that time of year you can keep a caged queen almost anywhere where the bees can get to her to feed her. A handy place is to stick her in the entrance of the hive. She may be kept caged for weeks, but after being caged too long she may not be worth much. Perhaps caging a week or two will not hurt her.

Best Size of Hive—Spacing Frames—Best Section and Separator.

1. What size of hives do you consider best, and which is the best brood-frame?

2. How would you space the brood-frames so as to make them self-spacing? Would you advise closed-end frames, or would you space them with small staples put into the end-bars? If the latter, where should the staples be put?

3. What is the best honey-section to use, and best separator, the fence, board or tin? WISCONSIN.

ANSWERS.—1. It's a very difficult thing to say what size of hive is best. For one who expects to give much attention to his bees, I'm inclined to favor 8-frame hives, as they can be increased anywhere up to 16 frames by having two stories. If little attention is to be given to the bees, probably a 10 or 12 frame hive is better, for there's more danger that with the 8-frame hive the bees would be left in one story with not enough stores for winter. It isn't any where nearly so important to have hives of the same kind as it is to have only one size of frames. You can have 8-frame, 10-frame and 12-frame hives in the same apiary, and find little trouble from it, and you may have different kinds of frames, but when you have different sizes of frames, then the trouble begins. The nearest of anything to a standard frame is 17 $\frac{1}{2}$ long and 9 $\frac{1}{2}$ inches deep, outside measure. I had frames by the thousand that were $\frac{1}{8}$ -inch shorter and $\frac{1}{8}$ -inch shallower, and the difference doesn't amount to anything only that it isn't the standard size, and as fast as I get new frames they are the standard size.

2. I believe closed-end frames are best for the bees, because warmer; but they are troublesome about killing bees, and about being glued together. For spacing, staples are good, and yet I prefer a common wire-nail with a head about 3-16 inch across, the nail being driven in all but $\frac{1}{4}$ inch. That spaces the frames 1 $\frac{3}{8}$ inches from center to center, top-bars and end-bars as well as bottom-bars being 1 $\frac{1}{8}$ inches wide. Staples or nails can be driven in the top-bar near the end-bar, and in the end-bar perhaps 2 $\frac{1}{2}$ inches from the lower end. Only four spacers are needed on a frame, two on one side at one end, and two on the other side at the other end. When you hold up a frame before you, there are no spacers at the right hand end on the side next you, but on the side away from

you, at the left end, the spacers are on the near side. An objection to nails for spacers, and even to the frames I have described, is that they are not regular goods, and have to be made specially to order. But if you start with a frame of the right size, it isn't such a hard matter to change the kind any time.

3. The standard section at present is the 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ x 1 $\frac{1}{2}$ with insets cut for bee-passages, to be used with plain separators—wood separators if they are to be used loose as in the T super—tin if to be nailed fast as in wide-frames or section-holders. The plain section and fence are now on trial, and only that trial will determine whether they should be adopted exclusively or not.

Making Increase by Division.

Of 14 colonies, three died during winter. How would this do, to get three built up to take their places? About May 1 (or would it be safe sooner) if we have an early spring, take a well-populated colony and divide, leaving the queen and two frames in the old hive; of the balance of the frames in this hive (six in number), put two each in three hives, with adhering bees; at the end of ten days cut all queen-cells and introduce queens. I want to get some new blood in, anyway, and would get queens from outside. Of the old combs left by the dead colonies, I have 18, fairly well-filled with honey, to give to the nuclei, as they need it. What would you do different from above? OMAHA.

