2. Or do you boil it *first*, then place it in the sun extractor? Until last season I was troubled with that "greenish, grayish, grainy residue" you speak of. I then made a sun extractor and put everything into it the first thing—old comb, scrapings from the bottoms of supers, etc. The final process being to put the wax from the extractor into a flour-sack—thin, slazy cloth—place the sack in a tin pail, one-third full of water, set the pail into an iron kettle of water, and the kettle on the stove. After the wax was thoroughly melted (it did not *boil*), the sack was raised from the pail, the wax squeezed out, and the pail set in a *warm* place to cool, to prevent cracking. With the exception of a thin, grayish-white substance on the bottom of the cakes, the wax seemed to be of excellent quality.

3. Do you think my process correct?

A. F. FOOTE.

ANSWER.—Your process is all right, and it would be difficult to recommend a better one. When I recommend the rendering of beeswax over water, it is not to the exclusion of the sun extractor, but for the benefit of those who have no sun extractors, or wish to render their beeswax, especially cappings, between the mouths of August and May, at a time when the sun extractor has no power. There are really only four mouths of usefulness in a sun wax extractor, and when a bee-keeper has a hundred dollars' worth of beeswax tied up he does not usually wish to wait till the sun gets high enough in the sky, especially if there is any process by which he can render his beeswax and have it clean and good without loss.

The sun extractor is available during the busy months of the apiary when you are likely at any time to have a few small pieces of comb, new or old, or a few scraps that would either be lost or drag about, or be eaten by the moth. With the sun extractor, usually in close reach of the apiary, it takes but a minute to put those scraps where they will at once, mechanically, be rendered into very good beeswax by the rays of the sun. If the sun extractor is kept, as is the custom with the careful bee-keeper, with neatness, the beeswax that will come from it will need no rendering unless residues or dark combs have been melted. Care must be taken that such residues as have been rendered up with acid be kept separate, as these are sure to have some effect upon the metal, and damage the color of the original beeswax.

Old combs usually are not worth putting into a sun extractor. They are so thick and loaded with foreign matter that it absorbs all the wax that would otherwise run out. The very best process to be followed with these was given years ago by my father in the American Bee Journal; these combs must be crushed as near to a pulp as possible, then put into water to soak for a week or so, loaded down so as to be under water, and then melted with plenty of clean water. When old combs are melted without having been previously crushed, it usually happens that some of the melting wax runs into the empty cells which still remain in shape, being held to this shape by the cast-skins and cocoons of the bee-chrysalis, and it is next to impossible to remove any of it. The soaking for a few days ahead thoroughly saturates the cocoons and cast-skins, as well as other residue of whatever nature, except the propolis, and the beeswax becomes much more easily liberated if properly melted.

The cappings, which are gathered together generally about October, are most generally rendered during the winter, and when the matter is attended to intelligently, the beeswax is as good as that from the sun extractor. The main advantages of the sun extractor are its availability at all times during the summer, as above mentioned, and the slight bleaching of the beeswax which remains a few days in it.

In this connection it is well to mention that it is not advisable to leave the beeswax too long in the sun extractor, unless the extractor is so made that the liquid wax runs into a pan sheltered from the light. Beeswax that has been thor-

oughly bleached loses its nice bee-smell, and takes up an odor resembling that of the old-time wax-candles. This is certainly not desirable. But the best service of the wax extractor is to prevent the water damaging of beeswax by inexperienced bee-keepers, or to return such damaged beeswax to its proper condition.

In any beeswax that is rendered by water, a small amount, more or less, of this water-damaged beeswax can be found. But if this is allowed to separate by a slow cooling process, it will be found that most of the impurities are dragged to the bottom with this beeswax. What must be avoided is the damaging of the entire mass by careless heating, and as sudden cooling of the mass. It is a very peculiar fact that water may be held in suspension in a large amount, and yet not perceptible to the touch. We have seen beeswax that was thus damaged, and seemingly dry, lose 20 per cent. of its weight by sun-rendering, which was evidently due to the evaporation of the water.

Hancock Co., Ill.

A Perpendicular-Disk Section-Cleaner.

BY FRANK J. CLARK.

I send you herewith a photograph of my section-cleaner. I have read several descriptions of section-cleaners, but I fail to see any that I should be willing to exchange mine for. The more I read about other kinds, the more I value my own, and I believe that on some points it is superior to all others.

I probably should not have thought anything more about section-cleaners if it had not been spoken of so many times in the bee-papers. It will readily be seen how mine is constructed, by the photograph. Sections to be cleaned on all sides have only to be turned down on their side to clean their top, and down on their opposite side to clean the bottom, where with all other machines you would have to turn the box bottomside up to clean the top, which is always the worst side to be cleaned, and in some cases would cause them to leak, which would be avoided with my cleaner.

As for cleaning the edges, you can clean all the edges on one side with one movement against the disk.

The disk is covered with sandpaper, No. 2½ or 3.

I cannot say whether this machine will clean sections any better than any other, as I believe they all clean them well; but I do believe this cleaner will clean sections faster, and with no leakage or breakage.

I have written to patent attorneys in regard to having it patented, and am about entering into an agreement with a firm of bee-supply manufacturers to make and place them on the market.

Cayuga Co., N. Y.

The Utah Law on Foul Brood or Bee-Diseases.

BY E. S. LOVESY.

I send a copy of Utah's new foul brood law. I have received a number of letters of inquiry in regard to this law, and have sent out some type-written copies, but in order to accommodate all interested I send it for publication in the American Bee Journal. While I am aware that no act of this nature is, or ever has been, perfect, and this law has no exception, I think that the copy presented to our legislature by our foul brood committee was an improvement on the one past. Still, I believe that if our bee-keepers will read and note this law carefully, they will find it one of the best, if not the very best, on the subject in the United States.

A great deal has been written, and much praise has been bestowed, on the Wisconsin law, some writers saying that it is the best law in force on the subject. While my object is not to decry the merits of any law, after a careful study of the Wisconsin law I have to admit that as far as our State is concerned it would be of very little benefit to us, and I fail to see where it can be of material benefit to any populous bee-keeping community, as it only provides for one inspector in the whole State, while we have single counties that no one inspector could cover. It will be seen that whether there are few or many bee-keepers or colonies of bees in any county or district, or in the entire State, this Utah law is so worded that it can be made to reach every colony of bees and every bee-keeper in the State, if necessary. It provides that the inspector shall visit all colonies of bees at least once a year, and as many more times as may be necessary. It is short and to the point, and it gives our bee-keepers ample authority to put it into active force. Then if bee-keepers will take an active interest I see no reason why it should not be a success.

Our foul brood committee have been energetic in this matter, and they have worked faithfully for years in importuning

our legislature to improve our foul brood law, and we thank and congratulate them on the success thus far obtained through their efforts.
Salt Lake Co., Utah.

[The following is a copy of the law referred to by Mr. Lovesy:—EDITOR.]

LAW OF UTAH FOR THE PROTECTION AND ENCOURAGEMENT OF THE BEE-INDUSTRY.

1. The board of county commissioners of the several counties shall, when petitioned by a majority of the bee-keepers thereof, appoint one or more qualified persons inspectors of bees for their respective counties.

2. Such inspectors shall hold their office for two years, and until their successors are appointed and qualified. They shall qualify by taking and subscribing their official oath, and by giving bonds to be approved by their respective boards of county commissioners, which oath and bonds shall be filed with the county clerk.

3. Inspectors shall be paid out of the county treasury for services actually rendered at such rate per day as the board of county commissioners may fix. The assessor of each county is hereby required to assess each colony of bees in this county in the same manner as other assessments are made. All taxes shall be assessed and collected thereon in the manner provided by law for the collection and payment of county taxes.

4. All hives of bees in each county shall be carefully inspected at least once each year by a county or district inspector, where such inspector has been appointed, and at any time upon complaint that disease exists among bees of any person, the inspector to whom complaint is made shall immediately inspect the bees said to be infected. The inspector shall have authority to take charge and control of diseased bees and their hives, and the tools and implements used in connection therewith for treatment; or destroy such bees, brood or hives and their contents or implements as may be infected; provided that if any owner questions a decision of the inspector he may appeal to three arbitrators selected from among the bee-keepers of the county, one of whom shall be chosen by the owner, the second by the inspector, and the third by the two so chosen, whose decision, concurred in by at least two of their number, shall be conclusive as to the condition of the bees at the time of such examination.

5. Any person who shall hinder or obstruct, or attempt to hinder or obstruct, a duly appointed inspector from the performance of any duty required by this title shall, on conviction thereof before a justice of peace having jurisdiction, be deemed guilty of a misdemeanor, and shall be fined for the first offence not less than five nor more than twenty-five dollars, and for any additional offences, any sum not exceeding fifty dollars.

Approved, March 11, 1897. To take effect Jan. 1, 1898.

How to Make Hives and Winter-Cases.

BY EDWIN BEVINS.

I have neither the ability, the inclination, nor the desire to invade Dr. Miller's province, but at the risk of being deemed meddlesome by him, and of being shot by the "Brothers" who dwell in central Minnesota (see page 215), I am going to tell how to make a bee-hive.

If it is the intention to make hives of the capacity of the 8-frame dovetailed hive, you should get some thoroughly dry pine-boards planed on one or both sides, $9\frac{1}{2}$ inches in width. I generally get boards 10 inches wide, and plane down to the right width after they have been sawed into pieces of the right lengths. The right lengths are 20 inches for the sides, and $12\frac{1}{2}$ inches for the ends of the hives.

You are probably a little curious to know how I rabbet these hive-ends without the use of any machinery or power except a common hand-saw and my good right arm, aided a little now and then by the left one. Well, I lay the hive-ends on a work-bench and measure from the upper edge down $\frac{3}{16}$ of an inch, and make a mark with a lead-pencil. Then with a jack-knife held perpendicularly I cut along the mark as deep as I can. Then turning the knife towards the top of the board I cut out a sliver of wood so as to make a groove to start the saw in. Then I put the board in a vise, measure $\frac{7}{16}$ of an inch from its inner edge, make another mark, and cut another groove as before. With the saw in good order one can quickly saw to the proper depth. Then lay the board on the bench, fasten at both ends, and you can quickly complete the job.

Having made the rabbets for 150 hives in this way, I think I may be believed when I say that the work is not so

formidable as it may seem before trial. Some of my hives are two-story hives, and besides rabbeting the hives I have made and rabbeted the supers for nearly all of them.

Having the rabbets sawed out you may consider the work of making a hive-body as almost done. The nailing should be started on a perfectly flat surface. It is best to have a sort of platform a little larger than the hive, with a cleat strongly nailed at one edge for a bumper to nail against, and another cleat nailed on another edge at right angles to the first one. The nailing can be finished by turning the hive on its sides, and the hive-corners can be kept at right angles by using a square.

The nails should be cut nails, made so as not to be wedge-shaped crosswise of the grain of the wood. When the hive is nailed, nail in the tin rabbets. You do not have to gouge out any hand-holes to lift the hives by. Make cleats 6, 8 or 10 inches long, plane them so that their upper edges shall slant outward and downward; whittle the ends so that they shall be rounding, and nail one on each side of the hive near the top. My bees have never kicked on the use of these cleats, and I like them better than the holes.

For covers and bottom-boards I get lumber a strong 14 inches in width, using the best of it for covers, and the poorer parts, if not too poor, for bottoms. Sometimes I make the bottoms of two pieces. All of the covers and bottoms are sawed exactly two feet long, and have cleats two inches square nailed under each end. The cleat at the back end of the bottom-board is nailed about $\frac{1}{2}$ -inch from the end for convenience in lifting, but the cleat in front is nailed just even with the end for the convenience of the bees. The cleats for the cover should be nailed so as to give a play of about $\frac{3}{8}$ -inch.

For all 8 and 10 frame hives of standard depth I use flat covers, and have never had but one to twist. This twist can be taken out by the use of the Dibbern hive-hook, and when once taken out it will stay out. Lath can generally be found of the right thickness to make the $\frac{3}{8}$ -inch strips for the bottom-boards. If too thick it is not much work to reduce them with a plane.

A word about painting hives: It may be that Mr. Doolittle's idea that an unpainted hive is just as good, if not a little better, than a painted one, is correct, but for myself I prefer to paint. No more expensive paints for me, however, except for covers. For these I use the best of white paint. For the other parts of the hive a paint made of sweet skimmed milk and hydraulic cement looks well, costs nothing, is quite durable, is odorless, and dries quickly so that it can be renewed with the bees in the hive without annoyance to them.

And now having incurred the liability of being run out of the country with some guns in the hands of enraged "Brothers," I will proceed to exasperate them some more by telling them how I make winter-cases for my hives.

For an 8-frame hive, dovetailed size, with super on for chaff cushion, I get two pieces of 2×4 stuff 19 inches long, and two pieces 2×2 the same length. These are posts to which the sides of the case are nailed. The boards for the sides are sawed 30 inches long. The 2×4 pieces come against the sides of the hive just even with its front. The 2×2 pieces serve as cleats to keep the end of the case in the rear of the hive from being prest outward by the packing. The boards for the end of the case are sawed 22 inches long, and held together by cleats so as to slip down between the sides of the case like the end-board of a wagon.

I prefer to have a bottom-board for the winter-case, and make it two feet wide and three feet long. This bottom is placed under the hive, and then the sides of the case are set up on top of it on each side of the hive, and kept from falling by a piece of wire bent around nails partly driven in the center of the posts. Then the end-piece of the case back of the hive is put in place and another piece of wire is bent around nails partly driven in the center of the two posts at the rear. These two pieces of wire are all the support needed by the case. The case can be quickly and noiselessly set up and as quickly and noiselessly taken down.

You will see that there are four inches of space on each side of the hive for packing, and a little more than that at the rear. The packing is straw and chaff from the straw-pile. This measure of protection may not be sufficient for the latitude of Minnesota, but it is just right here in southern Iowa. I have never had the entrance to one of my hives thus protected clogged with dead bees, and spring dwindling is unknown. Cellar wintering may be better for Minnesota, or, perhaps the winter-case may be modified to answer a good purpose there.

My cover for the winter-case is 3 feet long and $2\frac{1}{2}$ wide. The boards are held together by a 2×4 cleat set up edgewise and nailed near one end, and a cleat about one inch thick

nailed near the other end. The 2x4 cleat gives the cover the proper slant.

All the parts of this winter-case can be used for shade-boards in summer, or if piled up they need no great amount of space. They are made of lumber rough and cheap, but I think all will agree that they are strong and durable.

What about frames, did you say? For all hives taking the standard frames the V-edged Hoffman is good enough for me, and John Doe and Richard Roe. It is a little trouble sometimes to loosen up the first one so as to remove it, but when this is done it is an easy matter to do anything you want to do with the rest of them. But please don't get any of the bobtailed things that call for end-spacers. They get diagonally across the hive and slip down against the bottom-board so easily that one is made to feel sometimes as if he would like to shoot the man who invented them.

And, now, my dear "Brothers," let me entreat you to make some bee-hives. You will be very awkward at first, and make some mistakes, but after awhile you will acquire a degree of skill and carefulness that will enable you to do your work with a reasonable degree of accuracy and neatness, and while you are doing the work the whole subject of hives and their management will be revolving in your minds, and your knowledge of, and your interest in, the subject will grow and deepen to such a degree that you will hardly be persuaded to take a ready-made hive as a gift. Decatur Co., Iowa.

Managing Bees—Report for 1897.

BY D. B. MAHAN.

I remember reading, when a boy in school, that all Gall is divided *in partes tres*. I think, however, in some individuals, instead of being divided it has been greatly multiplied, and in attempting to write an article for the American Bee Journal I somehow have a suspicion that I may be one of these same individuals. Nevertheless, encouraged by the thought that many valuable lessons have been learnt from the ignorant as well as from the intelligent, I shall attempt to give a few thoughts on my method (?) of handling bees.

As to hives, I have found no better than the dovetailed, with Hoffman brood-frames, and supers filled with plain sections and cleated separators.

Altho I keep my bees adjacent to an apple-orchard, I do not utilize the trees for protection from the sun, but instead use for that purpose a comb roof $2\frac{1}{2}$ by 3 feet. To make this, I use three pieces 2 inches square and nearly 3 feet long; two short pieces 1x2 inches, and barrel-staves cut 20 inches long. I use these because they are so much more substantial than shingles. When completed, one of the 3-foot pieces is under the comb, the staves on each side of the roof being nailed to it. Each of the other two 3-foot pieces to which the roof is nailed is 16 inches from the comb. To the ends of these a 1x2 inch piece is nailed to prevent the roof from spreading. The staves are laid with the concave side down, and lapt so that the roof forms protection from rain as well as from the heat of the sun.

I set the hives about 4 inches from the ground, and 7 feet apart each way, and cover each with the roof above described. In September or October I set each hive in a store-box sufficiently large to leave a space at least 2 inches on each side and end of the hive, and 6 inches on the top. I remove the hive-cover and instead put one or two thicknesses of some kind of cloth, and on top of that a chaff cushion. The remaining space is filled with chaff or shavings, and the box-cover and roof (both of which are water tight) are then put on. The box is so arranged that the chaff or shavings in the front part of the hive come within 4 inches of the bottom. Underneath the box-cover a small space should be left for ventilation.

With this outfit I have been reasonably successful. In the spring of 1897 I had nine colonies. During the summer I increased to 26, and secured 800 pounds of nice comb honey, which I sold at an average of 14 cents per pound. Taking into consideration the fact that the bees were not fed a pound of anything during the season, I consider this quite a satisfactory yield. Two colonies (prime swarms) gave me 140 pounds each of surplus honey. The question now revolving in my mind is: Had I been thoroughly posted in bee-culture, and had I given my bees the best of attention, would it have been possible to take from each of the 26 colonies as much as from each of these two, and thus have secured instead of 800 pounds 3,640 pounds? If I had known as much about bees a year ago even, as I do now, I doubtless could have increased the product very materially.

I am reading the American Bee Journal with increased interest. Champaign Co., Ohio.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

[Continued from page 247.]

Mr. G. G. Liebhardt, of The G. G. Liebhardt Commission Co., then read the following paper:

Packing, Shipping, and Marketing Honey.

The matter of packing should receive attention as to style and uniformity of package. It is a subject in itself. The matter of shipping is immaterial at present, being embodied in the first and second subjects. The matter of marketing is at present the most important requiring your consideration.

Without proper compensation for your labor you cannot continue the business. Competition in all lines and branches of industry is daily becoming sharper, and those not watchful of changed conditions and tendency of the times will sooner or later find themselves battling against the stream and fate. The most casual observer must notice that the tendency of the times is for concentration and centralization. Trusts are being formed for the purpose of making a profit—an increase profit—or saving those interested from ruin. Trust goods are the only ones having a staple market price. Even laboring-men have trusts in the form of unions for protection, in various forms, of their wages. We realized ten years ago that associations formed in fruit districts were not only a benefit to the individuals interested, but a decided material advantage to the community where located. We have been instrumental in various parts of the country in assisting in the formation and successful operation of such associations. By forming an association you at once obliterate competition amongst yourselves. As it is now, you have too many competitors and not enough purchasers. Reverse the situation and you eliminate your element of weakness. By unity of action you can stop adulteration and increase the home consumption a hundred-fold.

The production of honey in the United States in 1881 was estimated at 200,000,000 pounds. It is probably not much more than that to-day. Just think of it, not three pounds of one of the most wholesome foods known to mankind is consumed annually by each of the inhabitants of this country! I know of no industry to-day that affords such favorable opportunity for expansion. It requires only protecting and educating the public—protecting them against adulteration, and educating them as to the wholesomeness and use of honey.

You should not delay in forming a Honey-Producers' Association at once, and the beneficial result will be apparent by the large and enthusiastic assembly you will find at your next annual meeting.

THE G. G. LIEBHARDT COMMISSION CO.

H. Rauchfuss—I have talked on this subject for years, and can only repeat that we ought to have co-operation. I would like to hear from others.

Mr. Dudley (Secretary of the Utah Bee-Keepers' Association)—What facilities has your firm for handling carload lots out of the State?

Mr. Liebhardt—Ourselves, and other firms, too, have facilities for handling all honey without difficulty. Other matters require attention. There is not one-tenth as much honey consumed as there ought to be.

Mr. Rhodes—I am in favor of co-operation. We ought to have an organization to handle all the honey we produce. This State ought to consume all we have. Any surplus can be handled better by co-operation than in any other way. The trade should be placed on a good business basis.

Mr. Adams—I have listened to Mr. Rauchfuss a good deal. There are difficulties. We do not produce what we should consume. Many who own 3 to 10 colonies produce a little, sometimes pretty nice sections, and don't care what they get for it.

Mr. Lyon—This is a most vital question. There was no need of selling our honey as we did last year. A man from the East offered me 20 cents a case more than we were getting. I did not sell to him, but went East with my honey. The prices here knocked me out, $2\frac{1}{2}$ to 3 cents a pound. If it

was not for that cheap honey here I could have done as well as in former years. I am selling ten times as much as others in my neighborhood, and sell for more (10 cents straight), simply because my customers cannot have it for less.

Mr. Liebhardt—Until a year ago the Rocky Ford melon-growers realized nothing. Many crates were sold here for less than the cost of the crate. They finally formed an association, and made a contract with an Eastern firm for 25 carloads. The firm used 118 carloads at 75 cents a crate. Last year they took 300 carloads at 95 cents a crate. Fifty crates were shipped to London. This year the same firm will probably have 600 carloads. It does not make so much difference what the price is, as that the parties cannot buy for less.

Mr. Varian—I'm an Irishman. I came here 20 years ago, and was recently on a visit home. Hardly any product could be more easily shipped to the other side of the Atlantic than honey. They could produce much there, but they do not do so. They get from a shilling to one and sixpence a pound, and extracted is higher than comb. There is a quantity of California and West Indian honey in London, but not in Dublin or other cities. I am sure there is quite a chance for the sale of our honey in England and Ireland, but it will need concentration and proper parties on the other side. It is just the same with honey as with butter and cheese—it is a matter of custom. England and Wales consume quantities of cheese; in Ireland none eat it at all but the wealthy.

The Secretary then read a letter from Mrs. A. J. Barber, of Montezuma Co., which follows:

Marketing Honey.

My first extracted honey was put into the home market in 1890. At that time this place had only one store and a meat market. The store-keeper did not want to bother with honey, so the meat man agreed to see what he could do. I did not know anything about the business, and neither did he, but we

Owing to foul brood, I had only 1,000 pounds of honey that year, but it all went for cash—no trading this time. I invited all the neighbors to come and see the extractor, and how it worked; also gave away lots of comb honey the next spring, after it granulated.

Since 1893 I have never produced less than 7,000 pounds of extracted honey, often much more, but have never had any left unsold when the new honey came on; and have not had a complaint for two years about honey granulating.

For the last two years I have sold several thousand pounds through a commission man in Durango. He ships honey to all the mining towns in southern Colorado, and as a result of the advertising given by my labels, I have shipped a lot of 60-pound cans to places that I never would have had orders had it not been for my labels on the pails, and stamp on sections.

I have made quite a home trade with the neighbors by trading honey for hay, wheat, beef or any other commodity. Many of our neighbors who used to think honey was only a luxury, now lay in their winter supply of honey as regularly as they do their flour and meat. For the home trade I buy coal-oil and gasoline cans, and cut the top out to insure their being well cleaned. These are filled early in the season, and a cap of white cloth put on. They granulate in a couple of weeks, and are ready to take anywhere. These are sold at \$1.50 per can. The large lard-pails sell for 60 cents, and the small ones for 40.

There has been considerable competition lately, but I make it a rule to put nothing on the market that is not first-class. I don't know where we shall end, as prices get lower almost every year, and as production increases I am afraid that we shall be obliged to give up the business. I believe I have mastered this granulated-honey business, in my neighborhood at least, but I can't control the price. I hope that other members may be able to tell us how to better that.

MRS. A. J. BARBER.

The Bee-Supply Factory of Page & Lyon Mfg. Co.—One of Our Advertisers.

tried all I had (500 pounds) in half-pint jelly-glasses. It went off nicely until it began to granulate, when our customers thought they knew that that honey had been adulterated. We had a lot of it to melt over, and then people seemed suspicious of it. We finally got rid of it, however, at 15 cents a glass, but I was not satisfied to sell something that people suspected, so I made up my mind to produce comb honey.

Before the next season came on, however, I took out some sections that I had put away in a box, and found them granulated hard. I could see no way out of the difficulty, but produced both kinds again. This time I traded nearly the entire crop of 1,500 pounds to the neighbors for anything that I could use. The meat man sold 300 or 400 pounds in pails; but the complaints were so many that if I had not been in love with the bee-business I should have given it up. I had that year about 200 unfinished sections. These I concluded to devote to the education of my customers, so after they had granulated they were given away to them as a specimen of genuine alfalfa honey.

In 1893 I came to this conclusion: "Honey will granulate, and I can't help it. Now the sooner people know all about it the better. I am well known here, and if I should stand back of every pound of honey I sell, perhaps it will make a difference." I had a lot of labels printed, stating that all pure honey will granulate, and telling how to liquefy it, and guaranteeing the purity of all honey under that label, giving name and address. These labels were put on the tin pails, and the campaign began.

Pres. Aikin—We might say that co-operation is intelligent operation. If all other lines of business organize, what can an individual do? Also the vastness of our country is such that only organized machinery can properly reach it. I marketed last year 5,500 pounds of extracted honey nearly all in our own market. As a rule, when once taken, it is taken again. The product must be brought before the people. Extracted honey is the most poorly packed of all syrups. Do you expect the retail dealer to retail from a wholesale package? Just so long as you do we will never have a market. Even E. R. Root says the public will not take it candied. It is simple. Mrs. Barber has convinced her customers. I have sold many three and five pound packages of granulated honey. I tell my customers that I would have to melt it up, and that they might as well save me the trouble. Some prefer it thus for carrying to the mountains.

H. Rauchfuss—We should adopt an original label, registered, as a guarantee that the honey is pure. It will increase the consumption. We have given jelly-glasses of honey to those who never ate it, and afterwards sold them 10-pound packages. If we could organize and adopt an original package, we could sell all our honey.

Mr. Whipple—I had considerable honey left over the first year I started in. I made it into vinegar. Since then I have not had enough honey left over to make all the vinegar I can sell. A demand for extracted honey has arisen, and I have bought some.

Mr. Pease—What is the market price of honey here in Denver?

Mr. Liebhardt—There is no market price. There never will be as long as present conditions continue. Will adulterated honey granulate?

Pres. Aikin—I think not.

Mr. Liebhardt—Then that is one of the main points that ought to be brought out, to show the purity of your honey.

F. Rauchfuss—California white-sage honey and some Cuban honeys will not granulate for a long time. But we have no honey in Colorado that will not granulate in a short time.

Mr. Brock—As to the market price, I askt 10 cents for my honey. A man said he could get honey for 6 cents. But I sold him 20 pounds at 10 cents.

Mr. Rhodes—I sold 5 to 6 tons per year several years ago of extracted honey in just one or two streets, by giving away tastes. The thing is to get honey to the people. Where we would sell a pint to begin with we would afterward sell much larger quantities.

Pres. Aikin—As a result of my work, The A. I. Root Co. say that if no other firm will take up the matter they will, providing bee-keepers take carload lots of cans. In the Canadian Bee Journal Mr. Holtermann says he is backt by the Goold, Shaply & Muir Co., in obtaining a suitable retail package, which sells itself, and can be packt in a 10-cent flour barrel, and shipt as granulated honey in barrels at a low rate of freight. I packt 30 four-pound palls in a 5-cent lime-barrel and shipt it as honey in barrels, at fourth-class freight, to Kansas at half the cost of former shipments. The Western Freight classifications of honey, as furnisht by F. Rauchfuss, are as follows:

In pails and cans, double 1st; in cans boxt, 4th; in glass jars boxt, 2nd; in tumblers boxt, 1st; in kegs, 4th; in barrels or casks, 4th; in boxes with glass fronts, 1st; granulated in pails, boxt, 2nd.

Mr. Pease—My sweet clover honey has not granulated. Suppose our honey does not granulate?

Pres. Aikin—That is why we must adopt a standard package that is sealed. Alfalfa honey, too, when it has once been melted, hardly ever gets really solid again, but consists of granules mixt in the liquid. It stays that way several years. I sold my extracted honey at a low price. I reasoned this way: If I pay freight, etc., how much have I left? About as much as California producers get, and we all know what that is. But here are a lot of poor people buying syrups; my neighbors have just as good a right to get it cheap as some commission-man. Granulated sugar makes a good syrup. It is a matter of cheapness. So I aimed to keep the price somewhere near that of granulated sugar. And advertising pays. I got more for my honey than if I had shipt it. If we produced 10, 20, or 100 times as much there would be a market for it. It would take the place of sugar and glucose.

Mr. Liebhardt, there has been a discussion about the relative merits of tall and square sections. Here are two sections of honey, one tall and one square. Which do you prefer?

Mr. Liebhardt—The square one. If the tall sections were adopted, we would have to prove they had not been trimmed off. The eye desires a perfect shape.

[Continued next week.]

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable, and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Formic Acid in Honey.

In what manner does formic acid get into honey? Can it be extracted from the honey? If so, how? ONTARIO.

ANSWER.—The best authorities seem to think it gets into the honey through the circulation of the bee. Probably there is no practical way by which you can get it out of the honey, and probably it wouldn't be a good thing to get it out if you could.

Managing an Out-Apiary.

I am going to start an out-Apiary this season of about 60 colonies, and will run them for comb honey. I want to tend the out-yard and home-yar I alone. Please give the full management. MICHIGAN.

ANSWER.—To give entire management of an out-Apiary would take many times the room allowed in this department. It involves all that is involved in the management of the home-Apiary, the principal points of difference being—at least in your case—that there is no one at hand at all times to watch for swarms. A queen-trap in front of each hive or some other plan must be used. Much information as to management of out-Apiaries is given in Root's "A B C of Bee-Culture."

[We mail this book for \$1.25, or club it with the Bee Journal for one year—both together for \$2.00.—EDITOR.]

Questions on Shallow Brood-Chambers, Etc.

1. Please give your ideas of the advantages and disadvantages of the Heddon or double-shallow-brood-chamber.

2. If you were to use double-shallow-brood-chambers, what kind would you recommend—the Heddon closed-end frames with screws, or two of our regular supers, 5 $\frac{3}{4}$ high with Hoffman's half-depth frames, 5 $\frac{3}{8}$?

3. Could we not use thumb-screws with the Hoffman frames and invert them if necessary?

4. Would the bees build brace-combs between the brood-chambers?

5. In this section we do not get over 30 pounds of nice honey from each colony; this we get from sourwood, and is nearly our last honey plant or tree. Now to change the brood-chambers just when we wanted the bees to store this sourwood honey in sections, would they not carry the dark honey already in the brood-chamber up into the sections, and also the sourwood? Then, of course, they would not have anything to winter on. I think it would be all right to change brood-chambers, invert them if they would not carry what honey they had in the brood-chambers into the sections. How is this?

6. How would it do to use two brood-chambers up to the sourwood flow, and then put all the bees into one brood-chamber, 5 $\frac{3}{4}$ high, until the sourwood flow is over; in the meantime keep one or two colonies, and put the extra brood-frames or hives on these colonies, and let them store honey in them, and after the flow put them back on the original colonies for winter?

I do not think it advisable to scatter these extra brood-frames over weak colonies, as the original shallow brood-cases would not have enough to winter on after sourwood flow. It would be very nice to give the extra frames to weak colonies if the original colonies could store enough to winter on. I have been using the Langstroth S-frame hive, but it's very hard to get bees into the sections. I cut one of them down to about five or six inches last season, and got 24 pounds of nice sourwood honey from it, while I got scarcely nothing from the others, except when I cut it out of the brood-frames.

7. What about queen-excluding boards for these shallow hives? Do you lay the queen-excluder down flat on the brood-frames, or a bee-space between the brood-frames and queen-excluder?

8. Does inverting these brood-chambers make bees tear down queen-cells? If so, this would be one good point.

9. In using a bottom-board $\frac{3}{4}$ high, or a bee-space ($\frac{3}{4}$ as in the Danzy hive), would the bees not build brace-combs between the bottom of the hive and brood-frames? And again, would $\frac{3}{4}$ high not hinder them from reaching or climbing up to the brood-frames with a load of honey?

10. How about the fence-separator and tall sections?

NORTH CAROLINA.

ANSWERS.—1. Not having had practical experience, which you have had, I can hardly give anything that would be of value to you.

2. I should prefer those that would hang true without any screwing together.

3. Yes, but if I were going to use thumb-screws, I should much prefer the Heddon frames. They will go together more solid than

the Hoffmans, which come together only part of their length, and have one sharp edge that, under the pressure of the thumb-screws, might cut in more than desirable.

4. Probably to some extent.

5. If they don't carry up the honey from the inverted combs, what object in inverting? Probably, however, the honey would not be carried up in all cases.

6. Concentrating the force of the colony in less space just as a flow is beginning, will, of course, have a tendency to compel them to store in the super, and may work all right, providing there is no trouble about winter stores and the colony being too weak afterward. But in the main it is probably better to have colonies powerful enough to work in supers without such cutting down. One season of failure I had just one colony that gave me a super of honey, and that was a colony with 16 Langstroth frames. If you have a bait section in a super there is little trouble, but they will store surplus in it if they are strong enough to store, and there is anything to store from. The point to aim at is to have colonies as strong as possible at the time the main flow opens. Possibly your colonies might be stronger to good advantage. It might be that you would not do badly to try the plan of John F. Gates, who gets good crops of honey by keeping strong colonies in big box-hives. But he doesn't get a pound of surplus from these colonies. He gets swarms from them, hives the swarms in small hives, gets his crop from these small hives, and after he has taken the crop breaks up the colonies in the small hives, relying on his big hives, or "breeders," as he calls them, to build up for winter and swarm again the next year.

7. It depends upon the kind of excluder you have. If you have merely the sheet of zinc, that can lie flat upon the top-bars. But you will probably be better satisfied to use an excluder with slats that will make a bee-space between top-bars and excluder.

8. It cannot be relied on.

9. They are not likely to build brace-combs, but in the course of the season they will build up little hummocks of propolis here and there, making it appear as if they were making something to climb upon. Theoretically they ought to be troubled no little to do so much climbing. Practically I never could see any bees waiting for their turn to get up, even when there was no chance to get up except a block at each corner.

10. As yet they have been tried by comparatively few. I think no adverse report has come from any one who have tried them, but some who have not tried them strongly oppose them.

Putting Bees Out Early.

I see by the Bee Journal that you have put your bees out. Why, what does that mean? I thought you always kept them in till they could gather honey and pollen!

I have been in the habit for years of putting my bees out as early as possible on any fine day so they can have a good flight. You see, by doing so, they commence to breed and have a lot of young bees to take the place of old ones when warm weather comes.

I put mine out on March 14, and since then we have had just such weather as I like, for it keeps the old bees in and prevents a good deal of what is called "spring dwindling."

Kane Co., Ill.

GEO. THOMPSON.

ANSWER.—This year I wanted to try the experiment of copying you Fox-river bee-keepers, so I put out 20 colonies March 14, the same day you put out yours, and left the rest to be put out the usual time—when soft maples bloomed and all things pointed to the opening of spring. But that time came only two days later, when maples were blooming, and frogs and meadow-larks singing. So I began putting out the rest March 17, and the two times of putting out were so close together that I don't know any more about the matter than I did before. Maybe I'll live to try it again next spring.

Experiments with Six-Frame Hives.

In answer to your question on page 763 (1897) I would say: I have wintered from 10 to 25 colonies of bees in six-frame hives for four years, and I am now beginning the fifth winter. I have been doing this as an experiment for the sole purpose of finding out the best hive for general purposes, especially for the farmer bee-keeper. I have been doing this experimenting for over 20 years, along with other business, and have experimented with all kinds of hives, and the hive which I shall describe is not just the exact one that I want, but I have in my mind's eye to-day a hive which I believe will be perfection for an all-purpose hive. I am going to experiment next season, and then as soon as I can find a suitable location I will engage in the bee-business as a business.

The hive which I have used for the last five years is a six-frame one, size $8\frac{3}{4}$ inches wide, frame 17 inches long, inside measure, and eight inches deep; top-bar $1\frac{1}{2}$ inches wide and one inch deep, $\frac{1}{4}$ -inch bee-space with $\frac{1}{4}$ inch to divide in seven parts to space.

I fed one fall (1895), as there was no honey to gather in this country, and this gave me a splendid chance to experiment. So I took one six-frame, one eight, and one nine-frame hive, and gave them equal amount of sugar, and then did not look at them again until the last of March, 1896. Now, how did I find them? The eight and nine-frame had not a live bee on them, but the six-frame was in fair condition, and had some stores yet. So this was good proof which hive was best for wintering.

Still one more experiment: June 20, 1897, there came out a nice swarm from an eight-frame hive, and before I had time to

hive it, out came another from a six-frame, and as a matter of course settled with the first swarm. Now I said to my wife, "Here is a good chance for an experiment," and we hived them in a 12-frame hive, and the next day another six-frame colony cast a swarm, and we hived it in a six-frame hive. Now, what did I get in the way of surplus? I got 35 pounds of fine honey from the 12-frame, and 48 pounds of the same kind from the six-frame. Please tell me which hive you would rather keep as a business hive, the 12 or the six. I know.

I want double-wall hives, and also want a follower both in the hive-body and in the surplus arrangement. I do not feed in the fall—March and April is the proper time to feed.

My colonies get very strong in six-frame hives. Five the past season averaged 130 pounds each of comb honey; best one 134 pounds, while the best I got from my nine-frame colonies was 70 pounds, and the eight-frame 94 pounds. These are the best. Now, these are big yields for this part of the county. They probably do not occur more than once in 10 years, altho I would like to see them often.

I prefer this hive because it takes less lumber to build it. A colony will give more surplus of comb honey, and it takes less honey to winter—three very important points. In five years' use I have only found the queen in the sections twice. Of course, Doctor, you are aware that it will take somewhat closer attention to use a six-frame hive than it will to use a larger one, but I think I got good pay for my watchfulness. I wish I could see you and describe to you the kind of hive we need. When I say "hive," I mean everything complete—hive, supers, frames and all.

If I have done you some good with this scribbling, I am happy indeed.

DAVID N. RITCHEY.

Franklin Co., Ohio.

ANSWER.—Mr. Ritchey, when one can get such results as you mention, it hardly seems that his practice can be much out of the way. Still, a question may yet be raised whether you would get the same results if you used exclusively six-frame hives. There's John F. Gates (I wonder if John has gone to sleep; I haven't seen anything from him for some time) he gets all his honey from very small hives, and he also has some very large hives from which he gets no honey, but he counts that his large hives are the most important, for he gets rousing swarms from them, and these swarms when hived in the little hives give him good crops, but he doesn't carry the little ones over winter.

There are certainly advantages in the small hives, and it's a big advantage to have such little fellows to handle, and altho you say they need closer watching, I'd be willing to give the closer watching if they'd give right results. You do not say whether in any case you have kept the same colony straight along for several years in a six-frame hive. That would be a better test. Possibly you have done so, but you don't mention it. For, in a locality where the main harvest comes directly after swarming-time, if two swarms are of equal ability, the one put in a six-frame hive ought to give more surplus than the one in the eight-frame hive, because it puts less honey in the brood-chamber. But the question is, how would they compare the following year? Can you have as strong a colony with five or six frames of brood as with seven or eight?

It will be interesting to know if you have compared the two hives separately for several years, and can give us results. I should not expect so strong colonies in six frames as in more, but the proof from the bees themselves is the most conclusive.

Pestered with Ants—Carrying Out Larvae.

1. Here in Southern Indiana, when we take our honey off and store it away for future use, the ants get into it and carry it off and destroy it to such an extent that they are a great nuisance. What can we do to prevent it?

2. I have three colonies that are carrying out young brood, and occasionally I see a moth among the dead larvae on the alighting-board. What is the cause?

INDIANA.

ANSWERS.—1. Various means of dealing with the pests have been suggested, but really the best thing is to have the honey in ant-tight cases, so the ants can't get at it all. In the meantime you might try a sponge lightly filled with sweetened water—altho it will be necessary to exclude them from the honey if you want them to attack anything less sweet—and then when the sponge is covered with ants, dip it in boiling water.

2. If the brood is somewhat mature and the number not very great, it may be that wax-worms have injured the brood so it is carried out. That's not very likely to be the case thus early in the season. More likely the brood carried out is mostly young and white, and the brood is destroyed because starvation has come. Unless stores are obtained from some source the end may not be far off.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitecomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

APRIL 28, 1898.

NO. 17.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Better Cleaning of Section-Honey.—Slovenly and careless bee-keepers will soon be at a great disadvantage. Section-honey will soon be freer from propolis and other stains—when the new section-cleaners get to work. What sense is there in shipping off to market a lot of "dirt" on sections of nice honey? The past winter we bought a most beautiful lot of clover honey, one 24-pound case of which we were to get 25 cents a pound for from a Chicago millionaire. What did we do? Why, we simply took out every section, scraped all *clean*, and then put it into a new case, as the case in which it had been shipped was a coarse, rough, home-made affair. That honey had a 50 per cent. better appearance after we put it into respectable shape.

Some bee-keepers are losing money every year on account of their shiftless, careless methods. And there can be no excuse for it at all. If a bee-keeper (man) is color-blind, or blind to uncleanness, then for pity's sake let the women of the household prepare the honey for market. Let them clean the sections of honey, grade them, and put them into shipping-cases. We venture in most instances the honey would bring a cent more a pound. We have great faith in the work done by women. They are close friends to neatness and fine appearance—having practiced so much on themselves!

Best work everywhere always finds least competition. Try it.

Langstroth Monument Fund Again.—On page 201 we had this to say in reference to the proposed Langstroth Monument Fund:

"We are inclined to think that before bee-keepers will be satisfied to let this matter rest, they will want to see at least \$1,000 put into a monument to mark the resting-place

of their beloved Langstroth. Why wouldn't it be a good plan for the large manufacturers of hives to contribute—oh, say about a couple hundred dollars each? Their prosperous business is practically the result of Langstroth's invention. And as bee-keepers are helping to support the manufacturers, indirectly it would be the bee-keepers' tribute to the memory of Langstroth."

Editor A. I. Root, in Gleanings for April 15, after quoting the foregoing paragraph, followed it with this:

"Personally it seems as though our good friend York had got the figures a little high; but, never mind; if the bee-keepers of the world think we should invest \$1,000 in this direction, The A. I. Root Co. will try to do its part. We therefore raise our contributions from \$10 up to \$25. If the other supply-dealers feel like contributing liberally also, we will increase our subscriptions to \$50."

Now Mr. Root is getting down to business. We thought all he needed was just a little stirring up on this question. People who are *able* to do great things ought to do them. We should like very much to match the figures mentioned by Mr. Root, but we are not doing the amount of business, and have not the capital, to justify us in doing likewise. Our own subscription of \$5, proposed in last week's Bee Journal, we feel is equal to about a \$200 subscription by the Root Company, when you come down to a comparison. But it isn't necessary to make comparisons, and we have made it only to show that it is right to expect great things from those who possess greatness.

But the right way is for each one to do what he or she knows he can justly and honestly do regardless of what any one else does. We cannot all know each other's circumstances, and so we are liable to misjudge in things of this kind.

We trust that this matter may soon take definite shape, and be carried through to a speedy, successful and satisfactory end.

Getting New Subscribers.—This is a good time of the year for many of our readers to get new subscribers for the Bee Journal. There are just thousands of bee-keepers all over this great country of ours that ought to be reading it every week, and thus learn how to make their bees more profitable. They would also learn the folly of ruining the honey market both for themselves and for their neighbor bee-keepers who are already reading the Bee Journal.

A good many of our readers have done nobly already in securing new subscribers, but there are more who have not made any attempt along that line. From time to time we offer some generous premiums to our present readers for the work of getting new subscribers. We often wish we could make them more generous, but the subscription price of the Bee Journal will not admit it.

Why not within the next month or two add several thousand new readers to our list? Will you help? If so, we will make our *present* readers this special offer on *new* subscriptions for the balance of 1898—about eight months:

Send us 60 cents, and we will mail the Bee Journal the rest of 1898 to any new name and address, and also allow, as your premium, 20 cents of the amount to apply on any of the books found in our book-list, on page 267 of this number, that you may select. The new readers would get about 35 copies of the Bee Journal for only 60 cents; and you would get a third of that amount in books. But remember there is no additional premium for the new subscriber on this offer.

Now, why not every reader, so far as possible, try to send in a few new subscribers on the above offer?

Making a Fortune with Bees.—Of course we mean in the production of honey? Editor Hutchinson gives this answer to that question, in the April Review:

"The man who makes his fortune in the keeping of bees must now keep a lot of them; scatter them around in out-apiaries, and then adopt such implements and methods as will

enable him to secure the honey with the least possible labor. It is not a question of how can I secure the most honey per colony; but, of how can I make the greatest profits. This is the broad sense in which bee-keeping must be viewed if we are to reach the highest commercial success."

Mr. Hutchinson, in the same editorial from which the above paragraph is taken, speaks of a neighbor bee-keeper who had been to Detroit to sell honey, "and found that the finest white comb honey could be bought for only 10 cents a pound." Then he quotes his neighbor as saying:

"Of course, there is a profit in it at that figure; but, I tell you, a fellow has got to produce a lot at that price to make anything."

But is there any necessity for the best comb honey selling at 10 cents per pound? We say *no*. There was no need of the price of honey going so low in this city the past winter. As we said some time ago, had it not been for a few unwise bee-keepers themselves coming in here with their own crops, and selling at too low a figure, and direct to grocers, we believe there would have been no necessity for commission-men to lower the price in order to effect sales. Our own experience in the honey-business the past winter proves that. And what applies here will apply in almost every other city. The trouble is, the whole honey-business is on a wrong basis; and until there is some sort of co-operation among bee-keepers themselves, we fear they never will realize a just price for their best honey in the city markets.

We have found that the majority of honey-consumers are not so very particular as to the price, if they only are satisfied that they are getting the *pure* article when they buy. And right here is where a national pure food law would help amazingly.

There is much more that could be said along this line, but we will reserve it for future occasions.

The Connecticut Convention.—The seventh annual meeting of the Connecticut Bee-Keepers' Association will be held at the Capitol, at Hartford, Wednesday, May 4, 1898, commencing at 10:30 a.m. The topics for discussion are as follows:

1. Is it any profit to the ordinary farmer to keep bees?
2. Which are the best, loose or tight bottom-boards?
3. Has the plain section and slat or fence separator any advantages over the section with bee-way?
4. Is it necessary to cover the sections in a super? If so, what is the best covering?
5. Are the wax-scales that fall to the bottom of the hive ever used by the bees?
6. How can queens be easily found?
7. Is the honey in our State adulterated to any extent?
8. Is there need of additional State laws for the protection of the food-consumer?
9. How can a demand for honey be developed?
10. Should a colony of bees be left queenless through the winter?
11. Does any one know of a case of foul brood in this State?

Mrs. W. E. Riley, 54 Hawkins St., Waterbury, Conn., is the Secretary, who can be addressed for further information, if desired.

Wing-Stroke of Bees.—The San Francisco Post reports that "a captive bee striving to escape has been made to record as many as 15,540 wing-strokes per minute in a recent test." That is almost bewildering to think of.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

MR. M. M. BALDRIDGE says in the Bee-Keepers' Review, that he thinks the great value of sweet clover as a soil-renovator comes chiefly from its dense shade.

MR. JOHN NEWTON—a successful young bee-keeper of Canada—is writing for the American Bee-Keeper. Mr. Newton's portrait graces the April number of that paper.

MR. T. F. BINGHAM, of Clare Co., Mich., wrote us April 11:

"Bees have wintered well about here. My apiary gathered pollen yesterday and to-day."

MR. H. LATHROP, of Green Co., Wis., wrote us April 8:

"The bees are placed on the summer stands. There has been little or no loss, and I never saw bees stronger or better supplied with stores at this season of the year."

PROF. MAX MULLER had this to say along the spelling-reform line:

"English spelling is a national misfortune; it is unintelligible, unhistorical, and unteachable."

MR. S. T. PETTIT, of Ontario, Canada, writing us April 18, said:

"The spring is here again, and all Nature seems to rejoice. Neither the bees nor the birds seem to carry any bitter grudges in their loving little hearts. I wish we were as good."

MR. J. B. WILHELM, of Seneca Co., Ohio, wrote us April 9:

"We have so many bee-keepers that are penny wise and pound foolish. They are so saving that they cannot afford to take a good bee-paper, and lose more than enough to pay for a number of them, provided they would follow the instructions and advice given in the papers from time to time. A person's life is too short to learn all by experience about the production of honey."

Just so, Mr. Wilhelm. It is surprising, the number of bee-keepers there are that seem determined not to learn how to keep their bees more profitably. But "where ignorance is bliss," etc.

THE NEW YORK VOICE, published at 30 Astor Place, New York, N. Y., is perhaps the most powerful newspaper the temperance reform ever had. It has lately been investigating the surroundings of some of the larger colleges and universities of this country, and the condition of things that has disclosed is enough to congeal the blood in every respectable man's veins. It has found that in some instances the students seem to devote more time in an attempt to see how they can distinguish themselves as drinking hoodlums and bums, rather than for high morals and intelligence. We believe that when parents once really learn that others have been rearing sons and sending them away to become drunkards, gamblers and moral lepers, they will be careful to select the college for their sons that is dead against the saloon, and bawdy-house accompaniment. What a shame that our American youth should find themselves in institutions of learning where the president and professors lend their influence toward encouraging the drink evil! Send for a free sample copy of the New York Voice, then subscribe for it, and learn about its great work. Price, \$1.50 a year.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

Horseradish for Stings is recommended in *Le Rucher Belge*. Apply the crushed leaf to the wound, and soon pain and swelling will disappear.

Weak Colonies and Propolis—Editor Holtermann thinks a weak colony, other things being equal, is worse at propolizing than a strong one. If that be true, it is another argument in favor of strong colonies.

Does Crowding Induce Swarming?—It is generally believed that when bees are crowded for room in the brood-chamber it is an inducement to swarming, but Editor Holtermann now thinks that crowding hives in an apiary has effect in the same line, because of the "many bees humming, flying and roaring about in a limited space."

To Lessen Brood-Rearing after harvest in places where there is no late flow, and where rearing a large amount of brood is not desired, *Le Rucher Belge* advises contracting the entrance to the hive, as brood-rearing cannot be carried on without abundance of fresh air. Possibly there is a hint here for those Californians who desire to limit brood-rearing where there is no harvest.

How to Report Crooked Firms is considered by the editor of the Review. He thinks there is no use in saying a word unless you give the name of the firm, and then give such information as will allow reading between the lines that the firm needs watching. But if the law will not allow a journal to say in plain terms that a firm should not be trusted, would it not be equally liable for hinting it?

Carniolan Bees.—R. F. Holtermann, apiculturist of the Ontario Experimental Apiary, reports upon 12 colonies of Carniolan bees. They were very gentle, built up well in the spring, but the queens being dark were much harder to find than Italians. Swarms hived on full sheets of foundation did all right, but those hived on starters built very poor comb, having a large proportion of drone-comb, and swarmed excessively, without waiting to complete their combs.

Pettit's Divider.—F. A. Gemmill has used and likes it, and thinks a better name would be "perforated follower." The only objection is, that it makes just so much additional furniture, and a super will not hold so many sections, but the outside row is filled about the same as the center. R. F. Holtermann thinks it would be better to use perforated metal for dividers, as the perforations are exact, and they can easily be cleaned by throwing them in a weak solution of lye.

Temperature of Bees in Winter.—The bee is warm-blooded. According to some the temperature of a bee's body under normal conditions is 81.5°—according to others 95°. Some bees that were torpid in a temperature of 48° brought to life in a temperature of 59°, showed a body heat of 77°. The cluster in winter is kept up to 50° to 53° at its outer part. When the surrounding atmosphere goes down to zero or lower, the bees in the center of the cluster run the heat up to 86° or more by means of eating and exercising. This increase heat in the center of the cluster is necessary so that the outer part of the cluster may not go below 50°, and explains how it is that breeding is commenced in colonies outdoors in winter, but not in cellared colonies. The center of the cluster in cellar is too cold for breeding, for it doesn't need to be heated up to keep the outer bees warm enough.—Dr. C. C. Miller, in *Gleanings*.

Coggshall's Way of Extracting.—According to the editor's report in *Gleanings*, W. L. Coggshall has a reckless, slap-dash way of working bees that would drive many a man wild. He seems to take no precaution against robbers, but pushes right ahead regardless. The robbers pounce onto the combs and the honey, and when a half-day's or a day's extracting is over there will be two to four inches of dead bees in the honey. But the honey being drawn off from beneath, there will be no bees in what leaves the extractor. The building in which the extracting is done being by no means fire-

proof, when the extracting is over "the bees simply have a glorious old spruce cleaning things up." Before condemning this plan too severely, it may be well to ask whether the expeditious way in which Mr. Coggshall rushes things through may not partly account for the fact that he succeeds with about 1,000 colonies of bees, and makes money at it.

A peculiarity of his extractor is that a pair of combs are put in each side, being separated by a sheet of tin. When one side of the combs are emptied, instead of taking out a frame, turning it around and putting it back in the same place, two frames are grasped by one hand, two frames by the other, all four lifted out, and without any turning the frames simply change places. Sometimes, however, only one frame is lifted by each hand. In either case, what a saving of time!

Doolittle and Root on Plain Sections.—Doolittle and editor Root do not agree as to the advisability of adopting plain sections, as anyone will conclude after seeing the 2½ pages of *Gleanings* they tramp over in their tussle. Doolittle estimates that it would cost him \$100 to make the change in his apiary, and allowing that only a fourth of the bee-keepers of the land should change, and that the average cost would be to them only a tenth as much, or \$10 each, it would make a total cost of \$1,000,000 to make the change to plain sections. He doesn't value the argument that the plain sections will be filled fuller, for lighter sections sell best. The extra price obtained for plain sections of honey he thinks is due to special pushing, without which the plain section would sell for no more than the other. Thinks when you come to count necessary cost of veneers for shipping-cases, there will be no saving.

Mr. Root thinks Mr. Doolittle overestimates the cost of the change, as old supers need not be thrown away, and instead of \$1.00 per colony, he stipulates to make the necessary change for Mr. Doolittle for 40 cents per colony, on the basis of 25 wide frames per colony. He says if it is better not to have the outer row of cells sealed, a slight change in the fence will effect that, but urges the importance of sealing next the wood to secure safe shipping. Mr. Root meets the \$1,000,000 outlay by saying the saving of expense for making bee-ways in sections, counted at 25 cents a thousand, providing one-fourth the bee-keepers use 5,000 sections a year, will amount to \$1,200,000 every year.

It's a neatly fought battle, and the reader will very likely not have his opinion very much changed after witnessing it.

Facing Comb Honey.—Editor Root and Doolittle have been winking at the practice of putting the best sections next the glass in a shipping-case. Oh, but doesn't Hasty go for them in Review! What he says couldn't all be boiled down for this department. It wouldn't be safe. It's so hot that if it were boiled down any more it would set fire to the whole batch. He refers to *Gleanings*, page 175, and quotes the following from Doolittle:

"And I also claim that there is nothing out of the way, if any one chooses to do so, in shipping cases of honey having XXX faces and XX or X honey inside, on commission. Yea, more, I claim that there would be nothing dishonest in filling the center of the case with buckwheat honey, the same having XXX white honey facers, providing it was *shipt on commission*, every case alike, and the producer thought it to his interest to do so."

Hasty thinks when Doolittle said that, he was not laying at the sleek and wonderful Devil with the sword of the Spirit—not laying at him with the kick of an honest man—just gently stroking him down the back. "One almost listens to hear his majesty purr. Every trickster will feel bolder after reading that quotation." Referring to the argument that veneering is common and deceives no one, Hasty says: "'All our people do so' is the Congo cannibal's argument—does it prove anything? The fact that schemes to deceive purchasers are almost universal is only a peremptory call to arms for all those who have been listening to the Man of Nazereth... If we believe in warfare against the world, the flesh and the Devil, we must not be talking 'armistice' all the while."

This Boiler is not supposed to have opinions of his own—only a parrot to repeat what others say—but would like to lay down his stirring-stick long enough to give Hasty a very hearty grip with both hands.

Beeswax Wanted.—Until further notice we will pay 27 cents cash for all the good yellow beeswax delivered to us. We accept only that which is absolutely pure. If you want cash, and want it *at once*, send us your beeswax now. Be sure to put your own name and address on each package, when shipping. Then mark it very plainly—George W. York & Co., 118 Michigan St., Chicago, Ill.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,
Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions to this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 230 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide to bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 176 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES AND HONEY, 10 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, by Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey," 80 p.; illustrated, 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2 in the artificial leather, with pocket, slate, and account-book. Price, 60 cts.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for fastening up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cures. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Bee-Keepers' Directory, by H. Alley.—Latest methods in Queen-Rearing, etc. Price, 50c.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only one book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

1. Langstroth on the Honey-Bee..... \$2.00
2. A B C of Bee-Culture..... 2.00
3. Bee-Keepers' Guide..... 1.75
4. Bees and Honey [Cloth bound]..... 1.65
5. Doolittle's Scientific Queen-Rearing..... 1.75
6. Dr. Howard's Foul Brood Book..... 1.10
7. Advanced Bee-Culture..... 1.30
9. Bienen-Kultur [German]..... 1.20
11. Rational Bee-Keeping [Paper bound]..... 1.75
12. Thirty Years Among the Bees..... 1.30
13. Bee-Keeping for Profit..... 1.15
14. Convention Hand-Book..... 1.15
15. Poultry for Market and Profit..... 1.10
16. Turkeys for Market and Profit..... 1.10
17. Capons and Caponizing..... 1.10
18. Our Poultry Doctor..... 1.10
19. Green's Four Books..... 1.15
21. Garden and Orchard..... 1.15
23. Rural Life..... 1.10
25. Commercial Calculator, No. 1..... 1.25
26. Commercial Calculator, No. 2..... 1.40
27. Kendall's Horse-Book..... 1.10
30. Potato Culture..... 1.20
32. Hand-Book of Health..... 1.10
34. Maple Sugar and the Sugar Bush..... 1.20
35. Silo and Silage..... 1.10
36. Winter Problem in Bee-Keeping..... 1.30
37. Apiary Register (for 50 colonies)..... 1.75
38. Apiary Register (for 100 colonies)..... 2.00
39. Bee-Keepers' Directory..... 1.30

Please Send Us the Names of your neighbors who keep bees, and we will send them sample copies of the BEE JOURNAL. Then please call upon them and get them to subscribe with you, and secure some of the premiums we offer.

GOLDEN BEAUTIES...

Three-band Italian Queens reared from Root's stock. Golden Queens, from the best selected stock, Untested, 50 cents; Tested, 75 cents. Carniolan Queens at same price.

GENERAL ITEMS

Winter Loss Light.

My bees are in good condition this spring. The winter loss was light. They have gathered lots of pollen, but not much honey yet.
Hamilton Co., N. Y. **GEO. H. PORTER.**

A Beginner With Bees.

Last fall I bought a colony of bees, and after I had brought them home the man told me the queen was clipped. I started last spring with 2 colonies, and got 5 swarms. I have 7 colonies in the cellar now, that are wintering finely so far. I have a cellar built for bees, and nothing else. I keep the temperature from 2 to 4 degrees above freezing. I have a cloth over the frames, and the cover on with a wedge under it at the back.
F. E. KNAPP.

Wadena Co., Minn., Jan. 16.

Cold Winter in Arizona.

We are having the coldest and most snow this winter that we have had in this part of the country for many years. The mercury runs down 12 degrees below zero. That is cold for this part of the country. We are located a little south of the 34th parallel of latitude, with an altitude of about 7,000 feet, but still my bees have been wintered on the summer stands in single-walled hives, and came out all right in the spring, but just how they will come out this spring is hard to tell at this time, but about 10 days ago they were all right. But I will not take such desperate chances another winter.

The honey crop in 1897 was very light here, owing to a dry time the latter part of May and first of June. The alfalfa did not yield much nectar. The American bee-plant which grows in great abundance here was fairly good. We don't have much sweet clover as yet. We are looking forward to a more profitable season this year.

JOSEPH A. LEWIS.

Navajo Co., Ariz., Jan. 27.

A Report from Florida.

There was a severe drought in this portion of Florida last summer, and many colonies of bees perished. Their owners say that "the moths eat 'em up." Lately I visited an apiary of four colonies; they were very small, black bees, and very spiteful. I've never come across any amiable ones here. One of the colonies was very weak, and many small, black ants were coming and going from the entrance. I account for the loss of the colonies in this way: There is a small amount of honey gathered during the winter, which causes them to rear brood, and in the spring they are very populous. I was enquiring of a lady as to how many colonies of bees she had. She told me, and I said, "You had that many seven years ago." She replied, "I never save a swarm; they all go to the woods. I never know when they swarm." Bees are allowed to swarm themselves to death, as black bees will, and the old colony not able to defend itself, the moths take possession.

The yellow jessamine has been in bloom since January, and is blooming still. The cultivated vines, trained to houses, climb to the third story, and the wealth of yellow bloom is very beautiful. I saw a tall tree yesterday whose top bent and swayed by its weight, and bees fairly swarm upon the bloom.

The bees are holding high carnival now. The titi is blooming, and the trees are white with its pretty racemes, redolent with perfume. Plums are through blooming, but peaches and pears are in all their glory. The Le Conte pear blooms in clusters, looking like hydrangea blossoms. I've counted 45 separate blossoms in one cluster. Dewberries cover the ground like a mat,

and are white with bloom, and are favorites with the bees. Phlox drommondii comes up in the fall, grows all winter, and is now in bloom. In some yards it is so thick that the ground is not visible, and waves in the wind like a field of grain; it is in all the colors of the rainbow, and is a lovely sight.

I have planted sweet clover every year, but have never been rewarded with a single plant. Early in January I planted crimson clover, and it came up in four or five days, as the weather was warm and damp. I trasplanted some, and it is growing beautifully. MRS. L. HARRISON.

Washington Co., Fla., March 24.

Dry Winter in Colorado.

We have had a very dry spell, not half the snow of last season, and a terrible lot of wind. We had it warm for a time, but two days this week have been below zero. I put no work on my bees when starting into the winter, on their old stands, but the whole 39 are all right at present. Last year I set a row of Russian sunflowers on the southwest side of a number of my hives, and I think it will prove the best of shade. The hives face southeast, because most of our strong winds are from the northwest. The sunflowers are hardy; the seed can be put in at any time to come up when it likes.

WALTER A. VARIAN.

Weld Co., Colo., March 23.

Qualities of Honey.

We sometimes see the statement that the Italian bees produce a finer quality of honey than the blacks or others. If it is a proper question, I wish to ask the wise ones how it is, when all have access to the same forage? If, as some say, the bees make the honey, then we may account for it on the supposition that the Italians are better mechanics or chemists, and are endowed with a more elaborate and perfect mechanism. Or if, as is said, they have a longer labia, and can work well on red clover, then we may account for it that way. I have talkt with old bee-keepers and all have said they never saw any honey-bee—red, blue, black or yellow—that workt on red clover enough to cut any figure.

One veteran said he once stood in a large field of red clover when a mower was at work, and noticed a big lot of bees following the mower, and swarming on the new cut clover, presumably after the sap, but not a bee on the standing clover. And how is it in localities where there is little or no red clover? I am not a "kicker," and pick bones with no one—I simply ask for information, and when in search of knowledge, where do we go but to the wise? And if, on bee-questions at least, they are not found in the "Bee Journal family," where are they?

A. W. HART.

Stephenson Co., Ill.

[Here is a chance for some one to distinguish himself.—EDITOR.]

A Mississippi Bee-Man's Experience.

I agreed to let you know how I came out after the overflow of 1897.

Well, I had about 100 very weak colonies left. The water staid just seven weeks. I never saw bees swarm as they did. I saw as many as 7 swarms go to the woods in one day. The water was so deep and the trees so high I could do nothing but let them go.

I commenced to build them up. I never saw bees do better. I got over a ton of extracted honey, and sold over 30 queens, and wintered 210 good, strong colonies with a loss of only one. Bees are just booming. Drones are flying, young bees are having a jubilee every day, coming out of the hives. You would almost think they were swarming. I am going through all of them and clipping all the queens' wings that I am keeping for honey-gathering. I am working about 100 for extracted, about 25 for comb honey, and the balance I am breaking up for nuclei. Some of my colonies have brood in as many as 7 frames.

Willow is just in bloom, and there are

Ho, for Omaha!

As we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, sooty-white Sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

Italian Bees For Sale !!

We have arranged with a large bee-keeper in Lee County, Ill., (about 100 miles west of Chicago), to fill our orders for Italian Bees at the following prices there, which include a good Queen with each colony:

- 8 L. frames of bees in light shipping-case, \$3.75
- 5 at \$3.50 each.
- 8 L. frames of bees in dovetailed hive, \$4.25.
- 5 at \$4.00 each.

Prompt shipment after May 1, and safe arrival and satisfaction guaranteed. Address

GEORGE W. YORK & CO.,
CHICAGO, ILLS.

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing *new* subscribers; as the majority remain, once they become subscribers to a *good* journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo.; or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden strain, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. **W. Z. HUTCHINSON,**

FLINT, MICH.

hundreds of acres of it in reach of my apiary.

While writing this letter my thoughts go back to one year ago this morning. When I arose there was just 4 feet of water where I am now writing, and over one-half of my bee-hives, and all was floating over the yard.

Let the American Bee Journal come along; I got more information from one copy awhile ago than its cost for five years. I would not keep 5 colonies of bees and do without the Bee Journal. I oftentimes think of an old man when I was keeping bees in Michigan, who kept a few bees, and would often visit me. I asked him to send for the American Bee Journal. He said, "What for? I know more about bees than the man that prints that book." Shortly after that he came to me and said his bees were doing nothing, and dwindling down. I told him I would go down and look at them. I went, and 2 colonies were queenless. He said, "What can I do to save them?" My answer was to give me one dollar and I would send for the American Bee Journal. He replied, "I will." So he did, and I sent for the Bee Journal for him, and also fixt up his bees for him. Less than six months afterward I was at his place, and he said to me: "Siple, I did not think the men up at Chicago knew so much about bees. I would not be without that little book for five dollars."

Well, I have two more just like him near me, who keep bees. They are after me to fix up their bees, often when I am busy at home. I have tried to get them to take the American Bee Journal, but they are like that Michigan man—they know it all!

I am working three apiaries besides my own this season, so I shall have a busy summer. I get 10 cents per gallon to extract their honey, and board. Last summer I left home at sunrise and walkt 6 miles, extracted 141 gallons, and quit at 6 o'clock and walkt home that night. I had a colored boy to blow the smoker. How is that for a man over 50? One of the apiaries I am working is 6 miles north. I have 118 colonies. The other is 5 miles south, with 106 colonies. The other 14 miles on the railroad south, so I will not have much time to play this summer. **J. H. SIPLE.**

Bolivar Co., Miss., March 30.

A Few Notes and Comments.

I wintered 10 colonies of bees on the summer stands without loss. They have been carrying in pollen for the last five days. To-day it is cold and snowing some.

I can hardly agree with Mr. Stone (see page 163) that the bees, not the queen, order the walk-out. My experience has taught me differently, for I have seen the queen run around at the entrance and then swarm out. I think the queen is the "boss." I have kept bees for eight years, and there is more to learn about them than I thought.

I have drones flying on warm days. I never before saw drones flying before June.

I have a neighbor across the road who bought a colony of bees, and he said they were pure Italians. I went to see his bees, and to my surprise they were hybrids. I told him that bees are a deep study, and he had lots to learn as well as myself.

Last year was a good honey-year. Prospects are good so far, and white clover is looking fine. Honey is cheap. Comb honey sells out of the city of Toledo at 10 and 11 cents a pound.

I was greatly surprised when I read that Dr. Besse lost his sweet-clover lawsuit. I was hoping that the Doctor would get justice. What is this world coming to, if a person can't plant what is valuable to him.

W. M. DANIELS.

Wood Co., Ohio, March 23.

Wintering—Alley Trap, Etc.

Bees did fairly well here in Vermont last year, tho it was a wet and rainy season. I have been in the habit of contracting the bee-space entrance from six to eight inches in cold weather, on the summer stands, packt with leaves or straw, and the super of sawdust on top of the frames. I find no

had results so far. I look at it as bad economy for one to leave the doors open the same as in summer, tho he had a house full of coal and provisions plenty. Part of the hives I put into the cellar to winter, using a sawdust super on top, and a two-inch narrow frame between the hive-body and the bottom-board. I find very little difference in time of bees building up at swarming time, in those taken from the cellar or those left on the summer stands.

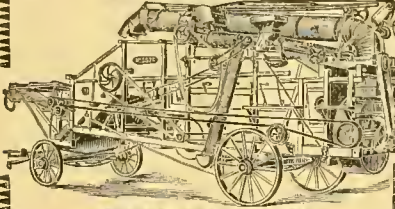

I have valued the Alley queen and drone trap very highly, tho I have had bees disappear that never returned. The traps need attention early mornings, to rid them of the drones, kept clear from getting clogged. I put them on swarms newly hived, and part of the working season leaving the return passage clear for return of queen if she enters the trap. I have this last year, as a consequence, one dozen empty hives void of bees, but with frames fairly filled with honey well preserved.

I have an inquiry as to what is the best plan to pursue, whether to hive swarms on full combs, or to use part foundation in the center of full combs. Would they rather start queen-cells and move out?

I have not had very much experimental practice in this line. I have only been in the apary business a few years. I enjoy being with the bees, and am interested in the "old reliable" American Bee Journal. May its banner forever wave.

HONEY and BEESWAX
MARKET QUOTATIONS.

Chicago, April 20.—Fancy white comb honey would bring 11 cents, but there is none here; other good grades of white at 9 to 10c.; dark and amber, 7 to 8c. Extracted, white, 5 to 6c.; ambers, 4½ to 5c.; dark and off grades, 4c., with exception of dark candied and amber grades. This market is bare of comb, and while prices have been low the quantity sold locally has been greater than last season. Beeswax scarce, and sells at 27c. for average lots.

R. A. BURNETT & Co.

Kansas City, April 20.—Fancy white, 9 to 10c; No. 1, white, 9c; amber, 8 to 9c. Extracted, white, 5 to 5½c; amber, 5c; dark, 3½ to 4c. Beeswax, 20 to 25c.

Comb honey is selling fairly well, but prices are low; considerable shows signs of candying, which makes dealers anxious sellers.

C. C. CLEMONS & Co.

Cincinnati, April 19.—Demand fair for extracted, at 3½ to 6c. according to quality. Demand for comb is slow at 10 to 13c. for best white. Beeswax in good demand at 20 to 25c. for good to choice yellow.

CHAS. F. MUTH & SON.

Boston, April 14.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, 9c. Extracted, white 6 to 7c.; light amber, 5 to 6c. Beeswax is scarce at 26c.

Our market on comb and extracted honey has kept active at old prices, and as a result the stock is well cleaned up. There is very little call for anything but white in this market.

BLAKE, SCOTT & LEE.

Cleveland, April 14.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c.

A. B. WILLIAMS & Co.

San Francisco, April 6.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5½c; light amber, 4½ to 5½c. Beeswax, 24 to 27c.

A ship sailing this week for Hamburg took 316 cases. Sellers are not nearly so numerous as early in the season, and are inclined to be quite exacting at present in the matter of prices. Market is strong for comb and extracted, with supplies of latter light and stocks of comb showing steady decrease. The firmness is based mainly on the poor prospects for coming crop.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax in good demand at 26@27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season.

M. H. HUNT.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging.

S. H. HALL & Co.

Indianapolis, March 24.—Fancy white, 11 to 13c.; No 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.

WALTER S. POWDER.

Milwaukee, March 8.—Fancy, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 10 to 10½c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4½ to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the best. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better.

A. V. BISHOP & Co.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.

Spring Management of Bees—Good Advice.

BY G. M. DOOLITTLE.

A correspondent who says he is a reader of the American Bee Journal, requests that I tell how I manage bees in the spring from the time they are put from the cellar till swarming-time arrives, which I will endeavor to do.

As I now feel in the matter there is only one thing which is really essential to look after as soon as the bees are put from the cellar, or in early spring, no matter which way the bees have been wintered; and that is to see that they have plenty of honey to last them till pollen becomes plenty, or steady warm weather arrives.

This part is something that can be done on any cool morning after a day or two of cool or cold weather, when the bees will be clustered compactly together, thus drawing off from much of the comb surface, so that you can peer down the vacant spaces between the combs, outside the cluster of bees. To do this, carefully remove the cover to the hive, then as carefully roll back the quilt or cloth covering over the combs, beginning at the end or side the farthest from the entrance, as the cluster is generally formed near the entrance, rather than next the back side of the hive. If you have been careful you can roll the covering back to the cluster of bees without arousing them but little, if any.

Now look down between the combs, noting the sealed honey they have, and if plenty is seen along the top-bars of the frames that colony is safe during the next month to come. If little or none is seen the hive should be marked in some way, and the very first day (when the bees can fly) should be embraced to feed all such colonies. To do this understandingly the frames should be taken out and examined to see how much honey they really do have, and enough be fed so that each colony has at least 10 pounds.

Sometimes we find colonies which do not show any honey along the top-bars of the frames on account of the bees carrying the honey from this portion of the hive down into the cluster during the winter, altho very few colonies do like this, in which case they may have honey lower down in the combs. Where this is the case an examination of the combs by lifting from the hive will reveal the same. When looking at the bees during the cool morning it is well to note how many spaces between the combs the bees occupy, and set it down on a piece of section, which is to be left on the hive, so that we may know something of what will be needed for this colony when we commence active operations later on. I write on the section piece thus:

Supposing it to be April 5, or the fourth month and fifth day of the year 1898—98, 4-5, H. P.; S. 6—which tells me at any time I may look at this piece of section thereafter, that on April 5, 1898, that hive contained plenty of honey and a cluster of bees large enough to occupy six spaces between the combs; or, in other words, it says that the colony was A No.

1 for that time of the year, and needed no further attention until the time for general work among the bees.

The markings on the different pieces of sections are varied to suit what is found in each hive, and are left on the hives till both sides of the section are completely covered over with this "brief" regarding the colony it contains. From this piece of section I can tell regarding the "standing" of many colonies of bees as far back as four years, and it is a great help in deciding which queens are best for further breeding purposes.

In deciding as to the amount of honey each colony should have it is well to remember that bees consume much more honey at this time than they do during fall and winter, and that it is better to err on the side of too much honey than on the other, which will mean a retrenchment of brood-rearing a little later on.

Having made sure that all have honey enough there is no further need of molesting the bees till the weather becomes generally warm enough for them to work in the fields or trees nearly every day gathering pollen and honey. In fact, I now believe that further disturbance is positively detrimental, inasmuch as it often causes the loss of bees and brood by breaking the cracks open about the top of the hive so as to let the warmth out, as well as a greater consumption of honey, without any proportionate gain to the colony.

Francis Danzenbaker—See page 276.

Six weeks is a sufficient time to build up a fair colony to one sufficiently strong to store honey to the best advantage, and as the clover usually begins to yield honey here about June 20, from May 1st to the 10th is soon enough to begin working for brood, and it is better not to touch them even now, unless the weather is warm enough so that the mercury

reaches from 60° to 75° during the middle of the day. With a temperature of less than 60° above zero, brood is liable to be more or less injured in handling, from which a positive loss is made rather than the intended gain. If the weather is fine about this time, the internal condition of each colony is inspected by taking the frames out of the hives, cleaning the dead bees off the bottom-boards should any remain in the bottom corners of the hives, seeing that each colony has a queen, and that there is honey enough to last at least two weeks.

A good queen is of no more importance at this time than is this two or three weeks of honey, which now means from six to ten pounds, for if the bees do not have enough stores so they need not feel it necessary to economize, a good queen and all else will not make up the lack, for bees will not rear much brood if they are obliged to economize for fear of starvation in the immediate future.

After seeing that all have a good queen and sufficient stores they are now left till willow and hard maple bloom, when, if the weather is favorable, the combs in the brood-nest are revert by putting those frames having the least brood in them in the center of the cluster, and those having the most at the outside, thus causing the queen to fill these center combs with eggs as fully as were those which were in the center before, or more so, while the brood in those now on the outside is not allowed to decrease at all. In this way a great gain is made, as I have proven by leaving rows of hives in the apiary untouched, and by treating others as here given. Understand I am speaking of the frames which have brood in them, or what is termed the "brood-nest," and not the brood-chamber. Only the frames having brood in them are revert—the rest are left untouched.

In about two weeks the brood-nest is revert again, at which time all but the very weakest colonies will have brood in all, or all but one, or two combs, after which there is no gain made in handling the frames, unless you have some special object in view, such as taking away the queen, changing brood from the stronger to the weaker colonies, or something of that sort. In two or three days after the last reversing is done the colonies are ready for the sections, if there is any honey coming in from the fields. If not, it is better to wait till the hives become a little more populous; yet, if we wait too long the colony is apt to contract the swarming fever before they go to work in the sections, in which case our prospect for a large yield of honey is lessened.

As a rule, the fewer swarms that issue the greater the yield of honey; yet where bees get the swarming fever, as they often will in spite of all precautions, better results will then be obtained to let them have their own way, using the Heddon plan of preventing after-swarms, or some other equally good plan, than to try to keep these "fractious" bees all in the old hive.

Onondaga Co., N. Y.

Do Bees Steal Eggs as Well as Honey?

BY "COMMON-SENSE BEE-KEEPING."

Yes, they do, if they are prest by necessity, and I know it, and this is how I proved it:

I had a few hives built so that after the swarm should issue I could make nuclei of the old hive without taking the parts away from the old stand, so that notwithstanding the separation the brood-nest would remain just as compact as before to retain the heat of the whole body for a greater protection against the fluctuations of temperature between cold nights and hot days. The entrances and approaches thereto were also duly separated so that the several nuclei could use the same alighting-board. At first the approaches were not divided by sufficient means to prevent the bees from seeing each other in coming and going. And when it was time for the young queens to begin to lay, I opened up their domiciles for examination.

The first queen to the right had begun laying nicely, having quite a stock of larvae and eggs, but the nucleus next to her showed no signs of a queen, tho her empty cell was there from which she had emerged, and all the brood was hatcht except a few scattering cells. I suspected at once that the young queen had mist her way on returning home after mating, and on entering the wrong place had been dualized by her sister. But I said possibly she hatcht late, and I can't find her among the bees, so I will give her a week or 10 days to show up signs of business.

When I opened them again the colony was weaker, as a matter of course, with less honey and nearly all of their combs empty. But as strange as it may seem, there on one comb hung five beautiful queen-cells all sealed over, besides about

40 worker-cells capt over, where there were empty cells at my last call.

Now if they had had a fresh young queen she would not have suspended work on the first hour of her fertility, which the condition of things would indicate if they hadn't borrowed the eggs. Again, if they had had a fertile young queen in their weak condition, they would have taken the first eggs she laid to build queen-cells with and fix for swarming.

The only solution I could reach that seemed reasonable was, that they had gone around the partition to the next nucleus on either hand, and had help themselves to eggs for a starting in their misfortune of being queenless.

If any one has a more reasonable solution I should be glad to hear it.

But the sublimest thing that I see in this whole case is the proof that bees have power to reason fully up to the necessities of their case. So they are not altogether creatures of instinct. See? Pennsylvania.

How to Prevent After-Swarming.

BY C. P. DADANT.

I have received the following letter, which I will answer in the American Bee Journal:

I would like a little advice about keeping my bees from swarming after the first swarm leaves the hive. In our location they swarm too much.

CARL ANDREE.

Cuyahoga Co., Ohio.

It is very difficult, if not impossible, to keep the bees from swarming when they are in small hives and crowded for room for the queen to lay. But there are methods by which the tendency to swarm may be increased, and others by which it is alleviated to a great extent. Any impediment to the free access to all parts of the hives, not only for the passage of the bees, but for a free circulation of air, will tend to make them uncomfortable and cause them to get the swarming impulse. The fact that when they get this desire to swarm it is almost impossible to change it is clearly shown by the appellation of this condition by old apiarists as "the swarming fever."

Separators, drone-traps, queen-excluders, and the thousand and one contrivances that have been praised from time to time by enthusiasts, but which hinder or confine the bees, are sure to help enhance the swarming fever. A much-divided super cut up into small sections has a tendency in that direction. It is for this reason that we have always been in favor, with Oliver Foster and other noted producers, of sections that were open so as to allow the bees to pass freely from one to another. The section open three ways has proven a step in the right direction; as it can either be used as closed or open top, and permits of the passage of the bee from one to another. With closed sections the bees have to descend to the lower apartment, or rather to the space above it in order to pass from one super to another. I can only compare this to a house in which the up-stairs rooms would have no door of communication with each other, but would have each a stairway communicating with the lower apartment—a rather sorry arrangement, indeed.

Your question is in regard to preventing all swarms after the first swarm. There is only one method that I know of to accomplish this result, and it is not of my own invention, but I read it years ago in the work of Hamet, a French writer on bees of "box-hive" fame, and this method has proven quite successful. I gave it in one of the bee-papers several years ago, and a number of apiarists reported favorably upon it, after having given it a thorough trial. It consists in giving the swarm and returning it to the parent hive about 48 hours after swarming. As the reader will see, it does not prevent swarming, but simply does away with the swarm and the inconvenience of having too great a number of weakened colonies, and the result is the same (excepting the labor involved) as if the colony had not swarmed.

This method has been tried on the first swarm. On this it is not very successful, for it leaves the hives with the same strength as it originally possess, and otherwise unchanged conditions. But when practiced on the second, or succeeding swarms, it has full effect in most instances.

The effect of this measure is easily reasoned out. When the colony has cast a large swarm, as the first usually is, the following issues are only a result of the feverish or excited condition of the bees, and of the fact that a number of young queens are hatcht, or about to. The second, if large, usually leaves the hive in a depopulated condition, and the fever abates at once. The remaining bees either destroy, or allow to be destroyed, by personal combat all the young queens that might cause another issue. If the swarm is returned in about 48

hours the young queen that comes with it, strong and vigorous as she is, being the oldest of the new queens, readily overpowers the remaining one, and at once begins her regular duties. This throws the condition of the colony back into the normal state, and honey-gathering is no longer interrupted unless a protracted honey crop of great proportions, or the neglect of the apiarist to give room should cause another spell of feverish excitement later. Such conditions are of unusual occurrence in this part of the United States.

When hiving a second swarm with the purpose of returning it to the hive, it may be temporarily put into any kind of a box, a nail-keg, or in fact any vessel that will hold them for the short time they are expected to remain. As a matter of course it is well to look to the comfort of the bees otherwise to give them plenty of room and plenty of air and shade.

Another method to prevent after-swarms consists in removing the hive from its stand at the issue of the first swarm, and place the swarm in its stead. This removes all the old bees, and throws the entire working-force on the first swarm, which then becomes the main colony, and may be looked to for the largest yield of honey.

Hancock Co., Ill.

Producing Only the Very Best Honey.

BY W. W. M'NEAL.

The first honey I ever ate, that I remember distinctly, was taken from a "cap" worn by one of the old box-hives. I tell you I thought that honey tasted good; and I believe to this day it *was* good. I have many times since eaten of honey that lookt better, but somehow the real delightfulness of my first experience has never been repeated. When a colony of bees in a great big box-hive climbs up into the hollow cap and builds comb and stores honey there, it is of a kind that "tastes like more." The comb is the real product of the bee, and the honey the real juice of the flower; and when left on the hive all summer—say, "haint" it then "real honey?"

If all the honey sold were so treated there would not be so much talk of a weakened demand for honey. When the bees are urged to hasten the completion of their work by the giving of full sheets of foundation or ready-drawn comb, the honey is not retained in the honey-sac of the younger bees as long as it should be, but is stored in the comb and capt prematurely. Such honey, if removed from the hive immediately, is almost sure to deteriorate unless special care is bestowed upon it. Comb honey should be so thick and ripe that when cut it is waxy, stringy-like. A single pound of it, even, is almost sure then to bring your customer back for more. When honey is mentioned in his presence he is almost sure to say the right word at the right time, and so a demand for honey is created. But if through carelessness on the part of the producer the honey failed to give satisfaction, how different the result. Not only is the customer himself lost, but everywhere he goes he hinders the sale of honey.

This state of things is more easily brought about with extracted honey, which is seldom left on the hive till it is really fit to eat. The thin, semi-ripened honey soon takes on a sour, rancid smell, which of itself is enough to drive any one to an utter dislike for honey. A poor grade of extracted honey is not so good as newly-made sorghum molasses that sells for a quarter a gallon.

But the trouble in the honey market is not wholly due to faulty methods in the production of honey. The unceasing cry of bee-keepers to use cane-sugar in the apiary has manifested its withering power. There is a boldness in this direction that bids destruction to the honey-business. Glucose, with all its contaminating hatefulness, has done no more to hedge in the sales of pure honey than has the use of cane-sugar. It is a fact that those who are unacquainted with honey believe pure honey ought always to remain a liquid. If the agricultural journals were read only by honey-producers the trouble would not be nearly so great; but honey consumers note the fact that sugar is fed to bees, and so when they are presented with a few pounds of the genuine article of honey, and the same sugars on their hands—which it is sure to do—there is then need of a right, real gilt-edged piece of logic to convince them that it is not of the sugar-honey kind they read about. No one who feeds sugar to his bees can long hold the confidence of those about him. The people know of but one purpose for which sugar is fed to bees, and that is to be "made" into pure honey. They naturally hesitate to pay living or honey prices for honey itself, so the home trade suffers, and the honey is thrown upon a distant market.

If it is wrong to use glucose it is also wrong to use cane-sugar; and it is surely a mistake to sound it through the length and breadth of the land that either is used with honey. Just so long as bee-keepers continue to do this; just so long

as they continue to put up and offer for sale unripe honey, will honey go begging a buyer.

Large hives or brood-chambers are the surest and best way of driving the sugar-barrel from the apiary, and the cutting down of expenses in general. There is no more trouble for me to get a strong colony of bees into the supers over a large and deep frame than it is to get a weaker one there over the small and shallow frame. The colonies in small hives are never, it seems, able to care for themselves, but always require a lot of coddling, which to me has few charms.

In retailing extracted honey I prefer the common tin pails, such as are used in almost every home. I do not approve of selling in very large quantities to new customers, for they are very apt to put the honey in some place where it will spoil before used up. Of course they then lose their taste for it, besides refusing to buy a fresh lot so long as there is any of the old left.

I find the poor, the children of the poor, to be excellent consumers of honey when given a chance to eat it. Bread and molasses forms a large part of their bill of fare, so they well know how to sop. But if the poor are to be made the receivers of the honey crop, they should be given the very best for their hard-earned money. I do not see how comb honey can be brought down to a price within their reach without selling it at a certain loss to the producer. Then if extracted honey only enters this broad field in competition with the many kinds of cheap table-syrups, how necessary it is that every means known to the fraternity for sustaining the reputation of liquid honey be called into service.

Unfortunately the recent leaflet by our good friend Dr. C. C. Miller, is telling a good many people (page 6, near the bottom) "it is a comfort to know that, when one buys comb honey, he may know without question he is getting the genuine article." The causer *should* receive prompt and vigorous attention, but I cannot see that the public ought to be told we have it to deal with.

Let all those who produce honey and have the love of the pursuit at heart, see to it that none but the *very choicest* of honey leaves their apiary for any market, and a good deal of the suspicion and prejudice now existing will dwindle away.

Those who believe there is or can be an overproduction of honey, need only to visit the homes of the poor and there see the hungry-looking little tots who would almost give their toes for all the good honey they could eat, to relieve their minds of any such delusion. The question with them, then, I think, would be, is it possible for there to be an overproduction of honey?

Scioto Co., Ohio.

Again a Defense of the Bee-Space.

BY W. C. GATHRIGHT.

I would not have offered my criticism on the article by the "Common-Sense Bee-Keeper" had he not made these claims, *i. e.*, that no bee-keeper uses the bee-space for any other reason than that it is handy; and that the bee-space is the cause of all bee-diseases.

By the way, let me say that an attack is generally replied to with the same spirit in which it is given. Mr. "Common-Sense Bee-Keeper" made a voluntary attack on the bee-space in a very aggressive style, and should not complain if replies are in somewhat the same spirit.

On page 98, Mr. "Common-Sense Bee-Keeper" thinks that I am much mistaken in saying that the bee-space was Mr. Langstroth's most important part of the movable-frame system. The bee-space was not only a convenience but a necessity. I saw frames in a bee-hive long before I ever saw or heard of a Langstroth hive, but the frames I saw were worthless on account of not having the bee-space. The bees had fastened them securely to the sides of the hive, and the owner had to tear them to pieces to get them out.

I made the assertion that it was a good thing for the air to escape from the cluster to the adjoining spaces, for it allows pure air to take its place. To this my friend takes exception and says: "If this be true, then wire-screen in the place of the regular cover and bottom would be better." This is in exact accord with the idea that if a spoonful of medicine is good for the patient, a cupful would be better. He is simply going to the other extreme from his non-bee-space idea.

Bees need pure air to breathe, but it does not require a strong draft of air through the hive to supply them. Our friend must certainly know that air once breathed is poison. There should be a *gradual* displacement of the warm air which they have breathed. The bee-space allows this displacement to take place just exactly as it should.

In support of the above theory, I call attention to Dr. E. Gallup's article, on page 4. He tells of a hive that was crackt

open from top to bottom, the crack being fully $\frac{3}{4}$ of an inch wide. He says he felt sure that colony would freeze, but "that colony wintered the best in the lot. My bees that I kept warm nearly all died that winter." This was in Canada. I have read of a dozen or more instances similar to this.

My own experience with bee-diseases was in Mississippi some years ago. In that wet climate we had to contend with all the diseases which bees are liable to. From what I could learn it was nearly as difficult to winter bees there and have them come through in *good condition* as it is in the North. The reason for this perhaps was the climate, which was very changeable and damp. I give here my opinion that disease is caused wholly and entirely from *dampness, foul air, and bad food.*

Here in New Mexico disease is unknown. The reason is plain. The air is so extremely dry that should there be any moisture accumulate during a cold night it dries out thoroughly during the day, and from the same cause a dry atmosphere. Our honey is thoroughly ripened.

Now I am not going to try to tell the bee-keepers in the North how to winter bees, but if I were keeping bees there I would fix them up for winter this way:

Stand the Langstroth frames on end, or use some other plan to provide plenty of stores *above the cluster.* On top of the hive (preferably on the outside) put on some protection to prevent moisture accumulating over the cluster. Give the proper ventilation, and with a good quality of stores I would not be uneasy as to the outcome. I believe this plan is the correct one, for the following reasons:

Bees never freeze. They die only from starvation or disease. In long, severe winters bees starve with plenty of honey in the hive. The cause of this is, the frames are shallow, and they consume the honey above them, but cannot reach the sides where there are full frames of honey, the cluster being able to move upwards but not sidewise on account of the cold.

With plenty of fuel (honey) right in their midst they can manufacture heat just as needed, and that heat is *inside the cluster,* and in a colony in a proper condition the bees are constantly changing places, those inside coming out to get fresh air, and those outside going to the center for food and warmth.

Dona Ana Co., New Mex.

BIOGRAPHICAL NOTES.

MR. FRANCIS DANZENBAKER.

The subject of this sketch was born Jan. 8, 1837, near Bridgeton, N. J., so he is now in his 62nd year. His great grandfather came from Germany; his grandfather spoke German as well as English, and, before "Francis" was born, owned over 300 colonies of bees. His father also kept bees, and so he has always been with bees and bee-work as it were by inheritance.

Mr. Danzenbaker's mother's injunction to her children always was, "What is worth doing at all is worth doing well." It has been his motto, and he has eagerly studied and aimed to have the best possible appliances for bees. This has brought him to where he may feel that he is well at the front in the production of comb honey.

Mr. D. has several patents on hives, one issued March 8, 1898, and one now pending; also one for a paper carton for comb honey, that he considers the most valuable thing that he will have contributed to the art of bee-keeping.

Mr. Danzenbaker was the first to lead in the use of the lock-corner hive, or so-called "dovetailed" hive, and has many features as important improvements of his that are now made by The A. I. Root Co.

Mr. D. may be clast with all of his ancestors for four generations, who were farmer bee-keepers.

We had the pleasure of making Mr. Danzenbaker's acquaintance at the Buffalo convention last August, where he took a very active part in all that came before that meeting.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

[Continued from page 262.]

A desultory discussion followed, of which a few remarks are here given:

Mr. Dudley (of Colorado)—I was troubled some years ago with a persistent ailment, not well understood, which was perhaps mild erysipelas. I found the homœopathists had a remedy which helped me. But in working with the bees I got stung at times, and found that I did not have to go for medicine. I have not been troubled since.

Mr. Adams—For ants I use equal parts of kerosene and coal-tar. Five drops of this clean out the biggest ant-hill. It is equally effectual with all kinds. I drop it on the hill or around the hives. It does not harm the bees, as I found by accidentally spilling some in a hive.

Mr. Varian—In the case of the small black ants, one has to find several holes. They get in the house.

Mr. Whipple—Common mint strewn in the honey-house will scatter them in 24 hours.

HANDLING CANDIED HONEY IN FRAMES.

QUES.—In the case of honey going over from year to year, what method do the members follow to prevent the granulation probable, and cause the greatest increase while doing so?

Mr. Varian—My neighbors lost a quantity of bees last year by having honey granulated in the hives, when the bees had no chance to get water. The honey should be replaced or worked over.

H. Rauchfuss—Those bees were out of condition. No candied honey will stay in the hive which a normal colony will not remove in the summer. I believe the bees died from some other cause. Likely they got wet.

Mr. Thompson—I have read in a foreign journal that one bee-keeper placed frames of granulated sealed combs in water just hot enough to liquefy the honey without melting the combs. I suppose the water buoys up the combs enough so they do not fall out of the frames.

Mr. Devinney—It won't work.

H. Rauchfuss—I have uncapt combs and sprinkled them with water from a Mason jar with a perforated cap. It has to be done several times. The main trouble is, that the bees are not strong enough in the spring.

Pres. Aikin—I have had a good many colonies that either starved or petered out. Their hives were heavy, without a pound of liquid honey in them. My remedy would be to use a brood-chamber large enough to hold about twice as much as the colonies want. In spring the colonies could pick out enough to get along. If the remainder is sealed, and the colony gets strong, it becomes soft enough for the bees to get out. Then perhaps have a double bottom-board, the upper part being of coarse wire-cloth, so that when the bees dig the grains out of the cells they will fall through out of reach of the bees. I have not tried it, and it would involve some little expense, but I think it feasible. Then the honey can be liquefied in the solar extractor. A solar for rendering wax will save a large amount of honey. You don't know how much honey and wax you lose by a plain bottom.

QUEEN-CELLS IN WIRE PROTECTORS.

QUES.—At what age will it do to put queen-cells in wire protectors in order to insure them to hatch?

H. Rauchfuss—The age does not make so much difference as the handling. If the queen-cells are capt they will hatch if they are not injured. They are not apt to hatch if handled too young. So it is best to wait until one day before hatching, using some artificial means of procuring cells, so as to know their age. Sometimes the bees thin the wax on the end of the cell shortly before it hatches, but this sign is not reliable.

EFFECT OF SMELTER SMOKE ON BEES.

QUES.—Does smelter smoke injure bees?

F. Rauchfuss—Most assuredly.

Mr. Dudley (of Utah)—For the last 10 years bees could not be reared in a space of about five by six miles near Salt Lake. The hay in that region poisons cattle.

H. Rauchfuss—Some horses died from eating grass near the smelters here. I believe our loss in bees was caused that way; not directly by the smoke, but because moisture absorbed poison from it and deposited it on the blossoms. It is just when we have a moist spring. It kills all ages, and only the weak and queenless colonies get through.

HONEY AS A FOOD AND MEDICINE.

QUES.—Is honey recommended as a healthy food? and, if so, for any particular disease?

Mr. Adams—For all pulmonary diseases and all diseases of nerves.

Mr. Rhodes—Some of our friends who had Bright's disease could eat no sweet but honey. It was also good for stomach troubles, because honey is already partially digested. This ought to be embodied in advertisements of honey.

Pres. Alkin—I have been troubled for years with an acid condition of the stomach. Most sweets that I eat start fermentation. But I can eat honey when I could not eat sugar.

Pres. Alkin was asked to explain his new hive, which he did as follows:

Hive Explanation by the President.

I shall use the fence or cleated separator in the super with plain sections. With this separator the bees do not lengthen those cells which are above and below the ordinary

the eighth day (full 8 days) every cell of the brood in the section from which the queen is excluded is sealed. It takes about two minutes to find which part of the queen is in. The part with the queen is then set on a new stand, after removing the queen-cells. The other part is hopelessly queenless. I then either immediately slip in a cell in a protector, or wait not more than two days for the cell, or put in a virgin queen just hatched (not a laying queen, or they may swarm). Then all the brood hatches by the time the queen is ready to lay. The colony is in the same condition as a colony which has swarmed. If increase is not wanted, I set the parts together after the honey-flow and let the queens fight it out. By this method but few colonies become queenless.

The frames are spaced 1 and 4/12 inches. Propolis will increase this a little. I know from practice that 1 4/12 inches will work all right, if the combs are true, and do away with burr-combs. Burr-combs have two chief causes, improper spacing and a crowded condition; they are caused also by the sudden stopping of the flow while wax is being secreted. (Wax-secretion is neither voluntary nor strictly involuntary. I hold that we do not lose nearly so much by bees being obliged to build their own comb as is generally accepted.)

A new brood-comb with sealed worker-brood is 3/8 inch thick. An old comb is one inch. I have my top and bottom bars exactly the width of the thickness of sealed comb, so that I can see every part of the surface when they are built down

The Bee-Supply Factory of The A. I. Root Company—One of Our Advertisers.

separator. Never make the cleat the full thickness of a bee-space, 3/4 inch. I think 1/2 inch is thick enough, tho the Root Co. are making them 2/12 of an inch.

I have been favorably impressed with the Heddon principles. I don't think a shallow frame is any better. I don't think it is quite as good as a deep one. No general size of hive is better, all things considered, than that which takes the American frame, which is square. Its defect is, it has not enough surface on which to place the surplus receptacle. I have used it almost constantly for 20 years. I cannot say positively, but I think that bees will build up faster in continuous large frames. But we must sometimes sacrifice advantages to convenience.

My frame, as you see it here, is of the Quinby style, 5 inches deep and 16 inches long. Hitherto we have always adapted the surplus apartment to the brood-chamber. I believe in adapting the brood-chamber to the surplus fixtures. I believe in tall sections. So my frame is as deep as one section, and as long as four sections. The brood-chamber is 16 inches long and 15 inches wide, making a large super surface (32 sections). It consists of two or more shallow stories, or hive sections. When three sections are used it approaches the cube, being 15 3/4 inches deep, making an almost ideal form of hive.

It is easiest to handle bees when a little honey is coming in. Eight days before the main flow I go around and put an excluder between the sections or apartments of each hive. On

to the bottom-bar; and when the parts are alternated the combs will be solid. I have for seven years used frames 13 inches long and 6 inches deep. The top-bars do not need to be 3/8 inch deep. That is just for strength.

A section of my hive is a super, a brood-chamber, or an extracting-super, at will. An inset or empty space back of the end-bars gives room for the ends of the separators, when it is a section super, and also for a Z-shaped piece of tin to support the frames, when a brood-chamber or extracting-super. Little tin shoulders on the lower ends of the separator-cleats take the place of T tins. Separators without cleats are used for the extracting-combs. Deep-cell foundation is still uncertain, but we know the value of bait-combs, and in this hive two extracting-combs, one at each side of the super, serve as bait-combs. It is compressed on all sides by ordinary stove-bolts, with the burrs inside, moving in slots, so that the last separator may be inserted. The hive is not so expensive as the Heddon hive.

I cover my sections with an inner cleated cover with a bee-space. The wax in sections is sometimes brought almost to the melting point beneath single board covers.

R. C. ALKIN.

FIRST DAY—EVENING SESSION.

BEST HIVE FOR THE AVERAGE FARMER.

F. Rauchfuss—What hive is best for the average farmer

who wants to know as little as possible about bees? I think the box-hive. I know several farmers who have a few box-hives who take up the heaviest and the lightest in the fall. They get some honey every year. The question of inspecting for foul brood appears to be a greater difficulty than it is. They have foul brood in England, and plenty of "skeps." It is an easy matter to invert and cut out a piece of comb with a crooked knife. A frame hive improperly managed is worse than a box-hive.

Pres. Aikin—At the Farmers' Institutes I tell the farmers to use boxes 16 or 18 inches each way for hives, and to select not to exceed five for a permanent stock. When these swarms the swarms are apt to be put in boxes with starters. About November, when all the brood is hatched, the bees of the swarms are to be sulphured and their combs cut out. All pollen-cells should be cut out. These may be detected by holding the combs up to the light. Then the combs are to be mashed up and strained in the old-fashioned way. If there is any disease the inspector would prefer to inspect a plain box-hive rather than a mismanaged frame-hive. I told them I was selling supplies, but in the face of my financial interest I would inform it was perfect foolishness to buy patent hives if they were not used right. If one has scruples about killing bees a large box may be put on for a super. But this honey should not be produced for market.

FOUL BROOD AND HONEY.

QUES.—In case a colony has foul brood is the section-honey infected?

Pres. Aikin—There is danger. It is a doubtful question. But when the colony is badly infected then the surplus honey partakes more or less of the odor. But if there are only a few cells of foul brood in a hive I would not hesitate about eating the honey.

Mrs. Rhodes—The trouble is, that the wood of section-honey is usually thrown away after cutting the honey out.

MELTING COMB HONEY—HONEY IN TIN CANS.

A discussion on melting comb honey followed.

Mr. Elliott—I extracted a good deal by heat, using a can like a coffee-urn with a water-jacket. Altho the honey was left in a long time it did not change its flavor.

F. Rauchfuss—We use a tank with a double wall, with two faucets, an inner and an outer one. With this arrangement honey may be spoiled by leaving in too long or heating too high.

Mr. Elliott—If the honey is drawn off as soon as melted it is all right; if left a little longer it shows a very little color.

Pres. Aikin—At the melting-point of wax heat has almost no effect on honey. At 180° it is colored. High heat is more effective in coloring it than a long-continued low heat.

QUES.—If honey is left in cans what is the effect on the tin?

F. Rauchfuss—Unripe honey corrodes the tin; ripe honey does not.

[Continued next week.]

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

Langstroth on the Honey-Bee, revised by The Danants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

See "Bee-Keeper's Guide" offer on page 284.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Boiling and Feeding Foul-Broody Honey.

What can I do with about 60 pounds of honey in Hoffman frames, from colonies that died of foul-brood last winter? Could I safely feed it by boiling? MICHIGAN.

ANSWER.—Put water with it, bring it to a boil, then after it comes to a boil keep it boiling for two hours and a half, and feed so as to have it used up in brood-rearing.

Hiving Swarms on Frames of Granulated Honey.

I have handled bees more or less for many years, but I am yet not satisfied whether it pays to keep frames of granulated honey to hive swarms on. Of course, they will remove the honey from the combs, but does it not cost them as much as the combs are worth? Do the bees get any benefit from granulated honey? WALTON.

ANSWER.—There is generally more or less of the honey that is liquid, and very likely this pays the bees well for the labor of getting it. It is also possible that they liquefy some of the solid part. Certainly, however, they throw out some of the solid grains. It might pay to have some arrangement like setting the hive in a shallow box, so that the granules they throw out might be saved and melted.

Italianizing Later.

I have a large colony of black and hybrid bees in a dove-tail hive. There are two small apiaries each within a mile of me, of the same kind of bees. Now, I would like to know whether to introduce an Italian queen now, before the honey harvest, or wait until afterwards? In the first case laying would be stopt for a short time; in the second case, if a swarm came out I should have to buy two queens. Would it pay to Italianize at all, being located so near black bees? MINNESOTA.

ANSWER.—Most surely I should Italianize. At the distance of a mile you may do very well, and even if you cannot keep the stock pure—very likely you can't—you will gain by the change of blood. Likely you will do well to Italianize at or near the close of the harvest. Not so much harm will come then from failure in introducing, and queens cost less at that time than now.

Bees Dying in One Colony.

What is the cause of bees' wings turning a light-brown color and withering, and in a short time they die? Can any thing be done for them? Since about the middle of February there has been about a foot of water in the root-house where I wintered them. But I hardly think that can be the reason, as of the 10 colonies only one of them is affected in this way, all the rest being in a strong, healthy condition. WISCONSIN.

ANSWER.—I don't know. "Wings turning a light-brown color and withering up" beats me, and I'll be glad if any one will help out. Wish I could see them. It is just possible it is a case of diarrhea, for sometimes in a bad case the wings get daubed. If that is the cause they will come out all right of themselves with this warmer weather, unless already too much depleted.

Effect of Honey as a Food.

I would like to propound this: In what way does honey act on the system as food? If it is to be considered as a food it must be reckoned among, or one, of the carbonaceous foods. I have also read that it is heat-giving. One author says that honey undergoes no process of digestion in the animal system, but enters the circulation at once, and enters the process of disintegration and the formation of lactic acid, and at the same time giving rise to heat, and so in this manner the heat

is produced; certainly a very valuable acquisition, and so the means for curing so-called colds are acquired. Now, if such is the case, it should follow that it is also a preventive to catching colds, and I hold a very strong opinion that it does do the latter, and to this latter I can ascribe the power of the virtues of honey. I have ample experience with it. I call honey a prophylactic, to that extent.

Also, I have read that it is a fat-forming element. If this is true, it cannot be correct as to the lactic-acid theory. This would be a very interesting question for the scientific doctors to elucidate.

It is also said that cane-sugar entering the animal system has to undergo a digestion process, the conversion into glucose, chemically the equal to honey in its nature. It is claimed quite commonly that cane-sugar produces fat in the animal system. If this is so, then the honey forming a fat cannot be a paradox. I am inclined to the theory that neither cane-sugar nor honey are fat-producing elements. ONTARIO.

ANSWER.—Yes, honey contains carbon, and like all carbonaceous foods, it is heat-producing. It is also true that it is a fattener, which does not conflict with the fact that lactic acid may be produced from it. Honey is much used, singly or combined, in the treatment of coughs, but I wouldn't like to place too much dependence upon it as a prophylactic. If you take the necessary steps to catch cold, such as sitting in a cold draft, getting the feet wet, etc., a previous feed of honey will hardly excuse you from the penalty.

Plan to Build Up and Prevent Swarming.

I have two colonies that are pretty strong, and five that are weak. I propose to take most of the sealed brood from the two weakest and distribute among the other three weak ones, and continue that until near the harvest-time. In the meantime give to the two strong and three that I am building up, a case of half-depth or extracting-combs, on top, to give the bees a chance to deposit any surplus they may get, so they may have every chance to fill up the brood-chamber, which is an 8-frame dovetail.

At about the commencement of the harvest I will put a super of sections on top of a queen-excluding honey-board under the extracting-combs, and take the extracting-combs off when the bees get to work in the sections. At the same time of putting on supers, I will also put a half-story of extracting-combs with full foundation sheets under the brood-chamber, to try to prevent swarming, after Simmins' plan.

1. What do you think of my plan?
2. Do you think I will need to use the queen-excluder?
3. If the plan does not please you, will you give your plan under the circumstances?

ANSWERS.—1. Not bad.
2. I don't believe you will.
3. Taking from the two weakest to give to the other three weak ones is good, unless indeed the best two have room for more brood. At any rate take from the weakest and give to the strongest till the strongest are full of brood, then these strongest and the weakest can both be drawn from to make the next strongest full. In this way you'll not need to put on extracting-supers before harvest, and may have a larger number strong. But don't take brood from a strong colony till it is crowded, or at least full. I've some doubt whether you'll like the frames of foundation under in harvest. Try only part that way.

Using Hives Where Bees Died—Painting Hives.

Last winter three of my colonies of bees died, and when I examined the hives I could find no queens or queen-cells in any of them.

1. What is best to be done with the honey that was left? Can I put new swarms into the hives just as they are? (I took out all the dead bees that were in the combs.)
2. Does it make any difference to have a hive with seven frames or more?
3. What color is best to paint a hive? Is there any objection to red paint?

ANSWERS.—1. Put swarms in them just as they are, honey and all. But look out that worms don't spoil the combs before swarming-time. If you keep them in a cool cellar the worms will not make much headway. If they are in frame hives, perhaps it may be more profitable to give at least part of the honey to bees in the other hives, for at this time of year they use a big lot of honey in rearing young bees, and may need

more than they have. If it's needed in that way that will be better than to keep it for swarms.

2. Yes, but I'm not entirely certain what the question means. If you mean to ask whether it will be just as well to have only seven frames in a hive, that depends on the size of the hive. In any case you will put in the frames at regular distance so they will be $1\frac{3}{8}$ or $1\frac{1}{2}$ inches from center to center. If that isn't what you mean, please ask again.

3. If the hive is to stand out in the sun, nothing is better than white. In the shade it doesn't matter particularly what color, and red is all right. But I'd rather not have the body of a hive painted, only the cover. G. M. Doolittle says he wouldn't let you paint his hives if you paid him a dollar apiece for the privilege.

The Kind of Hive.

What kind of hives do you prefer? I am a beginner.

OHIO.

ANSWER.—It doesn't make very much difference to the bees what kind of a hive you have, the old-fashioned straw skep being as good as any, and there are different hives that might suit you equally well, but in beginning it's just as well and better to have something that's standard, and that is always kept in stock. That makes it an easy thing to get more of the same kind at any time, also to get any parts you want, and being made in large numbers they cost less. Perhaps nothing comes so near a standard article in the way of hives as the dovetailed with frames $17\frac{3}{8} \times 9\frac{1}{8}$. It doesn't matter so much whether you have an 8-frame or a 10-frame hive; so long as the frame is standard size you can easily change from one size of hive to another.

Laying Two or More Eggs in a Cell.

The latter part of February, when examining my hives, in one I found no sign of a queen, but I knew I had seen one late last fall, so I closed it up snug on five frames. About three weeks later I found in the same hive a nice yellow queen, but no brood, so I closed it up again. Yesterday I found a little brood (about two inches) and a circle of eggs about three days old—a circle about three or four inches in diameter—but the eggs were doubled up, as it were, from one to three in a cell. Having seen nothing in the text-books to apply to such a case, except a laying worker, I ask if you think it will be all right? If so, what is the cause? OREGON.

ANSWER.—The probability is that all is well. The queen is likely a good one, and ready to do all the laying required of her and a little more. The space kept warm enough for brood-rearing is so small that she is obliged to repeat, laying in cells already occupied.

Bees Vary in Working.—The different reports as to this or that flower as a honey-plant are sometimes confusing. One man reports that bees work busily upon a certain flower; another says it is worthless as a honey-plant. Both are honest. A difference in soil or growth may be the explanation, but more likely it arises from the fact that in one case the bees had something better to work on, and in the other case not. An article in Australian Bee-Bulletin quoted from Agricultural Gazette, gives the following striking illustration:

"Some years ago, at Cooma, in a dry season, a bed of turnips ran to flower. They were sown on a sandy, thirsty soil. For three or four days they were besieged by bees. Almost suddenly the bees ceased to visit the turnip-blooms, altho they were still expanding. The cause of their forsaking the turnips became evident. About one-third of a mile away, on the banks of a creek, a small paddock of lucerne had flowered, and the bees were bestowing their attention on it, because it was yielding a greater supply of food. Their harvest from the lucerne lasted but a day or so. The scythe stopped the honey-flow, and the bees returned to the turnips. Was it the dark-blue flower of the lucerne that caused the bees to forsake the creamy-yellow flower of the turnip, or the superior quantity of honey contained in the lucerne? Undoubtedly the latter."

Putting Bees Out in Spring.—A. Bridge, in Canadian Bee Journal, objects to the plan of putting bees out of the cellar part at a time. He says the first lot will take a cleaving flight, mark their location, and then they are ready for robbing those set out later. Since adopting the plan of putting all out at once, he has no trouble with robbing.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

MAY 5, 1898.

NO. 18.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Thos. McDonald Relief Fund.—Mr. C. P. Dadant, whom we selected on page 248 as the receiver of contributions for Mr. Thos. McDonald—the unfortunate Shawneetown bee-keeper—reports the following names and amounts so far:

| | | | |
|------------------------|--------|---------------------|--------|
| Hon. Eugene Secor..... | \$5.00 | A. Y. Baldwin..... | \$1.00 |
| Todd & Arnold..... | 1.50 | H. W. McComb..... | 1.00 |
| A. H. Kemman..... | 1.00 | H. Lathrop..... | 1.00 |
| George W. York..... | 1.00 | G. W. Bistline..... | .50 |

Chas. Dadant & Son's contribution was \$10. We hope that others will yet send in what they can to C. P. Dadant, Hamilton, Ill., and thus help Mr. McDonald get started again in the bee-business.

Sweet Clover.—By thorough experiment it has been proven that sweet clover grows luxuriantly in places where few or no other plants flourish. Being a legume, it fixes atmospheric nitrogen and stores it, occupies lands that have become unfitted for growth of other plants, and thus ranks as a useful plant capable of increasing the fertility of land. "The plant is the farmer's friend, to be utilized and not outlawed," says the bulletin issued by the Ohio Experiment Station. Stock will thrive upon it if confined to it until accustomed to it. This last statement is one that Prof. Cook might do well to accede to, or else clearly prove its general falsity.

Langstroth Monument Committee.—On page 249 we suggested a committee to take in hand the raising of the Langstroth Monument Fund. But Mr. Doolittle offers the following in regard to himself:

DEAR BROTHER YORK:—I have just noticed what you say on page 249, about Doolittle being one of the proposed

"Langstroth Monument Committee." Now, please don't, for Doolittle is so overworked with what he has to do now that he hardly finds time to sleep, and this thing has got to stop somewhere, or Doolittle soon passes to the "beyond." I am up in the morning at 5 o'clock, and on a continuous "jump" from then till 10 or 10:30 at night, without accomplishing all that should be done, then. I tried hard to get out of writing for the bee-papers last year, but you all said *no*, so I finally concluded to keep on for another year, as it was thought no one could take my place in this writing matter. But some one *can* take my place on that committee from this State, as we have very many admirers of Father Langstroth here. Allow me to suggest that the name of P. H. Elwood take my place. Not but what we have others equally good, but he is probably the best known of York State bee-keepers, having been President of the North American Bee-Keepers' Association, and held many other important offices among our bee-keepers.

Very truly yours,

G. M. DOOLITTLE.

Mr. Doolittle's letter is all right, and so is his suggestion of Mr. Elwood. It will be remembered that we simply suggested five names as the committee, believing that the five named would make a good committee, and they would. No doubt the other four would serve, and with Mr. Elwood to help for the East would be all right so far as we are concerned. But don't forget that *we* are not *running* the thing at all—only trying to help a little. If the committee we offered meets the approval of the rest of the bee-keepers, well and good. If not, then it is all right, too.

But we think something definite ought to be done soon, so that by fall the monument can be erected and paid for.

The Prospects for the Season must be good among bee-keepers in general, for supply manufacturers complain of being behind orders in spite of running over time. But J. H. Martin says in *Gleanings*: "Southern California is strictly in it for a short crop of honey again. Ventura county, where the best quality of honey is produced, is as dry as a bone. . . . You Eastern honey-producers will not have the California crop to compete with you the coming year."

Disappointed Bee-Keepers will be in abundance a little later on, if the honey season should be a good one. Already some bee-supply factories have been running day and night for a month or two, and are still behind in their orders. It seems to us it would be well for those wanting supplies to send in their orders *at once*, so that any delay in filling may not affect them. Also, when possible, give your dealer a chance to substitute other goods if they can be used, in case he is out of the particular kind really desired. Often by so doing your order can be filled sooner.

But above all things don't get impatient and try to blow your dealer sky-high when he is doing his level best to serve you and many others who are equally deserving and anxious to get supplies. When the rush is on don't add to his worries by dumping on him an over-supply of boiled-down wrath. Keep cool yourself, and thus if possible try to help your dealer in his nerve-straining efforts.

Cost of Apiarian Improvements.—On page 225, Mr. F. L. Thompson had a criticism on the no-drip shipping-cases and some other recent improvements in bee-appliances. In *Gleanings* for April 15, Editor Root replies to Mr. T.'s criticism in the following manner:

F. L. Thompson, in the American Bee Journal, thinks the price of honey does not bear a just proportion to the price of supplies; and then he goes on to give the cost of the fence and plain sections. In regard to shipping-cases, while he does not condemn the no-drip style, he would like to have something simpler, something that requires less labor to fix up. I grant that there seems to be much of truth in this. But let us look into the matter from another standpoint.

Altho we may not at present seem to be doing it, we are striving to save in every way possible that one big item he refers to—labor—on the part of the *bee keeper*, and cost of sup-

plies. Regarding this, compare prices of a few years ago with those of to-day; sections especially have fallen. If plain sections ever get to be popular, it ought to be patent to any man who "can see through a ladder," that they can be made cheaper, and will consequently be sold for less money than the old-style sections *using more timber, and requiring more labor to make them.* Plain sections, of course, cost a little more than they will in the future, because this is really their first year in the market; *i. e.*, they have been pushed into prominence. It is hardly fair to compare the cost of these things with that of other separators and other sections that have met the competition of the markets for years.

Why, we are working as fast as we can to avoid the expense of the extra amount of lumber; and, moreover, we hope these new fads are going to *save labor.* The old fads have done so, otherwise they would not be in the market to-day. Mr. Thompson would not avoid improvements simply because they cost money at first. Smokers, foundation, and extractors, for instance, were costly improvements.

Honey-Mead, Metheglin, Etc.—It seems that a subscriber to *Gleanings* decided to stop taking that paper because it refused "to print a recipe for making mead or metheglin (intoxicating drinks) of honey." After giving his idea of such things, Mr. A. I. Root said:

"I should not be very much surprised if all the other *good* bee-papers would take the stand that *Gleanings* does. How is it, 'brother editors?'"

Well, we can only speak for this editor and this paper, and we can't imagine how any one could get us to so far forget that we had a conscience as to print a recipe of the kind referred to. Not much. There is too much of using brandy in sauces and pies even, and thus begin to cultivate a taste for something stronger in the children and young people of our land. Why any one with any kind of a head on him should want to so debase honey as to make it into mead and metheglin, we can't understand, especially in these days when there should be great alarm taken at the way strong drink is destroying our people.

We are not personally acquainted with an editor of a bee-paper that we think would print a recipe for making mead or metheglin. What decent man would want to be guilty of teaching people how to gamble? And strong drinking is worse.

A Course in Bee-Keeping.—American bee-keepers are given to pluming themselves upon their advancement and the enterprise of their government as compared with others. That this pride is not always well founded may be seen by the following notice of a German enterprise:

COURSE IN BEE-KEEPING IN OSSMANNSTEDT.—This year, as yearly, Pastor Gerstung will give a course in advanced bee-keeping at his apiary at Ossmannstedt, at Whitsuntide (May 31 to June 4). No charge for attendance, the only expense being for board and lodging. Those of limited means are informed that so far the government has always willingly afforded all necessary support to those who have made application for it. Apply direct to Pastor Gerstung, Ossmannstedt, Thurlingen.

Ginger Honey-Cookies are made as follows, according to a writer in *Gleanings*:

One cup granulated sugar; 2 cups honey; $\frac{4}{5}$ cup shortening; $1\frac{1}{2}$ cups sour milk; 1 tablespoonful of soda; 1 tablespoonful of ginger; 1 teaspoonful of salt, and enough flour to roll out good. Put the sugar, honey, and shortening on the stove and stir till all is melted together; then take off and add milk and all the other ingredients. A. C. L.

We would like to invite our readers to send in any good, new recipes that call for honey among the ingredients used. Bee-keepers' families might well use more honey in place of buying less-wholesome sugars.

Every Present Subscriber of the *Bee Journal* should be an agent for it, and get all others possible to subscribe for it.

PROF. LEUCKART, whom the older readers will remember as the able German scientist who helped to establish the Dzierzon theory, died in January, aged 74.—*Gleanings*.

MR. E. T. FLANAGAN, the veteran migratory specialist of the Mississippi valley, is at it again. This time Mr. F. has gone with 300 colonies nearly to the Rio Grande, in southern Texas, a move of about 1,400 miles from his southern Illinois home.—*American Bee-Keeper*.

HON. GEO. E. HILTON'S MOTHER died April 19. Had she lived a few days longer she would have been 72 years old. She was the mother of 10 children, 9 of whom are living. Her five sons acted as pallbearers. George E. Hilton is the well-known Michigan bee-keeper and supply dealer, also postmaster at his place in Newaygo county.

MR. G. M. DOOLITTLE'S writings show conclusively that he is not "carried away" with the plain section, as some others of the fraternity seem to be. A four-piece nailed section is still used in his apiary; yet we do not know of another man in the United States who makes a small apiary pay as big as does Mr. D.—*American Bee-Keeper*.