ANSWER.—Sorry to disagree, but I just wouldn't do anything of the kind. Let me explain a little, and then I'll be obliging enough to let you do as you please. It's the number of bees that count in a honey harvest rather than the number of colonies. When the honey harvest comes, I'd rather have an apiary containing 300,000 bees than one containing 400,000, if the 300,000 are in five colonies and the 400,000 in twenty. That's a proposition by itself. Here's another: If you make four colonies out of one May 1, the probability is that three weeks later you'll not have as many bees in the four colonies as you would have had in the one, if you had left it undisturbed. Until the queen gets up to about her limit of laying, it will be a losing game to divide. For 40,000 can take care of more brood in one hive than they can in two, and so long as the queen can lay more eggs than they can care for, what would you gain by dividing? So I believe I'd rather wait till the queens got to about their limit of laying—perhaps about swarming-time—then take a frame of brood and bees from each hive, making three fairly good colonies at the start, and not materially depleting any one of the 11.

Raising Hives from the Bottom-Board—Zinc Separators—Corn Syrup for Stimulative Feeding—Making Wax Sheets—Introducing Foul Brood with Queens.

1. I read so much about raising hives from the bottom-boards by means of blocks under the corners for ventilation and to discourage swarming. Is there no danger of robbers by having so much opening? and are there not a great many bees lost when the blocks are taken out, as the bees have been accustomed to enter from the sides and rear of the hive?

2. How would separators made of queen-excluding zinc do? They would be nicer and more durable than the fence-separator, and would take up less room.

3. I can buy nice, clear, almost tasteless corn syrup for 18 cents per gallon. How would that be for spring stimulative feeding, by adding part sugar or honey?

4. Is there any other method by which I can make wax sheets for foundation, than by using dipping-boards?

5. Is there any danger of introducing foul brood by sending for queens from any of the advertisers in the Bee Journal? I am wintering 42 colonies in the cellar; so far they seem to be all right, and I am anxiously awaiting spring when I can give them their liberty, for I love to see them at their work and hear their merry hum. I am very fond of reading the Bee Journal, and all bee-literature, of which I have stacks. WISCONSIN.

ANSWERS.—1. The hives are not raised till colonies are very strong, and I never knew of any trouble from robbers on account of the blocks. Theoretically I should be more afraid of bees being troubled to find the entrance when the hive is let down, but practically I've had no trouble. It isn't far, at most, to the front entrance, the call is there, and it's nearer than to any other hive. Besides, you may have noticed that wherever bees start to use the entrance at the beginning of the season, that's the part they'll continue to use, even when other entrances are given. By the time the hive is raised, the bees have established the habit of using the front.

2. They wouldn't be bad, but rather expensive, and colder than wood.

3. Some years ago it was tried, but I think it was finally condemned by all.

4. Perhaps none practicable, unless it be something like the Weed process, which is patented.

5. No honest man would advertise queens whose bees had foul brood, and I'm sure the Bee Journal would not knowingly accept such an advertisement, but of course there's no way by which it can be absolutely certain of all its advertisers.

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|----------------------|-----|--------|--------|--------|
| Sweet Clover (white) | .60 | \$1.00 | \$2.25 | \$4.00 |

GENERAL ITEMS

Bees at Work.

Bees were working lively yesterday and to-day on the box-elders. Peaches, pears and plums are just opening their bloom.

D. C. McLEOD,
Christian Co., Ill., April 11.

Wintered in Good Condition.

My bees came out of winter quarters in good condition. The weather is cold and backward.

W. A. SAUL,
Crawford Co., Iowa, April 7.

Bees in Fine Condition.

We are having good weather now. The snow is off the fields around here, but it is raining to-day. My bees are in the cellar now, and in fine condition.

GEORGE H. PORTER,
Hamilton Co., N. Y., March 14.

Cold Weather in Kentucky.

We have been having some very cold weather the past two weeks. The mercury has been as low as 29—something unusual for old Kentucky. It has been hard on the bees. But it has the appearance of better weather now.

W. S. FEEBACK,
Nicholas Co., Ky., April 12.

Midwinter—Not Midnight.

Please correct a typographical error that crept into my previous article on page 194, second column, the seventh line from the bottom, where your typo makes me say: "I once had a half-barrel of cappings which had been neglected till *midnight*." Did I write "midnight" or "midwinter"? I am perfectly willing that you should give your readers the impression that I am fond of working, whether it is true or not, but don't let them think that I work till "midnight" until absolute, urgent necessity.