REV. H. ROHRS, of Rock Co., Wis., called on us last week. Owing to his time being limited, his stay was very short. Mr. R. is a great reader of the German literature on bee-keeping, and is much interested in the controversies that arise concerning bees across the water. He is making a success of bee-keeping, as would naturally be expected of one so interested as he is.

MR. WM. STOLLEY reports in *Busy Bee* that his bees have been trapt and killed by the bushel at a beet-sugar factory, and asks if the Union can help him out. There's probably no help for him with present laws; but if proper efforts were made laws might be secured obliging such bee-traps to screen out the bees. Bee-keepers, however, are very shy about asking any legal protection.—A "Straw" in *Gleanings*.

MR. FRED L. CRAYCRAFT, of Havana, Cuba, we learn, to amid the rumblings of war is still extending his business there by establishing out-apiaries; and that he will extract from over 1,000 colonies next season. Fred L. is one of the American boys who have made a success of bee-keeping, and he knows by years of experience in Cuba just what her capabilities are in the line of honey-production.—*American Bee-Keeper*.

PRICE OF COMB FOUNDATION ADVANCED.—Messrs. Chas. Dadant & Son and The A. I. Root Co. recently advanced their prices of comb foundation 3 cents per pound, on account of the growing scarcity of beeswax. We presume other manufacturers of foundation will also raise their prices. Bee-keepers should always remember that the prices of comb foundation are liable to variation, according to the shortage or abundance of pure beeswax in the market.

MR. ED JOLLEY is one of the jolly kind of bee-keepers. He has often contributed to the columns of the *American Bee Journal*, and also to the *American Bee-Keeper*, in the April number of which he gives this paragraph about "Jacob Vetterstein":

"We have in what is known as the Pennsylvania Dutch settlement an embryo bee-keeper, who gives promise of making a name for himself. According to Mrs. Vetterstein, the boy's mother, 'Shakey has two leddle pokes of pees, and he make honey more as a horse could haul. Shakey,' she says, 'is a smart poy and he learns about pees like nottings. Mr. Kohlmeier, who knows efrydings apout pees, tolt Shakey of somedimes he dond know nottings apout pees, to come ofer and he vill told id to him.'"

We hope "Shakey" will found out somedings alretty, mebbe, ven he talks mit Ifans Kohlmeier apout doza pees und der honig.

Mailing Queen-Bees to England has not been allowed for years. Now the embargo is taken off, allowing the transit of queens to and from the British Isles.—Gleanings, page 311.

Plenty of Alighting-Room in front of a hive is supposed to aid in the matter of white combs, for if the bees drop on the ground in front, their dirty feet soil the combs.—Gleanings, page 309.

Big Pay for Bee-Work.—Gleanings works out that F. S. Arwine made \$15 per day from his bees in 1888, counting his honey from 184 colonies (16,240 pounds) at 10 cents a pound; \$18 a day for 1889—16,766 pounds from 186 colonies.

Markets for Tall Sections.—Gleanings, page 313, says the tall section may not be suitable for all markets. It has a big demand in parts of York State and in other Eastern States, and is regarded with some favor in California, but Chicago will none of it.

Time and Place for Drawing Out Foundation are: Before or after hottest weather; in an apiary well shaded; by medium rather than strong colonies; at the side of the brood-nest, never in the middle; preferably between two finished combs.—German Journal.

The Advantage of Big Entrances is shown by the fact that the bees are quietly at active work, while colonies with small entrances in hot weather roar like an approaching storm, some of the workers being thus kept from work to ventilate.—W. B. Ranson, Gleanings, page 308.

Tall Sections as made by the A. I. Root Co., are $3\frac{3}{4} \times 5 \times 1\frac{1}{4}$. O. P. Hyde & Son say, in Southland Queen, they prefer $4\frac{1}{4} \times 5\frac{1}{4} \times 1\frac{1}{4}$. Both are plain sections with fences. Altho the latter do not ship so well, they think the bees will build them out quicker, because more nearly the thickness of natural comb.

Uniting Weak Colonies.—Southland Queen says shaking bees off the combs into one pile will make them unite with little fighting, while they would fight if united on the combs. Cage the best queen, killing the others, shake all the bees into an empty hive, then give them the frames of brood and put the caged queen on top of the frames, the cage having candy in the orthodox way, so the bees will liberate her.

Bi-sulphide of Carbon for Foul Brood.—C. Davenport (Gleanings, page 296), repeats what he has already said in this journal about this cure, and the editor requests that those "given to an experimental turn of mind" whose bees have foul brood should try the bi-sulphide, calling attention to the fact that if successful, it is better than the McEvoy treatment in one respect, for it destroys only the brood, sparing the combs and frames.

Feeding Wax to Bees may be just as successfully done as feeding honey when the bees are in want of wax, says J. E. Crane, in Review, page 113. Scrape some thin shavings from the top of a cake of bright yellow wax, put them over sections the bees are capping, and in a day or two look at the mottled sealing of the sections. But he adds in a postscript, "After some experiments in feeding wax, I prefer to feed it in thin sheets—some call it foundation."

Young or Old Bees for Winter.—While in the opinion of many, late-reared bees form an important factor in wintering, C. Davenport, in Gleanings, thinks the age of the bees has little to do with the matter. In 1896 honey-gathering stopt with white clover, brood-rearing stopt early, and the following winter he lost only three out of 244. In 1894 a fall flow kept up breeding late, and the loss in winter was heavy, but he attributes it mostly to the character of the late honey. After all, it will be hard to convince many that young bees are not better. Even if 244 colonies came through with no loss

of a single colony, is it not likely that there was a greater loss in bees than if the bees had been younger?

Foul Brood and Foundation—As bearing upon the question whether there is danger from using in foundation wax from an infected colony, the Ontario Experimental Station made some experiments. Foul brood germs were incorporated with wax which was barely melted and at once cooled. Foundation thus made was given in full sheets to six colonies, but no sign of the disease followed. According to that there is little to fear from foundation.

To Prevent Brood in Supers, M. l'abbe Pincot says all that is necessary, is to place the supers so the sections shall run crosswise, whereas if the sections run in the same direction as the brood-frames, the queen will go up and lay. M. Ch. Legrain replies that he placed sections running crosswise and had brood galore. Dr. C. C. Miller replies to the other part of the contention by saying that his sections run in the same direction as the brood-frames, and he had only two sections with brood out of 18,000.—L'Apiculteur.

To Stop Robbing, F. Chatelain says, in L'Abeille et sa Culture, he finds out from which hive or hives the robbers come, then proceeds as follows: Take a well-loaded smoker, and smoke the robbers; after two or three minutes close the entrance. When the robbers that were outside have gathered in numbers at the entrance, smoke them away and make an opening large enough to introduce the nozzle of the smoker, and give them another dose inside. Open wide the entrance and allow all outsiders to enter, then smoke heavily till the bees rush in a stream out of the hive. That ends the robbing.

Ripening of Honey.—O. O. Poppleton had exceptional opportunity while in Cuba, as he relates in Gleanings, to determine the rate of evaporation of newly-gathered honey in the hives. The shrinkage from first-gathered to well-ripened honey was about one-fourth, and that shrinkage took place almost wholly during the first night, only one-tenth of the entire shrinkage taking place after that time. So he thinks it a mistaken notion that there is any material gain in any way by extracting honey before it is ripe. He also found that the bees gathered just as much honey when they had 50 pounds in the hive as when they had only five, so there was just room enough to store what they gathered.

Management with Empty Combs.—A man has a number of colonies and two-thirds as many combs as those that are occupied. He asks G. M. Doolittle (Gleanings, page 304) how to manage for best results, his principal trouble being swarming during the honey-flow. He is told to have laying queens ready in advance in nuclei. When a colony is about ready to swarm, set in its place a hive with eight empty combs, and brush all the bees into it, giving it the supers. Then move another strong colony to a new location, set in its place the hive of brood-combs and brood without bees, and give it a frame with queen and adhering bees from a nucleus. Do this at a time when the most bees are flying, and the returning bees will stock it. Thus you'll have three colonies from two, and in good shape for work.

Tests of Foundation are reported by R. L. Taylor, in Review. Drawn foundation was promptly undertaken at once, and it appeared it would be first finished, but on the contrary, at the end of the honey-flow (which was poor) a drawn-foundation section in the center of the case weighed only 70 per cent. as much as one of plain foundation beside it. If this was because the bees did not like the foundation and only used it until something better could be made ready, it condemns drawn-foundation. But he thinks it might be because the cells were promptly filled with thin honey which took a long time to be evaporated, in which case there would be no trouble if there were a whole super full of drawn-foundation instead of only six sections. He seems to think it is hardly a fair test to try a very few sections of drawn-foundation with others.

Dr. Beal, of the Michigan Agricultural College, measured the bases after they were worked out by the bees. The base of natural comb that seemed to be of about usual thickness measured about .007 of an inch. The others averaged about 11 per cent. less, all but the drawn-foundation, which was 37 per cent. thicker than the natural. The no-wall foundation was the thinnest of all, averaging .00433. It will be of interest to know how this will compare with the foundation the A. I. Root Co. are now making, whose base measures only .003 of an inch!

GENERAL ITEMS

Small Fruits in Bloom, Etc.

Everything favors a good flow of nectar this season. Apples, peaches, pears and cherries are in full bloom. This is a poor place to keep bees, as the honey-flow ceases on or about the first of June—five weeks ends the season for salable honey. One year ago frost killed all of the flowers, and I did not get one salable section of honey. I have been feeding heavily. Bees are in fine condition. Last fall, in looking them over, I found three queenless colonies. I sent for three queens, and they are as fine as can be. I have 27 colonies.

"New Jersey" wanted to know where his bees collected that pollen so early in the spring. It was from tag-alder and a little from willow. J. H. ALLEN.

Nansemond Co., Va., April 11.

I winter my bees out-doors, packed in chaff and sawdust. My bees are Italians, of the yellow kind. I clip the queens, so none go to the woods. I have taken the American Bee Journal about 20 years, and from it I have learned to make bee-keeping pay. Ashtabula Co., Ohio. L. D. ORMSBY.

Some Experiences with Bees.

Last summer I had a colony of bees that work in the sections for awhile and finally slacked up. At this time it seemed that there might be robbery connected with this colony, as the ground in front of the hive was black with dead bees. I saw the bees were fighting as if robbers were about. Then taking my coffee-pot smoker, I gave them a good smoke and left them. On returning the next day I found the same condition of things. I smoked them again, and this not helping matters, I determined to open the hive below. On lifting the super, which was about half full, and taking out the brood-frames, I found that they had the hive nearly full of honey below. So I took out over half the honey below, filling in with empty frames, and putting on the super again. Now the fighting stopt, and the bees went to work in earnest. It was not long till I raised the super and put on a second. Things went on at a lively rate the rest of the summer. I know nothing else than that the bees were discouraged with the condition of things.

My bees having been in double-walled chaff hives the past winter for nearly four months without a flight, and the snow being deep in the apiary, I concluded to give

them a flight at any rate. My hives face the east, so when the snow was melted enough so that bees would not sink in it and be frozen, and the air was warm enough so they would not chill, I began work. This did not come till about March 4. I began my work after dinner, by taking the hives out and placing them on the snow-drifts, behind the chaff hives, facing the west. Then I scratcht out enough dead bees so the live ones could get out. How they did fly! The whole apiary was in a delightful hum. I lost scarcely any bees that day. Those that lit on the snow would rest and then take to wing again. From this time on the queens and bees went to work. So as to keep the bees warmed up I soon took out one wall on the east side of the chaff hive—I put from 6 to 8 hives in one long chaff box—so the morning sun could warm them on fine days. This spring, so far, my bees are ahead of anything I ever had before. Remember, after I removed one wall there were two left—the hive itself and one wall of the chaff box.

March 14 I began to feed chop to my bees—ground corn and oats. I called just one man in to see them work on the chop. He said it beat anything he ever saw. This affords a good supply of pollen for beginning brood-rearing. I think this may be given as soon as they will work on it.

This is the second year that I am feeding ground corn and oats. Fresh chop should be given every day. Those who are curious to know something about this should try it as soon as they read this if pollen is needed. I had honey beside one box of chop one day, but the bees did not touch it. So I took it away. D. J. BLOCHER, Stephenson Co., Ill., March 25.

Wintered Well.

Bees have wintered well, and we have 300 strong colonies to begin the season with. We are in hopes to have a good season. F. A. LOCKHART, Warren Co., N. Y., April 3.

Have Wintered Well.

Bees wintered finely here. I put 83 colonies into winter quarters, and all have come through in fine condition so far, and the prospect for a honey crop is good. A. W. SWAN, Nemaha Co., Kan., April 7.

Five-Banders Winter Well.

My bees have wintered splendidly, and are in the best condition that I have ever had them at this time of the year. Tell some of the brethren to stand aside a little, as I might step on their toes in regard to the 5-banded Italians not wintering well. I had 73 colonies of the 5-banded, and 2 of the 3-banded Italians, wintered on the summer stands in single-walled hives, and lost only one colony, so I don't think 5-bands or 3-bands, or no bands, have much to do with the wintering problem. W. S. FEEBACK, Nicholas Co., Ky., March 31.

Cutting Alfalfa for Honey.

On page 97, I understood Prof. Cook to say that alfalfa is better for hay when cut just before it blooms. This is a sad mistake for both the stock and bee-men. Many have had the sad experience of dragging out a lot of their finest steers, killed by bloat, or a lot of washy hay by starting the mower too soon, and attempting to use it at the stage referred to by Prof. Cook. About 20,000 head of mountain steers are brought down from the mountains to feed on the alfalfa hay put up in the valley each fall and shipped during the winter and spring. We also ship out 15 to 25 carloads of honey annually. I believe every one of our stockmen—and I know all of our bee-men—will agree that the experiment stations were correct in their statements when they tested the question referred to by weighing three different lots of steers and cutting

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

As we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all apiarian supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellence. Polish, snowy-white sections, beautiful straw-colored transparent Foundation, improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking. Address, **Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

WHY NOT ASK YOUR NEIGHBOR BEE-KEEPER To Subscribe for the American Bee Journal?

BEE-KEEPERS! Let me send you my 64-page Catalog for 1898

J. M. Jenkins, Wetumpka, Ala.

Please mention Bee Journal when writing

alfalfa hay at three different stages, the first stage hay when in bloom, second a week later, and thirdly after the bloom had dropt and the seed nearly ripe. The first mowing was eaten greedily, but was too washy to fatten satisfactorily; the last mowing was too ripe and woody, while the middle stage was far ahead of either of the others, and was entirely satisfactory, thus establishing the fact that the All-wise Creator intended that the bees should get the benefit of almost the entire bloom before it is cut or pastured, and has attacht a penalty to those who violate His laws.

My neighbor tried violating this divine law by turning a fine bunch of three-year-old steers on his alfalfa before the bees got their share, and in less than half a day 16 of them were dead from bloat, and many more were only saved by sticking, to let the gas escape. Since then 360 colonies of bees feast on the bloom of his alfalfa before the mower or the cattle touch it.

Maricopa Co., Ariz. B. A. HODSELL.

All Wintered Well.

I took my 30 colonies out of the cellar April 2, after a confinement of just four months and five days. All are in fine condition, and not a colony perisht. I left 11 colonies on the summer stands, and 10 of them are all right. A. F. FOOTE.
Mitchell Co., Iowa, April 5.

Bees Wintered Nicely.

Our bees wintered nicely, and are in fine condition. I wintered 150 colonies in single-walled hives without any loss. A part of them were packt on the north and west sides of the hive, but those that I did not pack seemed to get through best. I am more than ever convinced that the principal thing in wintering is not outside protection so much as plenty of good, sealed honey; and that bees fed sugar syrup will winter as well, if not better, than on honey. J. L. GANDY.

Richardson Co., Nebr., April 9.

Bees in Florida and Southern Indiana.

While in Tampa, Fla., this winter I made inquiry to try to find if there were any bee-keepers in that vicinity, but I could hear of none, but suppose there must have been bees not far away for the orange trees were beginning to bloom, and I saw a few bees working on them. I found some Mississippi honey in the stores branded "White Clover," but it wasn't what our clover honey is, by any means.

I found my seven colonies in very fine condition, on my arrival home. I left them on the summer stands well provided with stores, and protected with covering over the frames. It is too early to tell what the white clover will be this season, but if as abundant as last season, I shall reap a bountiful harvest of honey.

The spring in southern Indiana is three weeks in advance. Peach trees are in bloom, and some other kinds of fruit-trees. Fears are entertained that the frosty nights and cold days will kill or injure fruit of all kinds. W. C. R. KEMP.

Orange Co., Ind., April 2.

Bee-Keeping in Virginia.

My apiary is located near the center of the Page Valley on the course of the Shenandoab river. I began bee-keeping in the spring of 1895, by buying two colonies in box-hives. The bees were kept in box-hives until the spring of 1896, as my neighbor bee-keepers told me they were the best hives in use, and they said that the frame hives were not fit to keep bees in. I could not think so, so I visited a bee-keeper who had 20 years experience in the bee-business, and he told me if I wanted to keep bees for profit I should get the frame hives. I bought one of his hives, 12x14 inch brood-chamber, the super 5 inches high, which held six 4-pound frames. I thought that it was the very hive that I wanted, so I made hives and transferred my bees to them. I

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

Illinois—The spring meeting of the Northern Illinois Bee-Keepers' Association will be held at the residence of Alexander Paterson, 5 miles northwest of Rockford, Tuesday, May 17, 1898. All are cordially invited.
B. KENNEDY, Sec., New Milford, Ill.

soon found that they were no better than the box-hives, as the honey was in such a shape that I could not market it. I subscribed for the American Bee Journal, and soon found out the hives that were in use. My neighbor and I sent for a lot of hives and other supplies, and I transferred my bees to the new hives. I now have my bees all in fine condition, waiting for the honey season when it comes in the spring. I will Italianize my whole apiary, as I think the Italian bees are superior to all others.

We have a very good location here for bees. First comes the maple; fruit and willow, which starts brood-rearing; then comes the locust, whitewood, etc., from which we get a fair crop of honey. Then our fall crop comes, the aster and golden-rod, which we generally get a fair crop from. Last season was a poor one, altho I got a fair crop of honey in the forepart of the season, when the drouth set in and I had to buy sugar and feed my bees to keep them alive. C. H. MAY.

Page Co., Va., Feb. 24.

Report for 1897.

I commenced in the spring with 46 colonies, and increased to 101. I sold 50 colonies. I have a neighbor that had 16 bee-trees, and he gave me the bees for cutting the trees. I gave him the honey. So I filled up some of my empty hives, and now have 67 colonies all in good condition. They have been gathering pollen this week from elm in the river-bottom.

Last year I got 3,000 pounds of comb honey, and sold it for 8 and 10 cents. Goliad Co., Tex. W. W. WILLIAMS.

Prospects Not Flattering.

Prospects are not very flattering here for a good honey crop. We have had a very dry winter and spring up to a few days ago. We had a good rain, but it has turned off cool. Flora in this section has been greatly injured by forest fires. Bees wintered in fine condition, and are now very strong and ready for what flow we may have.

The Bee Journal is always prompt, and like a picnic basket—full of good things. Lee Co., Ga., April 6. R. P. JOHNSON.

All Wintered.

Last season was a good year with me, and I had success in wintering, getting my bees all through without losing a single queen in cellar-wintering. I took them out of the cellar March 10, and I have been feeding rye-flour, which I think is a good thing in early spring, before natural pollen can be had; it keeps them from trying to rob, and I think it stimulates brood-rearing. It is surprising to see how much of it they will lug off in a day. The way that I got the bees to work on it was to sprinkle green sawdust over it, which they were to work on. C. W. GERRISH.

Strafford Co., N. H., March 29.

Moth-Trap—A Freeze.

I notice on page 183 a bee-keeper complains of the moth devouring his bees. If he would not leave pieces of combs scattered about, keep his bee-yard nice and clean, and have good, strong colonies, he would not be bothered with moths.

I will give a good plan to catch the moth-millers:

Take a big camp-meeting lamp and set it in a pan 16 or 20 inches across, and three or four inches deep. Set the lamp in the center and pour water in the pan till within an inch of the top, and put in one pint of coal-oil. Set the lamp in the bee-yard at night, and let it burn all night, and you will catch all the moths that come around.

Now, I don't want bee-keepers to think that I sit in the back end of a tin-shop, and want a patent on this moth-trap.

Put one lamp to every 25 colonies. Catch all "toad-frogs" in the bee-yard. Confine them in the garden, and they will catch all of the insects and cut-worms.

On the morning of March 23 a cold North

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

AUGUST WEISS, Hortonville, Wisconsin.

wind came down on us. The mercury was at 80 degrees, and in 15 minutes it fell to 40 degrees, and on the morning of the 24th froze out all of the corn and fruit. Bees were breeding up fine. I saw some chilled brood, and the bees were pulling it out. Texas has a great many slips 'twixt the cup and the lip, and I think this is a big slip.

F. J. R. DAVENPORT,
Ellis Co., Texas, March 20.

Pickled Brood.

My colonies the past year were sorely troubled with "pickled brood." I observed this disease in one or two colonies as early as 1890 and 1891. Then and subsequently it did not spread, and did not prevent the diseased colonies from storing some surplus. In 1897 the case was very different. Two colonies were well-nigh destroyed, while two others were seriously impeded. Only one colony escaped the disease altogether.

I tried various remedies without avail. I went so far in the case of two colonies as to remove with pincers all diseased brood every three days or so. After the removal the combs and bees were generously treated with germ destroyers. The disease continued unabated.

The disease appeared in April or early May, reached its height in June, began to abate in July, and it disappeared in August. It seemed to flourish in cool, cloudy weather. The hot, dry weather apparently killed it.

The two colonies that had the disease the worst were doubled in July, after all the old bees were removed. Later on the old bees were again removed. These old bees were put with a queen into a new hive with foundation. The disease did not show itself in this new hive nor in any swarms from diseased colonies.

ALLEN LATHAM,
Norfolk Co., Mass.

Alsike Clover—A Report.

Bees are in fine condition at present. We are having plenty of rain this spring, which we were badly in need of. The clover looks fine now, and the prospect for a crop from white and Alsike clovers is good, and there is plenty of it around here. Alsike is the clover for low land. I have seen water stand on it for weeks, and it did not injure it in the least. We have tried red clover, but it will not do well on low, wet land, but the Alsike clover will do all right. The right seeds in the right place and both clovers are good.

At present I have 68 colonies in fine condition. That is the most that I have ever started with. Last spring I had 48, and extracted about 5,500 pounds of honey, and had 500 pounds of comb honey besides. If I have such a crop it will pay to keep bees, but we will have to take what we get.

I have a fine locality for bees and honey. We have a fine honey-plant that I call "fireweed." It grows in the pastures; it has blue flowers, and blooms for a long time. It yields honey in abundance, and of fine quality. Sweet clover is started, and bees work on it all the afternoon till night. Hurrah for the American Bee Journal! Long may it live! As long as I keep bees I want the American Bee Journal.

JACOB WIRTH.

Henry Co., Ill., April 11.

Supreme Council of the Royal Arcanum will hold a meeting in Cleveland, Ohio, May 18-25, for which the Nickel Plate Road is authorized to sell tickets at one and one-third fare for the round trip, on certificate plan. Calahan, General Agent, 111 Adams Street. (13)

Bee-keeper's Guide—see page 284.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, April 20.—Fancy white comb honey would bring 11 cents, but there is none here; other good grades of white at 9 to 10c.; dark and amber, 7 to 8c. Extracted, white, 5 to 6c.; ambers, 4½ to 5c.; dark and off grades, 4c., with exception of dark candied and amber grades. This market is bare of comb, and while prices have been low the quantity sold locally has been greater than last season. Beeswax scarce, and sells at 27c. for average lots.
R. A. BURNETT & CO.

Kansas City, April 20.—Fancy white, 9 to 10c.; No. 1, white, 9c.; amber, 8 to 9c. Extracted, white, 5 to 5½c.; amber, 5c.; dark, 3½ to 4c. Beeswax, 20 to 25c.

Comb honey is selling fairly well, but prices are low; considerable shows signs of candying, which makes dealers anxious sellers.
C. C. CLEMONS & CO.

Cincinnati, April 19.—Demand fair for extracted, at 3½ to 6c. according to quality. Demand for comb is slow at 10 to 13c. for best white. Beeswax in good demand at 20 to 25c. for good to choice yellow.
CHAS. F. MUTH & SON.

Boston, April 14.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, 9c. Extracted, white 6 to 7c.; light amber, 5 to 6c. Beeswax is scarce at 26c.

Our market on comb and extracted honey has kept active at old prices, and as a result the stock is well cleaned up. There is very little call for anything but white in this market.
BLAKE, SCOTT & LEE.

Cleveland, April 14.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c.
A. B. WILLIAMS & CO.

San Francisco, April 16.—White comb, 8½ to 10c.; amber, 6½ to 7½c. Extracted, white, 5½c.; light amber, 4½ to 5½c. Beeswax, 24 to 27c.

A ship sailing this week for Hamburg took 376 cases. Sellers are not nearly so numerous as early in the season, and are inclined to be quite exacting at present in the matter of prices. Market is strong for comb and extracted, with supplies of latter light and stocks of comb showing steady decrease. The firmness is based mainly on the poor prospects for coming crop.

Detroit, March 22.—Fancy white is lower and now quoted at 11c. No. 1, 9 to 10c.; fancy dark, 7 to 8c.; No. 1 dark, 6 to 7c. Extracted, white, 5 to 6c.; dark, 4 to 5c. Beeswax in good demand at 26 to 27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season.
M. H. HUNT.

Minneapolis, Mar 18.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½ to 11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½ to 6c.; amber, 5c.; dark, 4 to 4½c.

Outlook for honey much more encouraging.
S. H. HALL & CO.

Indianapolis, March 24.—Fancy white, 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand.
WALTER S. POWDER.

Milwaukee, March 8.—Fancy, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 10 to 10½c.; No. 2, 9 to 10c.; amber and dark, 7 to 8c. Extracted, in barrels, kegs and cans, white, 5 to 6c.; dark, 4½ to 5c. Beeswax, 25 to 27c.

We are able to report an improved demand for fancy honey during the past few days, while the medium grades have also sold better, yet the surest sale is on the best. The supply continues equal to the demand, but the fancy grades are not in as good supply as the low and medium, which goes to prove that the fancy sells best—and the values better.
A. V. BISHOP & CO.

Buffalo, March 11.—There is a good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand.
BATTERSON & CO.

DR. PEIRO,

CENTRAL MUSIC HALL, CHICAGO.

GEO. W. YORK & CO.
118 Michigan st., CHICAGO, ILL.

BUYING DIRECT.—People living in the country or in isolated towns can get the benefit of manufacturers' prices if they so desire. Agents in out-of-town districts do not have as much trade as the factories get, and in order to make a living they must charge a larger margin of profit. In addition to this they do not carry a complete stock of any manufacturers' goods, and having but a few articles to select from, the buyer does not get as well suited. The Frank B. Barkley Manufacturing Co., Old Colony Building, Chicago, Ill., are conducting a mail-order business, and can give the buyer manufacturers' prices on bugles, harness, saddles, bicycles, sewing machines, poultry supplies, or anything else the farmer may want. They have no big reats to pay, for the goods are shipped direct from the manufacturer; they can save you money. They have issued a handsome, illustrated catalog for the benefit of their customers. It will pay you to write for it and get a copy, mentioning that you saw their advertisement in the American Bee Journal.

CHARACTERISTICS OF FOUL BROOD.

Exactly How to Detect It; and Also Exactly How to Get Rid of the Disease.

BY HON. R. L. TAYLOR.

Late Superintendent of Michigan Experiment Apiary.

Where foul brood exists or where its existence is suspected it is of prime importance that one have the ability to distin-

and nose, and giving attention, need be in any doubt in regard to its presence.

The one crucial test is the color and consistency of the dead larvæ affected with the disease before it dries up. At this stage the matter of the dead larvæ is always viscid or ropy like mucus. There is no foul brood without this characteristic, and I may safely say that with this characteristic there is always foul brood. This last statement, however, requires explanation.

In my experience of ten years with the disease I conclude that in a few years it spends its force and loses its vitality in a given locality, while it continues to retain in the matter of the larvæ in a considerable degree the viscid character. In such case there is likely to be found but few affected larvæ in any colony, and with a little experience and care the two conditions are readily distinguished, and in this way: In the weakened stage the dead matter is slightly less viscid, but a better test is that it is *paler in color*. The dead matter in the larvæ affected with this disease in its vigor is of the color of

A Comb Badly Infected with Foul Brood.—From a Photograph by Thos. Wm. Cowan.

guish it with certainty from every other disease or injury. Some degree of practical experience with the disease will alone make one adept in discovering and identifying it, yet its peculiarities are so pronounced that no one having good eyes

coffee when prepared for drinking by the addition of a moderate amount of milk. In the weakened stage of the disease the color is perceptibly lighter. To determine the consistency of the dead matter of larvæ, insert a sliver or a straw into it

and then withdraw it. If the matter pulls out in a string, adhering to the sliver, and is of the coffee-color described, it may be set down that foul brood is certainly present; but if it does not show this decided ropiness it is just as certain that there is no foul brood in that cell.

I just said there is no foul brood without ropiness, but this must not be taken too literally. That was said with reference to the stage during which the matter remains soft. After a few weeks the matter of each dead larvæ dries down and lies spread on the lower side—not the bottom—of the cell, a brownish-black scale of the thickness of a man's thumb-nail. This peculiarity is of great use in making a diagnosis of the disease at some seasons of the year, as in the fall or in the spring, in the combs of a colony which has perished during the winter, as colonies affected with foul brood are very liable to do. Soon after the breeding season is over these scales are about the only evidence of the disease that remains in a strong colony, as the cappings of the diseased cells are apt to be cleared away, but in a weak colony the discolored, defective cappings largely remain. It seems to be beyond the power of the bees to remove these scales, so if foul brood has been present they remain to reveal it if one will take the proper course to discover them. This is best done in this way:

Take the comb by the top-bar and hold it so that a good light falls into the cells at an angle of about 70° or 80° from the top of the comb, while the sight falls upon the cells at an angle of about 45°. The scales if present will be readily discovered lying as already described reaching almost to the margin of the lower side of the cell. I consider this a very sure method of diagnosis, tho in one or two cases I have seen similar scales where the death of the brood resulted from other causes.

Other characteristics of the disease which are useful in aiding in its discovery are the peculiar odor and the appearance of the cappings of diseased cells; such cappings, while they vary in color, are generally darker than those of healthy cells, almost always sunken or flattened, often having irregular perforations of varying sizes, and the comb containing much of the disease presents altogether an unprosperous, sickly appearance. The odor is very unpleasant, and may be described as an "old smell," and is well said to be like that of a poor quality of glue when heated. If a colony is badly diseased the odor is sometimes felt on raising the cover of the hive, and generally on applying the nose to the top of the brood-combs.

If one handles the combs of his bees frequently, and keeps the subject of foul brood on his mind, what I have already said will enable him to discover the disease very soon after its appearance in his apiary, but if brood-combs are handled but little it is quite important, if one would insure himself in some degree against losses from the disease, that a strict watch be kept on the condition, in respect to disease, of all colonies that appear from external indications to be lacking in prosperity, and especially of colonies to which robbers seem to be attracted, for the odor of foul brood has an attraction to bees, seeming to indicate to them that the colony emitting it is about in a condition to permit its being robbed with impunity. And this not because colonies wanting in prosperity are more likely to contract the disease, but because this condition may be the result of disease. If the disease is once discovered to be present, then it would be the part of wisdom to examine each colony carefully under strict regulation against robbing.

The cure of foul brood is difficult only because it is difficult to discover the disease in its incipient stages in every colony, and to determine every colony in which are germs of disease lying dormant ready to develop when favorable conditions are present, it may be after many months. And when the disease is disseminated among the bees in the neighborhood, especially among wild bees, a final cure may be the work of years, but with care, even under the worst circumstances, it may be kept in such subjection that the injury therefrom will not be great, and under favorable circumstances it may be quickly exterminated.

The cure of any particular colony is very simple and certain, the cautions to be observed having to do with preventing the access of bees from healthy colonies to the diseased combs, since such access would almost certainly spread the disease to other colonies. To preclude this danger all the necessary operations must be performed when no bees are flying, or when the pasturage offers so much nectar that there is no disposition to rob. These conditions being secured, take a hive externally as nearly like the one containing the diseased colony as possible, and having moved the hive with the colony to one side, place the new hive furnished with foundation or starters on the old stand, then run the bees into the new hive by shaking or driving. This is all that is necessary for the cure of the colony if nectar is coming in somewhat freely. If nectar

is scarce or absent, absconding must be guarded against and feeding resorted to. Without being certain that it is necessary, I advise feeding scantily for four or five days, and after that as plentifully as desired. From this it will be seen that it is preferable to attend to the cure during a honey-flow.

The plan insisted on by some that the colony be shaken out into still another hive after being allowed to build comb for four days I have proved in a hundred cases without a single failure to be entirely unnecessary.

I wish here to put in a word of caution against the placing of any reliance upon drugs for curing this disease. My earliest experience was with 30 diseased colonies upon which I tried the use of drugs thoroughly. I repeated its use upon other colonies later, sometimes with extreme care, but with entire failure in every case.

Sometimes when the disease is discovered in its early stages there are large amounts of healthy brood in colonies that are to be treated, and the disposal of this is a problem that deserves consideration. Sometimes such colonies cast swarms in the swarming season. In such case I hive the swarm on foundation or on frames with starters, always avoiding combs for that purpose. Then in three weeks I shake out the bees from the old hive according to the directions already given.

Other colonies that are fit to swarm during the swarming season but not disposed to do so I compel to swarm, *i. e.*, I shake out a swarm and then treat both old colonies and swarms as in case the swarms were natural ones. With weaker colonies and at other seasons this course is not always practical. Under such circumstances, if there are several colonies it is sometimes convenient to shake out all but one or two and give all the brood to that one or two, which are to be treated three weeks later. If there is but one colony it may sometimes be desirable to cage the queen for three weeks—but not often—it is generally better to sacrifice the brood and give the colony a new start.

If colonies have become greatly reduced in strength by the disease, as the bees are mostly aged under such circumstances, it is advisable either to unite or destroy them, but in doing this extreme care is necessary to prevent the escape of any of the bees into hives containing healthy colonies.

I have already intimated that the chief difficulty in effecting a final cure is the existence of the disease among neighboring bees, especially among wild bees. The reason of this is that the spread of the disease is owing principally, if not wholly, to the visiting of diseased combs by bees from healthy colonies—or, in other words, by the robbing of diseased colonies, and if there is any other way of contracting the disease it is because there are other ways by which the germs of foul brood may get into hives of healthy bees. If one considers that diseased colonies in the woods or belonging to careless neighbors are sure in time to fall a prey to healthy colonies, the serious nature of the difficulty is readily appreciated. This consideration also indicates the extreme care that should be used to prevent robbing in a locality where the disease is known to exist, as well as the care that must be given to secure from bees the combs and honey taken from diseased colonies. Their immediate and complete destruction by fire would be the safest course for many to pursue, but the honey and wax are sometimes of considerable value, and this extreme course need not be pursued if one is careful and has proper conveniences for disposing of the honey and comb.

When there is but little honey in the combs it is best to boil the combs at once and secure the wax. If there is honey which it is desired to save, first cut out all parts of the comb containing brood and boil or burn them, then extract the honey, which may be used for the table or boiled with one or two parts of water and used as food for the bees. Boil at least 15 minutes. The comb must then be boiled and the wax secured. Or if the honey is only desired to feed the bees, the combs, honey and all may be boiled in just the amount of water necessary and the bee-food and wax secured at the same time, and with less labor and trouble. It is to be borne in mind that all honey from these combs is dangerous for bees unless it is thoroughly boiled.

Not a few, I fear, will exclaim at my intimation a little ago, that foul brood could only come from foul-brood germs, and begin to assert that it can come equally well from brood that has been chilled to death. In Virgil's time swarms of bees were bred from the carcass of an ox; when good Izaak Walton lived the fish called the pike bred from pike-weed; lately chess grew from wheat, and now foul brood grows from something else!

Well, bees, and fish, and chess, have now come to increase normally, and if foul brood has not yet, it very soon will.

No, it is still true that men do not gather grapes of thorns nor figs of thistles.—Bee-Keepers' Review.

Higher or Lower Elevation for an Apiary.

BY PETER J. SCHARTZ.

On page 54, "Maine" asks Dr. Miller if an apiary located on quite an elevation has as good a chance to secure a crop of honey as an apiary not elevated. I say yes, for this is exactly how my apiary is located. My bees are located on the top of a hill, and I, like "Maine," secure good crops of honey, and sometimes more than my neighbor bee-keepers who are located on low ground. I will tell as nearly as I can why I have my bees on high ground.

This hill faces east; directly opposite is another hill facing west; between these two hills is a valley where we keep our stock, and our barns are located there. Our dwelling houses are built on the hill, and more favorably speaking the most of Cook county is on the hill.

I see no difference in the bees, nor do I have any trouble in keeping up the strength of my colonies. In fact, my bees are better on this elevated ground than they would be on lower ground, for the reason that the thermometer will register 20° more in this valley than it will on this elevation, so you see that it is decidedly in favor of the bees.

Bees never fly out on this high ground when it is too cold for them, but if they were below the sun would soon warm them up, and out they come never to return. I tried it once with a single colony, and will never do so again if it can be avoided. What a shame to see the poor bees come out of their hive and scattered everywhere, too much chilled ever to return again. It made me feel as if I could pick up hive, bees and all and carry them up these 17 flights of stairs and set them down alongside their comrades. That settled the experiment for me.

Spring dwindling I know nothing of, nor have I lost more than two colonies in wintering in all these six years. They are always wintered on the summer stands with but scant protection (while the north wind blows them full in the face), and there they are in the spring safe and sound, unless they have walkt off with two (to)human legs under them. Some of the hives have from 12 to 16 Langstroth frames each.

This is my experience, and if "Maine" doubts this, let him or her try low ground with one colony and be convinced.
Cook Co., Ill.

Spreading Foul Brood Among Bees.

BY PROF. A. J. COOK.

Mr. Jas. T. Lisonbee, of Maricopa Co., Ariz., asks me to answer the following question:

"Is there any danger of spreading foul brood by the use of the watering-trough as described on pages 204 and 395 of the American Bee Journal for 1897, which is, in short, a plank with holes bored in it and grooves cut to connect the same? Cheshire speaks of bees carrying the disease on their feet from a diseased colony to a healthy one. If you will answer, you will oblige me and others."
J. T. LISONBEE.

As this is a question of general interest I am glad to reply through the American Bee Journal.

In case of these microbe or germ diseases, there is so much yet to be learned that we may not any of us speak with over-much confidence. Yet no science of to-day is receiving more close attention and hard study than this one of Bacteriology. And we are fast becoming acquainted with facts that bid fair to become of vast practical importance.

It is true that the late Mr. Cheshire believed that foul-brood germs could be and were carried by the bees. If I remember correctly (I have not his work at hand) he also believed that the germs were not carried in honey. Mr. Cheshire did excellent service in his study of foul-brood germs, and discovered important facts, but I think experience and the consensus of opinion among our most intelligent and best informed bee-keepers would not agree with him in either of the above positions. Owing to the minute size of these lowest vegetable or plant germs, it is not easy to demonstrate the facts regarding their life history.

That bees do not carry the disease-germs to flowers, watering-troughs, etc., or that if they do the germs are impotent to develop seems obvious from the fact that the disease spreads so slowly from apiary to apiary and from colony to colony in the same apiary. With a little care on the part of the apiarist, as shown by Hon. R. L. Taylor, of Michigan, foul brood may be kept in certain colonies for days and weeks, and yet no signs of it appear in other colonies close along side. If the bees of the affected colonies carried the germs as they went out to flower or pool, surely the disease would be sown

broadcast, and all the bees in the region would very soon show the malady, and become doomed.

That the germs are in the honey is a generally accepted theory, as no other seems to explain the spread of the disease, as it very often occurs. I think Mr. A. I. Root, if my memory serves me, thinks his bees were inoculated through honey that leaked out at the depot.

It is now known that many microbes are speedily killed by exposure to sunlight, while sunshine is almost immediate death to these minute germs. The germs of consumption or tuberculosis are said to be quickly killed by sunlight, while the full blaze of the sun is immediate death to these terrible microbes. Thus a flood of sunlight, and better, sunshine, is the best disinfectant of a house that harbors a consumptive. Even then if Cheshire was correct in the belief that the germs were carried by the bees, we may have in the sunshine such an effective fungicide or germicide that the germs are killed before they are conducted to the hive and placed in a nidus suitable for their growth, development and multiplication.

The answer, then, which I would give to Mr. Lisonbee, would be that there is little if any danger of foul brood being communicated from a watering-trough visited by bees from a diseased colony. I believe the same would be true regarding transmission of the germs through the visits of the bees to the flowers. I think it is generally conceded that foul-brood germs are not transmitted in wax, and so foundation from comb that has harbored the disease-germs is entirely safe to use.

If the sunlight theory of destruction is true, then probably honey from a foul-broody colony would not be likely to bear the fatal germs. It may be possible that the immersion in the honey would protect against the sunlight, or tend to do so. It is presumable that the visits of robber-bees to diseased colonies, which are from their very depletion through the effect of the microbes specially liable to attack, are generally responsible for the spread of the malady.

I should like very much to hear from Mr. Taylor regarding the spread of the disease. From his long experience and close and most intelligent observation, I think he would be able to give some specially valuable hints.

Los Angeles Co., Calif.

The Bee-Industry in Arizona.

BY B. A. HODSELL.

The name Arizona recalls the many blood-thirsty battles with Apache Indians, the stage-robber, of men dying for want of water, of cactus and barren desert. Of course, when a sensational story is written they must locate it some place, and it appears that Arizona has been imposed upon. It may be of interest to know that the Salt and Gila valleys alone ship 29 carloads of honey to Eastern markets in a single year, besides a large home consumption.

My experience in bee-keeping commenced back in Ohio, 25 years ago, and many were the losses from drouth and cold winters. Here it is pleasant to keep bees. There is scarcely a day that they do not fly. There is no place in the United States that we look on as competitors, except Southern California, of which this is an inland valley. First in season are cottonwood buds, which furnish an abundance of pollen by Feb. 10, followed by agua motas, yielding both pollen and honey. Then come greasewood blossoms and a sea of desert flowers.

Bees commence swarming by March 15. Next comes the honey crop from mesquite, catclaw, ironwood, which extends into the alfalfa season, which begins about April 15, and continues until about Nov. 1.

In the fall bees gather honey from wild poppies, sunflowers and other desert flowers.

The bees here are nearly all hybrids or full Italians. Nearly all of our bee-keepers are members of two associations, through which they buy their supplies and ship their honey in carload lots.

We produce extracted honey almost exclusively. The yield ranges from 50 to 200 pounds per colony a year.

The country is thoroughly watcht for bee-locations, and is generally stocked, averaging about one colony to each acre of alfalfa. In order to secure suitable locations for a number of out-apiaries, I have them scattered 40 miles from home.

In my searches for out-apiaries I found a beautiful valley along the Gila river, near a railroad, surrounded by mesquite and desert flowers in season. Large herds of fat cattle were on the range in midwinter. Several farmers have built an irrigating canal and irrigate about six sections of the very best of valley land.

A quarrel over a drove of hogs arose between those who

had the most means. The time spent at law would have filled the canal with water. Each one declares he will rule or leave, and the result is, no water in the canal.

Well-improved farms are offered for much less than the cost of improvements. With proper care the 7,000 acres might just as well be seeded in alfalfa, which would support 7,000 colonies of bees, and cattle at the rate of two head per acre a year, and as many more on the range. All that is needed is a few farmers with some capital that would get along better together, as the bee-keepers are doing in the valley of the Salt.

Bee-keepers of Arizona are up-to-date and wide awake, using the latest and best hives, extractors and all modern improvements. Last, but not least, they read bee-papers and keep themselves informed. Maricopa Co., Ariz.

Strange Homes Selected by Bees.

BY H. A. FISH.

It is written in bee-books that the honey-bee likes no place for a home that does not smell "clean and sweet." Just fancy a swarm taking possession of an empty fish-barrel, using the bung-hole for an entrance, and doing just as much business as if they were in a fancy hive!

As queer a case as I ever saw was where they pre-empted a pigeon-cote that was made from a "Welcome soap-box." A roof had been put on it, and two entrances cut in the side, and over it there was printed "Welcome." The "soap" part had been obliterated by the use of the saw. Perhaps it was the sign over the door that caused this swarm to take possession of this place. It could not have been the smell of those pigeon-droppings. And as for other visitors, they were *not welcome*, as I can testify. They still live in the old home, and have plenty of ventilation, which may account for their staying. Runaway swarms can't always choose just the best hive.

I bought a Carniolan queen and put her into a nucleus colony, and she was such a prolific queen that in a very short time the hive was full of bees. On opening the hive one afternoon I found no queen, but several queen-cells. I concluded she had gone back to her former home, but a neighbor told me that he had a swarm come into one of the chambers of his home and clustered on the ceiling. I asked him what he did with them, thinking of my dollar queen. He informed me that he just got a wide board and "sputcht" the whole business.

One of my neighbors had a swarm go into one of the flues of his chimney, and he got a man to try to get them out, but he discovered that this particular flue had been stopt up some time, and the bees had to go down the other flue and go through a chink to get into the stopt-up flue. The owner of the house thus discovered *why* that flue would never draw.

Old box-hives left around in the woods often will be taken up by runaway swarms. I have gotten several that way.

I used to hunt wild bees, and often found them in places where I did not expect to. An old bee-hunter up in New Hampshire told me of a swarm he found the past summer in a tree, and it was marked with the name of the man who first found it, altho the date was 18 years ago. One would suppose that these bees had been in there all these years, but probably they had died out several times, tho the first man says those he found were Italians, and the last man says the ones he found were Italians, too. He believes they have lived there all these years.

I think this will do for the present. If some one doesn't try to tell a larger one, I'll tell of some other bee-trees later on.

Plymouth Co., Mass.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

[Continued from page 278.]

BEES LIQUEFYING GRANULATED HONEY.

A question on the best method of feeding outside of the hive was asked, which led to the following remarks:

Mrs. Rhodes—To get the bees to liquefy honey in the hives I set a pan of water with corncobs in it close to the hive. I never see granulated honey on the bottom-board when water is close.

Pres. Aikin—I had thought of feeding very thin honey for this, so as to get it stored over the granulated honey. I suspect the bees often liquefy by bringing water; but we lose a great deal in the granulated honey which is carried away from the hive by the bees.

Mrs. Rhodes—They liquefy as much as they need.

TRAPPING MOTHS—STIMULATIVE FEEDING.

A question was asked about trapping moths, by a bee-keeper who had kept bees many years ago in the East.

Pres. Aikin—I have come across a good many Colorado apiarists who have never seen a wax-moth. There is a grain-moth here. The larva is nearly like that of a codling-moth. It works on pollen or old black combs. It will cut holes in the comb, but not to eat the wax. The real wax-moth of Iowa has a larva several times larger than that of the grain-moth. It has two broods annually, one in April and the other in August. There is also a dark kind in Iowa, smaller and less numerous than the gray species, which works in the same way. The real wax-moths fairly riddle the combs.

Mr. Foster—Strong Italian colonies take care of them.

F. Rauchfuss—Emphasize *Italians*. I have seen strong colonies of black bees, brought here from Arkansas, make no objection to our moths.

QUES.—Will it pay to feed in spring to stimulate?

Pres. Aikin—I have done a big lot of feeding. I don't know whether it pays or not. It does if the colonies are short of stores. A large amount of unsealed honey next the brood has a great influence in building up. But if the bees gather enough from the fields feeding is not necessary.

Mrs. Rhodes—I know feeding pays. One spring we fed several pounds of sugar a week. It proved to be a poor season, but we got 1,000 pounds when our neighbors got nothing. Our bees built up and theirs did not.

Mr. Foster—I use a bottom-board for feeding, which I place on top, with the bee-space strips up. In this is bored a $\frac{1}{2}$ or $\frac{3}{4}$ inch hole, covered with a lath when not in use, and a pint of honey is poured on the board. This is covered with another board. In this way I feed 20 or 30 colonies in a short time.

BEES RENEWING THE COMBS.

F. Rauchfuss—How many have noticed bees renewing their old combs in the middle of summer? [Two.]

Mr. Adams—I have seen this in the spring, but not in summer.

Pres. Aikin—I have seen many colonies renew their brood-combs. The question how long brood-combs can be used is sometimes brought up in the bee-papers. If the writers had observed, they would not have brought it up.

F. Rauchfuss—Have you observed under what conditions it takes place?

Pres. Aikin—No.

F. Rauchfuss—I once noticed a lot of refuse in front of a hive, like the refuse which a mouse makes by gnawing the combs. I inspected, and found the colony queenless. The bees took advantage of a time when there was no brood in the way. Since then I have always noticed this in colonies queenless or made queenless. A neighbor bee-keeper last summer noticed it in six colonies at once, all of which he had de-queened.

Pres. Aikin—So far as I can remember the cases the colonies were always queenless.

F. Rauchfuss—This has never been mentioned in any bee-literature that I know of. We have two writers for the bee-papers present. They ought to bring it up.

WATER-TIGHT HIVE-COVERS—SUPER COVER.

Mr. Varian—What is the simplest way to make hive-covers water-tight. I have used paint, with a painted cotton-cloth over the painted cover.

Mr. Adams—It is not reliable. I am using elaterite—a white cloth filled with a new Utah mineral.

QUES.—What do you use for a blanket in covering supers during the flow?

Mr. Foster—I use nothing but a board.

Mr. Lyon—I like an oil-cloth as well as anything.

Pres. Aikin—How do you keep it down?

Mr. Lyon—That is a bad feature.

Mrs. Rhodes—On extracting-frames we use burlap. When it is raised we run a warm smoothing-iron over it.

Mr. Adams—I use brick to hold the oil-cloth down.

Mr. Lyon—I use several thicknesses of burlap over the oil-cloth. It helps to some extent.

Pres. Aikin—I used much muslin, but the bees stuck in a great deal of propolis. When I came to Colorado I made 20 inner board covers for use with Simplicity covers. On comparing the sections over which they had been used, with the remainder which had been under muslin, my employer had me make inner board covers for all the hives the next season.

Mr. Lyon—I have 100 of those inner covers which are all warped out of shape. Probably they were not properly cleaned. I used them in winter. Perhaps that warped them.

Mr. Elliott—Don't the bees discolor the tops of the sections when there is a bee space above?

Pres. Aikin—A little discoloration does not hurt for ordinary grades of honey. One is almost obliged to have a double cover when the hives stand in the sun.

Mr. Elliott—I used one thickness of muslin. The trouble was the propolis on top of the sections.

Mr. Thompson—Last season I used a good deal of paraffine paper. It was applied strictly according to instructions, with several layers of old newspapers, and thin boards over that. The paper was so well cushioned that no propolis was deposited on the tops of the sections. But thick lines of propolis were deposited on the paper adjoining the junction of the paper and the wood, thus rendering the paper useless after being used twice, once on each side; for I do not know of any practical way of cleaning it off. Then the application and renewal of the paper in a large apiary is extremely wasteful of time. I notice that Mr. Danzenbaker says in Gleanings that nothing but pure wax was deposited on the paper by his bees, which wax was easily removed by scraping with a piece of section. Perhaps the reason is, that his localities are in the South. Another correspondent of Gleanings, who was successful with the paraffine paper, lives in North Carolina. Here in Colorado our nights in the last half of the season are cold. But whatever the reason is, it is certain that propolis, not wax, is deposited here, even when the paper is well cushioned and warm. Because of the expense and the fussiness I do not want to use it again; but the tops of the sections were certainly kept bright and fresh by its use, free from the dinginess that Mr. Elliott refers to.

Pres. Aikin—For a strictly fancy grade it may pay to cover the tops of the sections. But in ordinary grades the customer doesn't care.

F. Rauchfuss—For ordinary dovetailed hives there is no provision made for an inner cover, and it involves some expense to have a proper cover made. With a single cover, even painted white, I have known sections to be melted down. I have not known it to happen when an oil-cloth was under the cover. A single cover alone is sealed tight; a cover with an oil-cloth gets ventilation between.

Pres. Aikin—When a shade-board is used sections under single covers alone do not melt down.

Mr. Lyon—Isn't there quite a difference between a board and a blanket in retaining heat, just at the beginning?

Pres. Aikin—Yes, until the board is sealed all around by the bees. But if there are enough bees to block the entrance they will regulate the heat by stopping the draft.

Mr. Lyon—Do you like a small entrance in the breeding-season?

Pres. Aikin—Yes, when the colonies are weak.

Mr. Lyon—Do you like an oil-cloth in winter?

Pres. Aikin—No. Moisture accumulates. When the temperature is high it doesn't make any difference.

Mr. Lyon—I know a man whose hive-covers were sealed tight. The bottom-boards and the combs were damp and moldy, in just such weather as we are having now (moderate). If the colonies had not been examined they would have been ruined entirely.

Pres. Aikin—I think we lose a great deal by moisture. I have claimed for years that upward ventilation is needed to carry it off. Bees can stand a great deal of cold without

moisture. The majority of those who make a success of cellar-wintering leave off tops or bottoms, or both, or maintain a high degree of temperature. The great trouble of cellar-wintering is diarrhea. Tell me how to prevent diarrhea and I will tell you how to winter bees. Since I came to Colorado I have formed the opinion that moisture is one of the principal factors in causing diarrhea, both directly and also by water condensing in the honey and souring it. Bees dry themselves by licking each other off. Where does that go to, which they thus take up?

F. Rauchfuss—We have had diarrhea in a cellar without moisture. We had two lots of bees in our cellar both alike. One was from the home yard, and the other brought from Harman. Our cellar was very dry. The bees from Harman were pretty nearly gone up in February, and we had to put them out. Those from the home yard, which had been in the lower part of the cellar, usually considered the most disadvantageous place, were all right, and were left in until May. The cause was probably in their food. The Harman bees had only clover honey; the others only alfalfa honey.

Pres. Aikin—Why, you have upset my argument. But I hold that moisture is a large element in causing diarrhea.

F. Rauchfuss—The temperature of the cellar was uniform, not varying more than 5°.

SECOND DAY.

THE RIPENING OF EXTRACTED HONEY.

Mr. Foster—I came from Iowa but two months ago. Most of you have heard of Oliver Foster. He is a brother of mine. I have worked near him for years. To get a good article we let the honey get thoroughly ripened before extracting. From the standpoint of Iowa work, this is when the combs are two-thirds or three-fourths capped.

Mr. Pease—Do you ever ripen honey after extracting?

Mr. Foster—We never thought it necessary.

F. Rauchfuss—We tried ripening extracted honey once because we didn't have the extra combs, and had to extract soon. Otherwise it is not advisable to practice artificial ripening because the bees can ripen honey much cheaper than you can. Last year we had a great many combs, too many in fact, but they come in handy in good seasons. Practically all our crop was stored before extracting commenced.

Mr. Geo. W. Mischke, representing the authorities of the Trans-Mississippi and International Exhibition at Omaha, then addressed the convention. The exhibition will be an assured success, as all other Western States have made appropriations. The Colorado legislature did not make an appropriation, but the matter is left with the County Commissioners of the several counties. A State Commission is responsible for the return of all exhibits of an imperishable nature not donated. The Arkansas valley and Grand Junction districts are taking active measures for exhibits, so that Colorado will have a good exhibit.

All present seemed to be heartily in favor of making an exhibit, providing we get the "wherewith" to do it.

Mr. H. Rauchfuss next read the following paper on

Management of Swarming.

I believe better results can be obtained by preventing swarming than by allowing natural swarming. With the latter management some one has to be with the bees most of the time to hive the swarms. We might use entrance-guards or queen-traps; but they do not work as well as one might think, especially in a large yard. To make bee-keeping on a large scale profitable, one has to handle bees in more than one yard with little or no help. Without some sure way to prevent swarming it cannot be profitably done in this location at the present low prices of honey.

I have practiced different methods. One was to introduce young laying queens before swarming-time. This was a success in preventing swarming and securing a surplus. I treated 45 colonies in that way. None swarmed that season. But it is too expensive to produce good laying queens before swarming in this locality.

Another plan was to give plenty of room and ventilation. Before the bees started queen-cells I gave them a brood-chamber with starters below their brood, then an extra super on top with a queen-excluder between, then raised the hive one inch from the bottom-board in front. This experiment was a failure. Most of the colonies swarmed before filling the extracting super, and with very little comb built below the brood-chamber. This proved to me that room had very little to do with swarming. I have seen many colonies swarm when the outside combs in the brood-chamber were almost empty. I suppose the strain of the bees, the locality and the season have much to do with this.

Dividing or artificial swarming I have practiced for a

number of years. In a prolonged season some of the colonies with the old queens will swarm late. Unqueening I have practiced on a large scale. The queens were removed at the commencement of the honey-flow, and all queen-cells cut out. Nine days after, all queen-cells were removed except one. This stopped all swarming, but many colonies were found queenless at the next inspection, and some colonies did not work satisfactorily as long as they were queenless.

Last year I tried requeening shortly before the honey-flow. I put the queen with two frames of brood above the queen-excluder in an extracting-super filled with empty combs. The vacancy whence I took the two frames was filled with brood and bees of certain other colonies, which were entirely used up for the purpose, so that I decrease the number of colonies 20 per cent. at that time. Nine days after I took the upper story with the old queen to a new stand, then cut out all the queen-cells of the one on the old stand, gave them a virgin queen three to six days old, and put on a super. The object of having the old queen above is to get all the brood in the lower brood-chamber sealed, and have some honey stored where the oldest brood has hatched. This puts the lower part of the hive in a hopelessly queenless condition, without having the colony queenless. To get virgin queens of the proper age, queen-cells have to be started about one week before the old queen is put above, and the ripe cells are put in queen-nurseries to be taken care of by a few colonies until wanted. My queen-nurseries are the size of a Langstroth frame, and will accommodate 34 colonies each. The cages can also be used for introducing-cages.

This management proved the most effective and profitable one I ever tried. Three operations completed the work of requeening. The only attention these colonies required was to supply supers and remove same when finished. It will be seen that by this plan one man can handle several apiaries, as about one inspection every week during the honey-flow should be all that is necessary.

H. RAUCHFUSS.

[Continued next week.]

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Disadvantage of Painting Hives.

What are the disadvantages of painted hives? The advantages are that they look better and last longer. One disadvantage I have seen stated, of white painting, is that they are more attractive to the moth-miller, and I have sometimes painted my hives other colors, but I like no other color as well as white. IOWA.

ANSWER.—Probably the chief disadvantage of paint on hives is that the paint does not allow the prompt drying out of the wood in spring. A large amount of moisture comes from the bees, and if the hive is painted this stays in the walls. It is perhaps best to have the cover painted, but not the body. It is hard to understand why moths should trouble white hives more than others, and if I should paint my hives at all, white would be the color.

Placing Hives—Question About Queen-Breeders.

1. On page 810 (1897) in answering a question concerning spacing hives, you mentioned that your hives were set in pairs; also, that you advised a questioner before to arrange his hives in that way. To the uninitiated it would seem that gaining more space was about the only reason for so doing, but there may be others. Will you give all the points which caused you to arrange in that way, and advised others to follow suit?

2. Queen-breeders, when testing queens, undoubtedly find a goodly number deficient in mating, one way or another. What do they do with those queens? I should like to know, as I am quite suspicious, and inclined to believe that they unload them on the unsophisticated buyer for untested ones. What is your opinion? Don't say "I don't know." CALIFORNIA.

ANSWERS.—1. If I had 10 acres of ground freely at my disposal, I think I would set my hives in pairs, and I think I would advise any one else to do so unless I should find a man that I hated worse than any one I've met yet, and I'd give him the same advice. I may not be able to give fully the reasons why I like the plan, but I suspect I can give enough to satisfy a reasonable man like yourself. In trying to think of an objection, the only one that occurs to me is that you can get at one side of the hive only, but I'm not sure that I care to get at more than one side. Yes, I remember a case in which it was bad to have hives sit so close. One time a

colony was made queenless and broodless (I'm not sure but combless) and in its desperate condition it marched straight out of its own hive into the neighboring one. But in an apiary of 100 colonies I think that would not happen once in 30 years. Now for the advantages:

If I had 10 acres of ground for an apiary, I wouldn't want to spread the bees all over it, for I wouldn't want to travel over so much territory in going from one hive to another. Suppose there are 40 hives in a straight row, 10 feet to each hive, that is, the hives measure 10 feet from center to center. I would move them together in pairs, having the pairs measure 10 feet from center to center, thus occupying just half the ground they did before, and they will be just as safe as they were before, so far as concerns workers or queens getting into the wrong hive. Or, suppose the 40 hives are placed in a row five feet from center to center, I would leave Nos. 1, 3, 5, etc., right where they were, and I'd move Nos. 2, 4, 6, etc., up to them, thus having the same ground occupied as before moving, but there would be only half the danger that any bee would get into the wrong hive.

For bees are familiar with form, and if they're accustomed to go to a certain part of a hive as their entrance, they persistently stick to that part. Try this: This spring cover up or close the entrance to a hive half its width at the right hand side, and after a few weeks open that side and close the left. You'll find that it will trouble the bees no little to find the entrance. They'll persist in trying to get in at the side that was formerly open, and to which they are accustomed. Now, in the eyes of the bees it seems as tho that pair were a single object. They will not make the mistake of going to the right side when they should go to the left. That is, they'll not make the mistake of going into No. 16 instead of No. 15. If they make a mistake at all, it will rather be to go into No. 17 instead of No. 15, for No. 17 is at the same side of the pair as No. 15.

By having hives in pairs you need only half the number of stands. It will take more lumber to make a double stand, but not twice as much, and it will be less than half the trouble to level the stands. For it's easier to level a long stand than a short one.

2. I hinted a little while ago that you were a reasonable man. I take that back. I don't call any man reasonable that will ask a question and then bar out the only answer on hand that will fit. But I will say that an honest man would never sell as an untested queen one that he had learned was mismated. He would sell it for what it was, or keep it himself, or destroy it.

Sour Honey and Moldy Combs.

I had a colony of bees die about March 10. They left about 15 pounds of honey, and some of it that did not get capt over has soured, and some of the combs are moldy in spots. There was not a cell of brood in any of the combs.

1. Would the bees clean the mold and sour honey out of the combs?

2. Would the combs do just as they are to hive new swarms on? If not, why not? MICHIGAN.

ANSWER.—1. Yes, they'll fix them up all right, only don't give one colony too big a job at a time.

2. If they're pretty bad the swarm might desert. But you can let the bees clean them up beforehand, and then they'll be all right for a swarm. One reason against holding them as they are for a swarm is, that they would probably be getting worse all the time.

A Beginner's Laughable Experience in Wintering Bees.

On page 170 you request "Iowa" to report as to how he came out with his top ventilation. Well, I'm "Iowa," and as my church advocates an honest confession, I'll obey and try to give facts as nearly as I can come at them.

First, I'll say we haven't a live bee on the farm. I am a beginner with bees, have made a failure in my first attempt, but I'm in earnest when I say I will try again, for I'm in love with the bee, and think probably the next lot will be carried through the first winter at least. It's an old saying, we never know what a boy will do. And I will add, 'tis also hard to tell what an older person may do when he embarks in the bee-business. And I suppose you will say an old fool is the worst of fools (and I don't care if you do.)

Now, I smelt trouble, hence only one colony would I buy when the fever struck me. My better-half jokes me about so much bee-literature about the house, and not a bee alive on the place. I tell her and the kids that my failure afforded us an early feast of honey, otherwise we would have waited a long time for it.

Now, Doctor, Joe will give you the particulars in full as to that colony of bees, then if you can tell which mistake was the fatal one, I'll treat.

Last fall I gave a neighbor four Bryan dollars for a colony in an old-fashioned box 16x16 inches, and 24 high. I got them home all right and set up in the orchard. Well, I've wintered for 20 years on Webster County prairies, and I know something about the blizzards that this country is subject to. I have seen snow blockades here as early as October 16. I am a farmer, and ever since then I have governed myself as much as possible to be in readiness for winter, and you can judge I had the bees in the cellar in ample time. If it was the first of November, it wasn't any later.

Now, the women-folks objected to having bees put in the cellar, but we finally compromised by my agreeing to put screen over the entrance of the hive. The bottom was nailed tight to the hive. Our cellar has only entrance from the outside.

Well, for a while bees appeared all right, by having the cellar door open through the day time, but finally it failed to quiet them, then I, Bowser-like, was ready to relieve them with a fresh idea I had hit upon. You see, I had my word out with the women that the bees were not to roam about the cellar. So I got a screen and screened in a portico from the alighting-board to the hive; I tore off the screen from the entrance, and let them out in the new portico, just for an airing! Well, of course you know what they did—died as fast as they rolled out—and I soon became convinced that at that rate they would soon be all dead—that something else must be done, and that immediately. So I plugged the holes, then wist I had been raised with the aid of a father, and one that knew something about bees.

Well, the kids were all around me in the cellar—watching "Paw" fix the bees. Then they askt, when I shut the holes, what I was going to do; if the bees wouldn't die if kept in the hive, and all such questions.

Well, I called for a piece of screen, took the nails out of the top board, and removed the same very carefully, and slipt the screen over in its stead. My, Mr. Man, what a commotion there was in that "gum!" Then they got quiet and staid so to their end.

The "gum" was about two-thirds full of comb. Every time old Bowser (that's me) went in the cellar, he had to take a peek in to see how the little ones were. The top of the hive was usually slipt to one side, and a match or two lit to give light to see them. All appeared O. K. until shortly after the time I sent in for advice about getting bees out for the early flow of sap from maple trees, as you remember. Well, from then I noticed they did not gather as high up in the hive as usual, and I thought maybe they went below for warmth. Then I closed the top a little more, but they kept sinking.

Finally one sunshiny day the idea struck me they needed some sunshine. So I slipt them over by the door where the sun shone in about noon, and took off the top of the hive (now laugh, Doctor,) and gave them a sun bath for half an hour. But all for "nix;" they kept going until I soon became aware that Blunkey had monkeyed the bees, and that soon we would have what honey there was. So we did. There was 20 or 25 pounds in the hive, and I know they didn't die for the want of something to eat. My ignorance killed them. But I am considerably wiser.

I will buy three or four colonies in good, respectable hives in the spring, or as soon as they can be had when they are brought out for spring from the best.

I am going to try my best to learn something about bees, for I have a lot of busky big boys, and I am not needed in the fields, except occasionally to look after them. The bees will afford me lots of pleasure, as I believe it's a fine study, and only regret that I lived 47 years before taking a notion to them.

You can well understand why I was experimenting with top ventilation. Doctor, I couldn't get around it, as the bottom had about a dozen 10-penny nails in it.

Now, as I said in the beginning, if you can tell me which move was the fatal one, I'll treat.

I think the Bee Journal is a fine bee-paper, especially for those who know something about bees.

Now, I'll pound around, and eventually may get to know something about bees. Doesn't it beat all bow ignorant some people are, and I one of the worst of the whole crowd? You may tell the readers of the Bee Journal that "Iowa" has satisfied himself that the bottom is the better place to ventilate, and that he will never—no, never—try the top again.

I would be pleased to know why it's best to have bees in darkness when in the cellar. I notice in my second communication, as to diarrhea, you advise the room to be dark when taking bees into the house.

My neighbor, who was seeking advice through me, says his bees are all right now. But say, Doctor, how can he tell?

Well, you must surely have plenty of patience to be doling out advice to such ones as I, and I will say I surely don't envy you your job, no matter what your pay may be.

We are having an unusually early spring. Our wheat was sowed 12 days ago. We will start the seeder on oats in the morning. There is ample moisture to start the crop, but the ground is dry below.

Many thanks for your kind advice. I hope you will lead us for years to come—at least long enough to see BlunkeyJoe get his eyes open on bees. IOWA, March 21.

P. S.—If you want to fan me about my ventilation, you are at liberty to do so.

ANSWER.—Your question as to which was the fatal mistake is too hard for me. I don't know. There were so many of them that you might as well draw cuts to find the fatal one. More likely it was a composite affair, the bees finally laughing themselves to death at the many different changes.

For your guidance in the future, it may be well to note some of the points that would help to bring about the final outcome. Now, I might do some years to cellar bees, but hardly last winter. There was a good chance for them to fly three weeks later, and they had three weeks unnecessary confinement, and long enough confinement without anything else is sure death. All the worse if the weather is warm after they are put in. Supposing they would have barely come through all right by being cellared three weeks later (as mine were,) that extra three weeks' confinement would be enough to kill them.

Screening them in, either with or without the portico, might make all the difference between success and failure. If a bee wants to leave the hive, screening it in will only make it stir up a lot of others, and it would be better to let the one out to die than to have

it die in the hive and a lot more with it. Bees that are all right will stay quietly in the hive without any screening.

In some cases it may do to have light streaming into the cellar, when they are all right otherwise and the temperature right, but generally the admission of light will make them come out of the hive and die. Your cellar had its door open a number of days, and that was probably pretty hard on them. If it's necessary to have the cellar door open, let it be at night.

The frequent disturbance from opening the hive helpt no doubt to shorten life.

Top ventilation may be just as good as any. Given a cellar at proper temperature, about 45°, or at whatever temperature the bees keep perfectly quiet, with air perfectly pure, and it doesn't matter a pin whether the ventilation is bottom, top or side, so there's enough of it.

After all, you didn't come out so badly. You got \$2 worth of honey, making the cost of the bees only \$2, and if you didn't have \$2 worth of fun you don't price fun high enough by the pound.

Questions on Queen-Rearing.

1. Suppose at the height of the season you took away all brood except one frame with the queen, inserting in its place empty combs. Then 48 hours after, take away the remaining frame of brood, queen and all. What kind of queens would you get?

2. Or, suppose you inserted in the middle of, say, six different hives, one empty frame of comb each, and at the end of 48 hours placed them in a populous colony that had been deprived of its queen and brood. NEBRASKA.

ANSWERS.—1. After scratching my head over that question, I'm rather inclined to reply that you'd get just about the same kind of queens you'd get if you took away the queen in the first place, leaving all the brood and bees. One disadvantage would be that it would take three or four days longer. Probably your thought is that you'd be sure of having queens reared from the egg—and so you would. But I don't believe it would be any better, if quite as good, to start with an egg laid to-day, as compared with a larva hatcht out of the egg to-day, and I don't know that a larva just hatcht has any advantage over one three days old, for the best authorities tell us that the food given to the worker-larva during the first three days is just the same as that fed to queen-larva. When a queen is taken away from a colony in the height of the season, there are eggs and larvæ of all ages present. Now, doesn't it look rather reasonable to you that the bees will select what will make the best queens if you leave it entirely to them?

2. In this case you'd have six different kinds of stock to breed from, and it would be a little better to breed from the best stock. Otherwise there would probably be no advantage over the plan first proposed. But there's no law against your trying it.

Transferring Bees—The Albinos.

1. I have a few colonies of bees in nearly as many different varieties of hives, all movable frames except one, which is a box-hive. I wish to transfer them into uniform hives. What I wish to know is, when is the best time to transfer so as to interfere least with brood-rearing and honey-collecting?

2. I intend to transfer by the "Heddon method." Does this method work equally well with movable-frame hives as it does with box-hives?

3. Kindly give a brief account of "Albino" bees and their relative value. AMATEUR.

ANSWERS.—1. The favorite time for transferring early is when fruit-trees are in bloom. But many prefer, especially when the bees are in box-hives, to wait until the bees swarm, then transfer three weeks later.

2. Just as well. But when bees are to be transferred from one frame hive to another, it ought not to be a hard matter—certainly not a hard matter in some cases—just to cut the combs out of one frame and put them into another. It is much easier than transferring from box-hives. In fruit-bloom is a good time for it. If the new frame is larger than the old one, it's easy to fill in a little by cutting up one of the combs for that purpose. If the new frame is smaller, it's easy to cut the comb down to the right size. If the old frame is smaller than the new one, it may work well to leave a top, bottom or end bar of the old frame attacht to the comb so as to make it the right size.

3. An albino bee, like an albino man, is one in which there is a deficiency of coloring-matter, making them lighter colored. The general rule is that an albino of any kind is, to say the least, no stronger for the change. Of late there has been little said about albino bees, and perhaps not a great many think them an improvement.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

MAY 12, 1898.

NO. 19.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Foul Brood.—It is just possible that some may question the wisdom of taking up space to copy the article on foul brood in this number, taken from the Review, and written by Hon. R. L. Taylor. There is nothing strikingly original in the article, and yet it would be difficult to find in the same space anything so instructive and complete that has ever been written upon the subject of foul brood. Some of the readers of these pages may not be interested in foul brood. Their bees are free from the disease, and there is no expectation that they will ever be affected by it. Therefore, there is no need of their reading up foul brood until they have practical need of the knowledge. The bee-keeper who thinks in that way is making a serious mistake. If he has no need of that knowledge now, there is no certainty he may not need it within a twelvemonth. Every bee-keeper should be familiar enough with the matter that he can easily spot the disease on its first appearance. After it has made headway it is a very difficult thing to handle it. Many a case occurs in which the bee-keeper hardly suspects the presence of the disease until one or more colonies are rotten past redemption, and the seeds of foul brood have been planted in every colony in the yard. The proper knowledge in advance might have nipt the thing to the bud.

Let every beginner, especially, not only read but carefully study that part of Mr. Taylor's able article which treats of the detection of the disease.

We wish here to acknowledge our indebtedness to the Review for the use of the splendid illustration on the first page of this number. It has been said by those who have had much experience with the foul brood disease, that they could almost smell its offensive odor by just looking at that "life-like" picture of an infected comb.

Crooked Honey-Dealers.—On page 120 we replied to "A Few Kicks and Growls," one of which referred to the guarded way in which we as publishers point out fraudulent honey-dealers. We replied that on account of certain existing libel laws we had to be careful, and "cannot publish all we would, sometimes." After copying a portion of the editorial in question, Gleanings had this to say in corroboration of our statement:

Mr. York has hit the nail on the head. Unfortunately we as publishers cannot even tell the truth in regard to what is morally certain is truth, unless we can prove the truth by affidavits or other undeniable facts. For instance, I may know positively, in my own mind, that a saloon-keeper is selling liquor illegally; but to prove it would be another thing. I may be pretty well satisfied that a commission-house is tricky and dishonest; but to come out broadly with the statement might render us liable for heavy damages in a libel suit, for the reason that we might not be able to produce the evidence necessary to satisfy the jury or the court before whom the case might be tried. So the next best thing we can do is to "hint at or tell on dishonest commission-men" in a general way. And very often this is all that is necessary. For instance, a snide house may have a very plausible and apparently honest appearance; but a bee-journal can often uncover the swindling schemes they are about to launch forth, i. e., how the wolf has put on sheep's clothing. Whenever the honest (?) old ram comes around, bee-keepers will be able to recognize at once the "true inwardness" of the "baste," whether under the name of A, B, C & Co. or X, Y, Z & Co.

Sometimes we get hold of enough proof that is strong enough to warrant us in giving names and particulars, but more often not. Most of the dishonest rascals are just "slick enough" to cover up their tracks far enough so that a publisher dare not reveal their swindling schemes in connection with their names.

Facing Comb Honey.—A battle upon this subject was mentioned on page 266. The scene of conflict has been transferred to the pages of Gleanings for May, occupying five of them. Mr. W. M. Whitney says:

"If a lot of poor stuff is put behind prime stock used as facing, no better evidence of intention to deceive could be presented, for it would convict the guilty party of an attempt to defraud, in any court in the country. . . . Every honest man should put his heel upon every such transaction as he would upon the head of a viper, and assist in stamping out the whole disreputable business. . . . Facing honey, with poorer honey back of it. . . is lying, pure and simple."

Mr. G. M. Doolittle replies to Mr. Whitney's very warm and truthful utterances, as follows:

"I ship a thing on commission, the commission man does the selling, and sells the thing for what it proves to be, unless I tell him he need not open it, as I guarantee it to be so. . . . Where no guarantee is made, the looks of any single article which is in sight speaks only for itself, not for what is out of sight."

Mr. F. L. Thompson refuses to be satisfied with the argument that people expect veneering, and says:

"That most people expect sharp practice is no reason why it is perfectly right to satisfy their expectations. If I expect to be waylaid in passing through a back street, nevertheless no one is justified in actually taking my purse."

Umpire Root calls time, and decides against Mr. Doolittle, which is exactly as we would decide. Mr. Doolittle of course has had no experience as a commission man, nor in buying honey from a city dealer, else he would not have written this paragraph in Gleanings some time ago, which has caused him to receive such severe whacks as has been given him by Messrs. Hasty, Whitney, Thompson, etc.:

"And I also claim that there is nothing out of the way, if any once chooses to do so, in shipping cases of honey having XXX facers and XX or X honey inside, on commission. Yea, more, I claim that there would nothing dishonest in filling the center of the case with buckwheat honey, the same having XXX white honey facers, providing it was shipped on commission, every case alike, and the producer thought it to his interest to do so."

We have had a little experience the past year in buying

comb honey from commission men, and so know whereof we speak. Several times—yes, almost every time—the honey was “faced”—dishonestly so, too, and we did not blame the dealer, either, but the bee-keeper, who, evidently, as Mr. Doolittle says, “thought it to his interest to do so.” Had the producers’ names been on the various lots, we would delight in holding them up right here in print, so that all might know at least a few of the frauds among bee-keepers.

It is *very* annoying—to say nothing of the sin on the producer’s part—to get in a lot of honey that *looks* very pretty next to the glass, and then when a grocer calls and wishes to open the cases before buying, to find that much of that back of the front row is so inferior as to cause the loss of a sale.

In our opinion, Mr. Doolittle can’t any too soon reconsider such “claim” as he sets forth in his paragraph that we have quoted from *Gleanings*.

A Tramp Swarm-Catcher.—The following tramp-bee “story” has been going the rounds of the newspaper press, and as several of our readers have been kind enough to mail us copies of it, we reproduce it so that all our subscribers can read it and laugh over it—tho not holding us responsible for its truthfulness:

As I sat on the veranda with the farmer after supper I askt him if he was not greatly bothered with tramps, and his reply was:

“Waal, a good many of ’em come along and want a bite to eat, and some of ’em are pretty sassy, but only one of ’em ever served me a real mean trick.”

“Poison your dog?” I queried.

“It was meaner than that. We was eatin’ dinner one day in the spring when a hive of bees started to swarm. I’d been expectin’ it and watchin’ ’em, and had a new hive ready. When bees swarm they will light on most anything handy—a limb, a bush, or even the pump. Just as the bees began to pour out of the hive and circle around along comes a tramp up the path to ask for somethin’ to eat. The queen-bee settled down on his old hat and the hull swarm followed her. In two minits that tramp’s head and shoulders was covered with bees, and I yells to him for heaven’s sake not to try to fight ’em off or he’d be stung to death.”

“He must have been terror-stricken,” I said.

“Not a bit of it, sir. He was as cool as a cucumber, and when I told him he’d have to stand in a smudge till the bees was killed off he jest laughd. When they’d all settled down on him and I was going to start a smudge he sez:

“Old man, what d’y e consider this swarm of bees wuth in cold cash?”

“About \$5,” sez I.

“Are you willing to give \$3?” sez he.

“What fur?” sez I.

“Bekase you’ll either pay me \$3 or I’ll walk off with the bizness and sell out to somebody else.”

“And you had to buy him off?” I askt.

“That’s where the meanness comes in,” replied the farmer. “Them bees was my property, and I wasn’t buyin’ what was my own. He offered to take \$2, but I couldn’t see how he could git away with ’em, and refused to come down. Then he starts off. I reckoned the bees would get angry and sting him to death, but nothin’ happened. He jest walkt out into the road and down the hill, and he carried them bees seven miles and sold ’em for a new pair of shoes.”

“And he wasn’t stung?”

“Not once, sir. The bees seemed to like the smell of him, and he paddled along the road as graud as you please.”

Getting Rid of Ants.—Vick’s Magazine for May gives the following methods of getting rid of ants:

Ants in the soil can be destroyed by means of bisulphide of carbon: Make a hole about six inches deep in the ant-hill with a round dibble or bar, and into it pour a tablespoonful of the liquid, and immediately close up the hole with soil. The liquid is very volatile, and will permeate the soil in every direction, and destroy all animal life, and not injure vegetation. It is very inflammable, and must be carefully kept away from fire. Ants can often be driven away by sprinkling about their haunts ashes saturated with coal-oil. They can be trapt and killed by placing sweet-oil where they can have access to it, as they are very fond of it, but it has the effect to close their spiracles and thus kills by asphyxia.

DR. E. GALLUP, of Orange Co., Calif., wrote us May 2 that for some time he had been in ill-health, but was getting better again. Referring to the bees, he said:

“My bees commenced swarming March 20, and are keeping it up yet. They are doing well here in the valley.”

SUCCESS IN QUEEN REARING is the title of a small pamphlet just issued by Henry Alley, of Essex Co., Mass. It contains 32 pages in all, about 14 of them being devoted to queen-rearing, and the balance to Mr. Alley’s catalog of queens, drone-traps, etc., and advertisements of bee-supply dealers. The price of the pamphlet is 25 cents, and can be had at the office of the American Bee Journal.

ELDER DANIEL WHITMER, of St. Joseph Co., Ind., when asking us lately to replace a lost copy of the Bee Journal, added:

“I do not want to miss a single number, for the reason I cannot rest good. I want to know all that is going on in the bee-fraternity.”

That’s right. If you “want to know *all* that is going on in the bee-fraternity,” of course you want the old American Bee Journal. We are ready to do our part in furnishing a bee-paper that will cause every bee-keeper in the land to “rest good.” Don’t be restless, but subscribe for the Bee Journal, and be easy and peaceful.

MR. CHAS. W. CONKLIN, of Logan Co., Ill., wrote us as follows May 2:

“BROTHER YORK:—I am very sorry to acknowledge that I am so far behind with my subscription. But that is the way—the good-natured editor is always imposed upon. But to partly redeem myself I will send you a new subscriber herewith.”

We trust Mr. Conklin will pardon us for publishing his letter, but it serves so well as an illustration that we couldn’t resist the temptation to print it.

Just suppose every one of our subscribers who is in arrears would pay up to the end of 1898 and send a new subscriber for a year, as did Mr. Conklin, what would happen? Well, in the first place, the Bee Journal would have at least 8,000 subscribers *at once*; and, in the second place, *all* the readers would soon get a paper about 50 per cent. better than they are now getting.

Give us the paid in-advance list of eight or ten thousand subscribers, and we’ll guarantee to furnish you the rest. “It is more blessed to give than to receive.” But we can make the *receiving* a blessing to you if you will *begin* the giving part.

MR. J. C. ARMSTRONG, of Marshall Co., Iowa, writing us April 30, had this to say:

“I always read the American Bee Journal with interest. I have taken it for over 30 years, with the exception of the last three years. Four years ago I had the misfortune to have foul brood among my bees. I got it cured up and saved a couple of colonies. On moving to this place two years ago I sold what bees I had, discontinued the Bee Journal, and destroyed a hundred back numbers, thinking I had gone out of the business forever, but I felt lonesome without them. Two years ago I bought one colony of our old friend, O. B. Barrows. From that one they have increast to seven. If I could have my way they should not increase any more. But they will in spite of me. I never had them winter better. They are booming with bees. The Bee Journal has past through a good many hands since I first subscribed for it. I presume I shall keep a few bees as long as I am able to take care of them.”

We think you are mistaken about the Bee Journal passing through “a good many hands” in the 30 years since you first began to read it. It has had but two different owners since 1873. That isn’t a bad record, surely.

Buckwheat Sown Early.—according to J. T. Van Petten, in Gleanings, yields honey on hot forenoons that succeed cool, damp nights. He has had two crops of Japanese in one season.

Curing Paralysis by Mixing Colonies.—O. O. Poppleton thinks this would not be satisfactory with him, as he never had a paralytic colony to cast a swarm. Moreover, many colonies, especially those lightly affected, seem to get well of themselves early enough for late swarming, and he wants a cure that will act early in the season.—Gleanings, p. 296.

The Disk Section-Cleaner.—James Roat (Gleanings, 98) says it must be run at high speed, 3,000 revolutions a minute or more, as the sand-paper doesn't clog as soon at high speed. He thinks a sufficient speed cannot be attained by foot-power. One sheet of sand-paper will clean about 70 sections, altho he has done twice as well. In his locality propolis is very bad.

Spraying Fruit-Trees.—C. P. Dadant says spraying does no good and may do harm before the blossoms have been off a week. "The fruit being well formed, the surface retains more of the poison, which is therefore more effective. It must be remembered that as the fruit grows, its skin expands, and a part of its surface is thus deprived of its protecting coat of poison."—Busy Bee.

Keep Up the Standard of Comb Honey is the cry of Editor Hutchinson. He says he would give a cent a pound more for his own eating for comb honey without any foundation, and the greatest blessing that has lately fallen to bee-keepers was the failure of the deep-cell foundation. He rejoices in the "change of base" on the part of the enterprising Medina folks, who have sent him a sample of their latest product, a foundation running 18 feet to the pound.

May Sickness, of which much is said in Europe, and which is much like, if not identical with, the spring dwindling of this country. M. Cl. Laurent says in *Le Progres Apicole*, is not especially confined to May, but may come any time, and is caused by eating spoiled pollen. For a cure he relies on giving frames of sealed honey of best quality, and on every fine day a half-pound of syrup consisting of one-third best honey and two-thirds sugar with one-half coffee-spoon of wine and a pinch of salt.

The Prime Thing a Beginner Should Know First is inquired for in Gleanings. Mr. Doolittle replies very fully, recommending two or three times careful reading through a good text-book, then getting a bee-paper. Then to know his locality, finding what plants give the honey harvest, then planning to have laborers ready for that harvest by having the eggs laid 37 days in advance. For that purpose "spreading brood" is advised 47 to 57 days in advance of the expected harvest, using the earlier period if weather is warm.

Plain Sections have thoroughly awakened the enthusiasm of the editor of Gleanings. The man of Straws says to him (Gleanings, p. 293), "Hold your horses, Ernest! Don't put it quite so strong as to say the plain section 'seems about to revolutionize' (p. 267.) Remember you're right in the storm center, and 500 miles from Medina the air seems quite calm." The editor thinks he is justified in his statement in view of the number of orders for plain sections, and the fact that 10 girls are kept busy with the latest appliances turning out 700 or 800 fences a day apiece.

Average Yield.—In this Journal for Dec. 23, in reply to the question, "What would be a fair average honey crop with an apiary of from 200 to 300 colonies, located in Central or Northern Illinois?" Dr. Miller replied it would be 20 pounds less than nothing. M. A. Gill (Gleanings, p. 303) thinks this about 20 pounds too little, altho he varies the original question by saying in a good location, and says he knows many locations in Wisconsin where 200 or 300 colonies would not only have made a good living, but given a fair surplus for the past 20 years, with the possible exception of three years. Then he tells of Utah and Colorado. Utah County is reported

to have 30,000 colonies of bees. At Payson, in that County, are 3,000 colonies on less than two miles square. Thos. M. Todd, who owns 200 of them, last year got an average of 200 pounds of extracted. 500 colonies on one block in the town of Benjamin averaged 77 pounds of comb honey.

Wants the Place Given.—"It would seem, from American Bee Journal, p. 87, that it's all right for hot water to get into the boiler, but still the Boiler don't like to get into hot water. I'm going to throw some hot water onto the outside of him because he doesn't give the page of the passage he refers to. I get disgruntled in mind when I try to refer to the original passage and can't find it."—E. E. Hasty, Review, p. 119, column 1, line 31-39. Bad to have Hasty disgruntled, and hot water isn't pleasant on one's back. Must try to give page at least part of the time.

Hot Water vs. Cold Water for Bee-Stings.—Referring to Dr. Gallup's advice (American Bee Journal, p. 68) to use a cold, wet-sheet pack for bad cases of bee-stings, Chalou Fowls thinks it might do harm and even in some cases result fatally. He uses hot water. Once a bee stung him in the bare eyeball. He groped his way to the house, applied cloths of hot water, and found the pain alleviated just in proportion to the heat of the water. In another case his horse and himself were fearfully stung, and he thinks the hot water saved the life of the horse.—Gleanings.

Bees Eating Away Upper Honey in Comb.—The editor of Gleanings said one trouble with deep frames was that bees sometimes ate away all stores at top where warmest, the bees starving with honey below them. Dr. Miller asking if there was no mistake about it, he replied that Dr. Miller would not likely have any trouble of that kind because his bees are cellared, but in Medina Co., Ohio, with bees wintering out, the trouble happens even with frames as shallow as the Laugstroth. Now the editor of Busy Bee asks for a picture of such a comb.

Introducing Queens.—Busy Bee says there's no need to have a colony queenless before putting in the new queen. Here's the plan given:

"When your queen arrives, remove the board covering from the wire screen which you will find over the top of the cage. Place the cage wire down on the frames of the colony where you wish to introduce the queen. Leave the cage here for two or three days and pay no attention to the old queen. After the bees in the hive have become thoroughly acquainted with the new queen, hunt out the old queen and kill her, and then turn back the wire so the bees in the hive can get at the candy in the cage and eat it out and release the queen. Close up the wire and let the bees alone until the next day, when you can examine the colony and see how the new queen is coming on."

Foundation 18 Feet to the Pound.—A report of actual trial of this exceedingly thin-base foundation is given (Gleanings, page 312) by O. O. Poppleton, of Florida. Sheets four inches deep were put to the brood-chamber. No stretching could be observed in the lower part. The upper inch stretch from 1-16 to $\frac{1}{8}$ -inch, and he thinks the stretching of the whole sheet would not exceed 3-16. This is very promising, and the editor thinks it possible that hanging the sheet differently might have given a still more favorable showing, for this 18-foot foundation is to be hung exactly the reverse of the usual way. He says it is lighter than the no-wall article, and the walls will prevent the warping to which the no-wall is subject. In a trial of thin and extra-thin, that is 11 and 13 feet-to-the-pound foundation, with the 18-foot, side by side, the bees accepted the latter quicker, and drew it out farther than the other two!

Cleats vs. Hand-Holes.—J. H. Martin and Dr. Miller are having a little bont concerning them in Gleanings, Editor E. R. Root standing by saying, "Sick him!" Mr. Martin says (p. 249) Dr. M. ought to know that cleats are a back number. Their chief use is to carry hives into the cellar, and when he did that in York State it was more comfortable to grasp the hive at the bottom. In moving hives the cleat is a nuisance, taking up the room of 20 hives in such big loads as Mr. Mendleson hauls. In reply Dr. Miller asks (p. 292) why under the sun the California man wants hand-holes if there's more comfort in grasping the bottom. Says you can take hold of a cleat where you like best, it is more comfortable than a hand-hole, and two can handle the same hive. Only the back cleat takes extra room in a load, and to take up the room of 20 hives he figures out that Mendleson must have had 500 hives in a load.

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing *new* subscribers; as the majority remain, once they become subscribers to a *good* journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo., or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden strain, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. W. Z. HUTCHINSON, FLINT, MICH.

Please mention Bee Journal when writing.

WOVEN WIRE FENCE
 With our Duplex Automatic Machine you can make a genuine Rabbit-Proof fence, and one that is also Horse-high and Bull-strong for a few cents for 15c, and a Stork or Chicken fence for 18c a rod. Plain, Cold Spring and Barbed wire to farmers at wholesale prices. Catalogue Free. RITSELMAN BROTHERS, Box 138, Ridgeville, Indiana.

In the multitude of counsellors there is safety.—Prov. 11-14.

United States Bee-Keepers' Union.

Query 71.—Of course you are interested in the success of the United States Bee-Keepers' Union. What would you advise in order that its membership may soon be so increased as to make it (the Union) of the greatest possible good to the bee-keeping pursuit?—P. O.

Rev. M. Mahin—I have no mature opinion to express.

C. H. Dibbern—I will leave this question to Dr. Miller. I don't know.

Prof. A. J. Cook—For it to show, as I believe it will, that it has a mission, and then to fill it.

E. France—I believe the Union is a good thing. How to increase its members, I don't know.

J. M. Hambaugh—The brains of the old "war horses" are at the helm. My advice would be insignificant.

Mrs. L. Harrison—When we have a fair crop of honey, and can sell at a reasonable price, we will all join.

G. W. Demaree—I once was interested in the Bee-Keepers' Union, but since it has switched off, I have lost all faith in it.

G. M. Doolittle—Let every bee-keeper become interested in the Union to the extent of \$1.00 annually, and "the thing will go."

Eugene Secor—I advise all people interested in putting down adulteration, and all in favor of compelling dealers in honey to be honest, to join it.

Dr. C. C. Miller—Perhaps constantly holding up its advantages to those not yet members. Write it up and talk it up. Business men advertise.

Chas. Dadant & Son—Talk it up, subscribe to it, and above all *stay with it*. Make it useful just as soon as you can. Perseverance and grit always succeed.

Jas. A. Stone—That the Union protect its members in the right, and the bee-keepers' interests against every fraud. To begin with, the adulteration of honey.

R. L. Taylor—You have the cart before the horse. "Make it the greatest possible good" to its membership, then its membership will be sufficiently increased.

Dr. J. P. H. Brown—Formulate its advantages in the strongest language possible, and then to send out to all the known bee-keepers in the United States with an earnest appeal for their support.

W. G. Larrabee—How would it work to have small societies join the United States Bee-Keepers' Union by paying to it a certain sum annually, and let each member of the small society be a member of the Union.

J. E. Pond—Who can advise? If the bee-keepers of the country are not now convinced that in "union there is strength," how can any opinion convince them? The Old Union became a power in the land—why should not a union which is a Union work out results that

GOLDEN BEAUTIES...

Three-band Italian Queens reared from Root's stock. Golden Queens from the best selected stock, Untested, 50 cents; Tested, 75 cents. Carniolan Queens at same price.

E. Y. TERRAL & CO., Cameron, Texas.

Baptist Anniversaries, at Rochester, N. Y., May 16-24, 1898

The Nickel Plate Road is authorized to sell tickets to Rochester, N. Y., and return, at one fare and one-third for the round trip, on certificate plan, account of above meeting. Tickets good on any of our through express trains leaving Chicago daily from Van Buren Street Passenger Station at 10:35 a.m., 2:55 p.m., and 10:15 p.m. Vestibuled sleeping cars and unsurpassed dining car service. You will save time and money by patronizing the Nickel Plate Road. For further information address, J. Y. Calahan, Gen'l Agent, 111 Adams St., or telephone Main 3389. (16)

will prove advantageous? Cannot every bee-keeper see that it is for his advantage to join with other bee-keepers spread all over the country, in an attempt to better his condition? Individual efforts will cover but a small territory, while a Union will cover the whole ground, and take in the whole brotherhood.

Emerson T. Abbott—I would advise every man (and woman, too, if she is interested in honey-production) who reads this to send in a dollar and become a member of the Union. All the Union needs is a large membership, and each individual bee-keeper should feel that he is in duty bound to do his part toward increasing that membership. Send in your dollar now, before you forget it.

GENERAL ITEMS

Swarming and Storing Honey.

Bees have been swarming since the middle of March. A swarm hived on March 17 and one on the 20th now have supers on. Some old colonies have supers nearly full of honey, and I have put on the second one.
SOUTH ALABAMA.
Washington Co., Ala., April 5.

Heavy Freeze Put Things Back.

We had a freeze here March 22, when drones were flying and bees preparing to swarm, but fruit is mostly killed, also corn and garden vegetables, so it will be brown and sear for a time at least, but warm weather will soon cause all Nature to be herself again.
G. W. BISTLINE.
Titus Co., Tex., April 4.

Wintered Well—Worms.

I have three colonies of bees which are doing nicely. One is bothered with worm-nests a little, but as they are in box-hives we cannot do much with them in the way of helping them to get rid of the worms. They wintered nicely, as it was a good winter for bees. They are on the summer stands, and had flights off and on all winter. They are doing nicely, as it is warm enough for them to be able to get pollen.
W. G. SAGER.
Venango Co., Pa., April 11.

Cronkleton Escape and Press.

Mr. Geo. W. Blair, of Mason county, Mich., askt what had become of E. J. Cronkleton and his bee-escape. We are out in Iowa, as usual. I am induced to write only through respect to Mr. Blair, not that I care so much about my bee-escape, or any other escape that is in use. I presume the Porter bee-escape is the best escape on the market. I use his in my apiary. The difference is 12 to 1—12 bees go out of my escape while 1 goes out of his. The way to demonstrate this is to cut out a narrow strip of the lower edge of the section-case and insert a strip of glass instead, and then lie down in the grass and take items.

When I invented my escape I had several things in view, the first being to take advantage of the natural instinct of the bees, cheapness and rapidity of work, and ventilation. My escape costs but a few pennies. It frees a case in from one to three hours.

There is a difference in bees leaving the cases, that I am unable to account for. Some seem loth to leave, and others seem very desirous to leave. These things I have learned through an observatory section-case. I said before, I take the advantage of the natural impulse of bees. I have a large unobstructed outlet; the bees come

Bingham & Hetherington Un Capping-Knife.

PRICES OF BINGHAM PERFECT Bee-Smokers and Honey-Knives!

EVERY BEE-KEEPER

.....To have a copy of.....

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy.

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

As we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apiarian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellence. Polished, snowy-white sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE tree, and a beautiful Catalog for the asking.

Address, Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Supreme Council of the Royal Arcanum will hold a meeting in Cleveland, Ohio, May 18-25, for which the Nickel Plate Road is authorized to sell tickets at one and one-third fare for the round trip, on certificate plan. Unexcelled dining car service. Vestibuled sleeping cars. Three through trains daily from the Van Buren Street Passenger Station. For full particulars call up telephone Main 3389, or address J. Y. Calahan, General Agent, 111 Adams Street. (13)

IN PEACE

most any soldier will do, but "when duty calls" we need genuine stuff. Crops threatened with invasion need a fence that really protects.

down into the escape from the sections, hunting an outlet; as soon as it is found they set up that joyful hum, swarming hum, that we are all familiar with. Then you will observe them pouring down out of the sections, and take up the line of march in a perfect sheet or column, pouring out upon the brood-frames, 10 or 12 bees going out at the same instant.

I am not writing up this little escape for any purpose in particular—it is no great invention. It is merely a thought, and any bee-master ought to get up the same thing or a better one in five minutes.

While I am on this subject of inventions, I tried to say something concerning a small section-press that I invented, probably six years ago. I tried to make something out of it but failed. I see that it is being very extensively manufactured now. I suppose there is no doubt but I invented it. I will try to describe it. It has a base and two upright posts 4 1/4 inches apart; guards and posts, and lever. It is not my place to say whether this is a good press or a bad one, but the public has it now. But I ask this much, that it should bear my name—"The Cronkleton Section-Press."

E. J. CRONKLETON.

Harrison Co., Iowa.

Wintered Extra Well.

Bees in this section wintered extra well, and are busy at work every warm day.

ERWIN GABRIEL.

Green Co., Wis., April 17.

Wintered in Good Condition.

I put into the cellar 12 colonies Nov. 17, and took them out April 15, all in No. 1 condition. That is about five months without seeing the light. **GEO. A. LAWRENCE.**
St. Croix Co., Wis., April 19.

Cool and Late Spring.

Our spring has been unusually cool, and probably the bees are like everything else—late. Peaches have not bloomed, but are in No. 1 condition. **T. F. BINGHAM.**
Clare Co., Mich., May 5.

Bees in Fine Condition.

Out of 54 colonies I lost two since putting them into winter quarters. The balance are in fine condition, but the weather is cold and windy, which holds them back from working on the soft maple and willow, which are in full bloom.

CHAS. E. CRAWFORD.

Oscoda Co., Mich., April 30.

A Beginner's Report.

I started last spring with one colony of bees and increased to three. It is very fascinating to me, and I like to read everything I see on the subject. I moved to this place from Fremont, Nebr., the first of this month. I believe this will be a good bee-country. **F. M. ROSEMAN.**
Crawford Co., Mo., April 19.

Suggestions on Bee-Organizations.

MR. EDITOR:—If your patience is not already exhausted I will try to tell "Inquirer" (see page 188) what kind of an organization I would like to see perfected among bee-keepers.

As most readers of the Bee Journal know there are two separate national organizations already in the field, whose aims and objects are almost identical. That their power for good would be multiplied many times over by being united is self-evident; and that should be the first step toward laying the foundation for a great organization.

The Board of Managers or Executive Committee of the united body should then invite every State and county bee-keepers' association in the United States to become a member of the federation by paying into the treasury of the executive one-half, two-thirds (or whatever proportion is deemed advisable) of their membership fees. Then,

instead of paying 50 cents or a dollar to a local association, and a dollar each for membership in the two national ones, one membership fee would cover the whole. Our local association would then be the Minnesota branch of the United States Bee-Keepers' Association.

It needs no argument to prove that such an organization is both desirable and possible, for we have already the material from which to construct it, in our various associations. Some changes in the constitution of the United States Bee-Keepers' Union might be necessary in order to allow the increase membership as above indicated; and also some changes in the constitutions of the associations joining, but in fact they would have no constitution after being absorbed by the federation. They would have to make by-laws in accordance with the constitution of the executive. However, it will be time enough to discuss details when the matter gets underway.

That is simply an outline of the organization for which I am willing to strive, and in the meantime I can only afford to be a member of the two to which I already belong.
WM. RUSSELL.
Hennepin Co., Minn.

A Correction—Cold April.

On page 259 I am made to say that I cut rabbits 3-16 of an inch deep. I said 13-16. [Right you are.—EDITOR.]

My colonies are mostly in good condition, with plenty of stores. April has been a very cold month, and brood-rearing is not very well advanced. Plum and peach trees are beginning to bloom. Apple trees are not in blossom yet. It was showery last night and to-day. EDWIN BEVINS.
Decatur Co., Iowa, April 30.

A Carpenter Bee-Keeper.

I had 17 colonies of bees last spring. I got 1,000 pounds of honey from them. This spring I have 31 colonies. I have had bees for 10 years, just for my own use, but not to make a business of it. I work at carpentry, but it is dull at my trade this spring, so I think I will see what I can do with the bees this year. O. D. FRENCH.
Jones Co., Iowa, April 18.

Profitable Fun with Bees.

I am not a regular bee-keeper, but a locomotive engineer, and keep a few bees for fun; or, you may say, to rest up my head after many a long run. I have 15 colonies nicely arranged in the back-yard, and I believe it rests me up when I am at home to go out among them and see them work and caper around. They averaged about 125 pounds per colony, half comb and half extracted, last year, so you see, we have a fairly good location. SANFORD HARTMAN.
Lincoln Co., Nebr., April 23.

Wintering—Spring Management.

Last fall I prepared 26 colonies for winter—six colonies in the cellar and the balance on the summer stands. Those that were not already in chaff hives I put outer cases over, packing the inter-space with fine planer-shavings, or something similar. On part of them were "sealed covers." On the balance was Hill's device, covered with a thick, porous cushion. The entrances were left open full width, with a board leaning against the hive, shading the entrance. This I remove when warm enough for the bees to fly.
Last week I examined them, taking out the frames from every hive. Contrary to a late writer in the Bee Journal, I believe in examining them at an early date, thereby aiding them in "house-cleaning." In almost every hive I find something I can do to aid them—a moldy piece of comb to remove, dead bees and mold on the bottom-board, a surplus frame of honey to remove, etc. This examination through, I have nothing more to do till swarming-time.
I never have occasion to feed in the

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. spring, as I always in the fall see that they have sufficient stores for winter and spring, believing that ample stores in sight a better inducement for them to build up in the spring than to live "from hand to mouth," depending upon "stimulative feeding."

I have now 25 strong colonies out of the 26, finding one queenless.

Now, after experimenting and careful observation for several years, I would answer the "wintering problem" in these words:

In the fall see that the bees have ample stores, pack on the summer-stands, in outer cases, with the inter-space packed with a dry substance, with a porous cushion over the frames, and a space between frames and cushion. This method has given me the best results. J. P. SMITH.

Sullivan Co., N. H., April 20.

Came Through in Fine Condition.

My bees have come through the winter in fine condition, excepting the loss of one strong colony, leaving about 30 pounds of honey. I think they must have been disturbed in a cold time, as they were scattered through the hive. About a month ago I commenced giving them rye flour, in a box covered with glass, as they seemed to have no bee-bread, and they have been breeding up very fast since. Three weeks ago they commenced to work on soft maple, but a big freeze put a stop to that, and they have brought in no natural pollen since, until the last two or three days. Everything looks favorable for a good honey-year. I could not think of trying to get along without the "old reliable" American Bee Journal. Hurrah for Omaha!

A. B. GINNIS.

Cass Co., Neb., April 11.

Cold and Rainy Weather.

I am a beginner in bee-culture, and very often I find in one copy of the American Bee Journal what is worth the price of a year's subscription to me.

I had 12 colonies packed in straw on the summer stands the past winter, and they all came through in good condition. They had a good flight March 9, and brought in the first pollen March 30; then we had cool weather until April 10, when they began bringing pollen in quite freely. I saw some drones flying in the yard also, which an old bee-keeping friend tells me is something uncommon in this part of the country so early. At the present time we are having bad weather—cold and rainy.

C. H. FIELD.

Cumberland Co., Maine, April 24.

Wintered Best for Years—Robbing.

The bees in this part of Iowa came through the winter in the best condition they have for years. My 141 colonies came out of the cellar so strong that it is hard to find weak ones to double the queenless ones with. No trouble with robbing. I see in the Bee Journal, to stop robbing, one should use salt and water. My experience with salty water is, it doesn't want much salt in; if you get too much in it will kill the bees. Clear water is better to spray them with. I sprayed with salty water once and killed a colony. With me a sheet is better to stop robbing. Spread it over the hive and occasionally turn it.

CHAS. BLACKBURN.

Buchanan Co., Iowa., April 21.

The Divider vs. the Fence.

On page 70 the Boiler turns out the following:

"The A. I. Root Co., in connection with the fence separator, proposes to make use of the Pettit plan by having a fence between the outside rows of sections and the sides of the supers. S. T. Pettit thinks this will not be so good as his divider with 3/4-inch holes, for with sufficient space between the slats the sections will be made ridgy."

But a good deal more serious objection to the fence as a divider consists in the fact that the fence provides for a bee-space only

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, May 2.—Fancy white comb honey would bring 11 cents, but there is none here; other good grades of white at 9 to 10c.; dark and amber, 7 to 8c. Extracted, white, 5 to 6c.; ambers, 4 1/2 to 5c.; dark and off grades, 4c. with exception of dark candied and amber grades. This market is bare of comb, and while prices have been low the quantity sold locally has been greater than last season. Beeswax scarce, and sells at 27c. for average lots. R. A. BURNETT & CO.

Kansas City, May 2.—Fancy white, 9 to 10c.; No. 1, white, 9c.; amber, 8 to 9c. Extracted, white, 5 to 5 1/2c.; amber, 5c.; dark, 3 1/2 to 4c. Beeswax, 20 to 25c.

Comb honey is selling fairly well, but prices are low; considerable shows signs of candying, which makes dealers anxious sellers. C. C. CLEMONS & CO.

Cincinnati, May 2.—Demand fair for extracted, at 3 1/2 to 6c. according to quality. Demand for comb is slow at 10 to 13c. for best white. Beeswax in good demand at 20 to 25c. for good to choice yellow. CHAS. F. MUTH & SON.

Boston, May 2.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, no sale. Extracted, white, 6 1/2c.; light amber, 5 1/2c. Beeswax is in very light supply, and if pure would readily bring 27c.

There is nothing new to note in our market for honey. As usual at this time of year, the demand has dropped to almost nothing, but as the supply is light, prices are well maintained and firm. BLAKE, SCOTT & LEE.

Cleveland, May 2.—Fancy white, 12 to 12 1/2c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & CO.

San Francisco, May 2.—White comb, 8 1/2 to 10c.; amber, 6 1/2 to 7 1/2c. Extracted, white, 5 1/2c.; light amber, 4 1/2 to 5 1/2c. Beeswax, 24 to 26c.

Market shows a healthy tone, especially for extracted, with very little of this class now remaining. Comb continues obtainable at former rates, with a fair business doing on local account. There will be little honey the coming season, and it is probable that values will further harden.

Detroit, May 2.—Fancy white honey is lower and now quoted at 11c. No. 1, 9 to 10c.; fancy dark, 7 to 8c.; No. 1 dark, 6 to 7c. Extracted, white, 5 to 6c.; dark, 4 to 5c. Beeswax in good demand at 26 to 27c.

There is considerable dark and undesirable honey on commission now, and some of it will be carried over to another season. M. H. HUNT.

Minneapolis, May 2.—Honey much more encouraging. Fancy white clover comb is selling here now at 10 1/2 to 11 1/2c. Not advisable to ship darker than amber. Extracted fancy white clover, 5 1/2 to 6c.; amber, 5c.; dark, 4 to 4 1/2c.

Outlook for honey much more encouraging. S. H. HALL & CO.

Indianapolis, May 2.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, May 5.—Fancy 1-pound sections, 11 to 12c.; A No. 1, 10 to 11 cents; No. 1 8 to 10c.; amber, 8 to 8 1/2c.; dark, 7 to 7 1/2c. White extracted in barrels and kegs, 5 1/2 to 6c.; amber, 5 to 5 1/2c. Beeswax, 26 to 28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & CO.

Buffalo, May 2.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & CO.

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c. WESTCOTT COM. CO.

2-12 of an inch against the super wall. Nothing less than 1/4 inch will give best results. This season I shall experiment with a large number of dividers with 5-16 inch bee-space outside the dividers. Of course, those who have room to do so can easily give the 1/4 inch bee-space. S. T. PETTIT, Ontario, Canada.

I ARISE

TO SAY to the readers of the BEE JOURNAL that DOOLITTLE

has concluded to sell - BEES and QUEENS - in their season, during 1898, at the following prices:

- One Colony of Italians on 9 Gallup frames, in light shipping-box \$6 00
- Five Colonies..... 25 00
- Ten Colonies..... 45 00
- 1 untested queen. 1 00
- 6 " " queens 5 50
- 12 " " " 10 00
- 1 tested Queen... \$1 50
- 3 " " Queens. 3 50
- 1 select tested queen 2 00
- 3 " " Queens 4 00

Select tested queen, previous season's rearing 3 00
Extra Selected for breeding, THE VERY BEST. 5 00
About a Pound of BEES in a Two-frame Nucien, with any Queen, \$2.00 extra.

 Circular free, giving full particulars regarding the Bees and each class of Queens.
Address

G. M. DOOLITTLE,

1A251 BORODINO, Onon. Co., N. Y.

21st Year **Dadant's Foundation.** 21st Year

Why does it sell so Well ?

Because it has always given better satisfaction than any other. Because IN 21 YEARS there have not been any complaints, but thousands of compliments.

We Guarantee Satisfaction.

What more can anybody do? Beauty, Purity, Firmness, No Sagging, No Loss. PATENT WEED PROCESS SHEETING.

Send Name for our Catalog, Samples of Foundation and Veil Material. We sell the best VEILS, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

LANGSTROTH ON THE HONEY-BEE, Revised. The Classic in Bee-Culture—Price, \$1.25, by mail.

Foundation and Beeswax Prices Advanced.—We quote an advance of three cents in Foundation, wholesale and retail, on the prices quoted in our Circular. BEESWAX WANTED, at advanced prices also.

CHAS. DADANT & SON,

Please mention the Am. Bee Journal. HAMILTON, Hancock Co., ILL.

OUR MOTTO—" Well Manufactured Stock ! Quick Shipments ! "

SECTIONS, SHIPPING-CASES, AND BEE-KEEPERS' SUPPLIES.

We make a specialty of making the very best Sections on the market. The BASSWOOD in this part of Wisconsin is acknowledged by all to be the best for making the One-Piece Honey-Sections—selected, young, and thrifty timber is used.

CONTRIBUTED ARTICLES

The Apiary of Mr. John Bodenschatz.

My apiary is situated on the northern slope of a small hill, and consists of 72 colonies, of which 60 are of pure Italian blood. I produce both comb and extracted honey, and last year, from 38 colonies, spring count, I increased to 72, and produced 5,700 pounds of honey. The best colony which I run for comb honey produced 190 pounds of very fine white honey; while 12 colonies which I ran for extracted honey produced 2,700 pounds.

The hives in the foreground are 16x20, by 12 inches high, outside measure, and hold 13 brood-frames. These hives give me the best results, as the bees winter safely on the summer stands, and the queen has a large brood-chamber, which a good queen can easily keep filled.

expect to graduate next month. So it keeps me quite busy this spring attending to my duties.

Last spring, while reading in the "Old Reliable" about the instinct of bees, a thought came to me that by placing boxes in the timber, selecting large trees in an open place, I might capture swarms that were off to the woods from the surrounding farm places, where bees are kept in a rather rude fashion, and the honey brought to the market in a very poor condition, which they offer very cheap, and therefore pull down the price of the fancy white comb honey that a careful bee-keeper produces.

Well, I placed four boxes of the Langstroth size in the trees, about 10 to 15 feet high, and as I came through the woods about eight days later, I found them occupied with thriving colonies of hybrids. I captured seven colonies in this way without the least trouble. By putting an old section (one which had comb in) into these boxes, the bees would occupy them more readily, and as soon as I took them home I transferred them into regular hives.

My principal honey-flow comes in June, July and August, from the basswood, white and sweet clover. I think sweet clover is the best honey-plant for bee-keepers to sow. It spreads very rapidly, withstands drouth, grows on any ground, and blossoms when the bees are the strongest.

Cook Co., Ill.

JOHN BODENSCHATZ.

Apiary of John Bodenschatz, in Cook County, Illinois.

With me bee-keeping has been a success. Starting in 1892, when but 15 years of age, with one colony, and buying 10 more two years later, I have now a fair-sized apiary. I work at the bees whenever I have a few minutes spare time, as I am employed in a drugstore, and am now attending the Northwestern University School of Pharmacy, from which I

Comb Honey—Leveled-Down and Bait Sections.

BY C. DAVENPORT.

Some have said, and no doubt there are many more who think, that there is nothing more that can be profitably written about the production of comb honey, but I am not one of

them, for I have not only read the standard works and most of the current literature on bees, but I have for many years produced comb honey by the ton each season, and last season, altho it was the poorest I have ever known, I lost at least \$300 by not understanding the business better than I do; and but a few years ago I lost probably \$400 for the same reason. But this was owing to such a peculiar cause that, briefly explained, it may be of interest to some.

That year white clover was quite abundant, and blossomed luxuriantly on low land, but it yielded very little honey. Basswood blossomed in great profusion, and yielded well. At that time I was running nearly 400 colonies for comb honey. They were located in three yards, all of them near basswood. Sections by the thousand were being (to borrow another's expression) "filled as if by magic."

I was keeping close watch of the bloom, and in a short time I noticed the blossoms were beginning to fall off very rapidly, to such an extent, in fact, that myself and assistants considered it best not to put on any more empty supers, in order not to have a large number of unfinished sections at the cessation of this basswood flow, which is the end of the white honey harvest here. Therefore, everything possible was done to meet the conditions of a flow which it was believed must very soon cease.

In a short time the trees were bare of blossoms, but there was not much, if any, left up in the amount of honey coming in. Investigating the matter it was seen that the bees were working on the blossoms which had fallen off and lying on the ground. But I did not believe that these blossoms would, or could, yield more than a day or two, but they continued to yield day after day. Still, I could not believe it was best to put on more supers until they had about ceased to yield. I believe there would have been nearly as much gathered after the blossoms had fallen as while they were on the trees, if room had been given to store it. But how they could yield honey after they had fallen the way they did, has always been a mystery to me. There was no rain while they were yielding on the ground, and if I remember rightly, none for some time before they commenced to blossom. From what a few colonies did, on which empty supers had been left, I have no doubt that a number of thousand pounds of honey was lost by crowding the colonies the way they were.

I believe the peculiarity of the basswood flow was that year general over quite an extent of territory, for a number mentioned the matter at the time in the American Bee Journal.

I am aware that there are many who consider it unwise to restrict colonies too much as to room in order to get as many sections as possible completed, even if there are poor prospects for the flow to continue, for they regard a large number of sections containing drawn comb as very desirable for use the next season. I have used many thousand sections containing full and partly drawn combs, but I have entirely discontinued their use even for bait sections, for the reason that in this locality at least first-class comb honey cannot be produced in sections containing comb drawn out the previous season.

When the comb-leveler is used, and the combs partly melted down, the honey in such sections may look fully as well when they are filled and sealed, but the old comb is tough and hard compared with new comb, and, besides, some seasons, at least, the honey itself, when put in drawn comb, is not equal to that which is put in fresh-built comb; for the latter is filled more slowly, and on this account better ripened, and has a richer and finer flavor.

Of course, if the comb-leveler is used, and the side-walls entirely removed, there is no material difference between what is left and so much foundation, but with me bees work the base thus left less readily than they do fresh foundation, and after considering all things in regard to this matter carefully, my practice of late is to render all drawn combs in sections at the end of the season into wax. But it is undoubtedly a fact that with drawn, or partly-drawn combs, a good deal more honey can be secured some seasons, possibly some more any season when any surplus is produced—honey that may look fully as well as that built from fresh foundation, but, as I have said, the quality is inferior, and much more so some seasons than others.

I will say for the benefit of those who may be intending to use drawn comb for the first time this season, that it is necessary, when combs are fully drawn or built out, to melt or remove in some way at least a small portion of the outside surface in order to have the honey in such combs appear first-class.

As to the use of bait sections, I believe their value has been over-estimated. I have no trouble about work in supers being commenced soon enough without their use, provided, of course, the yield is such that surplus work can be done. What I consider of great importance in order to have bees work

freely and willingly in supers, is to have them so the bees can easily get into them. With some sections and surplus arrangements sent out it is hard work for loaded bees to get into the sections. Southern Minnesota.

Strengthening Colonies by Exchanging Hives.

BY G. M. DOOLITTLE.

The plan of strengthening weak colonies of bees by exchanging the hive containing such colony with one having a strong colony in it, putting each on the stand formerly occupied by the other, is one which is quite generally adopted with good results, and I am asked what time of the day is best to do this exchanging. Some claim that it matters not when the exchange is made, for if made at midnight the bees come out in the morning without realizing any change has been made, and upon returning from the field go to the old location the same as if nothing had happened; hence the weak colony will receive as many bees in this way as they would if moved when bees were at full flight.

Perhaps a little looking into this matter would do no harm. When a colony is in a normal condition the young bees go out to take their first airing at the age of six days, if the weather is favorable; and in doing this they mark their location to a certain extent, but not to an extent great enough so that subsequent flights have a greater impression on their memory, for we find them taking these markings anew at every flight till they become field-workers, after which they take no more markings during the working season unless it be in the case of a swarm, or some very rude disturbance of their home.

If the hive is moved at midnight, on the coming morning all the bees over 16 days old, upon going to the field leave in a straight line, and having the location established in their memory, and not taking any markings that morning, come back to the spot where the old entrance used to be; consequently they go into the hive of the weak colony (if such has been placed on the old stand) or are lost, if no such provision has been made.

But suppose we wait till about 2 o'clock p.m., at which time all of the bees under 16 days old and over six days old will fly if the weather is fine, and we shall find that these young bees head toward the hive the same as they did the last time they were out before, hence notice the change which has been made, and instead of going to strengthen the weak colony which has been placed on the old stand, they return to the spot last marked, hence do nothing toward the desired strengthening. Now, had we waited about this changing till these young bees were in full flight, and moved the hives when the most of these young bees were in the air, we would have caught these also, in addition to all those which were over 16 days old. Then 10 of these young bees are worth 30 or 40 of the older ones for strengthening weak colonies, inasmuch as they are just commencing life instead of being near its close, as many of the field-bees must of necessity be.

Thus it will be seen that if we wish to secure the best results from this exchange of colonies, it should be done when the greatest number of young bees are flying from the hive, for we shall get the old ones in any event.

Onondaga Co., N. Y.

The Plain Section and Fence Separator.

BY G. S. CREGO.

Reading the contribution of J. S. Scott, of Utah (page 224), on the subject of no-bee-way sections, leads me to ask, as a matter of information, in what particular the plain sections are an improvement over the old 1½ section, open at top and bottom.

As I understand it, the cross strips on the fence separator effectually shut up the two *sides* of the section, leaving only the ordinary bee-way at top and bottom, with perhaps some advantage gained by allowing the bees to go freely through the separator.

For my own use I have adopted the 1½ section open on four sides, which allows the bees to run along the separator from end to end, as well as from top to bottom.

To give them still further freedom of action in the super I slot all my separators; that is, with a sharp knife and a straight-edge I cut out a strip ⅜-*inch* wide the full length of the separator with the exception of about 1½ *inches* at each end. This slot, being in the middle of the separator, allows the bees to go from section to section *through* the separator. As a result, the comb honey put up in such sections last season

was unusually fine in appearance, sections averaging very nearly one pound each all through, and many of them showing no "pop-holes" at all. Having an opportunity to go through the separator the bees seem willing to abandon, to a great extent, their usual habit of going through the section.