Hancock Co., Ill. C. P. DADANT.

[Yes, you are right, as usual. It must be our compositor had been out until midnight the night before putting your article in type. We have been quite ready to give you all credit for being industrious, but would hardly go so far as to think you would work until midnight in rendering wax.—EDITOR.]

A Soldier Bee-Keeper's Story.

It is not necessary for me to say that I appreciate the American Bee Journal—my subscription money tells that. I am an old soldier, and have handled bees more or less all my life, but I had never gotten right down to business until within the last three years. I started with one colony, bought eight more, and now have 70, all in good condition.

While I was a soldier in camp near Nashville, Tenn., I was nearly dead with camp diarrhea. December 25, 1863, we were ordered to move on the enemy at Stoney River. My captain carried my knapsack, and I trudged along and made out to keep in sight of the regiment. That evening, about dark, we went in camp near a residence of a rich old planter on a nice clover pasture. After stacking arms, I took a camp kettle and started down through a cotten patch for water. I had not gone far when I discovered some soldiers a little way from me. It was so dark I could not tell what they were doing, so I paused a moment to see if I could learn what they were at. Soon I heard a voice, "Do they sting?" This aroused my love for honey, and I went to them and found they had three old-fashioned round log hives, the heads knocked off, and the bees holding the party at bay. I asked the privilege to join them, and they

told me to help myself. I took from my pocket a long dirk-knife, and soon filled my kettle with nice poplar honey, and assisted them in getting what they wanted, as I soon learnt they were not accustomed to handling bees. When I returned to the camp-fire my orderly sargent had gone to the house to see if he could get a warm loaf of bread. I took our canteens and went for water, leaving my kettle of honey at the camp-fire. When I returned the orderly had gotten back and reported that a corn-meal pone of bread was under way, and as he returned past the barn he said a great big fat hen tried to peck him, so he arrested her. We gave the hen a trial, and decided she was guilty, and we broke her neck. You never saw as happy a set of soldiers in your life, as we were that night, sitting around our cracker pot-pie, kettle of honey, and our pone of corn-bread. To tell the truth, I entirely forgot that I was nearly dead with camp diarrhea, and I have not had it since. The honey, fat hen, and corn-bread made a final cure. I can recommend this prescription, for I carried my knapsack after that, went through the battle at Stoney River, lay on the cold ground, waded Stoney River to my arm pits several times, and underwent the privations common to war, and have never had the camp diarrhea since.

Pardon me for this lengthy army story—my object was to give honey what it merits as a medicine as well as food.

Kittitas Co., Wash. S. W. MAXEY.

Early Spring—Fair Prospects.

I have 15 colonies wintered on the summer stands. All are in good condition, and are bringing in loads of pollen, gathered from the soft maple. Indications are that we will have an early spring. Prospects are fair for a honey crop this year.

ALBERT ZIEGLER.

Huntington Co., Ind., March 21.

Wintered Well.

My bees wintered well, and have plenty of hatching brood at the present time. I enjoy reading the American Bee Journal.

W. READ CHAMBERLIN.

Johnson Co., Iowa, March 24.

Good Season Expected.

I wintered 40 colonies, and they seem to come out all right. I had them in the cellar. Last season was a poor one here for honey, but I think we are going to have a good season here this year. We have plenty of basswood, but for some reason or other we have not had any honey from it for three years. The best I have done is 127 pounds of honey from a colony, and the poorest—well, down to nothing. Success to the "Old Reliable."

G. JOHNSON.

Clark Co., Wis., March 25.

"Divider" in Producing Comb Honey.

I will try to answer Wm. Golden's article on page 187. He says: "After quoting what he says in his article on page 51," I confess I cannot answer that; I don't understand it. Then follows a quotation that is garbled, and the meaning destroyed. I will not give it here, but ask Mr. Golden to kindly compare it with the original, on page 51.