I should like to have some of our prominent bee-men try this plan, say with a hive or two, and note results.

Cook Co., Ill.

[As Dr. Miller is accustomed to having questions of all kinds "fired" at him, we sent him Mr. Crego's, and in answer received the following:—EDITOR.]

In answering Mr. Crego's question I may take the opportunity to refer to the article he mentions, on page 244, written by J. S. Scott. One who reads that would be likely to understand that the "Medicine Man of the Marengoes" had advised the adoption of the plain section. I cannot imagine upon what Mr. Scott can base any such idea. I have not decided to adopt the plain section for myself, and would hardly advise any one else prematurely in such a matter. I don't know whether such a thing is advisable or not, but I want to find out. If I think I can make money by adopting the plain section, you may be sure I'll adopt it, otherwise not. I suspect there are advantages claimed for it that will not pan out in actual practice, and on the other hand objections are raised that have a foundation in fact.

I am confident that the "Sage of Medina" is entirely honest in believing that the adoption of the plain separator and fence will lead to material gain on the part of the comb-honey producer. Whatever may be the price now of an irregular style of section, there is no question that if the plain section becomes one of the standards it will cost less than the old style. The claim is made that fences will cost less in the long run than plain separators. I don't believe that is true. On the other hand, I don't believe that there is ground for the objection so persistently urged that inexperienced clerks will make such havoc in handling plain sections. I don't believe there's a man who makes that objection who doesn't handle his sections by the narrow part at the top, where the comb comes just as close to the edge as does the comb in the plain section.

At the same time I believe it's the right thing to discuss fully the advantages and the disadvantages of making any such change, and I am glad Mr. Scott has spoken his mind.

All this is a long preliminary to answering Mr. Crego's question, in what particular the plain sections are an improvement over the old $1\frac{1}{2}$ section, open at top and bottom. The one distinct particular in which they are an improvement is the fact that in connection with a cleated separator, whether that separator be plain or fence, the section has the appearance of being better filled, and as a matter of fact is better filled; that is, the surface of the comb comes out nearer the surface of the wood. It may be just a little difficult for those who have always used nothing but sections with bee-ways and separators to understand this. The older members of the craft who remember the introduction of separators will have no difficulty. An objection to the adoption of separators was that they gave the section of honey a lean look. No one denied that the section had a less inviting look, but the advantage of having sections that were always straight and would make no trouble in packing were so great that the lean look was endured by most, but some have hung out against the use of separators till the present day. Whether the plain section will bring back the desired plumpness of appearance without costing too much, or bringing some other evil in its train, is a question to be answered by actual trial.

I think Mr. Crego is mistaken in supposing that "the cross strips on the fence separator effectually shut up the two sides of the section." In the latest fences the cross strips or cleats do not come out flush with the edges of the section, but cut short of that, leaving a passage-way at the corners from one section to the next one abutting against it.

Sections with openings on four sides, as also separators with slots made by machinery, have been in use to some extent for a number of years.

C. C. MILLER.

Is a Colony an Organism?—A German Controversy.

BY REV. H. ROHRS.

The American Bee Journal, on page 151, mentions for the first time of an American bee-paper, so far as I know, the controversy that is going on in Germany as to whether a colony of bees is an organism or not, and says that Editor Lehzen, of the Centralblatt, "seems to think time and ink can be

better spent in matters of practical importance." Now, I do not coincide with Lehzen, and if the "Beedom Boiler" had studied the question at issue I think he would have made more of this important question—Is a colony an organism?

The old school, with Dzierzon, says: The single parts are (each for itself) one organism; the whole can only, therefore, be called an organic formation.

The new school, with its champion, Rev. F. Gerstung, say: A colony of bees is one organism; the single parts (comb, queen, workers, drones, brood, supplies) are the organized members of the whole. Dzierzon replies: That is all nonsense.

To understand this question better let us first see and hear what an organism is. Webster says: "A being consisting of parts of which the functions of each are essential to the existence of the whole and of each of the parts; a whole, of which the parts are reciprocally means and ends." A horse or a cow is an organism, for it can and does subsist independently, but that cannot be said of the worker-bee, or queen, or drone, or any other part of the colony. Each one must perish if taken from the whole, of which they are only parts, being reciprocally means and ends to the whole.

Every one can see that the new school of Gerstung is right and Dzierzon and his followers are wrong; and all their ridicule and desperate fighting has been of no avail. From year to year Gerstung's friends and followers have increased rapidly. Why? Because whoever has tried his theory and system had more honey to harvest than the men of the old school.

Gerstung has published several pamphlets and books—his bee-journal—*Deutsche Bienenzucht*—has nearly 7,000 readers. I advise every one that is able to read German to get Gerstung's books. By his theory many a riddle is solved concerning the development of the brood, its nourishment, the building of worker or drone comb (the cause of it), of swarming, and of successful wintering. I hope to be able to say more of the last thing in the future.

Rock Co., Wis.

An Address to All Colorado Bee-Keepers.

BY R. C. AIKIN.

DEAR FELLOW BEE-KEEPERS:—There comes from all quarters a cry for help. Prices are low, and the questions confronting many apiarists are, "Shall I cease to keep bees?" Or, "How and where can I profitably market my product?"

Suppose you do cease bee-culture what will you engage in that will better your condition? Other lines are as full as ours, and the same story comes from all producers—"too many already in our line of business."

There is not too much of anything produced, surely not when thousands are starving and millions have not any of the luxuries, and millions more have scarcely the necessities. Were the products better distributed, and had the people the money to buy, all agricultural products would find ready sale, and we would be happy and count ourselves prosperous.

Of all products that are poorly marketed honey is about the worst of all. You have only to compare it with other things to convince yourselves of the truth of this statement. Cattle, hogs, sheep, wheat, oats, corn and other grain, as a rule, have a market—places in nearly all communities where they can be marketed, and usually for cash. I am not here discussing whether the price paid is just and profitable—almost every one knows of that; but the fact that they have markets and market values. Butter, eggs and potatoes also find a market at almost every grocery, and can be sold at some price in every city or village; but honey—well, it usually begs a buyer everywhere.

In apiculture every man is a law unto himself—produces, grades and packs to suit himself, so that there are scarcely any two lots of honey that are alike—no regularity, either in quality, appearance, supply or demand. We sell our honey wherever we can, and take what we can get, as do more or less all producers. We cannot expect to have full control and get any price we may demand, for the all apiarists in the world were organized in one united company, there are still the great systems of commerce to deal with, monster combinations and trusts whose objects are to control and manipulate everything within their reach to their own profit, the introducing of our product and getting the people to want it, and the great multitude of things we have to contend with.

It is just as impossible for the individual producer to meet these contingencies as to swim ashore if dropt in the center of Pacific Ocean. The individual producer can do much in his or her own community, produce a good article and introduce it at home, and in so doing help in a three or four fold way. In

marketing at home you become more independent of the middle-men, transportation companies, trusts and combines or other agencies whose aim is to sit in ease and comfort, and at the expense of the producer by getting a share of the profits. You make a demand at home that brings to your pocket a portion of the money that otherwise would be sent elsewhere for other sweets that your honey takes the place of. In selling at home you keep that much off the market elsewhere, avoiding in-so-far a glut and deprest prices in general markets. Your product being introduced into the homes of your neighbor producers in other lines, educates the people to the use of honey, and so makes a demand that will spread from locality to locality, thus increasing the general demand.

ORGANIZED METHODS.

There are, however, many localities that produce more than can be sold at home, hence must ship. The honey-producer can no more succeed in individual shipping than can the grower of a few cattle, hogs, sheep, poultry, eggs, or the many kinds of grains or farm products. We must sell and ship by organization, or through those agencies that are in a position to find out, and whose business it is to know when, where and how to get the product to the place of demand, to introduce and make demand where there is none.

The Colorado State Association was organized to aid its members and our pursuit. It has already been a great help to many apiarists, and is now at work to accomplish much more; and if the apiarists of the State will come in at once they will be surprised at what we can and will do.

While much has been done by the Association, much more that has been planned has failed for lack of a little help from all interested. It was through the efforts of the Association that we got a foul brood law. Part of the State that is the most thickly populated with bees, and where the disease has existed for years, through the aid of the law has been saved from the ruin of its apiaries.

We have now undertaken to do more than ever before, by taking hold of the marketing matter. This Association is still looking after the matter of legislation, and propose to guard the interests of the apiarists of the State along that line, but the matter of marketing is a very vital matter just now, and demands our attention.

Fellow apiarists, it is impossible for us small producers, shipping independently, to combat the many contingencies that confront us. Even the largest producers in the State are almost helpless in the general markets. So gigantic is the matter of conducting commerce, transportation and distribution of products and manufactures, that any person or organization handling or shipping goods in less than car or train lots is scarcely noticed.

It would take almost volumes to elucidate these matters in detail. The statements offered ought to show you the need of doing something, and that quickly. Don't say it is no use for you to become a member of the State Association because you live so far away you cannot come to Denver to attend meetings. It costs you just 50 cents for a year's membership. There surely are 500 bee-keepers in the State who ought to be members, and if they were, we could do much more for you. Just an advance of one cent per pound on 50 pounds of honey pays the bill, and if you cannot attend you can vote by proxy or written ballot. Ladies' membership only 25 cents.

Friends, a few of us have for years kept the organization alive, paid our annual dues, attended meetings at our own expense for car-fare and hotel bills, watcht over the interests of bee-keepers at the cost of time, labor and money. Won't you now send your name and fee and become members? The fees will help us in printing expenses, in hunting out adulterated goods and having them analyzed—some such work having already been done. There are postage and stationery bills to pay.

We are now hard at work trying to get the marketing done by our own Association where all bee-keepers will have an equal chance. We propose to fight adulteration and other evils, and do you good. Help us by your means and your influence, and thereby help yourselves.

Carefully read this and all matter which we send you, and sign and return promptly such as is calculated to be so used. Do not neglect the statistics. We want to know the resources of the State, and we want to put our honey in many markets. Colorado honey sells wherever it is introduced. There is probably not a State in the Union that has better honey than ours, and a little push in marketing will sell it wherever it goes.

Your membership in this Association will get your reduced rates on supplies. We now have rates that will save you much more than your membership fee, even tho you buy but a very few goods.

We propose to do something, and while we are helping

the members of the Association we are helping all apiarists more or less; but you ought not to expect others to labor for your good without helping some, nor can you get nearly so much good outside the organization as if members.

All moneys are accounted for at each annual meeting, and each member has the privilege of examining the records, and may know how the funds are used. Could we afford it—and we could if all would support the Association—printed statements would be sent out to all members so that all might know just what was being done; but as yet we have not had the means to do this, hence only those in attendance at the annual meetings hear or see the complete reports.

Again I appeal to every bee-keeper in the State to promptly send to our Secretary your membership. Write to him anyway. Ask for information. Send names of every bee-keeper you know of. Get others to join with you. Colorado is a big State, has lots of apiarists, much honey of fine quality, and can, will, and must show what she can do.

LATER.—Since the foregoing was written another meeting of the State Association has been held. At this meeting there was a unanimous vote to sustain a marketing organization. Now a little thought will convince all that a committee of five or six members will not be able to organize a marketing concern without some of "the substantial" in the way of capital, and since the State Association has not the funds in the treasury, and the committee have no specific orders from the Association to so use Association funds, nor as to the form of the organization, nothing can be done in the way of carrying out this work officially as a part of the State Association work. The time is ripe for something to be done, the Association have unanimously voted to support a move of the kind, bee-keepers all over the State have signified their desire for something to be done at once, and their willingness to help, we therefore expect to go ahead and get the matter started. After the machinery is going the State Association can then take up the matter at a later convention, and so make it officially the Association work. As it now stands the committee only have delegated to them a limited power, and to act to the full carrying out of the matter must do a considerable part of it on their own responsibility.

Now, friends, some capital is needed to start this matter. Let every member of the Association who will take a few dollars of stock write me at once and tell me how much you wish to put in. Also every Colorado apiarist who reads this write me even if you are not a member of the Association; tell me how much you are willing to put in, either of cash or honey, or both, to start the thing. Our committee will soon have a plan formulated upon which to begin operations, and a copy will be forwarded to those who wish to take stock. You are not askt to pay a cent into the matter till you have seen the plan in print, and I agree to send the plan to those who will send in membership fees to the State Association, or to others who wish to take stock. Editor York cannot afford to print this, nor I to send it out, without some compensation in some way, so be sure when you write to put in at least one stamp. I do not know what the editor will charge me for putting this in the American Bee Journal, but I am going to risk it for the good of the cause, and if I have a bill for advertising to pay—it is really an advertisement for Colorado apiarists—I guess I can pay the bill if the brethren will not help me out.

Now, friends—those of you who read this and are not now subscribers to this paper—just send your subscription to Mr. York, and while he has never said such a thing to me I feel sure he will let me off without any pay for printing this, tho I expect to compensate him for its publication. In sending subscriptions say you do it in reply to this appeal. The honey season is close at hand, and what is done in this marketing matter must be done quickly, so be prompt in sending your communications to me.

R. C. AIKIN,

President of the Colorado State Bee-Keepers' Association.

Loveland, Colo.

Improving Bees—Foul Brood, Etc.

BY C. A. BUNCH.

The only practical way to improve the working or honey-gathering qualities of our bees is to breed from colonies that will store the most honey. If this is followed out we need not go to the bother to measure their tongues.

For this locality I believe it very essential to have a strain of bees that will work well on red clover, for last season there was scarcely any honey gathered about here in the month of June except red clover honey, of which I took in the extracted form to the amount of 600 pounds, one colony storing some

over 60 pounds of this honey before basswood came into bloom—being the largest amount of red clover honey gathered in one season by one colony of bees that I know of, while the average of red clover honey per colony was but 30 pounds.

I breed several strains of Italian bees, but I have no queens for sale. I wintered 89 colonies out of 91 on the summer stands.

Separators or no separators, fence or no fence, plain sections or sections with bee-ways—well, it puts my head in a swirl. The finest comb honey put on this market is produced by a bee-keeper that never uses separators or fences, but uses plain sections set a bee-space apart in the super. Bees go all around the sections except where they rest on the bottom of super. All the first-class grocerymen here know Deitel's fine comb honey stored the way I have mentioned.

Query:—Is there a bee-keeper on earth that can use two S-frame Langstroth hives, one on top of the other, with sections above, and have anything like success at producing comb honey? If such a one lives, let him tell us how it is done.

Foul brood—a caution: I have never seen foul brood, but I fear it as something awful, and as a measure of safety when receiving queens by mail I let the queen out in the shop on the window, then catch and introduce her with one of my own cages, and burn the cage I received her in.

Marshall Co., Ind., April 28.

Some Wintering Experiences—Various Notes.

BY O. B. GRIFFIN.

It is with much interest that I always turn to Dr. Miller's department of the American Bee Journal. It is particularly helpful to the beginner, and even the veteran must get some new ideas, and reminders of what they may well know, but through attention to many cares would neglect but for the questions asked by those who have just entered the fields they have already past over. As I class myself with the beginners (tho I have owned and cared for bees nearly 10 years, never having over 20 colonies at one time), I hope the Doctor will not think me presumptuous in attempting to throw light on questions he has already replied to.

As there is a cause for everything, and also a remedy if we can but find it, I have always tried to find them when I have been confronted by anything that was detrimental to the successful care of bees.

The winter problem has given me more trouble than any other with which I have had to wrestle. When I was younger, and knew less about bees than I do now (which is little enough), I built a repository in which to winter my bees, very similar to the one described by "Wisconsin," on page 38. I had it arranged so that it had excellent drainage and ventilation as desired. That winter I placed therein 17 colonies of bees with plenty of stores, but quite a percentage of the stores was "honey-dew." Only six came through alive. Five of these were very weak and queenless, so I let them "peter out."

As I had been to considerable expense, and believing the honey-dew to be the chief cause of the failure to winter, the next November I again put in three colonies—one a choice Italian—and all with plenty of well-capt white honey. During the winter the mercury in cold spells would drop to 36°—at times it would reach the freezing point. At such times I would warm it up to 40° or 45° with an oil-stove, but in the spring all were dead.

The winter of 1896-97 I wintered bees in the cellar under the house, and they came out strong. I had five colonies in the same cellar the past winter, and tho the temperature remained near 40° (never below) they wintered finely. I could lift the cover and hold a lighted lamp near the hive without disturbing them.

From my observations I have come to the conclusion that the wintering problem for northern latitudes is solved, if the following requisites are closely observed:

1st. Healthy bees and plenty of pure white honey, or pure sugar syrup fed early in the season, if honey is a failure. From my own experience, which is somewhat limited, I give honey the preference. I would not extract honey from the brood-combs and feed sugar unless the honey was of inferior quality. In such cases I think it best to do so every time. But syrup should be fed early enough so as to be nearly all capt before cold weather sets in.

2nd. A dry cellar, or any other repository where an even temperature of 40° to 45°, or that temperature at which the bees are quietest can be maintained without the aid of artificial heat.

3rd. Last, but not least, pure air and quiet.

I do not think "Wisconsin" can be successful with the repository described, for a term of years. If he is, I hope he will report occasionally.

Somewhere—I think in Dr. Miller's department—I saw the question asked, why bees sometimes store so much pollen in the sections. I have had several bad cases. They occurred under these conditions:

A prolific queen, with brood-frames crowded with brood and little honey, with very little pollen. As pollen was needed they stored in the next nearest available place—the sections. I have had the most trouble in hives having small brood-chambers. The remedy would be to give such queens more room below.

FINDING BLACK QUEENS, ETC.

I have always had lots of bother in finding black queens in populous colonies. Last season I hit upon the following plan, which may help beginners where frame hives are used:

When the weather is warm enough so there is no danger of brood being chilled, take several hives—or prepared boxes that frames will fit—and proceed thus:

Move the old colony a short distance from the old stand and set an empty hive in its place. Set the empty hives near, and after using a little smoke open the hive and take out all but two or three frames, one at a time, glancing over them if you wish, as the queen may be seen. Set two or three frames in each hive, and cover up. In a few moments there will be excitement in all the hives except the one containing the queen, and the bees will be returning to the old stand.

Take the frames from all except the quiet hive and return them at once to the old stand; then proceed to find the queen. There is not much trouble to find "her majesty" when you know she is on one of two or three frames. This really takes less time than it does to write it.

I shall agree with the Editor (page 152) that it is a mercy to "Miss Flora" that her address is not given. Methinks some who might better be clad with the "old baches" rather than young bee-keepers, would be sending her flowery notes, and "hanging around" the postoffice awaiting replies. I am quite sure that if I lived near J. A. Golden's, I should be very much interested in that section-honey cleaner.

Say, Dr. Miller, are you not leading "Youngster" and "Tennessee" to expect too much of mortal woman, or is there all that difference between the women of Illinois and Maine? Why, if there was such a girl living near me I would go to her at once and ask her to—well, never mind what, but I should insist upon an answer in the affirmative before I came away.

I hope Editor York will not put the latter part of this article among the advertisements and send me the bill; for, tho like "Bachelor Hasty" and that Whitebread fellow my hive is "queenless," it is not intended as an advertisement.

Aroostook Co., Maine.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condense treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

[Continued from page 294.]

The committee on supplies reported that low prices had been offered by supply firms. It was voted to refer the matter to the Executive Committee for action. (The prices quoted are only made to Association members.)

Mr. F. L. Thompson next read the following paper, entitled,

Conditions of the Pursuit in West Colorado.

From what I could learn it seems that bees winter better there than around Denver. This may be due to the less rigorous winters, from which our low drops of the thermometer and northern blizzards are said to be absent; or it may be due to a better chance for development at the critical time in spring, or both. I arrived there too late to judge of the latter point, but noticed that the bees were busy enough at something to keep them out of serious mischief from that time until the main flow, which commenced June 11—a week earlier than at Denver. Fruit-bloom was abundant while it lasted, and in future years will doubtless greatly increase, as the neighborhood of Montrose is pre-eminently a fruit country.

A few bee-keepers down the river secured quite a fair yield from wild flax, which has never before given a surplus since the country was settled. I was told that the river-bottom gave a better flow of honey during the first half of the season, and less during the second half, than the mesa, on which I was, and I found it so last season. A high wind which prevailed during most of the first crop was exceptional, I was informed. I sincerely trust it will not occur again; for few things are more exasperating to the bee-keeper than a prolonged wind in the honey-flow. My average per colony, spring count, was 47 pounds of comb honey, which I was told by some was rather a poor yield, tho as usual in most localities there was some difference of opinion as to what constitutes an average yield. But I believe it has not gone below 40 pounds.

Swarms were abundant, and the Heddon method of preventing after-swarming but moderately successful with me—in fact, something of a failure. While the colonies were very strong at the opening of the first crop, they had dwindled rather more when the second crop came than I ever observed them to do around Denver. This trait of the Italian bee—of curtailing brood-rearing—is well enough for a single flow, but is certainly undesirable for Montrose country.

Poul brood has never existed in the county.

Alfalfa is the main dependence. Some autumn honey-yielding plants, as here, seem to vary the character of the honey. A hundred-acre field of Alsike near one bee-keeper gave him more of a variety. I tasted some comb honey which seemed to be from that source, and while it was not bad, I should prefer white clover, which I once tasted. I noticed a few scattering plants of cleome, and was told that off to the southwest there was considerable of it, but I do not know that it figures much in the honey-yield. Sweet clover and scattering alfalfa, and chico—a very abundant shrub, blooming throughout the season—bridge over the interval between the two crops at the rate of perhaps a pound a day.

The phenomena of the granulation of comb honey are about the same as here. First-crop honey properly kept does not, I believe, as a rule, granulate before it is consumed. The bulk of the second crop can also be sold without any particular hurry. But the latest honey is strongly inclined to granulate quickly. It is interesting to note that one bee-keeper there has observed just what has been observed elsewhere, namely, that early alfalfa comb honey gathered in damp weather does not granulate at all, but when gathered in dry weather is more inclined to do so, tho, as I have said, it does not as a rule granulate before being consumed.

The first-crop honey is second to none in color. The second-crop is so distinct in appearance that it can be told at a glance. It is not dark, but is unmistakably amber. One Montrose bee-keeper says that years ago both were white, and attributes the change to the weeds which cultivation has brought. Another thinks the difference in color of honey is

analogous to the difference in the color of the hay of the two crops of alfalfa, the second crop being a darker green.

Local freight-rates from Denver to Montrose are \$1.10 a hundred on bee-hives in the flat, and a cent a pound for honey from Montrose to Denver. Foundation of good quality can be procured there as cheaply as here, and last year the same was true of sections. But shipping-cases were 17 $\frac{3}{4}$ and 18 cents, and weighed almost five pounds apiece at that. Montrose being situated on a narrow-gauge railroad, shipments outside of the State have to be reloaded at Salda.

The greater part of the honey appears to go to Kansas. Those who preach that to sell outside of the home market is a sin, ought to produce honey at Montrose. They would be effectually cured of that propensity. Farmers' honey is produced in quantities sufficient to more than supply the whole county, and the teams with farm products which constantly go up to Ouray and Telluride keep those towns supplied with this farm honey. Gunnison is but a small town, and Leadville and Aspen are more directly controlled by the Grand Junction district. Salda is much nearer Pueblo than Montrose. The southern towns—Durango, Rico, Silverton—are supplied with honey from southwest Colorado, much of it being farmers' honey.

On account of the inevitable shipments and the high freights I should not advise any one who owns an apiary in an ordinary location in eastern Colorado to pull up and change to the western slope.

I have been asked to add to this paper some remarks on the importance of the honey-industry of Colorado.

F. L. THOMPSON.

[The "remarks" referred to above will be given next week.—EDITOR.]

[Continued next week.]

Does this Mean You?—It does if your subscription is in arrears. In the Rural Californian for April we find the following editorial paragraphs:

THE UPS AND DOWNS OF NEWSPAPER LIFE.

It may be that the ups and downs of newspaper life nearly balance each other, but there is considerable evidence that the "downs" are more frequent than the "ups," as they are surely more difficult to bear. Be this as it may, a disproportion can easily be established, and the solution is largely in the hands of subscribers. The subscription to a newspaper or magazine is a very small amount. The usefulness of the periodical is almost invariably far beyond its price. Subscriptions which are not paid promptly, or on which a percentage must be paid to cover cost of collection, postage, etc., represent a very little net income to publishers. The benefit to them, as well as to readers, would be greatly increased if subscribers were always to pay promptly in advance and renew without frequent solicitation.

Life generally has so many "downs" that many people must walk on their "uppers." The high road to prosperity is a delightful one to travel, but it is very high and rarely reached in these days.

The charm of newspaper life is rather in the editorial end, not in the business department, for debts are sometimes pressing the manager while the delinquent reader is forgetful that his attention might bring relief. The "ups" in the newspaper business really belong to the readers; the cares of the newspaper business do not attach to them.

If there is one thing that we dislike to take up our editorial space with it is the request that subscription arrearages be paid. And it is hardly fair to those who always do pay in advance, to occupy that space with calls on those who are delinquent. Of course we *could* stop off short every subscription when it expires, but very many wouldn't like to have us do that—they'd think we certainly could trust them for a few months or a year. But that means a good deal to us when two or three thousand think the same way, and do not pay.

Again, we could send a personal letter to each delinquent, say once a quarter, but that means an outlay of from \$50 to \$75, which could be so much better spent in getting more engravings for the Bee Journal, using a better quality of paper on which to print it, etc. Say, why not *all* who are behind in their accounts just pay up without a private request, and thus help make a better paper, and also make it easier for the publishers?

GEORGE W. YORK & Co.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. O. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Wintering Bees Under a Shop.

Would it do any harm to winter bees in the cellar under a shop with a single floor under the shop where there is pounding?
MICHIGAN.

ANSWER.—It will probably be a good place if the cellar isn't too cold.

Yellow vs. Darker Bees.

I have lots of combs in fair condition, and if I could get a pound of bees and queen of the yellow kind, would they be as hardy as the dark Italians so far North?
MAINE.

ANSWER.—Some say they are as hardy as the darker ones. Others, and perhaps a larger number, say they are more tender. Very likely they are not all alike.

Queen's Piping, Etc.

1. Does a queen make the piping sound with her wings, or voice?

2. I opened a hive and found an empty frame of comb, and put it by the frame the queen was on so that she would go on it to lay next. Having a frame like that paid for all the trouble it made the bees, did it not?
KANSAS.

ANSWER.—1. With her voice. She'll pipe just as loud after every vestige of a wing is cut away.

2. Very likely, supposing the empty frame took the place of one filled with honey and you didn't put the frame between two frames of brood.

Laying Eggs in Bunches.

I have one colony of bees which was rather weak in the fall, and seemed to work all right in March, but it is growing weaker every day. I lookt into the hive and found only about 100 bees in it. The queen is young, from last summer, but she lays her eggs in bunches, from 5 to 20 eggs in each cell; also, I found some chilled brood. What shall I do with the queen? Is she any good, or does she lay her eggs in bunches because there are not bees enough to take care of all of them?
NEBRASKA.

ANSWER.—The queen may be all right, and she may be all wrong. By the time this reaches you probably some of the brood will be sealed. If it appears flat, just like the most of the sealed brood in the other hives, she's all right. If, on the other hand, the sealing looks like a lot of little bullets laid together, the brood is all drone-brood, and the queen worthless. In any case, if only 100 workers are present it's hardly worth while to try to keep them, and the best thing will be to unite them with another colony.

Cleaning T-Tins.

How do you clean your T-tins? You seems to have an easy job of it, and altho we use lye we can't get them clean in one-fifth the time you do. I like T-tins, but I do not like to clean them.
COLORADO.

ANSWER.—There's very little to tell. The probability is that failure to succeed perfectly would come from one of two causes: Either the lye wasn't strong enough, or it wasn't hot enough. The lye must be boiling hot, and kept boiling hot while cleaning the tins. We used a metal tub on a gasoline stove. Filled the tub $\frac{3}{4}$ full of water, brought it to a boil, put in three 1-pound cans of concentrated lye, and were ready for operation. Put in as many T-tins as the tub would hold. In two or three minutes they were ready to take out. With a pair of tongs they were stirred a little so the lye would reach every part, and as soon as they lookt clean they were lifted out into a tub of clear, cold water. This rinsed them off and

they were put into the boxes in which they were to stay, the boxes being set on eod in such a way that the water would drain off readily. But they were not lifted out of the rinsing water immediately, for the first thing to do after lifting them out of the hot lye was to fill up the lye with a fresh lot. This cleaned 2,200 T-tins and was strong enough to clean more if we had had them. If they don't lift out of the hot lye perfectly clean, you may be sure it isn't strong enough.

Now, I've told *all*, I think, and wish you'd tell us why you don't use section-holders instead of T-supers. One reason I like T-supers is because the T-tins are so easily cleaned.

Moldy Combs.

I have five colonies of Italian bees, and wintered them all in the cellar. They were in good condition in the fall when taken in, and now I find all are doing well with the exception of one colony, which has mold on one of the outside frames in patches all through the comb, and in small patches near the bottom of some of the other frames. There is no brood except on two or three of the frames. What caused the mold, and what shall I do with it? Should I cut off the mold, or put in new foundation?

ANSWER.—No, don't cut out the mold. Just let it alone and the bees will take care of it all right. The mold came there just in the usual way because the cellar was not ventilated quite enough. The other colonies, being stronger, kept their hives better ventilated.

Young Bees in the Super—Rag Smoke.

1. I have a colony of bees I would like to know what to do with. I left the 60-pound super on it all winter, and lookt at it the other day and found it filled with young bees. What will have to be done with them?

2. Is rag smoke injurious to the bees and honey? If so, what is the best to use in the bee-smoker?
NEBRASKA.

ANSWER.—1. Depends a little on circumstances. If the super has frames the same as the brood-frames below, then you can do nothing better than to let the bees continue to occupy them, taking away the lower story if you think it has too much room. If, however, the 60-pound super contains sections, then you must work the bees out of them. Make sure that you get the queen into the lower story, put a queen-excluder between the two stories, and in three weeks all the worker-brood will be hatcht out, when the super can be taken away.

2. Rag smoke is all right. Of course it isn't a good thing for you to smoke them more than is necessary, and if you use too much smoke on honey it will taste of smoke.

Cage for Mating Queen—Jumbled-up Combs.

1. Is there any contrivance for caging a young queen after she hatches, and while being mated?

2. I have three colonies in good Langstroth hives (they are brown bees,) but I used no brood-foundation and they are all in a jumbled-up condition. It is impossible to get the frames apart. I want to give them frames this spring with foundation so as to be able to handle them in a more business-like manner, also to requeen with Italian queens. In what manner can I do it to get the best results, and at the same time get some increase in swarms?
ILLINOIS.

ANSWERS.—1. Surely not, for the queen is not mated in confinement, but out in the open air. If you can get up any way to have a queen mated while caged, your reputation, if not your fortune, will be made.

2. Perhaps as good a way as any is the following: Wait till the colony swarms, and then hive it on frames of foundation, setting the swarm in place of the old colony, and setting the old hive in a new place. It is possible there may be a second swarm in about eight days after the first. If so, hive it also on foundation, setting this swarm in a new place. Twenty-one days after the issue of the first swarm, drum out all the bees, queen and all, hiving them on foundation, and then cut out and melt up the combs. It will probably be more profitable for you to have only the one swarm from each colony, and if that be your desire, set the first swarm on the old stand, and put the old hive close beside it. A week later move the old hive to a new place. Then 21 days after the time of the swarm, drive the bees out of the old hive into a new one.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

MAY 19, 1898.

NO. 20.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Shipping Bees by Freight in less than carload lots is something greatly desired by many bee-keepers, and we believe that when the railroad men having in charge the arranging of freight rates once see the wisdom of permitting bees in hives to be thus shipped, they will speedily grant the request,

At the last meeting of the Wisconsin Bee-Keepers' Association, Mr. H. Latrop was appointed a committee to investigate this matter, and at once wrote us to see what could be done through the Western Classification Committee whose headquarters are in Chicago. Upon explaining what the bee-keepers desire along the line indicated, to Mr. G. S. Crego, who is a bee-keeper in the employ of the Classification Committee, he suggested that bee-keepers at once write Mr. J. T. Ripley, Room 604, Great Northern Hotel, Chicago, Ill., the Chairman of the Committee, telling him just what is wanted, and giving as many good reasons therefor as possible.

There is no more reason why bees should not go by freight in less than car lots than that live poultry should be limited to carload shipments. Bees can be safely and securely confined by the use of wire-cloth; and of course railroad agents should be careful to see that they are properly enclosed in the hive before accepting them as local freight. But we are not at all fearful that shippers of bees would be careless in this regard.

It will be necessary for bee-keepers to communicate at once with Mr. Ripley, as the next meeting of the Western Classification Committee is to be held June 14, at Colorado Springs, Colo. If favorable action is taken upon the subject there, it may be in time to be of some service to bee-keepers during the present season.

It will be highly advantageous, we think, to have Mr. R. C. Alkin, President of the Colorado Bee-Keepers' Association,

appear before the Committee at its meeting, for the purpose of answering any questions they may wish to ask in reference to the subject under consideration. We suggest Mr. Alkin as he is head officer of a large State bee-keepers' organization, and also because of his nearness to the place of meeting of the Committee.

We would also suggest that Hon. Eugene Secor, General Manager of the United States Bee-Keepers' Union; General Manager Newman, of the National Bee-Keepers' Union; and the Presidents of all other bee-keepers' societies write Mr. Ripley *at once*, so that he may see the desire is general on the part of bee-keepers to have such action taken by the railroad companies as shall permit the shipping of bees by freight in less than carload lots. The transportation lines will gain by the change, for the high express rates on bees practically prohibit the doing of much business in the way of shipping full colonies.

We believe that with the proper effort put forth now, bee-keepers can secure all they desire in this matter. Mr. Ripley, the chairman, is a broad-minded man, and the Committee itself we doubt not is composed of men who will be glad to favor bee-keepers, especially when they see that it will be to the decided advantage of the railroads to grant the petition presented.

The McDonald Relief Fund.—On page 280 we gave the first installment of contributions to this fund. The list stands now like this:

| | | | |
|-----------------------|---------|------------------------|--------|
| Former Amount..... | \$22.00 | Roderick McKenzie.... | \$1.00 |
| Sent direct to Mr. M. | 19.70 | S. P., Uniontown, Pa.. | 1.00 |
| Joseph Uebele..... | 1.00 | Reinhold Liebau..... | 1.00 |
| Volstad Bros..... | 1.00 | R. G. Vaus (Canada)... | 1.00 |
| G. S. Carpenter..... | 1.00 | | |

This makes a total of \$48.70 that we have now reported in the Bee Journal. Mr. McDonald was a Shawneetown bee-keeper who lost his all in the great flood there about two months ago. Contributions are being received by C. P. Dadant, Hamilton, Ill. Send to him what you can afford, if you wish to help a worthy fellow bee-keeper.

The United States Bee-Keepers' Union.—In answer to our question on page 233, General Manager Secor has this to say:

On page 233, Prof. Cook is quoted as saying: "I think we should all unite on *one* Union, and *that* the one that would fight *every* enemy to the knife" That's just what I think, too. I have been keeping my ear to the ground listening for the tramp, tramp, tramp, of the fifty thousand volunteers who are supposed to be rushing to join this Union army.

Isn't the platform of principles broad enough for all to stand upon? Here's the vital clause:

"Its objects shall be to promote and protect the interests of its members; to defend them in their lawful rights; to enforce laws against the adulteration of honey; to prosecute dishonest honey commission-men; and to advance the pursuit of bee-culture in general."

It appears to the writer as tho about ninety-nine out of every one hundred bee-keepers are very willing to let the other fellow do the hard fighting while they quietly enjoy the fruits of the victory.

But says some one, "As yet it [meanlog the Union] has only talkt."

What more could you expect it to do, pray?

In the first place, the infant is only about a year old. It is just learning the use of its legs. If it has learnt to "talk" before it could walk there are some hopes for the child—only precocious children do that.

But, really, does any one think that the General Manager can fight "to the knife" all the enemies of all the bee-keepers in this country without the "sineews of war"? Or is it supposed that one bee-keeper is capable of fighting the battles of ninety and nine who are safely sheltered in the fold of inactive security? Nay, verily. Don't ask us to. Three hundred Spartans defended the pass at Thermopylae, but there is no such narrow defile through which the enemies of the bee-

keeper are obliged to march. We need outposts on every side. If we give the adulterators "war to the knife" the dishonest commission-men will form in our rear, and the sweet clover cranks will attack our right flank.

'Tis a plucky four hundred that have already enlisted, but they need more support.

And something *has* already been accomplished, altho we haven't gone about it with the blare of trumpets accompanied by newspaper reporters.

I have noticed that the best lawyers are not the ones that talk loudest to the jury, or who try to amuse the spectators.

It is pretty generally believed that the walls of Jericho would not fall, now, by marching around the city and making a noise.

It takes powder or dynamite nowadays to reduce the works of the enemy.

If any one knows of a good lawyer who is devoting his best energies to his profession "for his health," I shall be glad to enlist his sympathies in our cause, but I hope no one will expect me to find such an one "lying around loose."

The United States Bee-Keepers' Union can be made the strongest defensive bee-keepers' organization in the world if the intelligent and thrifty bee-keepers of this country will unite.

An organization with a thousand members is a hundred fold stronger than one with a hundred.

The letters coming to this office develop the fact that there is need of a "union of hearts and a union of hands."

The Board of Directors is composed of men of experience and ability, and they are your friends. If they don't turn the world upside down the first year of their official life, don't lose your faith in the power of organized effort.

EUGENE SECOR.

General Manager.

Forest City, Iowa.

Those of our readers who have not as yet joined the United States Bee-Keepers' Union should read over what Mr. Secor says above, four times at least, and then send their fee of \$1.00 to him to help create the defense fund—the "sinews of war" so often mentioned.

We should be glad to hear from the Board of Directors now. Have they anything encouraging to say? We believe in agitation, and think that the New Union should be kept before the bee-keepers in some form constantly. If its objects can be successfully carried out it will mean much to the cause of American apiculture. But to do that, there must first be put in sufficient ammunition to move things when General Manager Secor wishes to "touch off" the Union's "gattling gun." If we ever expect Mr. Secor to be a Dewey in the war to be waged by bee-keepers against their enemies, they must supply him with the munitions necessary to push the fighting to the bitter end.

The Apiarian Display at Omaha during the Trans-Mississippi Exposition promises to be the largest and best ever witnessed. Commissioner Whitcomb wrote us April 28 that the apiary building was then nearing completion. The building is 128 feet by 75 feet, and after Swiss architecture, well lighted on the sides, ends, and from the roof. The cases for the exhibition of honey are located the full length of the building on either side, four feet wide, and arranged so that when the exhibits are in place they can be seen and admired from the outside as well as from the inside of the building. To protect them from the rays of the sun, awnings can be let down as occasion requires. The tops of the exhibition cases are of glass, so that the light from above will in no wise be obstructed.

The entire floor-space, exclusive of passage-ways in the center of the building, will be devoted to the exhibition of bee-keepers' supplies, and for such exhibitors who desire to erect their own honey-cases. Sufficient space has already been taken in this building to insure the grandest and most attractive honey and supply exhibition the world has ever seen, and the expectations of its projectors will in no wise fall short.

By the efforts of Commissioner Whitcomb, applications will be left open to those who desire to secure space to the shortest possible time prior to the opening, June 1, in order

that no one may be shut out who desires to participate in this part of the Exposition.

The buildings and grounds must be seen to be fully appreciated. Douglass county, in which Omaha is located, has taken 300 feet of space in which to show the wonderful honey products of that county alone, and Mr. Aug. C. Davidson, Vice-President of the Nebraska Bee-Keepers' Association, has been appointed in charge. Every grade of honey, wax, sweets, and all kinds of supplies have been cataloged for award, so that any one who has a meritorious article may have a fair opportunity of securing proper recognition when the jury of awards make their examination.

Mrs. Whitcomb has devoted considerable time to the preparation of a wax exhibit, and while we are not at liberty to state what it is at this time, yet we can safely say from what we know of Mrs. W.'s ability, that it has never been equaled, and, like the buildings, must be seen to be fully appreciated.

In the opinion of many who are prominent in the United States Bee-Keepers' Union, no time should be lost in locating the next meeting at Omaha. They feel that as good rates may be secured at Omaha as can reasonably be expected anywhere, and without the danger of being lost in the hurrah of war or an old veterans' reunion. At Omaha the bee-keepers of the East and West can meet on ground accessible to all, and hold such a session as has never before been held. But it is only a question of low railroad rates, which we fear cannot be secured—at least not as low as the Grand Army secures to its meetings, and this year they go to Cincinnati, Ohio.

California Notes.—Prof. A. J. Cook sent us the following, May 4, in reference to the honey crop prospects in Southern California this year:

The white sage (*Ramona polystachyæ*) and the black sage (*Salvia mellifera*) are now in full bloom, but curiously enough very few bees are seen on the flowers. The light rainfall makes nectar-secretion very slight. It looks as if there would be very little honey secured this season, except in places where alfalfa bloom can be counted on. It is to be hoped that in Ventura county beans may help the bee-keepers to secure a crop.

We have just had a nice rain of over one inch. It is too late to help the grain crop, which is almost a total failure; and it is to be feared that it will not help the honey crop. It seems to be the consensus of opinion among our experienced bee-keepers that abundant early rains are a *sine qua non* to a large honey crop. The bee-keepers are despondent this season, but they have abundant company. Owing to drouth and frost, the grain and fruit men are equally unfortunate.

A. J. Cook.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

See "Bee-Keeper's Guide" offer on page 300.

H. G. ACKLIN, of Ramsey Co., Minn., wrote us May 10 :

"Bees are doing well, and the prospect for a good honey crop is good."

Mr. W. B. CHAPMAN, of Orange Co., Calif., writing us April 24, said :

"The honey crop will be *non est* here, and bees will starve out for a certainty. Give us plenty of news of what the other fellow is doing, to keep our spirits up."

Mr. JOHN DOTY, of Grundy Co., Mo., who is a 74-years-old bee-keeper, wrote us as follows, May 12 :

"Bees are all right and doing well. I have 70 colonies : had 38 last spring, secured 4,000 pounds of surplus honey, and increased to 75 colonies."

Mrs. MATE L. WILLIAMS, of Wadena Co., Minn., reported May 11 :

"My 70 colonies came out of winter quarters in fine condition, and the weather has been very favorable so far. They are building up very fast. Very many hives are about full of bees."

Dr. C. C. MILLER spent the night with us Monday, May 9, when on his way to attend the 40th annual convention of the Illinois State Sunday School Association, which met at Galesburg last week. Tho in his 67th year the Doctor is as light-hearted and jolly as a youngster. But he is a very busy man. With his nearly 300 colonies of bees, and all the writing he does for the bee-papers, for the next few months he will have to work about 18 hours a day. We hope he will not overdo. Bee-keepers can't afford to let him off—not even to take a well-earned rest.

Mr. L. KREUTZINGER, of Cook Co., Ill., who has two apiaries near Chicago in charge of Mr. J. T. Hammersmark, wrote us as follows, May 12 :

"Your kind attention is called to the fact that the 'observatory' at my apiary, recently built, has been equipped with the newest improvements and appliances for the purpose of properly testing any kind of modern inventions pertaining to apiculture. Any new production, design or improvement of modern apicultural implements and fixtures will, if sent for that purpose, be subject to a careful examination and practical test in order to ascertain and establish their usefulness and merit."

Should any of our readers desire to send anything as suggested, they can forward it to us, being sure to prepay all charges.

Mr. H. H. BUCKMAN, of Bucks Co., Pa., wrote us May 9 :

"My bees commenced swarming this morning, and are in good condition."

Mr. A. D. FINK, of Jewell Co., Kans., when renewing his subscription, May 9, expressed himself as follows :

"The American Bee Journal is the paper for any person who eats honey, who is contemplating going into the business of rearing bees and producing honey, or who is in the business, and who loves to study the habits of bees."

Mr. J. H. MARTIN, of Los Angeles Co., Calif., wrote us May 3 to send his copy of the Bee Journal to Siskiyou Co., and added :

"This is in the extreme northern portion of the State, near the Oregon line. When we have it dry here in the South they get some droppings from the Web Foot State ; and there is a good prospect of a honey crop there, so I am going to look into the matter."

We will be glad to hear from Mr. Martin again, as to the outlook in his new field, after he gets there.

Ventilating Cellars.—The editor of Canadian Bee Journal proposes to supply air to bee-cellars by a clock-work arrangement that regularly pumps fresh air into the cellar and forces out an equal amount. When the weather is cold, the air is to be forced through a compartment having a stove, and when the air is too warm it is to be forced through a shaft containing ice. But the question may be raised whether any pumping is needed except at such times as those when the temperature outside is just about the same as that in the cellar.

Do Bees Empty Brood-Combs into Super ?—Ten strong colonies had their brood-chamber well filled with brood and stores, the latter being mostly buckwheat. When clover bloomed extracting-supers were put on over excluders. Seven of the ten showed plainly buckwheat honey in the supers, which goes to show that if there's any objectionable honey in the brood-chamber, it should be separately extracted as soon as the bees stop carrying it up, and if sections are to be filled an extracting-super must first be used till danger is past.—Ontario Experimental Apiary Report.

Spacing-Nails in Brood-Frames are supposed to be objectionable when the frames are to be put in the extractor, but actual trial proves that some at least do not find them so. O. O. Poppleton (Gleanings, p. 296) quotes Dr. Miller and E. R. Root to that effect, and says he has himself used spacing-nails for 25 years, finding no trouble with the old style of extractor, but with the reversible extractor the narrow baskets give less room for handling the combs, and the nails trouble by catching. Editor Root replies that the staples they use for spacing come just outside the wire-cloth, the comb-pockets being made shorter than a Langstroth frame.

Prof. Cook on Sweet Clover.—A. I. Root, in Gleanings, quotes Prof. Cook as saying, "I think the plant is worthless except for bees." Mr. Root cannot believe Prof. Cook meant to say just that, in view of the amount of testimony that has been given for years in bee and agricultural journals to the effect that in some localities farm stock eat it with avidity, and in view of its unquestioned value in rendering fertile the unproductive alkali lands of Arizona and Utah, and also in view of the immense traffic in sweet clover seed among those who have nothing to do with bees. He expects Prof. Cook to modify his statement, or say what he means.

Instructions for Handling Comb Honey.—A bright suggestion comes from G. A. Deadman, in Canadian Bee Journal. In every crate of honey to be shipped put a slip 5x8 inches (the editor says 3x4) printed as follows :

COMB HONEY.

HOW TO HANDLE IT.

You must not drop it. Hold it only by the wood, and when removing it from the crate, or at any other time, do not break the delicate cappings covering the cells, otherwise the honey will run out.

WHERE TO KEEP IT.

In a warm, dry room. No place too warm in which a person can live. Never put it in the cellar, as honey will draw dampness, and cause the cappings to break and the honey to leak.

Bee-Space Above Sections.—Editor Holtermann has no sympathy with the idea that a section not fully filled out all around is a desirable thing, and insists that a bee-space above sections helps to get them better filled. J. E. Crane having expressed an opposite view in Review, Mr. Holtermann proposes a test. Crane to select 50 colonies and have no bee-space above sections ; Holtermann to select 50 to be run with the bee-space. At the close of season each to have photo taken of best side of 200 sections, then if decision can't be made from photos, Crane to cross the line or settle it in some way, the loser to pay all expenses. Some will think that a more satisfactory test could be made by having all in the same apiary and at the same time on the same harvest ; and some might think better to make the test without anything that smacks of betting or gambling.

BEE-BOOKS

George W. York & Co.,
Chicago, Ills.

Bees Doing Well.

I have 110 colonies of bees. They wintered well, and are doing well now. I have been in the bee-business for about 30 years here. WILLIAM FLEMING.
St. Croix Co., Wis., May 2.

Lost None in Wintering.

I now have 57 colonies in good condition. I lost none during the winter. The poplars are in bloom, and bees are doing well. The outlook is good. The first pollen was brought in Feb. 14, a little earlier than usual. J. G. TETER.
McMinn Co., Minn., May 5.

Prospects Good.

Mr. Charles Koeppen, for whom I am now working, has about 325 colonies of bees, and he says the prospects are good for 10 tons of comb honey. How is that for Michigan? Mr. Koeppen produced about six tons last year with only clover, basswood being a failure. E. B. TYRRELL.
Genesee Co., Mich., May 7.

Wintered Well.

My bees wintered well, not losing a colony. I have a way of preparing my bees for winter that is different from any I have heard of. I have thought of writing it up. B. O. WILLIAMS.
Hardin Co., Iowa, May 2.

[We shall be glad to publish your wintering plan, Mr. Williams.—EDITOR.]

War May Interfere.

I am afraid my report of a honey crop for 1898 will be poor, as my bees will be without any attention if the Indiana National Guard is ordered to Cuba. My bees are in good condition; but I am willing to sacrifice almost everything to preserve the honors of our grand country. J. C. WALLENMEYER.
Vanderburgh Co., Ind., May 3.

Some Strange Experiences.

I have helped to take care of bees ever since I was old enough to do anything, and that is about 25 years, so in that length of time, and steady work with the bees, I ought to know something about them; yet there are times when I feel that I do not know much about them after all.

On July 1, 1897, I had a large swarm issue, and it settled on a cedar limb all right. I then placed an empty hive on a table close up to them, and shook them off on the table. They began to crawl into the hive, and when nearly all in they began to rush out. I went and looked at them, and on the table was a bunch of bees about the size of a baseball. I began to pull the cluster apart, and found a nice-looking queen. Just as I took her in my fingers one of the worker-bees stung her, and she died in my hand in a few minutes. I then pulled her to pieces to find out if she was

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful, as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 176 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers. \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES OF HONEY. 10 page pamphlet. Price, 10 cts.

Convention Hand-Book, for Bee-Keepers. Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cts.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cts.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cts.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p.; illustrated. 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2, in fine artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Care. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only one book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

1. Langstroth on the Honey-Bee.....\$2.00
2. A B C of Bee-Culture..... 2.00
3. Bee-Keeper's Guide..... 1.75
4. Bees and Honey [Cloth bound]..... 1.65
5. Doolittle's Scientific Queen-Rearing. 1.75
6. Dr. Howard's Foul Brood Book..... 1.10
7. Advanced Bee-Culture..... 1.30
9. Bienen-Kultur [German]..... 1.20
11. Rational Bee-Keeping [Paper bound] 1.75
13. Bee-Keeping for Profit..... 1.15
14. Convention Hand-Book..... 1.15
15. Poultry for Market and Profit..... 1.10
16. Turkeys for Market and Profit..... 1.10
17. Capons and Caponizing..... 1.10
18. Our Poultry Doctor..... 1.10
19. Green's Four Books..... 1.15
21. Garden and Orchard..... 1.15
23. Rural Life..... 1.10
25. Commercial Calculator, No. 1..... 1.25
26. Commercial Calculator, No. 2..... 1.40
27. Kendall's Horse-Book..... 1.10
30. Potato Culture..... 1.20
32. Hand-Book of Health..... 1.10
33. Maple Sugar and the Sugar Bush.... 1.20
35. Silo and Silage..... 1.10
36. Winter Problem in Bee-Keeping..... 1.30
37. Apiary Register (for 50 colonies).... 1.75
38. Apiary Register (for 100 colonies).... 2.00

A QUESTION.—Could you not send one or more NEW SUBSCRIBERS with your own renewal? You doubtless have neighbor bee-keepers that would be glad to take the Bee Journal if you would ask them, and send in their subscription money. You will find premiums offered by us from week to week for such work. We would like to have you help us roll up a large list of readers for the old American Bee Journal.

a laying queen, and as near as I could tell she was not.

I then went to the old hive to get a frame of brood, or one with a queen-cell on, to put into the new hive. I moved the old one away, put the new one in its place, and let them come back, but when I took the frames out of the old hive, there was not a particle of eggs, larvæ, brood or queen-cells to be found; in all my experience I never had anything like it.

Last summer I had 10 colonies; nearly all the honey they stored soured in the combs in a short time after it was put there. They were all strong colonies and filled the boxes several times, and every time it would be sour and foam in the combs. Sometimes they would cap some of it over and it would burst the caps and run down through the hive. When the combs were full of this stuff I would throw it out with the extractor, and make vinegar of it. Now, why was this? Can any one tell? If so, I would be much obliged.

In the last 10 years I have averaged about 10,000 pounds a year of extracted honey from 100 colonies, spring count, and it has sold for about \$70 a thousand pounds, making about \$700 a year.

F. B. FARRINGTON.

Clayton Co., Iowa.

Keeping Ants Out of Hives.

In a recent issue of the Bee Journal I notice complaints of ants in bee-hives. In this warm climate we have more ants and vermin to the square acre than in any place in the United States. Try this: Drive four stakes of old gas-pipe (wood will do) into the ground the height you wish the hives to stand. Put the bottom-boards on them, clean out all grass or weeds, and take some candle-wicking and saturate with coal-oil and bind around each post so that the ants cannot ascend without crawling over it; and I guarantee none will get into the hive. When the wick gets too dry saturate again.

J. H. HERMANCÉ.

Garland Co., Ark.

Backward Spring.

I put into winter quarters 104 colonies, and took out 104—all alive. This was March 25, and they had a good flight March 26. In the afternoon it rained, and on Sunday morning four or five inches of snow fell. I took sick, and for six weeks the bees had to take care of themselves. When I was so I could look after them I found five of them all cleaned out. I think this has been the poorest spring I ever saw—we have a fine day, then three or four rainy and cold. Yesterday was a fine day, and pollen seemed to be very plentiful, by the way they brought it in.

JOHN TURNBULL.

Houston Co., Minn., April 20.

Do Bees Move Eggs?

My experience teaches me that bees do move eggs, providing they need them badly enough to be moved, and if they are not put where they want them. Let us say a colony lost its queen, and has neither eggs nor honey to rear a queen from. Will not such a colony do almost anything in their bereavement, to restore them to their former condition? Most assuredly they will.

Suppose, now, we take two frames of

Bingham & Hetherington Uncapping-Knife.

PRICES OF BINGHAM PERFECT Bee-Smokers and Honey-Knives!

| | | | | |
|---|---------------|----------|----------------|---------|
| Smoke Engine (largest smoker made) 4-in. stove. | Doz. | \$13.00; | each, by mail, | \$15.00 |
| Doctor..... | 3½ in. stove. | Doz. | 9.00; | " 1.10 |
| Conqueror..... | 3-in. stove. | Doz. | 6.50; | " 1.00 |

We want

EVERY BEE-KEEPER

.....To have a copy of.....

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy.

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, snowy-white Sections, beautiful, straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

eggs from some of the other hives and exchange them with the outer frames of the queenless colony, if there are bees enough in the hive to give sufficient heat to hatch them where they are, they may, or may not, move them. But should they not have that sufficient heat, they will move them to where they want them, and the likeliest place will be, or is, in the center of the hive where they can give them the required heat to hatch them in due time. **F. HENTRICK,**
Sac Co., Iowa.

Bees Dying from Spraying.

My bees are dying by the hundreds. This is uncommon for this time of the year. My neighbors are spraying their fruit-trees, and poison my bees. I told them to wait till after the blossoms had fallen, but they won't I went to town yesterday to see a lawyer about it, and he said there could be nothing done about it. He said they had a right to spray their fruit-trees. There should be a law to protect bee-keepers in their rights. My neighbors' bees are all dying, too. I am the only bee-keeper in the neighborhood who takes a bee-paper.

I have 9 colonies at present, swarming out on the ground and kicking their heels up. Some are dying and some are dead. I hope by the next time I write my bees will be all right. It is discouraging at present. **W. M. DANIELS,**
Wood Co., Ohio, May 7.

Mating—Laying Worker—Ventilation

It is generally believed by bee-men that queen-bees mate up in the air and come down to the ground while mating. It is not always the case. Two years ago this May my nephew, E. D. Shryock, saw a black queen and black drone mate on a bunch of black locust bloom; after mating both flew away.

The way I manage laying workers is this: Put a colony with a queen with them, and let them fight it out.

There is much talk about ventilation. A bee-keeper in this neighborhood used to have some 20 colonies of bees in box-hives, flat on benches. During the winter he plastered all around the bottoms of the hives with mortar so the bees could not come out. Why did they not smother? **J. L. CRUTCHER,**
Franklin Co., Ky.

Fine Spring and Good Prospects.

We are having a very fine spring. Prospects are good for a good honey season. Bees are in fine condition. The past was a mild winter—bees were out almost every week.

I sent a carload of honey to Belgium, and would send more but I cannot get the quality. We could have sold five cars more if we could have gotten the honey, and now as the war is on we will have to wait awhile before we can ship again.

My bees in the Puyallup Valley are in fine condition. I have two apiaries, one in Puyallup and one in Sumner. I shall have to put supers on the hives in the valley soon, if they keep on as they are going now. Drones are flying, and they are getting ready for the clover flow, which may start about May 25 this year, if the weather continues as it has been; but it may turn off and rain

steady for three or four weeks, and we might "get left" on our fine prospects for a good flow.
G. D. LITTOY,
Pierce Co., Wash., April 28.

A Spring Report.

My bees wintered pretty well. Out of 24 colonies I lost 4, leaving 20 in good condition to build up for the white clover, which is my main crop of honey. I have a few colonies that have two hive-bodies of 8-frames each, which are nearly full of brood and running over with bees. From these I expect a large crop of honey. I have all my queens clipped, as I can manage them better and keep them on my own lot in the city. They do not bother any of the neighbors, only to gather nectar from their fruit-trees. My other apiary, which is located about eight miles from here, is in good condition for the coming harvest, and you will hear from me later.

W. H. HEIM.

Lycoming Co., Pa., May 9.

Onion a Bee-Sting Cure.

I find that when I get stung by the bees an excellent cure is to cut a common onion in halves, take part of it and rub the skin. It will not swell nor itch. If some one laughs at this let him laugh, I don't care. I am like Mrs. Brown and her wet dish-cloth.

We had very cold weather in April, many things frozen.

I like the Bee Journal and could not do without having it paid in advance, for it makes me happy, and I feel like giving three cheers. If not paid in advance I could not do it. I wonder if the editor will cheer with us.

E. B. KAUFFMAN.

Lancaster Co., Pa., April 18.

[Yes, lots of paid-in-advance subscribers ought to make a cheerful editor. We'd be willing to guarantee to be full of cheers if all our subscribers resolve to be like Mr. Kauffman in regard to their subscriptions to the American Bee Journal.—EDITOR.]

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, May 2.—Fancy white comb honey would bring 11 cents, but there is none here; other good grades of white at 9 to 10c.; dark and amber, 7 to 8c. Extracted, white, 5 to 6c.; ambers, 4½ to 5c.; dark and off grades, 4c., with exception of dark candied and amber grades. This market is bare of comb, and while prices have been low the quantity sold locally has been greater than last season. Beeswax scarce, and sells at 27c. for average lots. **R. A. BURNETT & CO.**

Kansas City, May 10.—The crop of 1897 comb honey in this market is about all sold, and we are ready for the new crop. The supply of extracted is fair—the demand light. Shipments of new comb honey would bring a fair price, probably 12c. **C. C. CLEMONS & CO.**

Cincinnati, May 12.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3¼ to 6c. according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. **CHAS. F. MUTH & SON.**

Boston, May 2.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, no sale. Extracted, white, 6@7c.; light amber, 5@6c. Beeswax is in very light supply, and if pure would readily bring 27c.

There is nothing new to note in our market for honey. As usual at this time of year, the demand has dropt to almost nothing, but as the supply is light, prices are well maintained and firm. **BLAKE, SCOTT & LEE.**

Cleveland, May 2.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. **A. B. WILLIAMS & CO.**

San Francisco, May 2.—White comb, 8½ to 10c.; amber, 6½ to 7½c. Extracted, white, 5½@6c.; light amber, 4½ to 5½c. Beeswax, 24@26c.

Market shows a healthy tone, especially for extracted, with very little of this class now remaining. Comb continues obtainable at former rates, with a fair business doing on local account. There will be little honey the coming season, and it is probable that values will further harden.

Detroit, May 10.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. **M. H. HUNT.**

Minneapolis, May 2.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c.; amber, 5c.; dark, 4@4½c.

Outlook for honey much more encouraging. **S. H. HALL & CO.**

Indianapolis, May 2.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. **WALTER S. POWDER.**

Milwaukee, May 5.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c.; amber, 8@8½c.; dark, 7@7½c. White extracted in barrels and kegs, 5¼@6c.; amber, 5@5½c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. **A. V. BISHOP & CO.**

Buffalo, May 2.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. **BATTERSON & CO.**

St. Louis, Feb. 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. **WESTCOTT COM. CO.**

Convention Notices.

Central California.—The next annual meeting of the Central California Bee-Keepers' Association will be held at Hanford, Cal., Wednesday, June 1, 1898, at 10 o'clock a.m. Election of officers and other important business to be attended to.

Loaded Field-Bees in the Sections.

BY G. M. DOOLITTLE.

There is much being said of late about raising hives up from the bottom-board, and providing the large entrances to

deposit their honey where it is wanted. And the claim is also put forth that by so doing the bees can more easily enter the sections, as they do not have to crowd their way up through the center, or most populous part of the hive, as they do when only the ordinary entrance is used. Of one thing all the advocates of this plan seem to be sure, which is, that unless the bees are thus forced to go from the fields to the sections with their loads of nectar, the same will of necessity be deposited by these bees in the comb-cells of the brood-chamber.

Now I wish to ask each of the gentlemen thus arguing, what reasons they have for believing that field-bees ever deposit their loads of nectar directly in the cells? Mr. Golden, I believe, claims that he knows that they do this, but if he has told us *why* or *how* he knows it, I have failed to see the place.

Mr. R. C. Aikin (and Family), President of the Colorado Bee-Keepers' Association.—From Gleanings.

those not fully raised, as above, so that the field-bees, with their loads of nectar, may be obliged to pass up the sides of the hive to the surplus receptacles, thus compelling them to

This craze that has come over the people for "high-up" entrances reminds me of a similar craze along about 30 years ago, when it was thought necessary to have from one to four

entrances direct into the surplus apartment, beside the lower or main entrance; for, in this way, the bees were saved all the extra travel up through the crowded hive. And then, as they could fly direct to these upper entrances much time would be saved, as the bee could fly much faster than it could go on foot, even tho' the lower part of the hive was empty. Thus a much larger yield of honey could be secured to the owner, for "time was honey" when the honey harvest was on.

Along about this time E. Gallup, I think it was, made the discovery and gave it to the world, that the bee which collected the nectar did not deposit it in the comb, but when it came into the hive with its load it gave that load to another bee—usually a bee so young as not to have become a field-laborer yet—the young bee holding the nectar in its honey-stomach till it was evaporated to the consistency of prime honey, when this young bee deposited it in the cells, wherever it was most needed, whether in the surplus apartment or in the brood-chamber. A few tried to argue Dr. Gallup down, but he had the proof on his side by telling how he saw the field-bees pass their loads of nectar over to the younger bees, how the nectar was evaporated, etc. This upset the direct-to-surplus-apartment-entrance plan, and to-day no such entrances are seen, except, perhaps, on some old hives which have been stored away for years.

Being of an investigating turn of mind, I wish to prove which was right—Gallup or the others—so some 25 years ago I constructed observatory hives, beside which I have watcht for hours, both day and night, and every observation proved Gallup to be right. Then the "rightness" of his ideas was also proved many times over by a change of queens from black to Italian, and *vice versa*, when at the proper time, before any of the new queens' bees became field-laborers, all the workers from the original queen would be seen coming in with their loads of nectar, while the sections revealed scarcely a bee but those from the newly-established mother.

If Gallup and myself are right, this doctrine now being put forth is as fallacious as was the old multiplicity-of-entrance plan, and if fallacious, it would be well to know it, for such knowledge will save much work to our bee-keepers when the little each one does along this line is put into the aggregate. Onondaga Co., N. Y.

Ripening Extracted Honey Artificially.

BY E. B. TYRRELL.

I promise to write concerning the ripening of extracted honey. I must thank Mr. J. A. Beardeu for his article on page 66, but he mistook my meaning, for I am in favor of artificial ripening of honey, providing it is practical. Altho I am not speaking from experience, yet for the sake of drawing out arguments and opinions of those who have had experience and getting at the truth of the matter as I wish to ripen artificially, if I can, and yet do not wish to make a mistake, I will take the artificial side of the question.

I will take the position that ripened honey is that which reaches a certain consistency, or thick enough so that a saucer of it when cold may be turned upside down without running out, and it doesn't make any difference whether it reaches this consistency while in the hive or out of it.

Admitting this to be a fact, I will venture the statement that honey can be brought to this consistency as well artificially as by the bees, because heat produces evaporation no matter in what way applied, and if honey is placed in a shallow pan with a large surface I can see no reason why it will not ripen as well as the bees can ripen it. Of course, no doubt the bees may ripen it faster, as the fresh nectar gathered each day must be reduced as much as possible during the night to make room for the next day's harvest.

Many, and in fact nearly all, writers admit that more honey may be secured if extracted as fast as gathered, and will not this extra honey pay for any extra labor implied by extracting during the flow? I believe that the reason that more honey is secured by extracting as fast as gathered must be because it draws from the field-force as well as from the honey to build the cappings, and as these cappings are of no use to the extracted-honey producer (except for beeswax), and in fact are a nuisance; for who would not rather extract honey from comb with no cappings, and especially this honey, than to be bothered with an uncapping-can and an uncapping-knife, making a slow, sticky job out of what would otherwise be fairly clean? I believe uncapping takes all the flower from extracting, and if I can do away with the uncapping can and knife I certainly shall do it.

Now, if you don't agree with me (and you certainly all don't) just jump right up and knock my theories all to pieces with facts; it certainly will take facts to convince me I am

wrong, and if your facts are good I am willing to be convinced, but I believe that this talk about artificially ripened honey not being as good as naturally ripened honey is nearly all prejudice, and most of those who extract after the harvest have not tried the other way, or else *did not do their very best in artificial ripening, and attend to every detail.*

Now, I don't wish any one to go into artificial ripening of honey on account of what I have said, but I do wish to know the truth about this matter, as it means dollars to me; and any light on this subject through the Bee Journal will be gratefully read by me. Genesee Co., Mich.

Something More About Section-Cleaners.

BY J. A. GOLDEN.

Upon request I am glad to give my experience as to propolis sticking and gumming the sandpaper when in a soft condition, which explanation inadvertently was overlooked in my former article.

Yes, if a section contains much propolis upon its surface, like sections when oilcloth is used over them, or any section badly gummed up; but as I use, in my method, a bee-space only, I have but little chunk propolis. In taking sections from the supers I use an old jack-knife to take off any bulky surplus propolis as I lift the sections out, consequently what remains on the sections I do not find any inconvenience in cleaning every vestige of stain and propolis from the section. As I am not a large producer, I usually set what honey I want to dress in the cellar until it is cool—sometimes over night—and dress it in the morning.

My experience is that a pretty coarse sandpaper—about No. 3—would be better than a finer grade. Of course the polish is not so nice.

On the wheel device, which was illustrated in the American Bee Journal, I cleaned over 1,000 sections beautiful and bright as ever was put on the market by any bee-keeper, before re-coating the wheel with sandpaper.

To re-coat, take a sponge and saturate thoroughly with hot water, then strip the old paper off and apply a new coating.

There is a great difference as to how a section is held to avoid gumming. If it is held crosswise the grain of the wood there is but little danger of propolis sticking, but if held the opposite the paper does not cut the wood so readily. That is my observation, at least.

There is also another thing, let me here add. If leakage, honey daubed on the section or propolis, it is sure to stick on the sandpaper belt or wheel. Of course, no one would expect a machine to overcome this, but if wiped off the work will be complete; but after propolis becomes hard I did not find a single section that caused any gumming of the wheel.

Morgan Co., Ohio.

Do Italian Bees Produce Better Honey?

BY EDWIN BEVINS.

It is with considerable hesitation that I attempt to answer the question of Mr. Hart, on page 269, because he confines the privilege of answering to the wise ones in apiculture, and I am not one of these. Then an editorial foot-note suggests that the question affords a chance for some one to distinguish himself, and I am not writing for distinction. Nevertheless, I am going to say something in the way of reply to Mr. Hart's question, as to why the Italian bees produce a better quality of honey than the blacks or others.

I do not know just how extensive Mr. Hart's reading has been, but this is the first time that I have known any bee-keeper to intimate that the quality of the honey produced by Italian bees was any way superior to that produced by other bees. Many times it is claimed that there is a difference in the whiteness of the cappings of the honey, but this difference is in favor of the blacks and some others, and against the Italians. As to the honey itself, I have never seen an opinion that the quality of the honey produced by any one race of bees was superior to that produced by the other races where all had access to the same sources of supply.

Mr. Hart thinks the difference, if there is any, may be accounted for on the supposition that the Italians are better mechanics or chemists than other bees, if it is a fact that bees make honey. Now, I believe that Mr. Hart is satisfied in his own mind that bees do not "make" honey. He is giving undue deference to the opinions of some who do not know much about bees, and yet can do considerable talking about them. The ignorance which leaves one to believe that bees make

honey may be excusable in the gentiles, but a child of Israel who has past through the Red Sea and the wilderness, and arrived at a land flowing with milk and honey, and still entertains the opinion that bees make honey ought to be ashamed of himself.

Then Mr. Hart comes at us with another *if*, which is entitled to no more consideration than the first one. If the Italians have longer tongues than other bees, it is an unquestionable fact that not many of them have tongues long enough to gather honey enough from red clover to cut any figure. Besides, who is able to say that the honey of red clover is any better than the honey of white clover? Has any one compared the honey from a bumble-bee's nest with the honey stored in sections in the midst of white clover bloom?

It looks a good deal as if Mr. Hart was "putting up a job" on bee-keepers, to get them to account for a difference which does not exist. I will therefore turn the work over to some one wiser and more covetous of distinction than I am.

Decatur Co., Iowa.

Watering Bees—Feeding—Cleaning Hives.

BY MRS. L. HARRISON.

I think watering bees is important. They should be accustomed early in the season to find water in the apiary, and not be frequenting watering-troughs, cisterns and wells. On cool mornings the water should be warm. Up to date (May 9) we fill their drinking-vessels with warm water, and are paid for doing it in preserving the life of many a bee. Wash them out occasionally, and put in a pinch of salt.

FEEDING BEES.

We keep a regular feeding-ground, and no robbing has ever been induced thereby. All sticky papers, sections or cases are put there for the bees to clean up. Any bits, or odds and ends of comb, the accumulation of the winter, are put there for the bees. When robbers attack a queenless colony we let them alone, and when they get all the honey gone and take the bees along. If the hive and stores are taken from them they will then try to rob other hives, and trouble ensues. When they are through, the hive can be cleaned and be in readiness for a swarm.

CLEANING HIVES WHERE BEES DIED.

Where colonies have died during the winter the bees should not be allowed to remain and rot, but pry up the combs, brush off the dead bees, and scrub out the hive, pouring in boiling water from the spout of a kettle, and turn it up to dry. Cut off all old queen-cells, and remove the drone or very thick, undesirable comb. The bees that are in the cells can remain and will rattle out when dry, or when given to the bees they will remove them, working cheaper than we can. This hive will then be a bonanza when a swarm issues.

ADULTERATION OF BEESWAX.

Those who sew carpets and manufacture overalls call frequently for beeswax, saying that what they buy at stores is not good—has grease in it. Are there complaints of this kind elsewhere?

Bees wintered well in this locality, and the spring has been favorable for the rearing of brood. They did well on peach and cherry bloom, which has just past; but there was very little bloom in this immediate neighborhood. Dandelions are very abundant, and fill the interim between fruit-bloom and clovers.

Peoria Co., Ill.

National Bee-Keepers, Union—13th Annual Report—for 1897.

BY THOMAS G. NEWMAN.

The appeals for assistance are the largest for any year in the history of the Union, and cover all phases of trouble—briefly reviewed as follows:

PROHIBITING BEE-KEEPING.

As stated in our last Report, the City Council of Clarinda, Iowa, was petitioned to pass an ordinance prohibiting the keeping of bees within the corporate limits. The Union forwarded to the Mayor, City Attorney, and each member of the City Council, copies of the "Decision of the Supreme Court," on the point at issue.

After some delay it came before the District Court. The Union's attorney was supplied with abundant ammunition to show that bees do not injure fruit, and the Union was victo-

rious. There were several apiaries there, and the rights of apiarists were maintained. The chief apiary there belonged to Mr. J. C. Strong, against whom the suit was brought.

WANTED THE APIARY REMOVED.

Thos. C. Stanley & Son had about 150 colonies of bees in Fairfield, Ills., where they owned 32 lots. A neighbor who owned a lot or two petitioned the City Council to order the bees removed as a nuisance. We wrote personal letters to the Mayor and each of the aldermen, and sent them copies of the Supreme Court decision, showing that bees are not *per se* a nuisance, and could not be legislated against in "omnibus." We informed them that should they pass such an ordinance as was prayed for, abridging the rights and privileges of bee-keepers, it would become the duty of the Union to test it in the Courts, as it abridged rights guaranteed by the Constitution of the United States. Our attorney attended the meeting of the Board, and argued the case as outlined by the General Manager. That ordinance then and there died a natural death. Mr. Stanley wrote thus: "We thank you for the assistance of the Union." Record another *victory* for the Union!

DR. BESSE'S SWEET CLOVER FIELD.

This case was mentioned in our last year's Report. The Township Trustees, against this protest, cut down his planted field of bee-pasturage (three acres of sweet clover), and then charged him \$27.20 as fees for doing the damage. This deprived his bees of pasturage, and cut short his honey crop in consequence. He sued the township and appealed to the Union for assistance. The case has been postponed from time to time, and is yet untried. The Union has contributed \$75 to aid in taking testimony showing that sweet clover was not a noxious weed, but a good honey-plant and an excellent bee-pasturage. The case will come up again for trial at the January term of the Court, and the Union is doing all in its power to secure justice for the Doctor.

[This suit came up for trial in January last, as stated, and was lost by Dr. Besse.—EDITOR.]

BEES "EATING" FRUIT.

O. W. Stearns, of Selma, Calif., had neighbors who claimed that his bees ate their fruit, and circulated a petition last June to have them declared a nuisance, and ordered to be removed. We sent the Union documents to each of his neighbors, showing that bees do not puncture the skins of fruit. We arranged for an attorney to attend the meeting of the Council, and present the facts in the case, but so far the petition has not been presented, tho it is six months ago. The prompt action of the Union doubtless settled the disturbance.

TROUBLE WITH FRUIT-MEN.

Mr. A. Unterkircher has an apiary at Riverside, Calif., and the fruit-men began proceedings to drive him away, averring that the bees destroyed their fruit. The Union's batteries were opened upon them, and a shower of documents in that locality proved that bees were incapable of puncturing the skins of grapes, etc. The Manager gave some points of law to the interested parties, which soon ended the trouble. Last January Mr. U. wrote to the Manager that he was proud of being a member of the Union, which had so completely silenced all his unreasonable opponents, and added: "No bee-keeper, great or small, can be at home outside of the Union. The bare statement that I was a member of the Union at once silenced all opposition."

AN INHUMAN NEIGHBOR.

John Uphouse, of Sedro, Wash., had an envious neighbor who, when a swarm had settled on his lot, and the son of Mr. Uphouse had watched it, and went with a hiving-basket to bring it home, the neighbor attacked the son and shook the bees from the basket down over the boy's head, saying he hoped the bees would sting him to death. He was badly stung, and the inhuman neighbor was sued by Mr. Uphouse. The Union posted the attorney in charge as to the rights of bee-keepers to follow swarms and capture them, and dosed the neighborhood with decisions of the Supreme Court, and the pamphlet entitled, "Bees and Flowers." Now peace is restored in that neighborhood.

TROUBLE ABOUT A SWARM.

August Bachman, of Seattle, Wash., had a swarm last July settle in a neighbor's lot. His wife saw the swarm alight, but was refused permission to enter the premises to take the swarm away. The neighbor did not own the lot, but had the privilege of keeping chickens there. The owner gave written permission to Mr. Bachman to take the swarm, but the occupant refused to let him enter. He got a constable

and took the bees away, but the neighbor claimed them as his property, and sued Mr. Bachman for them; and the justice decided in Mr. Bachman's favor. Then the neighbor appealed the case; and Mr. Bachman appealed to the Union for defense. Being a member of the Union we gave the points of law in the case to our attorney, who made good use of them, and the jury decided in favor of the owner, and the pugnacious neighbor had to pay the costs—another victory for the Union.

DECLARING BEES A NUISANCE.

Mr. W. A. Webster, a member in Pylema, Calif., last March reported that a petition had been circulated there, asking the Supervisors to prohibit the keeping of bees in that place by a city ordinance, and askt us for instructions as to what to do in the matter. We replied with advice, and documents for circulation. By posting the Board of Supervisors in advance about the unconstitutionality of such an ordinance if past, the members were fully prepared to deal with the matter, and promptly denied the petition. Thus defeated, they made trouble in Mr. Webster's apiary by overturning the hives and stealing the honey at night. We advised Mr. Webster to let it be understood that he was a member of the National Bee-Keepers' Union, and that we would make it *hot* for any one found meddling with the hives or bees. He did so, and that trouble also ceased.

COMMISSION MEN'S RATES.

In the case of S. T. Fish & Co., mentioned in my last Report, being a disagreement about the rate of commission on several carloads of honey, amounting to over \$200—altho we have written scores of lettres, the important documentary proofs have not been produced on which to successfully establish the claim—several letters having been mislaid or lost. Until these are found no further progress can be made. We regret this, because we have already spent so much time, labor and expense on the case. The Chicago commission men repudiate the contract made by their representative at 5 per cent. commission, and claim that the 10 per cent. they deducted is their regular commission. When proof is produced the case can be continued, but not before.

DEPREDACTIONS ON AN APIARY.

J. Kendall, of Blodgett's Mills, N. Y., complained that depredations were made on his apiary in the night, out of spite. We advised him to put up a sign stating that any one trespassing on his premises would be prosecuted—then if the miscreants could be found they would be dealt with according to law, and the Union would help to do it.

THREATENS TO POISON THE BEES.

Among the cases which are now on the docket is one in Pennsylvania, where a neighbor refused to allow a bee-keeper to enter a yard where a swarm had alighted, to capture it and take it to a hive—one that had a prized queen. Of course it went to the woods and caused a loss. In this case we have had a voluminous correspondence, as the neighbor threatened to poison the bees, and was otherwise pugnacious. We wrote to this neighbor demanding reparation. What the outcome will be is yet undetermined. It is not wise to give any further particulars in this Report.

DISPUTE ABOUT HONEY SALES.

Early in January Thos. C. Stanley & Son, of Fairfield, Ill., complained to the Union about the sale of some honey shipt to C. F. Muth & Son, of Cincinnati, Ohio, proposing that it be submitted to arbitration. We wrote to C. F. Muth & Son, and the matter was submitted to the following arbitrators: J. M. Hambaugh, A. I. Root and Eugene Secor.

Long documents were prepared by each party and sent to us, we forwarding these statements to each arbitrator, and having his decision reserved to be mailed to us on a certain day far enough in advance for all to come at once. These decisions were collated, summarized and reported to both disputants, who agreed in advance to abide the decision. This entailed much labor in type-written copies, documents, letters, etc., amounting to hundreds of pages.

The decision was rendered—then appealed from by C. F. Muth & Son—and re-submitted, reviewed, re-affirmed, and reported—covering a period of eight months, but the award of \$10 to T. C. Stanley & Son has not yet been paid.

LAWS RELATIVE TO APIARIES.

Reports have been circulated stating that the laws of California compel bee-keepers to remove apiaries from the vicinity of fruit-drying establishments, and restricted the location of apiaries to certain distances from such. Hon. J.

M. Hambaugh and others wrote to us inquiring as to the distances named, if such were legal enactments.

It was also reported that bee-keepers were required to shut up the bees during fruit-drying periods. Failing to do so, the bees may legally be enticed by poisoned sweets and destroyed. We were requested to look up the laws and ascertain what truth there was in such statements.

We went to the law office of a Judge of the Supreme Court, and made a thorough examination of the laws of California, but found no law in the Code containing any restriction relative to the location of apiaries, either specifying nearness to fruit-drying establishments or anything like it. Neither could we find any law allowing fruit-men (or any other men) to entice or entrap bees, for the purpose of destruction, under any circumstances.

The Judge who assisted us in this search has one of the largest law libraries in the State, and he assured us that there was absolutely no foundation for any such a report. If any such laws were enacted they would, he said, be unconstitutional.

This is an important matter, and we therefore mention it in this Report. Mr. Hambaugh was a member of the legislature of Illinois, and rightly concluded that if there was any such law "surely something is needed in the way of legislation in behalf of the bee-keepers of California." But such a law does not exist.

BEES NEAR HIGHWAYS.

Many threatened disturbances about bees being kept near highways have come up, and we have answered many letters advising bee-keepers to keep their apiaries far enough away to prevent the bees from being jarred by passing teams or

Thomas G. Newman.

annoyed by sweating horses, because either of these may cause trouble; to erect a high board fence where an apiary is near neighbors' residences, and otherwise to prevent annoyance. These matters have caused considerable correspondence, but have prevented many cases of neighborhood troubles.

PUT A BEE-KEEPER IN JAIL.

Frank S. Buchheim, of Santa Ana, Calif., a member of the Union, in September, 1897, was arrested, under Sec. 370, of the Penal Code of California, for keeping 100 colonies of bees on his premises, charging him with maintaining a nuisance in the neighborhood, averring that the bees ate up and destroyed the fruit belonging to the neighbors, and interfered with laborers who were engaged in caring for the fruit, etc. His apiary and premises cover 7½ acres. He built a fence 6 feet high to enclose 24x32 feet, in which he kept the hives of bees during the fruit-drying season, thus controlling the bees and preventing annoyance to the neighbors. But they were not satisfied with these precautions, and demanded that the bees be moved out of that locality.

Suit was brought against Mr. Buchheim for maintaining a public nuisance, and he was fined \$50 and costs. As he was a poor man with a large family to support, he did not pay the fine, and was committed to jail for 25 days.

After 10 days had elapsed an appeal was taken to the Supreme Court, and he was releast pending appeal.

The Union being appealed to for assistance, we collated some points of law upon the case to aid the attorney, and gave

advice on the course to be pursued, sending the Union's documents to be scattered among the interested parties. Meanwhile the Advisory Board decided that the Union should take part in Mr. Buchheim's defense. It is expected that the appeal to the Supreme Court will be heard in a short time, when a lively time will be given to the enemies of the pursuit.

ARE BEES A NUISANCE?

F. H. Hunt, of Redlands, Calif., has been sued by W. F. Whittier for damages, and prays for an injunction restraining him from keeping bees within one mile of his land, claiming that the bees defoul the water used for irrigating and domestic purposes, also sting men who work in the adjoining field to the apiary. Mr. Hunt's apiary was located there before Mr. Whittier planted his orchard, and should have prior right to the location—if there is to be any preference.

We have corresponded with the attorney in charge of the defense, and have given all the aid in our power, stating many points of law relative to the rights of bee-keepers, and furnished him with the Union's ammunition, printed arguments and decision of the Supreme Court of Arkansas, etc. The trial is to come off on Jan. 12, 1898, and we hope will be another victory for the rights of apiarists.

This case is of unusual interest, for many California apiarists are in danger of similar lawsuits instigated by fruit-men who are sworn enemies of the pursuit.

THOMAS G. NEWMAN, *General Manager.*

2096 Market St., San Francisco, Calif.

[While we are a little late in publishing the foregoing report, it nevertheless will be interesting reading, as it shows what the National Bee-Keepers' Union did during the year 1897. But we are now enabled, by the delay, to show our readers—many of whom are Mr. Newman's old friends—a reproduction of his latest photograph, which, to us, seems to indicate that his residence in California has not tended to improve his health very much.—EDITOR.]

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Convention.

REPORTED BY F. L. THOMPSON.

[Continued from page 310.]

The Honey-Industry in Colorado.

It seems that some member of the Horticultural Association lately claimed that our spraying law could not be enforced, and added something to the effect that bee-keeping was of small importance. I do not know who the man was, except that he was some Western slope man, and do not know his exact words.

I will consider his last assertion or implication first. Our Secretary has fairly reliable data to show that last year's product of the Eastern slope alone in comb honey was about 1,000,000 pound sections. I learn on good authority that Grand Junction sent out six carloads, and that the other portions of the Western slope sent out not less than six more, making 12 in all, or 240,000 pounds. Let us call the net gain on comb honey 5 cents a pound. That is surely low enough. Then 1,240,000 pounds of comb honey at 5 cents a pound represents a net gain to the State of \$62,000. I do not know how much extracted honey was produced; doubtless several hundred thousand pounds.

VALUE OF HONEY.

The farm honey of the Western slope is also not included in the above estimate. All in all, the lowest estimate of the direct cash value of the honey-industry cannot be less than \$70,000. But this is only half the story. R. L. Taylor, of Michigan, who was director of the Apicultural Experiment Station for several years, stated that the benefits arising from the cross-fertilization of blossoms by bees are worth more to the people at large than the cash value of the honey itself. He is a horticulturist as well as a bee-keeper. I have never seen

that statement contradicted; and, indeed, I do not suppose it can be, as many proofs show that such benefits are great, not only to the fruit-men, but also to gardeners and farmers. We might, then, modestly place the value of apiculture at \$140,000; but let us be very modest and say \$100,000. Perhaps my intellect is very feeble, but I really am unable to see that an industry worth \$100,000 is of small importance.

I know nothing of the comparative value of the fruit-industry; but we know that it has a Horticultural Board, whose mileage expenses are paid by the State, a Secretary with a salary of \$1,000, two rooms in the Capitol, a library, a number of display cases, appropriate furniture, a high grade typewriter, stationery, etc.; possibly, on the whole, an annual expense of \$1,500 to the State. Now, if the fruit-industry is worth \$100,000 to the State, why do we not get \$1,500? If it is worth \$200,000 to the State, why do we not get \$750? If it is worth \$500,000, why do we not get \$300? We have a few county inspectors, but the fruit people have theirs, too, except for the publication of our annual report, we get nothing from the State.

SEEMING INJUSTICE.

The truth of the matter seems to be that our legislators being only disposed to appropriate so much anyhow to industries benefiting the State, a few conceive it is to the interest of the industries already represented to keep others out, because every new sharer means a less share to each one. But if this is the case, I would recommend to those who discuss the matter to first recognize statistics to some extent. We bee-keepers may not be politicians, as some are, but we can see the sun at noonday; and if such motives peep out they put ideas in our heads that otherwise we might not have entertained. Injustice arouses a keener desire for justice. Judging by what the fruit-industry receives, what ought another rural industry, contributing as do all rural pursuits to the health of the Nation, not only physically, but morally as well, to have a State appropriation when it reaches the value of \$100,000? A room in the Capitol, expenses for displays both in and out of the State, advertisement of the value of honey as a far healthier food than cane-sugar or commercial glucose, this feature alone being worth more to the State than the whole would cost; a library, an executive administration, either independently or in connection with the Horticultural Board, and a remuneration for the exceedingly necessary and valuable services of a Secretary, which shall be in just proportion to that received by similar officials.

VALUELESS LAND USED.

Let us now suppose that the fruit-industry should be said to be worth some fixed sum of money to the State, such an estimate being based on the net value of the fruit alone. It has been suggested to me that if that were the only base of calculation, the result would be incorrect. The industry would really be worth less. For, as a rule, horticulture takes the best farming land—land that might have been put in grain, hay or potatoes; so that the real value of the horticultural industry, as such, is not represented by the net value of the crop, but by the difference in value between the fruit and the staple which might have been raised on the land the fruit-trees occupy. This will cut down considerably whatever figure may be assigned to horticulture, based on the net value of fruit; and this net value may sometimes be less than nothing, especially in the case of perishable fruit. Two producers of peaches at Montrose got back only enough to pay for the boxes.

On the other hand, estimates of the value of the honey-industry are influenced by no such consideration. Apiaries occupy an exceedingly small portion of land; and this land need not be, and generally is not, of any particular value for other purposes. Not only so, but the product is a spontaneous one in the form of floral nectar, which would utterly go to waste if not for the bees. The value of honey is a clear gain to the State, and, finally, what is not generally understood, honey is as valuable an article of diet as fruit, and should be as plentifully used. Being concentrated, it is one of our cheapest foods. It is not merely to be regarded from the chemical point of view as one of the sugars, but from a hygienic standpoint it is already what the other sugars have to be reduced to before they can be assimilated, thus saving the wear and tear of the system and the tendency to Bright's disease and kindred disorders which the free use of cane-sugar in modern times is causing. The muscular energy which science has discovered to be the result of sugar as food can be obtained in no safer way than by eating honey. It follows that the industry of honey-production is intrinsically valuable, as substituting a cheap and wholesome article for other more or less harmful members for an essential class of foods.

THE SPRAYING LAW.

About the other question, whether our spraying law can be enforced, not much need be said. It is a measure which is highly essential to the well-being of an industry worth \$100,000 to the State, cases having already occurred in which spraying out of season caused direct and great loss to bee-keepers. It does not in any market degree interfere with the welfare of other industries of the State. Unless these two statements are proved to be false, I do not see that the author of the assertion has any case. If I understand it rightly, he said that some trees would be blooming while others were not, hence the blooming season could not be defined strictly enough to apply the law. It seems to me this is splitting hairs. There is nothing to prevent one tree from being sprayed, when it has finished blooming, while at the same time another tree is not sprayed because it is yet in bloom. The spraying law is in force in Vermont and Washington and the Province of Ontario and perhaps elsewhere, and we have heard of no such objections raised to it.

But it is not enough for us to show the emptiness of such strictures. The very fact that they were made causes a suspicion that a spirit unfriendly to us exists in certain quarters. Last spring it was the Grand Junction horticulturists who for some reason which they did not see fit to impart, opposed the addition of a clause prohibiting the exposure of poisoned mixtures on which bees will work. We gave way to them in that. Now somebody from the Western slope carries opposition a little farther. We are justified in asking "Why?" It is not enough that some Eastern slope fruit-man tells us he doesn't know of any reason for discussion among bee and fruit men. We want to know what is the matter with those Western people.

A PERSONAL STATEMENT.

I have thought that perhaps occurrences in which I was concerned, in both of which cases certain private letters got in the papers without knowledge or intention, may have caused some person or persons who were not acquainted with the facts to assume that such action was intentional, and that it was also done with the connivance of the bee-keepers at large; and, as an inference, that bee-keepers in general are rather a grasping set, who need to know their place. Such assumptions, if they continue to exist, as they have existed (and, by the way, I have never received any assurance that they have ceased to exist, tho I should have expected it), have not an atom of truth. Further, there is not the slightest danger that such assumptions will ever again be even apparently true; for in consequence of the implied ascription of malicious motives which has never been removed, and also because I realize that I have not the necessary business abilities, I have determined hereafter not to do any work for either of our associations which involves any business, except in the way of informal assistance to committees and officers. That settles that. The opposition must show other grounds for their hostility than anything connected with those occurrences, and it would be well for them to recollect that if bee-keepers can be injured in the eyes of horticulturists by mistakes which have the appearance, but not the reality of injustice, horticulturists will surely be injured in the eye of bee-keepers by the genuine article.

THE TIME TO SPRAY.

I am glad to state, however, that in spite of my rather discouraging experience, I suppose that the majority of fruit-men are disposed to be fair-minded and courteous. Mr. A. F. Reeves, the fruit-inspector of Montrose county, I think is such a man. He has made a study of entomology, and appears to be competent. He told me that the spraying law was all right, and a good thing; tho in one respect only it might not be entirely just in its workings, because once in several years a peach-louse makes its appearance, which can only be killed by spraying during bloom. A provision ought to be made to meet this exigency. I recommend that the association correspond with Mr. Reeves on the matter. Whatever provision is made should, of course, do away with the essential part of the law; for not only could we ill afford to have our bees killed by the bushel just at the critical period of their development, but the horticulturists themselves cannot afford to dispense with the services of the bees in securing cross-fertilization, which means more and better fruit; nor can they afford to overlook the fact that, with the small exception noted, they are simply wasting their spraying material in spraying out of season, because all the common insects injurious to fruit can only be reached by spraying after bloom.

F. L. THOMPSON.

Mr. Devinney—No action was taken by the Horticultural Board on the matter.

Mr. Honnet—While some remarks were made, I cannot recollect anything of the kind as having taken place.

Mr. Milleson—If anything was said detrimental to our interests, I fail to remember it, with one or two exceptions. As County Fruit Inspector I have not met more than one or two who gave any indication of ignoring the law. Leading fruit-growers have no opposition to it. It is almost universally conceded that we have rights.

Pres. Alkin—I think that no feeling exists.

On motion of Mr. Devinney, the Association voted that the paper be given to the press for publication.

A LETTER ON SPRAYING FRUIT-TREES.

In the hurry of business the following letter from a bee-inspector of the Western slope was not read before the Association. It will be appropriate here:

"I think there will be a strong effort made to repeal the law that we work so hard for last winter, with regard to spraying during fruit-bloom, and many are making threats now that they will spray while in fruit bloom. I cannot see why any sensible fruit-grower should want to kill off all pollen-bearing insects (bees included) that so greatly assist in the setting of fruit, and that at a time when they are all he does kill. We will do all we can by persuasion up till that time, and then if they insist on spraying, we (the bee-keepers) will see that they atone to the offended law."

A LETTER ON TAXING BEES.

The following letter from a bee-keeper was read, which had been sent to the Secretary of the Denver Bee-keepers' Association, who, on account of absence, turned it over to Secretary Rauffuss:

"What I am interested in as I suppose we all are, is the point as to the legal right of assessors to tax bees. All property is taxable unless specially exempted, *i. e.*, all property recognized as such by law. If I understand the scope of the decision of the Attorney General, it is clearly that bees are not property at law in Colorado, and therefore not subject to taxation. It is this phase only of the subject that has practical import to bee-keepers, for I cannot conceive how we can protect at law that which has no standing at law. Of course I know that we can hold bees, birds, fishes and other wild animals, and the law will not interfere, but in case of depredation by others, what is the remedy? What is their legal value? Can an assessor list for taxation? As I understand it, the right to assess carries with it the right of legal protection, and I am of the opinion neither obtains in our State. Situated as you are where you can in the name of the bee-keeping interest have a decision settling these points made, I conceive it would be of great value as determining what course bee-keepers ought to pursue in asking such legislation as may be necessary to surround our interests by the law's protection. I believe I, in my former letter, stated that it had been necessary to have dogs made property by enactment. Surely, they are much more readily held, valued, recognized and recovered than bees. I know that in many places they were taxed, but that was in the nature of a license to provide a fund against their depredations, or for protection."

Mr. Nichols—I am the assessor of Montrose county, and a heavy bee-keeper. I am not posted on the law. My business is merely to list for taxation. They have never objected to taxing bees in Montrose county. Yet many bee-keepers get little or nothing from their bees. The commissioners value every colony at \$1.00. I think it is wrong, and that the assessor should fix the value. I believe a fixed valuation of colonies is just as unjust as a military tax, which was considered unjust at the recent assessors' meeting. A year ago I cut down the valuation of bees and equalized them, calling the best \$1.00, some 75 cents, and others lower; but the Board of Equalization said one colony was as good as another, and placed the value of every one at \$1.00.

Several members thought the county had no right to tax bees.

Mr. Rhodes—The real question is, Are bees property in law? Is there a value that can be recovered?

Mr. Nicholas was appointed a committee to interview the Attorney-General on the subject.

Officers were elected for the ensuing year as follows: President, R. C. Alkin; Vice-President, R. H. Rhodes; Secretary, Frank Rauffuss, Elyria; Treasurer, Mrs. R. H. Rhodes; Member Executive Committee, B. Honnet.

The Committee on Organization and Marketing, consisting of Messrs. Elliott, Whipple, Pease, and Lyon, submitted a report which caused considerable discussion. Some favored the agency plan, some that of a supervision by a Board of Directors. The committee's report, embodying the latter plan, was not acted upon, but a resolution by Mr. Tracy was past,

that the Association agrees to abide by the action of the committee. This gives the committee time to sound virus and perfect details. The result of their deliberations is expected to be made known at the spring meeting.

A complete recasting of the Constitution and By-Laws was presented by the committee for that purpose, and adopted by the Association, which it is believed will make the Association's work more effective than heretofore.

Mr. Nichols, by request, spoke of his scraping-machine for separators, which saves him some work and expense. The essential feature is two knives with springs.

THE BEE-INSPECTORS' REPORTS.

J. B. Adams, Boulder County—Total number of colonies inspected, 580; number diseased, 32; destroyed, 32.

Thos. A. Riggs, Arapahoe County—Number inspected, 942; diseased, 39; transferred, 26; destroyed, 13.

Peter Kranz, Otero County—Number inspected, 2,738; diseased, 27.

H. Porter, Jefferson County—Number inspected, 2,294; diseased, 15; destroyed, 15.

M. A. Gill, Mesa County—Number inspected, 2,733; diseased, 26; destroyed, 26.

Chas. Adams, Weld County—Number inspected, 18; diseased, none.

Mrs. A. J. Barber, Montezuma County—Number inspected, 192; diseased, 2; destroyed, 2.

FRANK RAUCHFUSS, Sec.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Trimming Down Brood-Combs.

When combs are very rough, is it a good plan to cut them down smooth in the flush of the season? CONN.

ANSWER.—You probably refer to irregularities on the surface of brood-combs. It's a good plan to trim down the worst of these at any time when convenient.

Langstroth and His Invention.

In the Bee Journal I often see a certain Mr. Langstroth mentioned. I suppose he is the inventor of a kind of hive or frame very valuable to bee-keepers. I would like to know something about him, especially the time and place he lived and died, and about his invention. WISCONSIN.

ANSWER.—Rev. Lorenzo Lorraine Langstroth was born in Philadelphia, Pa., Dec. 25, 1810. In 1852 he invented the movable frame, went to Oxford, Ohio, in 1858, and to Dayton, Ohio, in 1857, dying there Oct. 6, 1895.

Carrying Out Brood—Feeding Bees.

1. What is wrong with my bees? Two colonies began gathering pollen the first week in April, and seemed to be doing well, but now in the morning I find some of the brood on the alighting-board, some of which are about nine days old, I judge, and others have wings and eyes formed, some of which seem partly torn to pieces. Some of the former are alive when found. They are in old-fashioned box-hives, so I cannot examine inside very well. One of these colonies swarmed once last summer. The other did not.

2. I have another colony that did not swarm, and seemed to have very few bees all summer. This spring it has gathered no pollen. Are they queenless?

3. What is the best way to feed in box-hives? I intend to get rid of them as soon as possible. NEW YORK.

ANSWERS.—1. The probability is that your bees were near the starving point, hence destroyed brood. Very likely the coming of fruit-blossoms has corrected the trouble.

2. If they carry no pollen when other colonies are carrying in plenty, they are likely queenless, and should be united with another colony. Make a hole in the top of the hive if there is none, then set the hive under another that has a queen.

3. One good way is to use the crock-and-plate method; making a hole in the top of the hive, then covering over so that no bee can get in from the outside without going through the hive.

Getting Bees on New Combs.

I have 10 colonies of bees in standard hives, the combs of which are old and have a great deal of drone-comb in them. I want to get the bees on full sheets of foundation and use the old combs for extracting purposes. I thought of fitting up other brood-chambers with foundation, and raising up the old hive, set the new one under with a queen-excluder between them, with the queen below. Will this do? If not, how shall I do it? INDIANA.

ANSWER.—Sometimes a queen will sulk without laying for some time if confined on foundation below, with brood above the excluder. Give her one frame of brood below by way of encouragement.

Building of Drone-Comb.

1. If a hive-body filled with frames containing starters be placed under a colony of bees, will they build as much drone-comb as they would if it were placed above them?

2. How would you proceed to have a number of brood-frames filled with comb and have as little drone-comb as possible when only starters are used in the frames, and the apiary run for extracted honey? NEW YORK.

ANSWERS.—1. It would be more likely used for brood below, and on that account more likely to be worked; but if used for storing honey there might be no difference.

2. Have the comb built in weak colonies, and in colonies with young queens.

Gathering Pollen and Honey—Alfalfa.

1. Do bees gather honey and pollen at the same load?

2. Do bees get much honey from box-elder?

3. What is the general length of the alfalfa honey-flow?

4. Is there ever a failure of a honey-flow under irrigation?

5. We have thousands of acres of alfalfa, but most of it is kept for seed, and not irrigated, and that which is cut for hay is cut before the first bloom appears. Last year was my first year here, and I saw the bees working on alfalfa only about a week, just before frost. Alfalfa produces from 6 to 8 tons of hay per acre, and from 7 to 15 bushels of seed. Now, if you or any one else can tell me how to handle it, to get a honey-crop, I will be very much pleased. NEBRASKA.

ANSWERS.—1. They often bring honey without pollen, and when they bring pollen they may bring honey with it, perhaps not very often bringing pollen without honey. Possibly that may not be the rule in all localities.

2. I think they do, but I may be mistaken.

3, 4, 5. I confess ignorance, and will be glad if our alfalfa friends will help us out.

Swarming—Cells of Old Combs.

1. Does the queen, or do the bees, cause swarming?

2. Do bees swarm after or before queen-cells are built?

3. Can a queen's wings be clipped with scissors? If so, how?

4. When comb is used for a long time for rearing brood, do the cells get small enough to make the bees under size (for each bee leaves a web, I am told)? IOWA.

ANSWERS.—1. Both work together toward that end, but the immediate impulse to swarming at the time the swarm issues comes at times and perhaps always from the workers. It sometimes happens that a swarm issues when there is no queen in the hive, the queen having been taken away an hour or more before, the bees not having yet found out their queenlessness.

2. Generally queen-cells are prepared and well advanced before a swarm issues.

3. Yes. Hold the queen by the thorax or body (not by the soft hinder part) having the tail toward the hand that holds the scissors. Now cut off as much as you can conveniently from the two wings on the side next you (there are two wings on each side.)

4. Some think a difference in size of bees results. Perhaps most think there is no difference. I never throw away a brood-comb because of its age. The change made in cells is mostly at the bottom, making the thickness of comb greater, but not affecting the size of bees.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitecomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

MAY 26, 1898.

NO. 21.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Bees by Freight—Important.—Last week we mentioned the subject of shipping bees by freight in less than carload lots. The petition has gone in to the Western Classification Committee, J. T. Ripley, Chairman, Room 604, Great Northern Hotel, Chicago, Ill. Now what bee-keepers are to do is this: Write the Committee *at once*, urging the granting of the petition at their next meeting, to be held at Colorado Springs, Colo., June 14. We trust that several thousand bee-keepers will write immediately, addressing as above. There seems good prospects of the petition being granted, if bee-keepers will but show their interest in the matter. Especially the prominent bee-keepers should write, but no matter how few bees you have, your letter will have weight. All letters should reach the Committee by June 5—*not later*. Better write *now*.

Bee-Keeping Not a Nuisance.—We have received the following, dated May 16, from General Manager Newman, referring to a case mentioned in his Report, on page 324 of this number:

FRIEND YORK:—I am glad to inform you that Mr. Buchheim, referred to in my Annual Report as having been put in jail on the ground that bee-keeping was a nuisance, has, through the efforts of the National Bee-Keepers' Union, been fully exonerated, and his bail discharged. This was a case where the Union appealed from the Justice Court, which found him guilty of maintaining a nuisance and sent him to jail. I am just informed this morning of the success of our lawyer in the case.

This is another victory for the National Bee-Keepers' Union, which is fully in keeping with its victorious record in maintaining the rights of bee-keepers.

THOMAS G. NEWMAN,
General Manager.

Facing Cases of Comb Honey has considerable attention in the Review. Dr. Miller has a tilt with the editor, the latter claiming the battle because the former allows it to be the correct thing to put the best side of a section out, altho vigorously objecting to the practice of putting the best sections in sight. Mr. Doolittle stands firm on his former ground, giving the testimony of a commission man, who says it is his business to *know* what is in the middle of the case. Editor Hutchinson feels sure Mr. Hasty did not understand Mr. Doolittle, and thinks it well that Mr. Doolittle "has explained more fully." Whether Mr. Hasty or any one else besides Editor Hutchinson can see anything different from the explanation, remains to be seen. We stand right where we did on page 297. Wrong is wrong, and no amount of explanation will make wrong right.

Death of Chas. F. Muth.—The following item was sent to us by Dr. A. B. Mason, being taken from the Toledo Blade:

"CINCINNATI, OHIO, May 16.—Chas. F. Muth, a prominent and wealthy merchant of this city, and recently elected member of the Board of Control, committed suicide on his farm near Morristown, Ind. He was found dead with a rifle-ball through his head. It is supposed to be a case of sudden insanity, as he was heard to complain of his head."

This is very sad, indeed. We have received no further particulars at this writing, but hope to have more next week.

"Bienenzucht und Honiggewinnung nach der neuesten Methode. Kurz und klar dargestellt von J. F. Eggers, praktischer Imker bei Grand Island, Nebr. J. F. Eggers, Herausgeber und Verleger, Grand Island, Nebr." So reads the title page of a new book of 50 pages in which bee-keepers from Germany will find in their own loved mother-tongue in condensed form the principles of bee-keeping as practiced in this country. It is well up-to-date, and so simply and plainly written that it may well be recommended as a text-book to bee-keepers who are striving to master the intricacies of the German language.

The price of the book is 50 cents postpaid. It is bound in stiff board covers. Orders may be sent to the Bee Journal office.

Don't Ship Comb Honey by Express.—While it may be somewhat early to say anything about shipping honey, we feel that we ought to refer to a case that came under our observation about two weeks ago.

A prominent Chicago honey-dealer sent for us to come and see a lot of comb honey that he had just received—from a bee-keeper about 50 miles from Chicago. The honey was put up in double-tier out-of-date 24-pound shipping-cases, and two of them had been fastened together by nailing pieces of lath across their ends. There was perhaps 500 pounds of beautiful honey in the shipment. But it wasn't so beautiful when the commission man received it. It was the worst broken up—and broken down—leaky lot of honey we ever saw. It was shipped by *express*. That, of course, explained it. We could scarcely believe it, when we were shown the shipper's letter, to find that he was an old, experienced bee-keeper, and yet knew no better than to ship such a lot of honey by *express*! Of course he doesn't read the American Bee Journal.

The producer, in his letter of instructions to the dealer, was very careful to tell how carefully the honey was graded, and how well it was put up; and that he expected a good price for it, of course. But we wouldn't have given 5 cents per pound for it. Why, we wouldn't have wanted such a mess at any price.

It seems strange that after the bee-papers have been so careful to tell honey-producers just *how* to prepare and ship comb honey, those that should know better will simply go on

in their blindness, and then blame the commission man, very likely, if anything is wrong, or different from what was expected. And yet, if some folks think they know it all, and won't read, they will have to take the consequences, of course.

Now, *don't* ship comb honey by express. Put the shipping-cases of honey in large crates holding perhaps 200 pounds each, with several inches of straw in the bottom and at the sides of the crate. Then nail a 3 or 4 inch board on each side a third of the way down from the top, letting the boards extend about eight inches at each end, for handles by which two men will carry the crate. Honey thus packed will stand lots of bumping around, and will almost invariably reach its destination without any breakage whatever.

Pacific Bee Journal Discontinued.—We have received the following notice, dated May 8, and signed by Editor Bennett:

The publication of the Pacific Bee Journal has been postponed, owing partly to my connection with the National Guards of California, who daily await orders from the Government to take the field; and partly to the lack of support owing to the unfortunate dry year. I intend to resume the publication at some fitting time, advancing all paid-up subscriptions.
B. S. K. BENNETT.

Money but No Names.—We have received two letters accompanied by a dollar each, but the senders were evidently in such a hurry to pay up that they forgot to sign their names. On the envelop of one the postmark is "Pueblo, Colo.;" on the other, "North Adams, Mass." Will the guilty subscribers please write us at once, so that we can credit the money properly.

A War Relief Fund.—We appeal to our readers to join with us and thousands of other patriotic citizens throughout the country in raising within the next 30 days a relief fund of *one million dollars* to be placed in the hands of the American National Red Cross and of the Central Cuban Relief Committee, appointed by President McKinley.

We, with other publishers and merchants throughout the country, are volunteering to receive donations of \$1.00 each for the fund. It has been arranged to present every one, who donates \$1.00, with a copy of a beautiful picture, "The Accolade." This picture is a beautiful historical souvenir of this great uprising of the American people to defend and set free outraged Cuba. Every patriotic American should subscribe at once! Your help is needed! Our boys are at the front! Let us stand by them! We do not reserve any commission of any kind, and no profit is made by any persons from this fund.

The souvenir that is given in return for each dollar donated is a work of art fitted to adorn any parlor wall. It is a large picture, 18 by 38 inches in size. It presents Columbia, the allegorical figure of the United States, bestowing the Accolade on wounded Cuba. Judge Noah Davis, of New York, speaks thus of the picture:

"The Accolade is the name of the kiss given as the final ceremony in the bestowment of Knighthood upon the worthy heroes of the Age of Chivalry. It was the token of love for noble deeds—deeds done in the cause of Virtue—in the defense of innocence and in the rescue of the humble and poor. It was therefore 'The Kiss of Love'—the tenderest and sweetest kiss when given in the cause of suffering and helpless humanity. . . . It is well, then, that in this hour of her awful agony, America should clasp to her bosom the wretched and unhappy Cuba and give her 'The Accolade'—the kiss of charity and love, and the token of hope for peace and happiness, bestowed by a mighty people in the name of God and Liberty."

Now let every one of our readers send promptly to this office \$1.00 toward this Million-Dollar Relief Fund. The cause will commend itself to every liberty-loving humane American.

Remember no commissions are paid to any one for raising this fund. The contributions go intact to the Relief Fund.
All help, and help at once.

MR. HAMILTON PIPEB, of Calcasieu Co., La., writes:
"The American Bee Journal is good. The number for May 12 is worth a year's subscription to any bee-keeper."

MR. D. W. HEISE—the Ontario bee-keeping chap that noses around and picks up notes on bees wherever he can find them, for the Canadian Bee Journal—wrote us May 4 that his "bees are all right, but the weather unfavorable."

MR. E. W. BROWN, of Erie Co., N. Y., writing May 16, said:
"I had my first swarm May 13. It was brought down from the top of an apple-tree by my wife, while I was in Buffalo."

DR. PEIRO is now located at Central Music Hall, Chicago. Any of our readers contemplating consulting him are informed that the Doctor will be absent from his office during July. Appointments to see him should be made by letter in advance of starting, to insure certainty of personal interview.

MR. THOMAS G. NEWMAN, of San Francisco Co., Calif., writing us May 12, reported:

"The weather is cold and disagreeable here this spring. Fruit is killed, and of honey there will be none to spare, even if there is enough to keep the bees over."

MR. J. O. GRIMSLEY, of Pickett Co., Tenn., writing us on May 16, said:

"A very backward spring, but bees are working nicely now. Poplar is just in bloom."

Mr. Grimsley edits the bee-department of The Ruralist—a monthly paper published in Maryland.

MR. HARRY S. HOWE is the Secretary of the New York State Association of Bee-Keepers' Societies, organized at Geneva, N. Y., March 16. Mr. Howe's picture appears in the May American Bee-Keeper. He has become famous in his section of the country as the lightning extractor of honey and general all-around apiarian hustler. Howe's all right, "any-Howe."

REV. W. ANDERSON, of Bureau Co., Ill., called on us May 18, when attending a convention in the interest of his (the Congregationalist) church held in Chicago at that time. Mr. Anderson has some 30 colonies, and finds their care both pleasant and profitable. There doubtless are many preachers throughout the country that might find it to their advantage, both physically and financially, to have a few colonies of bees upon which to spend their leisure hours.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., writing us May 12, said:

"Since March our spring has been wet and cold—so wet that farmers are 'blue' on account of not being able to get in their crops, and bees have had only two days in which they could get anything from hard maple and willow—the only thing in blossom so far. Bees are really in poorer condition now than they were the middle of March. I will have to feed soon unless good bee-weather comes."

EDITOR HUTCHINSON's father-in-law died May 1, at the age of 74 years. He was a bee-keeper over half his life. Mr. Hutchinson says:

"I remember with pleasure the visits that I made him when scarcely out of my 'teens,' to 'talk bees.' It was during these visits that I made the acquaintance of the girl who has since been my good wife."

Yes, of course Mr. Hutchinson made those visits to "talk bees" to the father, and finally talkt "honey" to the daughter. Great scheme that. Favorably impress the parents, and half the battle is won—sometimes.

An End-Spacer at the Bottom of the frame is strongly recommended by the American Bee-Keeper. A staple driven into the end of the bottom-bar, projecting $\frac{1}{4}$ -inch, so that in rapid handling there will be no danger of crushing bees or queens between the end-bar and wall of hive.

Lime Good for Sweet Clover.—J. E. Crane, in Review, strongly endorses the idea that lime is needed for sweet clover, by saying that at the great marble quarries at Rutland, Vt., sweet clover grew in great luxuriance on the heaps of waste where to the depth of 20 feet there was nothing but marble, or pure lime.

Breeding Out the Swarming Instinct.—"If the desire to incubate has been so nearly bred out of some breeds of fowls," says J. E. Crane, in Review, "why may we not breed out the disposition in bees to swarm? I believe it can be done; and with far less labor and time than the desire in fowls to incubate has been eradicated."

Comb of Buckwheat Heavier than Clover.—"When we take the same brand of foundation and supply it to bees gathering clover honey, and to bees gathering buckwheat honey, we find invariably that there is a very much larger amount of added wax in the case of the buckwheat than in the case of the clover," says Prof. Shutt, in Canadian Bee Journal.

Strength of Flavor in Honey depends somewhat upon the yield, according to E. E. Hasty, in Review. The quantity of essential or flavoring oil seems to be about the same whether the secretion of honey be much or little. Same with coloring matter. So in a heavy yield both color and flavor will be light, and vice versa. Basswood honey is sometimes yellow by scant secretion, and apple honey over-flavored and bitter.

Section-Cleaners, so far, have generally been of sand-paper, which soon clogs and demands renewing. J. E. Crane, in Gleanings, thinks there might be a solid cylinder of emery, a cylindrical spring-wire brush, or a cylinder with knives so set as to wind around it like the threads of a screw, which last would not be likely to clog, or if it did it could be easily cleaned with the point of a knife while revolving very slowly.

Cane vs. Beet Sugar.—Dr. Miller asks in British Bee Journal whether definite experiments have been made as to relative value of the two for feeding bees. The editor says although no experiments have been specially made, it is generally accepted as a proved fact in England that the chemicals employed in making beet sugar are injurious to bees, and strongly advises the use of none but refined cane-sugars.

A Conspiracy seems to be hatching in the brain of the Noter and Picker of the Canadian Bee Journal, who has evidently noted this Boller as one to be pickt upon, and he is trying to poison the mind of that innocent youth, E. E. Hasty, inciting him to deeds of darkness by speaking in some heathen tongue such words as "exterminate annihilate reduce him to shadow." Such things in a civilized country are dreadful!

Basswood.—"I find by going over my diary that my bees have averaged fully 50 pounds per colony from basswood alone, each year, during the past 25 years. . . . I never knew of but one season when basswood did not furnish some honey, and that was the last. . . . When the secretion is at its best, I doubt whether there is such a thing as overstocking a good basswood locality, if 1,000 colonies were located all in one place."—G. M. Doolittle, in American Bee Keeper.

Apple-Bloom is highly valued by G. M. Doolittle, as it is by many others. It comes at a time when it tells greatly on the development of the colony, making it ready for the white clover harvest. As Quinby says: "This season often decides the prosperity of the bees for the summer." The best year Doolittle ever had for apple-bloom was 1877, and that year he got his biggest crop of honey, averaging 166 $\frac{2}{3}$ pounds per colony, spring count, mostly comb honey. One

day in apple-bloom he timed the bees. At 8 o'clock the number of bees that entered the hive in a minute averaged 43; at 10 o'clock, 49; at 1 o'clock, 51; at 5 o'clock, 43. A hive that was weighed gained 8 pounds 2 ounces through the day, and lost 3 pounds 2 ounces by evaporation through the following night, making a net gain of 5 pounds of honey for the day's work, showing that the nectar was very thin.—Bee-Keeper's Review.

A Little Scrap About the Plain Section takes place in the Canadian Bee Journal between Editors Root and Holtermann. The former doesn't want his firm clast as a swindle by pushing what Holtermann calls "a decided humbug." Holtermann replies he only meant it was "a piece of nonsense or folly." Root asks the statement to be pointed out where he said a section without bee-ways would *in itself* give fatter combs, or that a tall section is better filled out than a square one. To this request no reply is made.

Do Not Overstock Your Field.—Suppose within range of your bees throughout the summer there are 4,000 pounds to be gathered, and 80 pounds per year are necessary for each colony for their own use. If you have 50 colonies, and there are no other bees in the neighborhood, your bees will live through but afford no surplus for you. If, however, you have only 25 colonies, and these can gather all the honey, there will be 2,000 pounds of surplus for you. Something to think about.—Bienenzucht und Honiggewinnung.

Cane vs. Beet Sugar.—"There have been cases of dysentery in this county during the past winter, the bees were able to take flights almost daily up to end of January, showing that either cheap beet sugars are often used in preparing bee-food, or that, if cane sugar is used, the food is very badly prepared. I always make my bee-food from cane-sugar, besides feeding up a number of colonies for procrastinating bee-keepers in order to save them, and have not had a single case of dysentery," says Wm. Loveday, in British Bee Journal. He thinks America is just the place to make definite experiments as to using beet sugar for winter, where bees are confined four or five months in cellars. Isn't most of the sugar used for wintering in this country beet sugar? and isn't cane better?

Measurements of Comb-Bases.—The editor of Gleanings (p. 357) says they have a micrometer that measures "the ten-thousandth part of an inch as easily as you would measure off eighths of an inch on a foot-rule," and he has been measuring septums. He thinks the bees do thin the base of foundation slightly. Prof. Beal's measurements, as given in Review, made the base of extra-thin .0056, drawn foundation nearly .0100, Bingham no-wall .0043, and natural about .0067. Editor Root's measurements made the base of natural comb only about half as much, averaging from .0030 to .0036, and he thinks Prof. Beal must have used comb that was built when honey was coming in very slowly. Extra-thin Mr. Root found .0050 to .0060, about the same as Prof. Beal, and thin foundation running 11 feet to the pound .0071. He thinks the drawn foundation can be made with much thinner base by using the natural instead of flat base. He *hopes* they will be able to make the 18-foot-to-the-pound foundation with base .0030, which will defy connoisseur or micrometer to detect the difference between it and the natural product of the bee.

Drawn-Out Combs, or unfinished sections, to be used over again, are discuss somewhat fully by Dr. C. C. Miller (Gleanings, page 342.) While leaving a loop-hole for possible retreat by saying that he is ready to change his opinion upon sufficient evidence, he combats vigorously the idea previously held by the editor of Gleanings that for good results the cells must not be more than $\frac{3}{8}$ -inch deep, and challenges proof that B. Taylor ever intended leveling for any other purpose than to remove whatever of the edge might be objectionable, and claims it is a waste to cut down a cell, no matter how deep, after such objectionable part is removed. "One reason given for having cells not more than $\frac{1}{4}$ -inch deep is that, when deeper, the comb is tough. If there is any difference, ought not the part of the comb last made be the most tender? Then why cut away that, leaving the toughest part? Another is that with cells more than $\frac{1}{4}$ -inch deep, the honey is not as thick and of as nice quality. . . . If it is true that a cell $\frac{3}{8}$ or $\frac{1}{2}$ inch deep is better than a deeper one just because of its depth, I don't for the life of me see how it is possible to get away from the logical conclusion that the greater the depth the poorer the honey, and the less the depth the better the honey, the best honey of all being produced on the Michigan no-wall foundation."

Bees Doing Well.

I had three swarms last week during fruit-bloom, and all are doing well. Who can beat that? Alfalfa blooms in two weeks. Kansas is all right.

SILAS HARTER.

McPherson Co., Kan., May 15.

Colonies Short of Stores.

Bees have wintered very well, but we are having a very backward spell for them just now, and they are short of stores.

CHAS. ALEXANDER.

Onondaga Co., N.Y., May 16.

Too Dry in California.

It is too dry here. No honey in California this year. Most of the bees will starve if not fed. I have 75 colonies, and only two swarms, up to date.

DAN CLUBB.

Tulare Co., Cal., May 9.

Looking for Swarms Daily.

My bees have wintered well. I have 80 colonies, losing two in wintering. The Italians robbed them. I am looking for swarms every day.

P. E. CAMFIELD.

Shelby Co., Ill., May 16.

Beats Previous Records.

The weather has not been very warm so far this spring, but my winter and spring loss at the home apiary is only one colony out of 73, and this present condition beats all previous records, as over 1/4 of them have queen-cells, ready for swarming, and fruit-bloom is only commencing to open.

FRANK MCNAY.

Columbia Co., Wis., May 10.

Good Indications Now.