Mr. G. asks: "Why is it that the bees must be compelled to enter thus?" Answer: Simply because the divider affords two bee-spaces, and if the bees are allowed to go outside the follower, if one be used to fill up space, then there will be three bee-spaces—one too many, you see.

I may say right here, that I have on a large scale tested two, three, and even four bee-spaces at the sides of the section-supers, to my own conviction that while two, properly provided are of great advantage, any more than two tend to harm. And that is my reason for giving the caution with emphasis.

Mr. Golden's next question—"I have thought a good deal about it, and can hardly

Only 6 cts. per Pound in 4 Can Lots or Over.

tell why ... I like to have bee-space between the divider and the super wall," is also garbled. He stops short and doesn't give half the sentence. Why did he not give the whole sentence? He has entirely destroyed the purport of what I said, and then starts out with renewed vigor to kick me for the changed meaning that the garbling has put upon it. Will be please turn to page 51 and compare the original with his garbled statements?

Then he goes on to "suspect" that I have been appropriating some of his valuable thoughts on producing comb honey. No, no; I don't think I ever read one of Mr. Golden's articles to the end, except the one in question, and had my name not been in it, very likely it would have been neglected also. It may be a great lack of appreciation on my part. S. T. PETTIT, Ontario, Canada.

Bee-Keeping in Virginia—Robbing.

Last year I had some early swarms. I put them out in the country to look out for themselves; so sure was I that they were all right that I sealed them up and left them. Then I went around the country and bought up all the bees I could, along through August and September, and some as late as October, and transferred them to frame hives, taking all of the honey from them and fed them sugar. I also formed, and to save some queens, I put them in hives of 3 frames, with about a pint of bees, and fed them sugar. They came through all right except those in the country that had their own way, and so far I have lost half of them, so I will bet every time on sugar.

I have something I wish to give to the bee-keepers for them to study over, and see what they think of it—something I tried when bees began to rob. I put a skylight in the top of the hive, which doesn't seem to be noticed by the bees of that hive, but the robbers will fly to the skylight and try to get out that way, until they break down, then make themselves at home and remain there. What do you think of it?

I have 18 colonies to start with this spring.

I find I have a hard time in filling orders for my honey, because the people say they know my honey to be honey, and what they buy from the store they don't know about. W. S. SMITH, Henrico Co., Va., March 16.

A Promising Boy Bee-Keeper.

I received the Bee Journal and I was glad to get it, the papa reads it first.

Two years ago papa said if I would plow corn good he would get me a swarm of bees, as I had been wanting them for a long time. Well, I did my best and got my bees of Mr. George Reed. They came out in a large swarm on the Fourth of July, and Mr. Reed put them in a hive with a strip of foundation. So we went after them as soon as they had their comb built. Papa said they were patriotic bees, for they came out in the form of a swarm to celebrate.

When winter came we made a big crate with eight inches all around, and filled it up with prairie hay, and the bees were so warm that they reared brood all winter, and came out very strong in the spring.

Mr. Reed came up one day in May and said: "Goodness! that colony is going to swarm yet, for if they don't they can't all get in the hive." And sure enough they did.

I was out playing with my sister when I heard a big roar, and I looked out and saw the air just full of bees. I shouted to my mother, but she did not believe bees would swarm in May. They went back into the hive, and we got a new one down town. They came again and went back, and papa thinks the queen was too old and weak to fly.

Papa was disgusted with this kind of work, and said he would put a stop to it. He put on a bee-veil and some gloves and went into them. He put four frames with queen-cells on them in the old hive, and the four he took out of the new hive in the

Bee-keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apiarian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellence. Polisht, snowy-white Sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

Address, **Leaky Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

old hive. A blacker and an angrier colony of bees you never saw. They were so thick on the comb that we could not see it.

After they were divided they swarmed just the same. After they got done swarming I had four fair colonies, and one very weak one. We took off of these small colonies about 75 pounds of fine alfalfa honey. They have wintered fine this far, and I hope to have them build up strong.

LESLIE HAZEN.

Nemaha Co., Kan., March 13.