Fruit-trees are in full bloom, and the bees are working heavily on them, but we were having rain for the last three days, so they could not work. I put 18 colonies into winter quarters, and did not lose one—all came out good and strong. The indications at present are for a good honey crop this year.

JOHN H. RUPP.

Washington Co., Kan., May 17.

Italian Bees' Honey—Foul Brood.

Mr. A. W. Hart, on page 269, asks how it is that the Italian bees produce a finer quality of honey than the blacks or others, when all have access to the same forage. The editor thinks here is a chance for some one to distinguish himself. Let me take that chance.

You know, nature and the breeder's influence create different constitutions. For example, take 10 cochins with 10 leghorns. Let all have access to the same forage and you will have different quantities, qualities and even colors of eggs. What's the cause? You say, "Well, Asiatic hens are more flesh-producing; and Mediterranean hens more egg-producing." That's right, but that's not all. Nature and the breeder's influence did something besides that. It made

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,

Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dand.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 176 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. It is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principle portion of the book called BEES OF HONEY. 102 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, by Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yield of comb or extracted honey." 80 p., illustrated, 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2, in fine artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees. Poultry. Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only one book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

A QUESTION.—Could you not send one or more NEW SUBSCRIBERS with your own renewal? You doubtless have neighbor bee-keepers that would be glad to take the Bee Journal if you would ask them, and send in their subscription money. You will find premiums offered by us from week to week for such work. We would like to have you help us roll up a large list of readers for the old American Bee Journal.

Frank B. Barkley Mfg. Co., 835 Old Colony Bldg., Chicago, Ill., will sell you a bicycle or sewing machine direct from factory.

the leghorns active, and this activity made them hardy. So a leghorn hunts and hunts; it gets all that makes an egg fine and rich. With bees it is the same. Italians are more active and more hardy than others. You may see them flying soon in the morning and late in the evening, when others stay at home. So they have more chance to produce fine honey than others. Certainly, the bees "make" the honey, but first they must have something to make it from. It is not red clover they need, but they need plenty to select the best. Therefore do not breed from all Italian colonies—breed only from the most active. As a rule, even Italians show exceptions.

Mr. E. S. Lovesy, of Salt Lake Co., Utah, gave a copy of Utah's new foul brood law, providing that an inspector shall visit all colonies of bees at least once a year, and as many more times as may be necessary. Such inspections of hives without a good education of bee-keeping is monstrous. Don't call a State-guard when you may guard yourself. Perhaps Mr. Lovesy will be kind enough to tell why Utah's bee-keepers can't guard themselves as well as an inspector can. J. VOLKERT.

Chesterfield Co., Va.

All Wintered.

I have 34 colonies that I wintered outdoors, and they have come through in good condition. My wife and I examined the 24 colonies to-day, and elipt the queens in all but two, where there were so many bees I could not find her. During the past year I have sold \$160 worth of honey, besides using all we wanted, which is a large quantity, as I have a large family. LUTHER BROWN.

Litchfield Co., Conn., May 10.

No Loss in Wintering.

We wintered 30 colonies of bees without a single loss. All are now very strong except one. They work well whenever the weather is warm enough. There is a little new honey and plenty of old in the brood-chambers. We expect a good season and ready market for all the honey we can get.

The American Bee Journal is a wonderful help to me. F. C. McCLAIN.
Mason Co., Mich., May 12.

Perforated-Tin Section-Cleaner.

Believing that I have solved the difficulty connected with the use of sand-paper for cleaning sections, I thought possibly it might interest the readers of the American Bee Journal to know how. I have a frame made like the Aspinwall, having a small roller like his, also a disk 12 inches in diameter, but I believe Mr. Aspinwall has given us the only correct principle, as a disk brings the work too far from the shaft, thus requiring too much power for a foot lever.

With a 2½-inch roller I first cover it with tin tacked on for protecting the wood from hot water or fire. Next I cut another sheet of tin the size to cover the roller. This sheet I tack on to a smooth, hard board, then with a little nail filed to a long, tapering point I perforate this sheet as closely as can be done, never driving the nail up to where it is even sized, thus leaving the perforations like an inverted cone. When done, tack this sheet on the roll, tightly sinking the tack heads with a

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

As we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polisht, snowy-white sections, beautiful straw-

colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.

THE HATCHING HEN

HAS LOST HER OCCUPATION and in the production and brooding of chicks she has been supplanted by the better and every way

RELIABLE INCUBATORS AND BROODERS

They Hatch and Brood when you are ready. They don't get lousy. They grow the strongest chicks and the most of them. Reliable Incubator and Brooder Co., Quincy, Illinois.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail YOU a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

punch. Now run the machine rapidly, holding a file lightly on these sharp points, until the work done on sections is smooth.

I think by following these directions you will have the very best section-cleaner that has come to my notice. It does the work smoothly and rapidly, and these little cone points show little tendency to clog, but the propolis is almost entirely removed by holding a piece of soft wood on, and reversing the machine; but it can be cleaned with hot water or steam, or by holding a blaze under it may all be burned off.

This has the merit of being cheap. Any one can make it. It is also durable, as one will last years; and last, but not least, I believe it can be made to satisfy every demand for good work. My large belt wheel is 21 inches in diameter, the belt pulley above is 1 1/2 inches, with 2 1/2-inch roller. These put on a 1/2-inch shaft giving very high speed.

Montrose Co., Col. JNO. S. BRUCE.

Eupatorium Aromaticum.

The plant sent by Mr. Bucy, of Kentucky, is one of the large genus *Eupatorium*, to which belong the bonesets, thoroughworts, Joe pye weeds. The plant in question is probably *E. aromaticum*.

Prof. Cook says of the Eupatoriums, speaking of July plants, for honey purposes: "Now commence to bloom the numerous Eupatoriums, or bonesets and thoroughworts, which fill all the marshes of our country, and the hives, as well, with their rich, golden nectar."

All the Eupatoriums, as I have before stated, are well worth cultivating by bee-keepers for their superior honey-producing qualities.

H. S. PEPOON, M. D.

[Dr. Pepon is the biologist in the Lake View High School. Flower samples may be sent to him at 539 Byron Street, Chicago, Ill. He will then report on them through the Bee Journal, if so requested.—Ed.]

Wintered Well and Booming Now.

Bees are booming, and swarming since the first of May. I have some colonies that are storing honey in the sections, from fruit-bloom. I have 17 colonies—did not lose one during the winter—and were all on the summer stands. I have never before had such a strong, clean lot of bees at this season of the year, and will say for the benefit of "Iowa," on page 294, that I gave them top ventilation, too, but with different results.

I started with 12 colonies last season, which gave me 526 pounds of comb honey, mostly clover. My bees carried in pollen on the first day of March, and on the first day of April drones were flying. How is that for Western Pennsylvania? T. C. KELLY.

Butler Co., Pa., May 16.

Honey from Willows, Etc.

My bees did well last season, altho my neighbors' bees did nothing. I got from 100 to 125 pounds per colony, and we have good prospects this season, if we get rain soon enough to keep clover booming, for that is our main flow. I got about 24 pounds per colony this spring from white willow.

I have to believe our success is from

THEODORE BENDER, 20Atf Canton, Ohio.

First Excursion of the Season to Cleveland

via Nickel Plate Road, June 3 to 6, inclusive. \$11.35 for the round-trip on certificate plan. Tickets good returning until June 13, inclusive. Three through trains daily from Van Buren Street Passenger Station, Chicago. For further information address J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone Main 3389.

reading the Bee Journal. When I first took the Bee Journal my wife would hardly notice it. She said that was the driest truck she ever tried to read. But now if I come home Thursday nights without it, the first thing I hear is, "Where is the Bee Journal?" The only excuse I have is, "I haven't been to the post-office." Then she says to the little girl, "Won't you go and get it for papa?" But when it comes, mamma's hand is ready to receive it, and see the new items. I got her to read it by asking her to read aloud to me.

My bees wintered nicely without any loss whatever, and they came out of the cellar good, strong colonies.

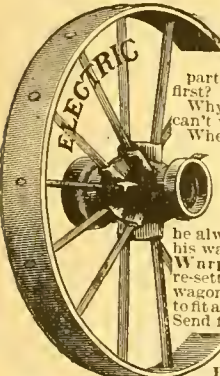

NATHAN RICHARDSON.
Steele Co., Minn., May 16.

Excursion to Cleveland.

The Nickel Plate Road will sell tickets from Chicago to Cleveland and return at a fare and one-third for the round-trip on certificate plan, good going June 3, 4, 5 and 6, and good returning until June 13, inclusive, on occasion of the annual meeting of the Congregational Home Missionary Society in that city. This rate will be \$11.35 for the round-trip, which is somewhat lower than via other lines. Those desiring space in sleeping-cars should make early application in order to secure the best accommodations.

Any further information cheerfully given by addressing J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone Main 3389.

Telephone Main 3389.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, May 19.—Very little call for honey, and the offerings also limited. Prices without change from late quotations. California extracted sells well and the stocks here are light. Weather now warm and prospects generally reported good in the surrounding States. Beeswax scarce, and 27 to 30c is bid for it. R. A. BURNETT & Co.

Kansas City, May 19.—The supply of 1897 comb and extracted honey is about all sold. Considerable inquiry for new comb. Something fancy would bring a good price. C. O. CLEMONS & Co.

Cincinnati, May 21.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3 1/2 to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Boston, May 20.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, no sale. Extracted, white, 6@7c.; light amber, 5@6c. Beeswax is in very light supply, and if pure would readily bring 27c.

There is nothing new to note in our market for honey. As usual at this time of year, the demand has dropt to almost nothing, but as the supply is light, prices are well maintained and firm. BLAKE, SCOTT & LEE.

Cleveland, May 20.—Fancy white, 12 to 12 1/2c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & Co.

San Francisco, May 11.—White comb, 8 1/2 to 10c.; amber, 6 1/2 to 7 1/2c. Extracted, white, 5 1/2@6c.; light amber, 4 1/2 to 5 1/4c. Beeswax, 23@25c.

The French bark Alice, sailing Sunday for London, carried 135 cases of extracted honey. This will probably be the last shipment to Europe for some time. Stocks of extracted are now very light. Comb is still in fair supply. Values throughout are being well sustained.

Detroit, May 21.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. M. H. HUNT.

Minneapolis, May 20.—Honey much more encouraging. Fancy white clover comb is selling here now at 10 1/2@11 1/4c. Not advisable to ship darker than amber. Extracted fancy white clover, 5 1/2@6c.; amber, 5c.; dark, 4@4 1/2c.

Outlook for honey much more encouraging. S. H. HALL & Co.

Indianapolis, May 21.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, May 20.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c.; amber, 8@8 1/2c.; dark, 7@7 1/2c. White extracted in barrels and kegs, 5 1/2@6c.; amber, 5@5 1/2c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & Co.

Buffalo, May 21.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & Co.

St. Louis, May 20.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c. WESTCOTT COM. Co.

Convention Notices.

Central California.—The next annual meeting of the Central California Bee-Keepers' Association will be held at Hanford, Cal., Wednesday, June 1, 1898, at 10 o'clock a.m. Election of officers and other important business to be attended to. W. A. H. GILSTRAP, Sec. Caruthers, Calif.

Fresno Co., Calif.—The next quarterly meeting of the Fresno County Bee-Keepers' Association will be held at the City Hall, in Fresno, Calif., Wednesday, June 8, at 1 o'clock p. m. Constitution and By-Laws are to be adopted. Marketing honey and other business is to come up for consideration. W. A. H. GILSTRAP, Sec. Caruthers, Calif.

As explained in former ads., publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo.; or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden straw, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. W. Z. HUTCHINSON.

No. 22.

CONTRIBUTED ARTICLES

Mr. D. W. Heise and His Apiary.

I was born on a farm in York county, Ontario, 20 miles north of Toronto, and within three miles of where I now reside, 37 years ago. My parents were of German origin, as the name would readily indicate. As soon as I was able to lend a helping hand, my time up to the age of 16 was spent on the farm summers, and attending a country school in the winter months, which was the extent of my theoretical educational opportunities; but the practical knowledge that I have acquired since leaving school I prize most highly.

The farm work became very monotonous, and out of harmony with my inclinations, having early in life formed a

country in consequence of having, in a moment of weakness, agreed with a person so to do. By the way, that is now, and has been since 1885, my "other half," as might be expected. And that moment of weakness is one which I have never had the slightest reason to regret.

At home again, and among friends, and as I thought a fully-equipped wood butcher, it was only a short time until I succeeded in working up a good trade in the building business. For a few years I took in as partner my younger brother, and together we conducted the business until 1891. During a term of eight years there were erected under the direct supervision of myself or brother, about 70 new buildings, including dwellings, barns, stores, school-houses, etc. I now look back with pride upon that record achieved by a stripling.

At the last named date I found the labor too arduous, and the responsibility too great in connection with the above business—for a lazy man; I therefore decided to retire from the same, which I did, and engaged in a general mercantile business.

I first became interested in *Apis mellifica*, to a very limited extent, when I was about 10 years old. Accompanying my father one late September afternoon to a neighbor's place, we past close along a worm rail-fence which enclosed an iso-

Apiary of Mr. D. W. Heise, of Ontario, Canada.—*Canadian Bee Journal*.

strong desire to learn a trade. So with the consent of my parents, at the age of 16, I adopted the carpenter trade as my choice. After following up this line of work for four years around my native home, I took Horace Greeley's advice and went West. I "pulled up" at Hamlin, Brown Co., Kans., March 19, 1881. Following my trade for two years more, I then, at the age of 22, entered into business on my own responsibility. One year later (1883) I returned to my native

lated pine grove, and in thus passing I observed what turned out to be a swarm of bees, which had settled on the corner of the fence where the rails intersect each other, and about 18 inches from the ground, with the sky for their roof, the grove on one side, and the open plain on the other for their protection. Here they built their comb in such size and quantity that when cut loose they completely filled a large straw hive.

Now for a little of my first experience with bees. But be-

fore relating it, I would just like to say I would give several Yankee silver dollars if I could find a swarm similarly situated, just to see how long they could survive in this climate by only placing a roof over them.

Of course, those bees were mine. My father assisted me, or I him, in cutting the combs from the rails, and placing them in the hive. But this was, as I now know, very improperly done. However, the work was completed by fastening small sticks in the bottom of the hive, to hold the combs from falling out. Everything was now ready to receive the large cluster of bees, and the marching in of that vast multitude I can assure you was a few moments of extreme delight to the young enthusiast never to be forgotten. The whole outfit was then carried home and placed in the bee-shed—something which could be found on nearly every farm in those days. But in the majority of cases it was the shed only tented with a few empty hives.

My "pets," as I now began to look upon them as being, appeared to make themselves right at home, and I would lie on the greensward in front of the hive and watch the little toilers go in and out about their business. One day, while thus engaged, a man past by, and asked where I got the bees. I forthwith gave him their whole history in detail as far as I knew. And do you know, that wiseacre of a bee-warrior just up and smashes all my air-castles into smithereens, by saying, "They won't winter; you must feed them," etc. But he failed to instruct me how to do the feeding. But not to be outdone, I decided to feed, and for several days a 10-year-old boy could be seen reclining in front of that hive after having placed a few spoonfuls of brown sugar (which he had hooled from his ma) in a saucer at the entrance. Of course, the bees would have none of it, and all petered out before Christmas.

This ended my experience with bees at that time, save a little incident through which myself and brothers learned that bees carry pins in that end which is not generally called the front.

Notwithstanding my misfortune with fence-corner bees, there was a spark of enthusiasm kindled within me which refused to die, and for a number of years my circumstances and surroundings were such as to prevent me from entering the pursuit, yet this spark lived.

In 1888, a venerable and generous old bee-master kindly consented to let me have a colony, which I was to manage on shares. Think of that—a know-nothing managing bees on shares! But I did, and that with profit to its owner. Said colony was the nucleus of my now small apiary, which has never exceeded 38 colonies. I aim to keep the number about 30. On account of limited room, and limited time, also, I am prevented from increasing the number. My experience during those nine years has been varied indeed. I have found myself, as I thought, on the mountain top of success, only to be hurled over the cliff of ignorance into the valley of disappointment. But by reading everything having the name of bee-literature that came before my eyes, my knowledge of the management of bees has increased from year to year, until I am forced to believe I know at least a little more of their habits than when I tried to feed them brown sugar.

Now, Mr. Editor, I am not nearly run down, but lest some Yankee should run me down unless I stop this nonsense, I beg to conclude by saying that the height of my ambition, for which I have striven, has been fully realized the past season, namely: An average surplus of 100 pounds of extracted honey per colony, spring count.

I trust that this bit of personal history may interest at least some of the readers of the American Bee Journal, as I have been interested in reading the biographical sketches of others.

Rendering Beeswax with the Sun Extractor.

BY C. P. DADANT.

The following questions have been sent to me for answer in the American Bee Journal:

"Will you please tell us what is the matter with our wax, which has been rendered by the solar wax-extractor three different times? We send a sample cut from a cake, the dark part of which gets darker as it nears the center of the cake, and also deeper. How can we get it all bright yellow? and would it be any advantage when next melting to raise the temperature of the extractor to about 140 or 150 degrees before placing the old combs in, and then allowing the melted wax to run into a pan that contained water of about the same temperature?—ALDER BROS."

The solar extractor is very efficient to render up combs, especially new combs or cappings, into beeswax, as it is always

at hand during the busiest season, but it is absolutely useless in purifying beeswax that has been rendered.

The sample sent with this enquiry is very clear in a portion of it, and darkish and opaque in another portion. This is not astonishing. When you put combs into the solar extractor, those parts which contain the most beeswax will be the first to soften, and therefore the purest beeswax will run first; when the bulk of it has melted down, the remaining liquid part comes also, with a portion of the dregs mixed into it. The cake is thus made to look darker at its center or at the portion which has last melted down.

It would be of but little use to melt up this beeswax several times in succession in the solar extractor, for these dregs are very fine and are sure to stay with the wax. The only method to purify the wax further is to melt it with water, allowing it to cool as slowly as possible. It must be brought to about the boiling-point of water so that there will be a perfect freedom for all the particles of dirt to settle, and as they are usually heavier than beeswax, the dirty portion will be found to have settled to the lower edge of the cake, from whence it may be scraped without difficulty. Several successive meltings with the sun extractor would only tend to mix the dregs more thoroughly with the beeswax and render it so much more difficult to cleanse. The sun, however, has the faculty of bleaching the wax, and would thus render it of brighter color. But even in this there is an extreme to be avoided. Beeswax that has been thoroughly bleached loses its pleasant smell and assumes the disagreeable smell of candles.

The reader will thus see that altho the sun extractor is very good, in fact better than the water process in many instances, yet it is not sufficient if a prime article is wanted, thoroughly purified, for commercial uses or for exhibit. But for comb-foundation making the wax may be shipped to the manufacturer without further trouble, as it is more readily and more easily cleansed of these light remaining impurities in large lots than in small parcels.

Very old combs will decidedly not do for the sun extractor. We have again tried them with negative results, for too much of the wax becomes soaked into the residue. The only paying method of melting old combs is by the water process given by me in the last article on this subject.

While I am on this question, I wish to cite a suggestion made to me lately by one of our friends—J. S. Willard, of Iowa—to put old, broken combs and scraps into a sack which may be sunk into a kettle of water so as to let the wax rise at the top. I have never tried this process, but it looks reasonably practical.

And, by the way, I was told once by a practical candle-maker, and have always thought and held without actual trial, that hard water was injurious to beeswax in the rendering, and that to the use of this hard water could be ascribed some of the spoiled beeswax that is made. But I must to-day acknowledge my error unless the conditions depend on the proportion of mineral in the water, for here is the reply I had from a man who always sends us the very nicest beeswax—Mr. Staininger, of Iowa—and of whom I asked his methods:

"In regard to the wax, I always take hard water and melt it from two to three times, according to the wax; use plenty of water and melt it till the water comes off clean; have a new tin can and *don't get it too hot.*" (Italics are mine.)

Now, here is another testimonial: Messrs. Toad & Arnold always have the very finest beeswax. This spring they sent us a small lot that looked dark and gray. We asked them what was the matter with it. Here is the answer:

"When the cappings were washed they were put into an iron kettle for a few days before melting. That was the first time we ever had a bad lot, and we want it to be the last."

Here is another: Mr. F., of Babylon, Ill., sent us the ugliest cake of water-damaged, blackish beeswax that we had ever seen. The cake is so abominably ugly and looks so little like beeswax that we are preserving it for exhibit as an object lesson. We asked this party about it, and stated that it was our opinion that it had been overboiled and rendered in iron. The answer is as follows:

"Probably you are right about the boiling of that beeswax, as it was boiled quite awhile in an iron kettle."

Now whether hard water has anything to do with it, as was held by the candle-maker, or whether some kinds of hard water have an effect on it, there is no doubt that to make good beeswax it must be treated as follows:

1. If rendered in the sun melt once, and afterwards either render it with water or let it alone.
2. If rendered with water it is probably best to use soft water, but it must be boiled slowly with plenty of water.
3. A tin, or tinned, vessel must be used. We use copper,

which is all right if kept clean. Iron may do if once coated with wax and kept from rusting.

4. The wax must be allowed to cool as slowly as possible, and must not be overboiled.

5. If very clean beeswax is wanted, it should be rendered till the water comes off clear.

6. Damaged beeswax can only be returned by sun heat, and must then be purified again.

While we are on this subject we might as well give it a thorough examination, and if any of the readers desire to make further enquiries they will be welcome

Hancock Co., Ill.

First Day of Spring Among Out-Apiaries.

BY HARRY S. HOWE.

On the morning of March 15, Mr. W. L. Coggs hall and myself were discussing "bee-prospects" by the door of his shop, when I remark: "The unusually early spring has started the season for out-door work with the bees from two to three weeks ahead in this locality."

"Yes," said he; "and those south yards should be seen soon."

"But the bottom has dropt out of the roads, almost."

"That is so; but there is no immediate prospects of their being any better, so if you want to take Topsy and the old

D. W. Heise.

buggy, go ahead. You can see your own south yards, too, while you are at it."

"All right."

Getting out a bee-veil I started over the worst possible kind of roads—roads which are a disgrace to the boasted civilization of the State of New York.

Mr. Coggs hall has no home yard, the nearest one being about one-third of a mile from home. This one, however, had been visited, so the first stop was at the Brown yard, seven miles south and east. Here are 50 colonies all alive.

The first work is to see that all of the hives that may have become tilted during the winter are properly leveled up. Next, the alighting-boards are put in place. This is very important at this time. There would be two or three times as many dead bees in front of the hives where the boards had got displaced as there would be in front of those having the boards in place. One good way of fastening them in place is to drive two staples in the entrance block and then hook two more through them. These are then driven into the end of the alighting-boards, the other end of which is allowed to rest on the ground.

The Brown yard is all in single-story Eclectic chaff hives, with old style Hoffman closed-end frames. This yard has given the smallest average loss since it was established of any of the yards.

The next yard south is Etna, where there are 60 colonies,

all alive. About half are in two-story chaff hives, the rest in Coggs hall's big packing boxes.

The work of cleaning out the entrances with a crooked wire, and then shutting them down to about 1½ inches was repeated. Each colony that did not clearly show its condition from the entrance was looked into and its condition noted. This yard was rather shorter in stores than any of the rest. Many of them had eaten the honey away from the top-bars, leaving that below. They seemed to have more brood than was good for them at this time of year.

There is another of Mr. C.'s yards at Ellis, five miles south yet, but it is over such a big hill, and the roads are so bad, that it has to be skipt for the present. This can be done the more safely, as they are all in packing boxes, and do not have to have their entrances contracted.

Turning to the west the Varna yard of 120 colonies, all alive, comes next. This is the yard that the editor of *Gleanings* took such a fancy to, when he was out here last summer.

Next in order is Forest Home, where all were alive a few days ago, so no stop is made.

Passing through Ithaca, the mile of smooth brick pavement made Topsy forget the 18 miles of mud she had waded through to get there. The Ithaca yard is just west of the city, where there are 107 colonies, still all alive. On the way back from this yard to Ithaca, where I put up for the night, I found a few blossoms of trailing arbutus.

The next two days see the same story repeated, with only slight changes caused by local conditions at the different yards, until 700 colonies with a loss of two is the record so far. There are several hundred colonies yet to see before the records are all in, but from the sample we can judge the balance.

"But the end is not yet."

The bees have more brood and less honey than I ever remember to have seen on the first trip in spring. This leads me to take rather a pessimistic view of the future. We can winter bees all right, but to "spring" them—there is the rub. It looks now as if we should have to feed to get through the spring, at least in some of the yards.

Usually we have the honey from the winter loss to brace up the light ones. Those that go out from now on will not have enough honey to do much good.

If the weather should turn very cold in April we would be almost sure to have a heavy spring loss.

Tompkins Co., N. Y., March 20.

[Accompanying Mr. Howe's article came this paragraph by Mr. Coggs hall himself, dated May 14:—EDITOR.]

I have just finished looking over the out-*apiaries*, and I find 7 per cent. dead. The balance are in fair condition. I expect to lose 5 per cent. from old queens, as I do not requeen. When I had only 300 or 400 colonies, and looked after them alone, I requeened every two years and clipped the queens. I do not know but it would pay to put on extra help and requeen.

W. L. COGGS HALL.

Can Bees Hear?—How Sound Affects Them.

BY F. C. KENYON, PH. D.

On page 197, in the report of the meeting of the Northwestern Bee-Keepers' Association, I note a question and a few remarks on the subject of the hearing powers of bees. Anyone who has handled bees and heard the different tones made by their wings, the angry buzz, the calling buzz when one lifts off the hive-cover, and noted the action of other bees must, it would seem, come to the conclusion that in some way or other they are affected by sound—and that is the essential part of hearing. That they have no visible organs of hearing similar, or rather like those found at the base of the abdomen of locusts, or on the legs of certain grasshoppers, is certainly true, and that is doubtless what Mr. Bruner meant that he had not been able to find.

The fact is, however, that probably must, if not all, insects hear; that is, are affected by sound or air waves; and as in all animals the nervous system takes part in the hearing. Various beetles make a squeaking noise by rubbing the abdomen and thorax together. The cricket chirps by rubbing its wings; some of the thousand-legged animals or millipedes have certain modified legs the rasping of which one on the other produces a noise. Some South African spiders have jaws and palpi so modified that sounds can be produced. In most of these cases the power of producing sounds appears to have the effect of letting other insects know of the whereabouts of the one making the sound. Even the mosquito apparently hears, and an organ has been discovered in the lower

surface of the abdomen of the ordinary bedbug that, judging from its structure, must have something to do with making a noise. Why not for the purpose of letting other bedbugs hear?

In the case of the mosquito hearing seems to be by means of the antennæ. These, as every one who will take the trouble to examine may see, are delicate structures which in the male are covered with fine hairs—feathered would be a better expression—and are affected by every little wave of air. Not many years ago a certain scientist succeeded in cutting the head and antennæ of mosquitoes, and a large number of other kinds of insects, into fine slices so that they could be more easily studied by observation through a microscope. He was able to make out the nerves and the nerve-fibers running from the brain into the antennæ and connecting with the bases of bristle-like and hair-like structures on the joints of the antennæ. Some of these structures were found to be situated on the top of the joints of the antennæ nearest the head, so that when the joint in front moved its base would strike against the tips of the structures. This would be equivalent to a touch, and would be carried through the nerve fiber to the brain.

As all of our higher senses—hearing, sight, taste, and smell—are really nothing more than a highly developed or modified sense of touch, there is little reason for not calling these hair-like organs of the mosquito's antennæ, organs of hearing. Organs very similar to them were found in greater or less abundance in nearly all the insects studied by the scientist, even in those having what have been called organs of hearing on the abdomen. They were found in insects closely related to the honey-bee, and there seems therefore good reason to believe that any person properly trained in the methods of using the microscope would be able to find similar structures in the bee's antennæ. District of Columbia.

Bees in Relation to Flowers and Fruits.

BY THOS. WM. COWAN.

(Delivered at the University Farmers' Institute at Pacific Grove, Calif.)

Most of us know that bees gather both pollen and nectar from blossoms, but it is not generally known why the wants of bees are supplied by the floral world. The answer to this question reveals to us a new meaning to the existence of these insects. Plants blossom in order that seed may be produced and perfected, and the race continued. Before the seed can be produced, pollen borne by anthers must be placed on a certain special part called the stigma. Should the pollen be of a suitable kind, and the stigma in a receptive condition, a delicate thread called a pollen-tube is thrown out by the pollen granule into the seed-vessel, by which the seed becomes fertilized, and, when mature, capable of germination.

Let us examine a flower and bear in mind the arrangement of the different parts. The calyx is the outer green cup, the cover of the bud, and expands as the flower opens, showing its sepals. In some flowers, as in the fuchsia and larkspur, the calyx is colored. Then we see the corolla made up of petals. This is the most ornamental and conspicuous part of the flower.

Just within the corolla are situated the reproductive organs. They consist of stamens and a pistil. The stamens are slender filaments surmounted by a pouch bearing pollen, and these are the male organs, while the pistil in the center is the female organ of the flower. This consists of an ovary containing the ovules or undeveloped seeds, and one or more thread-like styles arising from it, and each terminating with a fleshy stigma. The great majority of flowers possess both anthers and stigmas, thus carrying the two sexes within themselves. From this we might suppose that the form of the flower would be such as to secure the transmission of its pollen to the stigma in order that the end of its being may be accomplished. The older scientists thought so, and were puzzled to explain the various forms of blossoms they examined.

Very vague ideas prevailed as to how the pollen was carried to the stigmas. It was at first thought that the pollen simply fell on the pistil; but when it was found that in some cases the stamens and pistils were on separate plants, the question arose, How could the pollen be transferred at such great distances? It was only toward the close of the last century that Sprengel, after devoting a long time to patient investigation, came to the conclusion that the structure of a large number of blossoms was such as to prevent the flower being fertilized by its own pollen. Very little attention was paid to this until within the last half century, when the researches of Hildebrand, Delpino, Hermann Muller, and, above all, Charles Darwin, threw new light upon the matter. We now know that conspicuous flowers, generally speaking, are

especially arranged to prevent, or at any rate impede, fertilization by pollen which they themselves produce, while marvelous contrivances are found to secure pollen from some other plant or flower of the same species. Among those that have been studied there are a few apparent exceptions, but these under renewed examination are frequently revealing unsuspected adaptations to cross-fertilization. The protest made by nature against continuous in-breeding applies no less to plants than to animals, to flowers as well as bees. But as blossoms are fixt, and incapable of locomotion, it may ask, How is the fertilizing dust carried from one plant to another?

INSECT AGENCY.—In some instances it is carried by the wind, and such plants are called *anemophilous*. Among them we find Indian corn, wheat, barley, grasses, hazels, pines and others. *Anemophilous* plants, as a rule, bear inconspicuous flowers. In the Indian corn the sexes are produced on different parts of the plant. The pistils are the threads projecting from the ear, while the stamens are the tassels at the top. Such plants produce a very large quantity of pollen so as to insure each blossom having a sufficient number of granules to secure fertilization. But Sprengel was able to show that by far the larger number of flowering plants confide to insects the duty of bringing about those unions which, without them, would never be effected. The whole family of *apida* among insects is found to be most useful for this purpose, and of these *Apis mellifica*—our common honey-bee—stands out *par excellence* as the complement of the blossom. It has been shown that in the spring, when fruit-trees are generally in bloom, there are 20 bees flying and visiting the flowers to one of any other kind of insect.

As insects are necessary to the existence of most plants, the flower secures their visits by offering them pollen and nectar served in the most attractive fashion. Pollen is necessary for the flowers themselves, but it is produced in such profusion that there is more than enough for their purpose, some of the surplus going toward the flesh-forming food of the bee. Nectar, however, in most cases, is yielded solely for the benefit of the bee, and is the reward for her work. We thus see that insects perpetuate flowering plants and flowers continue the existence of insects, both being vitally dependent upon each other. The main function of the highly decorative corolla is to attract insects, but the anthers and stigma are absolutely necessary to secure the reproduction of the plant.

CHARACTER OF POLLEN.—Pollen contained in the anthers of various flowers differs greatly in form, color and size. In wind-fertilized flowers it is dry, but in *entomophilous* or insect-fertilized plants the granules are coated with an oily substance which gives them adhesiveness, and enables them to stick to the body of the bee. The stigma, when ripe or in a receptive condition, has a moist surface. When a pollen-grain comes in contact with this, it receives nourishment and the exterior coat bursts, while the interior protrudes and develops a tube which passes through the pistil with remarkable rapidity into the cavity of the ovary, sometimes to great distances, as in the crocus, in which the style is frequently five or six inches long. The pollen-tube enters the ovule by an opening called a micropyle, which it has unerringly found in the darkness. Every ovule requires a pollen-tube to fertilize it, but usually many more are produced than can be utilized.

(Continued next week.)

Does Bee-Keeping Pay?—A 17-Years' Report.

BY WM. STOLLEY.

On page 33 Mr. C. P. Dadant has a very interesting article, showing the outcome for one year in an apiary of 80 colonies, managed by expert bee-keepers, such as the Messrs. Dadants are. It may interest some "farmer bee-keepers" how bee-keeping paid me in 17 years, since I did not know anything at all about bees when I began, but being an enthusiast I no doubt spent a great deal more work on my bees than probably really was required until years of experience taught me better. And yet, I see that while Mr. Dadant figures on but 19¼ days work with 80 colonies of bees during the entire season, I work in all about 28 days with only 28 colonies, spring count, in 1897, and I had a boy to help me at times, besides, when my heavy hives had to be lifted.

I have kept a very accurate account of all money expended, as well as of the money realized out of bee-keeping in the 17 years. Before I present my statement, I will say that I figure all my surplus honey secured at 15 cents per pound, including what of it was consumed in our household, for that is the price I sell for, and for years I sold all I had at even 25 cents per pound. I have, and aim to keep, my customers who will buy only from me, knowing that they will get the pure

and unadulterated article, and they are willing to pay me a fair price for my honey. Thus I care little at what prices Chicago, St. Louis, Kansas City or Omaha commission men quote honey, and I have even a customer in St. Louis as well as in Kansas City, who pay me 15 cents per pound for extracted honey, and order annually.

In the summer of 1880 I began with but two colonies of bees, which by swarming increast to six colonies. By proper feeding, and guarded by the advice obtained from the columns of the "old reliable" American Bee Journal, I was fortunate enough to winter them well, altho for 105 days in one stretch they had no flight.

Now, the following is a correct statement for each year succeeding—1st, of the number of colonies, spring count; 2nd, the surplus honey taken; and 3rd, the average per colony secured:

| YEAR. | No. Colonies in Spring. | No. Pounds Surplus Extracted. | Average No Lbs. Per Colony. |
|-------|-------------------------|-------------------------------|-----------------------------|
| 1881 | 6 | 230 | 38 |
| 1882 | 14 | 314 | 22½ |
| 1883 | 25 | 320 | 13 |
| 1884 | 48 | 80 | 1½ |
| 1885 | 32 | 256 | 8 |
| 1886 | 23 | 2,635 | 114¼ |
| 1887 | 23 | 2,078 | 90¼ |
| 1888 | 21 | 1,474 | 70 1/5 |
| 1889 | 27 | 2,036 | 75½ |
| 1890 | 26 | 1,175 | 45 1/5 |
| 1891 | 18 | 2,358 | 131 |
| 1892 | 31 | 1,038 | 33½ |
| 1893 | 32 | 885 | 27½ |
| 1894 | 23 | 50 | 2 |
| 1895 | 17 | 3,002 | 176¼ |
| 1896 | 26 | 3,010 | 116 |
| 1897 | 28 | 1,570 | 56 |

The next table shows the amounts realized, as well as the annual disbursements, from 1880 to Jan. 1, 1898:

| YEARS. | Receipts. | Disbursements. |
|---|------------|----------------|
| From 1880 to Jan. 1, 1884 } (in three seasons) | \$331.50 | \$468.18 |
| 1884 | 79.00 | 67.58 |
| 1885 | 294.50 | 50.80 |
| 1886 | 550.00 | 35.05 |
| 1887 | 422.33 | 20.55 |
| 1888 | 248.25 | 38.75 |
| 1889 | 391.65 | 56.80 |
| 1890 | 174.55 | 28.00 |
| 1891 | 360.37 | 30.70 |
| 1892 | 203.65 | |
| 1893 | 256.40 | 63.35 |
| 1894 | 67.55 | 25.75 |
| 1895 | 465.25 | 24.61 |
| 1896 | 548.50 | 35.50 |
| 1897 | 319.70 | 44.75 |
| Total..... | \$4,713.20 | \$990.37 |

The amount realized over and above expenses is \$3,722.-83, which gives me an average income of about \$213 per year for my work and investment. Bees are, of course, a side-issue with me, but they are also a hobby, and I see, first of all, that they are well supplied for winter before I take a pound of honey away from them. I never extract from the brood-chamber, altho one-half of my standard hives carry 14 frames 11½x11¼, and the rest 10 to 11 frames of the same size.

During the 17 years I have sold 68 colonies of bees at a total of \$690, and besides 74 empty hives at different prices, according to the quality of the hive sold.

I do not pretend to deal in apiarian supplies, but was somewhat compelled to have some extra hives and foundation on hand for those who bought bees from me.

At the present I have a little, but model, apary of 36 colonies, in a well-built bee-shed of 90 feet in length, together with all appliances needed. Of course, if I would keep hundreds of colonies in several separate apiaries my mode of management would not answer. But the particular pains and care which I take with each colony is the very pleasure I get out of it, and that is in the first place the very thing I am after in keeping bees.

As I have said, I often have a boy to assist me when needed, and nearly always work with the bees in the afternoon so as to take advantage of the shade.

I think that bee-keeping on a small scale pays me in proportion to the capital invested as well as anything else on the farm.

If a person is not adapted to bee-keeping—if he has not a genuine love for his pets, and the business—such a person would much rather let fooling with bees severely alone. That is my unqualified opinion about keeping bees.

Hall Co., Nebr.

CONVENTION PROCEEDINGS

Report of the Ontario Convention.

Being the 18th Annual, Held at Hamilton, Dec. 7-9, 1897.

Mr. J. K. Darling delivered the following:

President's Annual Address.

Another season has past by, and we are again met together to compare results and lay plans for the future. The past season has been a varied one, the bee-keepers in some localities securing a fairly good yield of first-class honey, while in others there was very little, and in some places none whatever of a first-class article stored by the little workers. In some sections there was a small flow of dark honey in the fall, and in others the bees secured barely enough for winter stores, and a goodly number of colonies have had to be fed. As a consequence prices are firm, and the surplus of last year is likely to disappear before another season opens.

As an Association we can congratulate ourselves on making progress. Some years this advance is not as pronounced as at other times, yet "Onward" is the word, and we are living fairly up to it. If we take a statement made by the President of the Dairymen's Association of Eastern Ontario at their annual meeting, held in Brockville last January, and compare our work with theirs, we will have no cause to feel disheartened. After referring to the vast amount of butter and cheese which Ontario exports to England, he says:

"Now, how has this been brought about? In the first place, by orgaulzing a dairymen's convention at Ingersoll 30 years ago this spring, with the motto of 'Progress.' For the first 14 years all that the association did was to hold conventions, to teach cheese and butter making while attending and holding of cheese shows."

Surely, our record is as good as that, and while we cannot hope to accomplish as much as the dairymen can accomplish, or to increase the industry of bee-keeping to the magnitude of the butter and cheese trade, there is plenty of room for advancement. The work of the association must be mainly along the line of education, and I think we ought to begin at once to push that branch of our work with more vigor than we have ever done in the past. It is that kind of work that has placed the dairy interest of the Dominion in the front rank as it stands to-day.

ADULTERATED HONEY SCARCE.

There have been no complaints of adulteration during the past year, owing, no doubt, to the efficient work done in the Inland Revenue Department at Ottawa; and it is my opinion that with the law as it is now, and a proper watchfulness on the part of honey-producers, we will not have much trouble with adulterated honey. It is a matter upon which we can congratulate ourselves that not one of the adulterated samples was traced to a bee-keeper, and that most of the samples which were adulterated with glucose were traced directly or indirectly to one firm in Montreal; and, further, that the most of the adulterated samples secured were secured within a radius of that city. This is a matter that ought to be proclaimed from one end of the Dominion to the other, thus allaying the distrust that has arisen regarding pure honey. Only one sample in 15, and that in a limited area.

Regarding the standard for the specific gravity of honey, we are very much at a loss as yet how to proceed. The fact that the percentage of water in the samples analyzed at Ottawa ranged all the way from 12 to 33 per cent. would show at once that much more must be done before any definite

conclusion can be reached. This work we now have before us. The educating of the masses in regard to the use of honey, thereby increasing our home market, is a matter deserving the attention of this Association quite as much as teaching those who wish to keep bees how to care for them. The program which is placed before you will provide an opportunity for each one present to contribute something to our store of bee-knowledge. I hope that the friends who look forward after last year's meeting with the expectation that our meetings in the future would be less turbulent and more harmonious and useful, will not be disappointed.

I thank you for the confidence placed in me a year ago in elevating me to the position I now occupy, and I trust you will assist me in making these meetings both pleasant and useful during the few hours I shall remain in my present position.

J. K. DARLING.

Referring to the minutes and the President's address, Mr. Holtermann stated that there was too much unripe honey placed upon the market, and that we should take steps to have a limit fix as to the percentage of water honey should contain when placed before the public. In the discussion following attention was drawn to the difficulty of fixing a proper standard, and to the fact that the breed of bees, locality and season had much to do with the thickness of honey. Prof. Shutt, analyst from the Dominion Experimental Farm, referred to the English standard of 18 to 20 per cent., and that there are cases where the percentage far exceeds 25 per cent., but he considered the Association safe in putting it at 25 per cent.

Upon motion it was decided that this Association appoint one or more of its members, and that the Department at Ottawa, the Dominion Experimental Farm, and the Ontario Agricultural College at Guelph be requested each to appoint a man, and that this committee secure samples of honey capt in the hive, and find the percentage of water contained therein, and report at our next annual meeting.

MANAGEMENT OF BEES IN THE SPRING.—Mr. J. W. Sparling gave a paper on this subject. He emphasized the importance of commencing spring management in reality the fall previous. The first care is abundance of stores, and too much importance cannot be attached to young, vigorous queens. He advocated early putting out, no spring packing, and if stimulative feeding be practiced, that it only be done during the honey-dearth between fruit-bloom and clover. Mr. Alpaugh spoke of the desirability of early fall packing, and also stated that comparatively small colonies of young bees were preferable to large colonies of old ones.

Prof. Shutt gave the results of three years' experiments with foundation of various weights. The results pointed toward the use of heavy foundation, the bees seeming to add less wax when drawing out the foundation, thus making more use of what was given them.

A considerable discussion took place as to the desirability of opening up the British market for Canadian honey. It was stated that the clover honey from Canada was of a better quality than that from Australia and other foreign countries. The British market does not demand minty honey, hence it is a mistake to send basswood honey there. Nothing but the best clover should be sent to Britain, and many thought that we could not expect to realize over 7 to 8 cents net for it.

OUTLINE OF WORK DURING THE EXTRACTING SEASON.—Mr. Newton, in dealing with this subject, stated that he produces both comb and extracted honey. He selects his best colonies to work for comb honey, and the remainder for extracted. He uses queen-excluders and full-depth supers. When the first super he puts on is about two-thirds filled, he raises it up and puts an empty one beneath it and on top of the honey-board. Be sure the honey is well ripened before extracting, and have combs capt over before removing from the hive. He recommended being scrupulously clean and tidy while extracting. He renders cappings each day with a solar wax-extractor. At the close of the season he has the extracting-combs piled on the hives and cleaned by the bees before being put away. In the discussion following, the fact was brought out that the honey obtained from cappings when being rendered into wax by a solar wax-extractor would not be colored by the heat if the pan into which it runs were shaded; it was also necessary to keep the extractor clean if the honey was not to be colored by sediment or other matter in it. It was contended that it was a loss of time to the bees to give them extracting-combs during the day; they should be given in the evening, and they then will have the night to clean them up.

"THE PRODUCTION OF COMB HONEY" was introduced in a short, comprehensive paper by Mr. J. B. Hall. He stated

as a first requisite a right strain of bees, those that will fill the brood-chamber with brood, and not refuse to work in the sections when the time comes. He did not believe the hive had much to do with the securing of a large and nice crop of comb honey. He emphasized the necessity of seeing in September that bees had abundance of stores to last them until honey came again. He strongly urged the filling of sections with foundation, and not to use that which is tough. The apiarist must know about the time his honey-flow begins and ends, and give supers as soon as needed, and keep a little ahead of the bees, and remove the honey just as soon as it is capt.

Mr. W. M. Orr being present at one of the sessions, he was asked to address the Association. He stated that during the past year not a single sample of adulterated honey was traceable to a bee-keeper. Concerning spraying, he asserted that it was not only useless to do so while fruit-trees were in bloom, but absolutely injurious. He showed samples of the San Jose scale on both fruit and wood, and much interest was shown in the examination of these specimens. In speaking of it he stated that bee-keepers were interested in it as well as fruit-growers, inasmuch as the scale would attack any variety of tree except pine and cedar.

"What is your experience with Carniolan bees?" was asked. Mr. C. W. Post expressed himself as well pleased with them, but the majority of those present did not agree concerning their various qualities. In answer to other questions asked, it was thought advisable to have an opening through the center of the brood-combs in order to allow the cluster of bees to contract and expand during cold weather. In producing comb honey it was thought best to fill the sections with foundation, as it not only gave a better quality of honey, but far more of it. About 70 to 85 per cent. as much comb honey, it was thought, could be produced as extracted. A majority of those present advised the clipping of queens in order to control swarms.

Again referring to the subject of a British market for Canadian honey, it was moved by W. Couse, seconded by F. A. Gemmill, and carried, that we heartily endorse the action of the Government in placing a commissioner in London to look after the interests of Canadian products, and that we request honey to be placed on the list, and that we would recommend to the Government Mr. C. W. Post as an inspector to guarantee any honey which we may export.

Upon motion, Mr. J. Newton was recommended to the Government as a fit and proper person for Dominion apiarist.

OFFICERS ELECTED:—President, M. B. Holmes; 1st Vice-President, W. S. Brown; 2nd Vice-President, J. D. Evans; Secretary, W. Couse, Streetsville; Treasurer, M. Emigh. Directors, J. K. Darling, C. W. Post, J. W. Sparling, A. Pickett, Jas. Armstrong, J. Newton, F. A. Gemmill, W. A. Chrysler, and A. Wood; Representative to the Ontario Agricultural College, R. F. Holtermann; Inspector of Apiaries, Wm. McEvoy; Sub-Inspector of Apiaries, F. A. Gemmill; Representatives to the Boards of Management of the Industrial Exhibition, Toronto, A. Pickett; London Fair, R. H. Smith; Central Fair, Ottawa, J. K. Darling; Auditors, A. E. Hoshal and Jacob Alpaugh; Revising Committee, J. D. Evans and D. W. Heise.

Guelph was selected as the next place for holding the annual convention.—Farmer's Advocate.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. O. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

What Was the Matter?

1. I had a swarm of bees last summer settle in a tree over a large creek. I had the tree cut and drowned a great many bees, but succeeded in saving the queen. They worked nicely all summer, but in the fall got weaker. I examined them and found they had not an egg or young bee. They had a nice lot of honey and a beautiful, large Italian queen, but she died with the bees, leaving what honey they had.

2. Also, another colony, very rich, swarmed out in January, leaving a full hive of honey. What was the cause?

3. Also, another had plenty, with a large brood-chamber, kept coming out and going off, leaving the queen crawling on

the ground, then would return to the hive in search of the queen. What was the cause? NORTH CAROLINA.

ANSWERS.—1. There may have been some defect in the queen, or the trouble may have been merely weakness of the colony.

2-3. I don't believe I know, unless too weak in bees.

Telling Carniolans from Blacks.

By what particular marks can I tell the Carniolan bees from the common bees generally known as "blacks"?

ALABAMA.

ANSWER.—Rather hard to describe, but perhaps it may be said that in the Carniolans there is a light or whitish band that does not appear in the blacks.

Brood-Frames Partly Filled with Comb.

1. I'm a beginner and have at present six colonies, and the bees seem to be in good condition at present. I placed the supers filled with sections on all of them May 14. I examined all of the hives and found the frames with comb, but no honey in them excepting in one. Is this all right?

2. In regard to this one I wish the information. On opening the hive I found the frames partly filled with comb. To give you an idea you can see by the rough drawing I herewith send you. What is the cause of this? One comb has brood partly capt.

NEW JERSEY.

ANSWERS.—1. It is hardly wise to put on supers before the bees are ready for them. In your locality they are not likely to store any surplus before clover, and even then they would hardly store in sections until the brood-frames were well filled.

2. The peculiarity in the case seems to be that the frames are very irregularly filled, all being only partially filled, and no two combs being alike in size or shape. It hardly seems that bees, left to their own devices, would ever build combs in this way. It may be that the combs were put together from different hives, or it may be that the combs were wormy or otherwise bad, so that the bees gnawed away the faulty part, leaving them in this irregular condition. Of course only a guess can be made, and this guess may be entirely wrong. You will find nothing about such a case in the books, as no such case would ever occur under ordinary circumstances—only as an accidental thing.

Laying Workers and Foul Brood.

1. I have a colony that I found queenless in the spring, but found some drone-brood, and what I thought a queen-cell. I let it alone for two weeks and found no queen. I gave them two frames of brood and eggs, and they paid no attention to queen-rearing, but still found drone-brood. Then I gave them one more frame of brood and eggs, and in a week I found two queen-cells. Now, it has been 22 days since I gave them the last frame, and no queen yet, but a little drone-brood. Have they a laying worker and don't want anything better, or what is the matter?

2. I have a colony that I suspect has foul brood. In the spring of 1897 I found it weak. I gave it a frame of brood and discovered some dead brood, and they did not build up strong in the summer. I gave them two more frames of brood and they seemed to build up and clean out the hive nicely, and were in very good condition by fall, but I never put on a super at all. This spring I thought they were in good condition, but they do not get strong, and I find the brood scattering—eggs, brood, larvæ, and dead brood all mixt up. The dead turns brown but does not get rosy or smell offensive. This evening I set the queenless hive by the other, and in a few days I aim to double them up and put them into the queenless hive, and do away with the other. What do you think of that?

3. I also have a third colony that is strong, but I find some dead brood, and the brood scattering, but no bad odor.

KENTUCKY.

ANSWERS.—1. The probability is that they have not only a laying worker, but a whole lot of them. Better break up the whole business and give the combs to another colony or divide them among several.

2. I stopt and studied over this question some time, then turned to Mr. Cowan, editor of the British Bee Journal (who was at my house at the time, and who knows ten times as much about foul brood as I do,) and askt him what he thought. He thought it might be a pretty safe thing to destroy the snspcted colony, as the risk was so great. Occasion-

ally it happens that the disagreeable smell is not observed. The presence of dead brood scattered among the living is very suspicious. Turn back to page 289 of the American Bee Journal, and study the picture taken from a photograph by Mr. Cowan. Burn frames and combs, but the hive may be saved. Mr. Cowan's pamphlet says:

"The hive is disinfected by being either steamed or scrubbed with holling water and soap, and then painted over with a solution of carbolic acid (one part of Calvert's No. 5 carbolic acid to two parts water,) and when the smell has disappeared it will be ready for use."

3. The dead brood scattered among the living looks very suspicious, and suggests close watching, at least.

Hives in Which Bees Died—Uniting Second Swarms.

1. Last year three of my colonies died, and this spring I put one of the hives on top of another hive of live bees, thinking they should get out the honey that was left in them, but instead of taking the honey out they carried some more in it, and besides they had two combs filled with brood, and a good many of the cells were filled with pollen. What is best to be done with the matter?

2. Can I put second swarms together without taking one queen away?

3. I have two hives with honey in them which I put on top of other hives so that the bees can get the honey out, but they are very slow at it. Can I leave them stand that way till after swarming-time?

ILLINOIS.

ANSWERS.—1. The result would probably have been different if you had put the empty hive under instead of over. However, nothing very bad has happened. You can at any time take away the combs that are unoccupied and mass in one hive the combs of brood. If more than will go in one story and you don't want to have more than one story filled, it will be an easy matter to give such combs to colonies needing them, to nuclei, or to swarms.

2. Yes, if they are united at or near the time of swarming. A few days later it may be well to make one of them queenless 24 hours or more before uniting.

3. Better put them under, and it will be safe to leave them till wanted for swarms, or till later.

Drones in Fruit-Bloom, Swarming, After-Swarms, Putting on Sections.

1. Is it anything uncommon to have sealed drones in the hives at this time of the year (May 20)? I have seen one live drone, too. It is fruit-bloom just now.

2. How soon can a swarm be expected from now? The colonies with drones are very strong and have plenty of sealed workers.

3. Please give me a plan or plans (if you know several give two or three of the best) that you will warrant to prevent all after-swarms. I have only one empty hive for every colony of bees.

4. When is the best time to put on sections, and what are the signs? I mean, of white clover, if when I see the first blossom, some of the bees are whitening the top edges of the comb?

IOWA.

ANSWERS.—1. No. On the other hand it is rather unusual that you can find only one live drone in fruit-bloom.

2. Hard to say. Depends somewhat on the weather. If favorable, a strong colony might swarm in fruit-bloom, but not many colonies are likely to swarm till fruit-bloom is over and white clover has commenced to yield.

3. If you cut out all queen-cells but one, being sure to miss none, it's pretty safe to warrant there will be no after-swarms, but it's pretty safe to warrant that if you treat many in this way you'll occasionally miss a cell. Perhaps the best thing for you to do is to take this plan: When a swarm issues, set the hive with the swarm on the old stand, putting the old hive close beside it. A week later carry the old hive to a new place a rod or so away. The field-bees will return to the swarm, the parent colony will be reduced in numbers, and all supernumerary queens be destroyed.

4. You can't go by date. Go by conditions. Generally when you see bits of white wax put on the upper parts of the comb, it is time to put on sections. But hardly when this occurs in fruit-bloom. In Iowa, when the very first white clover blossom is seen, you may expect bees to be working pretty well on white clover, so if you are observing enough to note when the first lone white clover blossom appears, you may be ready to put on supers in about 10 days.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

JUNE 2, 1898.

NO. 22.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the Joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" indicates a preceding sound.

"If Bees made glucose some dealers would adulterate it with pure honey." So reads an "ironical if" in a daily newspaper. It expresses the thing about right, too.

Rates to Omaha.—We have received the following, dated May 25, from Commissioner E. Whitcomb, of the Trans-Mississippi and International Exposition, now in operation at Omaha, Nebr.:

FRIEND YORK:—The rates have already been fixed for both the Trans-Mississippi Exposition at Omaha, as well as for the G. A. R. reunion to be held at Cincinnati, and there doesn't appear to be much difference in them.

I have opened up an office in the Apiary building, where I am to be found at all times. Mrs. Whitcomb will be here tomorrow with her large display of wax work, which will by far outstrip anything before placed on exhibition in that line. We are a little late in getting the Apiarian Building ready, and will be able to extend the time for placing exhibits to July 1. Mr. Stilson is here and engaged in placing Nebraska's exhibit, and it will be a fine one.

The building and its inside arrangements are the finest ever opened to the bee-industries anywhere, and everything has been granted that has been asked for; at this time, if there is anything lacking, it is because we haven't asked for it.

Yours truly, E. WHITCOMB, Commissioner.

We may have been misinformed, but we understood some time ago that the round-trip rate from Chicago to Omaha during the Exposition would be \$20. That is about double the Grand Army rate of one cent a mile.

We regretted very much to notice that the Omaha Exposition management had decided to keep it open Sundays. We were hoping that they would not make the same mistake the

World's Fair people did, and offend those visitors who believe in observing Sunday in the right way. No doubt many will remain away from the Omaha Exposition when they learn that it is to be kept open on Sunday. It might do over in Spain, where they glory in Sunday bull-fights, but in the United States—well, when the Sunday of our honored forefathers is gone we think that our people will realize they have lost a good deal. We propose to do our part toward holding on to Sunday as a day of rest and worship.

We hope the Apiarian Building will be kept closed on Sunday during the Exposition in Omaha.

The New Union's Work.—There are now something like 400 members of the United States Bee-keepers' Union, but there ought to be 4,000. We recently asked the Board of Directors to offer any suggestions that they felt like making in reference to the New Union, and here is what Editor Root, of Gleanings, has to offer:

EDITOR YORK:—I notice on page 233, you would like to hear from the Board of Directors with regard to the United States Bee-keepers' Union. You know, of course, just how I stand; but as for complying with your request, I wish to offer nothing but encouragement; and the only suggestion I make is that General Manager Secor blow his horn a little more—that is, tell of some of the things he has done. A recapitulation of his works since he became General Manager would have good effect, in my judgment. You will see by Gleanings that he has settled a very difficult case.

Yours truly,

ERNEST R. ROOT, Director.

The "difficult case" referred to by Mr. Root is described as follows in Gleanings for May 15:

GENERAL MANAGER SECOR AS AN ARBITRATOR.

Some time ago I referred to a difficulty between a bee-keeper and a commission-house to the Manager of the United States Bee-keepers' Union. The case was a particularly difficult one, especially one where collection seemed well nigh out of the question. As a last resort, and with a feeling, I must confess, that nobody could do anything, I referred the matter to Manager Secor. The commission-house in question does a large business in one of our large cities. For certain irregularities we never admitted their quotations. Well, what was my surprise when I found that Mr. Secor had actually compelled them to pay up! and the bee-keeper who, I think, had also given up his case, was so pleased that he turned in \$2.00 to the Union for payment of membership in advance, saying that, if that was the way the Union was going to champion the rights of members, he was going to support it.

Manager Secor is a good arbitrator; and if he could bring about a satisfactory settlement in a case that seemed practically hopeless, as was the above, he is a captain.

For years back we have been acting as third party, or arbitrator, between commission-men and bee-keepers; but on many accounts the Union can and should do far better work, and at the same time bring to bear its moral prestige and strength; and I would suggest, therefore, that in future all cases be turned over to General Manager Secor, of Forest City, Iowa, for I am sure he will handle them with discretion and ability. But there is one thing you must not forget to do, and that is to become a member of the Union before you get into trouble. It is hardly fair to expect that the Union would come to your support if you are not already a member.

Every one of our subscribers ought to be allied at once to this organization that stands for the best interests of the bee-keeper and the championship of his rights. Do not wait till you forget about it, but plank down your dollar at once.

It has always been beyond our comprehension why bee-keepers hold back so from joining an organization like the United States Bee-keepers' Union—one that is managed wholly in their interest. It hardly seems possible that it can be on account of a financial lack, for the membership fee is only \$1.00 a year. That may be the reason (and a good one) in some instances, but any one who pretends to do anything at all with bees ought to be able, and very glad, to help in such a wise effort as is being made by the New Union in the interest of its individual members, and thus to the whole bee-keeping industry itself. If we as bee-keepers will not look after our own interests we may be sure no one else will, and

Manager Secor cannot be expected to do very much when there is but little to do with.

Now, we trust that those readers of the American Bee Journal who have not as yet joined the New Union, will do so at once. Why not make it 1,000 strong by the time of the next annual meeting, sometime next September, probably? We will be glad to receive the dollar membership fee from all who prefer to send it to us, and then forward to General Manager Secor, who will mail you a receipt therefor. Of course, you can send direct to Mr. Secor, instead of to us. Address him thus: Hon. Eugene Secor, Forest City, Iowa. If only 50 new members were added per week from now until the next meeting, there would then be almost the first thousand. Surprise Mr. Secor by rolling the dollars toward him for awhile. He's a very cool, quiet, backward sort of man. Pleasant surprises are always a good thing for such people. Encourage him to laugh heartily on account of the great number of dollar membership fees hastening toward them. Begin now.

The Queen-Breeders' Union.—We take the following paragraphs from the Bee-Keepers' Review for May:

This is an era of organizations, and unions, and fraternities. The latest in this line, in an apicultural way, is the Queen-Breeders' Union. The idea originated with Mr. J. O. Grimsley, of Tennessee. The object is to protect and benefit both queen-breeders and queen-buyers. No breeder will be admitted who has not a *clean* record; and any case of crookedness on the part of a member will cause him to be expelled. Only honest, straight-forward, reliable breeders will be admitted, and if it is found that a mistake has been made in admitting a man, that mistake will be rectified. Expulsion from the Union would practically ruin any breeder's business, and no man will be expelled unless his business proves to be such that it *ought* to be ruined. Of course, not to join the Union need not necessarily be construed as a reflection upon a man's honor or integrity, but to join it shows that he is willing and ready to stand with those who intend to do right; and to place himself in such a position that he *must* do right or be publicly branded as a rogue. If a man buys queens of a member of the Union he can rest assured that he will be treated fairly. If he isn't, he will have in his hands a pretty big club to hold over the head of the man who has dealt unfairly.

Another object of the Union will be to protect its members against dishonest queen-buyers. Occasionally there is a man who starts out with the deliberate purpose of defrauding queen-breeders. He orders queens and promises to pay at a certain time; gets all the queens he can on credit of one breeder, and then proceeds to "work" some one else. Of course, a man may not always be able to pay when he has promised to pay, but the man who deliberately goes to work to "beat" queen-breeders will soon find out that they are "on to him," as the saying goes.

The business of organizing this Union has, I believe, been all conducted by mail, and I am not certain that it is yet complete. It is likely that more particulars can be given later.

LATER.—The officers are as follows:

President, G. W. Hufstedler, of Texas; Vice-President, J. B. Case, of Florida; General Manager, W. H. Pridgen, of North Carolina; Secretary and Treasurer, J. O. Grimsley, of Tennessee.

We do not see why such an organization should not be a good thing for all concerned. We shall be glad to publish free a list of the names of the members of the Queen-Breeders' Union, and still gladder to insert continuously in the American Bee Journal, say an inch advertisement for each, at the usual rates.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

MR. S. T. PETTIT, of Ontario, Canada, reported his bees in extraordinarily good condition May 21. That's the general report this spring.

MR. M. M. RICE, of Grant Co., Wis., wrote May 20:

"Bees are in fine condition, and there is a good outlook for a crop of honey."

MR. M. M. BALDRIDGE, of Kane Co., Ill., reported two swarms, May 16 and 17. Another bee-keeper at the same place wrote us May 23 that he had had 7 swarms up to that date. Bees began to swarm very early this year.

MISS FLORA FITCH—J. A. Golden's fascinating young lady helper—is pictured in Gleanings for May 15. Poor Rambler; he'll be worse upset now, for not even the section-cleaner is shown with her; and when Rambler must face her face without a counter attraction, we don't know what will happen! But then, he's 2,500 miles away, so no one need get uneasy just yet.

MR. THOS. WM. COWAN, the noted editor of the British Bee Journal, was in Chicago last week, and we had the delightful pleasure of making his acquaintance, and also that of his wife, who accompanied him. We regretted exceedingly not being able to entertain Mr. and Mrs. Cowan at our home, on account of the ill-health of Mrs. York, who has for the past several months suffered from malarial fever. No one who has been thus afflicted need be told of its very weakening and lingering effect. We hope next week to be able to have more to say regarding Mr. Cowan's visit to this part of the country.

MR. O. O. POPPLETON, of Dade Co., Fla., writing us May 19, said:

"This is my busy season, running the extractor daytime and reading war news evenings. The honey crop is a very light one. I have out so far an average of only 40 pounds per colony; ought to have had double that by now. May possibly double it during the season. The fire was quite a serious loss to me, not only in bees and one full set of implements, etc., but almost our entire range is burned over. As pennyroyal takes about three years to recover itself, the loss will not be confined to this season only."

Mr. Poppleton's fire was thus mentioned in the American Bee-Keeper for May:

"Mr. Poppleton has recently suffered quite a heavy loss as the result of one of his apiaries being located in the wake of one of those destructive fires, which, during the spring months, are constantly raging through the woodlands of South Florida. The bee-house with all its contents, including a new Cowan extractor, uncapping-can, tank with several hundred pounds of honey, and numerous other articles of value, was destroyed. Many hives with bees were damaged, and 11 strong colonies were consumed outright."

We hope Mr. Poppleton will soon recover from the effects of the fire. It no doubt came in a very bad time for him.

THE GENTLEMAN FARMER MAGAZINE is in its 3rd volume. It is gotten up after the style and shape of the Cosmopolitan and similar magazines—only more beautiful, if that is possible. The May number has been on our desk for several weeks, but until now we have been too busy to notice it in this column. It contains about 100 pages, and is most fully illustrated with the finest half-tone engravings. This particular May number contains an article written by Rev. Emerson T. Abbott, of Missouri, entitled "Bee-Culture." We believe it is to be concluded in the June number. It aims to present the subject of bee-keeping in a popular and entertaining way—and Mr. Abbott can do that. Better get the May number. Price 10 cents; or one year for \$1.00; or we will club it with the American Bee Journal for a year—both together for only \$1.75. Address the Gentleman Farmer Company, Manhattan Building, Chicago, Ill., for a copy, enclosing 10 cents. Then after examining it send us your subscription. You will like the magazine very much.

Good Wintering.—According to Schweizerische Bienenzeitung, colonies have the fewest deaths in winter that are well surrounded with honey, sealed being better than unsealed. Late feeding is bad. If compelled to feed, crowd the bees on few frames, give warm feed rapidly, and keep the bees warm.

Moist or Dry Heat in a Hive.—Referring to page 123 of the Bee Journal, Hasty, in Review, thinks there's a chance for a fight as to whether the air in a hive is moist or dry. On the one hand, so much evaporation of nectar must make things wet, and on the other hand unless the air was pretty dry there couldn't be evaporation.

Young Queens to Prevent Swarming.—One year Graevenhorst, early in May, removed 20 old queens, replacing them with queens that had just begun to lay; 19 of the 20 colonies swarmed. But when the young queen is reared in the colony, he has never known such young queen to swarm that year.—Deutsche Ill. Bztg.

Finisht Sections—are they Desirable?—Editor Hill says this has been developed as a new question in connection with plain sections—whether sections should be filled and finisht to the wood on all sides—and he votes yes. But he thinks the projecting side-pieces of the section are a valuable protection to the comb in handling.—American Bee-Keeper.

Age of Queens.—Experiments at Flacht showed that in fall and winter 10 per cent. of two-year-old queens disappeared and no one-year-olds. Of colonies with two-year-old queens, 30 per cent. began breeding early in the last mild winter, and 60 per cent. of the colonies with one-year-old queens were already stronger than the preceding October.—Centralblatt.

Painting Hives is vetoed by Doolittle, but J. H. Martin says in Gleanings, that while such a view may be all right for York State, in hot climates honey will melt down in a hive not kept well painted and white. To which Doolittle may reply that the same rule holds in York State if hives have no protection from the sun, but in the shade a white hive will melt its honey as quickly as a black one.

Something Against Fall Feeding.—E. E. Hasty, in Review, refers to the interesting report of "Iowa," in American Bee Journal (page 122) and thinks the colony that lost 24½ pounds after having been fed, might have lost only four if it had not been disturbed by feeding. He says: "In my opposition to fall feeding, except when absolutely necessary, I have been pretty lonesome in this generation; but a hundred years hence there'll be more of me."

Wintering on Sealed Honey.—F. A. Gemmill united two normal colonies about Nov. 5, and put them on four Langstroth frames of sealed honey. They remained perfectly quiet when other colonies flew Feb. 10; and March 11, after 3½ months' confinement, they showed no more need of a flight than if they had only been confined a month. Pretty good evidence that empty cells are not absolutely essential for wintering.—Canadian Bee Journal.

The Ideal Super is the rather imposing name applied to a super that has won Editor E. R. Root from his loyalty to the section-holder, and seems to be in a fair way to secure the allegiance of Dr. Miller to the abandonment of the T super, if fences and plain sections are to be used. The Ideal takes tall sections, the super having a strip of tin as a support at each end at the bottom, the same as the T super, but in place of T tins it has plain wooden bottom-bars running lengthwise, the sections resting on these bottom-bars. Evidently the doctor cannot resist the temptation to poke a little fun at Editor Root, with whom he has for a long time been at sword's points regarding the matter of supers, and he reaches after him in the following style:

"And I've thought that, if he'd handle a lot of T supers for a single season as they ought to be handled, he might change his tune. First he believed in wide frames—wide frames with top-bar, bottom-bar, end-bar. For a time, if I'm not mistaken,

he believed in T supers, and then he went back to wide frames just a step nearer T supers than the old wide frames by leaving off the top-bar, and he called them section-holders. Now he's gone another step toward the T super, left off the end-bar, and dubs it Ideal. If he'll go still another step and leave off the bottom-bar, perhaps he'll stand square in line with me."—Gleanings, page 386.

Carbon Bisulphide for Fumigating Honey is recommended by J. S. Woodward (National Stockman) in preference to sulphur, as the latter makes him sick. Put the honey in a place that can be closed tight—for the size of a flour-barrel put two tablespoonsful of carbon bisulphide in a saucer or flat dish on top, then cover up. Leave over night, and treat again in two or three weeks. But be careful in handling it, for its fumes are poisonous, and it is inflammable and explosive.

Honey vs. Sugar.—In Stray Straws (Gleanings, page 378,) a case is mentioned in which physicians have forbidden the use of starch and sugar, but allow pure honey. The Stray Straw man uses honey instead of sugar in hot drink, and likes it as well as sugar if the honey is of best quality. The editor is very positive that there is a decided difference in his own case, as he is able to eat a certain amount of honey without inconvenience, but cane sugars, maple sugars, candy, and all such stuff, he is obliged to let alone.

Flights in Wintering.—D. W. Heise, in Canadian Bee Journal, referring to the statement "that the bees that have the greatest number of winter flights in cold, hard winters, are the ones that come out best in the spring," wonders whether that's the whole truth, and thinks if he could control the matter he'd have just one flight a month. But there is probably no conflict of opinion, for remember, Mr. Heise, it's "cold, hard winters" that are spoken of, and in "cold, hard winters" the bees are not likely to fly more than once a month.

Rate of Storing Honey.—To many who have been accustomed to hear of the large yields of honey in California, the natural supposition probably is that more honey is secured there in a day than farther north and east. But W. A. H. Gilstrap (Gleanings, page 391) says: "I am convinced that it is not common for bees to store honey as rapidly here as in the east. Your bees store perhaps over half as much in 30 days as ours do in 100. An apary storing three pounds of alfalfa honey per day for each colony would be a good run. I have never been able to extract so much."

Well-Finisht Sections for Shipping.—R. C. Aikin thinks there would be little trouble about combs breaking out of sections when shipped if they were well fastened to the wood all around (Gleanings, page 381.) Poor attachments are likely to be made in slow flows, with weak colonies, or when too much super room is given. He is strongly in favor of bottom starters, and has a large per cent. of sections better fastened at bottom than at sides. There is trouble with bottom starters curling over when too deep, but he finds they will answer the purpose nearly as well if only ¼ or ⅜-inch deep, and when thus narrow will not curl over.

Time of Mating and Laying.—Doolittle gives some figures (Gleanings, page 396.) The first young queen emerges from her cell in about seven days after the prime swarm issues. Queens which have their own way fly to meet the drone when about five to seven days old, and begin to lay two or three days later; 17 days is the shortest time a young queen is likely to be laying after the prime swarm issues. But eggs are so scarce that it is hardly worth while to look for them till three or four days later. If after-swarm issue, then the time is lengthened several days. Mr. Doolittle's practice is to look for brood or eggs the 23rd day from swarming if there are no after-swarms, and four days later if there are after-swarms.

Getting Big Prices for Honey seems to be a specialty with Chalou Fowls (Gleanings, page 384.) Last season he got an average of 12 cents a pound for his comb honey, and 10 cents for extracted, ⅔ of his crop being extracted. An article in a former number of the American Bee Journal gives his plan of selling, but that alone will hardly account for this fact, which he states: "It is a significant fact that in the town of Elyria, a town of about 10,000, every one of the grocers handles my extracted honey, paying cash on delivery, and they will not buy of others, even when offered at a lower price." Perhaps the chief secret lies in this sentence: "The extracted honey is ripeed in the hive, and always weighs 12 pounds or more to the gallon."

GENERAL ITEMS**Buckwheat in Bloom.**

I had only 3 colonies, and have had 2 swarms so far this year, but I expect 4 more. I am taking no honey from them, and won't this year, as I will let them increase. I have ½ acre of Chinese buckwheat in bloom, and the bees are working hard. PIERCE O'HURLEY.

Choctaw Nation, Ind. Ter., May 24.

Report for 1897.

I produced 2,500 pounds of comb honey last season, from 43 colonies, spring count, and sold it before winter, at an average of 13 cents per pound, all within 12 miles of home. I had calls for more, but I could not furnish it. I increased to 73 colonies, lost 3 during the winter, and I am now doubling some of my hybrids.

I had my first swarm of this season today—May 26. W. R. CLOVER.

Vermillion Co., Ind.

"Converted" Bees!

Our bees are doing well. Fruit-bloom is in all its glory. I cannot understand why so many of my bees have turned Methodists—they used to be Presbyterians—but now they swarm on Sunday! Two yesterday—one before 9 a.m. If I had my choice in the matter I would rather they would remain united for at least three weeks longer, as I am a cripple at present, and cannot attend to swarming. But I expect to be on toepath again in a week or so.

D. W. HEISE.

Ontario, Canada, May 23.

Starved in Winter.

I lost quite a number of my bees last winter through starvation—5 out of 20. The weather kept so cold that I didn't dare to open the hives, but the rest are in good condition. They swarmed first May 23. They didn't get much honey out of the fruit-blossoms this year, as the weather was so cold, but it is pleasant now. At present they work on the dandelions, which are plentiful here. The white clover is in fine condition this year, and will soon blossom. There is a great deal of it here. It is the main honey harvest in this part of the country. LEWIS HARTING.

Ida Co., Iowa, May 25.

Bees in Good Condition.

I have 14 colonies of bees all in good condition but one, which was weak and queenless. I gave them a frame of brood from another hive, and they have reared a queen, or at least there are a number of empty queen-cells, tho I have not looked for the queen. I will give them another frame of brood soon.

Apples and plums are heavy with bloom, and bees are working lively. I have about an acre of strawberries in bloom, but haven't seen a bee on them yet, while the dandelions are alive with them. They have always worked very lively, however, on the raspberries—especially the reds—of which I have about

A Book Recommended by Dr. Gallup.**THE NEW METHOD
In Health and Disease.**

By W. E. Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from Weakness to Strength so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings cannot be sick. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, not a drug treatment.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "New Methods" given here; even those who have been pronounced Consumptive have been entirely cured. While for Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

GEORGE W. YORK & CO.,
CHICAGO, ILLS.

Bee-keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

Frank G. Barkley Mfg. Co., 835 Old Colony Building, Chicago, Ill., will sell you carts, wagons, buggies, carriages and harness direct from factory. 21A4t

Basswood Honey FOR SALE

We have a limited number of barrels of very best Basswood Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash,

GEORGE W. YORK & CO.,
CHICAGO, ILLS.

three acres; but they haven't bloomed yet.

There is a good prospect for white clover. There is no basswood near me, but there is an abundance about five miles away. Will it pay to move my bees into the vicinity of the basswood about the time it begins to bloom, and then back again after it is over.

I have gotten a good deal of help from the American Bee Journal.

J. RIDLEY.

Winneshlek Co., Iowa, May 21.

[It depends very much upon whether the basswood yields or not, as to moving the bees so as to work on it. Some years it has bloomed profusely and still yielded no nectar. Just why is not known. But you could try the experiment this year, if not too much work, and report results.—EDITOR.]

Most Colonies Strong.

My 72 colonies of bees have wintered well in 8 and 10 frame "St. Joe" hives, on the summer stands with Hill's device, and from 2 to 4 inches of chaff over them. I lost one that starved, and have divided two, thus filling the empty hive and making a gain of one. Most of my colonies are remarkably strong for this time of the year, and will swarm 10 days earlier than last year.

I could not, and will not, keep bees without the American Bee Journal. I get valuable help from its reading.

WM. C. HUDNALL.

Fulton Co., Ill., May 20.

A Busy Bee-Keeper.

This is a very busy season for me. I am on a 200-acre dairy farm, with a milk route, which I run myself. I have 25 colonies of bees to look after, and am preparing to build a house, barn and well on a place of 36 acres which I have recently bought, and to which I expect to move next spring. I have been putting in small fruit and improving other ways.

Bees came out of the cellar in fine condition, and everything has been favorable. They are building up splendidly. I have had one fine, large swarm, and other colonies are preparing to swarm. Apple bloom lasted longer than usual, and yielded well, and then wild crabs followed. White clover is looking nice, and there is every prospect of a prosperous year for the bees.

I like the Bee Journal very much, especially the editorial comments, which I read first.

S. H. HERRICK.

Winnabago Co., Ill., May 25.

Sweet Clover—Wintering Queens.

The Bee Journal is always interesting to me, but sometimes more than usually so, as this sweet clover number of April 21. There is much in the experience of J. F. Rosenfeld that is parallel with my own. I, too, have a little patch from which each season I dig plants to put elsewhere. The main object of this is to spread the clover, but there is a secondary one, which is, to give the clover that is left opportunity for development. It likes abundant room, and I have had it growing as luxuriantly as it is pictured in the illustration, and a beautiful, fragrant plant it is when in full bloom. I was glad to be able to read this article,

PRICES OF BINGHAM PERFECT Bee-Smokers and Honey-Knives!

especially the closing paragraphs, to Mr. Amos, for he looks upon me as a sort of crank on the subject of sweet clover.

The paragraph on "Killing old bees in the fall," suggests a matter on which I think there is room for experiment and study—that is, how to keep queens without keeping more bees than are necessary or useful. I tried that in a small way myself the past winter. I wintered a young queen, reared late in the season, in an observatory hive. She came through in good condition, and is now laying vigorously, as I needed her for a queenless colony. Here our main honey-flow comes after June, so there is a long season in which to build up.

The past winter I carried through two small colonies whose queens began to lay in August, and were encouraged to lay as long as they would, so that most of the bees were young when put into winter array. They did not seem large enough to winter alone, so I took one of my big chaff hives and fitted a division-board bee-tight, and put a little colony on each side, seeing that the frames given them—four and five—were well filled. They came through the winter in good condition, and I would be well pleased to have more such double colonies. (MRS) A. L. AMOS.

Custer Co., Nebr., May 10.

All to Keep Sweet.

Bees are doing well and are in good condition. Locusts are in bloom, and white clover is just beginning to bloom. The prospect is good for a fair crop of honey. I hope there will be enough sweetness to keep us all sweet, and enough to sell, so that we can keep our subscriptions paid in advance, and the editor "sweet" as well.

W. S. FEEBACK.

Nicholas Co., Ky., May 23.

Prospects in Utah.

The chances for a good honey year here appear to be good. There has been an abundance of rain, which seems to have assured good crops even on the dry farms, which lie above the irrigating canals, while everywhere in the irrigated districts everything is growing in abundance. This will insure lots of bloom, which in turn will give us lots of honey, but of which I will write later.

Success to the American Bee Journal. The trouble is to get new subscribers; it takes care of the old ones itself. It is like the use of foundation, it needs some coaxing to get it started, but when once started it holds its own.

E. S. LOVESY.

Salt Lake Co., Utah, May 23.

P. S.—Since receiving the mail to-day, I find that the excessive amount of rain, and consequently more or less cold weather, is causing some loss among the bees in some portions of the State, but we believe the rainy season will soon be over, when a good honey-flow will be assured.

E. S. L.

Italians Behind So Far.

I started this spring with six colonies in 8-frame dovetailed hives, with the following variety of bees: Two golden Italians, one grey Carniolan, and three hybrids. I bought three box-hives of black bees, transferred them April 2 to 8-frame hives. I am running for comb

First Excursion of the Season to Cleveland

via Nickel Plate Road, June 3 to 6, inclusive. \$11.35 for the round-trip on certificate plan. Tickets good returning until June 13, inclusive. Three through trains daily from Van Buren Street Passenger Station, Chicago. For further information address J. Y. Calahau, General Agent, 111 Adams Street, Chicago. Telephone Main 3389.

honey. Up to date (May 18) I have gotten from one Carniolan colony, 47 pounds of well filled sections; from three Italians, 17 pounds—some of it from a swarm hived March 22. Three black colonies have furnished 39 pounds; the hybrids nothing, and little prospects of any. It is a bad showing for the much-praised Italians and their blood.

Our honey is all gathered from trees and bushes, only a small quantity from annuals, even the clovers, excepting the Japan, which will furnish some later on. Until that time is past, I will not pass sentence on the Italians, hoping they will redeem themselves. They are good swarmers. L. W. M. ROE.
Washington Co., Ala., May 18.

Wet and Cold Spring.

It is very wet and cold here this spring. Bees are not doing much. LUTHER BRYANT.
Wayne Co., Pa., May 23.

Cool Weather.

My bees are doing fairly well considering the cool weather. J. A. FLETT.
Hennepin Co., Minn., May 15.

Short Winter.

My bees all came through the winter on the summer stands without the loss of a colony. I had my first swarm for this year May 20. Bees brought in honey and pollen Nov. 20, 1897; brought me the first this year March 16. This was a short winter for this section of country. D. H. METCALF.
Calhoun Co., Mich., May 22.

White Clover in Bloom.

Bees are doing fairly well now, but have done nothing all spring until now, owing to a late freeze and too much rain. I have been out all week doing bee-work, for 20 miles around, and find the bees in fairly good condition. White clover is now in full bloom, and we look for quite a little honey from that source. J. R. GIBSON.
Ripley Co., Mo., May 19.

Good Prospect for a Honey Crop.

My bees are in fine condition. They commenced swarming April 2, but on May 1, all at once, they were quiet. I saved 21 swarms.

Myself and boy found a bee-tree in 1895 with Italian bees. We cut it, put the bees into a box-hive, and in three years we had 44 good colonies, and lost some by going to the woods, and some died in 1896—the hard year for bees in this country.

We have 78 colonies now. The prospect for a honey crop is good. A. R. YANDELL.
Scott Co., Ark., May 19.

A Very "Swarmy" Swarm.

Bees are doing well, and have been swarming for some days. They are very much inclined to want to go to the woods. Some years ago I had a swarm hived on a frame of eggs and hatching brood come out the next day; hived and put in another frame of brood, came out again the next day; hived again and

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipment with best machinery, all combine to enable this firm to furnish the

HONEY and BEESWAX MARKET QUOTATIONS.

Chicago, May 19.—Very little call for honey, and the offerings also limited. Prices without change from late quotations. California extracted sells well and the stocks here are light. Weather now warm and prospects generally reported good in the surrounding States. Beeswax scarce, and 27 to 30c is bid for it. R. A. BURNETT & Co.

Kansas City, May 19.—The supply of 1897 comb and extracted honey is about all sold. Considerable inquiry for new comb. Something fancy would bring a good price. C. C. CLEMONS & Co.

Cincinnati, May 21.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3 1/4 to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Boston, May 20.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, no sale. Extracted, white, 6@7c.; light amber, 5@6c. Beeswax is in very light supply, and if pure would readily bring 27c.

There is nothing new to note in our market for honey. As usual at this time of year, the demand has dropt to almost nothing, but as the supply is light, prices are well maintained and firm. BLAKE, SCOTT & LEE.

Cleveland, May 20.—Fancy white, 12 to 12 1/2c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & Co.

San Francisco, May 11.—White comb, 8 1/4 to 10c.; amber, 6 1/4 to 7 1/4c. Extracted, white, 5 1/2@6c.; light amber, 4 1/4 to 5 1/4c. Beeswax, 23@25c.

The French bark Alice, sailing Sunday for London, carried 135 cases of extracted honey. This will probably be the last shipment to Europe for some time. Stocks of extracted are now very light. Comb is still in fair supply. Values throughout are being well sustained.

Detroit, May 21.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. M. H. HUNT.

Minneapolis, May 20.—Honey much more encouraging. Fancy white clover comb is selling here now at 10 1/4@11 1/4c. Not advisable to ship darker than amber. Extracted fancy white clover, 5 1/2@6c.; amber, 5c.; dark, 4@4 1/4c.

Outlook for honey much more encouraging. S. H. HALL & Co.

Indianapolis, May 21.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, May 20.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c.; amber, 8@8 1/4c.; dark, 7@7 1/4c. White extracted in barrels and kegs, 5 1/2@6c.; amber, 5@5 1/2c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & Co.

Buffalo, May 21.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & Co.

St. Louis, May 20.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c. WESTCOT COM. Co.

CONTRIBUTED ARTICLES

Avoiding Pollen or Bee-Bread in the Sections.

BY C. DAVENPORT.

In my last I made mention of the fact that the previous season I lost a large amount—large at least for a bee-keeper—by not understanding the business of producing honey better than I do. This loss was caused partly by bee-bread. A number of thousand sections, when foisted, contained so much of this that they were unsalable, and the honey in thousands more was so poorly fastened to the wood that it was almost impossible to haul them to the nearest towns without breakage, let alone shipping them. In fact, a great many were broken in handling before they left the apiary, as a large part of them were but slightly attached to the wood at the top.

With but few exceptions, bee-bread or pollen in sections has always caused me some loss each season, and to a less extent sections containing honey imperfectly fastened also, but never before anything like this. The year before, under the same management, there was practically no loss from either cause. The season might, therefore, in some sense, be accounted to blame, but a bee-keeper in order to make a success of the business at present must be able, and understand how, to meet the conditions of different seasons, and I have no doubt this loss I have described might have been avoided if one had known how; and while I will admit that I might not be able to entirely avoid it if the same conditions were to occur again this season, yet I consider what I did learn in regard to the matter was of more benefit to me than what was lost; that is, that it will, or may, be in the years to come, for I am a young man yet, and expect to continue to follow bee-keeping as a business in the future.

As I have said, what I learned last year cost me hundreds of dollars, and now it is to be laid before the reader at a cost to them of but a fraction of a cent. I wonder if many of us appreciate what benefit a first-class journal like this is to its readers. By this I do not necessarily mean that anything from me may be of value, but there are hundreds of others who each year, through its columns, tell us their experiences, and what is constantly being learned that is of value to our pursuit. There have been in the past, and no doubt there will be in the future, single copies that are worth much more to me than the entire numbers cost for a year. But to return to the matter in hand.

I will first say that pollen in this my immediate locality is very abundant through the entire season, but as this is used mainly in brood-rearing, the natural instinct of bees causes them, when conditions are so they can, to store it in the brood-chamber, where it will be easily accessible for this purpose. But the plan I follow with swarms, either natural or artificial, and one which I believe is largely practiced, is to give them in a hive with frames containing only starters, when, if the supers from the parent hives, in which work has already commenced, is put on in a day or two, work will be resumed in

them at once, and a good queen will usually lay in a large part of the comb below as fast as it is built, so that most of the honey brought in is necessarily for sometime stored in the sections.

I do not believe there is any other method by which as much honey can be secured in sections, and in a good season, or during a good flow, a swarm when first hived will not bring in much pollen for a few days. Last year the flow, except during the first few days, was very scant and irregular, and as it was those swarms treated the way I have described that put pollen in the sections, it will be seen that this method should not be practiced during a poor flow in a locality where pollen is as abundant as it is here, for when they cannot secure honey, if pollen is plentiful, they will carry in an excessive amount of it, and must of necessity store it in the sections.

Now, I have not much doubt that two, or possibly one, frame in each hive containing drawn comb, then waiting until considerable comb was built before putting on the sections,

Bee-Supply Factory of The W. T. Falconer Mfg. Co.—
One of our Advertisers.

would overcome the difficulty, or if no frames containing combs were on hand, a like number filled with foundation would probably prove effective.

There is so much pollen here that colonies that did not swarm would oftentimes carry it into the sections; but years ago I accidentally learned how to almost entirely overcome this by changing the places of combs in the hive. This was done to discourage swarming.

My practice was, and is largely yet, at the approach of the swarming season to replace the two outside combs with those that contain the most sealed brood, the two from the outside which usually contain a large proportion of what pollen there is in the hive are then placed in the center. If done at the right time this has a tendency to check swarming, and I soon noticed sections over colonies so treated hardly ever contained any pollen. Such an abundance of pollen right in the center of the brood-nest may possibly act as a check to their gathering much more for a time. However this may be, there would soon be plenty of room for them to store a large amount again in the two outside combs.

As to sections containing honey but slightly fastened to the wood, I believe there are means by which this can be

largely avoided, no matter what the character of the flow is, and even if only small starters are used. But as this article is already so long I will have to wait to explain my experiments in regard to this matter until some other time.

Southern Minnesota.

The Influence of Change of Locality, Climate, Etc., Upon the Qualities of the Honey-Bee.

BY WM. S. BARCLAY.

It is with no small degree of trepidation that I approach the discussion of the above topic. Not because I think it lacks in importance or interest to attract the attention of the general bee-keeper, but because of my limited field of observation, and my probable inability to bring to bear the important points which the subject demands.

I have bred the bee with much care since 1855; in that time I have become pretty familiar with the characteristics of the German, Italian, Syrian, Holy Land, Hungarian and Carniolan—all, I believe, except the Cyprian. It is needless, I presume, to say that the Italian has led in all my experiments, if I may except a cross I effected of the Italian with the Syrian, which, after severe test of years, I still greatly prefer. But I am not now going into a discussion of the value of different races, which does not properly belong here, but which I will reserve for another article.

For a long time it has been my custom to introduce fresh blood into my apiary every third year, many times producing great benefits, but at other times, I am sorry to say, greatly to my injury. When this last result occurred, at one time nearly ruining my apiary, I was disposed to reflect severely on queen-breeders. (I have bought queens all over the United States, and at the same time bred from imported queens.) In selecting queen-breeders from whom to purchase, I chose those with whose reputation I was acquainted. After waiting until the progeny of the queens showed themselves, to find out after the lapse of a month I had been deceived, you may well believe I was greatly disappointed.

Of course, when the character of the bees proved materially different, and perhaps entirely opposite to that promised, I was disposed to reflect severely upon the queen-breeder, and this continued for years until I had nearly lost faith in queen-breeders—in fact, until I saw the result of some of my own queens sent away. It had never occurred to my mind that the cause of failure lie in another direction. It had never occurred to me that climatic influences, difference of locality, pasturage, water, and other conditions become the principal factor in the cause of change. We are quick to observe the effect of this condition in the breeding of other stock, and if with them, why not with the bee?

For instance, every bee-keeper knows to what great extent water enters into the composition of the food of the bee. Let this be materially different, may it not alone effect the change? What bee-keeper does not know that a very slight matter will affect the temper and disposition of the colony for a whole season?

I have as an illustration only mentioned one point, that of water. It would be natural to suppose that the changes of climate, and of location, with probably an entire change of honey resources, would effect still greater change in the disposition and characteristics of the bee.

I am loth to believe that those parties with whom I have dealt are at fault, and have written this not to beget controversy on the subject, but to suggest a reason for the apparently strange variation in the conduct of the bees, and as an apology for queen-breeders who may be unjustly blamed for acting unfairly.

Slotted or Cleated Separators and Drawn Comb.

BY S. A. DEACON.

The late Mr. Allen Pringle, in his essay, read at the Toronto convention, said it was a mistake to use wide sections, and we know that that equally good authority—the late Mr. B. Taylor—used, and advised others to use, narrow sections—I think 7 to the foot—together with his slotted and cleated separators; advice which for the last two years I have very satisfactorily followed. But as hitherto minute details have not appeared in the Bee Journal as to the easiest or most convenient method of making these cleated separators, I will venture to give a very simple plan recently adopted by myself.

First obtain a plank fully $4\frac{1}{4}$ inches wide, and fully 18 inches long. On this place four folded sections, and with a

pencil make a scribe where they come together. These pencil lines will be a guide for tacking down pieces of sections.

In the grooves thus made place the cleats ($5/16$ inch bits of section—the two end cleats being half inch wide). Now take a sawn wooden separator, and lay it over the plank, when the little cleats, lying loosely in the grooves, will be just in the right place, ready to be fixt with the wee wire tacks which are driven in the corresponding cleat lying accurately above it, *i. e.*, on the upper side of the separator.

Next place a bit of plank $\frac{1}{4}$ inches wide on the bench, place the separator on it—between the cleats—and with a $\frac{1}{4}$ -inch chisel chip out the groove. You have then a rigid, strong "B. Taylor grooved and cleated separator"—for use with 7 to the foot section.

HOME-MADE DRAWN FOUNDATION.

What a fuss you people over the water made about the new drawn comb! Why, it is nothing new at all. I have been making it for years past; and shall continue to do so in spite of Messrs. Weed and Root's patent-rights. I have long had an extensive factory, employing a vast number of hands, for the making of this same drawn comb; and, seeing that my employes work for nothing and board themselves, I can even undersell The A. I. Root Co. At this moment of writing I have four distinct factories going. Each factory has 10 brood-frames, mostly full of brood, and a super containing 10 shallow extracting frames, each frame containing a sheet of "extra-thin" super foundation. The little workers, by-the-by, do not altogether board themselves, for I give them a little syrup every evening, costing say 3 cents, and in return they draw out, in less than 48 hours, these 10 sheets of "extra-thin," so that the cells are nearly $\frac{1}{4}$ inch deep. They are then taken off, cut out of the frame, cut into squares with a $\frac{1}{2}$ moon suet chopping-knife (kindly lent by the presiding goddess of the culinary department), and fixt in the sections.

Weed's process may give a slightly thinner septum, but as my little experts make it, it is quite good enough, and the trifle the feed costs is really not worth taking into calculation. Of course, if the Root Company can supply the Weed comb at a very small advance in the price of ordinary foundation, and the extra freight does not materially enhance its cost, it would serve the convenience of many bee-keepers to buy that in preference to running their own little dovetailed factories, but the old way satisfies me.

To have the foundation drawn out expeditiously it is of course necessary to give a little feed regularly every evening.

South Africa.

Some Experiences of the Season of 1897.

BY GEORGE REX, JR.

During a summer's work among the bees one experiences much that is queer and droll; and if at the end of the season our thoughts lead us back to the blunders and mistakes of the past, we would all be ready to say: If I would have to do this or that over again I would do better, altho should we live it over again we likely would do as before. The past can be criticised, the present is in our hands, and the future is a blank.

In May, 1897, I had an experience in swarming which lookt disastrous at first, but later proved profitable. It was as follows:

One day a swarm issued from a hive (No. 1), but before it settled it returned to the parent hive again. Next day No. 1 came out again—they seemed undetermined what to do. The air and the grass in front of the hive was full of bees. I donned the veil and lookt for the queen. After looking a considerable time I saw her crawling in front of the hive. Father at once went for a cage, and I watcht the queen, when all of a sudden she took wing and flew about 10 feet, and fell down into the high grass (in front of my bees is a meadow), and search as we would we found no traces of her.

After a time the swarm returned. They tried it again—twice—but every time returned. Being convinced that swarming was a failure, they went to work with a will, and produced for me 104 one-pound sections of honey. Therefore, you see what first was a failure proved later to be well, and taught at the same time the lesson that a colony strong in bees at the proper time is the thing, and, to secure a large yield, swarming should be prevented as much as possible.

One thing which gave me great pleasure was, early in the season, when I fed rye chop before any flowers bloomed. How they hurried and hustled, and workt! The dust settled on some, and they lookt like a lot of millers in miniature.

They would tumble and roll around like clowns, and they seemed to enjoy it as much as I did to look on.

I have read that some have trouble to start bees on the meal. I have had no trouble at all. The first time I fed I sprinkled a little honey on top of the meal, and afterwards they came without until pollen was to be had elsewhere, when the meal remained untouched.

A very queer thing happened of which I have never read in the papers. During the latter part of August, in taking off supers, I put the escape on a certain hive, and in about 24 hours I went to take the super off, expecting it to be empty of bees, but it was the reverse. I waited another day, and still quite a number of bees were in the super. I thought that being late in the season was the cause of their not moving down. I then took the super and emptied it about 10 feet from the hive, brushing the bees off. Some fell to the ground, and others flew off and I thought no more about it.

The next day my father chanced to pass where I emptied the super, saw a small ball of bees there, and on brushing the bees apart he found the queen. We put her into a cage, opened the hive from which the super came, and let her run in, letting her take the consequences. The result was that in a week's time, on examination, we found her all right, with frames of eggs and brood, and I concluded the queen was not a jot the worse for her one day's leave from her prosperous and large family. Now the question arises in my mind, Why did the queen stay there and the bees cluster around her?

Shall Everybody Keep Bees?—How it Works in Practice.

BY J. H. MARTIN.

"Hello, there! howdy do, neighbor Jones? Say, what d'ye think about them editors, parsons, and professors advising every rancher to keep bees? Wonder if they don't know there's too many bee-keepers now? And ain't the edge of the market all knocked off now on that account?"

"Wall, now, neighbor Spink, don't you worry about every rancher keeping bees. Them fellers have got to have something to write about, and so they take up the universal-everybody-keeping brotherhood; it sounds well on paper, but how does it work in practice? You know old Toddlebottom over on the north fork of the Santa Ana river? Wall, he bought a dozen skeps of bees of Jimmy Ricks, and ha! ha! He expected to load a hull car of honey the first year. But he didn't; oh, no. Yer see the season was agin him; it didn't rain; there was no honey, and his bees all seemed to be going to rack when somebody told him that he would have to feed his bees. Then he went around axing people the cheapest thing that he could feed. Jim Billcracker—you know Jim? Says he, 'Why, Mr. Toddlebottom, why don't you feed 'em on watermelons? You know that if you break open a melon how alfiredly the bees will work on it.'"

"That's so," says Toddlebottom, "haddent thought of that. Why, they dig out the hull inside of a melon in no time. But, Jim, who's got the watermelons?"

"Why," says Jim Billcracker, "I've got a snag of them. Say, now, I'll sell you a whole wagon-load of them for two dollars; that orto feed your bees for a whole year."

"Toddlebottom accordingly fed his bees on cheap watermelon-juice, ha, ha! And what yer think, neighbor Spink?"

"Why, I think they all turned up stone dead."

"Yes, dead as a hammer."

"Then there is another case, neighbor Spink. Joe Windsucker, over on Hardscrabble Pint, he thought he'd keep bees, jest to git enough honey for the family, yer know. He started in with 20 skeps, and sot them over by the corral. Everything went along quite lovely till one day they had some visitors, and Mrs. Windsucker, says she, 'Joe, you jest get some honey for dinner; it'll be so nice a treat for Sister Mehitable.'"

"So Joe put on a mosquito-netting vell, and drew onto his hands a pair of Mrs. Windsucker's long-legged stockings, and he went forth to get the honey."

"Joe had one of them cheap smokers, and in his hurry and excitement he didn't get up half a smoke; the bees got awful mad, and they stung Joe through the stockings, crawled up his trowsers, and stirred things up lively all around the ranch. Joe got his honey, but I tell yer that he was mighty glad to get into the house. He spent about an hour pulling out bee-stings and putting saleratus on the wounds. But the worst thing happened when Joe went out that evening to milk Dinah, the black cow. She was lying down sort of reposed. 'Git up,' says Joe, giving her a kick. But Dinah didn't stir, and never did any more; her stripping days were

ore. You see when Joe got out of the way the bees tackled Dinah."

"And she turned up stone dead, too?" quoth neighbor Spink.

"Dead as a hammer," said Jones. That episode cured Joe's bee-keeping. He sold the bees right off for half the amount he gave for them. He says he has a cowlicky feeling every time he sees bees or honey around."

"Then there was Cephas Fritchmyer, he—"

"Well, well, neighbor Jones, that's enough. I won't be any further discouraged. Come to think of it I know of several cases akin to those you mention. The farmer, the widder, the widder's son, and the parson, nine times out of ten, will throw up the job. There was widder Spilletuses' son. I really thought he would make a dexterous bee-keeper with his nice little apy, but he all at once degenerated into a lawyer."

"Du, tell, neighbor Spink; what a pity. But don't you worry, everybody'll never keep bees."

"Ha, ha! Good-bye."

"Good-bye. Ha, ha!"

A Number of Notes and Comments.

BY P. A. NEWCOMER.

I have been a bee-keeper for 17 years, but never went at it in earnest till seven years ago. I run for comb honey entirely, only using the extractor in case of emergencies and where some colonies are inclined to loaf. This year I will run mostly for extracted honey.

I started in 1897 with 33 colonies, spring count, and increased to 57; got 1,500 one-pound sections, and extracted 300 or 400 pounds.

Our early white clover bloom was full of nectar, but after the first rain the flow was very light. I set the hives with a spirit-level, and give $\frac{1}{2}$ inch or $\frac{3}{4}$ slant to the front. I have them 18 inches apart in rows, the row that runs north and south faces the east, the ones that runs east are set facing the northeast. That gives the morning sun and a good view from the house, as the apiary is west of the house.

One thing I have been bothered with is queenless colonies. Long after swarming-time, in the fall flow, I miss the queens. It has always been a mystery what becomes of them. I have made up my mind they enter the wrong hive from their wedding flight. If not, what is it?

I winter my bees in the cellar, and have lost only four colonies in seven years in that way; but the last two years they have had dysentery quite badly; also the past winter. I keep the room from 42° to 45°. I would like to hear the general causes of this disease described; or is it a disease? To-day, while in the bee-cellar, they were very uneasy. All wanting to fly out to empty themselves. I want to hear from Dr. Miller on this question.

I often read in the American Bee Journal about golden-rod honey. I have been told by the oldest bee-men in the State that the bees gather only pollen from it, and no nectar whatever. Is this so? If not, I want to know it. We have a 25-acre pasture full of it, and I never saw a bee on it—I mean the button or flat top—that is the variety they claim as the honey-plant.

A year ago a Des Moines gentleman and I rode 36 miles right through a golden-rod district, and not a bee did we see on it. But the sweet clover by the wayside swarmed with them.

So it is with alfalfa—not a particle of nectar in it here. We have sown and tried it with the bees, and also applied it to a glass, and not a bit of nectar did it contain. But in the Western States it proves a success.

I have always been told that heart's-ease honey is dark and heavy—sort of a spicy flavor—while I am also told that it is light, and has a smart taste. I should like to send in a sample of each flora (or honey), and be informed as to the plant that produced each variety of honey.

I tell you, we can't educate ourselves too highly on this subject. When frauds and swindlers surround us on every hand, we must be able to stand by the truth (I mean honey) and battle to the end. I had a man in southern Kansas tell me last fall that manufactured honey was just as good as what bees produced. He said that God never did anything but what man excelled it. He could see no difference between genuine and imitation. Education did it. Let us educate our children differently, and may God speed the time.

Another singular thing is, so many try keeping bees without literature. They talk "gum" or "skep," and say they never read a bee-paper. I had a man undertake to tell a couple of us that he could tell every bit of honey, if it was from a

young or old colony; he also said it was no use to use separators, as the honey was just as good, and what was bulged he could eat. One man said "honey is honey." "Yes, if it is ripe," said I.

"Ripe, ripe," he replied; "I kept bees 20 years and never heard of ripe!"

Now, how can a man talk to such a person?

What is Bee-Poison?—Opinions Quoted.

BY D. S. HEFFRON.

EDITOR AMERICAN BEE JOURNAL:—In the number of your highly instructive journal, issued April 29, 1897, a rather facetious correspondent, who signed his habitat "South Africa," describes a personal "attack of toothache in the legs," and the remedy that he applied to produce an immediate cure. The writer of the article attributes the cure to formic acid, in which he possibly mistakes. Dr. Robert Kane, in his *Chemistry*, edited by Dr. Draper, page 645, says:

"The formic acid derives its name from existing in a very concentrated form in the common ant (formica rufa), and produces the pain of its sting on being injected into the puncture which the animal makes. It was formerly prepared by distilling the ants with a little water."

Dr. Kane says it is not necessary to distill ants, but if sugar, or starch, or barley, be simply heated with dilute sulphuric acid until it becomes brown, a certain quantity of formic acid is produced. Pure hydrated formic acid is a limpid, colorless liquid, which fumes slightly in the air; its odor is intensely pungent. In this most concentrated form it is an absolute caustic if applied to the skin, producing a sore very difficult to heal. And the formic acid burns and corrodes the skin after the manner of fluoric acid; it does not produce swelling as is generally the case with the poison of the bee's sting, which, tho containing formic acid, must contain an additional poison.

Under the heading, "The Poison of Bees," the Popular Science News (in its March, 1898, issue) remarks as follows:

"It is generally assumed that the poison of the bee is formic acid. Prof. Langler, however, finds that this is only partly true; the bee-poison which he examined was a bitter-tasting liquid with an agreeable odor, which, altho it contained formic acid, when diluted to a one per cent. solution, so that it no longer gave an acid reaction to litmus, still possessed appreciable physiological action. Moreover, when kept at a temperature of 100° for over six weeks, so that all the formic acid was entirely volatilized, the liquid still produced hyperæmia of the conjunctiva when introduced into the sac."

Prof. Langler, a chemist, has isolated the active principle, which he finds gives alkaloidal reactions, is unaffected by heat or cold, or by acids. Injected into the veins of animals, it produces effects similar to the venom of serpents.

I suppose Dr. Miller would tell us that hyperæmia is a collection or effusion of blood in any portion of the body causing swelling, while the place, conjunctiva, is the outer covering of the eye and inner of the lid.

It is not a little remarkable that the poison of the bee contains mixt two dissimilar principles—one is formic acid, secreted by the ant, the other a distinct poison that seems commonly to cause swelling, and, so far as I know, it is not yet named.

Cook Co., Ill.

Thinks He Has Discovered the Control of Sex.

BY C. THEILMANN.

Prof. Schenk, of Vienna, Austria, is reported as having discovered a way to regulate the process at will in the birth of a male or female. He says that he has left his secret under seal with the Scientific Academy, which can prove it, and then deliver it to the public. But he can give the results of his discovery and the scientific facts they rest on. The Professor says, further on, that his aim is the birth of males, and that he caused the production of males in 14 instances where his discovery was carried out according to his directions. The male has not the least influence, all lies on the female, but the treatment must be in advance of conception, and not after it. He has done this by proper nourishment of the female, etc.

Some readers will ask what this has to do with bee-keeping. For answer, I will say just this: If Prof. Schenk can regulate the sexes at will in the higher animals by proper food and nourishment, what should hinder the bees producing their different sexes at will by proper food and nourishment also?

My experiments convinced me years ago that bees can and will, if necessary, rear either of their sexes by way of food and nourishment, if newly-laid eggs are given them.

Some years ago, in swarming-time, I hived a big swarm of Cyprians which had a very prolific one-year-old queen. The colony went to work busily, but when I looked into the hive the next morning it looked as if half of the swarm went back to the old hive, and as I did not want any weak colonies for producing comb honey, I put another swarm in front of the Cyprians, after dosing them with diluted peppermint, as I knew their sensitive and fighting nature; but they would fight and kill the new swarm by the hundreds in spite of peppermint. I then dosed them again, and shook them off the frames in front of the hive with the new swarm, and dosed them the third time, so that they were all wet. By this time a number of other swarms came out, so I shut up the hive and attended to them, and swarming kept me busy all day until dusk.

The next morning I examined the Cyprians, and there was not a live bee there—Cyprians and swarm were gone. Two of the frames had two new combs built as big as a hand, all worker-cells, one of which was regularly occupied with an egg in each cell on both sides of the comb, and as far as the cells were built big enough; no egg was missing in any cell.

Immediately after examination a swarm issued, which was hived on these combs. The bees accepted their new home and worked vigorously.

About a week after I examined the hive and found it built full of drone-comb, except the two pieces that were built when they were hived. There were no eggs or brood, except sealed brood, in the piece where the eggs were, and here were three cap-queen-cells, and about 25 drones in worker-cells scattered among the worker-brood. I am positive there were no drone-cells built in that piece of comb, and I am thoroughly convinced that those eggs were all intended for workers when laid by that regular, prolific Cyprian queen, that filled whole combs of workers without a miss in her old hive.

The swarm that was hived on this comb had undoubtedly lost their queen in swarming, and their instinct directed them to produce queens, drones and workers from the worker-eggs they had on hand, to save their existence. Some of our learned men will not accept this, but Prof. Schenk's discovery will bear me out on what I have said here, and years ago in the "Old Reliable."

By the way, did any bee-keeper ever see drone-comb built the first day of swarming with a young, prolific queen? or drone-brood reared the first two or three days after the swarms were hived? If there are any it would interest many of the readers to hear from them in the American Bee Journal.

Wabasha Co., Minn.

Bees in Relation to Flowers and Fruits.

BY THOS. WM. COWAN.

(Delivered at the University Farmers' Institute at Pacific Grove, Calif.)

[Continued from page 340.]

NECTAR.—We must now notice the part played by the nectaries in the process of fertilization. Altho we usually speak of bees gathering honey it is not strictly accurate, for the fluid secreted by the flower is unlike honey in many particulars, and is called nectar, while the part by which it is yielded is called a nectary. Chemical analysis has shown that the sugar nectar contains is identical with that of cane or beet root, while the sugar of honey is similar to that of the grape. To those who have studied the physiology of the honey-bee it will be known that bees, by means of a glandular secretion, convert the cane sugar into grape sugar, just like the saliva does in our own case.

Nectar from different flowers differs in aroma, which is imparted to the honey, and it is by this means that we are enabled to distinguish honey obtained from various sources. In flowers, nectar is usually furnished abundantly in the morning, diminished till the afternoon, and again increase towards evening. The position of the nectaries in flowers differs with the kind of insects to which they are suited, and while some lie almost on the surface, as in the blossoms of carrots, most are found in deeper recesses, because this position insures the insects coming well into contact with the male and female parts, and protects the nectar from injury by dilution with rain or dew. For the latter purpose we also find wonderful modifications, as, for instance, the drooping habits of the fuchsia, or the up-standing water-resisting hairs of the common nasturtium.

I have already mentioned that the sexes do not always exist in the same flower, nor always in the same plant, and even when they do the flowers are so modified as to prevent self-fertilization and secure cross-fertilization by insects. Many

flowers in which both pistils and anthers are present prevent self-fertilization by maturing these organs one before the other, so that the two sexes are never present at the same time in one flower. When the anthers ripen first the plants are called *proterandrous*.

If we examine a nasturtium flower we find the nectar secreted in a long spur. When the flower first opens the style is short and the stigma immature; the anthers are also unripe, but they soon begin to rise so as to stand in a position, when ripe, that a bee entering in search of the nectar cannot fail to get dusted on the breast with pollen. The anthers mature one after the other, the process occupying from three to seven days, during which time the flower is in function only male, altho carrying both sexes in the anthers and pistil. The anthers now begin to fade and drop off, but the style has grown longer, and the pistil with the stigma adhesive and receptive now assumes the position occupied by the anthers, the flower becoming henceforward female. In this way a bee going from flower to flower with well-powdered breast carries the pollen from the younger to the older blossom, and produces cross-fertilization, the only one possible, as the two genders do not co-exist. It will also be seen that the lower petals are cut along their edges into narrow strips which are turned up so as to prevent water reaching the nectary. Then looking at the petals we find lines which really act as guides, pointing towards the nectary.

There is another class of plants called *proterogynous*, in which the pistils mature before the anthers.

We may take figwort as a representative. Here we find, as soon as the corolla opens, the stigma, already receptive, is arranged immediately over the front lip, just in the right position for bees coming from older blossoms to deposit the pollen they carry on their breasts as they reach after the nectar. Fertilization having been accomplished the stigma shrinks and dies, while the anthers, previously curled and hidden, rise and take its place. Most flowers are provided with contrivances so that the nectar can only be reached in a certain position, and in the figwort we find the back petal standing at such a height as to prevent the bee getting at the nectar from that side and compelling her to come in contact with the anthers and stigma.

Nature's resources to produce cross-fertilization are endless. For instance, we find in the willow-herb that when the flower first opens the style curves backwards and remains in this position until all the anthers have shed their pollen, and only then does it straighten and spread its four stigmatic surfaces—which up to this time had been closed—just in the right position to receive the pollen brought by the bee.

Then we have another class of plants in which the genders appear on different parts of the same plant, and these are called *monoecious*. Squashes, cucumbers and melons are examples of such plants, and when the last two are cultivated under glass, and bees are excluded, the operation of "fertilizing," or "setting," must be undertaken by the gardener. In *dioecious* plants the genders are placed on different plants. This was known even to Herodotus, who describes the process of "caprifigation"—the transference of pollen from the male blossom of one tree to the female blossom of another—by which dates in Egypt are insured. Being in Tunis one April, I witness this operation, and admired the skillful manner in which the Arabs climbed the bare stems of the date palms. Amongst plants of this class we find box-elder, persimmon, and many varieties of strawberries.

We have another class of plants in which the blossoms become practically *dioecious* by differentiating into two or even three forms. In the primrose or flax we find flowers having long and short styles. Those with long styles have the anthers placed half way down the corolla-tube, while in those with the short styles the anthers are placed at the throat, just in the position occupied by the stigma in the long-styled form. It is evident that if a bee visits the long-styled form, her tongue, protruded to reach the nectar, will get dusted with pollen upon the center, and, in passing to the short-styled form, will deposit the pollen on the stigma. Darwin found that the best seed and the largest quantity could only be produced by crossing the different forms. He also found that the pollen differed in size, and that grown from a different form of blossom was prepotent. Occasionally plants present three forms, as, for instance, in the purple loosestrife (*Lythrum salicaria*). Here we have flowers on different plants, with long, medium, and short styles and stamens. We find the long pistil is fertilized by the long stamens of the other two forms, the medium by the medium, and the short by the short, so that, as bees pass from plant to plant, the pollen finds its proper resting place.

No order of plants contain more that are useful to the farmer than the *Leguminosae*, which all have an irregular

corolla, adapted to insect fertilization. Amongst these we find peas, beans, alfalfa, clovers, sainfoin, vetches and many others. So dependent is this order on insect visits, that Darwin found that in 100 heads of common purple clover (*Trifolium pratense*) protected not a seed was produced, while 100 heads visited by lusects produced 2,720 seeds. Similar results were obtained with white clover. In New Zealand, I recollect, some years ago, owing to their being no bumble-bees—the special fertilizers of this species—no seed could be obtained from purple clover, and it had to be imported every year from England until these bees were introduced from the old country.

In the sage family we find some curious modifications to insure cross-fertilization, and in the order *cruciferae*, which includes cabbage, turnip, radish and mustard, we find the anthers in the young blossom face the style; but before they ripen they turn their backs and shed their pollen, which is thus in the most unlikely position to come in contact with the stigma, but is most favorably situated for adhering to insects.

[Concluded next week.]

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. O. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Killing Off Drones.

Why are my drones being killed off at this time of the year—May 26? We are having considerable rain this spring, and perhaps that may, to a certain extent, have something to do with it. I don't know.

CONNECTICUT.

ANSWER.—A very rainy time, or scarcity of pasturage from any other cause, would be sufficient reason. Sometimes a colony that has just reared a young queen will kill off its drones when they are left undisturbed in other colonies.

Making Wax Sheets for Foundation.

How are wax sheets made ready for the foundation machine?

MINNESOTA.

ANSWER.—Make a dipping-board of straight-grained pine lumber; soak a few hours in water that has a teaspoon of salt to three pails of water; dip quickly in wax at about 165°, then dip into cold water. When sufficiently cooled scrape the edge of the board with a knife, then peel off the sheet. If you want a heavier sheet dip a second time. To make heavy brood foundation you will need as many as five dips. It takes practice and skill to make a successful job.

Questions About Swarms.

1. When is the proper time to put supers on new swarms—when they are first hived, or afterward?
2. Why is it better to leave the old swarm close to the new one a week before moving it to a new stand?
3. If a swarm runs away do they know where they are going to when they start?

QUEBEC.

ANSWERS.—1. That depends. If the supers contain sections with starters that have never been touched by bees, you can put them on as soon as the swarm is hived. But if the brood-chamber in which the bees are hived contains only starters or sheets of foundation, and the super is one upon which bees have already worked, then there is danger that the queen will go up into the super and lay, unless you wait a day or two for the bees to make a start in the brood-chamber, or unless you have a queen-excluder between the brood-chamber and super. If the super contains extracting-combs, it will not do at all to put it on at once, and hardly later without an excluder.

2. The old hive is left close to the swarm and moved a week later so that the field-bees from the old hive will return to the swarm, making the swarm stronger for super work, and weakening the mother colony so much that it will not swarm again. If you move the old hive away to a new place at the time of hiving the swarm, you will fail of getting this accession to the swarm, and a second swarm may be thrown off, if

not a third and fourth. If you wish after-swarms, by all means set the mother colony in a new place at the time of hiving the swarm.

3. Sometimes they may start without knowing their destination, but it is supposed that they generally send out scouts and know their destination. If you have hives standing full of combs without bees, you may often see a small squad of bees busily engaged in cleaning out such hives. These are scout bees, and, if not prevented, a swarm of bees will be found to occupy such hive within a few days.

Space Between Super and Frames.

I have some dovetailed hives with section-holders, etc. There is nothing to hold the section-holders up from the frames in the hive except the follower and wedge, which seems to me to be insufficient. If they are allowed to rest directly on the frames the bee-spaces do not correspond in but a few places. How shall I manage them? IOWA.

ANSWER.—Possibly you may have overlooked the little strips of tin that are to be nailed on the bottom of each end of the super. These hold up the section-holders.

Swarm in Shade-Tree—Sweet Clover.

1. How can I get swarms out of a shade-tree near the house without cutting the limbs when they are clustered among the thick limbs?

2. Will robber-bees kill the queen in a hive they are trying to rob?

3. Will it pay to plant sweet clover for bee-pasture in this part of the country, on rocky upland that is not valuable for farming? ARKANSAS.

ANSWERS.—1. Of course, if too many limbs are not under them they can be shaken down, but probably you mean when that is not practicable. You may be able to set a hive over them and have them run into it, or you may have them run into a box or a basket. You may take a frame with some brood in it, hold it over the swarm or close beside it, and have the bees run on that.

2. As a rule, robbers will not kill a queen. A queen may be left in a hive with a few bees after all the honey and most of the bees are gone. But bees "do nothing invariably."

3. In all probability it would pay well, and the experiment would cost little. Try to have the seed well tramped in, either in fall or early spring.

A Beginner's Questions.

1. Do cool nights have any effect on the honey-flow?

2. How are drones produced? Does the queen-bee lay the drone-eggs, or are they laid by laying workers?

3. I have 10 colonies in standard frame hives. They are hybrid bees, are good workers, but very cross. My apiary is located in town, and people are complaining of being stung by them. Would it be well for me to stock my apiary with 5-banded Italians? Are these as profitable and gentle as 3-banded Italians?

4. How is the bee-escape used on a super containing one-pound sections?

5. Reading over your list of answers to queries this week, I noticed where you said that queen-cells were generally prepared and well advanced before a swarm issues. I was always of the opinion that before a swarm issues a young queen was hatched. If this is not always true, I suspect I did wrong the other day, just after a colony had swarmed. I looked through the brood-chamber to cut out queen-cells in order to prevent after-swarms. I looked first for the young queen, but not being able to find her, I just believed she was there anyway, so I cut out six (all there were) well advanced queen-cells. None of these were capped nor none were empty. Shouldn't I have left one of the largest cells? I didn't, tho, and I suppose the bees will have to rear another queen before they do anything farther. The colony seems to send out scarcely any workers. What is the cause?

6. Would it be safe for me to put poison on potatoes which are right in front of my apiary? SOUTHERN INDIANA.

ANSWERS.—1. Yes, temperature has much to do with honey-flow.

2. In a normal colony the queen lays the eggs that produce drones. When laying workers are present, then drones only will be reared.

3. Some say 5-banded Italians are very gentle, others say

not. They are probably not all alike. Either 3-banded or 5-banded bees will probably be an improvement, both as to temper and profit.

4. The usual way is probably to raise the super, put the escape on the hive or remaining supers, replace the filled super and leave till next day, or till the super is cleared of bees.

5. You are probably correct in thinking that the bees will have to start afresh to rear a queen, delaying the laying a number of days. One reason the bees do not fly much is because so many of the field-bees went with the swarm.

6. Probably as safe right in front of the hive as if a quarter of a mile away. It's hardly likely any harm can come, unless it should happen that the bees were getting water or dew from the potatoes, a thing that doesn't happen very often.

Management of Swarms.

1. What would the result be if I should put a new swarm into an old hive from which a swarm had issued a day or two before, first placing the old hive on the stand that the new swarm came from, cutting out all queen-cells, and giving plenty of surplus room? Would I get more surplus honey this way than if hived separately?

2. After a swarm issues and is hived on the old stand, would it be all right to put a bee-trap on the old hive, placing the hive close beside the new, and leave the trap on six or seven days, then take the hive away? Or would it produce a case of foul brood by excluding all bees carrying pollen?

3. Would you put on supers this early (two or three weeks before clover bloom) if the bees hang out for want of room, and some swarm? WISCONSIN.

ANSWERS.—1. If I remember correctly the plan has been tried, sometimes working all right, in other cases the bees swarming shortly. If the bees should not swarm you might get more surplus.

2. It would work all right, probably, but I don't see any difference (I suppose you mean queen-trap) the trap would make, for no young queen would likely be ready to leave the hive in that time. Lack of pollen would hardly occur, and if it did it would not cause foul brood.

3. If bees are hanging out and swarming for want of room, I surely would want to give them room, but before clover bloom it might be better to give them room by setting an additional brood-chamber under. But a super will be better than to have them crowded.

Wintering—Putting on Supers—Colony Hanging Out—Adel Bees, Etc.

1. In our crates of dovetailed, 8-frame supers, we find a package of five or six pieces which look like sections, but have no grooves where the corners of the sections would come. I find no such thing in the supers. Can you tell me the use of them?

2. Is it safe to winter bees out-doors in 8-frame hives?

3. When should supers be placed on the hives? Should they be put on when the first white clover blossoms appear, or not until it blooms in profusion and yields considerable honey?

4. I have a colony that hangs out on swarm-days, covering the front and sometimes part of the sides of the hive. If I divide them, putting their queen into the new hive (and leaving them unsealed brood,) about how many days will it be before they will rear another queen? Or would you enlarge the entrance? It is small, only about $\frac{1}{2}$ x 4 inches.

5. Do you consider the Adels superior to the Italians? Are they practically non-stinging and non-swarming, and as good honey-gatherers as the Italians?

6. Would bees store more comb-honey in a hive containing more than eight frames, after the first year? Would they not be a much larger colony?

7. In the old frames, where you use your fingers to space them, can the bees be prevented from building comb across from one to the other? ILLINOIS.

ANSWER.—1. Probably the bottom-bars of section-holders.

2. Not in Northern Illinois without protection.

3. Usually about 10 days after the very first clover blossom is seen by one who is on a sharp lookout. I saw the first blossom May 22, this year, and as you are in about the same latitude, that would make June 1 about the right time. The usual rule is to put on supers when you find the bees putting bits of white wax along the upper part of the brood-combs. A pretty safe rule if you wait till clover blooms, for sometimes such bits of wax will be found in fruit-bloom.

4. A new queen will probably leave her cell in about 12

days after the bees are left queenless, providing no queen-cells were started previous to the division. Most surely I would enlarge that entrance, if necessary making it extend the whole size of the hive and an inch deep.

5. I never had any Adels. You're not likely to find bees that are non-stinging or non-swarming.

6. If you limit the brood-chamber to eight frames, you will hardly have as many bees as with more frames, providing your queen is prolific. A stronger colony ought to store more honey. Some who use S-frame hives use two stories up to the time of putting on supers.

7. No; and if you succeed perfectly with any kind of frame be sure to let us know.

Wormwood to Prevent Stings.—In Muenchener Bztg., it is recommended to rub wormwood on the hands to prevent bees stinging.

Variety of Hives in Germany.—“Nowhere in the world,” says Carl Krueger, in *Brasilianische Bienenpflege*, “is there so great a variety of hives as in Germany. Some open at the side, some at the top, some at the bottom, and some both at top and bottom.”

That Big Texas Yield.—O. O. Poppleton says much has been said about E. F. Carroll's 1,000-pound yield, but he thinks the fact is often overlooked that this yield was from a colony and its increase. He says it would have been only play to have done that in his locality with any of the very best colonies in 1894.—*American Bee-Keeper*.

Old Combs for Brood.—Editor Hill, of the *American Bee-Keeper*, had a case in which bees under size were reared in comb 20 years old. He was inclined to believe it would not do to leave combs after so many years' use. Later he transferred combs from a box-hive that had been continuously occupied for 60 years, and the bees were full size. He concluded the first case was the exception, and that the bee-keeper could safely leave to the bees the matter of renewing combs.

Apis Dorsata.—Upon the invitation of the Chairman, Mr. Haviland narrated his personal experience with bees in India, especially with regard to *Apis dorsata*. The worker of that species, he said, was as large as an English queen. The queen has a very large thorax, much larger than the worker. He thought, from the habits of those bees, there would be no possibility of domesticating them. They always establish their home in the open, building their combs either on the boughs of trees high up in the jungle, or on the rocks. Bees were very fond of honey, and being good bee-hunters, climbed boldly up the trees for it; and the object of the *Apis dorsata* bee apparently was to build their combs where bears could not reach them. It was obvious that building as they did in the open air, they would be unable to stand a cold climate, and any attempt to introduce them to one would be sure to fail.

These bees also readily deserted their nests when disturbed, but that occurred in India even with bees that could be induced to build in a hive. But it was far more difficult to restrain the *Apis dorsata*, as he had himself proved by experiment, and unless the queen's wings were clipped she would probably be lost.

In their natural habitat the *Apis dorsata* build combs 5 or 6 feet in length and 2 or 3 feet in depth. The natives know the kind of trees and rocks where they may be found, and it is no uncommon thing—after an hour's climb—to find bears' “tracks” in the same direction. These bees migrate according to the honey-flow. When the honey is there, and the natives (who, like the bears, are expert tree-climbers) want to take it, they go after dark, and, with the aid of a torch, cut down the combs. They always ate the larvae or grubs, which they relish far better than the honey. In fact, they usually sold the honey and wax if they could find a buyer.

Asked as to the effect of being stung by this bee, Mr. Haviland said fortunately he was never stung by them, but there was no doubt their sting was very severe; and as the whole of the comb was exposed in the open air any victim of their

wrath would be attacked not merely by two or three bees, but by the whole colony. He did not think there was the slightest possibility of crossing them with European bees. The latter were closely allied to a species found in Northern India, and yet these never crossed with *Apis dorsata*.

Mr. Sladen exhibited specimens of *Apis dorsata*, *Apis indica*, and many other kinds of bees collected by him during a recent visit to India, which were past around the audience and examined with much interest. He also showed a piece of comb and cappings of brood of *Apis florea*.

Mr. Weston observed that there must be parts of the Southern States of America where the objection on the ground of cold climate did not exist.

Mr. Carr and Mr. Haviland said that the principal obstacle to domestication and crossing was the habits of the *Apis dorsata*, not the climate.

Mr. Sladen, while in India, went to Darjeeling and saw some ligurians there, but he never heard of a cross having been effected. He believed that a cross might be obtained with the Himalayan bee, but did not think it possible with *Apis dorsata*. He saw 40 or 50 colonies of black Himalayans at the goal at Darjeeling. The honey-extractor was in use there, and the whole business was looked after by the prisoners. They use wooden frames for the combs, and generally keep the bees on the modern system. He intended to bring some bees home from India, and started with three colonies of Himalayans from Calcutta; but, before reaching England, two had died, and in the third the bees had dwindled so much that it was useless as an effective colony. He therefore united the queen with a home colony, but she was killed by the British bees, and so his importation came to naught. He did not think it possible or desirable that *Apis dorsata* should be crossed with English bees, for several reasons. He was particularly struck when catching *Apis dorsata* on the wing, with the heaviness of its flight. It flew very much like a drone, flapping its wings comparatively slowly, and making considerable noise. It was also slow in its general movements, and would settle on a leaf to rest, as it were, besides visiting flowers in a heavy and lackadaisical manner. *Apis indica*, on the other hand, was very similar to European bees.—*British Bee Journal*.

Department of Criticism is a heading that stands on page 150 of *Bee-Keepers' Review*, the department to be hereafter a regular feature of the Review, conducted by Hon. R. L. Taylor. So far as can be judged from one number, the department is somewhat limited in scope, excluding what appears in the columns of the Review, and from the other bee-journals excluding all that should receive favorable criticism. In other words, Mr. Taylor confines his efforts to correcting mistakes found in other bee-journals. He thinks Mr. Aspinwall is wrong (page 148) in thinking there is danger that beeswax will be unwittingly adulterated with propolis, as propolis is much heavier than wax and melts at a much higher temperature. Takes the editor of the *American Bee Journal* to task for being severe (page 168) against the use of the word “hive” for “colony,” and promises not to be harsh himself—unless with editors. Thinks the plan given (page 182) for fastening foundation in brood-frames by means of a saw-kérif in the top-bar too slow, and prefers the old-fashioned way of running on melted wax and rosin with a spoon. Thinks Dr. Miller is wrong (page 123) in thinking a queen thrusts her sting in the spiracle of another queen. Thinks same man wrong (page 149) in saying bees can stand confinement from Nov. 15, if they have a good flight at that time. Seems to be some mistake in reference, as page 149 is wholly occupied with report of Michigan Convention, and it is just possible there is some mistake as to such a statement being made without qualifications. Mr. Taylor objects to the advice given on page 183, to stir up a colony that will not fly when warm enough, possibly overlooking the point that a foot of sawdust packing lies between the colony and the outside air.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

Every Present Subscriber of the *Bee Journal* should be an agent for it, and get all others possible to subscribe for it. See premium offers on page 362.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

JUNE 9, 1898.

NO. 23.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the Joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Telling Your Experience in the apiary is always interesting to a listener—or reader. One reason why discussions are so entertaining in conventions is on account of the fact that often much will be drawn out of bee-keepers who are present, who would likely never write out what they know. But there are many excellent bee-keepers who never attend conventions, and hence they keep themselves "bottled up," as it were, and unless they begin to put on paper some of their valuable experience, their apiarian knowledge will surely die with them.

Now, the object of this item is to invite all who feel that they can contribute something to the general fund of apicultural information, to write out their ideas and send them in for publication. For the next few months our columns will not be quite so crowded as during the past six months, so there will be good opportunity to place on permanent record much that were it not for this invitation might never be placed before those who are looking for all the information about bees that they can find.

Mr. Cowan's Visit to Chicago.—During Mr. Cowan's visit here we had the great pleasure of getting somewhat acquainted with him; also with his good wife who accompanied him. They had been spending the past nearly 18 months with their son in California, and were so delighted with their residence there that they anticipate returning next fall to spend the winter.

Mr. L. Kreutzinger and the writer engaged a two-seated carriage, and on Thursday afternoon (May 2—a most perfect day) we took Mr. and Mrs. Cowan for a ride over the north

side of the city. We called at the city water works first, then drove through beautiful Lincoln Park, which was just beginning to dress up in its lovely spring green.

After taking in the Park, we drove on up the famous Sheridan Drive, as far as Ravenswood, where Mr. Kreutzinger and the writer reside—only a few blocks apart. We stopt a short time at both places, so that our wives also might have the pleasure of meeting our distinguished guests.

We then drove over to Mr. Kreutzinger's main apiary, where he has about 100 colonies of bees, with Mr. J. T. Hammersmark in charge. We remained there an hour or so inspecting the many new things Mr. K. had prepared for his bees. The apiary this year will have an entirely changed appearance, and with an experienced hand at the helm, in the person of Mr. Hammersmark, we shall expect great things.

The first swarm of the season had issued that day, and was safely taken from the tree upon which it settled.

We must not fail to mention the honey-house, workshop, bee-cellar, etc., that Mr. Kreutzinger has erected in his apiary. The cellar was supposed to be water-proof, but at one or two places it failed to be so the past winter, consequently about 70 colonies were treated to a severe bath, resulting in their total loss. There was perhaps a foot of water still in the cellar the day we were there.

On top of the house is built a cupola or observatory, with stands on which to place colonies of bees in glass hives for observation and experimental purposes. Mr. Kreutzinger is now getting together several varieties of bees to place in his observatory.

In this house is a honey-room, a room in which to fumigate combs, a workroom, bedroom for the manager of the apiary, and on the second floor a large place to store the necessary stock. We hope soon to have a new picture of this up-to-date Chicago apiary.

Well, after inspecting all these things, the return drive of some miles was begun. It was, to us, a very delightful afternoon, giving fine opportunity to visit with Mr. and Mrs. Cowan, who are charming conversationalists, having traveled extensively, and being so highly cultured. Mr. Cowan speaks five different languages, and reads eleven. He possesses undoubtedly the largest library of apiarian literature in the world, containing over 1,000 volumes. Mr. Cowan showed us a small index of the works, which he carries with him. We had the pleasure of adding at least three new volumes to that great library, even if they were small; one of them was Mr. Egger's latest German book.

Mr. Cowan has been for 25 years chairman of the British Bee-Keepers' Association; is the author of a bee-book which has a regular sale of about 5,000 copies annually—now in its 40th thousand, we believe; and as is well known, he is also the editor of the weekly British Bee Journal, which he owns and runs wholly in the interest of the Association of which he is chairman.

Mr. and Mrs. Cowan expect to sail for England from New York June 11. We wish them a safe and happy voyage, and trust that we shall again be favored by their presence in Chicago next fall when on their way to the sunset clime.

Crimson Clover Honey.—Some time ago Mr. T. H. Sherman, of Richmond Co., Ga., enquired as to the quality of crimson clover honey. Dr. Miller replied as usual with his "I don't know," and askt Mr. Sherman to find out for himself and report, which he has kindly done, as follows:

EDITOR AMERICAN BEE JOURNAL:—I send you a small vial containing a sample of crimson clover honey. There is no doubt as to this being from crimson clover, as there was nearly 200 acres of it in my immediate vicinity, and the bees swarmed on it when in blossom, and ceased gathering the day after the clover was cut.

There will be an increase acreage every year of this plant in this section, as it has just commenced to be appreciated as

a forage-plant. The fields when in full blossom present a lovely picture; one field of 100 acres, as level as a table, with clover as high as a man's knees, lookt like a great crimson carpet on the field, and the bees were working on it about one to the square foot.

The cold winds of April held my bees back, and when the weather settled every colony I had swarmed, so my honey crop will be very short, but as this honey sells itself at a good price, I will realize about as much as some of the bee-keepers who are not so fortunate as to be in a clover neighborhood. Almost all the honey put on this market is poplar, and after one gets a taste of clover honey, no more red honey for him.

I think the flavor of this honey could not well be improved upon. Please advise what your opinion of it is.

All my bees are stroug, and will go into winter quarters with good greens. I am gradually Italianizing my apiary.

Yours truly.

T. H. SHERMAN.

The sample of crimson clover honey was duly received, and we can pronounce it exceedingly fine in flavor, tho not quite so heavy in body as some honey. Crimson clover honey, like the honey from any of the other clovers, is all right. And Mr. Sherman should be able to harvest lots of it with such extensive fields of crimson clover growing in his vicinity.

Relation of Bees to Horticulture—the able paper prepared by Hon. R. L. Taylor for the Buffalo convention of last year—we find is copied entire in the 40th Annual Report of the Missouri Horticultural Society, which has just come to our desk. It was read at their winter meeting by J. W. Rouse, a prominent bee-keeper and apiarian writer in that State. It was a wise thing to do. More of the State horticultural organizations ought to do the same thing. It contains just such information as horticulturists should know concerning the value of bees in the pollination of fruit-blossoms, and it also answers many interesting questions that often arise on the subject.

Honey-Recipes.—Mrs. R. C. Aikin—the good wife of the President of the Colorado Bee-Keepers' Association—sent the following recipes to Gleanings:

CHERRIES CANNED IN HONEY—Five pints stoned cherries and one pint extracted honey. This makes 1½ quarts.

GOOSEBERRIES CANNED IN HONEY.—Four pints gooseberries and 2 pints of cold water. Cook slowly until partly done, then add 1½ pints of extracted honey, and cook until done.

HONEY NUT-CANDY.—Use the recipe given in [Honey as Food] honey-leaflet for honey-caramels, cooking till it hardens in cold water, then pour over nut-meats. When cold, break in pieces.

Grand Rush for Bee-Supplies.—In a notice being sent out to its customers by one of the large bee-supply firms, we find the following, which will serve as a sample of the busy times now upon the manufacturers of apiarian goods:

We have been running our factory day and night since March 1, working a force of about 250 people (all we can make room for). We are turning out 500 to 600 hives, 80,000 to 100,000 sections, and 1,000 pounds of foundation every day, and other goods in like proportion. Shipments aggregate 1½ to 2 carloads in weight every day. We have bought 10 carloads of two other factories to help us keep pace with our orders, but all the other factories are behind as well as we; and, from all the data we can gather, the demand for bee-keepers' supplies seems to be double that of any previous year.

You may say we ought to have been better prepared; but reflect a little, and think what it means to provide for such an unexpected increase. If we were not shipping constantly we should, in less than a month's time, fill up all our available storage capacity, manufacturing at the present rate. Unless more bee-keepers and dealers are more forehanded, and order early in the fall and winter what they are likely to need, such times as we are having now cannot well be avoided in such seasons as this by any amount of preparation by the manufacturers.

We expect to put in a 500 horse-power engine, and build an addition to our wood-working factory nearly twice the size of the present one, and will do our part in getting ready for

another year; but that does not help us much for the present. If you cannot wait your turn to have your order filled, let us know at once and we will cheerfully cancel it and return the money you have sent with it. If we knew where to refer you, where you could get more prompt service, we would gladly do that; but (as far as we can learn) all factories are behind.

It is hard to discover the reason for such an increase demand for bee-supplies, unless it is that old bee-keepers are extending their apiaries, and new recruits are entering the ranks, as a result of the large honey crop of 1897. Perhaps there are other causes. But there is no time to hunt them up now. It's "busy as bees," and then fall behind in the work.

Honey Ginger Cookies.—A correspondent of the British Bee Journal sent in a recipe for publication, and also a sample cooky, upon which the editor of that paper remarkt: "After tasting the sample forwarded, we have no hesitation in saying they are by far the nicest honey-cakes we have yet tasted." The recipe reads thus:

Flour, 1½ lbs.; honey, 1 lb., warmed; cane sugar, 2 oz.; butter, ¼ lb.; ground ginger, 1 oz.; candied peel, 1 oz.; one good teaspoonful of bicarbonate of soda dissolved in a little lukewarm milk. Rub the butter into the flour, add the sugar, ginger, and candied peel (chopt fine); then add the honey, and last of all the bicarbonate of soda, mixt with enough lukewarm milk to make the mixture into a rather stiff paste. Roll out, cut into shapes with a small glass, and bake on a tin sheet in a quick oven.

EDITOR LEAHY, in the Progressive Bee-Keeper for May, tells about his visit to the home and apiary of Mr. G. M. Doolittle, of New York, last fall. It makes us want to go there, too.

REV. A. B. METTLER, of Will Co., Ill., dropt into our office last week one day. He's one of the preachers who find that Methodist preaching and bees mix very well. But all other kinds of good gospel preaching ought to mix with bees just as well as the Methodist brand.

ELDER DANIEL WHITMER, of St. Joseph Co., Ind., made us a very pleasant call last week. He has about 100 colonies, and reported the prospects good. We shall expect to hear from Elder Whitmer through his pen. He has been a reader of the American Bee Journal about 20 years. Evidently likes it.

MR. W. T. RICHARDSON, of Ventura, Co., Calif., after disposing of his 60-ton crop of honey, and finding that he would get no honey this year, has gone East, accompanied by his wife. He will spend several months with friends in the New England States. Mr. Richardson is not enjoying good health; and it is hoped that the journey and the rest from the busy cares of a busy life will have a beneficial effect.—Gleanings.

MR. J. H. MARTIN, in Gleanings, mentions the establishment of a "joke department" in the bee-papers. If that funny thing is ever done we will name Mr. Martin for the position as editor. One of the jokes he calls attention to, is the one about Mr. Wilkin's "fire-proof, concreted cistern" in which he stores his extracted honey. Of course, everybody thought Mr. Wilkin just poured the honey into the cistern and pumped it out as sold. Instead of so doing, he first put the honey "in five-gallon tin cans and in the good old orderly orthodox way." So much for the California "honey-cistern."

MR. J. W. OGLESBY, of Logan Co., Ark., when renewing his subscription May 23, said:

"Enclosed find the ever needful to pay for the 'ever needful' to all bee-keepers. I don't know but what I get my money's worth out of the 'Contributed Articles,' if no other

way—at least in the consolation that I am not the only ignorant 'cuss' that is trying to keep bees.

"It does seem to me that Dr. Miller is the modern 'Job' for patience. What simple questions are sometimes asked. Why don't they get a book and study some? Well, 'let her go,' if he can stand it, so much the better for the rest of us fools, for where we don't learn something we get a good laugh at the other fellow's ignorance; but I must say that I usually learn something. I read that department first.

"My bees came through all right on the summer stands. No loss. I have had 4 swarms. I have now 22 colonies in dovetailed hives, and all extra-strong.

"Do soldiers eat honey? May be we may find the market somewhat better on account of the war. But for my part it makes no difference, as I have a home market for all I can produce."

Yes, sir, we are quite sure soldiers eat honey—when they can get it! We think that they ought to be furnished honey in their bill of fare, just as well as beans, hard-tack, etc. It would help to sweeten them up, and make them feel more like defending a country that can produce the delicious honey that this can.

PRESIDENT MCKINLEY is to be given the unique distinction of having a number of a woman's magazine named for him and prepared in his honor. The July issue of The Ladies' Home Journal is to be called "The President's Number." It will show the President on horseback on the cover, with the President's new "fighting flag" flying over him; a new march by Victor Herbert is called "The President's March;" the State Department has allowed the magazine to make a direct photograph of the original parchment of the Declaration of Independence, while the President's own friends and intimates have combined to tell some 20 new and unpublished stories and anecdotes about him which will show him in a manner not before done. The cover will be printed in the National colors. For \$1.80 we will send the American Bee Journal and The Ladies' Home Journal one year.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

See "Bee-Keeper's Guide" offer on page 365.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, WITH HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles :

- 1. General and Introductory.
- 2. Bees.
- 3. Handling Bees.
- 4. Swarming.
- 5. Hives.
- 6. Foundation.
- 7. Supering.
- 8. Diseases.
- 9. Wintering.

This will be a series of practical articles that bee-keepers of the United States will not want to miss reading. They are copyrighted by Mr. White, and will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents-- To a NEW Subscriber—thus making it

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following 11st, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber :

- 1 Wood Binder for a Year's Bee Journals
- 2 Queen-Clipping Device
- 3 Handbook of Health—Dr. Foote
- 4 Poultry for Market—Fan. Field
- 5 Turkeys for Market—Fan Field
- 6 Our Poultry Doctor—Fan Field
- 7 Capons and Caponizing—Field
- 8 Kendall's Horse-Book
- 9 Mullen's Horse-Book
- 10 Foul Brood—by Dr. Howard
- 11 Silo and Silage—by Prof. Cook
- 12 Foul Brood Treatment—by Prof. Cheshire
- 13 Foul Brood—by A. R. Kohnke
- 14 Muth's Practical Hints to Bee-keepers
- 15 20 "Honey as Food" Pamphlets
- 16 Rural Life

For Sending TWO New 40-cent Subscribers :

- 1 Potato Culture—by T. B. Terry
- 2 Green's Four Books
- 3 Ropp's Commercial Calculator
- 4 Dr. Tinker's Bee-Keeping for Profit
- 5 40 "Honey as Food" Pamphlets
- 6 Winter Problem in Bee-Keeping—by Pierce
- 7 Hutchinson's "Advanced Bee-Culture"
- 8 Dr. Brown's "Bee-Keeping for Beginners"
- 9 Biene-Kultur—German
- 10 Bees and Honey—160 pages—by Newman
- 11 People's Atlas of the World

Please remember that all the above premiums are offered **only** to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium; but we will begin the subscription just as soon as it is sent in, which will secure several June numbers in addition to the last 6 months of this year, provided the subscription is forwarded to us **at once**.

If you want your bee-keeping neighbors to be **CERTAIN** of getting **ALL** the numbers of the last 6 months of 1898, you had better get their subscriptions **in before July 1**, as we may run out of copies before the end of that month.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if **ALL** who possibly can get a few new subscribers will kindly do so.

In the multitude of counsellors there is safety.—Prov. 11-14.

Hand-Holes or Cleats—Which?

Query 72.—Do you prefer hand-holes or cleats for hives, supers and shipping-cases?—Calif.

E. France—Hand-holes.

Eugene Secor—Hand-holes.

Mrs. L. Harrison—Hand-holes.

R. L. Taylor—Hand-holes, decidedly.

Emerson T. Abbott—Hand-holes, always.

J. A. Stone—For general purposes, the hand-holes.

E. S. Lovesy—Hand-holes. Cleats are in the way.

P. H. Elwood—Well-made hand-holes, as being less in the way.

Prof. A. J. Cook—I think hand-holes, tho I have no great preference.

Mrs. J. M. Null—Hand-holes for shipping-cases and supers; cleats for heavy hives.

O. O. Poppletou—Cleats for hives; hand-holes for supers and shipping-cases.

Dr. A. B. Mason—Cleats for hives and supers, always; and hand-holes for shipping-cases.

Dr. J. P. H. Brown—I prefer cleats for hives, and hand-holes for supers and shipping-cases.

Chas. Dadant & Son—Our own hives have a cleat all around, so we have no need of hand-holes.

Dr. C. C. Miller—Hand-holes for shipping-cases, either for supers, and cleats, very decidedly, for hives.

D. W. Helse—I do not use single-walled hives, but for supers give me cleats every time; for shipping-cases, I don't know.

C. H. Dibbern—Hand-holes every time, as they answer the purpose just as well, and are never in the way when piling up the cases in the honey-room.

Rev. M. Mahin—For hives I prefer cleats; for supers I do not use either, and do not see the need of them. I sell all of my honey at home, and do not use shipping-cases.

J. E. Pond—It makes no difference, one is just as handy as the other for actual use. In packing, the hand-holes take up no room, and consequently will store closer than cleats.

G. W. Demaree—I use hand-holes made with a wobble-saw—they are less in the way. Cleats just below the lids of the shipping-cases answer all purposes, and I prefer them to hand-cleats.

G. M. Doolittle—Cleats for the first two; hand-holes for the last. Hand-holes are best where it is necessary to pack things close in shipping, otherwise the cleats save time in handling.

S. T. Pettit—Cleats. To save room in packing or loading, place the cleats on about one-half of the hives a little lower than on the other half, so that the cleats on one hive will slip under those of the adjoining hive.

A Book Recommended by Dr. Gallup. THE NEW METHOD In Health and Disease.

By W. E. Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from **Weakness to Strength** so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings **cannot be sick**. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, **not a drug treatment**.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "New Methods" given here; even those who have been pronounced **Consumptive** have been entirely cured. While for **Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women**, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2 50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

CHICAGO, ILLS.

GENERAL ITEMS

Hard Spring on Bees.

This has been a hard spring so far on bees in this locality. I am feeding five colonies now to keep them alive till white clover blooms. If that fails, I will get out of the business.

JAMES W. WILLIAMS.
St. Clair Co., Mo., May 27.

Colonies Strong.

My bees wintered very well. I never had them so strong at this time of year. I had two swarms May 18, and another to-day, which hangs on a tree, and I am forbidden to take it. J. C. ARMSTRONG.

Marshall Co., Iowa, May 27.

Bees Starving—No Clover.

My bees are starving. We have no clover. There are a few coffee-bean trees near by, and also we have cherry-bloom. There are hundreds of dead bees under the trees poisoned. J. E. WALKER.

Pike Co., Mo., May 27.

Wintered Without Loss.

My bees are doing well, and wintered all right. I wintered eight colonies without loss. I cannot do very well without the Bee Journal, as I find much useful information in its columns that have been a great help to me. We are having a good deal of rain at present.

C. H. PETTENGELL.
Phillips Co., Kans., May 27.

Bees Wintered Well.

Bees are in fine condition. The brood chambers with 10 frames are boiling over with bees, and drones are flying. Fruit-trees are in full bloom, but we have rainy weather at present. Prospects are poor for a white clover flow in this neighborhood. A. E. KRUEGER.

Washington Co., Wis., May 22.

Grand Flow from Tulip.

Bees are just having a picnic. The tulip is producing the grandest flow of nectar, at this writing, that I have observed for years. Whiteclover is making a good start, and wherever a few blossoms, here and there, are found, we are sure to see the honey-bee. The season so far has been quite favorable for the apiarists throughout this locality, and we trust will prove up a bountiful crop at its close. J. A. GOLDEN.

Morgan Co., Ohio, May 30.

Honey from Box-Alder.

Some one asks Dr. Miller if bees get much honey from box-alder. For the first time in my experience as a bee-keeper I am able to answer the question. There are quite a number of box-alders here, and I never saw bees work basswood better than they did the alders when in blossom this spring. I found, on examination this morning, that these trees were alive with bees. The upper surface of the leaves is covered with a sticky substance which the bees were gathering. On examination, I found on the underside of the leaves immediately

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |
|---------------------------|-----|--------|--------|--------|
| Sweet Clover (white)..... | .60 | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | .70 | 1.25 | 3.00 | 5.75 |
| White Clover..... | .80 | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | .60 | 1.00 | 2.25 | 4.00 |
| Crimson Clover..... | .55 | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Frank B. Barkley Mfg. Co., 835 Old Colony Building, Chicago, Ill., will sell you a spray pump, gas engine, or cider press, direct from factory

over those which the bees were working, a small green parasite, which I think ejects the substance the bees are getting, onto the leaves below. Making a further investigation, I find in a cherry orchard—composed of several hundred trees—a similar condition, except that the parasite is black and very much smaller. Perhaps Dr. Miller can tell us something interesting in regard to these parasites, and the effect such honey will have upon the bees.

WILLIAM M. WHITNEY.
Kankakee Co., Ill., May 27.

Bees Not Doing Well.

Bees are not doing well this year in north California. S. W. DAMON.
Tehama Co., Calif., May 21.

Bees Died Away.

A year ago I had about 100 colonies; now I have only 2 weak ones left. Last year was a very poor one for bees in western Oregon. Almost all the bees around here have died away. The cause must have been, I think, old age. The colonies with plenty of honey died as well as those that had little. All the colonies went into winter quarters with all old bees, too old to live over. They didn't gather any honey at all the latter half of the season. C. J. LINDELL.
Clatsop, Co., Ore., May 23.

To Cheat is Too Costly.

The man who cheats another thinks that he has the best of a bargain, because the character for honesty and truth which he sold he valued at less than the few dollars which he gained. Yet those few dollars a single day of honest labor might have given him, while that lost innocence, that is beyond price, can never again be recovered.—Sunday School Times.

Getting Ready for White Clover.

The weather in this part of Iowa has been very fine almost all spring for our bees. I think, as a rule, bees throughout this part of Iowa came through the winter in fine condition.

I began 1897 with 14 colonies, averaged 66 pounds per colony, spring count, and increased to 31 colonies; four of the late ones were somewhat light, and I lost two of these. The rest, as a rule, came through in good condition, and are now doing well, getting a good ready for white clover and basswood, of which there seems a prospect for a good crop, especially if we still have rains and warm weather. J. W. SANDERS.
Marshall Co., Iowa, May 27.

House for Wintering, Etc.

The Bee Journal comes in good shape steadily. It is a great help to me. Some articles are well worth a year's subscription. In the winter I wrote and got an answer about keeping bees in Dakota. But the one answering did not get quite onto how I built my frame house, and about letting the bees out for air. I did not have the entrance through the wall to the outside; it was through the chaff packing to the inside. They came out all right. I gave them a fight about the middle of March.

I had a visit from an old Canadian bee-keeper (Mr. James Miller) who, when

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patters, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the

Best Goods at the Lowest Prices.

Send for Circular and see the Prices on a Full Line of Supplies.

Please mention the American Bee Journal.

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send me the Review for 1898 and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo., or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send me the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden strain, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

Unless otherwise ordered subscriptions will begin with the January issue; and the December, 1897, number will also be sent, free.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. W. Z. HUTCHINSON.

FLINT, MICH.

PRINTED Envelopes and Letter-Heads.

We have put in a new small Job Printing Press on which to print our own stationery, circulars, etc., and while being able to do this we may as well do some work for our readers, if they will favor us with their orders. If you

want Envelopes or Letter-Heads, send 2-cent stamp for samples and prices. We will make right prices for neat, good work. All orders can be filled by express, at small charge, as the weight would not be great.

GEORGE W. YORK & CO.,
CHICAGO, ILLS.

Frank B. Barkley Mfg. Co., 835 Old Colony Building Chicago, Ill., will sell you carts, wagons, buggies, carriages and harness direct from factory. 21A4t

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

looking at the Bee Journal, saw what was said about painting hives outside as being an injury, and making the hive damp inside. He advises painting both inside and outside, then the hive will never be damp, the lumber will keep dry, and the damp will run outside.

ROBERT MCCRADIE.

Norman Co., Minn., May 17.

Wet, and Bees Killing Drones.

It is very wet, and bees are killing drones. Honey is plentiful on the market, as that carload from California is not exhausted. I hear of a number of runaway swarms being caught in the parks. There are plenty of roses and other flowers for decorating soldiers' graves to-day. There was a large military funeral yesterday over the remains of a soldier who was reared here and enlisted in the Spanish war.

MRS. L. HARRISON.

Peoria Co., Ill., May 30.

Double Brood-Chamber Hives.

In a late number of the Bee Journal some one asks about using double stories of 8-frames for comb honey. I put the empty set of combs on top of the brood-chamber the forepart of the season; the queen uses about 1/4 of the upper frames, that is, a half circle out of the bottom of the upper frames for brood. The season of 1896 I took from one two-story colony 110 pounds of section honey, and the eight extra frames for extracted—about 40 pounds. The sections were on top of both stories.

For the last year I have been using honey to cure bee-stings. I put it on the place where I am stung, and with me it is almost an instant cure. It stops pain and there is no swelling. This may be an old remedy.

Bees wintered all right.

F. H. MOLBY.

Washington Co., Kan., May 28.

EGGS

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, sooty-white Sections, beautiful straw-colored transparent Foundation, improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leamy Manufacturing Company,** Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, May 19.—Very little call for honey, and the offerings also limited. Prices without change from late quotations. California extracted sells well and the stocks here are light. Weather now warm and prospects generally reported good in the surrounding States. Beeswax scarce, and 27 to 30c is bid for it. R. A. BURNETT & CO.

Kansas City, May 19.—The supply of 1897 comb and extracted honey is about all sold. Considerable inquiry for new comb. Something fancy would bring a good price. C. C. CLEMENS & CO.

Cincinnati, May 21.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3½ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Boston, May 20.—Fancy No. 1, in cartons, 13c.; in glass-front cases, 12c.; A No. 1, 11c.; No. 1, 9 to 10c.; No. 2, no sale. Extracted, white, 6@7c.; light amber, 5@6c. Beeswax is in very light supply, and if pure would readily bring 27c.

There is nothing new to note in our market for honey. As usual at this time of year, the demand has dropt to almost nothing, but as the supply is light, prices are well maintained and firm. BLAKE, SCOTT & LEE.

Cleveland, May 20.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & CO.

San Francisco, May 11.—White comb, 8¼ to 10c.; amber, 6¼ to 7¼c. Extracted, white, 5¼@6c.; light amber, 4¼ to 5¼c. Beeswax, 23@25c.

The French bark Alice, sailing Sunday for London, carried 135 cases of extracted honey. This will probably be the last shipment to Europe for some time. Stocks of extracted are now very light. Comb is still in fair supply. Values throughout are being well sustained.

Detroit, May 21.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. M. H. HUNT.

Minneapolis, May 20.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c.; amber, 5c.; dark, 4@4¼c. Outlook for honey much more encouraging. S. H. HALL & CO.

Indianapolis, May 21.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, May 20.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1, 8@10c.; amber, 8@8¼c.; dark, 7@7¼c. White extracted in barrels and kegs, 5¼@6c.; amber, 5@5¼c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & CO.

Buffalo, May 21.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & CO.

St. Louis, May 20.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5¼c.; dark, 4 to 4¼c. Beeswax, 20 to 22c. WESTCOTT COM. CO.

Large New Maps of KLONDIKE—ALASKA—CUBA FREE

To all who order the People's Atlas of us now we will send free maps of Cuba and Alaska, newly engraved from the latest governmental surveys and official information. Size of each map, 14 by 22 inches. The Alaska map accurately locates the Klondike country and other great gold-fields in that far-off land, and the routes by which they are reached. A brief history of each country accompanies the maps. See our offer below:

OVER 200 MAPS AND ILLUSTRATIONS

THE PEOPLE'S ATLAS contains over 200 large Maps and Illustrations, and 132 Pages, each page 11 by 14 inches. It gives the Population of each State and Territory, of All Counties of the United States, of American Cities, by Last U. S. Census.

HANDSOME MAPS.—The handsome Maps of all the States and Territories in the Union are large, full page, with a number of double-page maps to represent the most important states of our own country. All Countries on the Face of the Earth are shown. Rivers and Lakes, the Large Cities of the World, the Railroads, Towns and Villages of the United States are accurately located.

SPLENDID PICTURES embellish nearly every page of the reading matter, and faithfully depict scenes in almost every part of the world. It contains a vast amount of historical, physical, educational, political and statistical matters, comprising a General Description of the World.

EACH STATE.—This Atlas gives about each State the Population for the Past 50 Years, History, Miles of Railroad, Soil, Climate, Productions, Industries, Educational and Religious Interests, Interest Laws, Etc., Etc.

THE UNITED STATES.—This Atlas gives the Popular and Electoral Votes for President in the years 1892 and 1896, by States. List of All the Presidents, Agricultural Productions, Mineral Products, Homestead Laws and Civil Service Rules, Statistics of Immigration, Public Debt for the Past 100 Years, Gold and Silver Statistics, Postal Information, and Other Information that should be in every Home, Store, Office and School-room.

Miniature Cut of Atlas. Actual Size, 11 by 14 Inches.

OUR BARGAIN PREMIUM OFFER

We will mail this great Atlas for only 50 cts.: or for \$1.40 we will send it with the BEE JOURNAL for one year; or we will mail the Atlas FREE as a premium for sending us **one new subscriber** (at \$1.00) to the BEE JOURNAL for 1 year.

Cold Water vs. Hot for Bee-Stings.

BY DR. E. GALLUP.

On page 345 (of Gleanings), Mr. Chalon Fowls, also the editor, goes into spasms about Gallup's cold-water treatment for bee-stings. Now I propose to show that their conclusions about cold water driving any disease in, and causing congestion, is entirely wrong. The facts are the reverse. It draws poison out instead of driving it in.

I once treated 76 cases of measles, in both old and young, in six weeks. Not one of the cases were sick in bed over three days, and there was no relapse and no taking cold. All were put in the cold pack to bring out the measles. So rapid and quick were the recoveries that the doctors said they could not be measles. The medical doctors had nine cases at the same time, and three of their cases died, and the other six made a slow recovery. Of course their cases were genuine measles!

Dr. Brandt, of Stettin, Germany, uses cold water for typhoid fevers, and only has lost about two per cent.; and they have adopted the Brandt treatment in the hospitals in Germany and France. Before adopting the Brandt treatment the death rate was 42 per cent., and since, it only averages 7 per cent., and Dr. Brandt says that the reason why they lose the 7 per cent., is because they go at it half-hearted, and not as heroic as they should. I have never lost but three cases in all my 42 years' practical experience, and those three had perforation of the bowels before I had anything to do with them.

Dr. Page, of Boston, has treated successfully patients in New York, St. Paul, and other places, by telegraph, with the Brandt method.

I quote from a small pamphlet by Dr. W. E. Forest. He says: A Dr. Fenwick, reviewing the results of the treatment of 1,000 cases of pneumonia at the London hospital—the conclusion he drew was that the best results were obtained by the use of ice sponging and packs. Instead of mentioning 23 drugs, as Dr. A. K. Hill, of New York, did, he mentioned only four, and spoke ill of each of them. Dr. Marion Sims, of Chicago, went to Russia at the time of the Asiatic cholera, and was admitted to the hospitals there, and saved every case by the cold-water treatment that he tried it on. A doctor in Nashville, Tenn., saved every case of yellow fever that he treated with cold water. I saw his statement in "Brathwait's Retrospect," one of the foremost medical publications in the world.

Now we will take any case of cholera morbus, when the patient is vomiting, purging, and cramped; even after the medical doctors have given them up, put the patient into a cold, wet-sheet pack, not hot or even warm. The moment the patient is enveloped in the sheet all disposition to vomit or purge or cramp is stopt *instantly*. Let the patient lie in the pack 35 or 40 minutes. I have cured any quantity of pa-

tients in one hour, and they are entirely cured. I have cured cases of inflammatory rheumatism (where they had suffered for six weeks under medical treatment) in two hours.

We all know that under the drug and hot-water treatment the great danger is that the disease goes to the heart, and it never does under the cold-water treatment, either in rheumatism, pneumonia, erysipelas or any other disease. It is always drawn out instead of driven in.

Years ago I was given up to die by two physicians, with inflammatory rheumatism. They had drugged me to their heart's content, and applied hot liniments and hot applications until I expected to die, and by an accident I was saved by cold water.

I saw a neighbor carried onto the ferry boat by two men. He was entirely helpless with inflammatory rheumatism. A fractious team on the boat backed up and threw the man into

Chas. F. Muth.—See page 376.

the river, and there was ice in the water. He was entirely cured in an hour.

I saw a man go into the river to wash sheep; his feet were all swollen with rheumatism. The next day he was well. I might tell you case after case of that kind.

Now allow me to tell you how to treat a sprain. Rub it, then whether knee, wrist, ankle or foot, wet a sheet in cold water, wrap up the sprain and put a blanket outside the sheet. Sleep in it all night, and see how well it will be in the morning. I have seen the hot applications used and the pa-

tient a cripple from three to six months, whereas I never failed to cure one in three days.

My youngest boy, in Iowa, was stung by a single bee on the jugular vein. I am satisfied he would have been a corpse in 30 minutes, as he swelled up, dropt over insensible almost instantly. I pulled off his clothes just as quickly as possible, put him in a cold-sheet pack, and in 30 minutes he was well.

Now, Mr. Fowl's horse lived in spite of his treatment, and the poison had to run out in sores, according to his own statement. Suppose he had poured on cold water and wet the horse thoroughly, then wet a blanket in cold water and enveloped every part that was stung; then piled on dry blankets or quilts over all, left the nose so the horse could breathe, left the horse in the pack an hour, then rubbed him thoroughly—is Mr. Fowl's sure the horse would not have been entirely well in two hours, with no poison to run out in sores? I am positive about this. Mr. Fowl's and the editor's are theory pure and simple.

I saw a little boy bitten by a rattlesnake. Two doctors gave him the regulation whiskey and strychnine. Towards morning they decided the boy was dying. Then I was called in to see him die, I suppose, and I drew the whiskey, strychnine and snake poison all out with the cold-sheet packs, and the little fellow did not die worth a cent. You say it would have driven it in? Facts say not. Orange Co., Calif.

Forming Nuclei—How It is Done.

BY G. M. DOOLITTLE.

QUESTION.—In making nuclei I have always been troubled by so many bees going back to the parent hive that the prospective nuclei were nearly worthless. Then I wish to introduce virgin queens to the nuclei formed, and in this way I am not very successful. A friend tells me that you have a plan for making nuclei and introducing virgin queens at the same time, which you gave in the bee-papers some time ago. Will you please tell the younger readers about it, and how it works with you after years of trial?

ANSWER.—As it has been some years since I have said anything regarding the matter of forming nuclei, it may be excusable with the older members of the fraternity if I say a few words on this subject for those who have been added to the ranks of apiculture in recent years, especially as the plan has always proved successful.

The first requisite to the plan I use is a box made as follows: Get out two pieces of lumber 8 inches long by 7 wide by $\frac{1}{2}$ or $\frac{3}{8}$ thick; also two pieces 14 inches long by 7 wide by $\frac{1}{4}$ thick. The latter are nailed to the former so as to form a box about 12 by 7, inside measure, without sides. For sides I use two pieces of wire-cloth, cut 14 inches long by $8\frac{1}{2}$ wide. One of these is nailed on permanently, while the other is left so as to be easily removable, by nailing the wire-cloth to a little frame like a slate-frame, which frame is lightly tacked to the box, or hinged, according to the wishes of the operator. In the top of the box is bored a large hole, into which a funnel is to be inserted. This funnel is to be large enough to allow one of the brood-frames from your hive being shaken inside of it, and the hole in the small end should be $2\frac{1}{2}$ to 3 inches, so that the bees will readily roll or pass down through it and not clog. This funnel is very similar to those used five or ten years ago in putting up bees, when so many were sold by the pound. The hole in the box should also have something to close it, like a large button, made from your $\frac{1}{2}$ -inch stuff, or a tin slide.

Having a funnel and box ready, go to any hive that can spare from it from a pint to two quarts of bees, according to the size of the nuclei desired; take out a frame or frames having bees on the combs, and place on the outside of the hive. If at a time of honey-dearth, so that robber-bees may be troublesome, hang the frame in an empty hive, and throw some old bag or blanket over, thus running no risk of creating a row in the apiary, or having your nuclei robbed out after made. Give the frames several sharp knocks with your thumb-nail or a little stick, to cause the bees to fill themselves with honey, and when so filled, shake as many bees down through the funnel into the box as you wish in your nucleus. Take out the funnel and close the hole, when you will put the frames from which you shook the bees back into the hives, and close them.

In all such operations especial care must be used not to take the old queen with the bees thus taken; for if you do the colony will be greatly injured, and the virgin queen you attempt to introduce will be destroyed. To be sure you do not get the queen, it is always well to see her, and then set the

frame she is on out of the hive till you have taken all the bees you wish at that time.

Having the bees in the box, take the same to any room or shady place, or to the cellar, and throw a blanket, old coat, or piece of carpet over it, to darken it, where it is to be left for four to six hours. In an hour the bees will begin to realize their queenless condition, and tell of it by breaking the cluster they had formed, and running frantically about the cage; and, as time goes on, this distress will be more manifest till they fairly beg for something in the shape of a queen; and the longer they are kept without one the more sure you will be of their accepting the one you give them.

When the time has arrived that I think it proper to give the queen, which in no case should be in less than four hours from the times they were shaken into the cage, I go to the queen-nursery and get a virgin queen and give them. To put the queen in, set the box down suddenly, so that all the bees will fall to the bottom, when the hole is opened in the box and the queen allowed to run in with the bees. The bees will at once set up a most joyous hum, thus telling of their new-found treasure as plainly as if they could talk.

The box is now left as it was before the queen was put in, for from 5 to 12 hours, just in accord with the time the bees were put in. If put in during the early forenoon, then they are taken out near sunset; if during the afternoon, then not till the next morning. When ready to take from the box, a hive is prepared by placing in it a division-board, a frame containing a little brood, and one having two or three pounds of honey, all of which are put on the opposite side of the hive from where you wish the bees.

Now get the box, in which you will find the bees all compactly clustered like a swarm, and carefully remove the wire-cloth movable side, when, with a quick jerk, the bees can be dislodged from the box to the bottom of the hive. Now quickly draw the comb of honey, brood and division-board across the rabbets of the hive, in the order named, to where the bees are, and they will be immediately on them. The hive is now closed, the entrance opened on the side farthest from the combs; and if all has been rightly conducted, and works as it should, in a week you will have a nice little colony with a laying queen, from which a full colony can be built up, or queens reared for market.

If you do not wish to make the box and funnel, the bees can be shaken into a tight hive, some wire-cloth fastened to the top, the queen run in through a hole in the side, or under one corner of the wire-cloth, and the hive left bottom up after the queen is put in, so that the bees will cluster on the bottom. In hiving, turn the hive right side up, remove the wire-cloth, set in the combs and division-board, doing all so quickly that the bees will not have time to crawl up the sides before you get the combs in. Now close the hive at the top and open the entrance, when you have the same thing as before, tho the box plan makes one much more independent of the whims of the bees; and where many nuclei are to be formed, it amply pays for all cost in construction.—Gleanings.

Onondaga Co., N. Y.

Management of Shallow Brood-Chambers.

BY H. D. EDWARDS.

On page 262, a writer asks a number of questions in regard to shallow brood-chambers. As I have been using a shallow brood-chamber hive for a number of years I thought perhaps I might give the enquirer some information in regard to them.

In regard to his second question—What kind of a hive to use—I use a hive invented by a Mr. Armstrong some years ago. It is side-opening, self-locking, and is reversible, either the case or the frames separately; it is the best and most convenient hive I have ever used, and I have tried almost all the different hives placed on the market. The brood-frames are 5x17 inches, inside, and are interchangeable with wide frames that take the 4x5 section by putting a dummy one inch thick in the end of the wide frame.

Question 4—They will not build brace-combs between the brood-chambers to any great extent; sometimes a colony will build some brace-combs, while other colonies will not build any.

As to Question 6, I do not know that I can answer it any better than to give my way of managing during the honey season here in Illinois, where we have to depend on white clover for our surplus, having no basswood. What surplus we get here comes between May 15 and July 1—a period of 5 or 6 weeks, unless we have a fall run of honey, which has not often occurred of late years. My plan is not new or original, but seems to succeed better with me than any plan I have tried.

When the colony swarms, I move the old colony away and

place a shallow brood-chamber where the old hive stood. I then take off the supers from the old hive and put them on the new hive, putting a queen-excluding honey-board between the supers and the brood-chamber. I then put the swarm into the new hive, and in a few hours they are at work again in the sections. As the supers are filled I place another shallow brood-chamber on top of the first brood-chamber, and let them fill up for winter. If the honey-flow stops before the second brood-chamber is full, and there is no fall run of honey, then the bees will have to be fed; or, if I have bees enough, I unite them with the old colony, which usually has plenty of honey if the season is good.

I put a shallow brood-chamber on the old colony, and if the season is good, or there is a fall run of honey, they will fill it, which can be extracted. I leave the honey-board on only 3 or 4 days, or until they get started in the brood-chamber, and I am not troubled with the queen going into the supers. I use foundation in the brood-chamber as well as in the sections. Sometimes I use only starters in the brood-chamber.

I use two brood-chambers to winter the bees in, and think that bees winter better in them than any hive I have tried.

Jersey Co., Ill.

Suggestions on Section-Cleaners, Etc.

BY A. F. FOOTE.

I want to thank Mr. C. P. Dadant for his kind and comprehensive answer to my questions about rendering beeswax, on page 258. While I produce hardly a tenth of a "hundred dollars worth" of wax yearly, I want the best in that as well as for everything else pertaining to bees; that is why I subscribed for the "Old Reliable," and I am getting good interest on the investment all right, my only regret being that I did not begin before.

HOLDING SECTIONS ON THE CLEANER.

Mr. J. A. Golden gives me a little light (page 322) on how to hold the sections on the cleaner to keep the sandpaper from gumming. Thanks to him and the Bee Journal, I have a section-cleaner, patterned after the one illustrated on page 33, only mine is a combined perpendicular and horizontal affair, and works nicely. The wheel is 9 inches in diameter, a sheet of sandpaper being just wide enough to cover the perpendicular side, or I would have made it larger. I weighted the surface of the wheel by filling 14 holes of uniform depth and distance apart with melted lead, which gives it greater momentum and a steadier motion. No glue is used to fasten either the felt or sandpaper, but instead I tacked them on, close to the edge with small staples, which are not the least in the way, and can be removed in five seconds to renew the sandpaper.

I want to tell Miss "Flody" that to the end of the shaft that carried the needle I have attached a nice, little turning-lath, by which all sorts of pretty and useful things can be turned out, and also an arrangement for attaching a drill for drilling holes through iron.

After getting everything in working order, I invited my wife to the shop to see what could be done by "Foote"-power, "properly applied." What does she do—after looking it all over critically—but to ask mischievously if I couldn't contrive some way to attach the "barrel churn" to it and do the family churning at the same time while cleaning sections, etc.

If that man Clark gets his idea (page 258) of holding a tool on the side of a grindstone instead of the top, patented, I hope he will not sue me for infringement, for I had my machine all contrived before his letter appeared.

My 40 colonies of bees, with two exceptions, are unusually strong in all respects, and the prospects for a good honey harvest were never better. Plenty of moisture combined with warm weather has developed the clovers—white and Alsike—to a splendid growth, and I expect to see the blossoms within 10 days at farthest.

I have a convenient place fixed up in my shop on purpose to keep the Bee Journal for easy reference, and I find it a great help in many a time of need.

After writing the above I picked up the last Bee Journal and came across Jno. S. Bruce's description of his section-cleaner (page 332). The idea struck me so favorably that I went to work immediately and made one. In less than four hours I had it ready to attach to the turning-lath end of my machine. After cleaning a number of old and very dirty sections, bottom slats to supers, wedging-boards, etc., I decided that for rapid work it beats the sandpaper about "16 to 1." It cleans out the "scallop" in good shape, and I am not sure but it would "clean out" the Spanish fleet if Sampson could find it.

Instead of using a solid roller and extra piece of tin, as Mr. Bruce suggested, I used only a single tin, fastening each end to a block of hard wood about an inch long, thus leaving the space between the blocks hollow; this lets all fine propolis drop through the holes out of the way, doing away with the necessity of using "fire and water" to clean it, for it never clogs. To remove what accumulates on the inside, I bored a hole in one of the blocks. In perforating the tin, I used a small awl, first covering it with pieces of leather to near the point, as a gauge to make the holes of uniform size. Fitting sections for market, a little extra touching up with the sandpaper will be a good thing.

Thus, owing to the American Bee Journal and its willing-to-tell-what-they-know correspondents, I have another valuable addition to my apiarian fixtures. I will surely have to send the editor another \$1.00—next year.

Mitchell Co., Iowa, May 30.

FACING COMB HONEY.

Opinions, Suggestions and Advice from the Commission-Men.

Thinking that those who quote the honey market for the American Bee Journal, and handle honey extensively every year, might be able to help bee-keepers somewhat along the line of packing comb honey for city markets, we sent to them the following letter:

CHICAGO, May 31, 1898.

Dear Sirs:—You doubtless have noticed what has appeared lately in the bee-papers regarding the facing of comb-honey. The hottest part of the discussion was called out upon the publication of this paragraph, written by one of the most prominent comb-honey producers in this country:

"And I also claim that there is nothing out of the way, if any one chooses to do so, in shipping cases of honey having XXX facers and XX or X honey inside, on commission. Yea, more, I claim that there would be nothing dishonest in filling the center of the case with buckwheat honey, the same having XXX white-honey facers, providing it was shipped on commission, every case alike, and the producer thought it to his interest to do so."

Will you kindly write us your opinion of the above paragraph, and also on the general subject of facing or putting up comb honey for the city markets? As an experienced honey-commission man, we feel that your opinion, suggestions and advice, would be of great value to bee-keepers who desire to realize the most out of their honey.

We should be pleased to have as prompt a reply as possible, so that we can publish it in time to be of service this season.

Thanking you in advance for your kindness, we are

Very truly yours,

GEORGE W. YORK & Co.

We here give all the replies that were received in time for this issue of the Bee Journal:

GEORGE W. YORK & Co.—

Gentlemen:—I would not put up honey faced with a nice article and filled with inferior lots. It cannot but injure the business, and I think it would be a poor way to build up a business. I like to have things about what they appear.

Yours truly,

M. H. HUNT.

Detroit.

GEORGE W. YORK & Co.—

Gentlemen:—Replying to yours, just received. If a honey-producer desires to establish his reputation and brand of honey in any market, thus securing the very best results every year, we believe his only way to do so is to pack his honey absolutely honest, the front to be a fair sample of the entire grade. Those desiring to ship a lot of honey and let it sell for what it will fetch, without any brand or regard for reputation—it might be well enough to ship it well faced up without any owner's brand upon it, and thus sell upon its merits. Altho it is practical, it is hardly policy to advocate. Buyers, the last few years, seldom buy without opening several cases of any lot, and thus decide the question.

Very respectfully,

BATTERSON & Co.

Buffalo.

GEORGE W. YORK & Co.—

Dear Sirs:—We note your favor, and in regard to packing comb honey would suggest that the facers should repre-

sent the kind of honey the case contains. Each grade of honey should be packed separately. We expect the buyers to be as good as the case contains, but the difference should be but slight. It is a help to the commission-man to be able to say, "This honey is honestly packed."

In selling, we sell by the way the honey appears. The buyer, if he finds the honey to run different from what the face indicates, returns it to us—which he has a perfect right to do—and we take it back and refund him his money.

All honey put up for Fancy No. 1, or No. 2 White, should run even in color, and all sections be equally well filled. For lower grades it does not make so much difference.

We do not want to handle any falsely packed, or adulterated, honey.

Yours truly,
St. Louis. WESTCOTT COM. CO.

TO THE AMERICAN BEE JOURNAL:—

Is there ever a time when it is to the producer's interest to face his cases of comb honey with fancy white and fill in the center with dark grades? To my sorrow I am well aware that this is frequently done, but when a dealer receives such a lot he certainly remembers that he wants no more honey from that man. Suppose a dealer would attempt to establish a trade with his customers on this plan, how long do you suppose he would remain in business? The writer has, time and again, been obliged to re-crate large shipments of honey, sorting out the different grades and reweighing each case so that he could guarantee it to be all through alike.

I knew of one lot of extracted honey where the cans were filled nearly full of dark amber honey, which was allowed to granulate, and then the cans were filled with white clover honey and sold for white clover! This was a ridiculous trick, but not so awfully much worse than fancy white combs next to the glass with inferior grades in the center. Fortunately there are numbers of producers who do put up on the honest plan, and when we know them we are not afraid to offer the highest market price for their product.

Indianapolis. WALTER S. POWDER.

GEORGE W. YORK & Co.—

Dear Sirs:—Your letter is just received. We note the paragraph regarding the facing of comb honey. We cannot agree with the author of said article. Some time ago we received from a well known bee-man two large cakes of beeswax, to be sold on commission. A few days after receiving the wax we had an order from a bee-supply man for 100 pounds of wax. In getting it ready for shipment we had to break one of the cakes in order to pack properly in the box. Behold our surprise when we found in the center of the cake a stone weighing 11 pounds. We then broke open the other cake, and found another stone about the same weight. This we call dishonest, and we think facing cases of comb honey with white, and filling the center with buckwheat or honey-dew is also dishonest. We think these are parallel cases—one is just as honest as the other. And if we had a shipment of comb honey put up in the manner described, we would sell it on its merits, and would no doubt be sold as dark honey.

We have shippers, not only of honey but of other commodities, that we do not have to open a package in order to sell it if their name is on the package. Why? Because they are known as honest packers.

We may not be any more honest than the average honey-men, but we would not knowingly sell a case of honey to a customer faced up with white honey, for white honey, when we knew the inside was all dark. And to say the least, it is dishonest, and ought not to be encouraged.

Yours truly,
Kansas City. C. C. CLEMONS & Co.

GEORGE W. YORK & Co.—

Gentlemen:—In reference to your letter I would say, first, I do not handle any honey on commission. I now produce my own honey by controlling a large number of apiaries. I have a large fancy trade, and sell more honey than all the other dealers in this city put together. But your letter in question is just what drove me out of handling honey on commission from the producer.

My trade is such that they trust what I say. I never show samples of comb honey, but just sell it as Fancy, or No. 1, at one cent difference in price. I had one party who had sent me his crop to sell for several years. His crop was very white, but not white clover. One year he had a flow from some source of amber honey that lasted about four days, and came right during the white flow. He said nothing about it, but put four or five sections in the middle of about every third crate of 24 sections. It was not quite so dark as buckwheat. I sold several lots of it without opening it, and nearly lost every customer who received it. It was a hard thing to ex-

plain away, and was considered dishonest. I then sold it for one cent less on this account; but about two-thirds of the trade who handle pure white comb honey have no use for amber honey at any price. This has to be sold to another class of trade; therefore, mixing comb honey will ruin any fine trade. I stop that year (1894), and have never handled any honey on commission since. I now have control of the packing of my honey, and know what it is.

Yours truly,
Phlladelphia. WM. A. SELSER.

GEORGE W. YORK & Co.—

Dear Sirs:—Regarding the discussion about facing honey and stuffing the centers with imperfect or lower grade of honey—it seems too preposterous for argument that such imposition or fraud would or could be thought by any one as honest, let alone good business policy, besides being very injurious to the reputation and sale of all comb honey, no matter how well put up.

If comb honey is even fairly decently packed as to quality or grade, the buyer is generally somewhat charitable in his views, and expects that the honey on the outside of the cases is somewhat better than the centers, as the proverbial barrel of apples; but when combs only poorly filled, and buckwheat honey, or badly mixt honey, is packed in the center of the cases, showing a rank fraud, then the buyer becomes suspicious, and gets in the habit of wanting to look at the center of any crate he may buy, which, if the rule, would require much more closely grading than has been done before this.

Regarding the sin being less because sent to be sold on commission, we regret that there is not a better feeling or appreciation of the situation on the part of the producers toward the commission merchant. While there are no doubt careless commission merchants that do not make proper effort in showing up, understanding and discriminating in quality, etc., in selling honey, there are worthy commission merchants, and they are a very "necessary article" in working off honey to the best advantage. On the other hand, they are quite often imposed upon by bee-keepers selecting out all their best honey, and sending them only the refuse, or what they can't sell at home.

A commission merchant is practically one and the same as the consignor. It is much easier for the commission merchant to sell "straight goods" than crooked, and much more satisfactory all around.

The commission merchant's buyer is depending on him, and if the honey "pans out" fraudulently packed, he has either to take it back, sell over again at less price, or to make an allowance, which usually is a severe one, and of course has to be charged back to the consignor.

From our experience and observation we would say to bee-keepers, by all means grade your honey as evenly as possible, and if desirable to pack your cull honey, always pack it by itself, as it then can be sold for what it is, and at much better ratio of price than if mixt up with the whole crop, and thereby lowering the grade of the straight honey more than the entire value of the cull combs.

Respectfully,
Albany. H. R. WRIGHT.

GEORGE W. YORK & Co.—

Dear Sirs:—We hardly think that the author of the paragraph you call our attention to (as shown above) meant that he would deceive through the commission merchant, when he would not, in dealing directly with a purchaser, but rather we presume he reasoned the commission merchant will look into the cases, or the parties purchasing will, and consequently be governed according to the contents. Granting this to be the fact, it would then be bad judgment on the part of owner or shipper, as the price obtainable would be little above the value placed on the poorest grade found in the package, the buyer arguing that he had no means of ascertaining the true contents without sorting, reboxing, etc.

Then honey of different grades in the same package does not suit the wants of one person in a hundred, especially is this so in the larger centres; when white is wanted, dark and amber grades will not suffice, or *vice versa*. Our experience (extending over a period of 21 years in this market) is that honey graded so it is alike in each case or package, sells to the best advantage, and has the much-sought-for desideratum of giving the general satisfaction to all concerned. The exposed sections should be just as good as any in the package, and no better.

We often do things (without intent to deceive) in such a way that it has the appearance of deception to others. For instance, we have called attention to a shipment of honey that had different grades in the package; the shipper explained it by saying that he sent it just as it came off the hives—white, mixt, partly filled, dark, etc.—and put the white

on the outside just because it lookt the best, supposing everybody would know that all the honey gathered during the summer would not be alike.

Let the face be a true index, and thus have the satisfaction of knowing that we are not likely to cause discredit to come upon ourselves or those who may be concerned with our work.

R. A. BURNETT & Co.

Chicago.

GEORGE W. YORK & Co.—

Gentlemen:—Yes, we have noticed the controversies in the bee-papers as to the facing of comb honey. WE ARE IN FAVOR OF EVEN QUALITY IN A CASE. See those capitals? Firstly, if the sections run uneven in showing the stock every one must be examined. Secondly, a prospective purchaser sees the inferior portion of the case—not the superior. That's his business.

We have shippers who turn all their honey over to us, and, when their goods come in, a thorough examination of every section is unnecessary, and we can go to our trade and say, "Here is a lot of honey from —, and is like the last lot received from him. Can you use it?" He can. This applies to second grade as well as fancy. We know, and the buyer knows, that that man shows up his goods as they are. We cannot imagine what advantage could be obtained by any manipulated packing. This does not imply that a man shipping contrary to the above is dishonest. We are simply debating the question on the ground of the best sale for the stock.

If such a shipper as we speak of be interviewed, he would say that he has always received what his honey was worth. We know this, as we have received just such manifestations of satisfaction. On the other hand, unsatisfactory deals can be traced back either to very poor quality in general, or a certain amount of poor stock that more than counterbalances the attractiveness of the more desirable quantity. It is not so hard with the grocer—he sells a section at a time, and gets a price according to the individual worth. The commission-man can't say to him, "Now, here is a section that you can get 10 cents for, and here is one that you can get 11 cents for, etc." He says, "Here is a lot of honey which I offer you at 10 cents." He knows he can't boost up a price on a lot just because there are a few fine combs in, but knows to the contrary that these few superior sections are very liable to sacrifice. Irregular packing has taught us in nearly all instances to take three or four sections out of every case before we render a verdict. Some shippers always send in regular quality, and those are the men we like to deal with.

Honey shipt on commission direct to the groceryman could run very irregular and still command full value for every section, as he sees every one that is sold.

These are our views, not as honesty, but as policy.

Yours truly,

S. H. HALL & Co.

Minneapolis.

Per F. S. Cady.

GEORGE W. YORK & Co.—

Gentlemen:—Yours requesting our opinion in regard to the paragraph recently published in one of the bee-papers relative to the facing of honey shipt on commission came duly to hand, and in reply we beg to say that honey can be shipt as our good friend says, but the question is, Would the shipper be satisfied with the results financially? We desire to say that we have learned in the past 10 years that we have been engaged in the handling of honey, that it is to the advantage of producers of honey to grade and put their product up honestly. We think that if the author of that paragraph would devote about one or two weeks in a commission-house where honey is sold every day, he would change his ideas.

Very little honey is sold nowadays on the facing of it; nine out of every ten people who purchase a case of honey want it opened up, and look into the interior to ascertain its condition, whether it is broken or leaking, or not, and not one person in a hundred would pick out the section in front of the case to learn this information—naturally they will pick it out in the center or towards the back part of the case. What would be the result if the case were packed according to our friend's idea? The purchaser would refuse to buy that case of honey, or any of the same lot.

Most of the buyers of honey want some particular kind; some want only Extra Fancy, while others only No. 1 White, and others only desire the buckwheat. Were a case mixt it would be almost useless to them.

It is just as necessary to take as much precaution in the putting up and grading of honey shipt on commission as that which the honey-producer may sell himself. A good many shippers are in the habit of sending their poorest grade of honey to some commission-man to sell, and keeping their best at home to dispose of themselves, and expect the same price

for the poorest quality (markt Fancy) as they get for their *genuine Fancy* which they sell themselves.

The sooner bee-keepers learn to put up their honey honestly, and mark the cases just what they contain, and grade uniformly, the sooner will they realize better prices for their honey.

Very truly yours,

A. B. WILLIAMS & Co.

Per W. L. Geiger.

Cleveland.

Bees in Relation to Flowers and Fruits.

BY THOS. WM. COWAN.

(Delivered at the University Farmers' Institute at Pacific Grove, Calif.)

[Continued from page 357.]

ADVANTAGES OF BEES.—I am not able in the short space of time available to go into all the modifications which exist for securing cross-fertilization of flowers, but I have already said enough to show the farmer the advantage he derives from bees. I will now try to show how largely we are dependent upon bees for the delicious fruit we enjoy.

If we examine an apple-blossom we will find it contains five stigmas belonging to the five segments of which the core of the fruit is composed. The stigma comes to maturity before the anthers. Bees seeking nectar get dusted with pollen from an older flower and then transfer it to the ripe stigma of a neighboring flower. The apple is strictly a fusion of five fruits into one, and requires no less than five separate fertilizations for its perfect production. If fertilization does not take place the fruit, instead of swelling, drops and rots. It sometime happens that one or more of the stigmas are not fertilized, and in such a case the fruit develops imperfectly and becomes deformed. If such an apple be cut open it will be found that the undeveloped part lies opposite the section where the pit is shriveled.

The flowers of pears are similar in structure, altho they are not so dependent upon bees for fertilization. Small fruits, such as gooseberries and currants, are also dependent upon insects. Among plums sometimes the pollen of one plant is impotent upon the pistils of that plant, and fertilization is only secured by introducing a plant of another variety into the orchard.

In the raspberry the petals are smaller and placed wide apart. There are about 90 anthers, and each of the 60 or 70 drupels carries a stigma, while on the receptacle will be seen a ring of shining dots consisting of nectar. Here the anthers ripen before the stigmas, and a bee, on alighting on the drupels, as she applies her tongue to the dots of nectar gets dusted with pollen, which she carries to another and older flower, and in revolving in an opposite direction transfers the pollen to the ripe stigmas. Each seed thus fertilized develops into the juicy envelope which protects the seed from injury, and makes the fruit so palatable. It requires from 60 to 70 fertilizations to perfect each fruit, and should any of the stigmas escape fertilization the fruit does not develop in that part and remains green and hard. If we look at the strawberry we will find that it required from 200 to 300 distinct fertilizations for its perfect production, and if any of the stigmas do not receive pollen the development of the fruit is arrested in that part and the seed is not produced.

I would here point out that in the strawberry there is a tendency to a separation of the sexes, and that plants bearing large blossoms are frequently tending to become male and produce few fruits, while those of the same variety that produce small blossoms are tending to become female. These are abundant bearers, but produce few runners. Care should, therefore, be exercised in selecting runners, otherwise the male would in time supplant the female.

BEES AND FRUIT SHOULD GO TOGETHER.—I have shown the part bees play in the fertilization of blossoms and the benefits we derive from their labors, but I wish to point out that a danger exists in making a specialty of bee-keeping and cultivating bees in large apiaries, as is the practice in California. It is useless increasing the area under fruit cultivation without at the same time increasing the number of bees kept. As an instance, I would mention Lord Sudeley's fruit plantation in Gloucestershire, England. About 200 acres of fruit-trees were first planted, and for some years there was such poor success that it was a question whether the enterprise should not be abandoned. Lord Sudeley was, however, advised to introduce bees, as it was found that not many were kept in that district. Two hundred colonies, in charge of a practical bee-keeper, were introduced, and the result was magical. Thenceforward the trees bore fruit properly, and the former failure was turned into a success. Since then 500 acres have been planted with fruit trees, and a large jam fac-

tory has been started close by both undertakings, being in a prosperous condition.

Every farmer should keep bees, with the primary object of insuring cross-fertilization of his crops, and only look to the honey-yield as a secondary consideration. We are told that bees spoil fruit; but, altho I would show that the structure of the mandibles is such that they cannot pierce the skins, we need not rebut the charge, but point out that, while they gather nectar for themselves, they confer a greater boon on the fruit-grower, for they really give him his crop in return.—Pacific Rural Press. Loudon, England.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. O. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Keeping Wax-Worms from Comb Honey.

What is the best way to keep the wax-worms from eating the cappings off comb honey? I have about 500 pounds in shipping-cases stacked up in the second story of my house.

As I am a beginner in the bee-business, and take my honey out of the hives as it is sealed, I will be very glad to have an answer to the above question. Last season the worms damaged my honey very badly.

GEORGIA.

ANSWER.—Formerly I had the same trouble if I failed to fumigate my comb honey, but of late years it does not seem necessary. I suspect the reason is that formerly there was more black blood in my bees than now. Where Italian blood predominates there is less likelihood of trouble with worms. In the meantime the question remains what to do in case worms do trouble your surplus honey.

If you examine closely, after the honey has been off the hives two or three weeks, you will find places, especially at the lower edge where the comb is fastened to the wood, where a fine white powder can be seen. This is the work of the little wax-worm, as yet so small you can scarcely see it, and it is well to dispose of it before it gets any larger. Even if you see nothing of the kind, if you are afraid of worms, fumigate your surplus honey two or three weeks after taking it off. Fumigate with sulphur, and it matters little how, only so you get enough of the sulphur fumes to kill. It takes much less fumigation while the worms are small than after they become $\frac{1}{2}$ -inch long or more.

Have the honey in a box or room large enough to hold it, and close enough to confine the fumes. A roll of rags may have sulphur rolled in it, sulphur may be thrown on burning coals, or a hot iron can be put in the sulphur. In any case you must look out for fire. A safe way is to have a kettle containing ashes or something of that nature, and sitting in this a smaller kettle that contains the sulphur. You may open up after 12 hours, or you may find no trouble by leaving closed entirely. If you want to be sure, you will do well to fumigate again two or three weeks later, for some of the eggs may hatch out after the first fumigation. A pound of sulphur may be used for 100 feet of cubic space, but if the place is so close as to entirely prevent the escape of the gas, less will do. The only harm that will come of using too much is that some of the combs will be colored green.

Small vs. Large Hives.

DR. MILLER:—I will answer as best I can your questions on page 263.

I have experimented with 6, 8 and 9 frame hives side by side with the same colonies for six years, and I have got the best yield every time from the 6-frame. This spring my 9 and 12 frame colonies had not five pounds of honey when I examined them in March, but the 6-frame had 15 to 20 pounds, and I can surprise you by saying the 6-frame hives in April had more bees than the 9-frame by half; and in a hard season I have got surplus from the 6-frame colony while the 9-frame did not fill their brood-chamber.

You admit that to place two swarms of equal size, one in a 6-frame and the other in an 8-frame hive, that the 6-frame would give the most surplus. *Very true indeed.* Then please tell me what are we keeping bees for if not for the greatest amount of section or surplus honey. I am not speaking of a

warm climate where they get honey the year round, but a climate such as you and I have. We have no need of large hives except we have them so arranged as to contract or expand.

You mistook some of my figures. My top-bars are $1\frac{1}{4}$ inches wide instead of $1\frac{1}{2}$. You see, I could not get six frames $1\frac{1}{2}$ inches wide and leave bee-space in a $8\frac{1}{4}$ -inch space, see?

I will try several hives this season—the Danzy, Root chaff, the Champion, the St. Joe, the Hill, and some of my own make; but as I am depending altogether on hired help, I do not expect to get as good results. I am still unable to attend to any work on account of erysipelas in my leg. I have had a very serious time of it; have not done any work since I returned from the Buffalo Convention, but I hope to cheat the grave and undertaker for a good while yet. I hope, Doctor, that you will have another good season. It is very backward here now.

DAVID N. RITCHEY.

Franklin Co., Ohio.

ANSWER.—According to Mr. Ritchey's figures he ought to have no difficulty in deciding that 6 frames in a hive are enough for him. But there comes C. P. Dadant, who says twice 12 gives none too much room. I hope Mr. Ritchey will soon recover and be in good working trim, and then it might be very interesting if he and Mr. Dadant could compare notes.

Transferring with Tight Bottom-Board.

I have a colony which I want to transfer two weeks after it swarms, but the bottom-board is nailed on so tight that it is impossible to get it off. Is there any way to drum out the bees without taking the bottom off?

NEW JERSEY.

ANSWER.—If there is no chance for the bees to get out except at the entrance—top and bottom being nailed on solid—you may still succeed in drumming them out. Set the hive so the opening shall be at the top, that is, if the entrance is at the bottom, turn the hive upside down, giving them a little smoke. Then plug up the entrance and hammer on the hive till you can hear the bees buzzing loudly. Then open the entrance and hammer away for dear life, and the bees may rush out in a stream ready to enter any hive or box placed over. If, however, they do not come out freely after a lot of drumming, just tear off the bottom in the same way you would if there were no bees in the hive, for by this time the bees will not resent anything of the kind, and after taking off the bottom you can proceed in the same way you would have done had no bottom been nailed on at the start.

Prevention of Swarming, Etc.

I am peculiarly situated. A, B, C, D are the corners of a flat roof on which I have my bees. A, B and B, C are walls about 12 feet from A, D, which is the line of my lot. My bees, when they swarm, have invariably gone across that line on the adjoining lot. I have tried to prevent them but they will go. The lady who owns the lot has gotten tired of it, and has forbidden me to take any more swarms from there. I have about all the swarms I care for, and would like to prevent them swarming any more.

1. If I examine them every 12 days during the swarming season, will that prevent it by destroying all queen-cells?

2. If I do so, will not the queen crowd the brood-nest so that the workers could not have room to deposit enough honey there for winter stores, as most of my hives are 8-frame?

3. Can you suggest any means that would induce them to alight on my own lot?

IOWA.

ANSWERS.—1. You cannot entirely rely upon killing cells every 12 days. Once a week will be better, providing you don't miss any cells, but sometimes they'll swarm without waiting.

2. It will probably make no difference. There will, perhaps, be as much crowding of the brood-nest in one case as the other, altho in any case there may be a little trouble about scarcity of stores in an 8-frame hive.

3. You might succeed in getting them to alight on your own lot by putting there a decoy hive—that is, an empty hive with one or more empty combs in it. You might have your queens clipped, and then no matter where the bees clustered they would come back of their own accord. You might put a queen-trap on your hives. You might run for extracted honey and give your bees so much room they wouldn't care to swarm.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all others possible to subscribe for it. See premium offers on page 377.

Painting Hives.—W. C. Gathright says it may be all right in the East to have unpainted hives, but in New Mexico "unpainted hives are soon warpt, crackt and ruined."

The German, Austrian and Hungarian Bee-Keepers' Association—the society which holds such large and enthusiastic meetings as American bee-keepers never dream of—will have its 43rd annual convention this year at Salzburg, Austria, Sept. 4 to 8.

The Comb-Foundation Business is no small affair. In Revue Internationale Chas. Dadant & Son report that their sales of foundation, which in 1895 had gone down to 30,000 pounds, and in 1896 to 28,000 pounds, in 1897 rose to 52,000 pounds. If it averaged eight feet to the pound, this would make the output of 1897 cover nearly eight acres of ground.

Room to Prevent Swarming—Doolittle is very positive, (Progressive Bee-Keeper) that Quiby was right when he said "a large amount of room filled with empty combs will entirely prevent swarming." Doolittle says he has proved it hundreds of times, but says the room without the *empty comb* will not do. Editor Root stipulates that the empty comb must be given *before* the bees have contracted the swarming-fever.

Taxing Bees.—In his county in Iowa, O. P. Miller says bees are put on the tax list and are valued at \$2.00 a colony if a man has more than 10 colonies. He thinks this inconsistent, for the laws of Iowa say, "All animals over six months old shall be taxed according to their value, except dogs; they shall be taxed per capita;" according to which the queen is the only taxable member of the colony.—Progressive Bee-Keeper.

Time for Sealing Brood.—G. M. Doolittle takes R. C. Aikin to task (in Progressive Bee-Keeper) for saying that when a queen is removed "the seventh day will find just about all the worker-brood sealed." He makes a general appeal to bee-keepers to make observations on the subject—sure that nine days will be found to be the correct time—three in the egg and six in the larval form. Cowan gives three days for the egg and five for feeding a queen or worker; six for a drone.

Bees Swelling.—R. C. Aikin asks, in Progressive Bee-Keeper: "Did you ever notice how a colony seems to swell when a flow comes on? How a colony that seemed comfortable in its hive before this, now cannot find room to work, so piles out of the hive?" Doolittle explains that it is a real swelling in the size of the bees that stay in the hive, because they receive from the field-bees the loads of nectar for evaporation, thus becoming so large that two bees now take the same amount of room that three or four previously did.

Mashing Combs Between Rollers and then separating the honey and melting the wax, as suggested by R. C. Aikin, at Buffalo, was spoken of by Gleanings as a rather startling idea. Bee-Chat reminds Gleanings that the same thing was reported five or six years ago as being practiced by one of the correspondents of Gleanings, and adds: "It is well known that our Scotch friends have for many years used honey-presses for removing their heather honey, which is so thick that no extractor can force it from the cells after it has been stored a few days in the combs."

Prevention of Swarming.—R. C. Aikin (in Progressive Bee-Keeper) tells how he manages to get the start of the bees, and then gives a short cut as follows:

"Take two broad-chambers for your colony. Eight or ten days *before* the flow, put the brood all in one of the chambers and the queen in the other with an excluder-zinc between. The queen will be more contented and lay more promptly after the change if a comb with a little brood is put in her chamber. She accepts this as her brood-nest, whereas if removed from all brood, she labors to pass the zinc to the brood. As previously explained, the brood in the part from which the queen was excluded will all be sealed by the eighth day. Now, the

eighth day or after, just make a new colony with the chamber having the queen and put her on a new stand. This leaves the old stand with sealed brood only, hence impossible to build cells. In three or four days a cell or queen, better a ripe cell or virgin queen, can be introduced to the old stand. If a cell, your young queen will not lay till all brood is hatched, *just as in natural swarming*. This reduces the labor fully one-half, and I think just as good in every respect. I expect to practice this method the present season, 1898."

Box vs. Frame Hives.—A somewhat animated controversy has been taking place in Revue Internationale between two octogenarian leaders—Messrs. Dadant and Boyer. It is not probable they will be in entire accord at the close of the controversy. The showing M. Boyer makes of the cost of a movable-comb hive with its accompaniments is rather discouraging. He gives it as follows:

Hive, \$5.40; freight, 20 cents; cushion, 40 cents; painting, 40 cents; foundation, \$1.00—total, \$7.40.

Certainly hives must cost a good deal more in the French than in the English language, according to this showing, a showing that does not, however, agree with the statements of Mr. Dadant.

Simmins' Direct Fasting Method of introducing queens is thus given in his paper, Bee-Chat, remembering that the bees must have been queenless three days:

1. Keep the queen quite alone for not less than 30 minutes, without food, but warm.

2. Insert after dark, under quilt, first driving the bees back with smoke.

3. No further examination is to be made until after 48 hours have expired.

4. Make no division of, or nucleus, from the hive within three days prior to insertion, unless the original queen is then left on her own stand.

CAUTION.—As many queens are ordered for inserting with a divided half of a colony, it should be pointed out that the old queen must always be left on her own stand, and the new queen given to the removed part, unless three days are allowed to intervene.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitecomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

JUNE 16, 1898.

NO. 24.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

California has been blest of late with two fine rains. These will be of signal service to the orchardist, in increasing the water for irrigation, and in thoroughly wetting the earth twice in late spring. But they are too late to very greatly help the grain crop, and it is feared the same will be true of the honey product. It is to be hoped that the bees will produce enough honey to feed them. So wrote Prof. Cook, May 30.

Bee-Business Enlarging.—In a letter from one of the largest dealers in bee-keepers' supplies, written us recently, we find this significant sentence:

"It looks as if there was a general need of enlargement if the bee-business is going to increase as it has the last two years."

We presume unless the present manufacturers of supplies prepare to take care of the increasing demand, others will engage in that line of business, and to the benefit of all concerned. This country is developing in all its industries, and there is no good reason why the bee-business should not keep pace with the rest. The population is already here to consume every pound of honey that possibly can be produced, and at a fair price.

A Bee-Bed of Flowers.—Mrs. Effie Brown, the conductor of the apianian department in the Northwestern Agriculturist, writes thus about a bee-bed of flowers:

When we plant our posies this spring we are going to have one bed especially for the bees.

All flowers do not yield nectar, and many that do are never visited by the bees on account of the depth of the honey-cups. The rose, lilac, violet and snow-ball are among

the latter class. I think the flower that yields the most nectar to each blossom is the spider-plant. It is a hardy annual, blossoming in July and August. The blossoms are beautiful, odd little things with the petals all on one side, and long, spidery legs on the other, one sometimes containing enough nectar for two loads for a bee. These seeds we will plant in the center of our bee-bed because they are taller than the other plants which we will use. Around the patch of spider-plants we will sow a good broad band of mignonette. Every one loves this sweet, old-fashioned flower, and the bees delight to work on it from morning till night. All around the outside portulacca, or, as grandmother calls them, "moss-roses" will besown. One of the prettiest sights in nature is a bed of portulacca in full bloom, with dozens of bees hovering above, or resting in the hearts of the flowers.

I have never been able to discover whether or not they get very much honey from this plant, but I think I never saw so many bees to the number of blossoms as I have seen on a "moss-rose" bed.

Every bee-keeper ought to sow one of these bee-beds—not only for the enjoyment of the bees, but for his own pleasure.

While it requires a good many flowers to be of perceptible use to bees, still when planting even small garden beds of them, one may as well plant the varieties that yield nectar, especially when they are pretty as well.

Bee-Paralysis or Nameless Disease.—Prof. A. J. Cook, of California, writing us May 30, had this to say about a disease affecting the bees around San Francisco:

A well-known bee-keeper near San Francisco describes a disease that is affecting his bees quite seriously, but only a few colonies. It is, without doubt, the "nameless bee-disease" of some, or "bee-paralysis" of others. Is there any better way to treat this disease than to introduce a young vigorous queen? I think it would be well for the American Bee Journal to ask for the experience of all on this disease. It is not usually very serious, and, so far as I have observed, goes away of its own accord, before very long. A. J. Cook.

We shall be glad to publish anything relative to the disease, or diseases, referred to by Prof. Cook. Who can give something that will help?

Chas. F. Muth.—A few weeks ago we announced the death of Mr. Muth, of Cincinnati, by suicide. Since then we have learned some of the particulars which we will give in connection with a few items of interest relating to Mr. Muth and his career as a bee-keeper and dealer in honey.

From the Cincinnati Commercial Tribune of May 17, we take the following, mainly relative to the sad death of Mr. Muth:

The news of the death of Charles F. Muth, for years past one of the city's prominent business men, came yesterday as a shock to his personal friends and acquaintances.

He was found dead on his farm near Morristown, Ind., under circumstances tending to show that in a spell of mental depression he had taken his own life.

For some months past he had been feeling unwell, and at times appeared to be suffering from melancholy. He had suffered two attacks of sunstroke a few years ago, never quite recovering from the effects, and his family attribute his recent fits of depression more to that cause than anything else. Nevertheless, last Saturday, when he informed them that he intended going to spend a few days on his farm near Morristown, they opposed it, and tried to persuade him to remain at home. He persisted in going, however.

He spent Sunday examining at the grounds and houses on the farm, a tract of some 600 acres, and when last seen Sunday night by the man in charge of the place, was engaged in writing, and gave no signs of trouble.

Yesterday morning he did not appear, and at 10 o'clock the man in charge, tired of waiting for him, went to the little room he had fixt up as an office in the farm-house. A horrifying sight met the man's eyes as he pushed open the office door.

Mr. Muth was seated on a couch with a rifle between his legs, a gaping bullet hole under the jaw, and another over the right eye. The rifle had evidently been held under the chin while the fatal shot was fired, and the bullet had ranged up through the skull, causing instant death.

Mr. Muth was in his 64th year. He was born in Hesse, Germany. Coming to America in 1854, he engaged in the

tobacco business at Baltimore with a relative, but after a short stay there concluded to go further west. His first situation in Cincinnati was with Henry Franck, the pioneer grocer. With him he remained a year or two, then went to the Far West and tried mining and cattle raising. Not meeting with success, he returned to Cincinnati again. In a short time he was in business for himself as a dealer in honey and bee-keepers' supplies. For many years he was one of the largest dealers in the West in that line of trade, and did an extensive business in the West and South. He was active in extending it up to the time of his death, though in the past year or two he had suffered reverses. This fact, it is believed, caused in part the melancholy that marked him for some months past. The losses, however, were not serious, not more than \$12,000, it is said, but it appeared to wear on him.

Mr. Muth was a Mason, and a member of Hanselmann Lodge. He took an active interest in the German Orphan Asylum, and served as President of its Board of Managers for some years.

He was prominent in politics at various times. At the last election he was elected on the Fusion ticket as a member of the Board of Control.

Mr. Muth married Miss Carolue Muth, who was his cousin, and there are six children surviving him with the widow.

The body was brought to the city last evening, and burial will take place to-morrow.

The letter which Mr. Muth wrote Sunday night was found yesterday in the room in which he was found dead. It is as follows:

If I should die on my farm it is my wish that I be buried in the same graveyard with August Muller, and in the same simple manner. My family will respect my last wish. My honest debts must be paid.

CHAS. F. MUTH.

It will thus be seen that he contemplated the act. August Muller was an uncle, and was buried in a country graveyard adjoining the Muth farm.

In Gleanings for June 1 we find these paragraphs written by Mr. A. I. Root, who knew Mr. Muth well:

Our friends may remember that, when I first became interested in bee-culture, I very soon made inquiry in regard to the various bee-journals published in the United States or other parts of the world. I think my first acquaintance with Mr. C. F. Muth came through my desire to know something of bee-keeping in Germany. He was very willing to give me all the information in his power, and for many years we offered the *Bienenzeitung* to our German readers through Friend Muth's kind services. We had become quite well acquainted through correspondence, and I had promised to make him a call and see his apiary on the roof of his store. One day, however, I was surprised to meet a tall, fine-looking man who spoke English quite brokenly. He introduced himself as "Mr. Moot, of Cincinnati." He told me we had had some little correspondence, but somehow I did not quite catch on; but when I saw his name on some circulars, "Muth," then I knew him at once, and we shook hands over again, and took another start. He brought along some of his famous honey-cake. I took him over home and introduced him to Mrs. Root and the children. Then he sent me a lot of his honey-jars and tumblers in which he sold the honey in such immense quantities. Many of our readers, especially the older ones, remember how ably Friend Muth stood at the head and represented bee-culture in America among the German people. When I spoke of making him a visit, or putting the street-number on his letters, he said everybody knew him in Cincinnati, and I guess this was pretty nearly true—at that time, anyhow.

Mr. Muth was one of the cleverest, most whole-souled and generous men I ever knew. He tried to be right and fair; but when he met somebody who wanted to be unfair, or even if he got it into his head that somebody was trying to get more than was just, he sometimes showed that his good nature might give place to something quite different. Of late years I have felt that our jolly, whole-souled friend had too much business on his hands. I have heard him speak a good many times about that farm, alluded to in the extract above; and I fear, from what I have heard from those who had sent him money, that of late his prompt, energetic business habits have not been quite up to their former standard.

In view of the injury by sunstroke, he should have been careful about undertaking too much business. I fear our poor friend brooded over his financial affairs, and imagined they were worse than they really were. From the statement given above I infer that, after everything is settled up, there is a large property still for his wife and children. How gladly

they would have borne his cares and troubles, and let him take things easier had he permitted them so to do! The bee-keepers of our land can remember our departed friend with grateful feelings for what he has done to bring about the present advanced state of bee-culture, especially in the way of selling, and getting it into the regular channels of trade. Even if some of the friends have suffered somewhat by neglect, they may learn by the above that our old friend had been for years a sufferer; and we can afford to let a broad charity help us to forgive and forget whatever was not exactly as it should have been.

A. I. Root.

We think we can scarcely add anything of interest to the foregoing. We remember very distinctly meeting Mr. Muth at the World's Fair convention, and the part he took in some of the discussions. He was for years one of the American Bee Journal's best friends, and in his death we feel that we have lost not a little.

MR. L. W. LIGHTY, in *American Gardening*, says that "the man who rides hobbies and runs after fads in bee-culture will have a lean bank account."

MRS. MATE L. WILLIAMS, editor of the department of the apiary in *Farm, Stock and Home*, reported, June 2, the severe illness of her daughter who is her assistant in the apiary. We trust she may speedily recover.

MR. J. E. CRANE (in *Review*) thinks the swarming propensity can be bred out of bees with less labor and time than it has taken to get non-sitting hens. The simple fact that bees differ greatly as swarmers makes the case look hopeful.—*Gleanings*.

MR. GEORGE KORNRUMPF, of Kinney Co., Texas, wrote us June 3:

"I am going to the Philippine Islands as one of Uncle Sam's boys. If the Philippine Islands are a good place to keep bees, I will likely take the fever."

MR. E. E. HASTY says, in the *Review*, that he won't have his picture taken, because when he did the picture always looked sleepy. The idea of a man looking sleepy who writes so wide-awake! Say, Hasty, you'll have to show us the picture if you don't want your reputation for veracity shattered.—*Gleanings*.

MR. GEO. W. HUFSTEDLER, of Bee Co., Texas, the President of the National Queen-Breeders' Union, writing us June 4, said:

"Bees are booming this season so far here. Mesquite is just coming into blossom now, and the prospect for a heavy flow is fine."

DR. A. B. MASON, Secretary of the United States Beekeepers' Union, wrote us May 30 that he, as Secretary of the Union, recently effected a settlement with a large city honey-dealer for over three tons of honey that had been shipped him last fall by a member of the Union. You see it pays to belong to the new Union.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

FOR THE READERS OF THE
AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles:

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This will be a series of practical articles that bee-keepers of the United States will not want to miss reading. They are copyrighted by Mr. White, and will appear only in the AMERICAN BEE JOURNAL, beginning in July.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get

their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan Field | 14 Muth's Practical Hints to Bee-keepers |
| 6 Our Poultry Doctor—Fan Field | 15 20 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse Book | |

For Sending TWO New 40-cent Subscribers:

- | | |
|---|---|
| 1 Potato Culture—by T. B. Terry | 7 Hutchison's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Biencu-Kultur—German |
| 4 Dr. Tinker's Bee-Keeping for Profit | 10 Bees and Honey—160 pages—by Newman |
| 5 40 "Honey as Food" Pamphlets | 11 People's Atlas of the World |
| 6 Winter Problem in Bee-Keeping—by Pierce | |

Please remember that all the above premiums are offered **only** to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium; but we will begin the subscription just as soon as it is sent in, which will secure several June numbers in addition to the last 6 months of this year, provided the subscription is forwarded to us **at once**.

If you want your bee-keeping neighbors to be CERTAIN of getting ALL the numbers of the last 6 months of 1898, you had better get their subscriptions in **before July 1**, as we may run out of copies before the end of that month.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Southern Home of the Honey-Bee

Will continue to rear none but the **BEST QUEENS**. Untested, 50 cents; Tested, \$1.00.
GEO. W. HUFSTEDLER, Prop.,
President of National Queen-Breeders' Union,
24 Atf Beeville, Texas.
Please mention Bee Journal when writing.

—ITALIAN— —AND—

CARNIOLAN QUEENS,

Three or five-banded—Untested, 50c; Tested, 75c. Warranted purely mated. Safe arrival guaranteed. Postoffice Money Orders made payable at Caldwell. Address,

C. B. BANKSTON,
24 Atf Charlesman, Texas.

COMB FOUNDATION Wholesale and Retail.

Working Wax into Foundation for CASH A Specialty.

Hives, Sections, and a full line of Supplies. The best of everything. Write for Catalog, with prices, and samples of Foundation and Sections.

BEE SWAX always wanted for cash or trade.

GUS DITTMER,
AUGUSTA, WIS.

QUEENS From the best strains of bees in this Country...

I make the rearing of Queens a specialty. Untested, either 3 or 5-banded, 65 cents each. Tested, 95 cents each. **DANIEL WURTH,** Fairmonth, Rush Co., Ind. 24 Atf
Please mention Bee Journal when writing.

In the multitude of counsellors there is safety.—Prov. 11-14.

Honey Stored in New Foundation Combs vs. that Stored in Combs of the Previous Year.

Query 73.—Suppose in an extracting-super half the frames are filled with foundation, and the other half with combs fully built out and used the year before, but never used for brood. The honey is extracted after all is sealed. Which will yield the best honey, that starting with full combs, or that starting with foundation, or will there be no difference?—Tenn.

J. A. Stone—No difference.

E. S. Lovesy—In our locality no difference.

Rev. M. Mahin—There would be no difference.

Chas. Dadant & Son—No difference as far as we know.

J. M. Hambaugh—I think there will be no difference.

Dr. A. B. Mason—In experimenting last season with some of Root's drawn

Van Deusen Thin Foundation...

We have several 25-pound boxes of Van Deusen Thin Flat-Bottom Comb Foundation for sale, at \$2.50 per box. This Foundation is preferred by many. As we have only a few boxes of it, an order for same should be sent promptly. Address **The A. E. Root Co.**, 118 Michigan Street, Chicago, Ill.

Bee-Hives, Sections, Shipping-Cases—everything used by bee-keepers. Orders filled promptly. Send for catalog. **MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO.**, Nicollet Island, Minneapolis, Minn.

BEEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, **E. L. CARRINGTON,**
11 Atf De Funiak Springs, Fla.
Please mention Bee Journal when writing.

ONE MAN WITH THE UNION COMBINATION SAW

Can do the work of four men using hand tools, in Rippling, Cutting-off, Mitring, Rabbling, Grooving, Gaining, Dadoing, Edging-up, Jointing Stuff, etc. Full Line of Foot and Hand Power Machinery Sold on Trial. Catalogue Free.

SENECA FALLS MFG. CO.,
46 Water St. SENEOA FALLS, N. Y.
Please mention Bee Journal when writing.

Frank B. Barkley Mfg. Co., 835 Old Colony Bldg., Chicago, Ill., will sell you a Feed Cooker direct from the factory.

"A Queenly Deceiver."

"He fools his customers by sending more than is expected."—See page 105 current volume Bee Journal, and ask for the free pamphlet referred to. I am now prepared to fill orders promptly with FINE YELLOW TO THE TIP QUEENS, or daughters of imported stock mated to golden drones, at 75c each. Purely mated Queens reared from the best stock and by the best method known, is what I furnish, and will prove to all who give me a chance. Money Order Office, Warrenton.

Address, **W. H. PRIDGEN,**
22 Atf Creek, Warren County, N. C.
Please mention Bee Journal when writing.

Bees for Sale in Indiana!

Italian Bees in 8-frame Langstroth hives. Per colony \$5.00; 5 or more at one time \$4.50 per colony. I have only a limited number for sale. They are strong colonies, and ready for business. Address, **W. H. WATTS,** 19 Atf Ross, Lake Co., Ind.

Excelsior Incubator and Brooder Cheap

200 eggs capacity. Good as new. Used for only two hatches. Everything complete. Will sell it for **TWENTY DOLLARS,** half the cost price. Address, **P. W. DUNNE,** River Forest, Cook Co., Ill.

Please mention Bee Journal when writing.

foundation, comparing it with comb used before, our family were unable to discover any difference.

E. France—I don't think there would be any difference.

Dr. C. C. Miller—There hardly ought to be any difference.

Eugene Secor—I doubt whether any one can tell the difference.

P. H. Elwood—I should not expect any appreciable difference.

O. O. Poppleton—I don't think any difference can be detected.

Emerson T. Abbott—A good way to find out would be to try it.

Prof. A. J. Cook—I do not believe there would be any difference.

Dr. J. P. H. Brown—The best honey will be in the combs built on foundation.

Mrs. J. M. Null—If excluders are used, and the kind or source of honey the same, there will be no difference.

S. T. Pettit—If the combs were dried by the bees the previous fall, there will ordinarily be no difference, unless that starting with foundation should take up a soapy flavor.

D. W. Heise—Why, I would expect the latter to be the best. It is from the fact that in the latter the honey would be stored somewhat slower, and therefore would be better ripened.

G. W. Demarce—I have never discovered any difference in the quality of honey gathered at the same time, and under the same conditions of weather, no matter what the age of the combs were.

C. H. Dibbern—There will be some difference in favor of the foundation, as it will be better ripened, but I do not know that the difference is sufficient so that it could be readily noticed in the honey.

R. L. Taylor—If the honey-flow is slight there will be no difference; but if abundant, that in frames with foundation will be better, because it would not be as well cured in the comb on account of its being stored there more rapidly.

J. E. Pond—I can't see where there can be any difference. The conditions are so nearly similar that in theory one might decide either way. Is the matter of enough importance to make a test during the coming season? If so, let some one try it and report, and thus settle the matter.

G. M. Doolittle—The way you put it, the last year's combs would have their cells so lengthened that the foundation would have little honey in it, if the cells were drawn out at all. If the cells were drawn so the honey was deposited in them, the difference between this and that in the last year's combs could not be detected by one not in the secret.

Mrs. L. Harrison—If the comb is very white there would be but little difference. One season in preparing extracted honey to compete for a premium at the State Fair, I extracted only from white comb. My honey drew the premium, being lighter in color. The other exhibitors thought there was some trick about it, as theirs was all alike. I explained the "why." Colored combs will, to some extent, color the honey.

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

| | 5lb | 10lb | 25lb | 50lb |

White Clover Blossoming.

I wintered all my bees out-doors and all came through well and are doing fine. I had two swarms this week. White clover is just coming into blossom. The prospects for a good flow are fine.

P. D. WINE.

Cherokee Co., Iowa, June 4.

Working on the Mustard.

White clover is just beginning to show here and there. Bees are working on mustard at present, which affords no surplus, but allows the bees to "fatten up" for white clover. H. G. QUIRIN.

Huron Co., Ohio, May 3.

Bees Starvin

You may count this place a blank on honey production this year. Bees are in a starving condition now, and will have to be fed if they survive the season. We have had some showers but they came too late to affect the honey crop. The grain and hay prospects have been improved, and fruits never look better.

J. M. HAMBAUGH.

San Diego Co., Calif., May 30.

Good Crop Expected.

The bees are as busy as they can be, and they hum as loud as they know how. The fruit-bloom of all kinds was just immense. Now the red raspberries are in bloom, and the white and Alsike clovers are in blossom in great abundance; basswood is budding full for the first time in two years. I had 18 colonies, spring count, wintered in chaff hives, with the loss of one colony. I had one new swarm May 15, but none since. I expect another any day.

Long may the American Bee Journal live and prosper. I could not do without it. I have over 50 colonies to look after this summer. I. D. HYDE.

Washtenaw Co., Mich., June 5.

Fetid Marigold.

I send in a little box a nameless weed, and two little samples of honey, the larger bottle having the honey which is affected by the weed, and the smaller one is this season's honey which I would like to have your opinion of, as to the quality. We think it very fine, mostly white clover. The natives here claim that the bitter weed honey is fine for coughs, colds and such like, and keep it always on hand for that purpose. If you should find any merit in it, and some of your druggists would take hold of it, I could furnish quite a lot of it by August or September. Our honey now in a month or six weeks will have a bitter taste from the weed.

J. HARVEY DAVIS.

Avoyelles Co., La., June 1.

[We referred the plant and honey to Mr. D. S. Heffron, an old-time botanist, and now a bee-keeper, who reports as follows:—EDITOR.]

I have somewhat carefully examined the little plant sent you by Mr. J. Harvey Davis. If I do not mistake, it is named

First Excursion of the Season to Buffalo

Via Nickel Plate Road, July 14-17, at one fare for the round trip. Choice of water or rail between Cleveland and Buffalo within focal limit of ticket. For further information call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone Main 3389. (31)

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cents a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

New Sleeping-Car Line

Between Chicago and Buffalo on train No. 6, Nickel Plate Road, leaving Chicago daily from the Van Buren Street Passenger Station (on the Loop) at 2:55 p. m. Also a through sleeper to New York via Nickel Plate and Lackawanna Roads, in addition to the excellent through service heretofore maintained. (35-24-2)

Dysodia chrysaethemoides. It is very fully described by both Dr. Asa Gray and Prof. Wood. The plant seems to differ slightly only in one particular from the descriptions of the authors, and I think the very dried condition of the specimen was the cause.

The plant is found all the way from the Southern part of this State to Louisiana. It is quite bitter to the taste, and ill-smelling, which Dr. Gray says gives it the common name of "fetid marigold." The bitter principle undoubtedly makes a good tonic for colds and common bronchial coughs. Doubtful if there is any money in it, unless one has \$15,000 or \$20,000 with which to advertise it.

D. S. HEFFRON.

Rainy During Fruit-Bloom.

It has rained here nearly all the time for six weeks. Nearly all the apple-bloom and other flora was lost.

HENRY ALLEY.

Essex Co., Mass., June 3.

Bees Moving Eggs.

Do bees move eggs? This question I find answered in the affirmative to-day. A comb for seven days separated from the queen by a queen-excluding honey-board, shows a queen-cell with an egg in it. All the other cells have capt brood, and very large larvæ, but no eggs.

H. ROHRS.

Rock Co., Wis., June 3.

No Honey to be Had.

I had three swarms May 16, but there is no honey to be had, and swarming is at a standstill. But bees are all right yet.

CHARLES LEHNUS.

Kankakee Co., Ill., June 6.

White Clover Scarce.

Our 162 colonies of bees are in about as good a condition now as any year we have kept bees. All wintered without loss. Two this spring came up missing. All but one or two will be strong enough to gather white clover honey, and store in the sections, but white clover will be rather scarce—not quite so much as last year—and we thought it scarce last year, it being our principal honey crop.

MRS. L. C. AXTELL.

Warren Co., Ill., June 4.

Bees and Poultry.

I make a specialty of bees and poultry. I have kept bees at this place 33 years, and produce from 4,000 to 10,000 pounds of comb honey a year. I have about 2,000 pounds of white honey on hand now, which is nice and dry, in 12-section cases.

Clover is very short in this locality. Plenty of it came up this spring from the seed, but will be of no use this season. No swarms yet. Our fall bloom is usually good here, from Spanish-needle, heart's-ease and golden aster.

SYLVESTER PAGE.

Carroll Co., Ill., June 4.

Honey in Preference to Swarms.

We have quite a few bee-keepers here, some having as high as 50 colonies, but I can beat them all on producing honey per colony. One neighbor across the river here had 45 colonies, spring count, and he had his first swarm May 25, and

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip't with best machinery, all combine to enable this firm to furnish the

Address, **Leary Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

they have been swarming ever since. It makes him feel glad to have a swarm before I do, but I askt him if he had any honey yet, and he said no. So I told him to come over and I would show him some new honey. I have about 100 pounds of honey stored in the sections. I have only six colonies, but I don't let them swarm. I give them lots of room.

A. WURFEL.

Marinette Co., Wis., June 5.

Cool Weather.

I came here this morning with 117 pounds of comb honey, and sold it. I drew it from four hives on the 29th. Our flow is not as good as last year. Honey-blooms are limited this year, except sourwood, and yellow, or chittim, wood. Nearly all of April was cool and cold, four days of cool weather in the full moon in May. There is very little swarming this season. By the middle of July our summer harvest will be over. The cool weather was our drawback this spring.

JOHN M. RYAN.

Morgan Co., Ala., June 1.

One Fare for the Round Trip

To Buffalo, N. Y., and return, account Baptist Young People's Union meeting, July 14-17. Rates lower than via other lines. For full information call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone 3389 Main. (30)

Frank B. Barkley Mfg. Co., 835 Old Colony Building, Chicago, Ill., will sell you carts, wagons, buggies, carriages and harness direct from factory. 21A4t

Another Improvement in Train Service

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,
Chicago, Ills.

Bees and Honey, or Management of an Aplyry for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times." In all the improvements and inventions in this rapidly developing pursuit, and presents the applanist, with everything that can aid to the successful management of an applanist, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No applanist library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Aplyry, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 178 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hatchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called **BEES OF HONEY**. 100 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, by Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by THOS. G. NEWMAN.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from **BEES AND HONEY**. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from **BEES AND HONEY**. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kolnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p.; illustrated, 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2 in fine artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Bienezucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers. This book gives the latest, most improved methods of bee-keeping, in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50c.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st. How We Made the Old Farm Pay; 2nd. Peach Culture; 3rd. How to Propagate Fruit-Plants, Vines and Trees; 4th. General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book—35 pictures, showing positions of sick horses, and treatments on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only ONE book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

- 1. Langstroth on the Honey-Bee.....\$2.00
- 2. A B C of Bee-Culture..... 2.00
- 3. Bee-Keeper's Guide..... 1.75
- 4. Bees and Honey (Cloth bound)..... 1.65
- 5. Doolittle's Scientific Queen-Rearing..... 1.75
- 6. Dr. Howard's Foul Brood Book..... 1.10
- 7. Advanced Bee-Culture..... 1.30
- 9. Bienen-Kultur [German]..... 1.20
- 10. Rational Bee-Keeping [Paper bound]..... 1.75
- 11. Bee-Keeping for Profit..... 1.15
- 12. Convention Hand-Book..... 1.15
- 13. Poultry for Market and Profit..... 1.10
- 14. Turkeys for Market and Profit..... 1.10
- 15. Capons and Caponizing..... 1.10
- 16. Our Poultry Doctor..... 1.10
- 17. Green's Four Books..... 1.15
- 21. Garden and Orchard..... 1.15
- 22. Rural Life..... 1.10
- 25. Commercial Calculator, No. 1..... 1.25
- 26. Commercial Calculator, No. 2..... 1.40
- 27. Kendall's Horse-Book..... 1.10
- 32. Potato Culture..... 1.20
- 32. Hand-Book of Health..... 1.10
- 34. Maple Sugar and the Sugar Bush..... 1.20
- 35. Silo and Silage..... 1.10
- 36. Winter Problem in Bee-Keeping..... 1.30
- 37. Apiary Register (for 50 colonies)..... 1.75
- 38. Apiary Register (for 100 colonies)..... 2.00

A QUESTION.—Could you not send one or more NEW SUBSCRIBERS with your own renewal? You doubtless have neighbor bee-keepers that would be glad to take the Bee Journal if you would ask them, and send in their subscription money. You will find premiums offered by us from week to week for such work. We would like to have you help us roll up a large list of readers for the old American Bee Journal.

OUR GREAT PREMIUM OFFER! OXFORD TEACHER'S BIBLES!

WITH HANDSOME SOFT LEATHER COVERS, LARGE CLEAR TYPE, HIGH-CLASS WORKMANSHIP and MATERIAL. Containing all the FAMOUS OXFORD HELPS, which make Bible reading and study so DELIGHTFULLY INTERESTING AND EASY.

What the World's Greatest Scholars say of "Oxford Teacher's Bibles."

- "The very best. I have carefully examined it."—C. H. SPURGEON.
- "Superior to any I have seen. I think them perfect."—CANON TREVOR.

In this Edition of Teacher's Bibles has been attained a high perfection of typographical beauty, accuracy and excellence in workmanship and material.

The OXFORD TEACHER'S BIBLES are universally acknowledged by the BEST AUTHORITIES as SURPASSING ALL OTHERS. Their FAMOUS "HELPS" comprise NEARLY 400 PAGES of Tables, Explanations, Concordance, Maps, etc.; in fact, an exhaustive Cyclopaedia of Bible information, full of value to both critical and ordinary students. They are the life work of the most eminent Biblical scholars of to-day, and consist, in brief, of 12 Beautiful Colored Maps; Concordance (40,000 References); Index to Persons, Places, and Subjects (10,000 References); Calendar; Dictionary of Proper Names and Pronunciation; Harmony of Gospels, Tables of Parables, Miracles, Prophecies, Money, Measures; Exhaustive Articles on Jewish Sects, Biblical History, Geography, Ethnology, Animals, Plants, Geology, Precious Stones, Music, Antiquities and Customs, and thousands of other interesting and valuable subjects, admirably arranged for study and easy reference. To Bible readers their advent and possession is like issuing from groping darkness into a glorious and clear sunshine.

These Bibles contain, besides 150 illustrations of the Oxford editions, 32 full-page photo etchings on copper of steel engravings and modern photographs of famous scenes in the Holy Land, together with full description and explanatory text. Something not found in any other Teachers' Bible. The following is a list of these full-page engravings:

| | | | |
|-------------------------------|-----------------------|--------------------------|---------------------|
| Antioch. | The Dome of the Rock. | Jerusalem. | Pool of Siloam. |
| Bethlehem. | Gethsemane. | Monastery of Santa Saba. | River Jordan. |

Will be pleased with a ride to Buffalo and return over the Nickel Plate Road. Choice of water or rail route between Cleveland and Buffalo, within final limit of ticket. Call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago, for particulars. Telephone 3389 Main. (29)

Basswood Honey FOR SALE

We have a limited number of barrels of very best Basswood Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash, Geo. W. York & Co., 118 Mich St. Chicago, Ill.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, June 9.—Very little call for honey, and the offerings also limited. Prices without change from late quotations. California extracted sells well and the stocks here are light. Weather now warm and prospects generally reported good in the surrounding States. Beeswax scarce, and 37 to 30c is bid for it. R. A. BURNETT & CO.

Kansas City, June 9.—The supply of 1897 comb and extracted honey is about all sold. Considerable inquiry for new comb. Something fancy would bring a good price. C. C. CLEMENS & CO.

Cincinnati, June 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3 3/4 to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Boston, June 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c.; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. BLAKE, SCOTT & LEE.

Cleveland, June 9.—Fancy white, 12 to 12 1/2c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & CO.

San Francisco, June 9.—White comb, 8 1/2 to 10c.; amber, 6 1/2 to 7 1/2c. Extracted, white, 5 1/2 to 6c.; light amber, 4 1/2 to 5 1/2c. Beeswax, 23 to 25c.

The market is lightly stocked and in all probability will remain so throughout the season now opening, as very little honey will be produced in this State the current year. Supplies now offering are principally comb. Values for both comb and extracted are being well sustained at the prevailing rates. With no active inquiry for beeswax from any quarter, the market is easy in tone, despite the light stocks here and in the interior.

Detroit, June 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9 to 10c.; fancy dark, 7 to 8c.; No. 1 dark, 6 to 7c. Extracted, white, 5 to 6c.; dark, 4 to 5c. Beeswax 27 to 28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. M. I. HUNT.

Minneapolis, June 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10 1/2 to 11 1/4c. Not advisable to ship darker than amber. Extracted fancy white clover, 5 1/2 to 6c.; amber, 5c.; dark, 4 to 4 1/2c.

Outlook for honey much more encouraging. S. H. HALL & CO.

Indianapolis, June 9.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, June 9.—Fancy 1-pound sections, 11 to 12c.; A No. 1, 10 to 11c.; No. 1, 8 to 10c.; amber, 8 to 8 1/2c.; dark, 7 to 7 1/2c. White extracted in barrels and kegs, 5 1/2 to 6c.; amber, 5 to 5 1/2c. Beeswax, 26 to 28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & CO.

Buffalo, June 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATERSON & CO.

St. Louis, June 10.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5 1/2 to 6c.; amber, 5 to 5 1/2c.; dark, 4 to 4 1/2c. Beeswax, 20 to 22c. WESTCOTT COM. CO.

 **Talk about
... Comb Foundation**

WE can now furnish the very best that can be made from pure wax. Our New Process of **MILING** enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

**It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.**

If you once try it you will have no other. Samples furnished **FREE**. Large illustrated Catalog of all kinds of

Bee-Keepers' Supplies,

And a copy of the American Bee-Keeper, sent upon application. Address,

CONTRIBUTED ARTICLES

FACING COMB HONEY.

Opinions, Suggestions and Advice from the Commission-Men.

[Continued from page 373.]

[We have received the following responses to our letter on page 371, since our last week's issue.—EDITOR.]

GEORGE W. YORK & Co.—

Dear Sirs :—We are in receipt of your favor requesting us to give our opinion in regard to the question of facing comb honey, lately discust in the American Bee Journal. As the paragraph referred to is certainly one of great importance to the bee-keepers in general, we cheerfully comply with your request.

As to the facing of honey, Mr. Doolittle says that he sold his crop of comb honey one year to a New York party and the buyer instructed to have the honey faced. This was a long

Apiary Building at the Trans-Mississippi Exposition.—(See page 392.)

time since—perhaps 20 years ago—and the consumers at that time were not so much acquainted with comb honey as they are to-day. It was more of a novelty those days. The party who bought Mr. Doolittle's honey that year evidently had it faced to sell it for a better grade than it really was, perhaps for fancy white, or whatever the facers indicated. We dare say this party did not give orders to have the honey faced or mixt a second year. Abraham Lincoln is quoted as saying: "You can fool some of the people all the time; you can fool all the people some of the time; but you can't fool all the people all the time." If Mr. Doolittle's buyer succeeded in disposing of the honey to advantage, and succeeded a second year, his customers must have been among the *some* people that you can fool all the time.

Mr. Doolittle claims that there is nothing out of the way in facing honey if shipt on comission, every crate alike, if

the producer thought it would be to his interest. Whether a bee-keeper sells his honey outright or sends it on commission, he naturally expects to realize the highest market value in either case. The quality or the grade of the honey constitutes its value. White honey is of a higher merchantable value than the dark, because it can be sold all over, while the dark honey is objected to by a majority of the people on account of its color and its strong and pungent flavor.

Again, of the white honey, the whitest commands a better price than the travel-stained and yellowed combs, because it is of nicer appearance to the eye. These facts are generally

Sweet Clover.—(See page 388)

known among the bee-keepers at large, and because they are facts, the grading and the rules of grading comb honey have been materially improved of late years, so the producers *might* be enabled to obtain the highest market value.

How then can it be to the interest of any bee-keeper to

face or mix his honey? Would any man with common sense think for one moment that he would gain by such a practice, whether he shipped his honey on commission or sold it? To the contrary, it would be the height of folly, and we should consider such a man mentally disarranged. He might just as well face the crate with buckwheat combs and put the white honey in the center of the crate, for the result would be the same; he would only realize the price of buckwheat, or, in other words, the lowest merchantable value for all of it. Facing or irregular grading will depreciate the value of the entire shipment. This not only applies to honey but other products as well. Take California dried fruits for instance. Carloads of raisins, prunes, apricots, and peaches are rejected on account of irregular pack.

At the New York State Bee-Keepers' Convention, held in Albany in 1890, we read an article on "What Our Market Demands." It was published in full afterwards in the American Bee Journal and Gleanings. We called particular attention to the grading of honey, and as facing and grading are virtually the same, we desire to reproduce that part of the article, as follows:

"We would call your special attention to the grading of honey, which is as important a question as any of the former ones, and in which too much care cannot be taken. Very often we receive honey which is not properly graded, and where off grades are mixed in with the first grade and market No. 1 white honey. The outside combs will appear all right, but inside of the crate will be hidden the poorer grades. We cannot take the trouble to open and examine every crate and comb, but have to rely on the shipper, and go by the mark and appearance of the crate. We sell and ship the honey, and the first thing we know the party to whom we ship will write a letter complaining of the honey, and hold it subject to our order. We either have to have the honey shipped back to us, or make a liberal allowance, satisfactory to the buyer. This is certainly not very pleasant; it hurts our reputation, and we are apt to lose that customer. Not alone this, but the shipper is generally dissatisfied, too, claiming that the honey should have sold for more, and refusing to admit that the honey was improperly graded."

We also noticed Mr. A. Snyder's statement of facing. We think he was too severe. It gives us pleasure to state that, as a whole, we have had but very little fault to find of late years in the grading of honey. Bee-keepers have learned that it is to their interest to grade properly. Prominent bee-keepers, *i. e.*, large producers who have to rely on the city markets for the disposal of their product, generally are careful in grading. Yes, the vast majority of the smaller producers know how to grade, and we hope to see the day when careful grading will be universal.

Of course, when such distinguished and able writers like Mr. Doolittle defend facing or improper grading, which, as we said before, is essentially the same, we fear that day is in the far future. While we have had no fault to find as a whole, we admit that there are exceptions, but they are mostly among the inexperienced bee-keepers or the beginners. They will crate the honey as the combs may run into their hands. Here is a case of it:

Last fall we received quite a shipment of comb honey from Pennsylvania. The different grades of white, the mixt and the dark, all mixed together in all the crates. Some of the crates were faced with fancy white, while others with dark. We attempted to sort it out, but soon gave it up. After we carried the honey for a long time we sold it all for the price of dark honey then ruling—6 to 6½ cents a pound. If this honey had been properly graded, the No. 1 white would have sold for at least 10 to 11 cents a pound, and the off grades for 8 to 9 cents a pound. Was it to the interest of *this* bee-keeper to face or mix his honey?

Strange to say, we never heard a word of complaint from this shipper, which leads us to believe that he was a beginner. We wonder if he ever read a bee-journal? Every season we receive numerous letters from new parties, asking us for information—what shape, what size section to use, whether to glass them or not, or put them in cartons, how many to put into a crate, how to ship, when to ship, and what we can realize them for the honey. While we are always willing to give all the information we can, it seems to us that if they would spend a dollar a year they could learn more in one week in a bee-journal than we could explain to them in a year.

We admit that any bee-keeper has the right to crate his honey, face or mix it just as he chooses; but in the interest of the bee-keepers themselves we earnestly hope that they will ignore the statement (we will not say advice or suggestion) of Mr. Doolittle, and instead of paying any attention to it what-

ever, not face the honey, but have every case contain the same quality as shown in the outside row.

Yours very truly,
New York. HILDRETH BROS. & SEGELKEN.

EDITOR AMERICAN BEE JOURNAL—

Dear Sir:—Your favor regarding the facing of honey at hand, and carefully noted. As large handlers of honey on commission we have at all times tried to impress on our regular shippers the *absolute necessity* of grading their honey HONESTLY. In this way, and this only, is it possible to secure results satisfactory to the shipper, and give the purchaser what he may desire, and what to our mind should be the aim of every producer—the building up, by careful grading, of a demand for a brand, because it is *always* what it is represented to be, and what it appears to be.

While it might not be dishonest in the strict sense of the word, to mix fancy, No. 1 and No. 2 comb honey in the same case, provided it was so understood by the purchaser at the time of the sale, yet the result would without doubt be disastrous to the shipper, for the reason that the purchaser would at once decide that a large share of the honey was second grade, and only buy at a very low price.

Then, again, such a practice would most certainly destroy confidence in brands, and as a result prices would not, and could not, be such as to equal that realized from honey sold strictly on its true grade value.

Our opinion, after many years of experience, is to grade *very carefully*, marking each case in such a way that we can keep it separate; placing your full name and brand on the fancy and No. 1 grade, but only initials, or use a different brand, on the No. 2 and dark. In this way you will be able to keep your brand A 1 in every respect, where it should be, and thus create a *demand* and *reputation* which will be your best capital in the future.

For this market we strongly advise the use of paper cartons on each comb.

If these directions are carried out, we believe better results will follow in every case.
Very truly yours,
Boston. BLAKE, SCOTT & LEE.

History of the Honey-Bee; Honey, and Its Uses in Early Times.

BY F. GREINER.