Bee Keeping in the "Old Dominion."

Bees did tolerably well for me last season. I had 44 colonies, mostly blacks, in the spring, and did not increase much, not more than four or five colonies. I got about 2,000 pounds of comb honey, mostly white clover, as we had a splendid crop of it last season, and a very good flow from buckwheat and fall flowers. I sold most of my honey in the home market for 12 1/4 cents—some at 15 cents—but later on in the season I had to sell at 10 cents, as honey came in from some one else and cut the price.

I have now 43 colonies which are, I think, in very good condition. I do not think bees wintered very well here, as I hear a great deal of complaint about them dying. The winter has been quite open—not much real cold weather. The temperature has not been below zero during the winter—then only for one or two days at that point. I lost three or four colonies by neglecting to feed them more last fall.

Bees were flying for several days last week, and I fed them some while it was warm.

I am preparing to use all tall sections next season—only those of the 4 1/4 x 4 1/4 x 1 1/4 which have starters of foundation in them, and others that the bees made comb in and did not get them filled. I have about 500 of them on hand, and will be ready when the season opens.

I also tried the Pettit system, to get the bees to the outside sections, and it workt like a charm; but I got pretty tired of boring so many holes, as I had no boring machine, and had to do it with a common brace.

I will use fence separators next season, as I tried them sufficiently last season to know that they are the best.

I would like to thank Mr. Wilcox, of Pennsylvania, for his kind answer to my question about the locust bloom. I took notice and found it just as he said.

P. I. HUFFMAN.

Rockbridge Co., Va., Feb. 17.

A Hint on Section-Cleaners.

On page 102 "Wisconsin's" suggestion to Mr. Golden about the felt is business. May I make a suggestion? I would not use any of the glue on any of the sandpaper. It dries hard and stiff, and you injure the elasticity of the cushion. In the machine shops we use the felt on the wheels, and on the blocks on the bench, and some have blocks of cork for hand work. The felt or cushion under the paper not only does nicer work, but the sandpaper will wear much longer than without it. We fasten our paper this way:

A little glue will keep the felt in place. Saw across the face of the wheel about two or more saw-kerfs wide, and 3/4 or one inch deep; cut the paper so it will just draw tightly around the wheel, and each end turn sharply down so they will just tuck in the saw-kerf smooth and tight. Drive a strip of tin or wood between the ends of the paper a little below the surface clear across. It will not work out, and when the paper is worn out draw the tin wedge, and the paper comes right off readily. You can renew *ad libitum*, with no bother with the glue, and you always have a soft, yielding cushion. Now, this is my plan, and I never use glue to make the paper hard, and two or more thicknesses will do it.

Some might say that in this way there will be a seam where the ends come together. True, but the ends of the folded

paper come close together, and in practice you never know the difference. Our factories put the paper on in this way. I always do, and it is perfectly satisfactory, much better than to use glue. You see, two or more thicknesses of sandpaper glued together will make a hard surface, and defeat the object of the felt. A. W. HART, Stephenson Co., Ill.

Introducing Queens, Etc.

I commenced the spring of 1897 with 15 colonies, increased to 21 by natural swarming, reared several fine Italian queens, and introduced them in the place of hybrids.

Right here I want to give my plan of introducing queens, as I have lost 3/4 of the queens that I have introduced in cages.

When I rear a queen in a nucleus and she stands the test, I go to the hive that I want to introduce in, hunt out the queen and kill her, and the next day I take the three frames out of the nucleus and put them in a new hive with my young queen, worker bees and all. I then take two frames out of the hive that has no queen, and put one on each side of the three frames that has the queen, and leave them till the next morning. I then add two more frames, and the evening of the same day I finish filling the hive. I then have three frames of brood, honey and old bees left to go back to the nucleus to rear another queen.

I have introduced several queens with the above plan, and have not lost a single one while following it, and I think if one would take two or three frames out of a queenless hive and put into a new hive, and then introduce the queen in the cage to a small amount, there wouldn't be so much danger of getting her killed. Then after a few bees get used to her, follow the plan as given above.