It is now an undisputed fact that bees were in existence long before man. Petrified (or fossil) bees, *Apis adamantica*, have been found in numerous instances, here in a stone-quarry, there in the amber deposits, showing that bees are not a late production of nature. We have also evidence that, in prehistoric times, among people that must have been in existence then (judging from the remains of their work, tools, etc., found, honey-strainers among other things), bee-keeping was a branch of their industry. What kind of bees these people kept has, however, not been determined. The writers of later ages, and of times long past, have not made quite the distinctions between different races that we do to-day, altho Virgil, Aristotle, and others mention bees of a dark and of a light or yellow color. It seems to have been the principal aim of the ancient Germans, and, in fact, of the people in general, inhabiting North Europe, to produce honey for the purpose of converting it into a drink, evidently intoxicating. This tendency may be followed, like a red stripe in a carpet, from remote times. In the German mythology this drink, *met*, is mentioned a thousand times in the poetry of that time, altho nothing is said about bees and bee-keeping.

The German bee is common all over the northern part of Europe. It is of a dark brown, or nearly black color. This bee is not alike all over the territory named. Evolution has brought about slight changes according to existing environments, and so we find a number of different strains. First, the common brown bee, the same as we have here, the bee that was imported into America by the immigrants. In the heath sections of Germaoy we find the heath bee, resembling the first-named exactly in outward appearance, but differing from it in their great disposition to swarm. It may truly be called a "swarming bee." Vogel claims the heath bee, when brought into different surroundings, will acclimate itself in a few years and lose this swarming tendency.

In the mountains of Carniola we find a gray bee with a possibly slight admixture of yellow blood. It very nearly resembles our common brown bee. This Carniolan bee has been imported into America.

Going southeast we have the Caucasian bee, so named from the mountainous region, Caucasus, where it is found. It

is a dark bee, possibly a cross between an eastern and western bee.

The Smyrnian bee of Asia may also be a cross with an oriental race. Greece has a dark bee; also Hungary and Austria, and in North Norway. In fact, many other lands or districts may be named, each having its own peculiar bee.

Genuine black bees may be found in Africa. Mention may be made of the Tunisian bees, or Punics. They are probably of oriental origin. In examining the bees of the different lands, we find the blacks predominating in Norway, Sweden, Denmark, France, Germany, Russia, Austria, Carniola, Switzerland, Tyrol, Greece, Northern Asia, Northern Africa, etc. All have a dark bee. Yellow bees we find only in Syria, Southern Spain, Italy, Cyprus, and other islands in the Mediterranean Sea.

F. Benton thinks that since some insects have a way to protect themselves by assuming the same color as their surroundings, it is not unreasonable to suppose that bees may have done the same. And, indeed, so it would seem. Cyprus, on account of so much yellow sand, has a very yellow appearance, and her bees are the most yellow of any. The general appearance of Africa is black. She has the darkest bees. Germany, with its mountains and forests, seems dark or brown. Her bees are brown. Carniola, with her gray rocks predominating, has the gray bee.

So much about the different bees; and now for some glimpses of bee-keeping, uses of honey, etc.

Bee-keeping in India may be traced back to the year 2,000 B. C. It was said there that it would "rain honey" in the spring of the year in certain localities. To these the shepherds would drive their cows. Having fed on the sweetened grasses their milk would be so sweet as not to need any other sweetening. A baby boy received, for his first food, honey from a golden spoon (it might bother us fellows, who have not been to the Klondike, to find the golden spoons).

Egypt was once the land of knowledge and culture (Moses received his education there, as will be remembered, 1,500 B. C.). It abounded in honey-producing plants. The date-palm, for one, carried on a single fruit stalk as many as 12,000 nectar-yielding blossoms. The information we have from this land regarding bee-keeping in those early days, is principally gleaned from the hieroglyphics on pyramids, obelisks, sphinxes, and on remains of temple walls. Honey was used to embalm the dead; wax also for the same purpose, and to make coffins air-tight. Bee-hives were made of cane, and coated with clay. Others made them wholly of clay, and burned them. Such hives are being made up to this day. The Egyptians practiced migratory bee-keeping at an early date. It is recorded in history that Solon, "the Wise," made a special trip from Greece to Egypt about 600 B. C. for the purpose of learning this art of bee-keeping.

Palestine abounded with bees at the time the Israelites first occupied it. The many cavities in the chalk rocks and trees furnished all the needed shelter for the bees, and the people obtained all their honey and wax by simply robbing the bees. After the advent of Christ, bees were kept in hives and in apiaries. Even a smoker had come into use, in which well-dried droppings from the cattle-yard were burned. A law is recorded forbidding the lighting of the smoker on the Sabbath day (it might be well for a few of us to make a note of this).

Apiculture in Arabia seems of later origin, the people having copied from the Greeks and Romans. The first history we find in the Koran. Mohammed devotes a whole chapter in it to bees and bee-keeping. Mohammed's followers believed that honey was the principal food in "the happy land beyond."

Numerous Greek and Roman writers have given us bits of bee-history here and there. Virgil called the bees repeatedly "the children of the dead [rotten] ox." According to tradition bees might be produced at will at any time in this manner: Take a two-year-old steer [the Latin word for steer is *apis*, and so it will be seen that the word *apis* means steer as well as bee]; stuff rags or the like into his nose and mouth, no matter how much he may object, and now belabor him with a club until dead, but without breaking his skin. Now let him lie until decomposed. After a time, it was said, bees would come forth from the carcass.

It seems incredible that so absurd a story as the above could have found any believers; but this is unmistakably so; for even Melancthon, the bosom friend of Dr. Martin Luther, living 1497—1560, believed it. Yes, even later writers have recorded it as a fact. However, not all the "smart men" were as ignorant of the natural history of the bee as that. Aristotle, living between 400 and 300 years B. C., does not even mention this steer-story. His knowledge was away beyond that of other mortals of his time—yes, even of our times.

When talking with a man of high education but a year or

two ago on the subject of bees, the conversation turned to the sources of honey. I mentioned that our bees "made the most of our honey from basswood."

"I had no idea the bees *could* make honey out of any kind of wood," was the educated man's reply, and he meant what he said.

Aristotle was well acquainted with the nature of the bee. He knew the true sex of the queen, the workers, the drone. He knew the queen laid all the eggs, knew the time of development of the different bees; he was wrong, however, in supposing the old bees to be the nurses, the young the field-workers. It is hard to understand that this knowledge that Aristotle possessed in regard to the life of the bee did not spread more, and become the property of the people; but it is a fact that, during the following 2,000 years, more was forgotten than added, and this in the face of the fact that a great many bees were kept.

There was Julius Cæsar, 100—44 B. C. All of his farms were well stocked up with bees. Others followed his example. In the eighth century, Karl the Great, reigning over a vast empire, did a great deal to promote the keeping of bees. After the Roman Catholic church had gained a foothold in Europe, the monks, in their monasteries especially, made a business of keeping bees, and induced the people to do the same. During the eleventh century the church demanded of the people the tenth of all the honey and wax harvested of wild bees, and the third from bees kept in hives. In view of this fact, what bee-keeper of to-day has any reason for complaining of high taxes?

For illuminating purposes at these times, the wax candle was the best thing obtainable, and only the rich could afford it in a limited way. Others had to be satisfied with the light of a burning pitch-pine knot. The churches in particular consumed much wax for candles. Before Luther's time the principal church in Wittenberg used for this purpose in one year 35,000 pounds of wax. This demand for wax, and for an article to sweeten foods and drinks, stimulated the bee-business to a great extent, and the number of colonies increased. It is stated that, during the eleventh and twelfth centuries, whole shiploads of honey and wax were exported from Germany to Palestine via Constantinople. Regular honey-markets were held every year in the cities of Augsburg, Nurnberg, Frankfurt and Cologne. Large breweries were built, in which quantities of honey-beer were made—enough, it is stated, to subdue large city fires. I take a few items from a honey-market report, said market being held in Nurnberg in 1250.

Comb honey was offered on earthen dishes, strained honey in pails and tubs; chunks of wax were heaped up in large piles. The honey (strained) was sold by the "seidel," and, according to a chronicle of that time, the seidel contained "14 mouthfuls and 2 fingers." Druggists were bantering for wax. Who knows, adds a later reporter, what a mixture of pulverized toad-eyes and beeswax might be good for? The city clerk needs wax for seals, and he is picking out the nicest pieces. Suddenly the business comes to a standstill, as the market-master and his crew are making the round to inspect. Honey harvested before the birthday of the Virgin Mary is not wholesome, and must not be offered for sale. The market-master receives the statement under oath that the honey is of the proper character.

The honey is also examined as to its purity. The loss of one hand was the penalty for adulteration. It seems penalties were of a severe nature. I will name another such case. Any one stealing bees or honey, and caught in the act was, without trial, delivered to the sheriff to be executed in a most terrible way. His intestines were first wound around the tree from which he took the honey, and then he was hung to the tree.

The hives in use in those times were of a very substantial nature. Let us watch one of the keepers preparing a hive. We see him standing on a ladder about 10 or 12 feet above ground, cutting a cavity from 3 to 4 feet long in a large basswood tree. Basswood or pine was preferred, and oak rejected. If a hive was needed for immediate use, the cavity was burned out with a straw fire; if not, it was just left to dry out. It was then rubbed over with wax, an entrance-hole bored in, and a suitable door fitted against the cavity and fastened. For centuries after this time the most popular hive in use was the hollowed-out log, three feet long, and a door fitted against each end. The honey from these was generally not harvested until the winter was over. The bee-keeper would then go to work and cut out all the comb he could, whether filled with honey or not, just leaving what was occupied with brood.

After the forests had been more and more cleared off in Germany, and timber became scarce, straw hives came into use, and many bees are kept in such up to this day. The

majority of the modern bee-hives are made of the more porous timbers, like pine, basswood, etc., are double-walled, opening from one or two sides, cupboard fashion, not from the top, thus making it practicable to tier up colony upon colony without inconvenience (just the thing for bee-houses). Tenement hives are much liked. Of late years a few bee-keepers are commencing to construct their hives after the English and American pattern, giving access from the top, and also using pound sections.—Gleanings. Ontario Co., N. Y.

Something About Alfalfa and Sweet Clover.

BY PROF. A. J. COOK.

There are some subjects which are like Banquo's ghost, and will not "down," and the ones suggested by the above heading seem among them. It is good that they will not betake themselves away until they are rightly settled.

Regarding alfalfa, the work of the experiment stations prove conclusively that it is most valuable if cut while in bloom.

In Bulletin 48, Utah Station, will be found the following tables showing the results per acre of analysis:

| FIRST CUTTING. | | | | |
|-------------------|-----------------|---------------------|----------------------------|------------------|
| Date. | Height. | Protein, pounds. | Carbo hydrates, pounds. | Fats, pounds. |
| May 4..... | 6½ inches. | | 607 | 40 |
| June 1..... | 18 inches. | 697 | 1,247 | 103 |
| July 7..... | Fall flower. | 745 | 2,278 | 118 |
| August 10..... | Flowers fallen. | 644 | 2,298 | 116 |
| August 24..... | Leaves dry. | | | |
| August 24..... | Still dryer. | 428 | 1,776 | 94 |
| SECOND CUTTING. | | | | |
| Date. | Height. | Protein, pounds. | Carbo hydrates, pounds. | Fats, pounds. |
| July 7..... | Budding. | 334 | 657 | 50 |
| July 20..... | Medium bloom. | 519 | 1,140 | 78 |
| August 3..... | Full flower. | 551 | 1,529 | 81 |
| August 24..... | Leaves dry. | 388 | 1,484 | 81 |
| THIRD CUTTING. | | | | |
| Date. | Height. | Protein, pounds. | Carbo hydrates, pounds. | Fats, pounds. |
| August 17..... | | 138 | 317 | 17 |
| August 31..... | | 322 | 757 | 33 |
| September 14..... | | 298 | 934 | 43 |

From the above the conclusion is apparent that alfalfa must not be cut earlier than the middle bloom, and not later than fall bloom, to secure a large yield of dry matter and albuminoids. This gives two or three weeks after budding, and several days in which the bees may gather nectar. These figures are generally accepted, and agree well with what we know of other similar plants. They may well be published broadcast by bee-keepers, in the hope that farmers of Utah, Colorado, Arizona, California, etc., may be influenced to delay the cutting of this valuable forage and honey-plant.

About here the hay is generally cut just as it is coming into bloom, and so, except that there are always stray plants or early ones that come into full bloom in any case, the bees get almost no honey from alfalfa. The reasons that the hay is cut so early are two, first, it is thought that the less mature hay is better for cows, tho many who think this agree that for horses it is better to wait until it is in full blossom. Most alfalfa hay here is fed to cows.

Another reason—perhaps more influential, tho rarely urged—is the greater amount secured by the early cutting. Alfalfa hay may be cut six, seven or even eight times, while three, four or five times is all that are possible if uncut until the bloom begins to fade. The one, two or three extra cuttings will give more weight, even tho at the expense of real nutrition. If we could persuade the farmer that it is to his interest to tarry in the cutting, then alfalfa would become a valuable adjunct to bee-culture all over Southern California. It will take a long time to do this, even if possible to do it at all. The grower has ready means to test the profit in his own hands, and as long as he secures more income, or thinks he does, by early cutting, just so long will the hum of the mower precede and preclude the hum of the bees.

MELLOT OR SWEET CLOVER.

I am sincerely glad that I am wrong regarding the value of sweet clover as a food for stock. It is, however, signifi-

cant that Prof. A. W. Henry, in his admirable work on "Feeds and Feeding," which all interested in such subjects should own and study, makes no mention at all of this plant. The work is very complete and up-to-date.

I am glad, I say, that so many find it valuable for pasture and hay. I still fear that it will long wait general use. Red clover, east, and alfalfa, west, will, I believe, be too strong competitors. Of course, any legume is good for green-manuring, trapping as each does the wary nitrogen from the air and combining it into available food for the plant. Yet here again I fear that it will be hard to secure the sweet clover a place in general practice for such purpose. Red clover would be better in the east, while lupines and peas will give better satisfaction west.

The orchardist, in California, wishes to grow his plants for green manuring during the winter months, and plow under in late February or early March. The white sweet clover being a biennial would be of no use for bees, if treated in this way, and so if as good as other plants it would not be available for honey.

The yellow sweet clover is an annual here, but so far as I have observed is not of much excellence for honey; nor is it equal to other plants for green manuring. For plants to be of service to apiculture, they must be generally desirable so as to be grown in profusion, like white clover in the pasture-fields of the east, or basswood in the eastern forests, or white and ball sage in the brushwood or bush of California.

As a wayside plant mellilotus may take rank east, and help the bee-keeper out; but for planting by the general farmer is it at all probable that it will ever find a place? It is so good a bee-plant that I hope it will. I think it will not.

Los Angeles Co., Calif.

A Consideration of Our Bee-Keepers' Interests

BY JAMES A. STONE.

(Read at an Illinois Farmers' Institute.)

It matters not what pursuit we wish to enter in life, the first question that confronts us is—Will it pay?

It is an axiom that no business in this world will pay unless properly managed; and even then the time will come when it will not prove a success financially. We will take wheat-growing for example, which has not been profitable for a number of years, and yet in times many a farmer has paid for his farm out of the profits of wheat-growing. We might say the same of corn, hogs and cattle, and in fact all the products of the farm.

One of the great faults (we might call it) with farmers is their great disposition to rush to the same thing and overcrowd it, like a lot of frightened cattle on a boat—cause it to be sunk by all rushing to one side. The interests of bee-keeping are not so, for the reason that all will say the wild flowers are disappearing, and there are no honey-plants for bees to work upon as there used to be. And then there are so many who are afraid of bees. We have had many to tell us that they wanted to be let alone by the bees, they hurt too badly, and "their sting swells so on me," and is so painful—y! They will follow me a mile to get to sting me," and all such talk. If a person is not brave enough to stand an occasional sting, he would better never engage in bee-culture.

The writer, when a boy, was as badly affected by the sting of a bee as any one well could be. But by persistence and a determination not to give it up, he has grown to care less for their stings; and on several occasions is positive that they have cured rheumatism.

With Italian bees, a bee-veil, and a smoker, the only stings received will be on the hands, and by removing the sting immediately, and squeezing out the poison from the place affected, the pain is soon gone, and but little if any swelling occurs.

With the many barriers in the way, the interest of bee-keeping is overlooked, to the loss of everybody.

The first objection offered (that wild flowers are disappearing) can easily be overcome. No sane man ever thinks of keeping any kind of animals without in some way providing food for those animals. But when it comes to bees—because they have wings, their owner will say, "If you can't go and 'sponge' off my neighbor you can starve." To a certain extent this is all right, but suppose your neighbor has no pasture for your bees? Then comes up the original question, "Will it pay?"—to raise some kind of pasturage for them? I know it will pay largely. To illustrate:

The writer with his son not long since, in viewing a 20-acre piece of Alsike which they have, made this statement:

"Suppose we obtain only 50 pounds of honey per acre, at

only 10 cents per pound, that would pay the rent at \$5 per acre; then the hay will produce almost as much as red clover, and of a much better quality, and the seed (which is in the first crop) produces more than red clover, and also brings a higher price. And as a forage-plant we know of no plant that will attract any kind of stock away from it."

While in charge of the Illinois honey exhibit at the World's Fair, I was one day conversing with a man who proved to be a dairyman at Elgin. He said his cows on Alsike clover pasture gave more milk, and of a better quality, than did the cows of his neighbors which were on other pastures. Being suspicious that he was a bee-keeper, or that he had other interests, I began to quiz him thus:

"Perhaps you have a better strain of milkers than they?"

He answered, "They are the same cows I had previously on their pasture, and they did not produce then as now."

Then I asked, "Are you a bee-keeper?"

"No; but my neighbor's bees fairly swarm on my pasture."

That satisfied me, for altho I had raised it, I wanted to hear what others thought of it.

It has no superior as a honey-plant, unless it be sweet clover, and its quality (of honey) is as good as white clover. Its growth is like red clover, tho it has not as coarse a stem, and for that reason is a better plant to mix with timothy, as it cures as quickly as timothy. It has blossoms resembling white clover, except they have a purple tinge. Its leaf is solid green, while those of red and white clover are sprinkled with white.

In speaking of sweet clover I desire to say a word in its defense, taking the risk of incurring the ill-will of the commissioners of highways throughout the State. It has not gotten into our part of the State very extensively as yet—only here and there a patch on the highways—and everybody on first observing it, and hearing what the other fellow has to say of it, seems half frightened out of their senses, imagining they are going to be crowded out of existence by it because of its early and rapid growth.

One of our neighbors, who was thus affected, after he had been told that it was a biennial, and was very tender the first year, and did not bear seed till the second year, and then died root and branch, was seen the next spring digging up plants to take home and set in his yard.

During the World's Fair I received a very fine sample of sweet clover honey from Mr. Miller, of Lee county, 85 miles west of Chicago. I went out to buy it to add to our exhibit, and found that he had 2,300 pounds of comb, and two barrels of extracted honey from 35 colonies of bees; and all the pasture they had was the sweet clover in the adjacent highways, and 7 acres he had sown on his farm, on land that was too poor for corn; and he said that following sweet clover he had raised on this kind of land better corn than on his best land.

Why not such a plant as this be allowed to grow on the roadside instead of noxious weeds? Sweet clover is fast coming into favor as a forage plant, as it is being found out that all kinds of stock learn to like it.

At the meeting of the Northwestern Bee-Keepers' Association in Chicago, some of the bee-keepers reported that stock in the highways where they lived, kept it eaten close to the ground. Yet there are some people still living who are like the old deacon, who would not support a candidate for an office because he said he believed that the earth was round, and you couldn't make *him* believe such stuff, and he wouldn't vote for any man who did believe it!

I would not advise every farmer to be a bee-keeper, nor do I advise the planting of crops especially for honey. But as to the latter, you can draw your own conclusions from what I have said.

As to every farmer being a bee-keeper, it is not practical, for the reason that it would be in most cases on so small a scale that it would not pay him to spend much of his time with the bees, and to be successful they must have the proper care at the right time.

It is a fact that when there is no honey for the bees to gather, they do not need so much time applied to them, but the colonies will run down and be lost by becoming queenless, and from other causes that need a watchful eye occasionally, and an attentive ear to the sound of robbers, even if there is no honey being stored.

No one who is largely engaged in horticulture can afford to be very far removed from bees without more or less loss in his fruits—some seasons when bees are the only fertilizing agent to be had. The writer one year had a large crop of cherries, and got a good price for them because there were so few in the market; and I could see no reason for it unless it was the bees.

The President of the Missouri State Horticultural Society,

in relating the experience with the large sweet cherry growers along the Pacific Coast, said they were growing these cherries in California, and from there they were taken north along the coast, but the trees which were thrifty and healthy would not bear any fruit in the northern locality. On investigation they discovered that the cause was a lack of fertilization. Bees were introduced into those localities, and they had no more trouble—the trees produced fine fruit in abundance.

By the mode of procedure I have partially outlined, a good apiary of 75 or 80 colonies could be had to each 3 miles square, or 9 square miles, in the State, which would in the 56,000 square miles of Illinois, give us over 6,000 apiaries of 75 colonies each—450,000 colonies, with, in ordinary years, 50 pounds of honey per colony, or 22,500,000 pounds of honey—the purest sweet that the Lord has given to man. We do not want to discourage the sugar-beet industry, but how do these figures strike you, gentlemen? While these figures may be possible, yet the highest we have ever known—reported by the assessors of the State—was in 1889, when 2,128,060 pounds were reported, at 14 cents per pound, or about \$298,000. It is certainly possible to improve largely on these last figures.

Dr. C. C. Miller, of McHenry county, then President of our State association, last year received from three apiaries of 80 colonies each, over 17,000 pounds of honey; and C. P. Dadant, of Hancock county, from one of his apiaries in Brown county, of 75 colonies, obtained 8,000 pounds.

The beginner in bee-keeping must not think he can start in the business on the old plan any more than he would think of beginning to farm this spring, by going into the field with a hoe to cut corn stalks, or in the harvest time with a cradle or reap-hook to cut wheat, and his other work on the same plan, because his forefathers succeeded, and did that way. Neither must he listen to the advice of the old-timer, who will say:

"Talk about bee-keeping—why, bless your life, I have kept bees for 50 years, and I never seen a king-bee in my life. You needn't tell me that bees don't gather wax, for I have seen it on their legs. And I don't want you to talk to me about bees only living six weeks, for I have a stand of bees that my father gave me 30 years ago. And you had just as well talk to me about this earth a-goin' round the sun once in a year, as to make me believe that you can cause your bees to take one of the eggs that it would take 20 days to hatch into a worker-bee, and change it, as you say, so that in 16 days it will hatch into a queen. Nonsense!"

But what a beginner in bee-keeping should do, is to get some good book on bee-keeping and take a good bee-paper. Then with a small number of colonies of Italian bees, in a few years you will have all the bees you desire, and the knowledge needed to care for them. In fact, you will have so many that you will be ready to fall into line with bee-keepers to get a race of bees having a non-swarmling disposition.

We can claim for the industry of bee-keeping what can be said of no other, viz.: It does not take from any other thing that which would make it more valuable in retaining the same, but on the contrary adds to the value of that thing.

For example, when bees go into an orchard in full bloom, to gather what nature has placed there to attract them, or some other fertilizing agent to the blossoms, they carry the fertilizing dust from blossom to blossom, causing fruit to grow where there would be none without some agent to carry the pollen (as nature seems to abhor self-fertilization), and all that the busy little bee carries off as a reward for her valuable services is not needed, and is of no use in the growth of either fruit or tree, as it was placed there by the God of nature for them to carry away.

The same may be said of all the other fruit or seed-bearing plants. Red clover was without seed in countries where the bumble-bee did not exist until it was introduced into those countries, for the reason that other insects could not reach the sweets secreted in the cups of the blossoms, and therefore did not visit them to carry the fertilizing dust.

It has always been said that red clover did not produce seed in the first crop, but I have observed since I have had the Italian bees that in seasons that are dry, and the blooms of red clover not so large, the Italian bees work on them sufficiently to cause a quantity of seed.

Alsike clover, as I have already said, produces seed in great abundance in the first crop, because bees work so well upon it. Can this be said of any other industry, that by taking a part from these things we have named, the remainder is made greater? And yet it is so in all cases where our bees visit our own or our neighbors' blooming orchards or fields—they give back a double value for all they take away.

A bee-keeper friend living in the northern part of our

county said to me as I was viewing his alfalfa and Alsike clover fields, "I am going to get three crops from those fields. From the alfalfa [of which he had ten acres, and has for several years cut three crops] I will get three crops of hay [bees work very little on it here], and from the Alsike I will get a crop of honey—a crop of hay, and one of seed. And any one of the crops will pay the rent of the land."

In view of these facts I have shown that bee-keeping can be added to any occupation, and cause just that much more to be saved of what is otherwise going to waste, and with no loss except the time needed for their care. As an evidence of this, you need only to look at the membership of our Association, composed of ministers, lawyers, doctors, tailors, merchants, farmers and all occupations, as well as some who have retired from busy life, engaging in it for a pastime. The masses do not realize the value of honey from a hygienic standpoint, else it would have more than kept pace with sugar as an article of human consumption. Dr. Vance says: "Honey is a physiological sweet;" in other words, its constituents are such that it is absorbed into the blood without undergoing chemical change. "Such is not the fact in regard to sugar. Let me name the points of difference in ordinary sugars and syrups, and their comparative inferiority to honey as a saccharine food. Honey is an inverted sugar, consisting of levulose (fruit-sugar) and dextrose (starch-sugar), and readily absorbed into the system without being acted upon by the gastric juice, converting, as it is expressed in chemical language, inverting, it into dextrose and levulose before it is susceptible of absorption and assimilation into the blood."

Honey is not only a delicious form of sweet, but is a very healthful and nutritious form of food. It aids the natural functions of the alimentary canal. It is recommended by those who have used it as a refreshing drink, diluted with water in the proportion of from 2 to 5 per cent.

Mr. Tefft offers the following: "Sweeten your tea and coffee with extracted honey, and if you are troubled with gravel it will cure you. It is a true brain and nerve food and tonic. It improves the appetite, tones the system, and has proven to be of great value in many diseases, producing a contraction of the muscles, of the digestive organs, and as an aid to digestion it is wonderful in building up lost power. It is a cheap remedy for the consumptive, and, in fact, should take the place of sugar in many things."

In view of all the facts and possibilities herein stated, is it wise economy to let the interests of bee-keepers lag, or stand in the rear of other things not one-half as beneficial to mankind? I would answer No. Our bee-keepers' interests should be represented in the experimental station (for which we have sought, so far without avail), and we ought to have our pure food law enforced in this State, as we are endeavoring to have it. Sangamon Co., Ill., Feb. 18.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal or to Dr. Miller direct.]

A Double Quartet of Questions.

1. If a colony has foul brood, will there be any young bees hatching, and fresh-laid eggs?
2. Is there any difference between the color of the blacks and the Italians?
3. If so, have any of the black bees five bands?
4. About what time does the honey harvest come?
5. Is the Langstroth frame a self-spacer, or not?
6. Which would you prefer, if you were a beginner, the Langstroth or the Hoffman self-spacing frame?
7. About what time does the honey harvest begin, and what time does it cease?
8. Does a colony ever have worms with foul brood?

VIRGINIA.

ANSWERS.—1. Yes, the queen will keep right on laying, and some of the brood may mature, some of it dying.

2. Yes, you'll easily tell the difference when you see the Italians, which have three yellow bands.

3. No, blacks are not said to have any bands, altho they have the same rings or joints in the abdomen, but there isn't any yellow color about them.

4. The honey harvest comes at different times, owing to

the source. White clover comes in May or June, buckwheat in August or September, and other plants at different times, whenever the plants are in full bloom.

5. Properly speaking, every movable frame is a Langstroth frame, altho the name is sometimes restricted to the loose-hanging frame, which is not a self-spacer.

6. If the frames are not to be handled it doesn't make any difference to the bees which they have. For the bee-keeper it doesn't make a very great deal of difference. The Hoffman is a self-spacer, and has the advantage that it will always be properly spaced, while on the other hand it gets so badly glued that one might prefer the loose frame.

7. Referring to No. 4, you will see that it depends on circumstances. White clover, which is the chief crop with me, commences somewhere about the first to the middle of June, sometimes closing very early in July, and sometimes continuing well along in August.

8. A weak colony suffers more from worms than a strong one, and as foul brood weakens a colony it invites attacks of the moth.

Using Empty Combs with Swarms.

What is the best way to use a lot of empty combs? I have a fine lot of them, too nice to melt up for wax. If a new swarm comes from a hive working in a super, and the super is put over the new swarm at once, giving the new swarm the place of the old one, will the work be continued in the super while the lower part is full of empty combs? How much different would it be from having the room below filled with foundation?

It seems that the two could be made much alike if with a sharp honey-knife the cells were cut down nearly to the base, and the bees compelled to work out the combs before they could deposit much honey.

WISCONSIN.

ANSWERS.—Opinions differ somewhat as to the advisability of giving full combs to a swarm, some thinking that a mere starter is better than a full comb, but perhaps more think it an advantage to have the full combs. Some good authorities believe it best to have only foundation for the first half of the combs, adding full combs at the end of ten days or so. As to the matter of the super, the bees are likely to fill the combs in the brood-chamber first, but that may not make any difference in the long run. If at the end there is just as much honey in the brood-chamber in one case as in the other, it matters little whether it is put there first or last, so long as the same amount of surplus may be secured by the end of the season.

Yes, if you cut down the cells you will have the same as foundation. Perhaps you will do better to use the combs without cutting down.

Securing Increase—Other Questions.

One of my friends left three colonies of bees with me to be taken care of, and only asks that I return him three colonies. I have never handled bees, but I am anxious to learn, for I have an idea that if I can learn it and accomplish the work it will be a better business for me than trying to run a 200-acre farm. The work now is too hard for me, and I must try something that will not draw on my vital forces so strongly.

I purchased five Hilton chaff hives, and have them all ready for occupation—foundation and all. Now I want to work for increase as much as I can, and yet have what honey I want for family use.

1. How many colonies can I make out of the three I have, and have them strong?

2. I prefer to have the increase come by the latest approved and successful method, for when I am learning it is just as easy to learn the new way as the old. So what is the best way to obtain my increase? Please describe the process plainly. If I tier up supers for honey I get no natural swarms to speak of, so the book says. Is it a good plan to divide? And if I take a swarm, and take the frame that has the queen on, and another one with it, and put it with the bees into a new hive on the old stand, can I take the remaining six frames and divide it in two parts, and will they rear themselves a queen, or would I have to introduce a queen, or how would I manage?

3. When should dividing be done, if it is the best way?

4. When do you put on supers?

If there is any other information you can give me that will assist me I assure you it will be very thankfully received.

I may not be in as good a location for bee-keeping as I might be, but I can soon go where it is good, when I learn the

management of bees. I am in the Michigan peach belt, and have 1,000 trees on my place, besides 800 apple trees. I am one mile from Lake Michigan. We grow crimson, Alsike and white clovers. My bees have free access to plenty of haws-wood, alfalfa, sand vetch, etc., with acres of buckwheat in the fall.

MICHIGAN.

ANSWERS.—1. If the season should be extra good, you might close with 9 strong colonies, providing you made no bad moves; and if the season should be extra poor, you might not have more than three.

2. Pages of the text-books are written about the matter of increasing, and it would hardly be possible to reproduce it all in this department. Indeed, it is quite possible that you can do no better than to let the bees swarm naturally. You are mistaken in supposing that tiering up supers will prevent swarming. Unless you have very large hives you may tier up supers all you like and you'll have plenty of swarms.

The plan you mention would do, but it is hardly the best, for a weak nucleus will not rear as good a queen as a strong colony. At least during the time a young queen is fed in the larva state she should be in a strong colony. When you put the 3-frame nucleus in a new place, all the old bees will leave it and go back to the old stand, making the nucleus weak in bees, with no honey coming in for a few days, and in such a discouraged condition they will not rear the best queens. Just change your plan a little. Take the two frames with the queen and put them in a new hive on a new stand. Eight or nine days later put the old hive with the six frames on an entirely new stand. Then put the hive with the old queen back on the old place. Put an empty hive on the stand where the queen has been for the past eight days, and put in this empty hive three frames from the hive that has the six frames. Of course, you will fill up with frames of foundation. In this way your young queens will be fed in a strong colony.

3. Operate as soon as the harvest fairly commences. By waiting till this time part of your bees may swarm naturally, saving you the trouble of dividing.

4. The usual rule is to put on supers as soon as the bees put bits of white wax along the upper parts of the combs. If you divide in the way mentioned, put supers on the hives that have the old queens, at the time of making the last change.

Put in a good deal of time in studying faithfully your text-books. To be successful you should be familiar with the whole ground, and sometimes failures may come from the fact that you are not familiar with some principle that you may have thought had no practical bearing.

Be a little slow about giving up the farm till you know you can make a go with bees.

A Supposed Queenless Colony Swarming.

Do queenless colonies cast swarms? The following will be of some interest to the readers of the American Bee Journal no doubt:

On May 22 I had a colony cast a swarm at 1:30 p.m. I was at dinner at the time, and was startled to hear some one call out that the bees were swarming. This being a little unexpected, I had to get everything in readiness to take the cluster, hive them, etc., but to my surprise they never clustered, but went straight back to the hive, not having been out five minutes. Well, they simply covered that hive, and gradually went in. To make a long story short, I examined the hive carefully for a queen and for eggs and larvae. There were a great many sealed brood-cells, and quite a number that had just been vacated by the young, and which the bees had begun to store honey in; some had been almost filled, but there was not a sign of an egg or small grub to be seen.

Now, Doctor, this is the point: If there was a queen in that colony at the time of examination, she would have laid eggs in the cells that the young bees had left, would she not? I must mention here that they had three capt queen-cells but no queen, and no sign of recently having one.

On Wednesday, May 25, this colony cast a swarm again, and returned for the second time. On examination I found that the three queen-cells were still closed—no sign of egg or larva except remaining capt brood. On Saturday, May 28, they swarmed for the third and last time up to date, and returned as before. On examination I find as before, except most of the brood hatch, and a few large grubs here and there ready to be sealed. This colony is a very strong one (Italians), in an 8-frame Langstroth hive, with lots of honey. They came out of the cellar, having wintered well, in a strong and vigorous condition, April 8, and set to cleaning house and to work immediately.

Now the question is this: Will a colony swarm that has

no queen? From my experience with this, I am of the opinion that they will, the bees being so numerous and crowded in a hive that most of them have no chance to ascertain whether they have a queen or not, as she may have been about only a week or ten days, and being in a swarming-fever, light out, expecting their queen to accompany them, and discovering her failure to do so (which would be impossible under the circumstances), return to the hive.

What is the best thing for me to do with them?

TORONTO.

ANSWER.—It is hardly necessary to assume that bees with no queen will swarm, in order to account for the circumstance you relate. There may have been no laying queen in the hive for a number of days, but a young queen with defective wings may have been present. If so, the bees would act just as yours did.

Very likely there is nothing to do in the case, for by this time another queen has probably issued from one of the queen-cells and has commenced laying. If, however, you fail to find eggs in 10 or 12 days after the young queen has emerged, it may be necessary to give them a queen, a queen-cell, or a frame of young brood and eggs from which they can rear a queen.

You hardly give the bees the credit they deserve for finding out the absence of a queen. No matter how many bees are in the hive, when one bee finds out no queen is present, it doesn't take 10 minutes for the news to go through the whole hive, making a general uproar, and you may count on the matter being fully known long before the expiration of 10 days, or even two.

Is Bee Diarrhea or Dysentery a Disease?—Losing Queens.

In reply to P. A. Newcomer's request, on page 355, it is perhaps not entirely clear whether diarrhea, or dysentery, as he calls it, should be called a disease or not. It is an overloaded condition of the intestines, a slight giving relief. The confinement long-continued gives occasion for the accumulation of feces, and cold aggravates the matter, for the colder it is the more food will be eaten, causing more rapid accumulation. The character of the food makes a great difference, but those who say that food alone makes the trouble are clearly in error, unless the food be actual poison, for in cases where the food is bad and the bees suffer from diarrhea there would be no trouble if the weather was warm, or if the bees could have daily flights.

Your trouble in losing queens would probably be greatly lessened, Mr. Newcomer, if you would make just a little change in the placing of your hives. If I understand you correctly, your hives stand in rows with a space of 18 inches between each two hives. Instead of that, move No. 2 to within two inches of No. 1, No. 4 to within two inches of No. 3, and so on, moving each even number, and letting the odd numbers stand just where they are. That will make them in pairs, the two hives in each pair being two inches apart, and there being a space of 34 inches between the pairs. It will take no more room, but will practically make the hives twice as far apart, so far as relates to the queens finding their own hives.

C. C. MILLER.

Question About T Supers.

I have a T super with T tins nailed fast. The super is made of $\frac{3}{8}$ -inch sides and $\frac{1}{8}$ ends. I never saw any of them used, but I think they are good, if one knows how. Will I have to use followers and wedges, or how will I manage it? As you use the T super, you can tell me how I can use mine for different widths of sections.

WISCONSIN.

ANSWER.—It depends upon the width of the sections. Some sections will fit in the super all right without any follower and wedge, altho harder to get out. But if the sections and separators do not exactly fill the super, a follower must be used, that is, a board of proper size to shove up against the sections at one side, whatever space the follower does not occupy being taken up by a wedge, the wedge being not really in wedge form, but simply a plain stick to crowd in between the sections and the side of the super.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B. Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. JUNE 23, 1898. NO. 25.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Hives in Spain are made of cork-bark, and 10 colonies can be loaded on a donkey for migratory bee-keeping.

For Sunburn mix a spoonful of honey in a little lukewarm water and apply this to the sunburnt skin. So says the British Bee Journal.

Big Yields in Australia.—In the Australian Bee-Bulletin mention is made of 1,000 pounds of honey taken from one colony by Mr. Williamson, 1,000 by Mr. Vogel, and an average of 750 by Mr. Peterson, with 1,200 from his best colony. Australia seems to lead the world in honey resources.

The Apiarian Building at the Omaha Exposition is shown on our first page this week. It is of Swiss architecture, 138x75 feet, and while it is not the largest, it is admitted to be the best arranged building on the Trans-Mississippi Exposition grounds.

The interior arrangement is of the best possible to give light from windows and sky-lights, so that at no time can a shade be cast over any exhibit in any part of the building. Five feet from the wall on either side are the honey-cases, four feet deep, and running the entire length of the main floor. These are fitted with glass on both sides, and have glass tops, with ample storage-room for empty packages underneath, which are reached by movable panels in the bases. Three aisles running the length of the room give the visitors easy access to the exhibits of supplies, etc., located there.

On either side of the entrance are located the offices, and likewise at the exit is located the two liquefying rooms which

are furnished with gasoline stoves, boilers, etc., where exhibitors can reliquify their honey as often as they please, or whenever necessary.

The building is plastered both inside and out, and every piece of woodwork inside is painted white. The framework overhead is decorated with white and yellow, and with "Old Glory" hanging in each festoon. This will be the home of the honey-bee and of all bee-keepers during the entire Exposition, and it is desired that all shall make themselves at home while there.

Hon. E. Whitcomb is the superintendent of the Apiary Building, and we believe he expects to be in attendance during the Exposition.

LATER.—Referring to the foregoing, Editor Abbott, in his Busy Bee, has this to say, and also expressing a hope that the next meeting of the United States Bee-Keepers' Union will be held at Omaha:

The editor visited Omaha a few days ago, and it seems almost like a miracle the amount of work these people have done in so short a time towards completing the buildings for the great Exposition. The Apiary Building is rapidly nearing completion, and the exhibit promises to be a fine one. The management of the Trans-Mississippi have done more for the industry of bee-keeping than has ever been done before by any institution of the kind. It is safe to say that no such a building was ever erected for the exclusive display of apiarian products as is now nearing completion at Omaha.

Since I have seen the building and learned what has been done for our industry, I am thoroughly convinced that Omaha is the proper and only place to hold the next annual meeting of the United States Bee-Keepers' Union, and that it would be a serious mistake to think of locating it at any other point. We will secure more new members by locating the meeting here than it will be possible to secure in any other way. Here without a doubt will be one of the largest displays of apiarian products that was ever before put together in one building, and it will be worth a great deal to every bee-keeper who can go and see them, and at the same time join in the deliberations of the Union. On to Omaha!

Foul Brood Through the Mails.—The queen-traffic may be responsible for spreading foul brood, thinks Editor Hutchinson. Not that the queen herself carries the disease, but it is carried by the retinue or the food. He thinks it may not be a useless precaution to burn cage and contents—bees and all—as suggested by Mr. Bunch on page 309 of this journal.

Honey-Production of Tunis.—Among the countries which European bee-keepers have to fear in competition with their honey, Tunis in Africa is likely to take a prominent place. Nectar is abundant in certain regions, and the quality is excellent, being derived from the highly aromatic rosemary and heather. A German bee-paper reports this—Gravenhorst's Bienenzeitung.

Facing Comb Honey.—In last week's number of the Bee Journal, and again this week, we give the testimony of experienced honey commission men on the subject of packing and facing comb honey. We believe that this symposium will result in great good to all concerned if the suggestions and advice shall be followed by the producers of comb honey.

We cannot understand why any one should wish to face their cases of honey unless it be for the purpose of deception, thus hoping that a better price may be secured than if an honest packing were followed. But buyers or consumers don't care to be "caught" the second time, so ever after once being "bitten" they will think it necessary to be on the watch for faced honey when buying.

It is hardly necessary for us to repeat that we are wholly against facing cases of honey. Every honest man should be. There is altogether too much deception in the world, and just

because people have been brought up to expect to be defrauded is no excuse for any one practicing a dishonest thing.

We are pleased to see the unanimity with which the honey-dealers of the various cities have responded to our request, and the general agreement existing among them along the lines of packing and grading comb honey. They know that what is good for the bee-keeper is also good for themselves, hence their advice to so grade and put up comb honey for market that a reputation for honest packing and good quality may be established.

We trust that our readers may profit by the discussion of the questionable practice of "facing comb honey."

DR. A. B. MASON, of Lucas Co., Ohio, writing us June 13, said: "White clover is in full bloom, but bees are getting very little surplus."

MR. M. WOODARD, of Mecosta Co., Mich., wrote us June 14:

"Bees are doing fine at present. Prospects are good. The 'Old Reliable' is 'out of sight.'"

MR. O. L. PERDEW, of Marshall Co., Ill., wrote us June 10:

"I like the American Bee Journal very much, and would not be without it for ten times its cost."

MESSRS. VAN ALLEN & WILLIAMS, of Crawford Co., Wis., writing us June 14, reported their bees doing remarkably well at that time. They are the manufacturers of the Williams' Automatic Honey Extractor, and also dealers in queen-bees. See their advertisement in another column.

MR. WM. P. COLLINS, of Lincoln Co., Nebr., called on us last Friday, June 17. He is a railroad man, but finds time to do quite a good deal with bees. He says they have a great country out there for bees, with simply miles of alfalfa and sweet clover. Mr. Collins has traveled quite extensively in this country, but seems to think "there's no place like home."

DR. C. C. MILLER, of McHenry Co., Ill., wrote us as follows last week:

"More than three weeks ago the first clover blossom appeared, but there's less honey in the hives now than at that time. For days it has been rainy and cloudy, sometimes hot, but always wet and cloudy. Yesterday was the first day for some time that was clear, and the bees improved it by busily driving out the drones. To-day (June 15) it is cold enough for winter clothing. White clover bloom is fairly plenty, but it's a question whether there's honey in it. The market price of granulated sugar begins to interest me."

MR. THOS. WM. COWAN, a few days before sailing from New York for England, June 11, dropt us a few lines, expressing their appreciation and enjoyment of the afternoon drive Mr. Kreutzinger and the writer gave them (Mr. and Mrs. Cowan) May 26, when they were in Chicago. (By the way, that date was wrongly printed "May 2" on page 360.) Mr. Cowan also wrote that they had a pleasant visit with Dr. Mason, at Toledo, and with the Roots, and regretted not being able to prolong their stay so as to take in Mr. Hutchinson as well. We shall always remember with much pleasure meeting Mr. and Mrs. Cowan.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

Honey for Cooking.—Cynthia E. Tayne thinks honey is better than sugar for canning fruit, and especially in black-raspberry pies. For apple-pies and for cake she uses part honey.—Gleanings.

Pollen in Winter is consumed by bees, as shown by the investigations of Dr. Ciesielski, who found pollen-hulls in winter feces; but he agrees with the general view that they may be wintered without pollen.

To Increase Brood-Rearing, it is said many bee-keepers slide under the combs a slice of black bread soaked in honey, the bees not only taking the honey but bread as well, being thereby stimulated to greater energy in brood-rearing.—Centralblatt.

Immunity from Snake-Poison.—Th. Weippl, editor of Bienen-Vater, quotes from an Austrian paper, without vouching for its truth, the statement that a French chemist inoculated dogs with poison extracted from bees, and the dogs were then unharmed by the bite of deadly snakes.

Early Taking Out.—C. W. Post took out the first 66 colonies Feb. 11, leaving the balance in the cellar till March 5 to 12. He thinks if there was any difference it was in favor of those first taken out. They were packed after being taken out of the cellar, and for top packing he likes another colony.—Canadian Bee Journal.

Bearing the Market.—The sleepy writer that hails from Naptown, in Progressive Bee-Keeper, enters a very wide-awake protest against the custom of bringing down prices by making big reports in advance as to the crop. Some large dealers send out letters of inquiry in advance, and bee-keepers report great expectations, thus pulling down prices.

Preparation for Winter.—"Some of our forehanded bee-keepers begin preparations this month for the coming winter by securing extra combs of sealed honey for winter stores."—Editorial in American Bee-Keeper. Nothing particularly original in that, Mr. Hill, but all the same it is one of those things that needs to be thrust in the faces of many a veteran as well as novice.

Objections to Separators.—"Not only are sections less plump in appearance when built with separators," says Adrian Getaz, in Review, "but they are in some cases a hindrance to the bees, as when the temperature is so low in the supers that the bees must cluster in large bunches to produce the wax. He thinks it possible that the fence separator may not be thus objectionable."

Contraction.—Editor Hutchinson is very emphatic that contraction of the brood-nest is never practiced with an established colony, only at time of hiving a swarm. At such time to give full room in the brood-chamber would retard work in the super, hence the custom of giving a swarm only part of its complement of frames at hiving. He objects to Editor Root's calling contraction a fad.

Laying Workers Using Worker-Cells.—M. Devauchelle having said that laying workers deposit eggs only in drone-cells, Dr. C. C. Miller replies, in l'Apiculteur, that such is the fact when drone-cells are present, but in the absence of drone-cells they use worker-cells, to that case laying one egg in a cell regularly, so that the work cannot be distinguished from that of a fertile queen until the brood is sealed.

The Bee-Master Roof—A roof for bee hives is given in The Bee-Master, that the editor warrants rain-proof, although it may be full of cracks of any size up to one-fourth inch. Make a roof sloping from the top both ways at an angle of 45 degrees, letting the boards run up and down, and making sure that the eaves project over the hive. The editor says the rain will run down the cracks, but will not drop into the hive.

Specific Gravity of Honey seems a rather unsettled problem. Delos Wood, of California, in Gleanings, says he has

never sold a can of extracted honey that didn't weigh 12 pounds or more to the gallon. He thinks the ones who sell un-ripened honey are those who wait till it is sealed. When sealed it ripens very slowly, and when honey is coming with a rush the bees will not wait till it is thoroughly ripened before sealing. Editor Root thinks conditions in California may be different from those of the east.

Systematic Pilfering.—The editor of the Canadian Bee Journal complains that the practice of appropriating good ideas without giving proper credit is getting quite too common. As a good deal has been said about publishing names of dishonest honey-dealers, why not publish names of dishonest editors as well? But by all means, Mr. Holtermann, be sure you first follow the instruction given by the Great Teacher, in Matthew XVIII, 18.

The Schenk Theory of Controlling Sex by the nutrition given the mother before conception, which has stirred up some little dust among bee-keepers, has been characterized by scientific men at its true worth, to use Haeckel's words, as "Much ado about nothing." The secret of the whole thing lies in one word—business. In one week 150,000 copies of the book containing Schenk's theory have been sold at 75 cents each.—Bienen-Vater.

Poisoned Honey.—A writer in Australian Bee-Bulletin says: "The public need not fear eating honey on the score that it may contain Paris green as an ingredient, because the Paris green will poison the bees before they can bring it home to have it stored in the cell...In brief, no danger from poisoned honey is possible, because what will poison a human being will effectually poison a bee, and prevent it from storing the honey containing the poison."

Burn Foul-Broody Combs.—Not only should they be burnt, but burnt in such way that no remains can be worked upon by the bees. N. E. France reports, in Review, that he has seen a large pile of refuse from a solar extractor where diseased combs were melted, and bees were working freely on the pile; and he had seen cases of disease that had come from the same. His plan is to build a fire in a hole on level ground, burn all diseased material on the coals, then fill up the hole.

Why is Honey so Low in Price? is a question discussed in the American Bee-Keeper, by G. M. Doolittle and Ed. Jolley, a picture of the latter on page 101 making it seem that said Jolley might with entire propriety leave the "e" out of his name. As nearly as can be made out by everyday bee-keepers, Mr. Doolittle ascribes low prices to trusts and the accumulation of capital in the hands of the few, while he of the jovial name thinks bee-keepers are to blame for lack of co-operation.

Equalizing Colonies.—L. Wolff says he has experienced no loss of queens by making a weak colony exchange places with a strong one, provided he made the exchange at the beginning of a honey-flow and in the middle of the day when most bees were in flight. Another means he has employed to equalize colonies is to put a feed dish under a strong colony, and when well covered with bees take it to a weak colony, repeating as often as necessary. But with movable combs the object is more easily accomplished by giving combs of sealed brood.—Centralblatt.

Suspicious of Too Clean Sections.—W. H. Ritter reports in the Progressive Bee-Keeper that he sells sections better without cleaning. On his market the beautifully cleaned sections are looked upon with suspicion. All artificial! Made at a factory at St. Louis. He says, "When I begin to open up a case of my honey at the hotel or on a groceryman's counter, taking out a row of sections, then a division-board, all stuck up with bee-glue, then you will hear the bystanders talk: 'O, there's the sure-enough honey. No bogus honey about that.'" So he isn't interested in section-cleaners.

Two Stray Straws from Gleanings.—When trying to explain how a queen can see to lay in the right place on the opposite side of the comb, why not decide that she simply takes the warmest spot for her laying? [There may be something in this.—Ed.]

A screwdriver is too thick and blunt to take off supers. I had one ground sharp, the bevel running back more than an inch, and it is tip-top. But I'm ready for a better general tool. [Such a screwdriver would be far better than one with the regulation point, I am very sure.—Ed.]

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles :

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This will be a series of practical articles that bee-keepers of the United States will not want to miss reading. They are copyrighted by Mr. White, and will appear only in the AMERICAN BEE JOURNAL, beginning in July.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

**The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it**

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber :

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan. Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan. Field | 14 Muth's Practical Hints to Bee-keepers |
| 6 Our Poultry Doctor—Fan. Field | 15 20 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse-Book | |

For Sending TWO New 40-cent Subscribers :

Bees Doing Well.

Bees are doing splendidly in this section. There are indications of a great honey crop this year. All we want is for the weather to continue favorable. White clover is very abundant. They say there has not been anything like it for years—it is simply clover everywhere. Sweet clover also is of great promise. I will write later. **H. A. SMALL,** Ontario, Canada, June 9.

Bees Help the Peach Crop.

Our bees have not as much honey as they had a month ago. It is so showery. The flow here from fruit-bloom was very light. I have had only one swarm to date. Our peach-trees are very full of fruit, while those of our neighbors have but few, owing, no doubt, in part, to the close proximity of the bees.

MRS. L. HARRISON.

Peoria Co., Ill., June 11.

Wet Weather—Loss by Old Queens.

I am very much pleased with the Bee Journal; it has been of practical value to me, and that is what counts. My winter and spring loss in bees this year has been the heaviest since I have been keeping bees—six years—nearly 40 per cent. Old queens were mostly the cause. What bees I have left are all strong, and doing as well as the wet spring weather will let them.

F. E. HENRY.

Harrison Co., Iowa, June 11.

Utah's Foul Brood Law.

On page 332, Mr. Volkert, of Virginia, after offering a few comments on the above law, asks if I would tell why Utah's bee-keepers can't guard themselves as well as an Inspector.

In the first place I would ask Mr. V. how the bee-keepers of any State could interfere with the bees of any person, no matter how desperate the case, or how much his own bees might need protection? What could be done without some law for their protection and guidance? If all bee-keepers were educated or informed in regard to this matter there would be no trouble, but unfortunately they are not, and to think that they will be is too much to expect in the near future. We know of too many instances where bee-keepers, or rather bee-owners, having bees in box-hives, that became diseased and spread the same throughout the neighborhood, causing much trouble and loss; hence the necessity, at least as far as Utah's bee-keepers are concerned, of having a law that will protect the bee-industry.

I called on a bee-keeper having a large apiary, who came from a State less than a thousand miles from where Mr. V. lives, and altho he is a bee-keeper of 40 years' experience, I found him actually dividing foul-broody colonies. The result was that I received the thanks of the bee-keeper in question, and others in the neighborhood.

As the Utah law requires that all the inspectors shall be nominated or petitioned for by the bee-keepers themselves, there is not much danger of an

incompetent inspector being appointed. And while the law reads that the inspector shall visit all colonies of bees at least once a year, it is interpreted to mean that he shall visit all apiaries in his county or district, and wherever he may find any foul brood or kindred disease, he must eradicate it for the benefit of the bee-keeper, and for the general good of the industry.

Whether this is satisfactory to Mr. Volkert or not, I fail to see anything so very monstrous in our law, which is intended to encourage and protect the industry in this State, and, as far as my experience is concerned, it is doing so.

Salt Lake Co, Utah. E. S. LOVESY.

Too Wet Weather.

Bees are in good condition for the clovers, which are in bloom now. White clover is plentiful and very rank, but the weather is too cloudy and wet for yielding honey very much. Prospects are favorable if the weather will be good from now on. About one-half of the linden trees are loaded with buds, and will commence to bloom in about two weeks, or before. They are fully two weeks earlier than usual. All kinds of crops look promising for a big harvest. Some fields are getting too rank, and will fall down if this profusely-growing weather keeps on much longer. My bees commenced swarming June 5.

C. THEILMANN.

Wabasha Co., Minn., June 10.

Poor Season Expected.

Bees are doing very poorly here this year. I expect a very poor season, as the conditions seem to be against the bees.

GEO. M. STINEBRING.

Wayne Co., Ohio, June 15.

Miles Has No Smiles.

MR. EDITOR:—Please say to your readers that old Inwa is wet, wetter wettest; and while clover and basswood look extra nice, we are afraid if it doesn't stop raining soon it will be a Water—loo. The ground is white with clover bloom, yet the bees have killed their drones and thrown out drone-brood. Will it pay to feed? Brethren, what say you?

E. S. MILES.

Crawford Co., Iowa, June 11.

Feeding Sealed Honey.

I have kept bees for over 30 years, and for the past 25 years I have taken every tenth hive for a bank of deposit for the rest. My object has been to feed only sealed comb honey. If a colony needs honey it is better to feed it in this way than in liquid form, as in the latter method it stimulates brood-rearing, therefore requiring more feed. It is better to contract the hive of a weak colony by dummies or sealed frames of honey, and thus prevent brood-rearing beyond the ability of the colony to provide for itself.

I have been induced to write the above on account of the practice of most of the bee-keepers here in California, especially in this dry year when there is no honey in sight, and most of the bee-keepers will have to feed their bees to save them.

It is the practice here by most of the extracted honey men, to leave their extracting-combs on the hive throughout the year. When this is done the queen has unlimited room to rear bees, to eat

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$3.00, I will send the Review one year and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo., or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden stratu, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898. **W. Z. HUTCHINSON,**

FLINT, MICH.

To Buffalo, N. Y., and return, account Baptist Young People's Union meeting, July 14-17. Rates lower than via other lines. For full information call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone 3389 Main. (30)

up the feed that is given them, and liquid feed only makes the matter worse. What is the use of rearing bees to eat what you have given them? The smaller a colony of bees can be kept the better, in a dry season like this, providing they can sustain life until a honey season comes. It has not been as dry here for 25 years, old settlers say.

CYRUS C. ALDRICH,
Riverside Co., Calif., June 8.

Unfavorable Season.

I have 18 colonies of Itallans, but the season is very unfavorable.

H. RISHER,
Ouachita Co., La., June 13.

Artificial Queen-Cells by Kersten.

I always believed that Doolittle was the inventor and first maker of artificial queen-cells, but the Nordl. Bztg. declares that a blacksmith by the name of Kersten, in Biegen, Brandenburg, Germany, was the first. He exhibited his cells 26 years ago in Halle. But little notice was given him. **H. ROHR.**

Rock Co., Wis.

Outlook Not Encouraging.

It looks as if we were not going to get any honey harvest. The bees are only making a living now, and I had to feed during May, some little, to keep starvation down. It is too wet and cool. The small red clover did not bloom, and my Alsike is not hurting itself in blooming, and the bees didn't visit it very strong. The only thing we can depend upon now is the second crop of small red clover and the first blooming of sapping or peavine clover. I have 30 acres for my bees to visit, with blue thistle along the Potomac river and the mountain. About 100 to 125 acres of Alsike was sowed by neighbor farmers. I got the leaflets on Alsike, and gave them out to the neighbors last summer at picnics, and my brother, S. J. Hammond, raised about 17 bushels of seed and sold it to our neighbors.

I am not discouraged in the least, as I was so lucky as to hold my wheat crop of 1897—over 1,100 bushels—and got \$1.25 per bushel; and sold my last year's crop of honey in Washington, D. C., for 15 cents a section. It netted me almost fourteen cents.

L. A. HAMMOND,
Washington Co., Md., June 7.

Young Queens Swarming—Carniolans

Page 346, June 2, says: "But when a young queen is reared in a colony, he (Gravenhorst) has never known such young queen to swarm that year." I have just had such instance. May 19 I divided a colony, making three. I put one of the new ones in the old stand, and removed the old queen and colony some distance. The one on the old stand became very strong through desertions from the other two hives, and June 4 swarmed, thus making a third colony from one old colony, each of the three new colonies now having queens just reared.

Perhaps Dr. Miller can tell me why the new queens are dark when the mother is very yellow (leather-colored), and rears yellow bees.

Apropos of Carniolans (page 342), my experience so far is not satisfactory. I have one colony that has not workt a

A Book Recommended by Dr. Gallup.

THE NEW METHOD

In Health and Disease.

By W. E Forest, M. D., 12th Edition. Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from **Weakness to Strength** so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings **cannot be sick.** It is now in many families the only counsellor in matters of health, saying the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, **not a drug treatment.**

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "New Methods" given here; even those who have been pronounced **Consumptive** have been entirely cured. While for **Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentary, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women,** etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

lick in the supers—has not even drawn out several sheets of foundation given them, but has reared drones and queens-galore, and had almost swarmed itself to death till I got in and cut out about 15 queen-cells. The swarms cluster in the hive for a week or more before breaking and going to work.

GEO. H. STIPP.

Santa Clara Co., Calif.

Killed Off Drones—Italianizing.

We have had too much rain for the bees in this locality. Some had a few swarms in May, but most of the colonies have killed their drones, which we think says "honey is scarce." But if we get some fair weather soon, we may get some surplus from white clover. If that should get washed out as much as the fruit-bloom did, the bees will have to hustle to live. But what is our loss may be somebody else's gain, by way of a better price.

I am a beginner in the late style of handling bees, but was reared with bees in the old log and box-hive style, but by the help I could gather from the American Bee Journal and its contributors, I have learned to rear some queens, and have been successful in introducing the most of them. I had an imported Italian queen and am rearing my own from her for my little apiary. I think I can soon raise up my stock to a better grade.

Working in the Supers.

I am having some fun with the bees at present—swarming, etc. They are working in the supers nicely now. We are having lots of rain. A. J. FREEMAN.

Neosho Co., Kan., June 13.

Bisulphide of Carbon—Paralysis.

I have been conducting some experiments in the use of bisulphide of carbon in relation to bee-keeping. Even strong colonies in this climate will harbor the egg of the wax-moth, and this makes an item worth studying—how to preserve the frames of comb and honey other than allowing the bees to care for them.

I have found that I could tier the extra supers eight high with a close-fitting bottom, and a 3-inch rim between the top and the last super, place a saucer with four ounces of the liquid on the top of the frames of the top super, first sprinkling two ounces of naphthaline among the frames, and that pile of 80 frames was safe for two months, when it is necessary to renew the bisulphide of carbon.

A word of caution is necessary in regard to the return of the combs to the bees. I found that altho only a slight trace of the foul-smelling stuff hung to the combs, it was enough to kill many of the bees in a colony. I gave two frames to them without first giving the frames a thorough airing.

A colony having developed paralysis so as to cease to be of value, I shook onto frames of foundation, introduced a new

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, snowy-white Sections, beautiful, straw-colored transparent Foundation, improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leaky Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

The Baptist Young People's Union

Will be pleased with a ride to Buffalo and return over the Nickel Plate Road. Choice of water or rail route between Cleveland and Buffalo, within final limit of ticket. Call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago, for particulars. Telephone 2389 Main. (29)

Basswood Honey FOR SALE

We have a limited number of barrels of **very best Basswood** Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash, **Geo. W. York & Co., 118 Mich. St., Chicago, Ill.**

**PRINTED
Envelopes and Letter-Heads.**

We have put in a new small Job Printing Press on which to print our own stationery, circulars, etc., and while being able to do this we may as well do some work for our readers, if they will favor us with their orders. If you want Envelopes or Letter-Heads, send 2-cent stamp for samples and prices. We will make right prices for neat, good work. All orders can be filled by express, at small charge, as the weight would not be great.

GEORGE W. YORK & CO.,
CHICAGO, ILLS

Southern Home of the Honey-Bee

Will continue to rear none but the **BEST QUEENS**. Untested, 50 cents; Tested, \$1.00.
GEO. W. HUFSTEDLER, Prop.,
President of National Queen-Breeders' Union,
24Atf Beeville, Texas.

COMB FOUNDATION Wholesale and Retail.

Working Wax into Foundation for CASH A Specialty.

Hives, Sections, and a full line of Supplies. The Best of everything. Write for Catalog, with prices, and samples of Foundation and Sections.

BEESWAX always wanted for cash or trade.

GUS DITTMER,
AUGUSTA, WIS.

QUEENS From the best strains of bees in this Country....

I make the rearing of Queens a specialty. Untested, either 3 or 5-banded, 65 cents each. Tested, 95 cents each. **DANIEL WURTH,** Falmouth, Rush Co., Ind. 24A3t

Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases—everything used by beekeepers. Orders filled promptly. Send for catalog. **MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO.,** Nicollet Island, Minneapolis, Minn.

BEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, **E. L. CARRINGTON,** 11Atf De Funiak Springs, Fla.

Please mention Bee Journal when writing.

Van Deusen Thin Foundation...

We have several 25-pound boxes of Van Deusen Thin Flat-Bottom Comb Foundation for sale, at \$12.50 per box. This Foundation is preferred by many. As we have only a few boxes of it, an order for same should be sent promptly. Address **The A. J. Root Co.,** 118 Michigan Street, Chicago, Ill.

queen, and after fumigating the old combs of brood and honey, returned them, and have not seen any signs as yet of the return of the disease. The bisulphide of carbon seems to destroy the germ even in its early stages.

I could not detect that the fumigation of comb honey injured it in any way, unless there was a slight shrinking of the air-cells under the cappings, while one such fumigation is sufficient, destroying even the eggs of the moth as usual.

I wish to call the attention of beekeepers to the use of bisulphide of carbon, thinking that some one of the fraternity will find that foul-broody combs will be cleansed by fumigation with it, since it would appear that it is a cure for paralysis. **W. B. CHAPMAN,** Orange Co., Calif., June 11.

Very Wet Weather.

Our bees have wintered well, but so far we have had it very wet, and they could not get out much, making it necessary to feed them to keep up brood-rearing. I had one swarm June 8, and had to feed them the next day.

SANDFORD HARTMAN,
Lincoln Co., Neb., June 12.

Southern Honey-Plants.

Please give me the names and honey qualities of the enclosed flower. The first grows very thick in the pine meadows and looks at a distance like immense fields of grain, but I have been unable to find bees upon it, tho the long drouth may account for that.

The second is the blossom of a tree that grows in low, swampy places, along branches or ravines, and is quite eagerly sought by the bees. I do not think it is ti-ti, as that bloomed here over a month ago, tho it may belong to the same family. **ERNEST W. HALSTEAD,** Ocean Co., Miss., June 6.

Plant No. 1 has, so far as I can determine, no common name. In scientific language it is known as *Lophiola Americana* and belongs to the *Amaryllis* family—a family nearly allied to the lilies, and is without honey value, so far as I am able to find out, altho possibly furnishing nectar.

No. 2 is the Southern "leatherwood" or "ironwood," (*Cyrilla racemiflora*), a very near relative of the sumacs, and hence doubtless a good honey-plant, as are the sumacs themselves. It also has, on the other hand, a near kinship to the hollies common in the South. I can find no reference to it in any honey authority I have, and hence it is doubtless an untested plant. **H. S. PEPOON.**

Another Improvement in Train Service

On Nickel Plate Road, train No. 6 leaving Van Buren Street Passenger Station, Chicago (on the Loop,) at 2:55 p. m. daily, for Buffalo and local stations, with Buffalo sleeper. Also New York sleeper via Nickel Plate and Lackawanna Roads. Rates always the lowest. The excellent train service to Boston and New York City, with through day coaches and sleeping-cars to New York City and through sleeping-cars to Boston, and the excellent dining-car service, will continue as heretofore. (34-24-2)

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, June 18.—Not any new honey here, and the old stock is about exhausted. Market values about as last quoted for what little is being done. **R. A. BURNETT & Co.**

Kansas City, June 9.—Fancy white comb, 12c. No. 1 white comb 11c.; No. 2 white and amber, 10c; dark, 9c. Extracted, white, 5½@6c; amber, 5@5½c; dark, 4@4½c. Beeswax, 20@25c.

Stock of 1897 comb and extracted honey all sold. We have just received a shipment of white comb from Florida, the first of the season. **C. C. CLEMONS & Co.**

Cincinnati, June 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3½ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. **CHAS. F. MUTH & SON,**

Boston, June 9.—Fancy white in cartons 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. **BLAKE, SCOTT & LEE.**

Cleveland, June 9.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. **A. B. WILLIAMS & Co.**

San Francisco, June 9.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5½@6c.; light amber, 4½ to 5½c. Beeswax, 23@25c.

The market is lightly stocked and in all probability will remain so throughout the season now opening, as very little honey will be produced in this State the current year. Supplies now offering are principally comb. Values for both comb and extracted are being well sustained at the prevailing rates. With no active inquiry for beeswax from any quarter, the market is easy in tone, despite the light stocks here and in the interior.

Detroit, June 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. **M. H. HUNT.**

Minneapolis, June 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging. **S. H. HALL & Co.**

Indianapolis, June 9.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. **WALTER S. POWDER.**

Milwaukee, June 9.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c; amber, 8@8½c; dark, 7@7½c. White extracted in barrels and kegs, 5½@6c; amber, 5@5½c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. **A. V. BISHOP & Co.**

Buffalo, June 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. **BATTERSON & Co.**

St. Louis, June 10.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. **WESTCOTT COM. Co.**

**Talk about
... Comb Foundation**

WE can now furnish the very best that can be made from pure wax. Our New Process of MILLING enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

**It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.**

If you once try it you will have no other. Samples furnished FREE. Large Illustrated Catalog of all kinds of

CONTRIBUTED ARTICLES

Divider and Wedges in Honey-Production.

BY S. T. PETTIT.

On page 321 appears an article from Mr. G. M. Doolittle, which seems to aim a huge stroke at my system of taking comb honey. Some of the article is based upon fact, some upon theory, and some of it upon nothing at all. He says:

"Of one thing all the advocates of this plan seem to be sure, which is, that unless the bees are forced to go from the fields to the sections with their loads of nectar, the same will of necessity be deposited by the bees in the comb-cells of the brood-chamber."

That assertion is based upon nothing at all. Respectfully, Mr. Doolittle, but you are mistaken. I never said so, nor even insinuate so much. I am not arguing the point whether the field-bees go direct to the cells with their loads, or whether they hand it over to young bees. The fact that the field-bees do pass over to the young bees a good deal, if not all, the nectar, is a very important factor in the success of my system. All who have made careful experimentations in that line know that where the field-bees go up the young bees will meet them. Now, if the field-bees go up at the center, the young bees will draw away from the outside and congregate at the center; but if the field bees go up at the sides and rear end of the hive, the young bees will distribute themselves to meet the field-bees where they go up, and thus the bees are placed just where wanted with their loads; and now, with a good divider placed at each side of the super to hold a lot of bees at the sides, the work will progress pretty evenly from side to side of the super.

All right, Mr. Doolittle, just in proportion as you press the point that the field-bees pass over their loads of nectar to young bees, you help my system of taking comb honey. I want something to induce the young bees to go to the outside of the outside sections and remain there, and your contention throws light upon and helps to understand the reason of the success of the system. I see that point more clearly than I did a year ago. I thank you for that article, as it helps to bring out and emphasize a very important point.

And now, Mr. Doolittle, if you will try the large entrance recommended, I believe your condemnation will be turned into praise. Yesterday many hives had large quantities of bees hanging out. I went around and slipped the wedges under, thus giving large entrances, and to-day, the warm as yesterday, there are no bees hanging out. Before I raised them their entrances were $\frac{3}{8} \times 17$ inches.

Since the beginning I believe nearly every step in the advance of the arts and sciences has been opposed by some one, and I feel flattered to have so able an opponent as Mr. Doolittle. I have no anxiety about the future of my system—its success is certain.

Ontario, Canada, June 4.

Profitable Bee-Keeping, with Hints to Beginners—a series of nine articles by Mr. C. W. White, of England, will begin in the Bee Journal next week. See offers on page 410.

After-Swarming—How to Prevent It.

BY G. M. DOOLITTLE.

Probably there is nothing so perplexing to the farmer who keeps a few colonies of bees, or the novice with his decade or score of hives, nor, in fact, to the apiarist with his hundreds of colonies, as after-swarms. They are rarely wanted by any one, but are generally ever present to annoy, unless they are prevented from issuing by the apiarist. With box-hives and log-gums, coupled with the knowledge of 30 or 40 years ago, very few could do little else than let them issue at will. They were often returned, only to issue the next day, and often again on the same day, where they came out during the forenoon. The cry of "Bees swarming!" about as soon as we would get into the hayfield on some hot July morning during the fifties, and "Bees swarming" all through the day, decided my father to let this branch of agriculture alone, and as four-

G. M. Doolittle.

fifths of these bees were after-swarms, and not being wanted, they were the ones which gave the verdict, or caused it to be given.

But since the frame hives came into general use, this after-swarming nuisance can be prevented, but in order to do this we must know the conditions causing their issue, and when they are to be expected. One of our oldest bee-keepers, and one who has had years of experience, was heard not long ago to give expression to these words:

"A queen usually hatches on the eighth day after the first swarm issues, and it is on that day that the second swarm will come off." This I consider a mistake, and I am led to reason that if our oldest bee-keepers do not fully understand under what circumstances after-swarms issue, a few words to the novice, and those not professing to be informed on this subject, might not be amiss.

After years of study on this point and most careful watch-

ing, I find that where the colony casting swarms is in a normal condition, the egg intended for a queen is deposited in the embryo queen-cell from 3 to 3½ days before it hatches into a larva. This larva is in the larval form from 5½ to 6 days, at which time the cell containing it is sealed. After the cell is sealed it is in the chrysalis form 7 days, making a period of about 16 days from the time the egg was deposited in the cell to the time the queen hatches.

When the queen first emerges from the cell she is a white, weak thing, unless kept in her cell after maturity by the workers, as all who have handled queens well know, and is no more fit for leading out a swarm than she is for egg-laying; but during the next 48 hours she gains strength rapidly, so that when she is about 30 to 36 hours old she begins to "pipe" or "peep," as it is termed; and when she is from 48 to 60 hours old she is ready to lead out a swarm, where there are rival queens in other queen-cells.

From the above it will be seen that the second swarm does not issue on the day the young queen hatches, but about two days afterward, if the weather is propitious. This, I believe, is according to M. Quinby in his "Mysteries of Bee-Keeping Explained," which I have always found to be very nearly correct on all topics on which it treats.

Some may object to the term "leads out a swarm," and if it were applied to the first or prime swarm it would not be correct, for with a colony having an old or laying queen the bees seem to be the leaders in the swarming movement, but with all after-swarms the case is different, for with these we find the young queen first, or among the first, to leave the hive.

When a colony is in a normal condition, or when an apiary is not affected with the swarming mania, the first swarm issues with the sealing of the first queen-cell, unless kept back by unfavorable weather or circumstances. By issuing upon the sealing of the first queen-cell I mean this: If the cell is sealed at sometime during the hours of 8 to 12 a.m., the swarm is likely to issue from 12 m. to 3 p.m. of the same day; but if sealed from 2 p.m. to 8 a.m., then the swarm will doubtless issue during the forenoon, so that in the latter case, which is the usual one, the cell will be sealed anywhere from one to 18 hours before the swarm issues.

I have been particular in this matter, so that we could know just when to cut off the queen-cells to prevent these after-swarms. If we cut off all the cells but one on the fifth or sixth day after the issuing of the swarm, as has been recommended many times, we are not sure that the cell left will hatch; and, furthermore, the bees still have larvæ young enough to convert into queens, which they are almost sure to do, and in this case they will often kill the queen which hatches first instead of allowing her to destroy these later-started cells, when we not only have as many after-swarms as we should have had had we not cut the cells, but we have also the disadvantage of having queens reared from old larvæ, which all concede gives inferior queens.

Now, if we wait about this cutting of cells till the eighth day we shall run no risk of the colony swarming; where the first swarm was not kept back by foul weather there will be no larvæ young enough to convert into queens, and, as a rule, the first young queen will be hatched, and thus we can make a sure thing of the matter, if we are sure we cut off all the queen-cells there are in the hive. For these reasons I now wait till the morning of the eighth day after a prime swarm has issued, when I open the hive, take out the first frame and hastily glance over it for nearly-ripe queen-cells, and if none are found I shake the most of the bees off near the entrance of the hive, into which they will immediately run, when the frame is closely inspected for queen-cells, peering into every nook and corner for them; for, should some small, crooked one be met, swarming would surely result.

All cells are cut off after a frame has been shaken to rid it of bees, for this shaking of the young queens in their cells is likely to cause them to be deformed, if not killed outright. The next frame is treated in the same way unless ripe cells are found, in which case it is set outside of the hive awaiting the finding of a cell from which the queen has hatched, when all are cut off. Should none have hatched, then the best one of the ripe cells on the frame set out is saved and put back into the hive.

In this way we can make sure that no after-swarm will issue from this hive, and it is the only certain plan that I know of, and this I say after having tried nearly all of the plans ever given to the public, and quite a few that were given privately to myself.

Oneonta Co., N. Y.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all other bee-keepers possible to subscribe for it. See premium offers on page 410.

A Few California Notes and Comments.

BY W. A. PRYAL.

I notice that many, yes, all the California correspondents in the American Bee Journal mention the dry year in this State, and the failure of the honey crop. This may be all right for the southern and the greater portion of the central portion of the State, but I am having the best honey crop I have had in five years. I will get over 60 pounds per colony. If I had known the year was going to be so propitious here, I should have managed to work the whole apiary for honey.

Do you know, I have not so much faith in the honey-gathering propensities of the Italians as I used to have—have had 20 years' experience now. This is a good year as a test. I find that my darkest bees are as good as any Italians, and they are just as gentle, too. One or two colonies of them have beaten the best "Dago" blood in the yard. I have been running for extracted honey. Still, as I like the looks of the "Dagoes" the best, and as the queens are far the easiest to find, I am going to bring, as nearly as possible, all the dark bees to pure Italian blood. I am requeening all dark colonies this summer.

So Mr. Newman complains of the cold winds in San Francisco. Well, he should come to this side of the bay, where there is a decent climate. I pity the poor soldiers who are encamped on the Pacific side of San Francisco. 'Tis mighty cold and desolate there. Uncle Sam should look after the "boys" better than he seems to be doing. I saw Gen. Merritt in San Francisco to-day on Market street; I had a mind to stop him and command him to remove his troops to a milder climate—to Oakland, for instance; but I was afraid that he would tell me to mind my own business; or, perhaps, he might have said, "Just wait awhile and I will give them plenty of warm climate in Manila." Perhaps that would be a good climate for Gen.-(Manager) Thomas G. Newman, too. The next time I see him I will suggest that he take his Philosphical Journal to "pastures new and fresh"—in Manila.

I notice in the American Bee Journal recently that my friend, J. H. Rambler Martin, intended to run an apiary in the northern portion of the State. Those southern California folks only have to live long enough to find that if they want to get a living off the earth in this State they have to move up north. That is what sheep and cattle, even, are doing this year. 'Tis dry as a bone, so I'm told, down below.

I might remark that the rains that we should have had in April have been falling during the past two weeks, and the prospects are that they will continue to do so at intervals during June. Of course, rain at this time is bad for the fruit crop and hay that has been cut, or that is ready to cut. But it has been invaluable for late-sown grain, vegetables, and pasturage on the lowlands. Hay had run up to \$27 per ton before the late rains; now it is between \$15 and \$20. The usual price at this time is from \$8 to \$12 per ton. If we had not had this recent rain, thousands of head of horses, cattle and sheep would have to be wantonly killed—just for their hides and tallow.

I hope honey goes up in price—I have a lot for sale. What has the war done for honey, so far? No Cuba honey now, I guess.

Alameda Co., Calif., May 31.

FACING COMB HONEY.

Opinions, Suggestions and Advice from the Commission-Men.

[Continued from page 386.]

[We have received the following response to our letter on page 371, since our last week's issue.—EDITOR.]

GEORGE W. YORK & Co.—

Gentlemen:—Replying to your kind favor, we will say that we have read the letter on the "facing comb honey" question, and also remarks by other dealers regarding the matter; we are also much interested in the subject, and wish to bear record that we are *emphatically* and always in favor of comb honey in sections being placed in the cases so that when the face or glass side of the case is presented, the seller and the buyer will *know* that all the sections in the case are fairly and truly represented by the front or face. While in all the relations with each other a good appearance is very desirable and

pleasing, it also augments our pleasure, and prevents misunderstandings and unkindness, and ill-will, to know that we are not subjects of deception by appearances.

We are in favor of conducting business on the principle of right, and in a way that will increase confidence and faith in each with the other; we believe that there should be friendship in trade, and are sure it cannot come through the practice of selling an appearance of good and then deliver in fact that which is not good. We have talked and written many volumes to our honey-shippers to encourage the idea that we desire our shippers to be of that character that it would not be necessary for us to open a case of honey to prove that the back sections in a case were *not* just as good as the first or face sections, and we are pleased to report that we have many shippers for whom we have sold honey, and when the question came up, as it always will from the customer, about how it will run, and if the quality is as good all through the cases as represented by the face of the cases, we at once reply and assure our customer that it will, and then go farther and say if there is one section in the case that they can find which is of a poorer or inferior grade than represented by the face, we will give them two sections for every one of such found.

It seems to us a matter of no small consequence, and involves a very important question in business relations. Ask your correspondent how he would like to send an order for a case of fresh eggs, receive a case, and find a layer on top of choice, sweet, fresh eggs, and all the rest of the eggs in the case old and rotten! What sort of an opinion would he have of the merchant who sent him the eggs? And when he wanted another case of eggs, would he send the order to the same merchant?

The relation of the commission-man to the producer is a vital one, and the shipper should encourage honesty, and place himself with the commission merchant in the relation of a partner, and not as a tool or an inferior being who is expected to *lie* and *cheat*, and get just as much value and make as quick returns and realize just as much money for a shipper who sends in goods falsely packed or carelessly handled, as for one who puts up his goods—honey if you please—truly represented in quality and weight, showing honest care for the good name of himself and the commission merchant whom he employs, or with whom he has formed a co-partnership to handle his shipment; also a kind consideration for the customers whom the merchant invites to buy, and recommends the goods to be as represented.

After a long experience in selling property for others, we find the most difficulty in giving satisfaction to the shippers of inferior quality of goods, and it comes from the vicious principle of trying to work off through the agency of the commission merchant property which the shippers find difficulty in disposing of at home, and expect through this agency to obtain as much as for a good, salable quality.

Much more might be written on this subject, but time and space forbid.

A. V. BISHOP & Co.

Milwaukee.

Contraction of the Brood-Nest—A Reply.

BY W. Z. HUTCHINSON.

In a late issue of *Gleanings* the editor referred to the contraction of the brood-nest as a "fad;" classing it with self-hivers, etc. From the tone of Mr. Root's remarks it is evident that he has misunderstood the time and manner in which contraction of the brood-nest has been practiced. For instance, he says:

"But, oh, how the bees did swarm, and no wonder! The whole trouble was that queen did not have brooding space enough; and the bees were quick to catch on to the fact; and the result was the queen and bees connived together for larger quarters."

Mr. Root, so far as I know, no one has practiced contraction of old established colonies, those that had their brood-nests filled with bees, brood and honey—it was only in hiving swarms that contraction was practiced. It is *possible* that some practiced contraction with established colonies; it seems that you have understood it that way, but you are the first man that I have ever met who so understood it or practiced it. I have corresponded with many of the prominent bee-keepers who practice contraction of the brood-nest, have met many of them, and visited the apiaries of many of them, especially here in Michigan, where, as you say, contraction is practiced most extensively, and I have yet to know of a bee-keeper who contracts his brood-nests except in hiving swarms. If there are those who contract the brood-nest of established colonies, do it in the spring, or just before putting on the sections, or if there are those who have practiced it and abandoned it, I

hope they will speak out, for it will be news to me. According to my views and experience, it would be a most unwise course to pursue.

In the first place, we need to rear all the bees possible before the opening of the main honey harvest. We must have the workers or the harvest will be in vain. To rear them there must be cells in which to cradle them while babies. We need all of the cells that an ordinary queen will keep full of brood; and enough other cells for the storing of the honey and pollen to be used in caring for the brood. When the coming of the harvest finds these combs all filled with brood, honey and pollen, there is nothing to be gained in taking out some of these combs and putting in dummies. If the brood-nest is full when the honey comes, the surplus must go into the supers.

I am at a loss to conceive where, how or why there could have been conjured up the idea of contracting the brood-nest of an established colony in the spring or before the opening of the harvest. There is only one instance in which I could think it advisable. If a colony were weak in numbers, and the harvest already present, and it was thought advisable to secure some comb honey from that colony at all hazards, then a taking out of the occupied, or partly-occupied, combs and putting dummies in their places would force the bees into the sections; but with colonies in which the brood-nest is full of bees, honey and brood, contraction of the brood-nest is wholly unnecessary.

Contraction of the brood-nest in hiving swarms when working for comb honey is an entirely different thing; and when practiced intelligently in the right locality is a most important factor in securing a crop of honey. Here in Michigan, and similar localities, the surplus white honey is gathered in a short period—never extending over six weeks; usually lasting only a month; and sometimes the main harvest is all gathered inside of two weeks. Then comes a period of a month or six weeks in which no honey is gathered; this being followed by buckwheat or fall flowers in some localities. In some localities, like the one in which I am now situated, white clover furnishes the only surplus. Years ago, in localities similar to mine, when contraction of the brood-nest in hiving swarms, and several other "wrinkles," were unknown, how often we heard even the veterans lamenting the issuing of swarms, because, they said, with the swarm went all hopes of surplus. As the business was then conducted there were good grounds for lamentations. The management was about as follows:

The swarm would be put into a 10-frame hive, and no supers put on until the hive was filled. If they were put on they would not be occupied until the lower hive was filled, and by the time this was accomplished it usually happened that the white honey harvest was past. If the old colony did not swarm (usually it did) some return might be expected from that, unless the season was nearly over. If a colony is in condition to begin work in the supers at the opening of the white honey harvest, and continues faithfully at work without swarming, as I have already said, no contraction is needed; but, suppose the harvest is half over, the bees working nicely in the supers, there may be one case of sections nearly ready to come off, another two-thirds finished, and a third in which the work has only nicely commenced; now the colony swarms. What shall be done? By hiving the swarm in a contracted brood-chamber, upon the old stand, transferring the supers to the newly-hived swarm, and practicing the Heddon method of preventing after-swarming, work will be resumed and continued in the supers without interruption, and the surplus will be nearly as great as the no swarming had taken place.

In brief, contraction of the brood-nest, coupled with the plan of putting the swarm on the old stand and practicing the Heddon method of preventing after-swarming, enables us to throw the whole working-force into the super just at the critical time, and secure a crop of white honey that would otherwise have been stored in the brood-nest or used in the rearing of bees that would have come upon the stage of action when about the only thing that they could do would be hang on the shady side of the hive.

We all know that white honey brings a higher price than does the dark honey gathered in the fall; while the latter, unless it may be in some few special instances, is equally as good for winter stores. The contraction of the brood-nest in hiving swarms puts this white honey in the market and the cheaper grades in the hive for winter.

It has been urged against contraction that it results in small colonies at the end of the season. If it is carried to too great an extent, or too long-continued, it certainly does. If a man wishes to turn bees into honey, contraction will enable him to accomplish his object. If colonies are too weak in the fall as the result of severe contraction, they must be united;

but the course pursued by nearly all who practice contraction is to enlarge the brood-nest again in time for the colony to build up for winter.

If the locality is such that there is a continuous flow through the whole season, or if the main flow comes in the fall, as is the case in many localities, it will be readily seen that little or nothing would be gained by contracting the brood-chamber of swarms. There would be time in which to fill the brood-chamber and be all ready for the fall flow when it came.

Mr. Root speaks about the small crops of honey that have been secured, that perhaps 25 or 30 pounds were the average, and that some Michigan bee-keepers thought that they were doing well if they got 10 pounds to the colony, and he rather intimates that these are the results of contraction. He well knows that we have been having some very poor seasons of late, with the exception of the last year or two, and it seems scarcely fair to attribute them to contraction of the brood-nest. I have been practicing it now for at least 15 years. One year I got no surplus, and neither did those who did not practice contraction. By the way, I did not practice it *that* year, as there were no swarms to practice it on. Other years my surplus has varied from 10 pounds a colony to over 100 pounds. Perhaps the average would be about 60 pounds. Both Mr. Heddon and Mr. Taylor have practiced contraction for years; and it does not seem as tho bright men like these would continue a practice that they did not find advantageous.

But let us not forget in this discussion that there is a difference in localities, as I have mentioned. This is really very important. It is so difficult for us, sometimes, to comprehend conditions with which we are not personally familiar. Mr. C. P. Dadant and myself used to have arguments over the size of hives; and I can see now that we were both right, according to our localities and methods.

Since the foregoing was written, Gleanings for June 1 has put in an appearance, and I notice that Mr. E. R. Root, in his advocacy of large brood-nests, says that some one else says, "Oh, yes, every one believes in two or more stories when running for extracted." Then Mr. Root says, "Well, try it for *comb* honey; it will cost you nothing." Suppose, Mr. R., that you try a few colonies with two or more stories for a brood-nest in working for comb honey, and see what it will cost you.

As I have said so many times in reference to these "fads," if you must try them, do it on a small scale first. If you find it is profitable to double or triple the size of your brood-nests do it by all means, but first find out that it *does*.

Just one more word: If many, or any, of the experts who formerly practiced contraction as I have explained it, have "gone back on it," as Mr. Root says he believes they have, let us hear from them, with the reason *why*. It matters little which of us, Mr. Root or myself, is right, if we only get at the truth.—Review.

"California Squalls," for a Change.

BY SKYLARK.

MR. EDITOR:—We have "California Notes," "California Echoes," and why not "California Squalls?"

TO FACE OR NOT TO FACE?

I am now squalling for Mr. Doolittle. Altho they have wallopt him unmercifully; altho they have torn his shirt, pants and vest to tatters; altho his face and hands are begrimed with mud and dirt; altho his foes have wiped up the whole country with him, I will not desert him. Never, never! Come over here, Mr. D., and see how beautifully your excellent doctrine pans out. Here is a sack of potatoes. The commission man has never opened it, and *won't, if he can help it*. Large, smooth, and beautiful, they bulge out of the sack—hardly held in by the strings. Bottom and top and sides are alike—XXX. But throw off 6 inches from the top—do you suppose you will find XX? Not much. The whole center of the sack is filled with the merest scrubs—away down to z—ero—*buckwheat honey!* Is this honest? Of course it is—they are ship by the thousand sacks on *commission!*—and the unsuspecting tenderfoot is beguiled.

No. Let us be honest. I was raised and have been in commercial pursuits nearly all my life. I have not the least hesitation in saying that Mr. D.'s way of packing honey—or anything else—would be looked upon as an intentional fraud. I am sorry—no, glad—very glad, Mr. D., that you have come out of this battle with your masts shot away, your engines disabled, and your hull torn into smithereens. It was only a slip of the tongue—or pen! Come to my arms! Poor boy!

THE NATIONAL PURE FOOD LAW.

The sending of Secor and Abbott to the Pure Food Congress was a master stroke of policy. It is fraught with greater good to bee-keepers than any act performed by *any* association since apiculture became a regular pursuit. It will be recognized, in the coming pure food law, as an industry to be fostered and protected by National law. National protection is very different from that of the State—no matter which one. Evil doers are much more afraid of National law than any other. The Government does not give up the hunt for a criminal just because he is not at home, or that he has gone around the corner to sharpen his crowbar, to break open another mailbag. The United States is not a boy of that kind. Here is a case in point:

On a stage-route from my native city to a little country village the stage was held up and the mail robbed three successive nights. A detective was put on, and found out the robber only got altogether \$15, and that it was a boy 18 years old; but he followed him—followed him from city to city, and from State to State; followed him for three years! Finally he treed him in Florida and brought him home to Pennsylvania. He got 15 years in the penitentiary. Fifteen years for the paltry sum of \$15! This was the most outrageous time-card I ever got. Fifteen dollars!

Now, Mr. Editor, I don't want any of your suspicions, innuendoes, or insinuations. I never was in the penitentiary in my life—but once—and then I went to collect a bill for \$34, which was paid on sight. There, now.

But this is the way the United States executes her laws. No expense is spared to detect the criminal, and his punishment is sure. Therefore, if we can get a National law against the adulteration of honey, it will settle the price of it, as distinguished from glucose. I have no doubt that the extracted honey of the whole country is just doubled by glucose. Now cut off the glucose, and honey *must* and will go up. The most astonishing thing to me is, that bee-keepers should be so blind, heedless and penurious as not to see this and join the United States Bee-Keepers' Union. It has now more members than the other Union, but it has a wider range of usefulness, and a greater mission to accomplish.

The bee-papers should all make a rule to exclude the articles of all writers who are not members of the United States Bee-Keepers' Union. This would more than treble the membership, for what won't a man do to hear himself howl? I know this proposition will bring down an avalanche of inverted applause. But let it come! I have 300 battleships, 600 gunboats, and 900 torpedo boats and destroyers; and I can whip the united world—on this subject.

Squalltown, Tenderfootland.

A Bee-Keeper in Bad Luck—A Laughable Incident.

[A German bee-journal, *Blätter für Bienenzucht*, has the following story which has been translated into the French *Revue*, and is good enough, I think, to have an English setting.—DR. C. C. MILLER, in *Gleanings*.]

At the apicultural exposition at B., Antony Bumke became the happy possessor of an Italian queen. How he admired it with its eyes of gold, and its abdomen of yellow and black rings! In order to take it to his hive he made a box like a Swedish match-box, only, instead of a wooden cover he used a cover of paper pierced full of little holes. With the queen he imprisoned four workers. "She'll not be so lonesome," said this sensible young man.

What fine things he promist himself with the progeny of this queen, and with what joy he felt the little box in his trousers pocket! But he must, before taking the train for home, send a telegram to his betrothed and his future mother-in-law, whom he expects to greet for a few moments as the train passes the second station. Time presses, the train is about to start. The engine whistles, Antony makes rapid strides across the platform, and jumps into the first coach he comes to, the coaches being still of the ancient pattern that contain only a few passengers, these few being locked in by the guard, like so many prisoners. In his headlong haste he stumbles over the extended legs of an old gentleman, and his head strikes forcibly against the sharp knees of a precise-looking spinster, whose fright is expressed by loud cries. With a thousand apologies he succeeded in seating himself, when he overhears the hardly surpised remark, "The fellow is drunk," a remark which only deepens the blushes of the bashful young man.

He seeks, by his tranquility and upright bearing, to efface

this unjust opinion, but, unfortunately, he feels a strong tickling on his right leg. Furtively, Antony feels over the affected part, and in so doing brushes against his next neighbor, a big, Jewish butcher's wife.

"Don't let that happen again," she snaps out.

Antony reddened to the ears anew; but the next instant, with a wild look, he sprang into the air.

"You ought to be ashamed of yourself, to come among decent people in your present condition," said the old gentleman with threatening looks. "Such things ought not to be tolerated. It's an outrage!" he growled from his corner.

At this moment Antony feels anew a violent stinging. Summoning all his courage he bravely plunges his hand into his pocket. Mercy! he is not mistaken; the box was broken, and the cover crushed at the time of his fall when entering the coach, and there is no trace of either queen or workers.

And now that stung in two places! Antony utters a savage cry and leaps anew into the air.

"Mercy on us! He's going crazy," says the butcher's wife.

"Conductor! Conductor! let us out. There's a madman here," cry all the passengers.

Antony Bumke emits piercing yells.

"In the name of heaven! he's going into a furious delirium!" says the splinter.

"Silence! silence!" commands the old gentleman. Then turning to Antony, he says, "What's the matter? Tell us."

"I can't stand it any longer," cries Antony, "they are gone—every one of them! they sting—I am stung already! Leave the coach! It is very important that I should be left alone. Otherwise you may all be stung."

"He is mad! An escaped madman! Conductor!" cry all the passengers, beside themselves.

The conductor appears at the window. "Presently, ladies and gentlemen, the train is just going to stop. What! An escaped lunatic? The matter shall be looked into immediately."

The engine shrieks—station N. Full of affright they all precipitate themselves from the coach; and the station-master, informed by the conductor, slowly approaches; and when the passengers are all out but Antony, he carefully closes the door, posts himself before the open window, and commences his examination. "So this is an escape. You acknowledge it."

"Without doubt—certainly; they've all escaped," declares Antony, very much agitated.

"All?" says the station-master. "How many of them were there?"

"Five," says Antony, groaning; "four workers—their loss wasn't much—but the queen is gone, too."

"What? A queen? What was she like?" said the station-master in a bantering tone.

"Oh! she had eyes of gold, and the back part of her body was covered with rings of yellow and black."

"Beautiful queen!" said the station-master, laughing. "And what were the others like?"

"Why, just like all workers. One bee is just like another."

"Come, now, keep your thoughts together, young man, and don't go to getting bees in your head again," said the station-master severely.

"I haven't them in my head," said Antony, groaning, "but in—"

"And where then?" said the station-master, laughing.

"In my—in my—pants!" This last word Antony whispered in the ear of his interlocutor. "I had a hole in my pocket—they slipped through it."

"What slipped through?" asked the confused station-master.

"Why, the queen and the four workers."

"Ha! ha! ha! a queen and four workmen in his—ha! ha! ha!" laughed the station-master. "Come, be quiet. What are you crying about still?"

"Oh! oh!" cried Antony; "I can't stand it any longer."

The bell rings. Laughing as he goes, the station-master directs his steps to the telegraph operator to give orders to the next station concerning "the lunatic."

The train is in motion. Antony is alone. He can no longer stand those stings. Rapidly taking his determination, he takes off his pantaloons and approaches the window. Three bees gaily soar aloft into the air, but two stick tightly to the pantaloons. However, they must be got off, and Antony shake his pantaloons out of the window. "A pleasant journey to you, miserable queen," said he dolorously, when, at that instant, whiz! went the express train by on the other track. It seemed to the poor fellow, more dead than alive, that his head was torn away, but it was only his pantaloons that the express train had carried away triumphantly, and for good.

Antony Bumke stood petrified. It was night in his soul.

He remained some time without thought and without—the muse itself, horrified, veils its face.

Again a whistle, piercing, to make one shiver to the marrow. To Antony it sounds like a funeral-knell. The train stops boldly before a platform filled with people. They are there, his intended, his future mother-in-law, with many of their acquaintances. Ashamed, he hides himself, for the door has just been opened. The conductor appears; he makes a sign, and the station-master approaches with two officers. They seize him.

"He has dressed himself up now," said the conductor, laughing.

"Silence!" said the officer. "Bring a cloak." The second officer takes off his cloak and puts it on Antony. A struggle ensues, and the miserable youth succeeds in jumping out of the coach. The officer seizes him; he tears away, and the cloak remains in the hands of the officers. A cry escapes from two mouths. Blushing with shame, his intended turns away her head; the future mother-in-law is turned into a pillar of salt. Before their eyes Antony is again seized by his persecutors, and shut in with them in a charitably closed carriage.

By all the things ought to have been explained away at a later date. But Antony Bumke never had any further desire to try new races of bees, nor to attend bee-shows, and equally he never revisited his enamorado, for she wrote him that she had no desire to marry a sans-culotte.

Ah, yes; he was a bee-keeper in bad luck.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

What Caused Their Actions?

1. One of my colonies of bees came rushing out of the hive one morning about eight o'clock, on the alighting-board, and there were enough bees for a swarm, but it did not swarm, and went back into the hive at night. It has been 10 days ago, and they have not shown any more sign of swarming. What is the trouble?

2. Another colony laid out around the hive for 10 days and went back, but the hive is full of bees. I put supers on both hives to-day, as they did not seem to be working to suit me. Did they kill the queen, or what is the trouble?

MISSOURI.

ANSWERS—1. I don't know. If they didn't get any farther than the alighting-board, it hardly looks like swarming.

2. It is possible that they prepared to swarm, and then the weather or the honey-flow was so unfavorable that they gave it up.

Two Queens in a Hive—Cell-Protectors—Transferring.

1. I sent for some queen-cell protectors awhile ago, but I got no instructions for using them. How are they used?

2. Some time after getting the protectors I had a capt cell, but did not know just the age of it, and waited for some days to see about it, and when, sometime later, I went to examine it, it was broken open, and I thought it was done by the bees, but judge of my surprise when some 10 days later I looked again, and there were two queens walking around on one frame, and the young one laying eggs before my eyes. I did not know what to do with them, as none of my colonies were strong enough to take any brood away to start a nucleus, so I concluded to leave both in the hive, where they still are. The young queen must be now about 15 days old, if not more. The old queen has her wings clipped, and the young one has her flying gear all right.

3. I ask some time ago about the best time to transfer bees. Mine were not strong enough in fruit-bloom, and as the weather was very bad at the time I did not attend to it. If I do not want any increase, would it be safe to do it now? Would the young brood remaining in the old hive be safe after drumming out the queen and bees? ILLINOIS, June 2.

ANSWERS.—1. You will hardly need any special instructions for use of cell-protectors, after understanding the

special object they have in view. It is to protect the sides of the cells so that the bees cannot bite into them, at the same time leaving the end of the cell free so that the queen may make her way out whenever she desires. For it is a curious fact that bees do not tear open a queen-cell at the end when they wish to destroy the occupant, but at the side. When a queen is taken away from a colony, or when a nucleus is formed by taking bees and brood from a colony with a laying queen, if a cell is given at once it will invariably be torn down. Put it in a cell-protector, point foremost, so that the tip of the cell will project a trifle through the opening, twist up the four ends of the wire cloth so the bees cannot enter the protector, then put it in the colony or nucleus where you want it to hatch. You can put it between two brood-combs which will press together just enough to hold it, or you may tie a fine wire to the twisted part, tie the end of the wire to a small wire nail $\frac{3}{4}$ to $1\frac{1}{2}$ inches long, and lay the nail across two top-bars, letting the nail support the protector.

2. It is not a very unusual occurrence to find a mother and daughter laying side by side, but usually the mother is about exhausted and will soon be missing.

3. Yes, it is safer to transfer at any time when honey is coming in. The chief reason for taking the time of fruit-bloom is because at that time there is so little honey in the hive. If your bees have swarmed, you will find the best time to transfer is three weeks after swarming, as at that time there will be no brood present except perhaps a little drone-brood that you don't care to save. If you drum out when the queen is present you must leave enough bees to take care of the brood, altho it will take no more bees to do so now than in fruit-bloom.

The Queen-Trap in Swarming.

Will you please let me know to what extent the Alley trap has been used, to your knowledge, and with what success in controlling swarming? What per cent. of queens will enter the trap, and how many of them will crawl back through the cone? I have had no experience with them, but have tried, or studied, about all other methods to prevent and control swarms; and to produce comb honey contraction proved a failure—success lies in the opposite extreme. The bees have been repeating this lesson day after day, in season and out, and at last I comprehend. I think I can control swarming and prevent increase in the out-yard as well as at home.

ILLINOIS.

ANSWER.—I cannot give you a satisfactory answer from much experience, for I've had very little experience in that line. I have an impression that a good many of the Alley queen-traps are in use, perhaps not so largely by those who have large numbers of colonies, and that you may quite safely rely on the queen going up through the cone and staying up. Possibly some of those who have had experience will tell us what per cent. of the queens, if any, fail to go up into the trap, and what per cent. go back through the cone.

Heated-Plate Plan of Fastening Foundation in Sections.

What is the "heated-plate plan" for fastening foundation recommended by G. M. Doolittle, on page 245?

NEW JERSEY.

ANSWER.—The Daisy fastener, of which Mr. Doolittle speaks none too highly, has a metal plate that has a lamp placed under. The section is put in place, the starter is allowed to slide down with its edge resting against the hot plate, and the hot plate is immediately slipped out from under the starter, letting it come in its proper place on the section, where it quickly cools, making a secure attachment.

A Whole Lot of Questions.

I was so late in getting my supplies that it has ruined my honey crop. I put my largest colonies into hives with 13 frames, and they filled them; then I put on another story the same size. My frames are 12x12, and they would not go up. Then I took two frames of brood out of the bottom story and put them into the upper. Some of them reared the brood, and others came down, and one of them sent out a swarm. Another went to work in the upper story.

1. What will stop them?
2. If I put the bottom story on top, will that make the honey too dark to sell?
3. I have eight colonies in 11-frame hives, frames 12x12;

they filled them before I got the sections. I have smoked some of them up, and with all I can do they will not go up.

4. To-day (June 10) I put the super of sections under the brood until they started in them. How, do you think that will work?

5. Last night I put queen-traps in front of some that I am sure would have swarmed if I had not done so, but they are packed close in the trap. Will the trap prevent them from working?

6. If I can save the queens when they swarm with about a quart of bees, and build up with brood after the honey season is over, will that be a cheap way to get a stock for next year?

7. In one colony the bees seem to be so large that they can hardly get through the Root zinc. Have you ever heard of such a thing? Some stay out all night on account of being so hard to get through. What is the best to do?

8. Is it necessary to put a mat on top of the frames or sections in summer, if the bees do not go above it? If so, ought not the mat go on flat, or have a bee-space under it?

9. Ought the bees be disturbed in the honey season, to cut out queen-cells?

10. I cut drone-comb out of only one hive this year, and there are not as many drones this year in 15 hives as there were last year in one. Do they ever swarm without rearing drones?

11. My bees put comb and honey between sections and brood. Do all do that?

12. Can you tell the day before a colony sends out a swarm? If so, how?

13. Ought the bees to have ventilation on top in summer?

14. What will keep bee-stings from swelling? I don't mind the hurt, but I have to stay from church on account of a swelled face.

15. I had a swarm Monday, and hived them, and late in the evening they came out and settled on a limb, then left the limb so slowly that I could not tell where they went. Did they go away, or into some other hive? VIRGINIA.

ANSWERS.—1. You would have pretty certainly stopt them from swarming if you had done a little more mixing of the brood with the empty frames. Take two or three frames of brood from the full story and put in the empty story, and put the empty story under the full story, alternating the full frames with empty ones. If they have not already started queen-cells, they will not be likely to do so, and if they have, cutting out the cells may stop them, after you have them scattered through the two stories. It will help the matter no little if you have an entrance to each story, or in some way ventilation between the two stories, and even ventilation at the top.

2. If you mean to cut the honey out of the frames, it would not do very well. More likely you mean to extract, and in that case it will be all right. Honey in new combs is a little whiter after being extracted, but there isn't a big difference, and generally it would not be noticed.

3. Don't try to smoke bees into sections. Even if you forced them up with smoke they wouldn't stay there. Don't try to drive them; coax them. Put in the super a section that has been already partly filled. If you have none of that kind, cut out a piece of comb from a brood-frame and fasten in the section. A piece of drone-comb will do, and if it has drone-brood in it they'll be more sure to go at once.

4. Better do the other way.

5. Of course it will hinder a little, but with plenty of room inside they may stand it all right.

6. I'm a little afraid you're fixing to get into trouble, with the idea that after you've taken away the old queen with a quart of bees the colony will not try to swarm again. They surely will, and with a young queen. Better not try your plan on more than one colony, for you'll not be likely to like it.

7. Yes, Dr. J. P. Murdock has a strain of bees that are larger than common, and I think it is in Cuba they complain that bees get too large for ordinary perforated zinc. If I had that colony, I think I'd manage to let them get along without perforated zinc, giving them abundance of room.

8. It depends on what your arrangements are. If you have board covers like many others, that leave only a quarter of an inch or so between the section and the cover, there's no need of any mat. If there's an inch or so of space between the sections and the cover, the mat will probably be necessary, but in some cases they might do all right without it.

9. It is well not to disturb bees unnecessarily, but some of our best bee-keepers think it pays well to disturb enough to cut out queen-cells.

10. They may.

11. Probably they do, if there's room enough. There ought to be only $\frac{1}{4}$ -inch between top-bar and sections, and even then they may build some.

12. There's no sure way. If they hang out and are idle

when other bees are busy, it looks suspicious, and if you find sealed queen-cells present that's also a sign, but you can't be sure. Sometimes they have queen-cells and don't swarm; sometimes they swarm and have no queen-cells. Sometimes they hang out without swarming, and sometimes they swarm without hanging out.

13. They seem to like it, but it hinders the finishing of the sections that come nearest the opening.

14. There are cures by the hundred, but likely you'll swell in spite of them. After you've been stung a good many times the stings will not swell much.

15. They probably went back to their own hive, or into some other hive in the apiary.

Trying to Prevent Swarming.

It was very cold and rainy here all the month of May, but my bees have filled their hives on willow and apple-bloom, and are very strong in numbers, so that I have put hives filled with old comb on top to keep them from swarming. I shall leave them on until raspberry blooms, then move the bottom hive to a new stand, keeping the queen in the bottom hive, giving frames of eggs to the upper hive on the old stand, and put on the super for comb honey. Do you think that will do, or would I better put the queen into the upper hive and let the bottom colony rear a queen? They will have all the brood and eggs. I do not use a honey-board, but I never have had the queen go into the upper hive. MASSACHUSETTS.

ANSWER.—Better leave the queen on the old stand with the story that has no brood, shaking off part of the bees from the brood before setting it on a new stand. But don't shake off more than half the frames, for all the field-bees will go back to the old stand anyhow.

Separators Necessary.—R. C. Aikin says weak colonies that build slowly must have separators or they will make combs bulged and uneven, as will strong colonies in a very weak flow.—Progressive Bee-Keeper.

Smoker Fuel.—Mix a little rotten wood with planer shavings, and your fire will hold better. Take a dead limb of a tree, bone-dry, break it into proper lengths, and four or five of these mixt with the shavings will make a smoke to bombard Dewey fashion.—Gleanings.

Viciousness in Bees may be a result of rough handling, and it may be because they are seldom visited. We got some bees from an apiary whose proprietor was practically never seen by the bees. At first they could only be approached well veiled, but after a few weeks they were as gentle as the others.—Le Progres Apicole.

Sitting at Work, while in the apiary, is strongly defended by Mrs. Harrison, in Gleanings. Sitting, she takes things more leisurely, doesn't get nervous and stir up the bees, and so does not get into trouble with the neighbors. Some prefer standing, some sitting, but those who change their minds seem to go all one way—to the sitters.

A Load of Honey.—Loading a bee with honey adds to its weight a trifle more than one-half, according to some experiments made by Prof. C. P. Gillette, of the Colorado college. A pound of empty workers contains, on the average, about 5,500 bees.—Bee-Keepers' Review.—But is it not true that loads vary as the pasture varies?

Fastening Foundation in Sections.—Our American friends appear to think bee-keepers in England can know nothing of their foundation fastening machines, because we go in so much for split and grooved sections. Fact is, we can assure our cousins across the water that, with us, such machines have "been and gone." It is nearly 20 years since our starters were secured by machines of our own make, both by heat and by simple pressure, without heat, on both wood

and glass. We afterwards found the split top-bar answers our purpose more satisfactorily; and later, the section split on three sides; while finally we divided the section entirely in two, placing a long sheet of foundation right across the three sections at one operation.—Bee-Chat, of England.

United States Bee-Keepers' Union.—The American Bee-Keeper quotes the reply of R. L. Taylor to the effect that its membership will be increased by making it the greatest possible good to its membership, and propounds the supplemental question: "How can the Union be made of any possible good to its members without an increase membership?"

Unqueening.—In Progressive Bee-Keeper, R. C. Aikin thinks unqueening is more labor than to allow swarming, but it allows the work to be more methodical, and better kept under control. He can unqueen 25 colonies in a day, or cut out cells from an equal number nine days after unqueening, besides doing the necessary work with supers, making a total of eight days' work for an apiary of 100 colonies, and he thinks he would have to spend as much time with swarms, besides being badly interrupted about super work.

Prof. Cook on Sweet Clover.—Prof. Cook says: "I gave, as the result of my own experience, the opinion that sweet clover, while a very excellent honey-plant, was of little worth for hay or pasturage.... That it has great value for green manuring.... there can be no question. There is no quicker method to restore lost fertility than to plow under a rich, vigorous clover crop, and surely melilot is just that.... I am very glad that so many report *Melilotus alba*, or the white sweet clover, as furnishing appetizing feed for cattle and horses."—Gleanings.

Facing Apples and Honey.—The replies in this paper from commission-men lead to the conclusion that they are a unit against facing. But according to an article in Gleanings, from W. S. Fultz, there are exceptions, the commission-men of Saint Paul practically obliging shippers to veneer. Mr. Fultz says:

"Last summer apples were so plentiful here that they went begging at 15 cents a bushel, and as I had over 400 bushels, I knew that I should have to find a market somewhere else, or my apples would go to loss. I sent a trial shipment by steamboat to St. Paul, and realized 47 cents per bushel net. During the summer I sent 120 barrels to St. Paul, and they averaged me \$1.20 per barrel net. All of these apples were faced with the nicest, and the only trouble was that I could not supply the demand that I had for apples. When I was sending my Dutchess apples, one of my neighbors asked me to allow him to put five barrels of the same kind of apples with mine. This I would not do, but I allowed him to ship his when I shipped mine, making two consignments. When the returns came I had \$1.20 net per barrel, and was asked to send more. My neighbor had 40 cents net per barrel, and was told that his apples did not sell well because they were not faced. His apples were just as nice as mine. I got well paid for all my labor and trouble, and he nearly gave his apples away, just because they were not faced.

Large vs. Small Entrances.—Instigated by Editor Root, Messrs. Doelittle and Miller have locked horns with regard to the amount of entrance-room given under hives, and especially its relation to swarming. Dr. Miller says, in Gleanings, that years ago, following the lead of Adam Grimm, he shoved forward his super of wide frames, allowing an opening of $\frac{1}{4}$ to $\frac{1}{2}$ inch at the rear end between the two stories. When he ceased the practice there was a notable increase in swarming.

Mr. Doelittle says that in the days of box-hives there was plenty of swarming when all hives were raised. To which Dr. Miller replies that there were abundant reasons for swarming in spite of large entrances, and he thinks box-hives thus raised were not so entirely given up to swarming as at the present day. Surplus room was not given then as now.

To the argument that when bees hang out in hot weather and then all go in when the hive is raised on four blocks, Mr. Doelittle says the only difference is that in the latter case the bees have plenty of room to loaf under the frames, and he'd just as soon they'd loaf outside. But Dr. Miller insists that it cannot be so warm with all four sides open as with only one. But he admits it isn't pleasant to have the hives open at the sides so the bees may sting one's ankles, and hives raised on blocks are a little unstable.

The editor occupies middle ground, wanting an opening front and rear, with some appearance of favoring the big entrance on all four sides.

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Engene Secor, Forest City, Iowa.

VOL. 38.

JUNE 30, 1898.

NO. 26.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Awful Rush for bee-supplies is about over for this year. It is strange that so many will wait until they really *need* the goods, and then send in their orders and expect them to be filled "by return mail." Then if the goods don't come as expected, some at once begin to berate the dealer, when perhaps he had several hundred orders in ahead, and may also be entirely out of goods on account of the factories not being able to supply them as fast as he and other dealers had ordered.

The way to do is to order enough goods early—say in March or April—so that should they even then be delayed there would be no doubt about their arrivlug in plenty time for use when needed. We gave this advice in these columns very early in the season, but it seems quite a number failed to heed it, and consequently suffered severe disappointment.

We have had experience enough in the bee-supply business to have genuine sympathy for the overcrowded and over-workt dealers when the grand rush for goods arrives. It is a terrible strain, and we wonder that many of them are not found in the insane asylums after an experience of a year or two.

National Pure Food Law.—The Ohio Farmer, in a recent issue, referred thus to the Pure Food Bill which was introduced in Congress some time ago:

We have lookt over the Pure Food Bill introduced in Congress—a modification of the original measure prepared by the recent pure food convention in Washington. It is lengthy, and relates largely to drugs. In so far as it will aid State pure food authorities to enforce their laws we commend it. Of course, it can only apply to interstate traffic. Adulterated goods sold in the State where made do not come under its jurisdiction.

It organizes a section in the chemical division of the Department of Agriculture for analysis and investigation of samples of goods offered for sale anywhere in the United States. If any article under its jurisdiction is found to be adulterated, the Secretary of Agriculture informs the United States district attorney where the sale was made, and he must prosecute. As we understand it, such sales must be referred to the Department of Agriculture, or, in other words, are taken out from the State authorities' hands. If so, the Bill should be revised in this particular, as State laws should in no case be interfered with.

Section 2 of the proposed law provides a fine of \$200 for introducing any adulterated goods into any State from outside, and \$300 for each subsequent offense, or imprisonment not to exceed one year, or both.

Section 9 requires all manufacturers and dealers to furnish samples to any one authorized by the Secretary of Agriculture, with a fine of \$10 to \$100, or imprisonment, or both, for refusal.

Another section provides for the confiscation and sale of adulterated goods carried from one State to another, the proceeds to be turned into the United States treasury. Other sections define what adulterations consist in, the fixing of standards, and providing for enforcement of the law.

On the whole we think the Bill is a good one, and we trust that Congress will find time, amidst the war excitement, to pass it. It is as good as we can expect, with our present constitutional limits to the jurisdiction of the national government. We shall never be able to control the production and sale of adulterated goods until Congress has complete jurisdiction, or laws of all the States are uniform and uniformly enforced.

It will be remembered that Messrs. Secor and Abbott, of the United States Bee-Keepers' Union had a hand (or two) in the work done by the pure food congress last March in connection with the Bill referred to. We hope it will soon be past by Congress. We are glad to notice that the large and influential agricultural papers of the country are lending their influence in the right direction. We trust that more of them will fall into line in defense of a measure so closely in the interest of public health by way of honest preparation of food products.

Drawn Foundation with Natural Bases.

—It turned out last year, that in some cases the bees would not perform satisfactorily with drawn foundation having a flat base. The A. I. Root Co. now announce that they have completed machinery to turn out drawn foundation with natural base. They will make the cell-walls only about $\frac{1}{4}$ inch deep, about twice the natural thickness, and the base as thin as the bees make the natural base. This will make it run about the same number of feet to the pound as the ordinary thin super foundation. As yet it is only made in pieces $3\frac{3}{8} \times 4$ inches. A half-pound costs a dollar, postpaid. Here is what Editor Root has to say about this new natural-base deep-cell foundation, in Gleanings for June 15:

Several have written of late, asking why we had nothing to say about drawn foundation. I will explain: It will be remembered that the dies that were made last season at so great an expense (nearly \$1,000) turned out a product with *flat* bases. Our early experiments seemed to show that, when cells were deep, the bees would accept such a base as readily as the other. But the developments of the season went to show that the bees did not in all cases take kindly to it. In some instances, at least, they thickened the midrib in their effort to make concave cell-bottoms. While they did not do so in all cases, the fact that the bees did so at all in a few instances was sufficient reason to induce us to abandon the dies, as much as they cost, and go to work on a set that would produce *natural* bases.

Mr. Weed thought the problem would be easily solved; but altho he has been working on it for nearly a year, meeting with repeated failure, he has only just succeeded in having a set made that makes drawn foundation with natural bases a success in every way—at least so far as the mechanical construction of it is concerned. In the mean time, while he was experimenting, we feared that he might not be able to perfect his dies, and it seemed wise to say nothing about the new product until we were *sure* of what we could do.

I am now glad to report that the new dies are in opera-

tion, and making a superb drawn foundation with *natural bases*. This product differs from the old in two quite important respects. First, it has the natural bases already referred to, and, second, the cells are only $\frac{1}{2}$ inch deep. I suppose we could make them deeper; but a few of our friends, fearing that deep walls will either give rise to the comb-honey canard, or else make thick cell-walls in comb honey, we refrain. With the cell-walls only $\frac{1}{2}$ inch deep, it will run almost as many feet to the pound as the ordinary super foundation. It is nothing more nor less than a beautiful transparent foundation having bases as thin as the bees make them, with cell-walls about twice as thick as we find them in nature. Indeed, it looks very much like common foundation, except that the walls are nicely started for the bees, and the bases are much thinner.

Mr. Weed is very confident that they will not remodel the bases, nor will they stick in an accumulation of wax as they did do with the old flat-base drawn foundation. From the tests he has made in the hive, it appears the bees have a decided preference for it. Samples of ordinary foundation and the natural-base drawn foundation were placed side by side. The bees immediately accepted the one (deep-cell) and ignored the other; that is to say, I have myself seen the drawn-foundation piece thickly covered over with bees while the ordinary article had not a bee on it.

I make no predictions as to what the new product will accomplish; but I feel reasonably confident that it will give rise to no thick midrib in honey-comb as did the old-fashioned flat-bottom drawn foundation; and as the cell-walls are only $\frac{1}{2}$ inch deep, there should be no occasion for fearing that it will give rise to canards about manufactured comb honey.

A moment ago I said the cell-walls of the new drawn foundation were twice as thick as we find them in nature. It would be possible to make them just as thin as the bees construct them; but Mr. Weed is satisfied that the bees will thin the walls when they will do little or nothing with the bases. The extensive experiments we have made in the past satisfy us that this is correct.

Universal testimony (with, perhaps, one or two exceptions) went to show that drawn foundation, imperfect as it was last season, was readily accepted by the bees; but owing to the fact that the base was flat, they did not seem to like it after they had further acquaintance with it; and in some cases, at least, comb honey was not completed from it any sooner, if as soon, as from common foundation. But now that we have given the bees the same article with a *natural base*, we expect different results. But if, however, the bees make from it a "gobby" article of comb honey, no one will be quicker to drop it than the Root Co. The fact that we abandoned the flat-base foundation last season because of this defect is pretty good evidence that we will do as we agree. But neither Mr. Weed nor ourselves would have put a lot more money into the new-dies if we had not felt reasonably sure that the article we are now offering to the public would be free from the objections found against that which we put out last season.

We have received a sample of this new drawn foundation to experiment with, and it is beautiful indeed. We shall give it a trial, and hope to furnish a favorable report later on.

Selling Extracted Honey.—In a recent issue of the *Northwestern Agriculturist*, Mr. Ernest E. Conner, of St. Croix Co., Wis., gives his experience as follows in working up a market for extracted honey:

When I first began to extract honey I had to literally give it away. People told me it was half sugar, or that "strained honey" wasn't fit to eat. I then had to explain the difference between extracted and strained honey, and by following it up, by always putting the pure article before my customers, I have, to-day, a demand that always exceeds the supply, for my extracted as well as my comb honey.

Every bee-keeper should make it a point to build up a permanent trade, whether it be private or wholesale.

Put your honey up in an attractive manner so that it will be pleasing to the eye, and it is then half sold. Have some labels printed, and on each package, whether large or small, have your name and address and the kind of honey the package contains. Distribute small samples, so markt, among people who like honey, and are willing to pay for a first-class article.

You may think this is throwing honey away, but you will make it up in the end by increast demand; at least I have found it so.

If your honey is very fine, put your name on it and sell it.

If it is dark and will grade second or third, put your name on it and sell it for just what it is, and make the price to match.

There are plenty of people who will buy a cheap article if they know it is pure and clean.

As the time will very soon be at hand when bee-keepers will have honey to sell, we will be glad to have any of our readers who have been successful in retail marketing tell how they did it. It may help some one as you have been helped by reading the methods of others. We all should be as willing to give out information as to receive it.

"Profitable Bee-Keeping, with Hints to Beginners"—the nine articles by Mr. C. N. White, of England, will begin next week in the *Bee Journal*, as we have received the first two of the nine. See page 410 of this number for further information concerning these articles, and also the premium offers for getting new subscribers for the last six months of 1898.

We would like to have all our readers, if possible, get and send in the subscriptions of their neighbor bee-keepers. The way to get rid of slipshod, old-fogy bee-keepers is to place under them the jack-screw of good bee-literature and raise them up to the level of those who are striving to keep bees in the modern and proper way. By so doing all will be helped.

Many of our subscribers have already sent in new subscribers on the offers made on page 410, but there is room for many more. Before Aug. 1 we hope to add 1,000 new subscribers to our list. It can be done if every one will do only half as well as some others have already done.

Send for free sample copies to work with, or send us the names of non-subscribers, and we will mail the sample copies to them.

MR. CHESLEY PRESSWOOD, of Bradley Co., Tenn., wrote us June 18: "My bees are doing splendidly so far this year."

MRS. EFFIE BROWN, of Eau Claire Co., Wis., writing us June 12, said:

"Bees here are unusually forward this year. I can take off some comb and begin extracting June 15."

MR. H. H. PAGE, of the Page & Lyon Mfg. Co., died May 23, aged 80 years. So reports *Gleanings* and also the *Progressive Bee-Keeper*. We have not learned any of the particulars, but understand that the firm will go right on in their large lumber business and as manufacturers of bee-keepers' supplies. Their advertisement appears regularly in these columns.

MR. G. STOUT, of Hennepin Co., Minn., sent us a picture showing a disk section-cleaner on the Golden plan, attached to a grindstone axis. He says he has cleaned about 500 sections with the disk, and it is good for half as many more without renewing the sandpaper. Mr. Stout runs his grindstone with a treadle, so he can sit down and clean sections or grind the butcher-knife. Of course he's a very "Stout" man.

MR. EDGAR B. WHIPPLE, of Hillsboro Co., N. H., wrote us as follows, June 20:

"FRIEND YORK:—No. 23 of the 'Old Reliable' failed to reach me—the first copy I ever mist in all the years I have been a subscriber. Please send me No. 23, and oblige.

"I have borne a great deal from the 'Old Reliable,' and never kickt. Gave up the old editor (Newman), and learned to love the new. Gave up with regret the neat, little booklike pages, and learned to look for the long wrapper and broad leaves. Endured the horrid spelling, and learned to like it.

Noticed the leaving off of the post-office address of all correspondents, and blamed not the editor, but our miserable competitive system, that almost compels us to do all sorts of mean things we would never do under an up-to-date system.

"No, I have not kicked, and I don't now; but when you print as good an article as Mr. Cowan's, and I get it with the middle dropt out, I can't stand it.

"Please send me No. 23, current volume."

We are always glad to replace lost copies if notified in time, before the edition is all gone.

DR. MILLER, after being favored with a visit by Mr. and Mrs. Cowan, of England, sent this "straw" to Gleanings:

"I can sing 'God Save the Queen' more heartily than ever, after a visit from Mr. and Mrs. T. W. Cowan. They are delightful people, and, above all, they're good."

Right you are, Doctor. We wish that they could attend the next meeting of the United States Bee-Keepers' Union, where many of our bee-keepers could get acquainted with them. It would be well worth going a long way in order to meet them—among "the Queen's best."

MR. R. C. AIKIN, President of the Colorado State Bee-Keepers' Association, writing us June 20, said:

"My honey-flow is just starting, with everything apparently favorable. I will probably be exceedingly busy for the next few weeks."

Mr. Aikin appeared before the Western Classification Committee at its meeting in Maultou Springs, Colo., June 14, in the interest of the less than carload rates on bees by freight. As yet nothing is known about the result of their deliberations. But we hope to learn soon that the petition of the bee-keepers was granted.

EDITOR E. R. ROOT, in Gleanings for June 15, copies entire our editorial on "Shipping Comb Honey by Express," found on page 328 of the Bee Journal. He then followed it with this paragraph:

"It is almost unnecessary for us to state that our experience in handling comb honey leads us to endorse every word. Indeed, I should like to underscore every line of it in red ink if I could."

It is not often that an editorial in these columns receives such a "red-hot" endorsement as that, and from such an able source.

In a letter to us dated June 18, Mr. Root had this to say about the honey prospects in his locality in Medina Co., Ohio:

"There is no clover honey here of any consequence. Bees are being fed, altho the prospects from basswood is very good; but we may be disappointed in this also."

A WESTERN BEE-SUPPLY FIRM, that had been written to in a joking manner, tho at the same time being urged to rush on a carload of goods at once—if not sooner—replied in the following manner—we omit, of course, all names:

"DEAR SIR:—Referring to your communication we beg leave to advise that we promise we would ship the car on or before June 30. This is the very earliest that we could promise it.

"We certainly do not wish to see you go to the insane asylum for a good many years to come, altho we do not doubt but what you and all of the rest of us will ultimately land there, for of all the impatient, unreasonable people on the face of the earth, the bee-keepers are the worst—when swarming-time comes around.

"We will do our very best to get the car there as many days before the 30th as we possibly can, as we wish Mrs. — to have her husband with her as long as possible.

"You say you have a mail full of kicks. That is nothing. Get hardened to it the same as we are. Before you have many more gray hairs on your head you will find that the bee-supply business is not all that it is crackt up to be."

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles:

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This will be a series of practical articles that bee-keepers of the United States will not want to miss reading. They are copyrighted by Mr. White, and will appear only in the AMERICAN BEE JOURNAL, beginning in July.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

**The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it**

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give YOU, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silt and Slage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan Field | 14 Muth's Practical Hints to Bee-Keepers |
| 6 Our Poultry Doctor—Fan Field | 15 20 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse Book | |

For Sending TWO New 40-cent Subscribers:

In the multitude of counsellors there is safety.—Prov. 11-14.

The Progress of a Colony.

Query 74.—Suppose a colony has, on March 21, two frames of brood with bees enough to cover them

1. Given the best care as to protection, and to every way, and setting them over a strong colony so as to get the heat from that, how many frames of brood will there be bees enough to cover three weeks later?

2. How long after March 21 will it take to reach the queen's capacity, supposing that is 10 frames?—Illinois.

Mrs. L. Harrison—I don't know.

Emerson T. Abbott—I do not know.

J. A. Stone—1 and 2. I don't know.

J. M. Hambaugh—This is too knotty for me.

E. France—It would depend very much upon the weather.

Chas. Dadant & Son—Too much guesswork about that to reply knowingly.

Rev. M. Mahin—I could only guess, and my guess might be wide of the mark.

Eugebe Secor—1. There ought to be bees enough to cover five frames. 2. Eight weeks.

Dr. C. C. Miller—1. I don't know. Perhaps two and a half. 2. May be two or three months.

Prof. A. J. Cook—So much depends upon queen, season, and other conditions that a positive answer is not possible.

R. C. Aikin—1. Two combs (full) of brood should hatch enough bees to cover all of five. 2. Five weeks. These answers approximate.

C. H. Dibbern—1. That depends upon many things, and cannot be answered with any certainty. 2. That would be about as uncertain as the first question.

S. T. Pettit—There are too many conditions to be considered in this problem to answer with anything more than a guess. Not knowing the age of the brood March 21 adds to the difficulty.

R. L. Taylor—1. On account of the dying off of the bees no more brood can be covered April 21 than March 21. 2. If everything is favorable, and the queen is excellent, three months and a half might answer.

Dr. J. P. H. Brown—1. About four frames. 2. "How long" will depend altogether upon the conditions of the weather. If these are favorable, I would say the "capacity" would be about the middle of May.

Dr. A. B. Mason—1. That will depend upon the locality. In this locality (Lucas Co., Ohio) a colony that hasn't bees enough to cover more than two combs of brood is a poor colony, and would breed very slowly.

J. A. Green—1. There could not be more bees than would hatch from the first two frames, added to the original number. As a large proportion of the latter would die, you could not count on

Sweet Clover

And Several Other Clover Seeds.

more bees than would cover three to five frames, depending upon the weather. 2. No definite answer can be given to this. It would depend very much upon circumstances. Somewhere between May 15 and June 30.

E. S. Lovesy—1 and 2. This would depend upon conditions, such as location, weather, honey-flow, etc. Here in Utah we do not experiment with the bees in March, only to see that they have sufficient stores.

W. G. Larrabee—I have never experimented on this, but should say a colony with two good frames of brood March 21 would make a good colony by June 10, or the beginning of the honey-flow in this locality (Vermont).

Mrs. J. M. Null—I have no experience in placing over a strong colony to secure heat, and by using a division-board without this extra precaution, the queen's capacity may be reached by the last of May or first of June.

O. O. Poppleton—1 and 2. No definite answer can be given to these questions. Seasons vary too much as regards weather and honey-flow. Some years such a colony would build up in half the time it would other seasons.

G. M. Doolittle—It depends upon the season and size of frame. As a rule, such "fussing" does not pay the practical apiarist. Some seasons bees build up rapidly. Often it is June 15 in this locality before there are 10 frames having brood in them in any hive.

D. W. Heise—1. In the absence of more data as to the amount of comb space occupied with larvæ and eggs in addition to the brood mentioned, my guess would be about double the number. 2. All depends on circumstances.

J. E. Pond—1 and 2. The above questions are of such a nature that no intelligent answer can be given. It is something like asking, "How big is a piece of chalk?" No data is given as to locality and general climatic conditions, consequently "I pass."

G. W. Demaree—O, my friend, there are too many "ifs" about your questions. How about the weather? How about the honey and pollen resources? Such a nucleus as you describe, in my climate (Kentucky), usually would get ready for the white clover harvest in about eight weeks from March 21.

P. H. Elwood—This is too deep a question for me. It will depend upon the weather, the amount of stores in the hive, etc. Here (New York) there was not a large increase of brood during the three weeks following March 21. That amount of maturing brood May 21 would usually be followed in three weeks by a hive full.

The Nickel Plate Road

Telephone Main 3389. (28)

GENERAL ITEMS

Clover Contains No Nectar.

We had a heavy rain last night and it still continues. Bees have barely made a living so far. I noticed a large colony yesterday that was starving, and I fed them immediately.

The heads of white clover are large and quite plentiful, but contain no nectar. I seldom see a bee at work upon it. Yellow sweet clover is blooming nicely, but does not attract the bees, and the white variety is just beginning to open. Basswood is full of buds, and will soon be in bloom. MRS. L. HARRISON. Peoria Co., Ill., June 23.

Catclaw their Hope.

We have had fine rains lately, and are hoping for a crop of honey from the second flowering of the catclaw in July. Our spring crop from "guajilla" was nearly a failure, owing to atmospheric conditions, so we will be doubly pleased to reap a harvest next month.

CLAUDE STERT.
Uvalde Co., Texas, June 15.

Outlook Not Encouraging.

White clover is a failure here this year. I have just moved the home apiary out in the country, where they are now revelling in Alsike "up to their eyes." The "tent-caterpillars" or "army worms" have also stripped every leaf from the basswood in this vicinity, so that the outlook is not very encouraging.

JOHN ATKINSON.
Crow Wing Co., Minn., June 21.

Too Rainy and Cold.

'Tis rather a hard season for bees; too much rain and cold weather. The fields are white with white clover blossoms, but the bees can do nothing on them. The season will close in 10 days, as the farmers have commenced to cut the grass.

HENRY ALLEY.
Essex Co., Mass., June 21.

Starving—What Ailed the Bees?

On account of so much cold rain here this spring the bees got but very little good of the fruit-bloom. In this locality the bees, as far as I can learn, are almost in a starving condition, and there has been but very little swarming here so far this season. Out of 26 colonies I have had only two swarms, and they were put on empty combs. I have been feeding for the last two weeks. The sweet clover is beginning to put out, but this is the off year for it, and we won't have a very heavy crop. The white clover is not what we expected it would be after so much rain.

Now I'm going to tell what happened here this spring in a neighbor's apiary of some 40 colonies. They acted about the same as bees with the dysentery, with the exception that they came out and died outside of their hives. Probably this was owing to the warm weather so they could get out. When they would come out they would be bloated or swollen so that they were almost twice their usual size. They were purged,

A Book Recommended by Dr. Gallup. THE NEW METHOD

In Health and Disease.

By W. E. Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It takes the way from Weakness to Strength so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings cannot be sick. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, not a drug treatment.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "New Methods" given here; even those who have been pronounced Consumptive have been entirely cured. While for Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

SENECA FALLS MFG. CO.,
46 Water St. SENECA FALLS, N. Y.

The Nickel Plate Road

will sell excursion tickets to Chautauqua Lake and return on July 8, at one fare for the round trip, with return limit of 30 days from date of sale by depositing tickets with Secretary of Chautauqua Assembly. Tickets good on any of our through express trains. Cheap rates to many other points East. Communicate with this office, 111 Adams St., Chicago, for any further information desired. Van Buren Street Passenger Station, Chicago. Tel. Main 3389. (41-26-2)

and their discharges were yellow, just like the dandelion bloom, but there was no bad smell about or in their hives. They would come out of the hives and tumble and roll over the ground and die by the thousands, until there were scarcely enough bees left in the hives to take care of what little brood they had. There were three or four colonies that died outright.

This circumstance occurred during the time the dandelion was in bloom, and I thought that the dandelion was probably the cause of the trouble, as the discharges were so yellow, but if that was the cause, why did it not affect other bees in the same vicinity? These bees were the only ones that had the disease. Some thought they were poisoned, and that theory would hardly hold out, for other bees would be apt to get the same thing.

I have handled bees for over 40 years, and I have never seen or heard of such a thing before. Now, we should like to hear through the "Old Reliable," the opinions of some of our best and most practical bee-keepers in regard to what I have written about our neighbor's bees. He would also like to hear, as he is quite an apiarist. We would like to hear from Dr. Miller and others. J. S. SLEETH.

Livingston Co., Ill., June 18.

"The Goose Hangs High."

My bees are in fine condition. I did not lose any last winter. They were on the summer stands, and came through in fine condition. I had my first swarm May 24. I was not looking for them to swarm, so they got the start of me while I was away from home. They left for parts unknown to me. I soon put a stop to such nonsense. They are full in the supers now, and I shall extract this week. I am waiting for it to cure. Everything is lovely, and "the goose hangs high," as the old saying goes.

S. T. CRANDALL.

Washington Co., Wis., June 22.

Season a Failure.

The honey season here is a failure. Clover is over, Linden is passing, and yet the combs are dry. JACOB TATE.

Miami Co., Ind., June 20.

Bees Doing Well.

Bees are doing well. Horse-mint is in full bloom. I have taken 30 pounds per colony already. J. C. BEAVER.

Dallas Co., Tex., June 20.

An Unfortunate Bee-Keeper.

While nailing shingles on an out-building the scaffolding fell when we were putting on the last course of shingles, and I fell to the ground, head foremost, and unjointed both hands and broke both arms just above the wrists, and stove the left shoulder up quite badly, and I had to be helped like an infant for a long time, being unable to write or help myself. I am old and my hands are both stiff. My object was to sit under my own vine and shade-tree in my old days and see a few nice Italian bees work, as it greatly delights me.

While I was lying on my sick bed I would use the splints that my broken bones were bound up in, and turn the pages of the Bee Journal and read it in preference to any paper we take. And, O, how I would like to shake the hand

Select-Tested Golden Adel Queens.

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polish, snowy-white sections, beautiful straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leahy Manufacturing Company, 1730 South 13th St., Omaha, Neb.**

The Baptist Young People's Union

Will be pleased with a ride to Buffalo and return over the Nickel Plate Road. Choice of water or rail route between Cleveland and Buffalo, within final limit of ticket. Call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago, for particulars. Telephone 3389 Main. (29)

Basswood Honey FOR SALE

We have a limited number of barrels of **very best Basswood** Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash, Geo. W. York & Co., 118 Mich. St., Chicago, Ill.

of a certain class of men that are writing for the American Bee Journal. Some of these men are the great head-lights, and are building for themselves a monument perhaps more lasting than granite. I keep a scrap-book and when I see articles by certain men into the book they go—except one man. We can't spare paper enough to put down all he says. He must be the most patient man of his day. [This last man must be Dr. Miller. —EDITOR] W. J. MORRISON.

Dade Co., Mo., June 15.

Prospects Never Better.

Bees are doing fine in this locality. Prospects for a honey crop never were better. I have 80 colonies hard at work. I run expressly for comb honey.

FRANK COLE.

Mecosta Co., Mich., June 15.

Doing but Little Good.

Bees are doing but little good here on account of the wet weather this summer.

S. B. DAY.

Richardson Co., Nebr., June 18.

Paper Bags for Extracted Honey.

I have used paper bags like I enclose for putting up extracted honey for the last four months for customers that will take honey if I have anything to put it in. I have had syrup in one for six months, and it has not leaked a drop yet. Fill these bags with honey, and tie a string around the top and see how much hard usage you can give them before they leak. Let me know what you think of the idea. I sent a few to a bee-supply firm, and they say they are quite in-

terested in them, and believe it to be a good idea. I would like to hear from you. The bags certainly are not expensive. A New York firm is trying to secure a United States patent for me.

Quebec, Canada. T. R. WOODARD.

[We were quite pleased with the two sample bags sent us by Mr. Woodard. They seem to be made of stout paraffined paper. We think they would be just the thing to be filled with liquid honey, and then let it granulate, and sell it in that form. We do not know the price of the little paper bags, but we should think they would be quite cheap. They could be made to hold from half a pound up to any size desired. We should like to try a few of the "baglets," to see how they would go in our local market. —EDITOR.]

Bees Not Doing Much.

Bees do not seem to be doing much at present. The white clover doesn't seem to have any honey in it. I took a stroll over a quarter-section to-day, and did not see or hear a bee. We have had a good deal of rain of late, and I thought when it cleared up the nectar would come in it, but we have had several days of fair weather, but it does not seem to come.

J. C. ARMSTRONG.

Marshall Co., Iowa, June 20.

Fourth of July Excursion

over Nickel Plate Road, at one fare for the round trip, between points on that line within a radius of 200 miles from starting point. All particulars furnished at 111 Adams St., Chicago. Van Buren St. Passenger Station, on the loop. Telephone Main 3389. (36-26-1)

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, June 18.—Not any new honey here, and the old stock is about exhausted. Market values about as last quoted for what little is being done. R. A. BURNETT & CO.

Kansas City, June 21.—We have several shipments of new comb honey from Florida, the first to our market this season. The demand is fair at 11 to 12c. The demand for extracted will be light until September. C. C. CLEMONS & CO.

New York, June 20.—Comb honey: We closed out all of our old crop some time ago. We have received several lots of new crop from the South, good, No. 1 white, which sells readily at 11c per pound.

Extracted: Receipts of new crop from the South are large. We quote: Common, 48 to 50c a gallon; good, 52 to 55c a gallon; choice, 5 to 5½c pound. Demand is good, especially for the better grades. Beeswax remains firm at 28 to 29c. HILDRETH BROS. & SEGELKEN.

Cincinnati, June 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3¼ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Boston, June 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand.

BLAKE, SCOTT & LEE.

Cleveland, June 9.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & CO.

San Francisco, June 8.—White comb, 8¼ to 10c.; amber, 6¼ to 7¼c. Extracted, white, 5¼@6c.; light amber, 4¼ to 5¼c. Beeswax, 23@25c.

Not much now coming forward from any quarter. Supplies will doubtless be light throughout the season, admitting of little other than small local trade. Former quotations remain in force, with tendency on best qualities to higher figures.

Detroit, June 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring.

M. H. HUNT.

Minneapolis, June 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c.; amber, 5c.; dark, 4@4½c.

Outlook for honey much more encouraging. S. H. HALL & CO.

Indianapolis, June 9.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, June 9.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c.; amber, 8@8½c.; dark, 7@7½c. White extracted in barrels and kegs, 5¼@6c.; amber, 5@5½c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & Co.

Buffalo, June 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & Co.

St. Louis, June 10.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. WESTCOTT COM. CO.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Southern Home of the Honey-Bee

Will continue to rear none but the BEST QUEENS. Untested, 50 cents; Tested, \$1.00. GEO. W. HUFSTEDLER, Prop., President of National Queen-Breeders' Union, 24 Atf Beville, Texas. Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases—everything used by beekeepers. Orders filled promptly. Send for catalog. MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.

Please mention Bee Journal when writing.

QUEENS

From the best strains of bees in this Country....

I make the rearing of Queens a specialty. Untested, either 3 or 5-banded, 65 cents each. Tested, 95 cents each. DANIEL WURTHL, Falmouth, Rush Co., Ind. 24A3t

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

ITALIAN

CARNIOLAN QUEENS,

Three or five-banded—Untested, 50c; Tested, 75c. Warranted purely mated. Safe arrival guaranteed. Postoffice Money Orders made payable at Caldwell. Address,

C. B. BANKSTON, 24Atf, Christman, Texas.

BEEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, E. L. CARRINGTON, 11Atf, De Funiak Springs, Fla.

July 8

the Nickel Plate Road will run an excursion to Chautauqua Lake, at one fare for the round trip. Write to J. Y. Calahan, 111 Adams Street, Chicago, for particulars. Tel. Main 3389. (39-26-2)

 Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.

If you once try it you will have no other. Samples furnish FREE. Large Illustrated Catalog of all kinds of

Bee-Keepers' Supplies,

And a copy of the American Bee-Keeper, sent upon application. Address.

PROFITABLE BEE-KEEPING.

—WITH—
HINTS TO BEGINNERS,

—BY—
C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 1.—INTRODUCTORY.

No one who has given the subject of bee-culture, or the relationship of bees to flowers, the least consideration will deny that bees play a most important part in the economy of nature, and it is not too much to say that without bees our fruit and seed supply would, to say the least, be extremely limited. Bees are as necessary to flowers as flowers are to bees. The flowers by their beauty and the delicate perfume they give off, attract the busy bee to the nectaries from which they extract the honey there secreted; but while busy upon this work they at the same time become dusted with pollen-grains released by the anthers when in a state of ripeness. This pollen, or fertilizing dust of the flower must be carried from the male to the female flower, or to the stigmata, the female organs of the flower of the same species, otherwise fructification cannot take place, and fruit and seed would be impossible. This is frequently noticed to be the case when, owing to continual bad weather during the time that fruit-trees, for instance, are in bloom, the flowers are not fertilized, and consequently there is a failure of the crop. The important work of fertilization is thus unconsciously being carried on by the busy bee, while it robs the nectaries of their sweet secretion. The peculiar formation of the flowers in many instances proves that the bee, or other insect, is intended to be the agent in the fertilization of bloom.

Cross-fertilization is also evidently intended, for those flowers upon which both the anthers and stigmata are found are not both at the same period in a state to effect fertilization; that is to say, when the anthers of a flower, also bearing stamens, are scattering their pollen, the stigmata are not in a condition to receive it; hence, it must be carried to, and used by, that or those flowers on which the stigmata are in a receptive condition. Thus cross-fertilization is effected, and vigor transmitted instead of feebleness—the usual result of self-fertilization. From this point of view alone it is most desirable that bee-culture on modern principles should be taken up more generally in rural districts.

BEE-KEEPING PAYS.

Then, again, the direct pecuniary result of careful and systematic management is so encouraging that it is surprising apiaries are not met with on every farm and in every cottage garden. The number of colonies kept would of course be determined by the interest taken in the work and by the extent of bee-pasturage in the immediate neighborhood, but certainly a few hives might be stood in almost every garden if only as a source of interest and a means of providing a valuable and pleasant food.

For many years the effects of agricultural depression have been felt throughout the country; at the same time prices of agricultural produce have fallen until it is difficult, sometimes impossible, to make both ends meet. Various means have been suggested by those interested in the prosperity of agriculture, the oldest of our national industries, to minimize the effects of the general downward tendency—for instance, improved systems of dairying; more extensive and better management of poultry; fruit-culture; and the manufacture of jam. But important and valuable tho such occupations may become as a means adopted to add to the profitableness of farming, there is a most interesting, intellectual, and at the same time exceedingly profitable, rural occupation—*bee-keeping*—which, if properly, that is, intelligently, pursued would prove of great value to the agriculturist.

The extension of bee-culture as a means of adding to the income has been rapidly going on since it was demonstrated that bees could be managed without discomfort to the operator, and that a profit of 50 per cent., 100 per cent., and even more was easily procurable.

Some countries or districts are well known for the extent of the honey-producing crops grown. Flowers alone, unac-

A Piece of Comb.

companied by fine weather, are useless; but usually when the weather is favorable to the blooming of flowers, it is equally so to the ingathering of nectar by the bees.

It is at such times when both the crops and the weather are in favor of the apiarist, that the large returns per hive recorded are obtained. No one need despair of making bee-keeping a success, for it seldom happens that two bad seasons come together, and generally during any season, if one crop is mist through unfavorable weather, advantage may be taken

of another that succeeds it; but then it is only the intelligent bee-keeper who, like the successful man of business, having laid his plans works them out and receives the due reward of forethought and energy.

ONE SEASON'S WORK.

It may reasonably be asked: "What will an ordinary colony of bees gather in one season?"

"Bees do nothing invariably" is a trite saying. It is not only in what may be termed poor honey-producing districts that the returns are the worst, for I call to mind a parish where one bee-keeper took over 100 pounds per hive, another over 90 pounds, and another not 10 pounds per hive, tho all were working on the same system. The difference was undoubtedly due to forethought and energy in the first two cases, and lack of these desirable qualities in the third.

The best example of continued success I know of is that afforded by Mr. A. Abraham in the management of his three colonies. He is a farmer's son, and attends to his bees in the odd hours he can get after the ordinary work on the farm is over.

In 1892 he took 120, 105, and 103 pounds of honey, or an average of 109 pounds per hive: in 1893, 175, 167, and 126 pounds, average 156 pounds; in 1894, 205, 203, and 156 pounds, average 188 pounds; and in 1895, 185, 180, and 154 pounds, average 173. These three colonies have yielded honey that has produced on an average £3. 10s. per hive for the past four years.

A farmer living at Downham, near Ely, commenced bee-keeping with one fully equipt colony, in the spring of 1894, after attending a course of lectures in his village. At the end of the first season his balance sheet showed an expenditure of 42s. 6d., and income by the sale of honey of 101s. 5d., a profit of over 120 per cent. This year's return was better still. In many parts of the country, this year, the return of over 100 pounds per hive is by no means uncommon. One bee-keeper in Cambridgeshire, with 26 hives, took an average of 75 pounds per hive.

These are a few examples that might be multiplied, but they are sufficient to show that if situated in a good district and favored with genial weather, the bee-keeper must be to blame if, carrying out a few simple rules, he does not make bee-keeping a profitable undertaking.

CONTENTS OF THE HIVE.

In addition to the bees an examination of any hive of bees will reveal the presence of combs, composed of wax and containing honey and pollen. There will also be found, very frequently in undesirable quantities, propolis—a product valuable to the bees, but a nuisance to the bee-keeper.

The combs are made from wax, secreted in the body of the bee, from honey or syrup it has consumed. They consist of cells not quite half an inch in depth on each side of a mid-rib. The cells are built horizontally, and from the mouths of those on one side to the mouths of those on the opposite side of the mid-rib, measure $\frac{3}{8}$ inch. The distance from the mid-rib of the comb to that of the next is $1\frac{1}{2}$ inches barely; therefore, the space between the faces of the combs is about $\frac{1}{2}$ inch. The great majority of the horizontal cells are, or ought to be, worker size, measuring across the mouths of the cells 5 to the inch; but upon the bottom edges of the combs, and often in larger quantities as the result of bad management, there are found larger horizontal cells measuring 4 to the inch. These are drone-cells.

There is still another kind of cell, acorn-shaped, built upon the bottom edges of the combs, and sometimes on the face of the combs among the worker-cells, termed queen-cells, but they are only built when the hive is becoming too crowded with bees, and they decide to send out a portion of the colony—a swarm—to found another colony. The building of combs not only represents the loss of much energy by the bees, but it also means the loss of a large quantity of honey and much valuable time.

Various calculations have been made as to the amount of honey the bees consume in order to secrete one pound of wax, some putting it as high as 20, and others as low as 10 pounds. But whatever the bees really use it is an amount we cannot, with a view to profit, afford to lose. At the same time, by preventing the bees building their combs from the wax they secrete, we have their energies for several days directed to the gathering and storing of honey, when they would otherwise be comb-building. The immense importance of this saving of time will be rightly understood when we consider that it may make a difference of 20, 30, or more pounds of honey in favor of the bee-keeper. It was recorded in the British Bee Journal in 1888, that one colony gathered 40 pounds in less than three days, and another 58 pounds in six days. The late Rev.

G. Raynor stated, in 1889, that on June 15 his best hive gained 9 pounds in weight.

In the cells of the combs the bees store their two kinds of food—honey and pollen. Honey is the carbonaceous heat-giving and fat-forming food, and alone forms the food of the bees in winter, but at other times it is used by the bees in conjunction with pollen, the nitrogenous or muscle-forming food, as a perfect food for themselves when working, and for the rearing of grubs. The two foods together form a food without which brood-rearing is impossible; hence, the advisability of giving a supply of artificial pollen when the supply from natural sources fails.

The best substitute is pea-flour, which may be scattered on shavings in a straw-skep or box. The bees must be enticed to it by a little honey; then, when they have once found it, they will not cease to carry it into the hive until they can obtain the genuine article from flowers. Honey is also one of the choicest foods for man, and not the least valuable, as it is the only food that, having undergone chemical change in the body of the bee, can be taken directly into the system and used as a force-producer without having to pass through the ordinary digestive process. Certain flowers produce pollen in great profusion, and then it often happens that there is a superabundance stored in the combs. In movable-comb hives this is not a serious disadvantage unless all the hives are in a similar condition. If there are only a few hives in which the combs are overloaded with pollen, some such combs may be given to other colonies requiring a more liberal supply of this kind of food.

Propolis is a resinous substance found oozing from the trunks of certain trees, and is gathered by the bees for the purpose of filling up cracks and crevices, as well as covering intruders, such as snails, that enter the hive and cannot be removed. To the bee-keeper propolis is a great annoyance, as it makes such a sticky mess of the fingers and other things touched during manipulations. Some bees gather more propolis than others; therefore, those who aim at perpetuating any particular strain of bees should endeavor in the breeding to eliminate this and other undesirable traits.

[Continued next week.]

Loaded Bees in the Sections, Etc.

BY J. A. GOLDEN.

In the February Review, I said Mr. Doolittle and others have told how the field-bees give the honey to the nurse-bees, and the latter store it in the cells. My bees, as a rule, do not follow that practice. I know this to be true, as I have spent a great deal of time sprinkling bees with flour and then watching them through the glass as they pass up and deposit their loads of nectar in the sections.

Now, in calling attention to my observation as to the above statement, I did not wish to be understood that field-bees did not transmit their load of nectar to other bees on return as well, but to show that bees also deposited direct in the cells.

Having read Mr. Doolittle's article on page 321, I doubt not he has reference to my article, having overlooked how I was convinced. He says: "Mr. Golden, I believe, claims that he knows that they do this; but if he has told us why, or how he knows it, I have failed to see the place." But as Mr. Doolittle seems to intimate in his concluding paragraph that if E. Gallup and himself are right, all other observations are nothing but fallacious, and if deceptive, it would be well to know it.

Now, for the benefit of the readers of the American Bee Journal I will here give my observations more fully, and I want it distinctly understood that my evidence for believing as previously stated, is seeing, which is in itself believing. Therefore, it has been a fixt rule (with me) in the study of bees and their manipulation, to make careful and painstaking observations upon every subject relating to them, their habits and their work coming under my observation, and thus I have found much convincing evidence that greatly conflicts with others upon the same subject, work or habits of the honey-bee, regarding which they have been equally vigilant in their observations. Now, this being true, it does not prove, to my mind at least, that one observer has given facts and the other falsity.

In regard to the question of where and how field-bees deposit their load of nectar on returning from the field, I had learned long before reading Mr. Doolittle's observation, by the aid of two observatory hives, and at a time when bees were working in the height of the flow. My plan was this: When bees were dropping by the hundreds upon the alighting-board, I would sift flour over them, see them pass in, then care-

fully lift the frame and would find floured bees passing here and there. Keeping a close watch, I would see one enter a cell, deposit her load, then withdraw therefrom, brush herself, and fly from the comb in search of another load. Others, as I also observed, would pass here and there over the combs seeming somewhat bothered. I supposed from this that they were depositing their day's gathering in some other comb, and were hunting for it. But other bees could be seen giving up to those which we designate as house or nurse bees.

Continuing my observation, I fitted up supers, glassing the sides, thus showing the sections, and continuing the dusting process, I found the same convincing evidence, that the market bees were seen depositing nectar in the section-combs. Thus, I was theoretically led to devise the side-entrance from the bottom of the hive, intersecting the same in supers, keeping the entire force of the colony together during the season, as per my method previously given in the bee-papers. I greatly enjoy this manipulating, and not only so, but, as I have previously stated, it has been the means by which I was enabled to satisfy every claim, financially, that stood against me, both just and unjust, from the fact that it reduced the expenses for hives, frames, comb foundation, and other expenses in wintering, etc., besides giving greater yields, nearly doubling in comb honey the amount by that of the increase method. Now, please remember, I am speaking only for my locality.

In regard to the entrances that Mr. Doolittle speaks of, I know nothing about that, but I do remember the kind of entrance my father gave for his bees, over 50 years ago. It was so large that one day in wheat harvest an old neighbor who, having lmbbed the contents of an old, long-neck wine-bottle, came for some honey. No one was at home but mother and myself, and as no honey had been taken, mother could not fill his order, so the old man swore he must have some honey, and staggered out to the apiary of a hundred colonies. Selecting one of the largest hives, he laid down and rolled himself under the hive, thrusting his hand and arm up into the hive, drawing down a great bunch of comb and bees, and, as mother and I rushed to the rescue of the old man, we were badly stung, but not in comparison to the old man, who did not appreciate eating his honey after getting it, but was taken home and a physician called. But in three months the old man died. So you see large entrances were used in those days, and my father used to say that bees would not swarm so much when no bottoms were used; and many times the combs were built clear down to the ground from those great big hives, and whether hereditary or not, I surely advocate a large entrance.

As to the side passage-way, as I use in my method, it is as eagerly accepted and used by the bees as a pedestrian with a crate of honey on his shoulder would seek the unobstructed sidewalk in Chicago to avoid delay. Morgau Co., Ohio.

Home Marketing of Honey—An Experience.

BY F. L. THOMPSON.

Three years ago I tried to get up a home market for extracted honey by soliciting from house to house. In this way I sold from perhaps 700 to 1,000 pounds—I have forgotten the exact amount. I concluded, however, that it did not pay. By intense application I could make good daily wages, but that was all. The work was not at all what I was fitted for, and the perpetual feeling of being a round bolt in a square hole was wearing, to say the least, without mentioning the time thus wasted for a mere pittance (the difference between the wholesale and retail price, with the expenses of retailing) which might have been far more profitably employed, mentally, if not financially. At that time my plan was simply to show people the honey, letting them taste if they wanted to (but very few did).

The past winter I concluded to try it again, on a somewhat different plan. I had read of the wonderful success attending the plan of giving away samples, together with honey leaflets. I accordingly provided myself with a number of these leaflets, and printed some of my own, giving the gist of the matter in a very few words, so that it could be read through in half a minute or so. I gave away samples of my honey (a good quality), pouring it out of a nice, little majolica pitcher, holding about a quart and a half; and also at the same time samples of granulated honey, wrapped in little squares of parchment paper. In this way I called at about 500 houses, distributing my leaflets and circulars at each place.

Quite a number, perhaps 5 to 10 per cent., refused to take the samples at all. Perhaps about half of those that did take samples would take a quarter's worth of honey when I made my second call. Some took 10 cents' worth, and a few

5 cents' worth. A very few took a dollar's worth. I sold in all about 500 pounds. Not more than about one-third of those who had bought the first time did so again, when I made my third call. At many places I had to make three, four and five calls—they "hadn't the money" just then, or "had company," or something. I had learned by my former experience that when any one said "not to day," he or she (generally she) meant "not at all." Sometimes they would say, "Perhaps some other time." I made second calls at such places, but might have spared myself the trouble. Almost invariably it turned out that the above formula had been a mere evasion.

In giving away the samples, I took occasion to remark that the granulated sample was a proof of purity; that many would buy extracted honey if they thought they could get it pure; that I was a bee-keeper trying to get enough customers to take all my own honey; that the circulars told just why honey was a healthier food than sugar, and contained a number of recipes for cooking with honey; and more talk, if the opportunity afforded. I was generally well treated, perhaps more civilly than when I did not give away samples. But I met all the mean people I wanted to see, and a few more.

It will be seen that the sample-and-circular plan was not even as successful as my former one, which was poor enough. I do not know why that was; but I want to offer both these experiences as a solemn example to those who are enchanted by the siren voices of those who sing that the home market of the individual is the remedy for all ills. I have proved by two actual, prolonged trials that, for me, it is not; hence, it is reasonable to infer that the experience of some others may be like mine.

Of course, explanations may be given for my want of success. I know one or two who have had good success in selling honey from house to house. I think the appearance of their rigs and outfits "gave them away" as coming from the country. Result, confidence. Unfortunately, I couldn't fall back on that. When I put on poor clothes, or rather when I don't put on good ones, people take me—not for a farmer—but for a "sheeny" of the rag-buying or tin-peddling variety. My conscience wouldn't let me hire a female in a calico dress to sit in the wagon and personate the "old woman," and I couldn't afford a horse and wagon anyhow, just for that. Then, as intimated, I am a poor hand at the work. I can't think of the right thing to say, or the right words to express what thoughts I do have, until the opportunity has past.

Another bee-keeping friend sells a great deal of honey—always 10 pounds at a time—through his friends. When I started out in the work, he thought of course I could sell 10 or 15 buckets a day. I venture to say that if he had tried my plan, he would not have sold much more than I; while I can't try his because I haven't a wide circle of acquaintances, nor any who are apt to take orders from others for me. So it goes.

In every case, if instances of success in selling honey were analyzed, I believe it would be found that those who advocate the general plan of home marketing fail to take account of peculiar favoring circumstances in their own case. A man with a wide circle of acquaintances, in a thickly settled rural district, where he has lived 15 or 20 years, sells all his extracted honey without any trouble. He thinks, of course, anybody can do likewise. What nonsense!

Another, having all the peculiar qualifications of a salesman, has the luck to live not far from several unsophisticated rural towns, the inhabitants of which hang on his honied words, and tumble over each other in their efforts to contribute boodle to him. He writes an article telling of his fabulous successes. Very naturally; I would, too, in his place. Only, his experience is not representative. I fear mine is, to some extent—on the principle that fools are commoner than geniuses.

Some other results of my experience run counter to accepted ideas; especially the idea, that once get a person to taste good honey, and you have a customer. The saying that if a person once buys good honey, he will keep on buying, was also knocked into flinders. Now, I have a theory to account for the latter fact. The stomach craves just so much of each class of foods. More than that, it does not care for, except occasionally, as a tidbit or luxury for the palate. Now, usually, when people buy honey, and eat it, they eat just as much sugar and fruits, and so forth, as they ever did; consequently they don't feel the need of any *stomach room* for the honey. See?

Again, it would astonish the advocates of home individual marketing to ascertain how many people there are who don't like honey. Yes, I mean what I say. They *don't like it*. Does that sound heretical? It is so, tho. I can appreciate this attitude, because I am one of that class myself. After eating honey for years, under all circumstances, I am forced to the conclusion that I don't like honey, and never will. Neverthe-

less, I shall keep on eating it, for the considerations in Prof. Cook's article on honey as food, a year ago, affect me powerfully. But it goes without saying that the vast majority of those who don't like a thing, won't have it, and that settles it.

And yet, in spite of my poor success, I am of the opinion that all those who would like honey well enough to buy it continuously, if it was brought to their notice, are numerous enough to take all our honey at a good price. My point is, that they are not numerous enough to make the attempt of the average bee-keeper, and average salesman, to reach them, a paying job.

I think that those who advocate home marketing in general terms without qualification, are making a mistake. They are advocating something that it will not pay the average man to undertake.

All the foregoing is an argument for organization, as the one thing left. I need not enlarge on the familiar topic. But two thoughts occur to me that I have not elsewhere seen mentioned, except a hint or two in foreign papers. One is, that advertising by means of honey leaflets does not hit just the right spot. Do we generally read the printed matter that comes with "Rough on Rats," or "Hood's Sarsaparilla?" If we depended on that, we wouldn't have much idea of those articles, or any other proprietary drug or food. But we have a pretty vivid idea of many such things—Ivory Soap, and Scott's Emulsion, and Liebig's Extract, etc. How did we get that idea? From newspaper advertisements, of course. That is my second thought—that it is possible to properly advertise honey. But only a powerful organization can ever do it. Bargain store grocery advertisements show that common foods, also, come under advertising with profit. "The newspaper habit" is a bad one; but it is an ill wind that blows no one any good, and we might as well take a pecuniary advantage of the fact that the average American citizen does depend for his mental sustenance on that species of literature. There is no question that it would pay if once consistently carried out. It is what all successful firms do. Montrose Co., Colo.

Feeding Back Extracted Honey to Produce Comb Honey.

BY HON. R. L. TAYLOR.

It has been thought worth while to repeat the experiment in feeding back extracted honey for the completion of unfinished sections. It has also been found more convenient and desirable to do so owing to the fact that the character of the season has been such that the percentage of partially-filled sections has been greater during the past season (1896) than ever before. This was owing to the shortness of the honey season and the slender character of the honey-flow. The extent of this was such that but now and then a colony completed even one case.

For the purposes of the experiment four colonies were selected. All were hybrid bees, so-called, and very strong. For a brood-chamber, each colony was given a single section of the Heddou hive, containing frames equal to five Langstroth frames. Doubtless a brood-chamber even smaller—perhaps as small as 2½ Langstroth frames—would have been better, and this for two reasons:

First, much less of the honey would have been required for the rearing of brood, as the extent of that would have been reduced by one-half. I have heretofore given reasons tending to show that it requires two pounds of honey for the production of one pound of brood, and that a section of the Heddou hive, if almost entirely devoted to brood, would contain about ten pounds of it. If this is substantially correct, it will be seen by consulting the table presented herewith, that 20 pounds of honey would be required every three weeks to produce the brood of each of the colonies used in this experiment. This amount of brood might have been reduced by one-half without detriment to the well-being of the colony, and one-half the colony saved.

Second, what I have just said appropriately introduces this point. The number of bees continually hatching from five Langstroth frames full of brood constantly increases the strength of the colony so that if feeding is continued any length of time, with the crowding necessary for the production of comb honey, swarming is induced. This would be detrimental to the highest success of the work. With about half that amount of brood the strength of the colony would be kept good, and swarming avoided, for it must not be too readily accepted that a small brood-chamber without reference to the degree of smallness conduces to swarming.

The feeding was begun July 15, soon after the closing of the flow from clover and basswood. Two or more cases of

sections were kept upon each colony, and the honey given as rapidly as the bees would take it. The honey was prepared for feeding by thoroughly incorporating with it about one-half its own weight of water, on the supposition that in this condition the bees would handle it more rapidly.

The work with colonies 2, 3 and 4 was closed Aug. 6, one day more than three weeks, owing to the fact that on that date, or shortly before, they had cast swarms, rendering it undesirable to continue them in the work. Colony No. 1 was retained in the experiment until Aug. 29, nearly 6½ weeks. This colony was particularly adapted to comb-building, and showed that, during the first half of the period, but later owing probably in part to the low temperature which prevailed during August, its work was less satisfactory.

Up to Aug. 10 there was no noticeable amount of honey coming from the fields, but later there was some considerable being gathered, the colony No. 1, being fed, seemed to participate to a very small extent in it, not bringing enough to tinge the color of the comb honey in process of construction, and so I judge not sufficient to make it an appreciable element in the problem under consideration.

Turning now to the table, we find some questions presented which are not altogether easy to answer. We find there so striking a difference between the work of colonies as that one requires more than two pounds of honey to enable it to add one pound to its store of comb honey, while another required but a trifle more than a pound and a third. It might be surmised that the one requiring the larger amount had ex-

| NUMBER OF COLONY. | Net weight in pounds of unfinished sections put on the hives. | Amount fed, in pounds. | Amount of honey, in pounds, when completed. | Gain in pounds. | Per cent. of gain to amount fed. | Pounds of honey fed for each pound gathered. | Gain in honey in brood-nest. | Per cent. of gain to amount fed with honey in brood-nest considered. | Heddou frames of brood July 15. | Heddou frames of brood at the end of the experiment. |
|-------------------|---|------------------------|---|-----------------|----------------------------------|--|------------------------------|--|---------------------------------|--|
| 1 | 225 | 168¾ | 317¾ | 92¾ | 55. | 1.81 | 10% | 61. | 7% | 6¾ |
| 2 | 62 | 76¾ | 111¾ | 46¾ | 64.7 | 1.54 | 2½ | 65.7 | 8 | 8¾ |
| 3 | 99¾ | 75 | 136 | 36¾ | 49 | 2.04 | 5 | 35.7 | 8 | 8¾ |
| 4 | 66 | 67¾ | 114¾ | 48¾ | 71.9 | 1.34 | ¾ | 72.5 | 8 | 8¾ |
| Total | 452¾ | 378¾ | 679¾ | 227¾ | 58.7 | 1.70 | 16% | 63. | | |

ended it in the production of a larger amount of brood. If, however, we allow that No. 3 reared an amount of brood equal to that reared by No. 4, viz.: eight Heddou frames full, and deduct from the amount fed each the 20 pounds supposed to be necessary for the rearing of the brood, we see No. 4 accounts fully for all the remainder in its case, while No. 3 lacks 18¼ pounds of doing so.

In like manner, on the above supposition, No. 2 accounts for nearly all the honey given it, while No. 1 comes short of it by more than 30 pounds. It can hardly be that the amount of honey required by different colonies for the rearing of the same quantity of brood can vary very greatly, nor the amount required by the adult bees for food where the strength of the colonies is about equal. At present I see only two other ways of accounting for the deficit, viz.: quiet robbing and varying amounts required for the production of wax. Robbing as an outlet is hardly to be relied upon; wax-production seems more likely to afford some measure of relief.

If the table is examined closely it will be seen that the sections given Nos. 1 and 3 averaged much heavier than those given Nos. 2 and 4. Can it be then that the much greater proportionate amount of cappings of the honey to be done in the one case calls for the production of wax for use in the capping as to account for the apparent discrepancy? It may in some measure, and, besides, some colonies may practice putting more wax into a given extent of comb so as to make it stronger and safer. It is plain there are abundant subjects yet for investigation in bee-culture.

Figures may be made in different ways to determine the amount of profit there is in feeding back. I consider the value of the unfinished sections as about equal to that of the extracted honey, say 6 cents. This would make the value of these two articles entering into this experiment \$50.38. I compute the value of the 679¾ pounds of comb honey produced, at 12 cents per pound, which gives a total value of \$81.57, or a profit of nearly 62 per cent.—Review.

Lapeer Co., Mich.

Making Improvements in the Race of Bees.

BY A. BEAMAN.

In looking over the pages of the American Bee Journal for this year, I find two communications and several references to the improvement of the race of bees. It is to be regretted that in one or two instances the thoughts of the writers ran off on the side line of creation—away from the fact that, as every observant bee-keeper knows, bees vary in many particulars as to size, prolificness of queen, hardness, disposition, etc.—and come to the conclusion that bees are now as perfect as they were in the beginning. Such a conclusion involves a very nice distinction as to what is meant by "perfect." Surely, the writer could not have meant precisely what large numbers of people might think him to mean, namely, that bees have now the same form, and do the same things in exactly the same way as they did at first, rather than that when bees were created they were created perfect in accordance with the conditions that would surround them, and that as they were in perfect accord with their surrounding conditions then, so they are now in accord with present conditions. But conditions have greatly changed, and consequently so must have the bees.

When one tries to change the form or the honey-producing qualities of bees, or the prolificness of queens, or do what we ordinarily call "improving our stock," we change the conditions under which the bees generally live. Rev. Templin mentioned how Mr. Darwin changed the form of his pigeons and produced new breeds. Mr. Darwin, by selecting out some pigeons for breeding together and rejecting others, made a new condition that had the effect of making a new breed. The breeding of pigeons, of chickens, of cats, dogs, horses, sheep, hogs and cattle, to obtain a better quality or kind of stock; the selection of seed corn, of seed oats or wheat having certain characters that are thought to be the best for the purposes in view, is more or less familiar to every one.

If any one has doubted that bees or insects can be changed in form, or in disposition, or improved, it must be because the person has not observed closely enough, and has consequently always thought of these small creatures always the same, each bee exactly like every other—of course forgetting the old saying that there are no two things alike under the sun. Really, the creatures have been too small for him—beneath his notice. But observant bee-keepers, those that love their bees, and are to be found working over and about or among them at every spare moment, or to the neglect of other work, as already mentioned, have found differences between bee and bee, and hive and hive. Beyond a doubt, many differences not found by them can be found by one properly trained in powers of observation, and with proper aids to his five senses, who looks for variations.

Some of our common flowers have only five petals, so far as the most of us know, but some scientists have looked into the matter and have found that once in awhile one can find a flower with six petals. All of us are aware that four and five leaved clovers can be found in white clover, and less often in red clover.

In the Scientific American, or in the Scientific American Supplement, last spring there was an account of a scientist having produced monsters in moths, by grafting pieces of the pupæ of several moths together and holding them in place with paraffine, very much as one does the bark in grafting trees. One of the illustrations showed a moth with two bodies.

The Chinese make monster gold fish by performing certain surgical operations upon them when they are very young. Certain scientists have made monster animals develop under peculiar conditions.

It seems, then, that those who know how to go about the work can do much more with animals than most people suppose, and it looks very probable, therefore, that the proper person could produce new races of bees that might be much better than those we have at present.

The lengthening of the tongues mentioned by Rev. Templin is a case in point. Certainly if the stores of honey that from a human standpoint now go to waste every year in the corollas of red clover and other flowers with long clovers could be added to the stores that are obtained from the bees from other sources, there would be a gain for the bee-keeper. So there would also, if, as suggested by Mr. Getaz, bees were larger and could carry larger loads. Many other points might be brought forth, in many of which the scientists would be deeply interested. There is then no doubt that bees can be improved by those that know how and have the opportunity, or that such improvement is desired.

The question is, How to go about the work. Mr. Getaz informs us that we cannot, like the breeders of cattle and horses, make note of the points of bees and keep them re-

corded in a book. Here I think he makes a mistake, and that there is not an animal living, large or small, that cannot have its qualities good, bad, or indifferent, written down on paper. True, the workers do not lay the eggs that keep the colony alive. But whatever qualities they may have can be charged up to the queen. The real difficulty is the time that would be necessary to obtain small results. But time is required in the breeding of all animals, and it is not probable that any one can be found who regrets the time spent in breeding up our best Jerseys, Durhams, our Percherons, Clydesdales, our Chester Whites, Poland Chinas, Essex, or Berkshire, our South-downs, or our Merinos, or our Plymouth Rocks, or White Leghorns. All of these were once nothing more than ordinary wild animals.

There is also the item of expense, if a single bee-keeper should undertake all the improvements that might be made. To a considerable extent he would be obliged to sacrifice profit from annual crops of honey and wax, or colonies of bees, for improvements the good results of which he might not be able to realize for some 20 years, or perhaps he might be obliged to pass some of them on to his children, and never realize them himself at all.

If the single bee-keeper is not likely to undertake the work of improvement, who will? If the improvements are wanted, as all improvements are, and the necessary time and consequent expense makes it practically impossible for the individual bee-keeper to undertake it, who can?

District of Columbia.

Marketing Honey—Some Excellent Advice.

BY A. E. HOSHAL.

The first requisite in the marketing of extracted honey for table use is quality. Nothing but an absolutely first-class article should ever be placed upon the market for this purpose. Good extracted honey will cultivate a taste and sustain a demand for itself, while that which is a little off in quality will destroy such a taste, and consequently with it the demand for extracted honey. A bee-keeper who may happen to have some off-grade extracted honey on hand would better use it for stimulative or winter feeding, make vinegar of it, sell it for manufacturing purposes, or, if the worst must be done, throw it away, rather than place it upon the market for table use. And so long as bee-keepers persist in extracting their honey before it is well capped and thoroughly ripened on the hive, just so long will they have some of this kind of article to dispose of.

Comb honey in sections should never be marketed in the cases in which it was stored by the bees, but should be removed from these, the sections scraped clean of propolis, and, unlike extracted honey, graded into about three grades. Each grade should be crated by itself in new, clean, fresh-looking shipping-cases, and the honey which is seen through the glass in the side of each crate should be a fair sample of that within. These cases can be obtained from any aparian supply-dealer, and those holding 12 sections each usually take the best on the market.

For marketing extracted honey in bulk, we have nothing better than the 60-pound square tin can encased in wood. With these, extracted honey can be shipped anywhere with safety, and in convenient shape. For retail purposes neat packages holding 1, 2, 3, 5 or 10 pounds would be required. If the honey be peddled or sold at home, a 5 or 10 pound tin pail will be much in demand, but if placed in a grocery or other store, packages holding 1, 2 or 3 pounds will sell decidedly the best.

I know of no article where cleanliness, neatness and taste count for more in marketing than with honey. Let it once get daubed about, or on the outside of the package, and it is a sticky mess, attracting flies and other insects, and retaining whatever dust or dirt comes in contact with it, making of it the repulsive rather than the attractive sweet of nature. Comb honey which may have become daubed should be returned to the bees for a half hour or so to be cleaned up again. All shipping-cases for comb honey should have their bottoms covered on the inside with a loose paper, the edges being turned up about $\frac{1}{2}$ of an inch, so as to form a kind of shallow paper tray, and in this tray small cleats so placed as to support the sections when placed in the crate. The paper trays will catch all drippings from the honey, and prevent it getting outside of the case, while the cleats supporting the sections will prevent them becoming daubed, as they otherwise would if allowed to rest on the bottoms of these trays.

It is best, usually, that extracted honey reach the consumer in liquid form; also, in placing it in grocery or other stores for the retail trade it should be in such packages that it will be impossible for it to spill or slop out, even tho' it

should be turned upside down. Each package should have upon it full directions for liquefying the honey it contains should it granulate in the consumer's hands; also be neatly and tastefully labeled, and bearing the bee-keeper's name and address.

Be willing to pay a fair wage to those who will undertake to sell for you, and don't expect them to be able to sell your honey at a higher price than what you can yourself, unless they have a better article. Possibly the best way to arrange all this—and it is done and recognized in about all kinds of commerce—is to fix the selling price, and then allow a certain percentage off to the trade, or those who sell our goods for us. If a grocer or other merchant will undertake to handle your honey then don't go and retail to those who might otherwise become his customers, nor peddle it throughout his market field at the same price which you charged him for it. This would be refusing to pay an honest wage to those who work for you, besides cutting the price of honey and doing much to drive your own product out of the market. Yet, how many bee-keepers there are who do not recognize this.—Farmer's Advocate.

"Profitable Bee-Keeping, with Hints to Beginners"—the nine articles by Mr. C. N. White, of England, begin this week in the Bee Journal, as we have received the first two of the nine. See page 426 of this number for further information concerning these articles, and also the premium offers for getting new subscribers for the last six months of 1898.

We would like to have all our readers, if possible, get and send in the subscriptions of their neighbor bee-keepers. The way to get rid of slipshod, old-fogy bee-keepers is to place under them the jack-screw of good bee-literature and raise them up to the level of those who are striving to keep bees in the modern and proper way. By so doing all will be helped.

Many of our subscribers have already sent in new subscribers on the offers made on page 426, but there is room for many more. Before Aug. 1 we hope to add 1,000 new subscribers to our list. It can be done if every one will do only half as well as some others have already done.

Send for free sample copies to work with, or send us the names of non-subscribers, and we will mail the sample copies to them.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book, postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all other bee-keepers possible to subscribe for it. See premium offers on page 426.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. O. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Difference in Queen-Progeny—Swarming.

In reply to Geo. H. Stipp (page 397,) I don't know why it is that the queen progeny of a pure queen differs so much from the mother and from each other; I only know the fact. Some pure imported queens are very dark, and their queen progeny will be varied, altho they all will be uniform as to their worker progeny.

Mr. Stipp is right in thinking a young queen may swarm in her first year, when reared in the same hive. Such cases occur by the thousand. But they are virgin queens, and Mr. Gravenhorst was probably talking about laying queens. If a colony rears a young queen on its own account, and that queen swarms after commencing to lay, it will be a very notable exception to the rule. C. C. MILLER.

Trying to Keep Down Swarming.

I am running for comb honey. Now, if I should keep three or four supers of sections on my hives, giving them an abundance of room, would they be so apt to swarm? Would they fill the sections as nicely as they would if they were more crowded?

Two of the nuclei I bought last year (1897) did not swarm last year, and they are just rolling in the honey, and if I can keep them from swarming I am sure they will give me surprising results. CENTRAL WISCONSIN.

ANSWER.—No amount of super room will make sure work in keeping down swarming. Pile them up 10 high, and your bees will be likely to swarm. But plenty of super room will do something toward prevention of swarming. A colony crowded for want of enough super room may be forced into swarming that otherwise would not have thought of swarming so soon, if indeed it would have swarmed at all. So it may do a good deal to prevent swarming if you have three or four supers on at a time. But it's running a good bit of risk. If the season should suddenly close, there you would be, with three or four supers full of unfinished sections, when if you had been satisfied with one or two supers less on a hive, you might have had nearly all finished. Sometimes, however, it may be well to run some risk. Last year I did it, and it came out all right, but it made the cold chills run down my back sometimes when the question came to my mind, "What if the flow should suddenly stop and the 15,000 pounds of honey or more, scattered among the sections, should be left unsealed?" So, unless there's a big flood of honey coming, with every appearance of continuing, don't take too much risk.

Raise up your hives by putting a block under each corner; $\frac{3}{4}$ -inch to an inch will be none too high to block up.

Section-Holders and T Supers.

1. I use the section-holder and one-pound section. I find that between the first section-holder and the side of the super there is not space enough for a good bee-passage. How shall I manage to secure the necessary space?

2. When using full-width wood-separators, the upper edge of the separator comes up even with the tops of the sections and divides the passage between the sections, practically closing the spaces. How can I tier up with such arrangement?

3. I have only 20 supers. What will have to be done to them to change them from the section-holder super to the T super?

4. What do you think of tin separators if made from perforated tin and zinc? And what would be the probable cost per hundred? ARKANSAS.

ANSWERS.—1. There is probably no good way to make the passage greater; but are you sure it's a matter of any importance? A sixth of an inch is all the passage needed, and the bees will go up in the next passage if they can't get up at the side.

2. If your section-holders and supers are made the usual way, the super is deeper by a bee-space than the depth of sep-

arators and sections, making a full bee-space between the contents of one super and the next one above it, in which case there is no difficulty about tiering up.

3. Plane down the super so as to be $4\frac{1}{2}$ inches deep. Put a board inside at one end so as to make the inside length $17\frac{3}{4}$, and nail on this a strip of tin, the same as at the other end. Drive in at the proper places the six staples of the particular kind used for supporting the T tins.

4. That's a thing that seems naturally to suggest itself to a great many, but I don't know of any one who has continued using anything of the kind, and it's doubtful if you'll like it. Cost, probably \$3.00 or \$4.00 a hundred.

Wintering—Sun and Shade, Etc.

1. Which is the better way for wintering out-doors, a 2-story 8-frame hive, or a single-story 8 or 10-frame hive? If wintered in a 2-story 8-frame hive, is there not too much room? And if it is the better way, will the bees commence to rear brood earlier than in a single-story hive? Are there any other reasons?

2. Is it best to leave the bees packed summer and winter in chaff-hives or winter-cases?

3. Does it make any difference for brood-rearing if the cells are $\frac{1}{4}$ of an inch longer than they need be?

4. Is it better if the hives get the sun at morning and night, than if they stand always in the shade?

5. Will the bees winter well in a 2-story hive of five or six frames each?

WISCONSIN.

ANSWERS.—1. If a colony is strong, there is probably an advantage in having the two stories, and possibly even if it is weak. I don't know that they'll commence rearing brood any earlier in the double story, but they are a little more remote from the outside air in the upper story, and if they are strong enough they will need some of the room in the lower story for stores and brood.

2. It is probably best to remove winter-cases. Chaff-hives are left the same winter and summer, as they cannot well be changed.

3. The bees will cut the cells down to the proper depth, but of course it makes just so much extra work.

4. It is probably better.

5. Yes; but if a colony is very strong it would be better to have larger hives.

Preparing Bees for Winter—After-Swarms, Etc.

1. I live on the northern shore of Lake Ontario; the mercury frequently falls anywhere from 20° to 30° below zero, and we have a great deal of north wind. Would it not be a good plan to line the winter case for single-wall hive with building-paper, filling the space between the paper and the winter-case with chaff?

2. Which would be warmer, to leave the summer cover on the hive, or chaff-cushion? and will I need to remove some frames and put in chaff division-boards?

3. Would it be best to have all hives face the south, in this locality, or will it make no difference?

4. Would you contract the entrance in winter, or leave full width?

5. When you transfer from box-hives by placing a new one filled with foundation over it, do you close the entrance of the old hive? and would the bees work up through a couple of small holes, perhaps two or three inches long, or would I have to remove the top of the old hive?

6. Can I unite several small after-swarms until I have one good, strong colony, by shaking some of the bees from the frames, with the new swarm, and allowing all to run in together?

7. Has the A. I. Root Company a branch office in Canada?

NEW YORK.

ANSWERS.—1. It would probably be a good thing.

2. The chaff-cushion is likely best on top, but it's hardly necessary to take out any frames to replace with cushion.

3. It isn't likely there's much difference, some favoring one direction and some another.

4. Leave open full width.

5. Transferring by putting the empty hive over isn't much practiced, and you might not like the plan so well as to drum out 21 days after swarming. If you have only small holes for the bees to go up, the queen would be a long time going up, and she might not go up at all, but they might be drummed up, and if there was a frame of brood above they would stay there. In any case it would be a big help to put

a frame of brood in the new hive. If the bottom of the old hive is not nailed on, you can turn it upside down and set the new hive over it. It will be at least as well if the entrance is only to the new hive.

6. Yes, and it will be much better than to have a lot of weaklings. But why not prevent all after-swarms in the way already directed several times? Set the swarm on the place of the old colony, putting the old colony close beside it, and a week later move the old colony to a new location. That's better than to have the trouble of hiving after-swarms and then uniting them. 7. No.

Pollen in Sections—Other Questions.

1. How can bees be prevented from putting pollen in the sections, if at all? Will a greater number of frames in the brood-chamber help to prevent this?

2. Will bees store honey enough in an 8-frame hive to winter out-doors, with protection?

3. Can I use Hoffman frames in two Ideal supers, for extracted honey?

4. How much more extracted than comb honey will a colony produce, provided they have comb built for extracted honey, and are allowed to cap it? Authorities differ.

ILLINOIS.

ANSWERS.—1. I don't know. Sometimes bees put pollen in sections when there seems to be no special reason for it. I suspect they are more likely to do so if the sections are very close to the brood-combs. Yes, it is quite possible that plenty of room in the brood-chamber may make a difference.

2. Sometimes, and sometimes not. It may happen that the room is so largely taken up with brood when sections are taken off that very little honey is in the brood-chamber, and if no late honey comes in the bees may starve.

3. They would be quite too deep.

4. I'm very much like the authorities—I differ too. And seasons and conditions differ. In my locality I don't think there is such a great difference, while in Nebraska some say they can get three times as much extracted as comb, where heart's-ease abounds.

Why Don't they Swarm?—Opening Hives.

1. I have a colony of bees that I put into a new hive. I clip the queen's wing and she went to work all right for a few days, and she has young bees in the combs. Now I can hardly keep her in the hive. What can I do?

2. I have four other good colonies, and they have not swarmed yet. What is the matter with them?

3. How often can I look into the hives without doing any damage to the bees?

IND. TER.

ANSWERS.—1. You don't say whether the queen leaves the hive alone or with the bees as a swarm. If she leaves it alone, it's a crazy streak, and the only thing you can probably do is to confine her with perforated zinc. If she leaves with a swarm, then the case is to be treated as any case of swarming bees. If the queen was regularly reared in the hive, according to all rules she ought not to swarm this year.

2. That's a good deal like saying, "My neighbor is sick; what's the matter with him?" It is possible that they have all the room needed for a brood-nest, and on that account have no desire to swarm, for no matter how strong a colony may be, it is not likely to swarm if all the right sort of room is present. Again, it may be that forage is not plenty enough to warrant swarming.

3. Probably if you should open a hive for a short time every day when warm enough, you might not notice any particular harm from it, yet every time a hive is opened it must hinder somewhat. Better not disturb the bees unless there is some fair reason for it.

Bee-Space Above Frames and Sections.

Is it necessary, to insure the best results, to have a bee-space above the frames and sections?

TORONTO.

ANSWER.—The bees will do just as good work without the bee-space, but if you try both ways you will probably decide that you want the bee-space for other reasons. If there is no bee-space you are likely to kill a lot of bees every time you set the sections over the frames, and with the bee-space there is not the same gluing.

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.
 BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.
 GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. JULY 7, 1898. NO. 27.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Omaha the Place.—We have received the following from Dr. A. B. Mason, Secretary of the United States Bee-Keepers' Union, which fixes the place of the National convention for 1898 at Omaha, Nebr.:

EDITOR OF AMERICAN BEE JOURNAL:—Please say in the next issue of your journal that after thoroughly considering the matter of the place for holding the next convention of the United States Bee-Keepers' Union, the Executive Committee has decided in favor of holding it at Omaha, Nebr. The exact date for holding the convention will be fixed by Mr. E. Whitcomb, upon whose broad shoulders will be put the pleasure of securing reduced railroad and hotel rates, and a place for the convention to meet, etc. His shoulders are broad, and he is right on the ground.

A short time since Mr. Whitcomb sent me some particulars regarding rates from which I take the following:

"Every day during the Exposition tickets will be on sale from all Western Passenger Association territory to Omaha at one and one-third fare for the round trip, except their rates from the following points, which will be as follows: Chicago, \$20; Peoria, \$17; St. Louis, \$17; Denver, \$25. Tickets will be limited to return 30 days from date of sale, not to exceed Nov. 15. From June 1 to Oct. 15 the passenger rates to Omaha from all the principal cities and towns in the United States beyond the Western Passenger Association territory will be 80 per cent. of double the first-class fare. Tickets will be good to return until Nov. 15."

But I'm expecting (?) lower rates, for Mr. Whitcomb told the convention at Buffalo last summer, that if the Union would hold its next convention at Omaha during the time of holding the Trans-Mississippi Exposition, we should have "as low rates as to any place on earth."

We know that Mr. Whitcomb will do "his level best" for the comfort of those who attend the convention, and show us "the sights" on the Exposition grounds.

A prominent Western bee-keeper wrote me a few days

since that "the rate, however, cuts but a very small figure." If we poor bee-keepers were all rich like him it wouldn't, but this is only another evidence of the old saying, that localities differ.

It is probable that the convention will be held during the first part of October, and further notice of rates and time of meeting will be given when known. A. B. MASON, Sec.
 Sta. B, Toledo, Ohio, June 30.

Now that the place of meeting is settled upon, let all begin to make arrangements to be there, trying, if possible, to have even a larger attendance than at the World's Fair convention. Dr. Miller, who was then president, said that convention was too big for him to properly preside over. Now, the one whose duty it is to preside at Omaha is not one-tenth as big a man as Dr. Miller, and has to say "I don't know" ever so many more times than he does, and yet the present president hopes that there will be at least twice as many in attendance at Omaha as at the World's Fair convention. Not that he is a more capable presiding officer than Dr. Miller, but he would like the privilege of looking into the faces of 500 or 1,000 bee-keepers at one gathering. And when he can't handle the presiding part, he will call on several ex-presidents to help.

All can expect that the Secretary, Dr. Mason, will provide a great program. He knows how.

Southern California.—Prof. Cook has sent us the following paragraphs, dated June 23, from Los Angeles county:

We notice that some of the red-gums are just now coming into bloom. In the early morning these trees are noisy with the hum of bees, as they are beautiful with their clusters of bloom. We notice, also, that the peppers are crowded with bees all the day long.

Even here at my home the bees are getting considerable honey, despite the unprecedented drouth. I lookt in some hives a few days since, where the single tier of supers were well filled with fine honey, nearly all capt. It is to be said, however, that few localities in southern California secured as much rain as did this place the past season.

About Ramona and Julian—noted for their fine apples—in San Diego county were exceptions in all southern California this season. Each had copious rains, more than was needed. Thus in these localities bees are doing wonderfully well, and crops are exceptionally good. Our friend Taylor, ever alert for the worm, caught him in going to these favored regions with his bees, and is securing, as we learn, a fine crop of honey. A. J. Cook.

The Home Market for Honey.—Mr. F. L. Thompson, on page 419 of this number of the Bee Journal, gives a very interesting experience in attempting to sell honey in the home market. All are not cut out for salesmen, and evidently Mr. T. belongs to that number, tho he gave it a thorough trial, and is to be commended for the plucky way in which he did it.

Of course, selling honey from house to house is not a rapid way to acquire riches. Many can make four times as much at something else. But there are doubtless bee-keepers without number who can do well at selling their honey crop themselves in surrounding towns. Surely, there are many who would have done better, last year, had they disposed of their honey near home, rather than ship it to a distant overcrowded city market and take what the dealer was able to realize for them.

This question of profitably disposing of the honey crop is one that must ever be of great interest to the producers. Upon it depends their success more than upon any other one thing—aside from nectar in the flowers. But after the crop is secured, unless it finds a remunerative market, only loss and discouragement can result.

We have much faith in Mr. Thompson's suggestion of cooperation among bee-keepers. We believe that if a number of bee-keepers would combine in the marketing of their crops,

a much better net result could be secured. Each city should have in it, from Sept. 1 until April 1, a honey depot in charge of an able bee-keeper or two, whose business it should be to see that the retail groceries are supplied with honey, and that only pure honey is put on the market. The bee-keepers should in a way control the market—have a monopoly in the honey line, if you wish to call it that—and wholesale to the grocers all the honey that is sold in the town where they have their headquarters, so far as is possible for them to do.

We should like to see this plan tried first in a town of say 10,000 population. A city like Chicago would be almost too large to begin on.

Ship Surrendered to Bees.—This was not one of Dewey's or Sampson's squadron—theirs is not of the surrendering kind. A newspaper correspondent in Tacoma, Wash., reported that the bark Shirley, which has carried millions of feet of lumber on that coast, is now said to have aboard a small cargo of honey. Her owners recently decided to put her in the Klondike service, and Mr. L. B. Mitchell was sent to Quartermaster Harbor with men to get her ready for repairs. Mr. Mitchell says:

"We found that she had been taken possession of by honey-bees, and in going into her we found every passage and room was apparently full of bees. We shut the hatchway and thought we had them imprisoned, but we found a steady stream going and coming through the hole left for a stove-pipe in the cabin. We were on board 30 minutes, and in that time the column of bees continued to move, making a noise like escaping steam. We were unable to work on board until something should be done. We lowered into the hull a plank of burning cedar bark, and closed up everything. A great many of the bees were killed, but we were unable to go into the bark the next day. Some think she may contain a ton of honey, or even more."

Bees at the North Pole.—The man who gleanes the "Stray Straws" for Gleanings—why not call him the "Straw-carrier?"—finds in Le Rucher Belge that "the explorer Ejrind Asrup found many bees in latitude 83° north. He thinks they may be at the North Pole, as the remaining 7° would make no great change in flora. There's only three months summer; but as the sun doesn't set in that time it's as good as six months here, and plants develop with astonishing rapidity and vigor, and the flora is of extreme richness."

We wonder if some enterprising bee-supply dealer won't establish a branch house next door to the North Pole now. Talk about hardy bees—why not get a few queens from that semi-sunless land. They ought to be tough enough to extract sweetness from the "snow-ball" bush!

Honey as Food is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey among should-be consumers. The forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 30 cents; 50 for 50 cents; 100 for \$1.00; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

HON. EUGENE SECOR, of Wlunebago Co., Iowa, reported as follows, June 27:

"Basswood will open in about a week. But little honey has been stored so far."

MR. A. W. SMITH, of Sullivan Co., N. Y., wrote us June 23:

"The weather has been too wet and cold for the bees to get a large crop of white honey here."

REV. H. H. FLICK, of Lycoming Co., Pa., wrote us June 24:

"It is a poor season for bees here so far—cold and rainy, tho the weather is good to-day. We hope for a better honey-flow."

DR. A. B. MASON, of Lucas Co., Ohio, writing us June 30, reported:

"Sweet clover began blossoming a week ago, and the bees are quite busy. I've been so busy for a few days that I haven't lookt to see what the bees are accomplishing in honey yielding."

PROF. A. J. COOK, of Los Angeles Co., Calif., wrote us June 24:

"We have vacation now, and I am going to rest, as I need it. I shall work at institutes. Shall hold two in the region of Ramona, and hope to see bees and honey booming."

Prof. Cook is a very active man, and evidently does not believe in trying to rust out in the sunny clime of California. The world needs the busy workers—both men and bees.

HON. R. L. TAYLOR, in the Review, seems to have started in to reform the grammar used by some of the correspondents of bee-papers, and also that of the editors thereof. He will have a large job—and likely his trouble for his pains; and, judging from some of his "criticisms" so far, a lot of painful trouble (to him). We are perfectly willing that he shall waste all the space the Review will allow him, in trying to reform the language printed in the American Bee Journal. But lest he forget, and devote more time to criticising the literary than the aparian part of this journal, we will say that this is neither a grammar nor a rhetoric, but a paper devoted to telling in a simple, plain way how to keep bees.

By the way, as a criticism on Mr. Taylor's writing for the Review, we wish to say that we do not authorize the use of the letters "A. B. J." for "American Bee Journal" in public print. As we are the highest authority on this particular case, we would suggest that Mr. Taylor either discontinue referring to this paper as "A. B. J.," or else be consistent and use "A. B. K." for "American Bee-Keeper," "B. K. R." for "Bee-Keeper's Review," etc.

The Largest Apiary in England is claimed to be that of T. B. Blow & Co., at Welwyn, Herts, consisting of more than 200 colonies.—British Bee Journal.

Age of Hives.—I have hives that I made more than 30 years ago that have never needed repairs, except a second coat of paint.—C. Dadant, in Revue Internationale.

Wintering Without Pollen.—Gilbert Wintle had nine colonies of bees given him late in September—just the bees with no stores. He put the nine lots in three hives, either on foundation or empty combs, and fed up with sugar syrup.

They came through in fine condition, and he thinks it good proof that bees have no need of pollen for wintering, as the latter part of September was too late for gathering pollen.—Canadian Bee Journal.

The Yield of a Linden Tree is equal to that of a whole acre of buckwheat, according to A. Sonsiedsky, in Revue Internationale. Would York State men agree to that?

Improvement in Extractors.—Rambler, in Gleanings, has continued after a long vacation his series of rambles. He mentions an improvement in G. W. Brodbeck's extractor. There is a deep receptacle at the end for the wax and honey to collect, and this saves the honey from being so much colored by the heat.

The Mosquito-Hawk and Bees.—This insect, which is also called dragon-fly and darning-needle, has been accused of destroying bees. A. J. Wright says, in Gleanings, that whatever it may be in other localities, he considers it a friend. In the day-time it makes havoc among gnats and mosquitoes, and at night it devours bee-moths.

Honey-Vinegar.—Boil 25 quarts of rain-water with two quarts of honey, skimming frequently for about an hour. When cool put into a 30-quart vessel, and fill full with strong vinegar. Put it in a warm place with the bung open, to ferment for 9 or 10 weeks. If too weak, add strong vinegar. Draw off half to bottle, then fill afresh with honey-water.

Wintering Bees in Cellars.—Henry Alley doesn't believe in keeping the temperature of the cellar continuously as high as 40° to 50°—too much hot-bed plan. His bees were confined from the middle of December till March 9, the temperature varying with the weather. When at zero outside the thermometer stood at 20° inside, and it never went above 45°. His bees came through in fine condition.—Gleanings.

Transferring.—The question being asked in Canadian Bee Journal as to the best time and way to transfer from box hives, all agree upon the time of fruit-bloom except A. D. Allan, who replies as follows:

"Wait till they are strong, nearly ready to swarm. Operate as follows: Reverse the hive and set an empty box on it, drive the bees up, divide about equal, put one part with queen in the new hive on the old stand, the other part put back in the old hive and move to a new stand. In 21 days repeat the operation, only put all the bees in the new hive, set the old hive at the side of your apiary until the bees have removed the honey, then cut out the old combs and put them into the wax-extractor."

Eight or Ten Frames—Which?—Editor Root has been advocating large brood-nests, and a correspondent rather accuses him of inconsistency in advocating 8-frame hives. Mr. Root replies:

"I do not know but I am like Dr. Miller—I don't know which is better—the 8 or 10-frame. I know this: That the 8-frame with single brood-chamber is not nearly large enough. I am pretty well satisfied, also, that the 10-frame is too small. I am not sure that a 12-frame Langstroth brood-nest is large enough. An 8-frame body is plenty heavy enough to lift when it is full of honey; and I am almost inclined to believe that two 8's—that is, 16 frames in all—are none too big for a brood-nest; but 10-frames would be too large. No, I prefer an 8-frame to a 10-frame; and I think I should prefer a 12-frame to a 10-frame; but if a 12-frame is too small, then I should rather have two 8-frames."

Leveling Unfinished Sections.—C. Theilmann gives an interesting bit of history regarding B. Taylor's comb-leveler, in Gleanings. Mr. Taylor opposed the use of drawn combs, but after seeing what beautiful sections Mr. Theilmann got by means of them, he repented, and the next year he brought to the convention his comb-leveler. Mr. Theilmann says the whole secret of getting as nice sections of honey from these drawn combs as from foundation is in getting rid of "the big rim around the cells, which is generally soiled more or less; and if not taken away, the bees will use part of it for capping the honey, which gives it a yellow tint." Editor Root—who has stoutly maintained that it was necessary to reduce the depth of the cells to $\frac{3}{8}$ -inch—now says: "I think we can assume that the whole purpose of leveling, as was once advocated by the late B. Taylor, was to get rid of the thickened, soiled edges of the cells as they are ordinarily left by the bees."

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles:

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This will be a series of practical articles that bee-keepers of the United States will not want to miss reading. They are copyrighted by Mr. White, and will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

**The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it**

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Slo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan. Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan. Field | 14 Muth's Practical Hints to Bee-keepers |
| 6 Our Poultry Doctor—Fan. Field | 15 20 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse Book | |

For Sending TWO New 40-cent Subscribers:

- | | |
|---|---|
| 1 Potato Culture—by T. B. Terry | 7 Hutchinson's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Blencn-Kultur—German |
| 4 Dr. Tinker's Bee-Keeping for Profit | 10 Bees and Honey—160 pages—by Newman |
| 5 40 "Honey as Food" Pamphlets | 11 People's Atlas of the World |
| 6 Winter Problem in Bee-Keeping—by Pierce | |

Please remember that all the above premiums are offered **only** to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Southern Home of the Honey-Bee

Will continue to rear none but the **BEST QUEENS**. Untested, 50 cents; Tested, \$1.00.
GEO. W. HUFSTEDLER, Prop.,
 President of National Queen-Breeders' Union.
 24Atf **Beeville, Texas.**

Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases—everything used by bee-keepers. Orders filled promptly. Send for catalog. **MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO.**, Nicollet Island, Minneapolis, Minn.

At Buffalo, N.Y., July 14-17, the Nickel Plate Road will sell tickets at rates lower than via other lines. The accommodations are strictly first-class in every particular, and it will be to your advantage to communicate with the General Agent, 111 Adams Street, Chicago, before purchasing your ticket. Telephone Main 3389. (28)

In the multitude of counsellors there is safety.—Prov. 11-14.

The Queen and Her Mating.

Query 75.—Under favorable conditions—
 1. How many days will elapse after the queen hatches from the cell before she takes her flight?
 2. How many days after hatching before she commences laying?
 3. Is it true that the mating of the queen and drone always causes the death of the latter?
 —Utah.

Emerson T. Abbott—1 do not know.
 J. A. Stone—1. From 1 to 5. 2. From 8 to 15. 3. Yes.
 J. A. Green—1. 6 or 7 days. 2. 10 days. 3. I do not know.

Dr. C. C. Miller—1. 5 days or more. 2. Something like 10. 3. Probably.
 Chas. Dadant & Son—1. About 6 days, never short of 5 days. 2. 2 to 4. 3. Yes.

Mrs. J. M. Null—1. 5 to 11 days. 2. 10 to 16 days. 3. Death is a physical necessity.
 R. L. Taylor—1. From 4 to 8 days. 2. From 6 to 15. 3. I think so, of necessity.

Dr. J. P. H. Brown—1. Usually in 4 or 5 days. 2. On an average, in 10 days. 3. 'Tis true, I believe.

Prof. A. J. Cook—1. 3 to 6—usually 5, with suitable weather. 2. 3; occasionally 2. 3. Yes.
 J. M. Hambaugh—1. From 3 to 7 days. 2. 6 to 10. 3. Yes, according to our best authority.

E. France—1. I don't know. 2. A week to 10 days. 3. I don't know, and don't think any one knows.
 O. O. Poppleton—1. From 6 to 9 days usually; but there are many exceptions. 2. Add a couple of days to above figures. 3. I don't know, but think yes.

D. W. Heise—1 and 2. That will vary greatly, depending much upon the weather, and other conditions. 3. I give it up; ask them that know.
 W. G. Larrabee—1 and 2. I never saw a queen take her flight, but she will commence laying from 3 days to a week after hatching. 3. I don't know.

J. E. Pond—1. Usually 2 or 3 days. 2. 5 or 6 days. 3. Yes, the drone loses the male organ at the time of mating, and death, as a rule, immediately results.

Mrs. L. Harrison—1 and 2. It will depend upon the weather as to the time of flights and the laying of the queen. 3. I don't know. What is the difference, anyhow, whether he lives or dies?

C. H. Dibbern—1. From 12 to 16 days. 2. I am not sure about this, but I think the time varies somewhat. 3. That is the common understanding, but there may be exceptions.

E. S. Lovesy—1. About 5 days. 2. 8 to 9 days. 3. I would very much like to know. I have many times seen a young queen come out of the hive with the bees, circle in the air, and usually return and enter the hive in about 10

Sweet Clover

And Several Other Clover Seeds.

(31)

minutes. I have seen her settle with the bees as if tired, and I have seen them hived as a swarm, but they always rush out and enter their own hive. But I have never seen anything that would shed any light on this question.

Dr. A. B. Mason—1. The time varies. I have had them fly in 5 days, and also not for 8 days, under the conditions named. 2. From 2 to 4 days. 3. I don't know, but our leading writers say it does.

Eugene Secor—1. Prof. Cook says 5 to 6 days; Cheshire, 6; Cowan, 3 to 5; Langstroth-Dadant, 6 to 7; Root, 5 to 7. 2. Prof. Cook, 2 to 3 days; Cheshire, 2; Cowan, 2; Langstroth-Dadant, 2; Root, 2. 3. I don't know.

P. H. Elwood—1. Cowan says from 3 to 5; Cheshire says 6 days. 2. Cheshire says 2 days. We believe it takes with us nearly 10 days on the average, from hatching to laying. 3. I do not know that it ever causes death, but suppose it is so.

R. C. Aikin—I believe 3 to 4. 2. All favorable, 9; some 8; some 10 to 12. 3. I never saw the mating act, but have seen a number of queens evidently very soon after mating, a string trailing after them $\frac{1}{4}$ to $\frac{1}{2}$ inch long—supposed to be a part of the drone.

Rev. M. Mahn—1. Usually about 5, if the circumstances are very favorable. 2. Under very favorable circumstances in 7 days, but that is much under the average. 3. I suppose it is. I discovered in my boyhood that the extrusion of the male organs produced instant death.

G. M. Doolittle—1. If the bees allow her to emerge (not hatch; the larvæ hatch) from the cell as soon as mature, from 5 to 7, as a rule. If held in the cell by the bees, then from 24 to 72 hours after allowed her liberty. 2. A queen commences laying about 2 days after successfully meeting the drone. 3. Gently press a "ripe" drone till the sex-organs protrude, and the drone expires at once. See?

G. W. Demaree—1. It depends upon the weather, and to some extent on the time of year. About 18 years ago I spent nearly a whole breeding season to test all these questions, and have observed closely ever since. To put it definitely, she will commence her wedding flights—she makes not less than three—on the evening of the 7th day of her age. 2. She begins to lay in 2 or 3 days. 3. I believe it is.

**Report from an Old Bee-Keeper.**

I have kept bees for 50 years, and have experimented in several ways to get the most honey. Some 14 or 15 years ago I got the Simplicity hive. I have lots of neighbors that are wondering how I get so much nice comb honey. They can't do it with their hives and supers. I got more than 2,000 pounds of as fine comb honey last year as could be wisht for, from 14 colonies. My hives are all alike, each super holding 56 sections. I just pile up in the spring say 112 sections at first, in April; in May I put on one more super, and when the bees get

ITALIAN BEES AND QUEENS FOR SALE...

Queens, \$1.00; after August, 50 cents. Mrs. A. A. SIMPSON, Swarts, Pa. 27A6t
Please mention Bee Journal when writing.

to work on it I put on one more, so I give all the room they can fill, and keep ahead of them all summer. I got from 200 pounds down to 56 from them last year, according to the size of colony. Last year I got from 50 to 100 pounds each from the new swarms, all from natural swarming. Give me natural swarming, by all means. I now have 24 good colonies, with over 2,800 sections on them. I have lost two swarms.

E. D. BACON.

Shelby Co., Ill., June 25.

Very Little Honey So Far.

Bees are strong, but no swarms, and very little honey yet, tho plenty of bloom. Red clover seems to be the only thing that will furnish honey, but the bloom is so deep that it is hard for the bees to work. ALBERT HOLLADAY.

Clinton Co., Ind., June 22.

Threatened with Foul Brood.

My 27 colonies are in fine condition at present, but as foul brood has gotten into an apiary 3 1/2 miles south of here, it is hard to tell how things will come out.

Is there any law in Michigan to compel the apiarist to try to get rid of the disease? The disease was brought about through his carelessness.

I. D. BARTLETT.

Charlevoix Co., Mich., June 27.

[Yes, Michigan has an old law on foul brood, which was published in the Bee Journal last year. Some suggestion was made at the last Michigan State convention looking toward its revision, we believe.—EDITOR.]

Wet Spring, Sweet Clover, Etc.

I had intended to send a few apiarian notes some time before this, but the weather was so very hard on the bees that it took all my spare time to give them a little courage and consolation in order to keep them from deserting their hives. The spring was very wet, and bees could not make a living in this part of the country before the first of June; since then they have been working on white and Alsike clover enough to breed up well. However, they are now ready for that flow we long have waited for, but it has not yet appeared.

My experience with sweet clover is just opposite to some that are having a world of trouble trying to get rid of that "notorious weed." The spring of 1896 I got some seed from a reliable source, sowed some of it on wheat ground, the same as red clover seed, and the rest I scattered around in fence corners, on good ground, where I was sure it would grow. Of that lot of seed I found one small plant. I staked it up so nothing could hurt it, and the second year it grew to about 14 inches in height and bloomed some, but I never saw a single bee near it. That stalk was in a fence-corner in the best of soil. This spring there is not a plant to be found in that vicinity.

Last spring I gave it another trial, sowing some with oats on good, mellow ground; some along a spring run (on its banks, where there was wash ground,) but so far I have been unable to find a single plant, and I came to the conclusion that I could get along very well without sweet clover.

I had a very curious experience with a

Two Special Offers.

As explained in former ads., publishers can afford to put forth extra efforts in securing new subscribers; as the majority remain, once they become subscribers to a good journal. It is from this point of view that I make the following offers:

Offer No. 1.

To any one not a subscriber to the Review who will send me \$2.00, I will send the Review one year and 1,000 strictly first-class, snow-white one-piece Sections. After accepting this offer if any one wishes to buy more sections, I will furnish them at the following prices: 1,000, \$2.75; 2,000 for \$5.25; 3,000 for \$7.50; 5,000 for \$12.00. Sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Medina, O.; Jamestown, N.Y.; Higginsville, Mo., or Omaha, Neb.

Offer No. 2.

To any one not a subscriber to the Review who will send me \$1.50, I will send the Review one year and a fine, TESTED Italian Queen. Purchasers may have either the bright, golden strain, or the dark leather-colored reared from imported mothers. After accepting this offer, if any one wishes more queens, they will be furnished at the following prices: Single queen, 90 cts.; 3 for \$2.65; 6 for \$5.00; 12 or more at 75c each. Orders will be filled in rotation, and safe arrival guaranteed.

If you are not acquainted with the Review, and wish to see it before subscribing, send 10 cents for three late but different issues, and the 10 cents may apply on any subscription sent in during 1898.

W. Z. HUTCHINSON,
FLINT, MICH.

Van Buren Street Passenger Station, Chicago. Tel. Main 3389. (41-26-2

colony of my bees this spring. Along the first of June I opened hive No. 38 to see how they were getting along. Well, I found two capt queen-cells and some not yet capt. Thinking they were about ready to swarm, I closed the hive and gave orders to watch for a swarm the next day from No. 38. The next day came, but the swarm did not. The second day and no swarm. So I waited five days and not an (external) sign of a swarm. Then I opened the hive again, and on the first frame I found a ball of bees. Says I to myself: "You are going to supersede your queen, and are killing your mother." So thinks I, "I'll save her"—a young tested queen one year old. I caught hold of her wing, and, to my astonishment, it was a young queen instead of the old one. Then the other frames were examined and the old queen was found to be all right.

The virgin that had been balled hatch out of one of the cells that were found capt on the first examination. A few days later another virgin was found dead in front of that hive. Now, why did they allow those cells to hatch if they did not want any of the queens? The weather was warm and fair at that time. Or, why did they not swarm?

PAUL WHITEBREAD.

Luzerne Co., Pa., June 22.

The Foul Brood Inspector.

On page 332 I askt Mr. Lovesy, of Utah, why Utah's bee-keepers can't guard themselves against foul brood as well as an inspector? In reply I am askt how the bee-keepers could interfere with the bees of any person without an inspector who shall visit every apiary in his district at least once a year to eradicate all foul brood and kindred disease.

Mr. L. says whether this is satisfactory to me or not he fails to see anything so very monstrous in this law. Don't be mistaken. I want to encourage and protect the bee-industry, like you, but we differ in the means. I want a law against all that's foul—not foul brood only; but I don't want so many inspectors. There are more officers than bee-hives already; decrease them and increase the bee-hives—that makes less burden and more honey, and therefore it is better.

About foul brood, every bee-keeper can learn as much as an inspector. Let each one learn by distributing good periodicals like the American Bee Journal; teach him to observe, and to act, and by law compel him to restrain from every harm towards the community. By creating inspectors you make everybody pay for a few neglectful persons. Make these persons pay for their neglect—that's enough.

If you have fire on your place you will have to guard, and not an inspector; and if you do harm to your neighbors you must bear the consequences. Every person is cautioned under the penalties of law to watch his apiary, that disastrous thing called foul brood, that destroys so many colonies only by neglect. This is a correct way to protect the bee-industry.

An inspector visiting every hive at least once a year is a monstrous thing. I am going to show you it is. You know small-pox, cattle-fever, hog-cholera, and San Jose scale are things as bad as a mad dog. Have you an inspector visiting at least once every year your family to find out if there is small-pox, or visit-

ing your stables to find out about cattle-fever, visiting your hog-pens to find out about cholera; visiting your orchard to find out about the pernicious scale, or visiting your dog about his madness? Oh, no! If you would need an inspector for this you would better have no children, no cows, no hogs, no fruit-trees, and no dog. If you need an inspector for foul brood you would better have no bees. That inspector can't help you among so many—help yourself! This is and ought to be the first axiom. The inspector might visit you one week, and the disease the next, therefore such an inspection without a good education is monstrous. Anyhow, Utah's foul brood law can be dissatisfactory only for those who are taxt for it. In this respect I don't care for it as I would't care for it if there would be a face in Utah with an unusually long-pointed nose. But if the man with that nose would say: "There is a nose finer than any nose in Wisconsin;" then he must allow being told, "Your nose is very satisfactory, but you could do with half an inch less."

You criticised Wisconsin's foul brood law and called yours better because it provides an inspector for every district. Now, let me tell you, you might do better yet. Put an inspector on every bee-hive. That's probably an advantage over Wisconsin. But I think all these inspections could be done with half an inch less.

J. VOLKERT.

Chesterfield Co., Va.

[Mr. Volkert's ideas may be very good in theory, but they are quite impractical at the present time. It is one thing to say that all bee-keepers should be as well-informed on the subject of foul brood and its treatment as is Mr. McEvoy, the foul brood inspector of Ontario, Canada, but it would be quite another matter to do the educating or get the rank and file to take the interest in it that they should. We must take things as we find them, and then gradually improve them, but not try to do the impossible at first.—EDITOR.]

A Young Bee-Keepers' Experience.

I have but 5 colonies now, numbered 1, 2, 3, 4, 5—1 and 5 in 10-frame hives, and 2, 3 and 4 in 8-frame. No. 5 is a swarm that came out May 28. No. 4 was a last year's late swarm; 1, 2 and 3 are 2 years old.

Last year my bees did no good. I had 5 colonies, and got only about 75 pounds of honey, and one swarm; and all the bee-men say that the bees would not work last year on the little white clover, while we had a very good crop of it; consequently there had to be a great deal of falling.

This year the prospect was better at the start, but got nipt in the bud. In March we had very fine weather, and the brood-combs were well-filled with brood, but there were few bees. In April we had some very cold weather, and the bees could not protect the young bees and larvae, consequently it died in the cell except in the strong colonies. The weak ones have not yet recovered from the setback.

Another thing I do not understand: I have sat at my hives for two hours at a time watching for drones, and have taken out all the frames, and I do not

"A Queenly Deceiver."

One Fare for the Round Trip

To Buffalo, N. Y., and return, account Baptist Young People's Union meeting, July 14-17. Rates lower than via other lines. For full information call on or address J. Y. Calaban, General Agent, 111 Adams Street, Chicago. Telephone 3389 Main. (30)

think I have seen a half dozen drones in my apiary. June 22 I weighed my bees, and No. 1 was 45 pounds net, or deducting the weight of the hive; No. 2, 15 pounds; No. 3, 11 pounds; No. 4, 24; and No. 5, only 25 days old, weighed 56 pounds net, or 88 pounds gross; this is over 2½ pounds per day gain of honey, and yet none of my bees are working in the supers yet.

I gave them all good, clean supers, with new sections and starters. They all seem to be very busy, working nicely, but are neither swarming nor putting honey into the supers.

I am young in the bee-business, and I am going to experiment some on those two weak colonies. If I lose them it will not be much loss, and if I gain it will be so much ahead.

I was told by old bee-men that I could not rear bees on sugar, but all the same I did. I caught a nice swarm some years ago in August, about the 20th, and on the first of November they had about 3 pounds of honey and about a half gallon of bees. I fed them sugar, about 25 pounds, during the fall and spring, and the same colony gave me in return for my kindness 24 pounds of section honey, and 2 good swarms, the next year.

On page 369, is given cold water vs. hot for bee-stings. A few years ago I undertook to capture a runaway swarm of bees, and did capture them. I got the bees to settle all right, but when I went to hive them it seemed to me they just all let go of the cluster and began to sting me. I did not put on any protection, and I was stung all over the hands, arms, legs, face and neck, and then they were not satisfied, but they crawled down my back and stung my body. In trying to get away from them I got one hand in the mud, and it seemed to ease me, so that I just plastered myself with a thin mud, of clay and water, and there was scarcely any swelling, and it did not make me the least bit sick or sore. Since then this is the only remedy I have for bee-stings.

S. R. GUSEMAN.

Preston Co., W. Va., June 26.

Rendering Combs in Iron Kettles.

I send you sample of wax which has been boiled in an iron kettle, and I will tell the best I can how it was made. I first put the combs into the kettle and then put wire-cloth over them and weighed them down to keep them in the bottom of the kettle, and then filled it with soft water. I do not boil any after all the combs are melted. I took a dipping-board and dipt the wax out of the kettle while hot, the same as dipping for foundation sheets. Allowing wax to cool in the kettle will darken it.

REUBEN PALMER.

Jefferson Co., Mo.

[The sample of sheeted wax has a beautiful golden color, and is quite clean and nice. From all that has been said against rendering combs in iron kettles, one would hardly believe that the sample sent was so rendered. But it may be all the trouble comes from allowing the wax to cool in the kettle, and thus darken it.—EDITOR.]

Basswood the Only Hope.

Bees have not done much since locust bloom, when they commenced working in the supers. White clover is in bloom,

but not as profusely as last year, and I think bees do not gather so much honey from it as last year. We can only hope yet for basswood, which is going to bloom soon. AUGUST BUCHHAGEN.
Jefferson Co., Ohio, June 27.

Everything Looks Favorable.

My 350 colonies of bees are in fine condition, working now on white clover. Basswood will begin to bloom about July 1. At present everything looks favorable for a large honey crop.

A. G. WILSON.

Vernon Co., Wis., June 27.

Please Send Us the Names of your neighbors who keep bees, and we will send them sample copies of the BEE JOURNAL. Then please call upon them and get them to subscribe with you, and secure some of the premiums we offer.

Basswood Honey FOR SALE

We have a limited number of barrels of very best Basswood Extracted Honey, weighing NET about 280 lbs. which we are offering at 6 cents per lb. f. o. b. Chicago. Do you want a barrel or so of it? If so, address, with the cash,

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, June 18.—Not any new honey here, and the old stock is about exhausted. Market values about as last quoted for what little is being done. R. A. BURNETT & Co.

Kansas City, June 21.—We have several shipments of new comb honey from Florida, the first to our market this season. The demand is fair at 11 to 12c. The demand for extracted will be light until September. C. C. OLEMONS & Co.

New York, June 20.—Comb honey: We closed out all of our old crop some time ago. We have received several lots of new crop from the South, good. No. 1 white, which sells readily at 11c per pound.

Extracted: Receipts of new crop from the South are large. We quote: Common, 48 to 50c a gallon; good, 52 to 55c a gallon; choice, 5 to 5½c pound. Demand is good, especially for the better grades. Beeswax remains firm at 28 to 29c. HILDRETH BROS. & SEGELKEN.

Cincinnati, June 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3¼ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow.

CHAS. F. MUTH & SON.

Boston, June 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand.

BLAKE, SCOTT & LEE.

Cleveland, June 9.—Fancy white, 12 to 12½c.; No. 1, 11c.; No. 1 amber, 9 to 10c.; buckwheat, 8c. Extracted, white, 6c.; amber, 4 to 5c. A. B. WILLIAMS & Co.

San Francisco, June 8.—White comb, 8½ to 10c.; amber, 6½ to 7½c. Extracted, white, 5¼@6c.; light amber, 4¼ to 5¼c. Beeswax, 23@25c.

Not much now coming forward from any quarter. Supplies will doubtless be light throughout the season, admitting of little other than small local trade. Former quotations remain in force, with tendency on best qualities to higher figures.

Detroit, June 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring.

M. H. HUNT.

Minneapolis, June 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c.; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging. S. H. HALL & Co.

Indianapolis, June 9.—Fancy white 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. WALTER S. POWDER.

Milwaukee, June 9.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents; No. 1 8@10c.; amber, 8@8½c.; dark, 7@7½c. White extracted in barrels and kegs, 5¼@6c.; amber, 5@5½c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. A. V. BISHOP & Co.

Buffalo, June 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & Co.

St. Louis, June 10.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. WESTCOTT COM. Co.

 Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.

If you once try it you will have no other. Samples furnished FREE. Large illustrated Catalog of all kinds of

PROFITABLE BEE-KEEPING,

—WITH—
HINTS TO BEGINNERS,

—BY—
C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 2. — BEES.

As it is necessary to the successful management of the apiary that the occupants of the hives, their ways, wants, and peculiarities should be understood, it is advisable that we should now give our attention to the bees.

In every colony of bees, whether it be located in a skep, the hollow of a tree, or in a modern hive, there will be found at some time of the year three kinds of bees—queen, drones, and workers. It is only, however, during the summer that the three kinds are found at the same time in any hive, for only when honey is being brought into the hive freely are drones brought into existence, or being in existence are allowed to remain alive.

THE QUEEN.

The queen, as the most important bee in the hive, first claims our attention. She is the egg-layer, and as such is the mother of the bees in the hive, whether they are workers, drones or queens. Only one queen is, under ordinary circumstances, found in a hive, but occasionally two—mother and daughter—are for a time living together. The queen's sole duty being to lay eggs, she has no other cares to claim her attention, in fact she does not even attend to her own food supply. The nourishment needed to keep up the extraordinary egg-laying power she possesses, is supplied by the worker-bees which are for the first fortnight of their existence what may be termed nurse-bees. If a comb be taken out of a movable-comb hive quietly, and without disturbing the bees, the queen may be seen surrounded by a cluster of workers. This interesting spectacle has given rise to the idea that the queen, as such, is in a position of authority, and is being attended by her respectful followers. This is far from the truth of the matter.

A queen has been known to lay more than her own weight in eggs in 24 hours; and as this work, and the taking and digesting of food could not be carried on by the queen, the latter important function is discharged by the workers—the nurse-bees—that are ever ready to supply her wants with food that has already undergone the necessary digestive processes in their bodies. Thus it is that the queen is enabled to do that enormous amount of egg-laying which we know she

performs. The eggs that the queen lays are fertilized and unfertilized. The former, if placed in the small worker-cells, produce in 21 days a worker or immature female; or if placed in a queen-cell they produce a fully-developed queen in 16 days. Unfertilized eggs deposited in the drone-cells produce drones in 25 days.

The remarkable fact that the same egg may under altered circumstances produce either workers or drones proves of great value, for if the queen should be lost or killed during the summer while there are such eggs in the hive, the bees quickly set to work to produce from them queens. This they do by cutting down the cell walls around them, and giving the grubs a food greater in quantity and richer in nitrogen; that is, it contains a greater proportion of pollen than the ordinary bee-food.

The number of eggs laid daily varies with the season and the income of food; but even then depends almost entirely upon the quality of the queen. Early in the new year small patches of brood will be found in the very center, the warmest part of the hive, giving evidence that only a few eggs are laid daily. Subsequently, as prospects brighten the queen increases the number of eggs laid daily until, during the summer, when there is the greatest income of honey, and consequently the greatest inducement to the queen to put forth her energies, she lays over 2,000 eggs a day.

Her length of life depends upon surrounding circumstances. The bees themselves re-queen their hives when through feebleness or otherwise of the queen, they deem a successor necessary. The bee-keeper who has a desire to make bee-keeping a really profitable occupation for spare

DRONE

QUEEN

WORKER

hours, will see that the length of life of a queen is determined by her usefulness, which means that as soon as, from an egg-laying point of view, she becomes unprofitable, she must make way for a successor.

The queen mates with the drone, or male bee, only once during her existence, generally before she is a week old, and then she does not again leave the hive except with a swarm, for the rest of her life.

As the result in honey returns depends upon the strength of the colony at the commencement of the honey-flow, the bee-keeper must urge on the queen to lay eggs in greater number early in the season. By so doing he will obtain strong colonies earlier, but he will much quicker wear out the queens. It is generally believed that queens are at their best in their second season; therefore, queens bred in 1897 will be of the greatest service in 1898. Consequently all colonies should be headed as far as possible each year with queens in their second season.

THE DRONE.

The drones are the large, bulky and noisy humming bees that appear about April, earlier or later according to the season. When drones appear swarming-time is at hand. But no

bee-keeper with an eye to profit will allow unlimited swarming; in fact, he will endeavor to prevent swarming altogether, nor will he allow the over-production of drones. The drones have apparently only one object in life, and short work is made of them by the workers at the close of the honey-flow, or when there is, through bad weather, a probability of stores running short. They are then turned out to die, so that the remaining part of the community may remain alive and continue the life of the colony. The length of life of the drones is very uncertain, but it really only extends through the season of plenty. The presence of drones in any hive after the honey-flow has closed, while those of other colonies have been massacred, is usually a sign of queenlessness. If a fertile queen be introduced, the bees quickly settle down to the work of turning out of the hive the drones that are then left.

THE WORKER.

Workers, the smallest of the three kinds of bees found in the hive, are, as their name indicates, the bees that do the work of the hive. They act as nurse-bees in preparing and administering food to the queen and grubs; then they gather honey and pollen, secrete wax, build combs, and carry on all the other little duties that fall to workers in such a well-arranged hive of industry, until worn out, as they usually are at the end of a few weeks' work. If it were not that the life of a worker-bee was short, there would be enormous populations, far beyond the capacity of modern hives. The length of life of a worker-bee is determined by the amount of work it performs. Those brought into existence, say in May, have before them a period of the greatest activity, and consequently their lives are short, only six weeks at the most; while those hatched in September, having little work to do, may get through the winter, only to be quickly worn out with the hard work that then falls to their lot. The average length of life of a worker-bee is said to be 46 days. Quite recently a noted American bee-keeper, who has been carefully testing the matter, finds the average length of life to be 47 days. This shows that those who gave the former number evidently gave considerable and painstaking attention to the solving of such an interesting question.

LAYING WORKERS.

Occasionally when a queen is lost or killed a worker develops the power of egg-laying, but the eggs only produce drones. The presence of a laying worker is known by the irregular manner in which the eggs are deposited, and later on by the bulky and protruding cappings which are the characteristic covering of drone-brood.

As laying workers are not only useless, but a nuisance in an apiary, they should be got rid of as soon as their presence in the hive is known. The introduction of a fertile queen will have the desired effect, as bees do not tolerate a laying worker when they have a fertile or ordinary laying queen; or without the introduction of a queen, the hive may be freed of the laying worker by taking it some distance from its stand and shaking all the bees off the combs. A laying worker only being found in queenless colonies, the bees would be all adults, and would therefore at once fly to their own stand; but not so the laying worker, as it is supposed that she obtains this extraordinary power through having been bred near the queen-cells, and received some of the royal jelly. Be this as it may, this bee is not accustomed to flying abroad, and consequently will not return to the hive on the old stand; and if should endeavor to enter another hive it will at once be killed.

VARIETIES.

In addition to the well-known English bee there are other races that have been imported with a view to improving our own bee and establishing a better strain for general purposes. The foreign races that have most generally been imported are Ligurian, Carniolan and Cyprian.

The Ligurian, or Italian bee, is a handsome bee, having yellow bands across the abdomen, three being distinctly marked. In America many bee-masters have produced by selection and propagated a strain of Ligurian showing five yellow bands, but the majority of reports on this production are by no means in its favor. In England the Ligurian is favored, but tho the queens are more prolific than the English, and the bees better workers, this race can only be used for the production of extracted honey, as the workers cap the honey-cells so that the comb presents a damp and unattractive appearance.

The Carniolan, from southwest Austria, is a silver-banded bee, and in appearance most nearly approaches the English, but the queens are wonderfully prolific, and the bees good workers. Still, tho such bees on account of these two qualities, are apparently desirable, they are inveterate swarmers, a colony sending out sometimes swarm after swarm until it is only the size of a small cast itself. This swarming is a most

undesirable trait, and one that bee-keepers are anxious to control; therefore, the keeping of this race has by no means become general.

The Cyprian is the handsomest bee known, being a little like an insect of gold. It is, as may be inferred from its name, imported from the island of Cyprus. I have had these bees in my apiary at a time when they were really golden bees, the price of the queens being 22s., but their stay with me was of short duration. At times they were as harmless as flies, and could be manipulated without either veil or smoke, but on other occasions they were veritable demons, and not to be subdued. At stinging, these bees can, in the words of "Brother Jonathan," "lick creation." Such vicious bees are best left alone, or, at any rate, by any but the most expert in bee-management. It is stated that one colony of Cyprians owned by an American bee-keeper stored in one season 1,000 pounds of honey. It is, however, certain that if the wonderful egg-laying power of the queen be properly directed, a truly immense population might be obtained for the honey-flow, and an abnormal quantity of honey stored. One colony of Cyprians, in my apiary several years ago, was expected to give over a hundred pounds of honey, but when it was taken to pieces (a task I never desire to repeat) only about a dozen pounds of honey were taken. The honey gathered by this colony had been used in feeding the grubs, and to such an extent was breeding carried that when this examination was made the 31 standard frames in the three stories of which the hive was composed, were almost entirely sheets of brood. Other colonies then had little brood, and many full supers.

The Syrian and other Eastern races bear much the same character as the Cyprian, and have found little favor in this country. If any imported race is introduced into any apiary, it should be pure specimens of either the Ligurian or Carniolan, but as an all-round bee our English bee is not to be beaten.

[Continued next week.]

Prevention of Swarming and Grass Growing.

BY MRS. EFFIE BROWN.

Of late we see a great deal in the bee-papers about prevention of swarming and hive ventilation. Every one seems interested in the subject from the "Marengo medicine man" to the beginner, and as so many are talking about it I will tell how I manage my bees. I am not quite certain, but I think the Roots follow the same plan, to some extent. Probably many others do also.

Five years ago I partially gave up comb honey producing and began extracting, and from that time until now I have had but very few swarms that I did not expect and want. My hives are all 10-frame, and nearly all have cleats. I agree with Dr. Miller on the cleat question, and even if they are going out-of-date, I like them better than those having hand-holes. I am also a very "strong 10-frame man." I would rather have a 12 than an 8 frame hive.

Our last important honey-flow is from buckwheat, and when this begins to fail I see that every hive contains at least 6 frames sealed to the bottom-bar. Of course there will be some honey in the center combs also, and the more the better; but if the required 6 is not in each hive, I exchange the partly-filled combs for full ones from an extracting story. By doing this I never have to feed in the spring, and the colonies all build up very rapidly.

When there is brood in 8 frames, I raise the 2 middle ones to the upper story and fill both up with extracting-combs. As soon as the combs begin to look "frosty," I either put on another story or extract. Some colonies are used to build comb, and these are sometimes tiered up to five stories.

When the bees begin to get interested in clover, I raise the cover of the hive about $\frac{1}{2}$ of an inch at the back end, and put a stick under so as to keep it so. The cloth over the frames is also taken away at the same time. About the middle of July I raise it up a good inch, and tho some may doubt it, I can say I have never had any trouble with robber-bees except in case of queenless colonies. This is better, I think, than raising the hive on blocks, for it insures a freer circulation of air. I wouldn't think of opening my front door for cool air without opening the back door also. I have an idea that the bees can ripen their honey faster with both "doors" open. I know that my kitchen floor, that has just been scrubbed, dries faster with the wind blowing through the room. Then with plenty of ventilation the bees never cluster outside unless I forget to leave the cover up, and, when I do, I can send them all in to work again by raising it and puffing a little smoke among them.

THE WEEDS AND GRASS THAT ANNOY.

When I began with bees the weeds and grass used to annoy me so that I felt like setting the hives on top of the house. All around our house the ground is so rich that angle-worms have come to stay, and every spring my chickens make such holes hunting for them that it is impossible to run a lawn-mower. If I put my hives on plowed ground the weeds would grow. Now, I can almost build a house with a hammer and a screw-driver (if it is all cut out like hives are), but I can't handle a scythe without running the point into the ground, so I just couldn't keep the stuff down myself, and my husband and the hired men were always afraid to go near a bee-hive unless I first went and blocked the entrance.

I tried sawdust and chip-dirt, but with the wind and chickens neither would stay. But like a great many other difficulties I have met I kept at it till, unlike the ghost, it did down. Mr. Brown happened, one spring, to get a lot of cheap cull lumber for making fences, and among it were a good many boards a foot wide and over, and all about 16 feet long. I took some of these and laid them down "three abreast" until I had a "sidewalk" as long as my bees would need, each hive set in a row about 18 inches apart. The front end of the alighting-board rested on the edge of the "sidewalk," and the back end was raised up and a block put under to make it level. When the grass began to come up between the cracks, I turned the boards over, turning it all down under. With one of my little boys (the children are not afraid of the bees) at the opposite end I could turn the boards all over in a little while.

I am still using these boards, not having found anything better. They give a strip the whole length of a row of hives, and over 3 feet wide entirely free from weeds and grass. They make a very good alighting-board, and in swarming-time the clipped queens from the comb-honey hives can be found very easily.

Does All the Honey in a Foul-Broody Colony Contain the Disease-Germs?

BY HON. R. L. TAYLOR.

Two cases of foul brood were discovered during the season of 1896. These were treated as heretofore by putting the bees into clean hives furnished with foundation, and the diseased hives with their combs disinfected with heat. The treatment was completely successful, as has uniformly been the case heretofore. The two all-important considerations in the operation are that the management be so careful and guarded that no bees from the diseased colony be driven to other colonies, and that no bees from healthy colonies be permitted to visit the combs of the diseased colony.

The reason upon which this caution is founded is that the germs of the disease are liable to be carried from the diseased colony to healthy ones in its honey—at least it is the supposition that there is such liability. We know certainly that robber-bees, when engaged in robbing a diseased colony, carry the infection to their own hive. We are certain also that honey extracted from combs which have contained the diseased larvæ convey the disease to colonies that use it. But to have this effect it is not necessary to suppose that every cell of honey contains germs, and when we consider how small a proportion of the larvæ are freshly affected with the disease at any one time, and that the progress of the disease in a colony is generally quite slow, it is rational to suppose that but a small proportion of the cells of honey contains the germs. There would perhaps be an exception to this if a strong colony became badly affected with the disease towards fall, say in August, when its hive was well filled with brood, and when a good flow of honey occurred in September, for, in that case, in the ordinary course of things, as the dead matter of the larvæ dried down, the cells containing it would be filled with honey. It would seem inevitable, then, that a large proportion of the cells of honey should contain floating germs so soon as sufficient time were given to allow the honey to soften the dried matter. After this the cells containing affected honey may be largely increased in numbers by the removal of the honey from cell to cell as in the spring when brood-rearing is resumed.

Cowan, in his celebrated work, laid it down as a scientific fact that the germs of foul brood were not to be found in the honey. This conclusion was not accepted in this country because it was found that practically at least it was not true. I doubt if Cowan himself would deny that the germs could be mingled with honey by the hand of man, and if they could

then they also could in the ways I have hereinbefore indicated by the bees. With these exceptions was not Cowan correct?

This is a matter of considerable importance, because a true answer to the question would give us a pretty clear insight into the methods by which the disease in question may be disseminated. If Cowan is correct, with the limitations suggested, then the disease cannot be conveyed by germs floating in the air or carried about on the bodies of the bees, otherwise they must certainly be carried to the honey in open cells throughout the hive.

With these thoughts in mind I made an experiment with honey taken from one of the colonies operated on. The colony was quite badly affected, there being in the space occupied by the queen from one-fourth to one-third of the cells that contained dead brood. The honey was contained in the two outside combs of the upper section of the Heddon hive. The combs contained five or six pounds of honey, and had apparently never contained any brood. The honey was fed to a colony of moderate strength, and very short of stores, but actively engaged in the rearing of brood, by placing the combs in a story above the honey-board through which the bees came and carried the honey below until it was all gone, and evidently all, or nearly all, used in nourishing the growing larvæ.

In this experiment the thought was that if the honey contained the germs that fact would certainly be revealed by the appearance of the disease among the brood below, and that the continued absence of the disease would be pretty satisfactory evidence that that honey contained no germs, and, consequently, in so far as one experiment goes, that they are not carried about by the action of the air, nor upon the bodies of the bees. Several examinations were made of the colony during the latter part of the summer and early fall to discover the existence of foul brood, if such were the fact, but no trace of the disease was found.

If enough further experiments give the same results, a decided relief will often be experienced in dealing with the disease, as where there are considerable amounts of surplus honey above the honey-boards.

Continued observations have been made in the cases of two experiments which have been heretofore reported; one of these was the immediate introduction to a healthy colony of a queen taken from a colony so badly affected with foul brood as to be about worthless. Examinations the last season show that the colony to which the queen was introduced remained healthy, as had been anticipated from the fact that it had revealed no signs of disease the previous season. This seems to show pretty conclusively that a queen is not necessarily diseased herself, tho she has been for a long time in a badly diseased colony.

The other one was the case of a colony of which mention has been made several times heretofore, in which what to all appearance was foul brood showed itself without making apparent progress, disappearing altogether at times and reappearing again to the extent of a few cells only. During the last season it did not show itself in the colony at all. It would be of interest to know certainly whether this was a case of true foul brood, and if it reappears an effort will be made to have the point determined by a competent microscopist.—Review.

Apis Dorsata and Bee-Improvement.

BY W. A. VARIAN.

There has been much said for and against the government going to the expense of arrangements for the introduction of *Apis dorsata*. It seems to me that the coming occupation of Manila and the Philippine Islands by the United States may prove a good chance in this matter. If any one will look at the maps and descriptions given in Alfred R. Wallace's "Island Faunas and Floras," it will be found that these islands have almost the whole fauna and flora of the East Indies, part of that of China and Japan—"temperate Asia"—and part of that of Australia and the Pacific, thus being about the richest in this respect of any place on the globe.

I think it almost certain that there will be among the volunteer troops going there (who are not, it seems, likely to be workt to death) bee-keepers enough to make a pretty strong committee, who, with very little aid in the shape of material from the agricultural department, if the great bee, or a closely allied variety, inhabits the region, can test them there, and if they prove adapted to hiving, introduce them. There will be such chances in natural history out there that each regiment should have its Scientific Society, and the boys, in those cases where they have time before leaving San Francisco, should buy and carry along a small library of the latest works

on natural history and sciences. Garrison societies for special study of the particular branches can be afterwards formed when there.

IMPROVING OUR BEES.

There have been several methods and principles of selection for the improvement of the bee published since I began to read on the subject, but I do not think the simplest, most rapid and effective has been mentioned. That is, to require one-half of the apiary from the young queen of the best colony in the other half the year before, and repeat back. Each season is a double selection by the honey record of one-half of the apiary. Of course, it may be necessary to keep a few yellow out-cross queens in places where the wild stock is black.

A "Six-Year-Old" Tells Some Experiences.

BY OLIVER P. JOHNSON.

As I have had six years' experience as a local newspaper correspondent, with various other experiences, I will endeavor to "do a few" for the "tormentation" of the readers of the valuable Bee Journal. I am a natural-born lover of bees. I do not keep a very large apiary, just enough to be experimenting some in that line. My principal occupation is farming (tilling the soil), and as it is on the medium Iowa scale, one has not time to indulge very largely in apiculture.

When I was but a "kid" I would make daily visits to the old box-hives in my father's garden. Tho I was often advised to give them plenty of room, I would often venture too near and get a genuine reception, which, very often, would result as "Paddy O'Brien's Picnic."

But even this did not satisfy my desire. I continued to be inquisitive about the "critters," visiting the most learned bee-keepers near me, and asking all sorts of questions, some of which, no doubt, sounded very queer to them.

Through an immediate neighbor I received a copy of the Bee Journal, and thereupon subscribed for it, and the book "Bees and Honey," and since then I have learned many things in regard to bees, by reading them and everything else in that line that came to hand, and experimenting in their teachings.

I learned to do away with the box-hive by transferring to the movable-frame hive—one of my own make, which accidentally happened to be the same size as the original 8-frame Langstroth, but was so imperfect in its construction that it turned out to be a fraud, being more of an injury to the industry than anything else.

The hive I now use is the most substantial, and produces the best results of any that I have yet seen. It contains nine frames, and is both longer and deeper than the Langstroth. It is used and manufactured in the nearest apiary to me. I think that it was originated by one Beldin. The hive completed with foundation is worth \$2.50 or \$3.00. I thought it a little expensive for a novice, but have since discovered that the dearest is sometimes the cheapest.

A QUEEN-STINGING EXPERIENCE.

During the swarming season of 1897 an after-swarm issued, and desiring to return them Mr. B. O. Cook caught the queen and proceeded to press her to death with his thumb, whereupon the queen stung him in the hand, but it did not appear to be so severe as the sting of a worker. I mention this because I have read of some that claim queens will sting nothing but royalty, but perhaps the writer of the article I read accidentally inserted the word "queen," and really meant to say "drone!"

RHEUMATICS AND FORMIC ACID.

July 20, 1893, I was seized with a slight headache and other pains in all parts of my body. Thinking that I might feel relieved I went to the creek, took a bath, and came back completely exhausted. The next day found me no better—just able to be about.

The pain halted in my neck for a short time on the 23rd. In a week I was worse. I thought that I was getting the typhoid fever. I called the family physician, and after a careful examination he pronounced it acute rheumatism.

Pains would be in my neck, then in my shoulders; then a lively game of hide-and-go-seek about the hands and arms. The physician did me no good. Various patent medicines proved to be worthless. I heard that one might be cured by the sting of a bee, so I resolved to try. I would go to the hive-entrance and catch them and force them to sting me, but I could not feel the sting at all. Finally I gave it up.

Some days I would be bedfast. The affliction then would

be in one knee until it had swollen as full as the skin would hold. It would then pass instantaneously to the other knee, the swelling gradually following.