I think my bees are all in fine condition. We have had several warm days, and I noticed to-day they were bringing in the bee-bread by the wholesale. W. W. BUCK, Calloway Co., Ky., Feb. 10.

Convention Notices.

Connecticut.—The seventh annual meeting of the Connecticut Bee-Keepers' Association will be held at the Capitol, at Hartford, Wednesday, May 4, 1898—10:30 a.m. Every bee-keeper in the State should take an active interest in this meeting. All are cordially invited. Mrs. W. E. RILEY, Sec., Waterbury, Conn.

Illinois.—The spring meeting of the Northern Illinois Bee-Keepers' Association will be held at the residence of Alexander Peterson, 5 miles northwest of Rockford, Tuesday, May 17, 1898. All are cordially invited. B. KENNEDY, Sec., New Milford, Ill.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, April 13.—Best grade of white, 10 to 11c; fair grade, 8 to 9c.; dark, 7 to 8c. Extracted, white, 5 to 6c.; amber, 4 to 5c. Beeswax, 27c.

The active season for sale of comb honey is over until the marketing begins of the yield to be obtained in 1898.

R. A. BURNETT & CO.

Boston, April 14.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, 9c. Extracted, white 6 to 7c.; light amber, 5 to 6c. Beeswax is scarce at 26c.

Our market on comb and extracted honey has kept active at old prices, and as a result the stock is well cleaned up. There is very little call for anything but white in this market. BLAKE, SCOTT & LEE.

Cleveland, April 14.—Fancy white, 12 to 12 1/2c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & CO.

San Francisco, April 6.—White comb, 8 1/2 to 10c; amber, 6 1/2 to 7 1/2c. Extracted, white, 5 1/2c.; light amber, 4 1/2 to 5 1/2c. Beeswax, 24 to 27c.

A ship sailing this week for Hamburg took 316 cases. Sellers are not nearly so numerous as early in the season, and are inclined to be quite exacting at present in the matter of prices. Market is strong for comb and extracted, with supplies of latter light and stocks of comb showing steady decrease. The firmness is based mainly on the poor prospects for coming crop.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax in good demand at 26@27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season. M. H. HUNT.

Kansas City, April 9.—Fancy white, 1-lbs., 9@10c; No. 1, white, 9c; amber, 8c. Extracted, white, 5@5 1/2c; amber, 4 1/2@5c; dark, 4c. Beeswax, 20@22c.

Demand for both comb and extracted honey is fair. C. C. CLEMONS & CO.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10 1/2@11 1/2c. Not advisable to ship darker than amber. Extracted fancy white clover, 5 1/2@6c; amber, 5c; dark, 4@4 1/2c.

Outlook for honey much more encouraging. S. H. HALL & CO.

Cincinnati, Mar. 21.—Demand fair for extracted, with insufficient supplies. Prices range from 4@6c, according to quality. Demand for comb is slow at 10@13c for best white. Beeswax in good demand at 20@25c for good to choice yellow. CHAS. F. MUTH & SON.

Indianapolis, March 24.—Fancy white, 11 to 13c.; No 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, March 8.—Fancy, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 10 to 10 1/2c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4 1/2 to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the BEST. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better. A. V. BISHOP & CO.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & CO.

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c. WESTCOTT COM. CO.

Just the Machine every bee-keeper ought to have, the Improved McCartney Foundation Faster and Section Press combined.

THE BEST machine ever invented for pressing the sections together and fastening in starters. It cuts the foundation any desired length, and presses it on, all at one operation. If you want one this season order at once. For further information,

CONTRIBUTED ARTICLES

Bee-Culture in the State of California.

BY PROF. A. J. COOK.

Despite the numerous "off" seasons, too frequent to please bee-keepers, California takes first rank as a honey-producing State. Her product in favorable seasons, of from 100 to 200 pounds of honey per colony, and that in apiaries with from 200 to 600 colonies, is surely a record that few localities in any section of the world can equal. Yet if we can judge the future by the past, not more than one-third of the seasons can be counted on to give a full crop. Yet, as the bee-keeper can know far in advance, at the very dawn of the season, that the failure is to come, he is better off, as "forewarned is fore-armed," in that he can seek other employment, and can avoid expense which would otherwise be incurred, and would be put by as so much useless capital.

As I have before hinted, the cause of the great honey-flow here in good seasons is the long blooming period of the most valuable honey-plants. The sages—source of our white honey—are in bloom for weeks, and the wild buckwheat, the chief source of our amber honey, hangs out its profusion of flowers for months.

The best honey section is undoubtedly Southern California, with its seven counties, of Santa Barbara, Ventura, Los Angeles, San Bernardino, Riverside, Orange and San Diego. The southern central counties—Fresno, Kings, Kern and Tulare—are favored in that they are in a great alfalfa region, which is irrigated and so independent of drouth. These regions have produced large crops, even in the very dry seasons, like that of 1894. East of this, over the mountains, is Inyo county, which, like San Luis Obispo on the west, afford some excellent bee-ranges.

Northern California is not so favorable for honey-production, altho they have more rain. They have not the sages, or other honey-plants, to take their place. There are large alfalfa areas, and possibly much more honey might be produced in the great northern sections of our State.

In the great California honey-region—I refer to Southern California—Santa Barbara county is the least important. The bush and watered canyons with rich acres of sage are not common, and there are not many bee-keepers in that section.

Ventura county is the great bean-region, and also possesses some canyons with a fine growth of white or ball sage. The famous Sespe region is in Ventura county. Some of our most successful bee-keepers, like McIntyre, Richardson, Touchton and Mendleson, live in this county. The records from some of these apiaries have been startling. With abundant rain the honey-product from sections in Ventura is enormous. In dry seasons the bean blossoms add materially to the honey-yield if bee-keepers will avail themselves of this opportunity.

Los Angeles county ranks among the first, tho the range of the honey-producing flora is not so extensive as of some of

the other counties. From the Newhall Tunnel north, and skirting the famous Antelope valley, is one of the best bee-regions of the world. In the seasons of copious rains, the honey-product in these ranges is exceeding large. There are also fine producing tracts all along to the south of the mountains from Glendale and La Canada to the eastern boundary of the county. Apiaries situated near the canyons have the advantage of the early bloom of the valley, and the later nectar-flow of the canyons.

The two counties east of Los Angeles county—San Bernardino and Riverside—are both justly famous for their bee-keeping ranges. There are no better honey-regions than are found in some of the canyons of these great counties. Even in this dry season, the bee-keepers confidently expect some honey, in some of the sections of this favored section. The same may be said of limited areas of Los Angeles county.

Orange county, to the south of Los Angeles, tho not large, has some fine apiaries, and the bee-keepers of this county expect a small crop even in this season of excessive drouth.

The San Bernardino apiarian tracts are like the great county—of exceeding extent. About Fallbrook, Escondido,

A Perpendicular-Disk Section-Cleaner.—See page 258.

and farther south, are canyons rich with honeyed bloom. Many carloads of the finest honey were produced last year. This county has one disadvantage, in that the rainfall is less than farther north, tho the honey-product of the county has not been behind other regions, if we take the seasons together. The fact that honey-plants, like white sage, may bloom

in profusion, and yet yield no honey, shows that plants need water to develop at their best, and should suggest to orchardists that they irrigate liberally in the winter, especially if the summer supply of water is likely to run short.

Los Angeles Co., Calif., March 25.

More Suggestions on Rendering Beeswax.

BY C. P. DADANT.

I have received the following questions to be answered in the American Bee Journal:

MR. DADANT:—Tho I was much interested in your "Suggestions on Rendering Beeswax," on page 194, there are some things I do not fully understand. In previous articles you have recommended the sun extractor; in this you urge heating the wax slowly with water, but boil a little you say.

1. What I want to know is, whether this is the final process following the extractor.