I continued to love the bees, and when I was able I would be examining some of them. I had a very quiet swarm that "knew me," and I thought they wouldn't sting, so without veil or smoker I opened the hive, and, in so doing, accidentally pressed one of them, which raised the scent usually accompanying the expulsion of formic acid. This enraged one of the "critters," which immediately rose up and proceeded to drive its awl into my face. (It is needless to say that I felt it.)

The rheumatic pains were then in my feet. In less than ten minutes the pain of the sting was in my feet also. (My feet are very large, consequently they can contain lots of pain.) I was on my back in the middle of the floor, and, "suffering Isaac!" such pains as I did have in those feet! I might have died, but I had so much pain that I couldn't. I took nothing to counteract the sting, but just let it take its course. In three hours the pains had all left. I was a new man, and the happiest fellow to be seen.

I have not had a rheumatic pain since, and hope that I never shall have.

COURSE TAKEN BY AN ABSCONDING SWARM.

I saw an article in the Bee Journal on absconding swarms, and why they "go out west." This was a fact which I had always observed when swarms escaped from my father's garden—they invariably flew west. My present location is in the edge of a 200-acre linden grove that might well be classed as a forest, it being quite aged, and containing very many large trees, hundreds of which are hollow. West of me, two miles, is a very large oak grove. A neighbor joins farms with me on the west. He has quite a number of colonies, and I believe that from 20 to 50 swarms escape from there every year. I have seen very many of them go. He will not sell them, and I have never seen one swarm that left in any other direction than west, tho some claim that they occasionally do.

Cedar Co., Iowa.

Rearing Early Queens—A Good Point.

BY C. P. DADANT.

I have received the following letter, with the request that I answer in the American Bee Journal:

"In 'Langstroth Revised' we are told (page 513) that in April queenless colonies should be given a frame of young brood to rear a new queen. We are told in another place that queenless bees will most likely select a larva three days old from which to rear a queen. In that case the bees will have a new queen in about 13 days from the time the frame is given. Even if the queen should be reared from the egg, is it not likely that the bees will have a virgin queen long before there will be any drones in the apiary to mate with her? Is it not likely that before there will be any drones we shall have some pretty old virgin queens on hand? Will these old virgins make as good queens as those reared later? I found one or two queenless colonies and hesitated about giving frames of brood for reasons above indicated, preferring to send South for queens.—EDWIN BEVINS."

There is certainly a very good point raised by Mr. Bevins. We must say that in very early or sudden seasons we have found quite a little difficulty in rearing queens too soon. But this is not a rule. It is an exception. Generally spring opens slowly, with only occasional warm days and many a reverse. In the average season the best colonies will have drones ready to hatch by the time our queenless colonies can be prepared to hatch their queens.

Our drones should be reared in the best colonies, always. It seems to be an undisputed fact, accepted by all physiologists, that the characteristics of a race are best perpetuated through the male. If this be correct, our drones are of more importance than our queens. That is, we should take more pains to mate our queens with drones of a prolific mother than to rear these queens from a prolific queen. I know many of our bee-keepers will say that this is impossible since we cannot control the fertilization of the queen, but it is equally evident that we can to a very great extent encourage the production of drones in the best colonies, which are already—mark this—more prone to rear drones than the others, from the very fact of their strength and greater prolificness. We can also, and to a still greater extent, discourage the rearing of drones in indifferent or weak colonies, by removing the drone-comb and replacing it with worker-comb whenever opportunity offers. This point I have been fighting for, for a number of years, and I am glad to see that it has not all been in vain.

We have queenless colonies every spring, and also every spring we follow the instructions given in Langstroth, and

usually succeed in rearing good queens in fully three-fourths of the cases. Yet we can say that we take particular pains to induce the rearing of early drones, which could be done by a little stimulative feeding of the selected colonies. If queen-rearing is contemplated to any extent during the year, it becomes almost indispensable to resort to stimulative feeding, for there are many seasons when the drones are killed by the bees of nearly all the hives only because the crop does not happen to come when expected by them. The present season is one of this sort, and the drones were nearly all killed late in May, in our apiaries.

To get bees from the South is certainly a very good method, and our Southern brethren are very reasonable in their prices, for they sell them at rates for which we do not think we could rear them profitably. Yet, an apiarist will often hesitate to spend three or four dollars to save several queenless colonies. Then it sometimes takes longer to get the queens, when ordering them early, than it will take to rear them in your apiary. No one but a novice will send an order for a queen in April with the expectation of receiving her by return mail in every instance.

If you feed up one or two strong colonies about April 1, they will have drones by May 1 to 10. Then you may begin your queen-rearing April 15 with but little fear of their being unable to find drones during the first two weeks of their life. Should a young queen get lost from having to take too many flights, the colony which reared her is much better prepared to rear another than a colony that would have been left all this time queenless. The only thing that renders a colony unfit to rear a queen is the presence of an old, barren queen, or of one or more laying workers. In either case, the bees seem to be satisfied that they have all they need, and it is a hopeless task to try to save them unless a number of fresh bees are added.

There is a method by which we can be sure of having early drones. It is to rear young queens from good stock and in full colonies late in October. Such queens do not become impregnated, because the drones are no longer alive, and by the end of winter they have become drone-layers. They are prolific, being young, and rear a hive full of drones. The only trouble is that they must be killed promptly and replaced or the colony would soon die. We had an experience of this kind very involuntarily one year—about 1870 or 1872—on six or seven colonies, the mother queens of which had been sold by us very late in the season. These young queens were all magnificent drone-layers the following spring, and gave us a very good opportunity of rearing a lot of queens. This is a method which it is hardly advisable to follow, however, and we would much prefer to trust to natural conditions for our supply of early drones.

Hancock Co., Ill.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Alfalfa in Texas—Other Questions.

1. While talking to Mr. Davenport, of this county, a few days ago, I said that next year I intended to sow about 12 acres of alfalfa, and cut three acres early in the spring, in a short while three more, and so on, the last being cut when ripe would do for hay, and by the time it was cut the first three acres would be ready to bloom. Thus I would have continual bloom of alfalfa. But he (the barbarian) with ruthless hand hurled his missile at my air-castle, and it disappeared. He says that alfalfa yields very little honey in this climate. How about that?

2. I have 15 colonies of bees, six of which I transferred this spring, four are still in box-hives, and four, which I bought, in home-made, movable-frame hives. One of the latter which was very strong and active in early spring, is not doing well. About three weeks ago I examined it, and finding it almost full, I gave them a super. I examined this from time to time and never found a bee in it. A few days ago I took off the super and looked into the brood-chamber, and it seems to me they are not as full as when I put the super on. While the other bees are working thickly in and out, these lie about the entrance and do nothing. I have never been able to find a

queen in this or any other hive, so I don't know whether they are queenless or not? Is it probable?

3. In the early mornings I notice from one to five or six young bees, still white, dead in front of the hives. What is the cause? I notice no disagreeable smell as of foul brood.

4. I notice a great deal said in the Bee Journal about "preventing swarming." Now, not to show my ignorance but to get information, I would like to know what would be the effect on the bees if all queen-cells were kept pinched off at the time when it is desired that they do not swarm?

5. How does Alsike clover do in this climate? TEXAS.

ANSWERS.—1. If he has kept close watch of the matter his word is worth more than mine. I know that not long ago a report came—I think it was from west of here, perhaps Iowa—that alfalfa yielded no honey, and the only field of alfalfa I ever examined when in full bloom in my own county had not a bee on it.

2. It is very probable that they are queenless. If so, you will find no unsealed brood present, unless they have been queenless so long that laying workers have set up business, in which case you will find sealed brood in worker-cells that has not the usual flat sealing, but round, like little marbles close together.

3. It isn't foul brood, for in that case the brood is left in the cell and it isn't white. It may be drone brood that is thrown out because the bees don't want drones, or it may be from some other cause, but it need cause no uneasiness unless there is a good deal of it, in which case it may point to starvation. But if there's honey in the hive it isn't starvation.

4. It doesn't always work the same. Sometimes the bees will give up swarming if you destroy the queen-cells, but generally they will start others, and in some cases may swarm with only eggs in queen-cells, if indeed they have that much. If you don't die till you find out how to prevent swarming without in any way interfering with a good crop of comb honey, you'll probably be gathered to your fathers at a very ripe old age.

5. It probably does well, as I don't remember seeing any unfavorable reports from Texas.

Building Irregular Combs.

I wired all my brood-frames and used strips of foundation about an inch wide on the top-bars. I now find the bees are building comb about $2\frac{1}{2}$ inches thick on one frame, and about one inch thick on the next, and so on alternately across the hive. Why is this, and is there any remedy for it?

MINNESOTA.

ANSWER.—The only thing I can think of to account for such irregular work is the irregular spacing of the frames. If you have the foundation in the middle of each frame and have the frames all spaced at equal distances, it is hardly possible there will be any such trouble.

Feeding Back Extracted Honey.

1. We wish to buy some pure extracted honey, to feed back in order to get comb honey in one-pound sections. Will it pay us to do this?

2. What per cent. would the bees use in converting extracted honey into section comb honey? Or, how many pounds of finished comb honey would the bees produce from 100 pounds of the fed extracted honey? VIRGINIA.

ANSWERS.—Very, very doubtful.

2. That depends. You might not get 10 pounds of comb honey from 100 of extracted, and you might get a good deal more. If you feed the 100 pounds of extracted to one colony you'll get a good deal more comb honey than if you feed it to five colonies. But whether you feed it to one or five, there seems to be a shrinkage that can hardly be accounted for. At a rough guess, from what I have read and from some little experimenting in that line, I should say that if you get 40 pounds of section honey by feeding 100 of extracted honey, you'll do well. I know that some claim they can do it at a profit, but I don't believe you or I could.

Use of the Division-Board—Hanging Out.

1. I have the dovetail hive and have put the division-board in the middle of the frames. Is that the right place for it? If not, where does it belong? and of what use is the division-board?

2. I caught a swarm about two weeks ago and put them into an S-frame two-story Langstroth hive, and last Tuesday

the weather was very close and warm, and the bees came out and hung on the front of the hive in a large bunch. Did they do that on account of the hot weather, or on account of lack of room?

ILLINOIS.

ANSWERS.—1. What you call a division-board isn't intended to be used as such, but as a dummy. It is to be used, not in the middle, but at one side. Put in all the frames, crowd them all close to one side, then put the dummy close up against the last frame. If the hive were made just wide enough to take in the frames, you would find it almost impossible to get out a frame after the bees have filled and glued them. But there will be a space between the dummy and the side of the hive which the bees will always leave clear. That gives play enough for the dummy so it can easily be taken out, and after the dummy is out there is plenty of play to get out the frames.

2. Very likely it was only because the weather was very hot and the hive close. You can easily find out whether they are crowded for room by taking out the combs and seeing whether the cells are all filled with honey that do not contain eggs or brood. If you raise the hive on four blocks about $\frac{3}{4}$ -inch, it will give them enough air so they will not be likely to hang out.

The Best Hive—Number of Frames.

1. What make of hive is the best for bees?
2. What number of frames is the best, 8 or 10-frame?
3. What make of hive does Dr. Miller use? Are they 8-frame or 10 frame?

IOWA.

ANSWERS.—1. Probably if the bees were consulted in the matter they would tell you that there is no better hive for bees than the old straw skep our forefathers used. But this has been displaced by the movable-frame hive, not because the frame hive is better for the bees, but because it is more convenient for the bee-keeper when he wants to take out the combs.

2. For extracted honey it is likely 10 Langstroth frames in a hive are best. For comb honey, if the bees are to be left without much attention the year round, likely 10 frames are also best. If they are used with two stories when supers are not on, perhaps eight frames to each story are best.

3. The majority of my hives are very old, and were originally 10-frames, afterward reduced in size to take 8 frames. As fast as I am changing into new hives I use 8-frame dovetailed hives, allowing the bees all the room they will use up to 16 frames, except when supers are on, when all are reduced to one story except a few for experiment. As yet I have only about 50 dovetails in use, but hope to close the season with a good many more.

Signs of Swarming—Hanging Out.

1. If a colony in a box-hive is about to swarm, will there be any particular signs by which I can tell?
2. What is the matter with some of my bees? They gather in large bunches and hang down in front of the hives the biggest part of the day, fanning with their wings; while others are busy they make a great noise at night.

OHIO.

ANSWERS.—1. None that you can be sure of. They generally hang out, but sometimes they hang out with no thought of swarming. They work less actively, but neither is that a sure sign.

2. It may be they are preparing to swarm, or it may simply be that it's too hot in the hive and they prefer to stay where it's cooler. It may be that they are crowded for room. See that they have room enough, either in the hive or in supers, and raise the hives by blocks at the four corners, and they will not be likely to hang out very long.

Don't Work on White Clover or in Supers—Placing Hives.

1. Why did the bees not work on white clover in 1897, which is the best honey-pasture we have?
2. Why do my bees not work in the supers?
3. Why are there no drones this year?
4. Do you advise setting the hive on the ground when it can be done, or would you set it on a platform two or three feet high?

WEST VIRGINIA.

ANSWERS.—1. I don't know. It happens some years in this locality (this is one of the years) when white clover blooms abundantly but bees don't store any honey from it. I don't

know why. I only know that white clover is very plenty, but there seems to be no honey in it.

2. Very likely they haven't anything to put in the supers, or else there is room not yet filled in the brood-nest. They'll not commence work in the supers while there is plenty of room in the brood-nest. But you may hurry up matters by putting bait sections in the super, that is, sections that have been partly drawn out the previous year. Or, you may put a small piece of brood in the super.

3. If you watch closely you will probably find drones this year. There are plenty in my hives, but not as many as in some years, because the bees have been driving them out in the month of June and in the first of July, on account of the scarcity of honey.

4. I wouldn't do either, but set the hive on a stand somewhere from two to six inches high. That makes it better for bees to get into the hive than when it is two or three feet high, and you can sit on a seat to work at the hives.

Sowing Buckwheat—Hybrid Queen's Progeny.

1. What time should buckwheat be planted in Southern Mississippi to produce the most honey?

2. If a half-breed queen meets an Italian drone, what would the progeny be?

3. I had a trial with laying workers in one hive this spring. They refused to rear a queen; several times I gave them brood, but no queen-cells were built, so I gave them a black queen, as I did not care to risk an Italian, and sure enough they balled her to death. So I got a frame with two ripe queen-cells on it, and gave to them; 12 days later I found plenty of fresh eggs in regular form, so I closed the hive, and I see they are getting strong in bees. They were very ill-natured (?) until they reared a queen.

MISSISSIPPI.

ANSWERS.—1. In the North, as early in July as possible, and I suspect the same time would be all right in Southern Mississippi.

2. Her worker progeny will be $\frac{3}{4}$ Italian blood, and her drone progeny the same blood as herself, only it must be added that, theoretically, her drone progeny will be slightly tinged by the blood of the drone with which she mates.

Drones and Egg-Fertilization.

1. Is the drone hatch from an unfertilized egg?

2. After the queen meets the drone, is the process of fertilizing the egg at the pleasure of herself?

I discovered a superabundance of drones in one hive, and upon examination I found nothing but drone-eggs in it, hence the above questions.

OHIO.

ANSWERS.—1. Some believe that the fertilization of the egg is at the will of the queen, and some believe her volition has nothing to do with it, but the kind of cell controls the matter.

2. You can hardly tell by looking at an egg whether it will produce a drone or a worker, but you can easily tell when the brood is sealed whether it is drone or worker, and that is probably what you mean. In your colony which had so many drones, the queen may have commenced laying without having been fertilized (a very unusual thing) and in that case would produce only drones; or she may have been a played-out queen, producing mainly or entirely drones, or there may have been no queen present and laying workers were at work.

Solder on Tin Packages.—Der Deutsche Imker aus Boehmen says tin is all right as a package for extracted honey, but all soldering must be on the outside and not on the inside.

Apis Dorsata.—Different writers speak of from three to seven varieties of native bees in India, but all seem agreed that *Apis dorsata* (mentioned in nearly every paper under a native name) cannot be domesticated on account of its intractable nature. Among other things—(1) It is said to be exceedingly vicious—often attacking men and beasts on the slightest provocation; (2) It preserves the same habits and

appearance wherever its habitat; (3) Has never been known to build its nest under shelter, but mostly on the most isolated and lofty trees and overhanging rocks; (4) When they desert trees and combs of the season they frequently travel for a week or ten days, to distances over 100 miles, even crossing such mountains as the Ullgiris in their migration; (5) Build single combs; (6) Are used to approach from north, south, east and west; (7) Rarely remain in the same locality for more than three months at a time; and (8) Emigrate when flowers become scarce.—British Bee Journal.

Top Ventilation in hot weather is considered in Gleanings. One man proposes a special device for it. Dr. Miller believes six square inches of entrance at the bottom and six more at the top gives more ventilation than 24 inches all at the bottom, because the two entrances allow the air to pass through the hive. But bees are slow to seal sections if an opening is too close to the sections.

Wholesale Feeding.—W. H. Pridgen does it this way: Nail 3-inch strips to the edges and ends of an inch board. Tack strips across the bottom an inch apart, give the board a little incline, turn on a little sweetened water from a faucet in a barrel at the higher end, graduating the supply according to the demand, and when the bees all get to work make it the full strength of syrup wanted. A point that demands special attention is the manner of closing the work of feeding without startling robbing. Instead of simply stopping the supply, water is gradually added till there is so little sweet that the bees do not care for it.—Southland Queen.

Management of Pollen-Filled Combs.—G. M. Doolittle says he lives in a region where the bees probably store as much pollen as anywhere in the United States, but he has never melted a comb of pollen, and he wouldn't give a cent for a means of extracting it. He has never known bees to throw out pollen unless it was mouldy. His bees store an excess of pollen during hard maple bloom, and again during white clover. During hard maple when the pollen begins to crowd the queen, he moves the frame of pollen back from the brood-nest, putting between the brood and pollen a frame of honey. This stimulates the laying of the queen. When the hive is too full for this proceeding, he removes a frame of pollen for future use. After apple-bloom it is returned, the bees having used up their store.

The maple pollen has no honey stored over it, but white clover pollen has. Combs of the latter are stored away for the following spring, care being taken as to worms. Placed near the brood-nest in spring, it stimulates to laying better than the feeding of rye-meal or other substitutes.—Gleanings.

British View of Facing Honey.—W. Woodley, a valued contributor of the British Bee Journal, says he has been surprised at the "points" that have been brought forward in America in favor of facing, and gives his own views as follows:

"If all the sections are equal in quality throughout the crate, there is surely no harm in placing the sections best side out. Anyone with experience in working for comb honey knows that one side of a section is generally better or more evenly capped than the other side; and if the inside rows of sections are equal to the outside ones, no injustice is done, and no deception practiced. If, on the other hand, the outside row are superior as sections to the inside ones in the same crate, they are not a fair sample, and in my opinion there is fraudulent intention to deceive the purchaser on the part of the seller. Moreover, this method of doing business must in the long run recoil on the head of the man who practices it. I think that every bee-keeper who has honey to sell should take care that every section or jar of honey is equal to the sample, and sell those not up to the mark at a lower price, or at a fair value compared with the price charged for the first selection or quality."

Selling Honey to Grocers.—Like a good many others, G. K. Hubbard advises against the practice of crowding so much honey upon the markets of the large cities, seemingly preferring, however, those places that are some little distance from home. The large producers of California must of necessity ship to the large markets, but the smaller cities should be supplied by bee-keepers not far distant, without the grocers having it shipped from the wholesale cities.

Start with a load of 10 to 20 cases, according to the size of the place you are going to visit. Make a special point to be neat and gentlemanly in appearance—best suit, collar, necktie, boots black. Fix prices on different grades, and stick to them, treating all alike. Better miss a sale occasionally by

sticking to price, as it will save time in the future. Be pleasant, polite, and make known your business at once; or, if the proprietor is busy, leave and come back again later. If a grocer doesn't seem ready to buy, don't press unpleasantly, but take leave pleasantly, promising to call some other time when he may be ready to buy. Don't start by offering to sell a single case, but offer to sell a number of cases, or the whole lot. It's easier to come down on the amount than to go up. If the grocer says he can get honey for less money from Blank City, call attention to freight, breakage, quality of honey, and also to the fact that you will take off his hands every section that is not just as represented, and that you will call again in 60 days or so and will pay him 10 cents each for the empty cases if in good condition.—Gleanings.

"Profitable Bee-Keeping, with Hints to Beginners"—the nine articles by Mr. C. N. White, of England, began last week in the Bee Journal. See page 442 for further information concerning these articles, and also the premium offers for getting new subscribers for the last six months of 1898.

We would like to have all our readers, if possible, get and send in the subscriptions of their neighbor bee-keepers. The way to get rid of slipshod, old-fogy bee-keepers is to place under them the jack-screw of good bee-literature and raise them up to the level of those who are striving to keep bees in the modern and proper way. By so doing all will be helped.

Many of our subscribers have already sent in new subscribers on the offers made on page 442, but there is room for many more. Before Aug. 1 we hope to add 1,000 new subscribers to our list. It can be done if every one will do only half as well as some others have already done.

Send for free sample copies to work with, or send us the names of non-subscribers, and we will mail the sample copies to them.

Honey as Food is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey among should-be consumers. The forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 30 cents; 50 for 50 cents; 100 for \$1.00; 250 for \$2.00; 500 for \$3.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Bee-Keeping for Beginners is the title of a 110-page book just out, from the pen of that expert bee-keeper of the South, Dr. J. P. H. Brown, of Georgia. It claims to be "a practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit." Price of the book postpaid, 50 cents. Or, we will club it with the Bee Journal for one year—both together for \$1.40; or, we will mail it as a premium to any of our present subscribers for sending us one new subscriber to the Bee Journal for a year (at \$1.00), and 10 cents extra.

The Wood Binder for holding a year's numbers of American Bee Journal, we propose to mail, postpaid, to every subscriber who sends to us 20 cents. It is a very simple arrangement. Full printed directions accompany each Binder. Every reader should get it, and preserve the copies of the Bee Journal as fast as they are received. They are invaluable for reference, and at the low price of the Binder you can afford to get it yearly.

Langstroth on the Honey-Bee, revised by The Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both together for only \$2.00.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY
 GEORGE W. YORK & COMPANY
 118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. JULY 14, 1898. NO. 28.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the Joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Bee-Supply Trade.—According to all reports the year 1898 has exceeded all others in the large demand for bee-keepers' supplies. All the factories seem to have been crowded to the utmost, and even then to have been away behind orders. But it is just possible that the honey season is not going to be as good as some anticipated, or as prospects indicated a month or two ago.

The Omaha Convention will be a large affair if E. Whitcomb can have his way about it. And he usually "has his way." In a letter written to us July 2, he said:

"We rather hope to turn out 1,000 Nebraska bee-keepers at the meeting."

Why, Uncle Whitcomb! Think of it—1,000 Nebraskan bee-keepers at the next meeting of the Union! Why, we'll have to engage the whole Exposition grounds, and then have a regular bee-keepers' camp-meeting. All right. We'll get Presbyterian Dr. Miller to open with a song, Baptist Dr. Mason to follow with a prayer, Congregationalist A. I. Root to preach a sermonette, and Methodist Eugene Secor to follow with an exhortation, or give his 'sperience!

Talk about camp-meetings! Well, we should say so. But why not all the States go to work and try to see how many of their bee-keepers each can have in attendance? Illinois ought to have—well, we won't say just how many, but if Nebraska gets one-fifth of her proposed 1,000, Illinois can more than double it. And Iowa—how many, "Gen." Secor?

Let all begin to talk up the coming convention. Plan now to be there. Help to make it the crowning apiarian event of

this closing wonderful nineteenth century. We will try to do our part, and we know Mr. Whitcomb and many others will do theirs.

It's now "O. O."—"On to Omaha!"

The Illinois State Fair has greatly reduced the list of cash premiums offered in the department of Bees and Honey for the 45th annual Fair of 1898, to be held Sept. 26 to Oct. 1. The total amount offered for the whole Fair is \$45,000, and of this amount only about \$275 goes to apiarian exhibitors.

We take the following from the Premium List recently received:

LOT 193—BEES AND HONEY—OPEN TO THE WORLD.

The judges in this lot will be governed by the code of rules adopted by the Illinois State Bee-Keepers' Association.

Five hundred pounds will receive full score for quantity in displays of comb and extracted honey. Fifty pounds will receive full score for quantity in display of beeswax.

| | | | |
|---|------|------|-----|
| Display of comb honey..... | \$25 | \$15 | \$5 |
| Collection of labeled cases containing 12 or more pounds of white honey from different flowers | 10 | 5 | |
| Collection of labeled cases containing 12 or more pounds of amber or dark honey from different flowers..... | 10 | 5 | |
| Case white clover comb honey, 12 to 24 pounds. | 5 | 3 | |
| Case basswood comb honey, 12 to 24 pounds.... | 5 | 3 | |
| Display of extracted honey..... | 25 | 15 | 5 |
| Display of samples of extracted honey, named.. | 5 | 3 | |
| Display of candied honey..... | 15 | 10 | |
| Display of beeswax..... | 15 | 10 | |
| One-frame observatory hive of dark Italian bees | 5 | 3 | |
| One-frame observatory hive of golden Italian bees | 5 | 3 | |
| One-frame observatory hive of Carniolan bees... | 5 | 3 | |
| One-frame observatory hive of Albino bees..... | 5 | 3 | |
| One-frame observatory hive of Cyprian bees.... | 5 | 3 | |
| One-frame observatory hive of Holy Land bees.. | 5 | 3 | |
| One-frame observatory hive of black bees..... | 5 | 3 | |
| Group of queen-bees, comprising 2 dark Italians, 2 golden Italians, 1 Carniolan, 1 Albino, 1 Cyprian, 1 Holy Land, 1 black..... | 10 | 5 | |
| Display of honey-plants, pressed, mounted and labeled..... | 5 | 3 | |

The only reason we can imagine for dropping the special list of awards to the bee-keepers of this State is because of the few local bee-keepers who took enough interest in the Fair last year to make an exhibit. This was a mistake. The Fair officials were very generous toward bee-keeping last year, but of course when they found that their generosity was unappreciated, they decided to use the premium money in other departments. Perhaps by putting up a good show this year, another year bee-keepers may be able to recover what they have lost. We were hoping that the Illinois State Fair might continue at the head of all Fairs in its amount of cash premiums offered for apiarian exhibits.

The Honey Season and Prices.—Editor E. R. Root in Gleanings for July 1 has this to say concerning the present season and the price of honey:

Up to within a few days, at least, the honey season as reported over the country has been very indifferent, not to say poor. We have, up to within a day or two, received only a very few reports where honey was coming in to any extent; but these few report an extra honey-flow; but the localities are so scattered that, if no honey should come from now on, there will be a great scarcity of both comb and extracted honey; for in California the season has been almost a complete failure. I think I have never seen such immense areas of clover as I have this year; but for some reason or other it does not seem to "give down." Occasionally, here and there, there will be a few bees, but nothing like what we might expect if nectar were being secreted in the usual way. Our colonies at the home yard and at the basswood yard have been on the verge of starvation, and have had to be fed in order to keep brood-rearing going. Our neighbors report a similar condition with one exception, and to this exception I shall refer later on.

But since June 26 I can report for this locality, at least,

a change for the better. Basswoods were never more promising than this year; and by the way the bees are roaring on the trees, and tumbling in at the entrances, it begins to make it look as if we *might* get our usual quota of honey. But the season has been so peculiar that we do not propose to count our chickens before they are hatched. But as I sit here I can see great droves of bees flying past the window and over factory buildings; and our men in the yards tell us that it begins to look like business now.

In the last few days we have received some very encouraging reports. In some cases clover seemed to be the source, and others basswood. Rains have been frequent, and copious at times; and altho clover has been out some six weeks, there are still vast areas of it on the hills and pasture lands. Perhaps we shall have a second crop. An immense quantity of clover will go to seed this year, and this augurs well for next season's clover.

I have deferred the writing of this till the very last minute, so that I might be able to present to you as exact an idea of the situation as possible. Taking everything into consideration, honey ought not to sell as low as it did last season; for I am morally sure that there will be less of it; and do not be in a hurry to rush it off to the commission men, even if you do get a little crop. As the output will be limited, prices should rule higher.

White clover, at least in the northern and middle States, is the main dependence for honey; and even tho basswood may yield well, it is confined mainly to particular localities, and would not, therefore, greatly affect the general market.

No doubt Mr. Root is right in saying that the prices of honey this year should rule higher than last year. But will they? So far as we have noticed, the prices quoted by commission men are about the same as in 1897. We fear it will be a very difficult matter to raise prices. It is easy enough to come down, but when you try to raise prices it is a different matter.

Perhaps in the local or home markets it will be easier to get the price of honey up a little this year, and if bee-keepers will just hold back their honey a little from the city markets, it may help to raise the prices there, too.

The United States Bee-Keepers' Union

continues to grow. We have received a number of new memberships lately, and so has Secretary Mason, if we may judge from the following, dated June 30:

EDITOR YORK:—On the 25th I received a list of 17 names (with \$17) from J. Webster Johnson, Secretary of the Salt River Valley Honey-Producers' Association, of Arizona, with the request that they be placed on the list of members of the United States Bee-Keepers' Union. Perhaps you'll remember that last year Mr. Johnson sent a list of 24 names of members of that Association. He writes now that some have already sent in their names, and others will send theirs later.

I don't know but we now have a thousand or more members, but I think as Editor Hill, of the American Bee-Keeper, writes me—that "we ought to have ten thousand."

A. B. MASON.

General-Manager Secor, writing us also June 30, said:

"We shall have a very respectable membership to report at the close of the year."

We have been hoping all the past year that in some way bee-keepers might become sufficiently interested in their own welfare to help roll up a membership of 1,000 by the time of the annual meeting at Omaha. It could be done so quickly and easily, if only the many who are abundantly able to send their dues of \$1.00 would only do so. Dues may be sent to the office of the American Bee Journal, to the Secretary, Dr. A. B. Mason, Sta. B, Toledo, Ohio, or to the General-Manager, Eugene Secor, Forest City, Iowa.

Now, we trust that every reader of the Bee Journal who can possibly spare the dollar, and who desires to have a part in an organization established solely in the interest of bee-keepers, will at once forward that dollar to one of the three places mentioned above, and receive a receipt therefor.

If any one, before becoming a member, desires to see a copy of the Union's constitution, write to Mr. Secor for it. He

will be glad to send out any number of free copies, and then receive the membership fees as fast as the mails can carry them to him.

Why not roll up that 1,000 membership by the time of the Omaha meeting? Then our presidential successor could feel that a responsibility more than ten times greater rested upon his shoulders than came upon ours when we accepted the office at the Lincoln convention, nearly two years ago.

Special Premiums at Omaha Exposition.

—The following special premiums are offered in advertising by the Nebraska Farmer in the Apilary Department of the Trans-Mississippi and International Exposition:

1. Best, largest and most complete display of apilary goods and supplies.....\$10
2. Best and largest display covering the greatest number of varieties of comb honey, quality and marketable shape to be taken into consideration..... 5
3. Best and largest display covering the greatest number of varieties of extracted honey, quality and marketable shape to be taken into consideration... 5
4. Largest and best display of designs of beeswax work 3
5. Largest and best display in unrefined beeswax.... 2
6. Largest and best display of bees and queens..... 3
7. Largest and best display of honey-producing plants, mounted and with their botanical and common names attach..... 2
8. To the person giving the best exhibition on Trans-Mississippi Honey-Day of handling bees and extracting honey..... 5
9. To the State making the best display of honey, supplies, bees and queens on Trans-Mississippi Honey-Day..... 5
10. To the person making the best display of honey, supplies, bees and queens on Trans-Mississippi Honey-Day..... 5
11. Best and largest display of culinary products, in which honey is used instead of sugar..... 3

The above special premiums are opened to the world, and will not in any manner interfere with the awards to be given by the Exposition.

The bee-papers of the United States and Canada are requested to copy the above list of premiums.

MR. GEO. W. BRODBECK, of California, is shown in Gleanings for July 1, in a fine half-tone engraving. Rambler has been visiting him, and writes about Mr. B. and his apilary.

THE LEAHY MFG. Co. report business still good. For nearly six months previous to June 23 they had run their factory day and night.

MR. E. C. CAMPBELL, of Ontario, Canada, gave us a short call last week, when in Chicago visiting his son. Mr. Campbell has been for years Secretary of the Haldimand Bee-Keepers' Association, and quite an extensive bee-keeper. He is a publisher of a newspaper where he lives.

MR. A. I. ROOT is planning to take a trip through Yellowstone Park on his bicycle some time this month or next. He wants to get some others to go with him lest he become lonesome. Perhaps he fears getting lost if all alone! But when "A. I." is lost anywhere he'll be a good deal older than he is now. He has been around this country too long not to know "where he is at," no matter in what corner he finds himself.

MR. O. O. POPPLETON, now in Brevard Co., Fla., wrote us as follows July 2:

"I moved about two-thirds of my apiary up to this place, some 30 miles north of Stuart, Dade Co., early in June, to obtain the small amount of honey given by the black mangrove

on the Islands here. We are having a slow but steady yield, which looks like continuing a couple of weeks longer. If it does, I will get a crop of about 100 pounds average per colony for the year, which, altho small, is as good, if not better, than any season since the big freeze. I will return the bees home early in August.

"I am living with the Keeper of the House of Refuge, United States Life Saving Service, on the ocean beach. When not busy with the bees I can go bathing in the surf, fishing, hunting shells or turtle eggs. I have found four nests, about 500 eggs, since being here, besides turning one turtle that weighed over 200 pounds. I wish you could be here for a few days. I think I could show you many curiosities, and help you to a pleasant time."

Yes, Mr. Poppleton, we, too, wish that we could be with you awhile and rest up after one of the busiest summers of our life. But we must stay here and keep on grinding out the American Bee Journal week after week. We are glad you are having a pleasant time, and also getting something of a honey crop besides.

MR. THOS. WM. COWAN and wife have arrived at their home again across the Atlantic. In a letter dated June 27, Mr. Cowan says:

"We have now returned home after a very enjoyable journey and visit to bee-keeping friends. . . . I send you a copy of the new edition of my 'British Bee-Keepers' Guide-Book,' just out, which will give you some idea of our methods of bee-keeping in this country."

We are glad to note the safe homeward voyage of our good English friends, and wish to thank Mr. Cowan for the copy of his book. It is what its name indicates—a bee-keeper's guide-book. It is in its 15th edition and 35th thousand; bound in cloth, gilt-lettered, and contains about 200 pages. Any of our readers desiring it, we can have their orders filled on receipt of 75 cents. The book is fully illustrated.

Mr. Cowan also has another book entitled, "The Honey-Bee: Its Natural History, Anatomy and Physiology." It is the most recent work on the subject, and the one used for all examinations of experts in England. The price is the same as the "Guide-Book." To any one desiring both books, we will have them mailed for \$1.40. All orders may be sent to this office.

MR. PORTER A. M. FEATHERS is the somewhat long, tho apparently light and downy, name of a correspondent of the July Progressive Bee-Keeper. He starts off thus:

"Say, did you know the Progressive is a 'daisy?' Why, I did not know it until I subscribed for it. . . . Really, there is no journal in my estimation which is any more full up to the brim with business and good, sound bee-advice than the Progressive."

The above testimonial will be valued more correctly perhaps when it is known that this same Feathers has for over two years owed us \$2.25 on his subscription to the American Bee Journal previous to that time. He promised a year or so ago to pay up, but we presume he found it cheaper to subscribe for another bee-paper than to first fulfill his promise to us.

It might be a good plan for publishers of bee-papers to exchange lists of those who will take a paper for several years and then fail to pay for it. Mr. Newman, who publishes the American Bee Journal for some 18 years, had lists upon lists of bee-keepers who failed to pay their subscription, amounting to fully \$10,000. During the six years since we have had the Bee Journal, we have accumulated several thousand dollars of what might be called bad subscription debts.

We cannot understand how any honest man will continue to take and read a paper and then refuse to pay for it.

We would be willing to unite with the other bee-papers in an agreement to send only to paid-in-advance subscribers. Dare the other papers agree to that?

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all other bee-keepers possible to subscribe for it. See premium offers on this page.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles:

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This is a series of practical articles that bee-keepers of the United States will not want to miss reading. They will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

**The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it**

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Bieder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan Field | 14 Muth's Practical Hints to Bee-Keepers |
| 6 Our Poultry Doctor—Fan Field | 15 "20 Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse Book | |

For Sending TWO New 40-cent Subscribers:

- | | |
|---|---|
| 1 Potato Culture—by T. B. Terry | 7 Hutchinson's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Blenen-Kultur—German |
| 4 Dr. Tinker's Bee-Keeping for Profit | 10 Bees and Honey—160 pages—by Newman |

For Meeting Baptist Young People's Union,

At Buffalo, N. Y., July 14-17, the Nickel Plate Road will sell tickets at rates lower than via other lines. The accommodations are strictly first-class in every particular, and it will be to your advantage to communicate with the General Agent, 111 Adams Street, Chicago, before purchasing your ticket. Telephone Main 3389. (28)

In the multitude of counsellors there is safety.—Prov. 11-14.

Average Cash Value of Taxable Colonies.

Query 76.—In Iowa 10 colonies of bees in the hands of any one owner are exempt from taxation, and the cash value of all his other colonies, as given by him, is divided by four, and the quotient becomes their asset value. If a similar law was in force in your State, what is the average cash value you would place on each of your taxable colonies?—Iowa.

Eggen Secor—\$4.

R. L. Taylor—\$2.50.

Mrs. L. Harrison—\$6.

Chas. Dadant & Son—\$2 to \$3.

O. O. Poppleton—Not less than \$5.

J. M. Hambaugh—About 75 cents.

Dr. A. B. Mason—\$6 in my locality.

W. G. Larrabee—About \$5 per colony.

Mrs. M. J. Null—50 cents per colony.

Prof. A. J. Cook—I suppose \$5 would be about correct.

G. M. Doolittle—No; bees are not as set in these parts.

Dr. J. P. H. Brown—I would place the cash value, on an average, at \$6.

Dr. C. C. Miller—It would hardly make any difference on the market value.

E. S. Lovesy—\$4, for the reason that I would not sell at even those figures.

P. H. Elwood—We could not replace our bees in our hives and furniture for less than \$6.

E. France—Under those conditions I would put them in at the price that they would sell for.

R. C. Aikin—\$3 or \$4. Taxes here amount to about 3 to 5 cents a colony; valuation about \$1.

Emerson T. Abbott—I should leave that to the men who fix value. Most people pay as little tax as they can.

Rev. M. Mahin—If by "cash value" you mean the amount for which they could be sold, \$5 would be the highest limit.

Jas. A. Stone—If the colonies were heavy, I would say the first of May when values are asst—\$3 for blacks, and \$5 for Italians.

J. E. Pond—Circumstances would determine the matter, but in this State (Massachusetts) bees are worth in March, as an average, assuming they are in good condition, \$5 or more per colony, including a plain 8 or 10 frame Langstroth hive.

C. H. Dibbern—The cash value placed on personal property of various kinds by most assessors is very low. My bees are tax at \$1 per hive, which would make the cash valuation \$4, but I consider them worth at least \$5 just before swarming, when usually asst.

J. A. Green—As I understand the question, the details of the law have nothing to do with it. The question is, "What is the cash value of a colony of bees at the time of assessment?" As this would depend on locality, kind of

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order:

Via Nickel Plate Road, July 14-17, at one fare for the round trip. Choice of water or rail between Cleveland and Buffalo within final limit of ticket. For further information call on or address J. Y. Calahan, General Agent, 111 Adams Street, Chicago. Telephone Main 3389. (31)

bees, kind of hives, etc., the cash value might run anywheres from \$2 to \$10. In this locality I should consider a fair average value \$5, tho at a forced sale they would not bring that.

G. W. Demaree—The only solution to a proposition like this would be to value them according to your best judgment. My bees—if taxable property—under our general statutes, which is not the case now, are worth more some years than others, owing to the outlook. Simply exercise your best judgment—and be satisfied.

D. W. Helse—The questioner does not say at what season of the year the assessment is to be taken, or whether the value of the hive is to be included in the estimates. As my hives are worth \$2, I would at this season (May) place an average cash value of \$5 upon my colonies. Their value will fluctuate with the different seasons of the year, as well as one year with another.

Late Crop Expected.

Bees here are in good condition. I have had five swarms to date. I will not get much comb honey until the flow in August and September, as there is no white clover here this season, and the excessive rains here will insure a good crop of fall honey, if the weather should be favorable. A. WORTMAN.
White Co., Ind., June 27.

Clover and Basswood a Failure.

There is no nectar in the clover, and the basswood is a failure. Unless we get a flow from heart's-ease and Spanish-needle, the bees will have to be fed or starve. My 1897 crop of honey was 2,500 pounds from 24 colonies, spring count, all sold in the home market at 10 cents for extracted and 12 1/2 cents for comb. C. L. BOWEN.
Ray Co., Mo., June 28.

No Surplus or Swarming.

My bees have built up splendidly this spring. I had supers on during white clover and basswood; both are now passing out, but no surplus from either. I don't know why it is thus.

Bees have not swarmed with me—only two swarms to date; and the bees continue to kill the drones up to this time.

I started in the spring with 57 colonies. My winter loss was 15, by queenlessness and uniting in the fall.

D. A. CADWALLADER.
Randolph Co., Ill., July 4.

Improved Tin Section-Cleaner.

I have improved the tin section-cleaner so much, and noticing that Mr. A. F. Foote has tried one, I will describe my latest.

I turned the roller to a diameter of 1 1/2 inches; this I covered with T tins running parallel with the shaft, thus making alleys from end to end to catch the stuff that drives through. I now punch the tin with a thin chisel-punch 3/8-inch wide, running the work in rows diagonally across the sheet of tin, always holding the chisel so as to make

the long way of the holes parallel with the roller. With a strip of wood in one of the alleys to nail the tin to, the roller is covered, and when properly put on and filled, sand-paper can't approach it for smooth, fine polish.

We produce honey in beeway sections, so I made the main sheet just 4 inches long, and raised the T tins at the ends $\frac{1}{8}$ -inch, put on a strip of tin with one row punched with the chisel, then with platform and two guides just $4\frac{1}{4}$ inches apart, I clean the beeways. I believe anyone who will try this will abandon sand-paper in any form.

There are two things essential to success—a perfectly round roller after the tin is on, and even, regular work in punching the tin. JOHN S. BRUCE.
Moutrose Co., Colo. June 28.

Yellow Sweet Clover.

The plant that Mr. Hall, of Hardin Co., Iowa, sends, is yellow mellilot or sweet clover, and has all the good honey-producing qualities of the common white sweet clover. It is a much rarer plant here in the West, only found occasionally, but more common eastward. It bears the euphonious botanical name of *Melilotus officinalis*. The first part of the word "mellilotus"—"mel"—attests its honey value. It is a plant well worth cultivation by bee-men, if you are not troubled with the bugaboo notion that it will become a weed, as some claim for its near relation the *Melilotus alba*, or common sweet clover. H. S. PEPOON.

Beard-Tongue or Foxglove.

I enclose two samples of flowers which I think belong to the same family. The larger one is more abundant and is a fine honey-yielder. It began blooming about May 30, and somewhat resembles snapdragon, but the mouth of the flower is open, and the color is light blue.

FRANK ADELBERT.

Flathead Co., Mont.

[The two plants sent by Mr. Adelbert are members of the great figwort family that furnishes many fine honey-plants. The plants in question are known botanically as *Pentstemon*, and in common language "heard-tongue," or occasionally "foxglove." There are a great many different kinds found in the United States, and they are particularly numerous in the far Northwest—Montana, Idaho, Oregon, etc. Doubtless all the varieties are good honey-plants, as the family to which they belong furnishes many that are of much use to the bee-keeper. The common figwort, especially, is rich in honey, and is one of the plants figured by Prof. Cook in his Manual, and praised by him for its value as a nectar-producer.—H. S. PEPOON.]

Facing Honey—Gathering Slowly.

MR. EDITOR:—I am glad that it occurred to you to get the opinions of the commission men on the subject of facing comb honey. These opinions are just what might have been expected, and will be of value to honey-producers. It is quite possible for a man to face his honey without the intention to deceive, but that some one will be deceived is more

"A Queenly Deceiver."

"He fools his customers by sending more than is expected."—See page 105, current volume Bee Journal, and ask for the free pamphlet referred to. I am now prepared to fill orders promptly with FINE YELLOW-TO-THE-TIP QUEENS, or daughters of imported stock mated to golden drones, at 75c each. Purely-mated Queens reared from the best stock and by the best method known, is what I furnish, and will prove it to all who give me a chance. Money Order Office, Warrenton.

than probable, and the honey-producer ought not to take the risk.

Bees are gathering slowly now, and I have put the second super on a few of the strongest colonies. During the first half of June almost all colonies got very short of stores, and many were on the point of starvation. White clover bloom is scantier than I ever observed it to be before at this time of year, but there is a great abundance of white clover plants.

Last week was quite a hot week and some swarming took place, but I am not looking for much of it this season. There was a heavy rain Saturday afternoon and night, and I look for a steady but not very abundant flow of honey.

EDWIN BEVINS.

Decatur Co., Iowa, July 4.

White Clover Prospects Blighted.

As the rain is again pouring, and all prospects for white clover honey now laid in the dust, I think this report will not come amiss, as those more fortunate bee-keepers may quiet themselves accordingly, and hold their crops for good prices. I have gathered information from a number of bee-keepers as to the white clover crop, and so far not an ounce has been stored in the supers. We have at this date 250 colonies in fine condition, and the clover never looked better, but no honey. The number of colonies that I report from is about 500. We are now looking for basswood, and if it falls, then we have not white honey-yielding flowers enough to make a surplus, unless it be the willow-herb, which, if it yields, makes very white honey.

AUGUST BARTZ.

Chippewa Co., Wis., June 30.

Prospects Good for a Honey Crop.

I have 40 colonies of Italian bees in Langstroth and dovetail hives, all doing well. The prospect for a good honey crop has never been better. The white clover crop is good, and a heavy honey-dew falls every night; when morning comes the leaves on the timber are covered with honey-dew. The bees get honey from this in quantities. We are having a fine farming season—a good prospect for a good crop. A good farming season is generally a good honey season. What causes the honey-dew?

M. W. MCPHERSON.

Giles Co., Va., June 30.

Too Much Rain.

The honey crop will be light here this season. There has been too much rain.

JACOB FRAME.

Braxton Co., W. Va., July 5.

A Gratifying Depression.

A well known commercial authority in reviewing the liquor trade says: "Wine and liquor merchants think the times are out of joint. All sorts of liquor they say, except perhaps beer, seem to have lost a large part of their charm for the public, and some fear is entertained that with New Englanders the days of convivial habits have gone never to return. The man who before the hard times began, some five years ago, slacked his thirst with brandy and soda in the company of a friend, to-day contents himself with a modest glass of beer alone, having learned during the period of depression that stimulants are not positively essential, and that hospitality

may be carried too far." Very few reports of stagnation in business can be read with satisfaction, but this is one of the few. We cannot help rejoicing over some of the things that are interfering with the prosperity of this business, viz.: liquors are "losing their charm," are "not essential," convivial habits "gone never to return." We hope to hear of continued depression in the market for the same good reasons, and wish both consumers and producers of liquors "a safer and honest trade."—National Stockman.

Poor Honey-Flow.

It has been a poor honey-flow in this section of country this spring until last week, as it has been so very wet.

H. C. GORTON.

Bureau Co., Ill., July 4.

Rain Lessens the Honey Crop.

I will begin marketing my honey this week, if it will only stop raining. I took off a few cases last week. We have had too much rain, and it is raining now. The honey crop will be cut in half by the rainy weather.

J. D. GIVENS.

Dallas Co., Texas.

A Report from Vermont.

I put into winter quarters 84 colonies, and 86 came out in the spring. I think this is the best report I have seen yet. I supposed one colony did not have a queen, which accounted for one; and I made a mistake of one in counting.

Spring opened up early, and has continued cold up to the present time, the thermometer registering from 40° to 80° this month. Bees have gained steadily now every day for a week. Yesterday and to-day were very good days. Prospects were never better, if the weather would continue good. Red raspberry bloom is in its prime. I counted 225 loaded bees that entered one hive in a minute, about 6 o'clock a.m.

I saw by the Bee Journal that the caterpillars were making sad havoc with the basswood in some places in Minnesota and Wisconsin, one and two years ago. I would like to have members of the bee-fraternity report through the Bee Journal if there was any place where they killed the trees, and whether they still continue their depredations, or are they gone? Some maples were killed by them in this State, and this County, last year. I rode past a sugar-orchard last week that lookt as if the fire had been over it.

M. F. CRAM.

Orange Co., Vt., June 30.

Illinois.—The annual meeting of Northern Illinois Bee-Keepers' Association, will be held at the Court House, in Freeport, Ill., Tuesday and Wednesday, August 16 and 17, 1898. All interested in bees are invited to attend.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,

Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit. by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 176 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES OF HONEY. 100 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, by Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p., illustrated. 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2, in fine artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers. This book gives the latest, most approved methods of bee-keeping, in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50c.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember that only ONE book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

BEE-SUPPLIES!

We have the best equipment factory in the West. Capacity 1 car load a day; and carry the largest stock and greatest variety of everything needed in the apiary, assuring best goods at the lowest prices, and prompt shipment.

Illustrated Catalog, 72 Pages, Free.

We also manufacture TANKS of either wood or galvanized steel, all sizes, any form, and for all purposes. Price-list Free. Address,

E. KRETCHMER, Red Oak, Iowa.

An Italian Queen-Bee Free!

UNTESTED OR TESTED. AN OFFER TO REGULAR SUBSCRIBERS.

FOR getting and sending us ONE NEW Subscriber to the Bee Journal for one year (with \$1.00 to pay for the same) we will mail you, as a premium, one Untested Italian Queen. For TWO new subscribers (with \$2.00) we will mail one Tested Italian Queen. These Queens are reared near Chicago, Ill., and are fine ones. Will YOU have one? Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

We want **EVERY BEE-KEEPER**

.....To have a copy of.....

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

As we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, snowy-white Sections, beautiful, straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Lehy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

Select-Tested Golden Adel Queens.

Each, \$1.00. A practically non-swarming and non-stinging strain of golden bees. "How to Prevent Honey Candyng" given to each customer. Tested Queens, each, 75 cents. 26A1f **HENRY ALLEY, Wenham, Mass.**

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, July 7.—A little of the new crop is coming, and it sells at 11 to 12c for the best grades of white comb. No ambers at present on the market. Extracted is coming freely from the south, and a little from the West; white brings 5 to 7c; ambers, 5 to 6c. Beeswax, 27 to 30c.

We do not look for a settled price on honey before September; meantime the offerings and demand will be limited to immediate wants. **R. A. BURNETT & CO.**

Kansas City, July 9.—New comb, No. 1, white, 11@12c; amber, 10@11c. Extracted, white, 5@5½c; amber, 4@4¼c. Beeswax, 22 to 25c.

Old stock of honey all cleaned up. Few shipments of new in market. **C. U. CLEMONS & CO.**

New York, July 9.—Comb honey: We closed out all of our old crop some time ago. We have received several lots of new crop from the South, good, No. 1 white, which sells readily at 11c per pound.

Extracted: Receipts of new crop from the South are large. We quote: Common, 48 to 50c a gallon; good, 52 to 55c a gallon; choice, 5 to 5½c pound. Demand is good, especially for the better grades. Beeswax remains firm at 28 to 29c. **HILDRETH BROS. & SEGELKEN.**

Cincinnati, July 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3¼ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. **CHAS. F. MUTH & SON.**

Boston, July 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. **BLAKE, SCOTT & LEE.**

San Francisco, July 9.—White comb, 8¼ to 10c; amber, 6¼ to 7½c. Extracted, white, 5¼@6c.; light amber, 4¼ to 5¼c. Beeswax, 23@25c.

Small quantities of the new crop have been offered by sample, but nothing of consequence has been yet done in the same. There will be very little white sage honey this season, but a moderate amount from the alfalfa and tulle districts. Values remain as previously noted.

Detroit, July 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c; fancy dark, 7@8c; No. 1 dark, 6@7c. Extracted, white, 5@6c; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring. **M. H. HUNT.**

Minneapolis, July 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10¼@11¼c. Not advisable to ship darker than amber. Extracted fancy white clover, 5¼@6c; amber, 5c; dark, 4@4¼c.

Outlook for honey much more encouraging. **S. H. HALL & CO.**

Indianapolis, July 9.—Fancy white honey 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. **WALTER S. POWDER.**

Milwaukee, July 9.—Fancy 1-pound sections, 11@12c; A No. 1, 10@11 cents; No. 1 8@10c; amber, 8@8¼c; dark, 7@7½c. White extracted in barrels and kegs, 5¼@6c; amber, 5@5¼c. Beeswax, 26@28c.

The demand for honey continues very good indeed, and values fairly sustained. While the best grades are most salable, the inferior grades meet attention, and the movements are quite satisfactory. **A. V. BISHOP & CO.**

Buffalo, July 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c., when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. **BATTERSON & CO.**

St. Louis, July 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5¼ to 6c.; amber, 5 to 5½c.; dark, 4 to 4¼c. Beeswax, 20 to 22c. **WESTCOTT COM. CO.**

 **Talk about
... Comb Foundation**

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS,

—BY—
C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 3.—HANDLING BEES.

If it were not that the bee is so apt to use what Josh Billings appropriately terms its "business end" too freely, doubtless many more would embark in such an interesting and profitable hobby.

The bees are provided with a means of defense, which they sometimes use in the most provoking fashion, by a better knowledge of how and when to work in the apiary, stinging may be reduced to a minimum. It is no uncommon thing for a bee-keeper, who is by no means expert in bee-management, to examine his hives and take off full supers without a single sting. Bees differ in temperament as much as we do, some being almost as tame as flies, while others are quite the reverse. If any particular colony is found to contain bees that are in the habit of attacking one without provocation, they must be got rid of, not by destroying the whole colony, but by killing the queen and replacing her with another that is known to produce more amiable workers.

The spectacle of an expert at the various bee-exhibitions held in connection with the Agricultural or Horticultural shows, driving bees and handling them like so many flies, is familiar to most people who have taken any interest in this part of the show. But easy as it all seems to the onlooker, even at a show a different state of things sometimes prevails. Robbing, when more than one colony is used, or when bees are kept near by, may be commenced, particularly if the manipulations take place at the end of the season: and then, except for his skill in bee-management, the expert would fare little better than the novice.

It must not be supposed that colonies of bees can at all times be managed with the same ease as in a bee-tent; but by increased knowledge of bee-keeping, and particularly of what, to the bees, are disturbing influences, we shall know the proper methods to adopt under the varying conditions in which we may find the bees, and become able to conduct all ordinary manipulations without discomfort. Still, as there is neither hobby nor business that does not, along with pleasure, at times cause inconvenience, and it may be, pain, we must not expect to reap the great advantages of successful bee-keeping without an occasional sting. Quietness and confi-

dence are most essential in managing an apiary; and neither can be obtained without practice. Any one who determines to succeed will do well to arrange with a friend or neighbor, or an expert if one is near, for a course of practical instruction in the ordinary work in an apiary worked for profit. The information obtained by such a course of practical instruction would doubtless prevent much waste and loss by experiments.

It is well-known that old bee-keepers often boast of their ability to hive swarms without protecting either face or hands. They may double up their sleeves, and better for them if they do, and hive the bees without a single sting being received; but that proves nothing in favor of the old, and nothing against the new system of bee-keeping. It must, however, be inferred by any casual observer of such performances that there are times when bees may be managed without much fear of the operator being stung. That is exactly what teachers of the modern system wish to become generally known, viz.: that if bees are only interfered with when they are in that amiable mood exhibited by them when swarming, bee-keeping will lose much of its terror. Previous to leaving the hive as a swarm, bees fill their honey-sacs, and it has been found that they will also do this when frightened. Now, tho it appears strange to talk of frightening bees, it is really an easy thing to do, for a little smoke driven into the hive-entrance has the desired effect. The bees at once rush off to their honey-cells and commence gorging, that is, filling their honey-sacs, and it is while they are thus busying themselves that combs may be examined. If any of the bees show any disposition to attack the operator, a little more smoke must be

given, but it should be borne in mind that a large amount of smoke is harmful, and may not have the soothing influence desired. At all times when there are in the hive cells containing unsealed honey, an occasional puff from the smoker will be ample to subdue any even-tempered colony.

The proper time to open hives is in warm, sunny weather when the bees are working merrily. If they appear restless, and run about the alighting-board, there is, probably, a dearth of honey, and consequently manipulations are not advisable.

HOW TO PROCEED.

To be quite prepared for easy and thorough examination of any hive we must provide ourselves with veil and intimidant. The veil should be made of white mosquito net, with a

front of black silk net. Round the top an elastic band should be run in a hem, so that it may be fastened around the hat, while the bottom of the veil is tucked inside the coat.

The intimidant, or frightener, may be smoke or carbolic acid; if smoke, it will be produced by burning coarse brown paper, fustian or rotten wood in the tube of a specially made "smoker." In preparing the smoker, the lighted end of the substance used should be put into the tube first; then upon the tube is fixed a funnel. At the bottom of the tube there is a hole; therefore, while the tube is in an upright position smoldering of the contents continues. To produce smoke in volumes, a small pair of bellows is fixed to the tube, the air being forced through the hole at the bottom. If the smoker is no longer required, the fire will go out by laying it in a horizontal position.

The fumes of carbolic acid are used either by saturating a sponge and placing it in the barrel of a smoker, or by dipping a cloth in a solution, and after wringing it dry, laying it up on the frames as the quilt is removed. The solution is prepared by putting 1½ ounces of Calvert's No. 5 carbolic acid and 1½ ounces of glycerine into an ordinary wine or spirit bottle, and shaking them until they unite. If then the bottle is filled with water a proper solution is obtained. If the glycerine is omitted, the contents must be well shaken before being used.

Having made all necessary preparations, first frighten the bees at the entrance, then remove the roof and lift and turn back the quilts from the outside frames. As they are being removed drive down the bees with a gentle puff of smoke along the tops of the frames. If the carbolic cloth is used it should be laid upon the frames as the quilts are removed. Almost at once the frames may be moved gently, and without jarring, so that the bees are not disturbed. If the hive is a tiering hive accommodating ten standard frames, the outside comb next to the operator should first be taken out of the hive so that the others may be removed with less inconvenience, and with less fear of crushing the bees. All examinations of the brood-chamber should be conducted with particular care, and as seldom as possible. By practice a thorough knowledge of the condition of each colony will be known; then from the time that supers are put on until the close of the season, it is seldom that further interference will be either necessary or desirable.

RE-HIVING SWARMS.

The method of hiving swarms into the straw-skep will be fully explained in a future article, but inasmuch as the skep should only be a temporary home, that is, until the evening of the day the swarm issued, how to get bees to change hives remains to be explained.

In the first place, the hive should be well painted and thoroughly dry. To get a swarm to take possession of a movable-comb hive is by no means a difficult matter, but the operation must be carefully conducted, otherwise among crushed bees may be the queen upon whose presence inside the hive success in hiving and afterwards depends.

First prepare the hive with frames, each containing a full sheet of foundation. But if the combs are to be evenly built in the center of the frames, the foundation must be wired into the frames, or only a few loose sheets be given when first hiving the swarm.

Starting with unwired frames, as the great majority of bee-keepers do, each sheet must be fixed in the saw-cut which runs through the middle and nearly from end to end of the top-bar. The foundation is quickly inserted by placing a small screw-driver in the middle of the saw-cut, and turning it around at right angles. While the sides of the bar are thus held apart the top of the sheet is placed between them and raised until it is level with the top of the bar. Being thus held, the screw-driver is removed, and the sides of the bar return towards their former position, thus holding the top of the sheet of foundation securely. The sheet thus hangs down from the top-bar. If then the hive is set perfectly level, the sheets of foundation will hang in the center of each frame.

Now in order to get these loose sheets of foundation properly and evenly built into combs in the center of the frames, the following rule must be observed: Place in the hive one more frame than the number of pounds the swarm weighs. For instance, if the swarm weighs four pounds give five frames. See that they are kept the proper distance apart by metal ends or other devices; then place at the side a plain board or dummy, so that the bees when in the hive will be kept compactly in the part occupied by the five frames. The bees should be confined to this number so that they will be compelled to spread out evenly on both sides of each sheet of foundation. Then being evenly balanced by the weight of bees on both side, the sheets hang in the center of the frames,

and remain there until the bees have attached them to the ends of the frames.

The following evening a slight examination of the frames may be made, but only by gently drawing them apart; then it must be only to see if any of the sheets have broken down. In a couple of days another sheet of foundation may be inserted between the outer frame and the next, and so on every three or four days, more or less according to the weather and the quantity of bees. By no means give more frames than they can well cover, but rather keep a moderate sized brood-nest, particularly if the swarm issues about the middle of the honey-flow. If the swarm be confined to six or seven frames, a small super may be given. Then, when the honey-flow is over, the super may be removed and the brood-nest enlarged by additional frames, but if breeding is to be continued, feeding will be necessary. Late swarms thus treated often give a nice super of honey, and are afterwards built up into magnificent colonies by Oct. 1, when all colonies should be closed up for the winter.

[Continued next week.]

Rendering Beeswax with the Solar Extractor.

BY O. O. POPPLETON.

On page 338 Mr. C. P. Dadant writes quite an article under the above caption, at the close of which he suggests that it might be well to give the subject a thorough examination.

My experience with purifying beeswax in the sun extractor has been exactly opposite to what Mr. Dadant's seems to have been. When I first read his article I was almost lost in amazement to understand how it was possible for two such experienced men as we are, to have had such directly different experience. A careful re-reading of what he wrote explains it, I think, and if I have misunderstood him he can set me right.

The details of our extractors, as well as our methods of using them, must be quite different, he only getting from his the one result of melting the comb, while I get both melting and the best results in purifying the wax of any method I have ever tried. It seems that Mr. Dadant allows the wax, as it drips from the comb-pan in his extractor, to cool and harden as it drips. This works exactly as he explains in his second paragraph, and more or less dregs and dirt comes off and is mixed all through the wax, and remelting in the extractor is only doing over again the same process with the same results.

Mr. Dadant has fully explained in the next paragraph the method and principle of purifying wax by allowing it to remain for several hours at a temperature between its melting and the boiling points, giving a chance for all impurities to settle to the bottom. This is exactly what can be done in the sun extractor just as easy as not to do it, and I had no idea that any one was using an extractor any other way. All one has to do to secure this in an extractor is to have it made enough larger to allow the dish which receives the melted wax from the comb-pan to be in the sun under glass, which keeps it in a melted condition for hours.

The extractors I use are of a size to take glasses 30x40 inches in size. The comb-pans are made from 20x28 inch sheets of tin, thus allowing ample room inside of the extractor for both comb and melted wax pans to remain in the sun.

When the melted wax is in the right condition, that is, just before the sun sinks low enough so the wax commences to cool, I dip off the wax into molds, using oblong square-cornered bread-pans for molds, and a small flat-sided dipper. Empty square cans, such as those used for cocoa or corned beef, one-pound size, are good. With care, nearly all the wax can be dipped off in an absolutely pure condition, leaving all the dirt and a thin layer of wax. These last thin cakes of wax, with such dirt as adheres to them, are allowed to accumulate until there is enough to make a charge for the extractor, when they are re-melted and treated the same as were the original combs.

Of course, if one doesn't wish to take the trouble of dipping off the wax into molds, he can, after it has hardened, scrape off the adhering dirt, as suggested by Mr. Dadant, but I greatly prefer the dipping process.

In either rendering wax, otherwise than caps that contain more or less honey, or purifying any that has already been rendered, I use water in the wax dish, substantially as suggested by Alder Bros., except that it is unnecessary to heat either extractor or water before placing combs in it, as the same heat that melts the wax will heat the other things. I use about an inch of water in the wax dish for two purposes—to keep wax from sticking to the dish, and having water in the dish makes it much easier to dip off the melted wax.

In one of the numbers of *Gleanings* (Aug. 15, I think) in

1883 appears the original article describing solar wax extractors, which article was the starting-point of all the extractors now in use, east of the Rocky Mountains, at least. Attention was especially called to this point, of the advantages of these extractors for the purifying of wax. I was at first much puzzled to understand how such an able, practical man as Mr. Dadant could have overlooked this feature of the sun extractor, until I thought of the fact that his establishment is equipt with as good a steam-purifying apparatus as exists, and it is much easier for him to use this than to fuss any other way with small lots. To the ordinary bee-keepers, however, who are the real users of these extractors, my method of using them will, I think, be much the best.

Dade Co., Fla.

[Accompanying the foregoing article by Mr. Poppleton, was the request that a proof of it be forwarded to Mr. Dadant before publication, so that Mr. D.'s comments might appear in the same number with it. Here is what Mr. Dadant has to say further:—EDITOR.]

This article of Mr. Poppleton's is excellent, and I can add nothing to it except the advice to those who use solar extractors to follow the instructions he gives.

I will say, however, that in rendering up residues, as we do here, where the beeswax rendered has been water-damaged, and has carried with it the very lightest of the impurities, it is necessary to still purify it with water, as the water becomes loaded with much of the coloring-matter which would otherwise remain in the wax, and we can obtain a better result than from the sun melting alone.

Allow me here, if I have not done it before, to criticise our manufacturers of sun extractors who use *iron pans*. The iron discolors a great deal of beeswax before it becomes sufficiently coated with it to cease damaging it. We have been several times enabled to test this to our entire satisfaction. The rust darkens the wax, and no amount of sun melting would remove this stain. Water alone can help it.

C. P. DADANT.

Do Italian Bees Produce Better Honey?

BY A. W. HART.

Will you permit me to briefly review Mr. Bevins' "answer" (page 322) to my question on page 269? It seems to me only an unfair, unjust criticism, and no answer at all. I prefer to appear fairly before the bee-keepers on whom he is pleased to intimate I am "putting up a job." He says he hesitated considerable about answering, etc. He need have had no hesitation, trepidation, perturbation, or any other 'ation, from his own admission. My question, clearly, was not intended for him, and was "confined" to one one, but for those who were wise and could answer, and he said he was not one of these. He said he was not writing for distinction, etc., yet he must have been, for he said he was not one of the "wise"—did not answer my question, and at the last left it to others.

He does "not know how extensive Mr. Hart's reading has been." Of course he doesn't. Isn't expected to, and I presume the limit of a short bee-article is rather poor data from which to find out; but is there not a sort of covert intimation that he does not think it very extensive, or at least not so much so as his? for he proceeds to say: "This is the first time I have known any bee-keeper to intimate that the quality of the honey produced by the Italian bees was any way superior to that produced by other bees."

Again, he says: "I have never seen an opinion that the quality of the honey produced by any one race of bees was superior to that produced by the other races," etc. Now, I have seen just that opinion, and so have hundreds of the Bee Journal readers. He says: "Mr. Hart thinks the difference, etc., if there is any." Mr. Hart does not think there is a difference, did not intimate it, only intimated the only way he could account for it, and is a skeptic in that theory; hence the "question." Had Mr. B.'s reading been a little more extensive he would have "hesitated" a little longer before he called in question, criticised, and disparaged mine, for have I ever held the idea that bees *make* honey? It seems to me any fair, candid, careful reader could have seen my sentiments all the way through my "piece." I ask the question in good faith, because some do hold those ideas.

Mr. B. says: "He is giving undue deference to the opinions of some who do not know much about bees, yet can do considerable talking." Well, that's good. I wonder if some of the Bee Journal readers with whom I have compared notes will feel complimented when they are informed by Mr. B.

that they can do considerable talking, but know little of bees. The only ones I have ever consulted with have been old, experienced, practical bee-keepers—some older than I am (and I have almost reached "the allotted age of man")—clergymen, doctors, professors, scientific farmers, etc. I wonder if they will smile, for some of them read the Bee Journal.

He says I "came at them with another if which is entitled to no more consideration than the other," plainly implying that neither was entitled to any. Why, then, did Mr. B. go to the trouble, after so much hesitation, to notice either of the ifs, if it was not for distinction?

"Who is able to say the honey from red clover is any better than that from white," etc. Has any one compared? Now on this point there may be opinions and intimations Mr. B. has not read, tho they may be from men who can "do talking but know little about bees." As to his reference about the "ignorant" and "ought to be ashamed," etc., I will pass by—there is no point.

It was from the opinions and statements expressed on pages 133 and 134 that I was led to ask my question. May be my question was entitled to no consideration, but the same question it seems came up in open convention, and was discussed by men perhaps of extensive reading, experience and wisdom, and whose opinions Mr. B. has never seen.

I submit to the bee-keepers if my question was fair and legitimate, and with no thought of putting up a job on them.

Stephenson Co., Ill.

Comb Foundation—Is Its Use Profitable?

BY E. S. LOVESY.

After reading what Messrs. Deacon and "Sage-Brush" had to say on this subject (see pages 599 and 708, 1897). I send a little of my own and other bee-keepers' experience. There are considerable sound, practical comments, and some reasonable conclusions drawn by Mr. Deacon, and while I agree with him to a considerable extent, my experience in this matter is such that some of my conclusions differ from his, and my object in this article will be to show wherein and why my experience does not agree with his.

He admits that there is an advantage in the use of foundation in excluding an excessive amount of drone-cells, but there is one point I might name here in favor of foundation, which neither Mr. D. nor "Sage-Brush" mentions, namely, that a plentiful use of foundation in the brood-chamber will insure not only nice, straight worker-combs, but it gives the queen ample laying-room, which in turn gives strong colonies, and without strong colonies no one can succeed in the bee-industry.

I might give considerable of my personal experience. The season of 1897, in the spring and early summer, our bees did not gather much honey, as a rule. There were a few exceptions, but soon after the middle of July, in many localities, a heavy honey-flow set in, and in many instances the bees brought the honey in so rapidly that as fast as the brood hatch the bees filled every possible space with honey, thus crowding the queen out of laying space. In traveling through this county I found hundreds in this condition, some with a few cells of brood, some with none, and some that were weak from this cause. But in every instance where the bees were not weakened down too much by taking out three or four combs of honey, and by replacing with sheets of foundation, the bees went to work drawing out the combs immediately, and in a few days the queen had these new combs full of eggs, even by the time the combs were half drawn out, keeping the bees busy finishing the combs and sealing the brood. Under those conditions the foundation was more preferable than to extract those combs and replace them, because in that case the bees, instead of cleaning out the cells for the queen to lay, would have filled them with honey again, but by using the foundation, and by extracting those combs and putting on another story with more foundation, the bees build up fast both in honey and numbers; but many of those not so treated proved a flat failure.

I also found hundreds of strong colonies with empty boxes, or boxes with empty frames, and bees would not work in them, but they would hang on the outside of the hive, while new colonies with frames of comb and foundation, with less than half the number of bees, filled their hives full of honey, gathering five or more pounds per day.

In the saving of time, by the use of foundation, Mr. D. asks, "Is this as great as is generally assumed?" He says: "Take two exactly strong colonies at the commencement of a good honey-flow, give to the one $\frac{1}{4}$ -inch starters, and to the other full sheets of foundation. Would there be any appreciable difference in the time the hives would be furnished with

completed combs? And even should there be a slight saving in time, would it be proportionate to the extra cost?"

According to mine, and the experience of many other bee-keepers here, I answer yes. I will give some illustrations of the season of 1897.

I divided some bees for a bee-keeper who would not use much foundation because of the cost. I took one of the new swarms, but when it came to putting on the surplus boxes mine were the weakest, owing to the hive being new and of a different shape from the others. The bees did not take to it as readily, but I put in four drawn combs and five sheets of foundation; in 16 days those nine Langstroth frames were full, filling a 10-frame hive, and weighing 72 pounds. I put surplus boxes on the 11 remaining hives at the same time, putting small starters on about half of the frames; three of them had no starters, and two had empty boxes and no frames, and while nearly all those colonies were strong, some of them did not gather 15 pounds in the 16 days, and the best one of the lot did not produce 35 pounds in the same given time.

I also sacrificed one of my own colonies in this experimenting. I had 10 colonies in 10-frame Langstroth hives, three stories; those colonies were so strong that they past in and out of the hives 40 or 50 bees in a cluster. I took one of the strongest of them and put small starters on half the frames, with the rest of the frames empty. On the other hives I put half drawn combs, and half with sheets of foundation. In 10 days the best of those colonies produced 93 pounds of honey, and the others ranged from 50 to 75 pounds, except the one with the starters and empty frames—it managed to partly build out the combs, and produced 32 pounds.

I might go on and give a hundred illustrations of this kind, but it is not necessary.

Mr. Deacon says the secretion of wax goes on, and by the use of foundation the scales fall wastefully to the floor of the hive. This is not my experience. In the use of foundation the wax that the bees produce is needed to draw out the combs, and the more we use of it, and the more drawn combs we have, the more honey we get, and the wax is needed for capping. Thus, while we use an abundance of foundation, we always use it for profit. But when it comes to the use of heavy brood foundation, five or six feet to the pound, I fully agree with Mr. Deacon. This building-out or pulling-out process never did give me any satisfaction. My experience has been that instead of saving time in pulling out heavy foundation the bees lost time thinning it down; besides, this objectionable feature, to have to pay 8 to 10 cents a surface foot for it, makes it much more expensive than the thinner variety.

I am aware that many bee-keepers think that heavy foundation is all right; under those conditions I would say, let all those buy it that want to, but for my part I don't want to.

The following report, from a Salt Lake county bee-keeper, speaks for itself. These results were obtained by proper management, and by a liberal use of foundation and drawn combs. I can vouch for this report, for I divided the bees, and I saw the crop of honey put up in 60-pound cans:

SALT LAKE COUNTY, Nov. 19, 1897.

MR. LOVESY:—I send you a report of my honey crop from 16 colonies of bees, spring count, taken off as follows the past season, extracted on the dates named:

July 2, 96 pounds; July 13, 206; July 23, 313; July 31, 432; Aug. 10, 513; Aug. 17, 510; Aug. 24, 630; Aug. 31, 635; Sept. 7, 550; Sept. 14, 537; Sept. 22, 690; Oct. 12, 688. Total, 5,800 pounds.

I have also taken off 100 frames from the top boxes containing from one to three pounds of honey, that I will use in the spring in building up. I also had an increase of 19 colonies, making 35 in the fall.

All of the above facts I'm willing to swear to if necessary. I thank Mr. Lovesy, our county bee-inspector, for his timely advice and assistance in the management of my apiary, and especially his method of increase by dividing pleased me very much. To him I owe, perhaps, my success.

WILLIAM.

This gentleman has personal reasons for not giving his full name and address. One reason for this bee-keeper's success was this: Through unwise counsel he packed his bees air-tight the previous winter, and smothered more than half of them, leaving an abundance of drawn combs, many of them partly filled with honey. Those frames and foundation were one of the main causes for the success obtained, because with them, and by exercising caution and wisdom in dividing, in a few days we had the new colonies working in the supers. This materially helped to produce the above results, as 3,000 bees can work on a sheet of foundation as easily as 300 can work on a bare top-bar.

In regard to the article by "Sage Brush," after asking,

"Is the use of comb foundation profitable when used in large quantities?" and after giving an emphatic No, he fails to give us one sentence in favor of his side, or the negative side of the question, and altho living in the wonderful honey-producing State of California, and in a locality, as he says, where the bees gather honey more or less all the year, thus making it possible to succeed better in experiments—yet, with all those experiments, and after getting such an abundance of nice worker-combs, he reports two good extractings from them the same season, while our Salt Lake bee-keeper got 12 extractings in 3½ months.

Still, "Sage Brush" must live in a good bee-country, for he says that after the honey or extracting season was over, he took all the frames except three from a number of colonies and started them to building worker-combs till he had all the combs he needed. But to adopt this method in some localities after the honey season is over, would be equivalent to killing the bees, but if he lives in a locality where the bees gather honey more or less all the year, why punish them by making them build combs instead of gathering honey? I think if "Sage Brush" will use plenty of foundation next time, he will have more profits and a better report.

Salt Lake Co., Utah.

Laws of Heredity—How Honey-Producers and Queen-Breeders Working Together May Profit by Them.

BY J. E. CRANE.

In previous issues of the Review I have given a number of illustrations showing the great changes in plant and animal life brought about by the agency of man. It may be briefly noted that such changes have been made as are most *useful* to man, or have most pleased his fancy. Thus we see that the blossoms of different varieties of cabbages or potatoes remain quite unchanged, as man has taken no special interest in them; while in plants cultivated for the beauty of their flowers, we find the greatest changes made in these parts.

There is really very little that is new in knowledge regarding the laws of heredity; as in an ancient Chinese encyclopedia, the principles of selection are fully given. Explicit rules are laid down by some of the Roman classical writers; and we find Jacob, nearly 4,000 years ago, breeding for color. In early English history, laws were made prohibiting the exportation of choice animals, and also for the destruction of horses that were undesirable.

The most eminent breeders do not favor the *crossing* of different breeds, but rather that of taking that breed that most nearly approaches their ideal, and then, by the most careful selection, breed out defects and up to their standard. To do this the greatest skill is required; as the law of reversion comes in which all improved varieties tend to revert back to their former type. Charles Darwin says:

"What English breeders have actually effected is proved by the enormous prices given for animals with a good pedigree; and these have been exported to almost every quarter of the world. The improvement is by no means generally due to crossing different breeds; all the best breeders are strongly opposed to this practice except sometimes among closely allied sub-breeds. And when a cross has been made, the closest selection is far more indispensable even than in ordinary cases. If selection consisted merely in separating some very distinct variety, and breeding from it, the principle would be so obvious as hardly to be worth notice; but its importance consists in the great effect produced by the accumulation in one direction, during successive generations, of differences absolutely inappreciable by an uneducated eye—differences which I for one have vainly attempted to appreciate. Not one man in a thousand has accuracy of eye and judgment sufficient to become an eminent breeder. If gifted with these qualities, and he studies his subject for years, and devotes his lifetime to it with indomitable perseverance, he will succeed; if he lacks any of these qualities he will assuredly fail. Few would readily believe in the natural capacity and years of practice requisite to become even a skillful pigeon-fancier."

It may be objected that the breeder of bees cannot control his male bees, consequently his work is largely one of chance; and there is some ground for this objection, but, on the other hand, the queen-breeder can rear several generations in a single season, or rear and thoroughly test two or three generations, while the breeder of domestic animals can rear only one; which will largely compensate for his inability to control the mating of his queens.

Before the advent of movable combs the breeding of bees, or the improvement of bees, was attended with far greater

difficulties than at present; and we are not surprised that they have changed less than other animal life under domestication; but now with the improvements of the last 50 years, and the light these improvements have given us, may we not expect that future improvement will be rapid?

The separation of bees into several well-known breeds, and the tendency of these breeds to vary, aided by the skill of some of our queen-breeders, leads me to believe that we may some day have a distinctively American breed adapted to our hot summers and cold winters, and great variety of flowers. Already I believe we have much lighter-colored bees than may be found in Europe. As there has been a demand for light-colored bees, the change in this direction has been more marked than in any other, but we must not forget that the amount of honey gathered by a colony of bees does not depend upon their color, but rather upon other and more valuable points of excellence.

I do not object to color, for bright-colored bees give pleasure to our love of the beautiful, and our climate and flora seem well adapted to such a race of bees, but I believe this matter of color has been carried far enough for the present. Let us rather select for queen-breeding those varieties the workers of which show the greatest ability to gather honey—white honey if it is to be had, and if not, can gather that which is darker; and those in which the swarming-impulse is but feebly developed.

Strength of constitution, gentleness, comb-building, prolificness and other qualities should not be neglected in making up the scale of points. A stream cannot rise above its fountain. Let our ideal bees be far in advance of our present breeds, and let us do what we can to bring our bees up to our ideal standard. "Bring the flag back to the ranks," was the command of the captain to his color-bearer, who had planted his flag in advance of his company. "Bring your ranks up to the flag," was his heroic reply. How shall we reach our ideal? Says a popular writer:

"The key is man's power of cumulative selection; nature gives successive variations; man adds them up in certain directions useful to himself. In this sense he may be said to have made for himself useful breeds."

Doubtless honey-producers must depend to a considerable extent upon the queen-breeder for these improvements. His experience, the time at his command, and the skill he has acquired, gives him greatly the advantage of those who are working for honey alone. The efforts of the queen-breeder may also be greatly aided by the honey-producer. Both must work together for a common object. The honey-producer from his larger number of colonies has a better chance to test the value of queens than has the queen-breeder; while the latter can do more to multiply and make valuable qualities permanent.

Sometimes a single colony will be very marked in almost every good quality, in a yard of 100 colonies. Such a colony came under my observation some years ago in one of my yards. Quiet, gentle, businesslike in breeding and comb-building, without any disposition to swarm, it worked on year after year for three years, when I moved it home to obtain brood from it to improve my home yard. Here it remained two years more with the same queen, always maintaining the same character. If I could have every queen as good as the one in this colony, the profits of my bees would be largely increased—I believe twice what they now are. But a long series of years and many generations with the most careful selection will be required to make such traits permanent, so they will "come true."

Already the outlook is hopeful. Already there is reason to believe that some of the queen-breeders are working along these lines, and if these papers shall stimulate others in the same work, I shall feel that they have not been written in vain.—Review.

Addison Co., Vt.

Selling Granulated Extracted Honey.

BY G. M. DOOLITTLE.

Selling extracted honey in the granulated state, according to my views, is the only real, practical way of selling such honey. If you sell it in the liquid state, and it is not consumed soon, it will granulate, and in that case requires more explanation to convince your customer that he has not been defrauded through a spurious article, than it does to tell him how he can liquify that in a granulated state. Then honey in the granulated state can be handled quite roughly without any leakage, while when in the liquid form there is nothing quite so easy as having everything all daubed with the stuff,

for customers seem bound not to keep it "right side up with care."

But there is one way of marketing honey, which is the "selling by sample." In all of my building up a trade for honey, I have found this the easiest. Go on every street in country, town or city and leave a sample of your product at every house, with the slip telling how to liquify it, or, if comb honey, cut off a "chunk" according to the number in the family, and then go around with what you have for sale two or three days later, and the houses where you do not make a sale, especially if you are willing to exchange the honey for the product of others, will be few and far between. This sample causes the "mouth to water," and the "good wife" and children prevail along the "honey line."

Then there is another way of marketing, applying wholly to extracted honey. When the honey has so granulated that it will but just run, pour it into light basswood boxes, holding 5, 10, 25 or 50 pounds, the same having been prepared during the leisure winter months, and having the inside corners paraffined, when it is to be set away till candied hard. Now put paraffine paper over the top, on this the slip about liquifying, and nail on the covers.

Next, from some of the same honey, cut out chunks weighing about two ounces, putting the same in a block of wood, having a suitable hole bored in it, or in a little box of suitable size, and mail the same to different parties in different towns, in regions where honey is not produced to any extent, putting in the slip about liquifying and telling of price, etc., when you will find orders coming in from fields rarely canvast for honey.

It is a good idea to mail such packages to postmasters, offering them wholesale figures on the honey, or offering a five or ten pound box at sample rates for introduction, and after once introduced, you will find a permanent market at such places. Such boxes of honey go at a low rate by freight, and as the honey is solid within there is little or no danger from breakage, even tho the boxes be made of one-fourth inch stuff. Years ago I shipped considerable honey in boxes this way, and never had a complaint from breakage.—Progressive Bee-Keeper.

Onondaga Co., N. Y.

Too Much Honey in the Hive.

BY HARRY LATHROP.

As a rule bee-keepers are not troubled with too much honey; but there are times when the brood-chamber may have too much for the best interests of the colony. In the earlier days of the extractor some writer advised to "keep the extractor going," and added that it would even pay to extract from the brood-chamber, and throw the honey away in order to give the queen room. If bees are properly handled there will be very little extracting from the brood-chamber. The ideal condition for colonies in the spring in this climate is to have them as my Browntown yard was this year; that is, come out of winter quarters quite heavy in stores, breed up rapidly, consume the honey in the combs, and replace it with brood, all stores to be consumed, and hive completely full of brood at the time honey begins to yield in excess of the daily consumption, at which time supers are added.

There is another condition I do not like, but one which I find in my Monroe apiary—a condition in which the colonies come out heavy with honey but rather weak in bees. Colonies build up slowly, and, instead of reducing the amount of honey in the combs, add to it from early sources. In such cases this honey must be promptly removed, or the colony will not amount to much.

My plan is to remove full combs and insert sheets of foundation in the center of the brood-chamber. The full combs removed, I sometimes use to contract brood-chambers in which I hive colonies to be run for comb honey. A full comb of honey is as good as a dummy for that purpose.

I was quite interested a few years ago in Mr. Boardman's plan of feeding-up in the spring, and two years ago last winter I spent a very pleasant day visiting at his home, and conferring with him in regard to it. I expected to try his method, and got a lot of feeders ready, but I have to confess that at this time I have had no chance to do any spring feeding since then, for the reason that I got all the honey I wanted, and sometimes a little more than necessary, from the fields. For my part I am glad of a condition which enables me to dispense with all feeding.—Gleanings.

Green Co., Wis.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Melting Down or Levelling Unfinished Sections.

Has it proved a success to melt off the face of unfinished sections in order to make them even, or would an uncapping-knife be better? What should be done when the melter forms a cap over the comb? About how many sections can be melted to their proper shape in an hour? IOWA.

ANSWERS.—Melting down the surface of sections by means of the Taylor handy comb-leveler is a decided success, doing the work more rapidly and more satisfactorily than it can be done with a knife, for the combs being tender, unless the knife is exceedingly sharp, there is danger of breaking down the cell-walls. It is a very unusual thing, I think, for the melted wax to form a cap over the comb. If any such ever did form, I always left it to the care of the bees. I never timed the work of the leveler, but at a guess I should say 200 might be done in an hour.

As I never had experience with very large quantities (I try not to have many sections that need leveling down), I leave the way open for others to answer.

Questions on Contraction and Reversing.

1. In contraction of the brood-nest, as W. Z. Hutchinson advises on page 403, how many Danzy brood-frames with only 1-inch starters would you give a new swarm? Also, how soon would you put on the super?

2. What would be the effect if the brood-frames were reversed containing both sealed and unsealed honey, just as a super is put on?

3. What would be the effect on sealed and unsealed brood in reversing?

4. How many frames should be reversed at a time? And how soon should they be changed back to the proper position?

5. In using a deep-entrance bottom-board, are the bees liable to build comb between the bottom of the frames and the top of the board, if there is an inch space? OHIO.

ANSWERS.—1. Give half of the 10 frames at the start. Put on the super at once if a queen-excluder is used under the super, otherwise wait two or three days.

2. If there was no brood in the comb it would probably have no effect at all. If brood were in part of the comb it might force some of the honey into the super. At one time such practice was considerably discussed, but at present it is hardly considered advisable.

3. Nothing, unless in a case where it might throw it out of place in a rather weak colony, running the risk of chilling if the weather should be cold.

4. Reverse the frames of only one hive, just enough to satisfy yourself that you don't want to follow up the practice. I don't know when is the best time to reverse back, but should think it might be in about two minutes.

5. With only an inch space it will be a rare thing to find any comb built down.

Do Not Work in Sections, Etc.

I started in the bee-business last year with seven colonies, and now have 65. I could have had many more but could not handle them.

1. My bees don't seem to work, but want to swarm all the time. Some of them will start and build comb in the super, and then quit. But few bees stay, and perhaps they will fill two or three sections. They have plenty of alfalfa, button-willow and white willow to work on. I am located on the San Joaquin river where there is plenty of bee-feed. Then they are very cross and will fight me at all times. Some of my new swarms have worked well, and had the supers filled in a few days, but the majority of them will go into the super and seem to work, and then quit. I could find no moths or anything bothering them, so could not decide what is the matter. The hives and supers are all nice and clean, as I always wash them out in strong salt water. They have become so bad that I

lose about one-half of them by their losing their stingers. They even go after the chickens and ducks. My neighbor's bees across the river are just as bad as mine.

2. I use the common box-hive 16x20 inches, with V-top brood-frames. What is the best hive to use?

3. What is the right way to handle beeswax for market?

4. What about straining honey? CALIFORNIA.

ANSWERS.—1. As nearly as a guess can be made from the particulars given, the trouble is that your bees always swarm about the time they get fairly started in the surplus apartment, and after swarming they are left so weak that they stop working above. The thing for you to do is to throw all the strength possible into the swarms, and depend upon them for your surplus. When a colony sends out its first swarm, set the swarm in the place of the old hive, setting the old hive close beside the swarm. A week later take the old hive away, setting it in an entirely new place. By that means you weaken the old colony so much that it will swarm no more, and you also strengthen the swarm so much that it will be strong to work in the supers. The super may be put on the swarm two or three days after hiving, unless you have a queen-excluder under the super, in which case the super may be put on at once.

I hardly know what you mean by half of your bees losing their stingers, but perhaps if you should make a careful count you would find that a very small number have lost that useful appendage.

2. The term "box-hive" is used as applying to a box or hive in which there are no movable frames. As you have V brood-frames, you must have frame hives. It is quite possible that the hive you have is as good as any, an objection, however, being that it has a frame of an odd size. If you make a change, you will probably do well to adopt the frame that comes nearest standard in size, that which is commonly called the Langstroth frame, 17 $\frac{1}{2}$ inches long and 9 $\frac{1}{2}$ deep, outside measure.

3. If you should see the beeswax that is thrown on the market, you would probably conclude that there is no wrong way. But the brightest, cleanest wax brings the highest price. If you will get a solar extractor you will probably be all right as to the quality of your wax.

4. About the only way in which honey is strained, nowadays, is the straining of extracted honey, and all that is necessary is to let it pass through cheese-cloth, or some thin stuff, to take out the small quantity of bits of wax, or other objectionable parts that may be present.

When to Remove Surplus Honey.

When shall I take off the sections? A bee-keeper friend advises doing it when every one is filled and capped. Another, take off every box you can find in your super properly capped, and not wait until all are full. I never put on but one story of one-pound sections, and on a box-hive. I noticed the last row of 3 out of 18 in all remained uncapped over a week after others were all capped, so I removed 15 and put back the 3, and it would seem there would be a period of idleness unless this was done, as the whole colony could not work in 3 sections. Yesterday I took off 15 sections completely capped, from an early swarm in a 10-frame Langstroth hive, and put back 12 sections, about $\frac{1}{2}$ of the cells being capped, with 3 of the sections (in the outside row) the comb not extended. Now I could have waited longer, without doubt, in this case. Is it any damage to disturb the super? A few bees will get hurt. Will this white honey (stored from white clover) change color any for a difference of two or perhaps three weeks in time of removal? MASSACHUSETTS.

ANSWERS.—Answering your questions in their spirit rather than in their order, it may be said that any harm resulting from the disturbance of the colony in taking off supers is hardly enough to be taken into account. If a section of honey is left on three weeks after it is sealed over, the cap-pings will become darker, and such section will not be quite so good for the market as if taken off just as soon as sealed, for the market demands the very whitest. As to the quality of the honey in the cells, it will not become any darker in color, but will become riper, as it is called, that is, it will become thicker and better. So if you want the sections for your own use, and don't care so much for looks as you do for eating qualities, you will do well to leave the sections on some time after they are sealed.

If you leave a super of sections on the hive till the last section is sealed, not giving any additional room, the bees will be crowded for room while sealing up the last, if honey is coming in. Better give additional room by putting a second

super under the first when the first is perhaps half filled. If you want sections very white, don't wait till the outside sections are all sealed. Some advocate taking out the sections singly as fast as each one is sealed. You'll hardly keep that up very long on a large scale. Too much work. Take off the whole super as soon as all are sealed except the four corner sections, and perhaps a few others. Then take out of the filled supers all that are not fully sealed, put them together in a super, filling up with empty sections, if necessary, and put back on the hive to be finished.

Getting Honey When Others Do Not.—Gleanings reports Vernon Burt as getting honey when others in his region were getting none, the secret being that Mr. Burt had followed the Boardman plan of feeding in advance so as to have the brood-nest full, which otherwise would have had to be filled with the honey that was put in the supers.

Hive-Tool.—For prying loose frames, supers, etc., a screw-driver is quite commonly used. The editor of Gleanings is on the hunt for a better tool, and the fraternity, as usual, are prompt to give help, so it is to be hoped that a good tool of the sort will shortly be on the market. Fred S. Thorington says, in the Progressive Bee-Keeper, that he takes the top layer of a buggy-spring.

Comb vs. Extracted Honey.—R. C. Aikin seems to think there is not such a very big difference between the amount produced by a colony, whether comb or extracted; while G. M. Doolittle says he has repeatedly proved that the average yield of extracted will double that of comb. But he says that with the same labor he can sell double the amount of comb, and generally get double the price.—Progressive Bee-Keeper.

Weight of Sections.—F. Greiner says, in Gleanings, that the wood in sections should not be less than $\frac{1}{4}$ -inch thick; 1,000 sections weigh about 60 pounds. When they are enough thinner to weigh only 50 pounds, the bee-keeper loses \$3.50 on a thousand sections, because the wood is sold with the honey at 10 cents a pound, bringing \$6.00 a thousand or \$3.50 more than the cost. The editor says many western bee-keepers prefer sections nine to the inch, because the freight is less. But it would have to be a long haul to make the freight on 10 pounds equal \$3.50.

Improvements in Section-Cleaners still continue. In Gleanings, Arthur Howe describes a cleaner he has made, using an old bicycle as the power, geared so that one pedal revolution equals a wheel 66 inches in diameter. Above is a master-wheel of an old sewing machine, connected with a pulley on the polishing-lathe, which has two polishing-wheels, one covered with No. 1 $\frac{1}{2}$ sand-paper for the rough work, and the other with emery-cloth to finish with.

In the same paper, H. Perry's suggestion is to have a disk fitted out with rasps next the periphery, and with sand-paper in the center. The rasps are to take off the bulk of the propolis; then by sliding the section to the center of the disk the sand-paper is to finish the job.

Contraction of Colonies.—Messrs. Hutchinson and Taylor are in controversy with the editor of Gleanings. The latter referred to the contraction of the brood-nest as a fad that had perhaps past away. Editor Hutchinson replies:

"So far as I know, no one has practiced contraction of old established colonies—those that had their brood-nests filled with bees, brood and honey—it was only in hiving swarms that contraction was practiced. It is possible that some practiced contraction with established colonies; it seems that you have understood it that way, but you are the first man I have ever met who so understood it or practiced it."

Mr. Root says contraction of established brood-nests is referred to in "Langstroth-Revised," and in Root's "A B C of Bee-Culture." After consulting back volumes of the Review, American Bee Journal, and Gleanings, he confesses that there were more cases than he had supposed of contraction at time of swarming, but still thinks the majority were of the other

kind, and gives the following from Miller's "Year Among the Bees":

"Up to the time of putting on supers, the desire has been to have the bees occupy as many combs as possible. . . . When it comes time to put on supers they are reduced to four or five frames."

Bringing the matter down to recent date, he gives the following quotation from the Belgian L'Abeille for June, 1898, in its regular department of instruction for the month:

"In order to force the bees to occupy them immediately, it is advisable to limit at the same time the space which the colony occupies to about $\frac{2}{3}$ of its capacity. If this practice brings the colony to the swarming point, the swarm is put upon a few frames."

It is very evident that the two gentlemen have been looking at opposite sides of the shield, if indeed they have not been looking at two different shields.

Marketing Honey.—R. C. Aikin gives, in Progressive, the general principles upon which he proceeds, as follows:

"Having studied out the situation I try to do what is right, and what I can do. If the city and general markets will not pay good prices, I decide that the poor at home have a better right to cheap eating than has the man with capital. It costs me a little more to sell out in small lots than to sell at wholesale, so I charge a little above the wholesale price, and let my neighbors have my honey. The poor man's 50 cents will buy just as many pounds as the rich man's, one price to all—no cut for quantity. I try to make my extracted take the place of foreign sweets—sugar, syrups and glucose. My comb honey I hold higher, because it requires more skill, which means more preparation on my part to be able to do it well—to produce it. I take trade whenever my neighbor has what I need, and would buy."

Bee-Quilts.—Those who still use sheets or quilts over their frames may be interested to know how Fred S. Thorington manages it, as given in the Progressive Bee-Keeper. He says:

"For a cloth cover over frames, sections, etc., I use heavy, unbleached sheeting boiled in linseed oil, in which some rubber cut in small pieces has been thrown, the oil and rubber boiled together for a few moments before the cloth is put in. The cloth should be held upon a stick in the air occasionally, and be kept well stirred while being boiled. When done, hang to dry a short time before being folded or cut into blankets to fit the hive. Rubber from the soles of shoes or boots, if good, will do to use. I have used blankets made as above mentioned for years, and find the bees do not gnaw them much. Oil enough to cover the cloth when boiling is all that is wanted."

Selling Granulated Honey.—R. C. Aikin says he has changed his practice, and now does not try to keep his extracted honey liquid, but sells it in the granulated state. He thinks there is no trouble about it when people get to understand it. Of course he gives printed instructions for the management of granulated honey. G. M. Doolittle thinks it is the only really practical way to sell extracted honey. If sold in the liquid form, the customer thinks he has been imposed upon when the honey granulates. Grocers have less "daub" with granulated than with liquid. Another very important point, if correct, has perhaps not been given in print before. Mr. Doolittle says:

"Then every time granulated honey is liquefied, there comes to it that nice aroma, so inviting to the smell and taste, which it had when fresh from the combs, while that long standing in the liquid state, loses this aroma, to a certain extent."—Progressive Bee-Keeper.

Honey as Food is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey among should-be consumers. The forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 20 cents; 50 for 35 cents; 100 for 65 cents; 250 for \$1.50; 500 for \$2.75. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Every Present Subscriber of the Bee Journal should be an agent for it, and get all other bee-keepers possible to subscribe for it. See premium offers on page 458.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

JULY 21, 1898.

NO. 29.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Still There's Room.—General-Manager Secor, of the United States Bee-Keepers' Union, writing us July 9, said :

"Say, those Arizona bee-keepers are hustlers. They sent in 18 names and dollars in one batch recently. We are 'getting there' slowly. Still there's room in the largest organization ever known in America for bee-keepers."

Yes, of course there's room for more, and we hope that a great many others will join the Union at once. It should be 1,000 members strong now, then when the Union started out after anything it would be more likely to get it. We would like to know that every reader of the American Bee Journal is a member of the United States Bee-Keepers' Union. Why not?

Plain Sections a Success.—Hon. Geo. E. Hilton—one of Michigan's largest bee-keepers—wrote Gleanings recently: "My men report the plain sections a success." Another correspondent reported: "I have just taken off some of the new plain sections, and they are a success, sure—well filled—not too full."

All will be interested to know the final verdict on the plain sections and fences after general and thorough trial this year.

Important to Minnesota Bee-Keepers.—We received the following letter just a little too late to appear last week :

EDITOR YORK:—Will you please ask the bee-keepers of Minnesota, through the columns of your paper, to correspond with E. L. Danforth, Secretary of the State Commission of the Trans-Mississippi International Exposition, 221 Kasota

Building, Minneapolis, Minn., with the view of furnishing honey for exhibition at Omaha? Bee-keepers will be paid for their product as soon as it can be sold after the Exposition. Any damage or breakage will be made good by the Commission, and the highest market price will be obtained. It is very important that the Commission have honey right away, both comb and extracted, in order to make a creditable display for our State.

Yours truly,

Mrs. H. G. ACKLIN,

Chairman Committee Minnesota State Bee-Keepers' Association.

In a note following the above Mrs. Acklin suggested that we add "something which will arouse the interest of Minnesota bee-keepers, as they are responding very slowly to the call for honey." We cannot see how anything that we might say would emphasize the foregoing appeal for honey. State pride alone should cause the bee-keepers of Minnesota to write at once to Mr. Danforth, and offer him all the honey he can use—that is, if the bee-keepers have any honey that they can furnish.

Treating and Curing Foul Brood.—Mr. N. E. France, Wisconsin's foul brood inspector, in the Review reports on his work. He says, among other things :

"In general, I follow Mr. McEvoy's treatment, and, so far, have cured every case I have handled—burning only two hives. Such property as can be saved I never destroy. The old, diseased combs and frames contain the danger, and in most cases are burned."

We are glad to note that Mr. France is having such uniform success in his efforts. He has a large field to cover, and evidently is doing a good work. He seems to be the right man in the right place.

Great Basswood Bloom.—Early Tuesday evening, July 12, we mounted our bicycle and rode some 8 miles from Chicago to see Mr. H. S. Jones—a bee-keeper who has 30 colonies—and also to view the wonderful basswood bloom near him. We could inhale the delightful perfume of the blossoms some rods before arriving at the trees. The tops of some of the stately basswoods presented the appearance of fruit trees laden with their abundance of luscious fruit at harvest time. One tree was measured, and it had a diameter of full 30 inches, being perhaps 75 to 100 feet tall.

We understand there are several hundred acres along the river in one strip, and the bees fly like bullets to and from the basswood bloom. Of course there will be a large yield from that source.

The country surrounding this forest with its numberless basswood trees is well stocked with bees, and their owners will doubtless secure a good crop. There is also much sweet clover all along the roads, so that from both the basswood and clover the bees should render a good account of themselves by fall.

Freight Rate on Bees.—Some time ago there was a petition sent to the Western Classification Committee, requesting that bees in hives be given a less than carload rating. That petition came before the Committee at its late meeting at Manitou Springs, Colo. We wrote the chairman of the Committee, Mr. J. T. Ripley, to learn as to the fate of the petition, and the following is his reply :

GEORGE W. YORK, Esq., Editor American Bee Journal.—

Dear Sir:—Answering your favor of the 7th inst.

At the late meeting of this Committee, the petition to provide for shipments of bees in hives in less than carloads was considered, but no change in the classification was made.

The members of the Committee seemed to feel that it is not safe to carry the goods by freight trains, and that it is fairly express traffic. No other objections were urged, as I recall it.

Yours truly,

J. T. RIPLEY,

Chairman Committee.

Indirectly we understand that the petition came very nearly being granted; and that if bee-keepers had shown the slightest interest in the matter it would almost certainly have been

approved. We urged bee-keepers to write letters to the Classification Committee, calling their attention to the justice of the petition, and that it be favorably acted upon. And yet we learn that *only two or three* letters were received by the Committee! How is that for apathy and general indifference on the part of bee-keepers? And that, too, when it comes to a matter that is wholly in their interest.

It seems strange that it is so hard to get bee-keepers united on one thing. Nothing can be accomplished in any other way. "In union is strength" is as true to-day as ever. Bee-keepers need to learn that truth, and then whenever there is an important object to be gained, *all* pull together and win.

Wortman's Handy Tool.—A short time ago we received the following from Mr. A. Wortman, of White Co., Ind.:

I send you a rough sketch of a combination tool I had made out of a heavy file. It is just the thing for lifting

frames and supers, and cleaning off any wax on supers, covers, etc. I will give it to the bee-keeping fraternity.

A. WORTMAN.

The illustration shows the tool very well. Mr. W. calls it, "Wortman's handy tool for bee-keepers, being a hammer, tack-puller, frame-lifter, super-lifter, knife for cutting burr-combs, scraper for cleaning propolis from hives, etc."

Sugar-Honey in Germany.—The following paragraph appeared in the Chicago Inter-Ocean for July 13:

SUGAR-HONEY.—A substitute for honey has been introduced in Germany under the name of "sugar-honey," and consists of sugar, water, minute amounts of mineral substances, and free acid.

We can see clearly enough where the "sugar" part comes in, but fail to find any "honey" about it. But perhaps some of that "free acid" is formic acid! There's lots of it to be had "free" around our hives. You needn't even go to the trouble of asking for it!

But, seriously, why should any one want a substitute for pure honey when there is plenty of the latter to be had, and at a low price, too? Simply another fraudulent scheme to get money under false pretenses. But Germany is not alone in that business.

MR. N. E. FRANCE, of Grant Co., Wis., State inspector of apiaries, writing us July 12, said:

"Basswood is doing well at this date, but is not going to last many days longer. We have extracted 20,000 pounds of honey to date."

MR. EDWIN BEVINS, of Decatur Co., Iowa, sends us the following paragraph:

"I notice that Editor Hutchinson has engaged R. L. Taylor to be general critic for the Review. I hope Mr. Taylor will turn in page 152 of that paper for May, and see if there is anything to find fault with in that paragraph which relates

to the "curling of comb foundation." My school-teachers did not allow me to use adjectives for adverbs."

The sentence to which Mr. Bevins refers, we think, is this:

"In their troubles the lower edge of the foundation turns *invariable out*, away from the center of the super, etc."

Of course Mr. Taylor should have used the word "invariably" instead of "invariable," in the sentence referred to.

"People who live in glass houses shouldn't throw stones," is pretty good advice—unless they are willing to take a few smashes themselves in return.

MR. J. F. EGGERS, of Hall Co., Nebr., wrote us July 11:

"White and sweet clovers are booming, and so are the bees."

Mr. Eggers is the author of that latest German bee-book—"Bienenzucht und Honiggewinnung." It is up-to-date, and is sent postpaid for 50 cents. Orders may be sent to this office.

MR. LOUIS R. LIGHTON, of Omaha, referring to the meeting of the United States Bee-Keepers' Union there this year, said in a letter to us:

"I can assure you that Omaha will appreciate a convention of this kind; and you may have no fears but what you will have a *royal good time*."

No doubt Nebraska bee-keepers will do grandly by the convention this year, as they did when it was held at Lincoln, in 1896.

EDITOR R. F. HOLTERMANN, of the Canadian Bee Journal, will have charge of the apianian exhibit at the Exposition and Industrial Fair to be held in Toronto, Ont., Aug. 29 to Sept. 10. Our esteemed contemporary says:

"It will show the natural history of the bee, and how honey is produced. . . . It will be one of the most attractive exhibits on the grounds."

We don't doubt it at all, for those Canadians know how to put up a good apianian show. And Editor Holtermann will supervise it all right.

MR. H. H. KNAPP, of Fairfield Co., Conn., wrote us June 27:

"Please discontinue the American Bee Journal to me after my subscription expires, July 1, 1898. I will not renew again, as I am now nearly 80 years old, and cannot attend my bees as I used to, so give up the Journal. I wish you every success for the future of your paper."

Quite frequently we receive letters like the above. There is a sadness about it, as we must all come to the evening of life some time, and lay down all earthly cares. The bees must be left behind, and the papers as well. It is sad to part with the old friends who have been with us long, who know us well, and whom we know. But there is comfort in the thought that when we have grown old in our work here, "over yonder," in that better home, we'll all be young again, and begin anew that higher life. So while we may feel saddened when the old friends leave us, yet we can rejoice with them in the thought that shortly they'll be where cares come no more—where there is no more sickness and pain—where there's rest.

There is also encouragement in the thought that while some are giving up the work others are coming on the stage of action, and will take up their share of the world's burdens. And so it ever goes on—some are going, others coming, and all marching "onward and upward."

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles :

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This is a series of practical articles that bee-keepers of the United States will not want to miss reading. They will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents--
To a NEW Subscriber--thus making it

SIX MONTHS FOR ONLY FORTY CENTS--

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of one of the following list, for each NEW 40-cent subscriber you send :

For Sending ONE New 40-cent Subscriber :

- | | |
|---|--|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood--by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage--by Prof. Cook |
| 3 Handbook of Health--Dr. Foote | 12 Foul Brood Treatment--by Prof. Cheshire |
| 4 Poultry for Market--Fan Field | 13 Foul Brood--by A. R. Kohnke |
| 5 Turkeys for Market--Fan Field | 14 Muth's Practical Hints to Bee-Keepers |
| 6 Our Poultry Doctor--Fan Field | 15 15 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing--Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse Book | |

For Sending TWO New 40-cent Subscribers :

- | | |
|--|---|
| 1 Potato Culture--by T. B. Terry | 7 Hutchirson's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Blenc-Kultur--German |
| 4 Dr. Tinket's Bee-Keeping for Profit | 10 Bees and Honey--160 pages--by Newman |
| 5 40 "Honey as Food" Pamphlets | 11 People's Atlas of the World |
| 6 Winter Problem in Bee-Keeping--by Pierce | |

All New Subscriptions Begin July 1.

Please remember that all the above premiums are offered only to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Be It Known

To all Men, we are prepared to fill orders promptly for

CHOICE QUEENS of the best strains of Golden or Leather-Colored Italian....

Tested \$1.00; Untested--one, 75c; three, \$1.50. After July 1, 50c each. Remit by Express Money Order, payable at Barnum, Wis. One and two-cent stamps taken. Address,

Van Allen & Williams,
25 Atf BARNUM, WIS.

Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases--everything used by bee-keepers. Orders filled promptly. Send for catalog. MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.

Please mention Bee Journal when writing.

ONE MAN WITH THE UNION COMBINATION SAW

Can do the work of four men using hand tools, in Rippling, Cutting-off, Mitring, Rabbering, Grooving, Gaining, Dadoing, Edging-up, Jointing Stuff, etc. Full Line of Foot and Hand Power Machinery Sold on Trial. Catalogue Free.

SENECA FALLS MFG. CO.,
46 Water St SENECA FALLS, N. Y.

Please mention Bee Journal when writing.

BEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, E. L. CARLINGTON,
11 Atf De Funiak Springs, Fla.
Please mention Bee Journal when writing.

In the multitude of counsellors there is safety.--Prov. 11-14.

Should Everybody, or Every Farmer, Keep Bees?

Query 77.--Is it to the interest of the honey-producers of America to advocate that everybody, or every farmer, should keep a few colonies of bees?--Calif.

- E. France--No.
- W. G. Larrabee--No.
- A. B. Mason--No, sir.
- D. W. Heise--I think not.
- Rev. M. Mahin--Of course not.

Prof. A. J. Cook--I do not think it true, and so not for the interest of anybody.

O. O. Poppleton--I doubt whether honey-producers will be very much affected either way.

Jas. A. Stone--If it would encourage them in producing honey-plants I would say yes. If not, I would say no.

Emerson T. Abbott--It is to the interest of the farmer, and, if he follows my advice, he will be a honey-producer.

J. A. Green--I think that it is very decidedly against their interests financially. If we had only one-half or one-

fourth the present number of honey-producers we would get much better prices for honey, and it is the small producers who damage the markets most.

R. C. Aikin—Everybody should not keep bees, but the majority of farmers should produce their own honey. That is my advice.

J. E. Pond—No, not in my opinion. Reasons are ample for my opinion, but as they are not asked for, I will not take space to give them.

J. M. Hambaugh—While I believe it would be to the best interest of humanity in general, it might not be to the best interest of the specialist.

Mrs. L. Harrison—No; but it is for the good of the land in which we dwell. Plenty of bees to fertilize the flowers—more fruit, clover, vegetables, etc.

Dr. C. C. Miller—I don't know. Whatever is the thing that will be the greatest good to the greatest number is the thing that ought to be done.

Eugene Secor—Perhaps not to the interest of the specialist, but I think it to the interest of the people if said farmer will so inform himself as to produce what his family needs.

R. L. Taylor—No, it's not to the interest of honey-producers. The interests of the public and the interests of the followers of any occupation are very liable to clash.

C. H. Dibbern—No. I am a merchant as well as a bee-keeper, and I should consider it a very foolish, as well as suicidal proceeding, to preach to everybody to go into my line of business.

Mrs. J. M. Null—No. Most generally the breaking down or ruin of markets is directly attributable to this class of bee-keepers, and they succeed equally as well in the line of overstocking a locality.

Chas. Dadant & Son—It matters but little, for no matter what you say or advise, there will only be a small proportion of successful apiarists among our farmers. Only those who like the pursuit will stay with it.

P. H. Elwood—No. There can be an over-production of honey as with everything else. And it is the observation of bee-keepers that those who keep but a few colonies are more liable to cut prices than those who keep many, or are more dependent upon their bees for a living.

Dr. J. P. H. Brown—I am not so selfish as to believe that the interests of the specialist honey-producer would suffer. There are too many mouths in America to take in the honey if the taste is cultivated. Each producer must do his part toward developing the taste.

G. W. Demaree—There is mighty little to trouble intelligent bee-keepers along this line. People who keep a few colonies of bees don't know enough about bees to hurt the honey-trade. Sometimes they have them and sometimes they don't. Bees are not like weeds! Don't be disturbed. It requires knowledge, and work, too, to succeed with bees.

G. M. Doolittle—Is it to the interest of the producers of poultry, hogs, sheep, cattle and grain to advocate that everybody, or every farmer, should keep or raise a few or as many of the above as he pleases? It is not well to get little and mean in our ideas regarding keeping others out of the business we are in. The world is broad enough for all who are willing to work, but should have no

A Book Recommended by Dr. Gallup.

THE NEW METHOD

In Health and Disease.

By **W. E. Forest, M. D.,** 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a **HOME PHYSICIAN,** and as

A Guide to Health.

It makes the way from **Weakness to Strength** so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings **cannot be sick.** It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, **not a drug treatment.**

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "*New Methods*" given here; even those who have been pronounced **Consumptive** have been entirely cured. While for **Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women,** etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "*New Methods*" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

place for the "sponge" who does nothing but appropriate from the labor of others.

E. S. Lovesy—No, not unless they are more or less practical bee-keepers. Because they often through ignorance injure the industry by their bees becoming diseased, and by scattering the same. And they too often entirely demoralize the home market by offering a mixture strained from melted wax, pollen and honey, for any price, and, as with some people, everything is "honey" that is called by that name. Thus, when the bee-keeper comes along with the best that the market affords, he is expected to sell it for the same price as the inferior article.

The Honey-Harvest Morn.

BY MRS. J. W. SUTTON.

When the frosty winds have left us,
And green foliage decks our land,
And the countless million blossoms
Greet us like a fairy hand—
Then with joy we greet the dawning
Of the honey-harvest morn;
And we hail the sweet alfalfa,
And the blossom on the corn.

For to us 'tis sweeter music,
Than the sweetest voice can sing,
Just to listen to the humming
Of the bees upon the wing,

As they gather in the nectar,
Tuck it safe for winter store.
And we do not blush to steal it,
If a dozen times or more
They with toil should fill the supers,
With the sections smooth and clear.
We appropriate their earnings
With a conscience void of fear.

Fear of law, but not of stingers,
For the plucky little bee
Can with stings defend its treasure,
That is very plain to see.
But when taken in the summer,
"Take it, hog!" they seem to say,
"We will work again the harder,
After the next rainy day.

"And will fill again our supers,
So that when the frost winds blow,
If you then would steal our treasure,
We stand guard all in a row.
And we'll sting with all our fury,
For it is our winter's store.
And if you should rudely take it,
We would search in vain for more."

—Progressive Bee-Keeper.

Bees Doing Nothing.

Bees are doing nothing so far this year. We had a terrible freeze here March 24, everything being killed. There was not a drop of honey till May 15. I had to feed a number of colonies. I have not had a swarm yet. The bees are working in a few of the sections now.

A. BISHOP.

Callahan Co., Tex., July 2.

Poorest Season of All.

We have had several poor seasons since 1890, but this season beats them all, as from nearly 100 colonies we have not had a single swarm up to date, while bees are driving out drones as fast as they hatch. We had almost constant rain in April, May, and part of June,

Excursion to Chautauqua Lake

over Nickel Plate Road July 29 at one fare for the round trip. By depositing tickets with Secretary of Chautauqua Assembly, same are available for return passage within 30 days from date of sale. City ticket office, 111 Adams St., Chicago, Van Buren Street Passenger Station (on the loop.) Telephone Main 3389. (43-28-3)

and bees quit breeding during that time. There is no sign of their working in the supers as yet. If the fall flow is no better, we may have to feed to take the bees through the winter.

MAX ZAHNER.

Johnson Co., Kans., July 12.

Slow to Go into Supers.

I have 30 colonies in 16x20 hives, and think they are about the right thing in this climate. I have a few colonies that are doing finely, and some that are slow to go into the supers. I wish I could learn how to get them to start in the supers. I am working for comb honey, mostly; am also getting ready for extracted, as soon as I get enough to work in the top stories.

GEO. H. LAWRENCE.

Juneau Co., Wis., July 9.

Very Dry Time.

The season has been a very poor one for honey so far. White clover is all gone—mostly dried up, bees working but three days on it while it was in blossom. Sweet clover is drying up, and unless we get rain soon that, too, will soon be gone. Catnip seems to thrive in spite of the dry weather, but even that would do better if it had rain.

H. G. QUIRIN.

Huron Co., Ohio, July 14.

Bees Did Well.

Bees did well until a few days ago. Basswood is not yet in bloom.

CHAS. E. CRAWFORD.

Oscoda Co., Mich., July 10.

White Clover Scarce.

I have 12 colonies, which I will run for comb honey. I got but little honey from white clover, as it is very scarce. Basswood is just beginning to blossom, and I expect a good flow from that source.

JOHN V. BARKER.

Miami Co., Ohio, July 3.

Honey-Dew.

There is plenty of white clover here, but no honey. My bees are very strong. I had several swarms. I examined the bees last week, and took off about 100 pounds of "honey." O my! the blackest, nastiest stuff you ever saw—honey-dew of the very worst kind. But I will try again for a fall crop. I gave them a fresh supply of nice, new sections, and I do hope the next take-off will be nice honey, for I am fond of honey; but I can't go the honey-dew.

C. V. MANN.

Sangamon Co., Ill., July 10.

Bee-Keepers' Photograph.—We have now on hand a limited number of excellent photographs of prominent bee-keepers—a number of pictures on one card. The likeness of 49 of them are shown on one of the photographs, and 121 on the other. We will send them, postpaid, for 30 cts. a card, mailing from the 121 kind first; then after they are all gone, we will send the 49 kind. So those who order first will get the most "faces" for their money. Send orders to the Bee Journal office.

Illinois.—The annual meeting of Northern Illinois Bee-Keepers' Association, will be held at the Court House, in Freeport, Ill., Tuesday and Wednesday, August 16 and 17, 1898. All interested in bees are invited to attend.

B. KENNEDY, Sec., New Milford, Ill.

Large New Maps of KLONDIKE—ALASKA—CUBA FREE

To all who order the People's Atlas of us now we will send free maps of Cuba and Alaska, newly engraved from the latest governmental surveys and official information. Size of each map, 14 by 22 inches. The Alaska map accurately locates the Klondike country and other great gold-fields in that far-off land, and the routes by which they are reached. A brief history of each country accompanies the maps. See our offer below:

OVER 200 MAPS AND ILLUSTRATIONS

THE PEOPLE'S ATLAS contains over 200 large Maps and Illustrations, and 132 Pages, each page 11 by 14 inches. It gives the Population of each State and Territory, of All Counties of the United States, of American Cities, by Last U. S. Census.

HANDSOME MAPS.—The handsome Maps of all the States and Territories in the Union are large, full page, with a number of double-page maps to represent the most important states of our own country. All Countries on the Face of the Earth are shown. Rivers and Lakes, the Large Cities of the World, the Railroads, Towns and Villages of the United States are accurately located.

SPLENDID PICTURES embellish nearly every page of the reading matter, and faithfully depict scenes in almost every part of the world. It contains a vast amount of historical, physical, educational, political and statistical matters, comprising a General Description of the World.

EACH STATE.—This Atlas gives about each State the Population for the Past 50 Years, History, Miles of Railroad, Soil, Climate, Productions, Industries, Educational and Religious Interests, Interest Laws, Etc., Etc.

THE UNITED STATES.—This Atlas gives the Popular and Electoral Votes for President in the years 1892 and 1896, by States. List of All the Presidents, Agricultural Productions, Mineral Products, Homestead Laws and Civil Service Rules, Statistics of Immigration, Public Debt for the Past 100 Years, Gold and Silver Statistics, Postal Information, and Other information that should be in every Home, Store, Office and School-room.

Miniature Cut of Atlas. Actual Size, 11 by 14 Inches.

OUR BARGAIN PREMIUM OFFER

We will mail this great Atlas for only 50 cts.: or for \$1.40 we will send it with the BEE JOURNAL for one year; or we will mail the Atlas FREE as a premium for sending us **one new subscriber** (at \$1.00) to the BEE JOURNAL for 1 year.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

The BEEKEEPERS' REVIEW has added a new feature. It is called the

Department of Criticism.

It is conducted by Mr. R. L. Taylor, of Lapeer, Michigan, who is a fair minded man and a broad thinker. To this may be added years of experience in a large apiary. He also, for several years, had charge of the Michigan State Experiment Apiary, and made some of the most practical experiments ever made with bees.

Attempts at criticism are often couched in language so apologetic and "mealy-mouthed" as to nearly rob them of all force; but Mr. Taylor's criticisms are most vigorous in style, and, thus far, his main shafts have been aimed at the views and teachings of some of the most prominent writers. It is my honest belief that this department is to result in untold good by warning bee-keepers against the fallacies that will creep into the journals in spite of the best of intentions.

The editor of the "American Bee-Keeper," a man who has had years of practical experience with bees, writes me that "That new Department of Criticism is a rare morsel." In his journal he gives it the following public notice:

"In addition to its intensely critical content view of bee-writings, by E. E. Hasty, together with other marked improvements, the BEEKEEPERS' REVIEW has introduced a new 'Department of Criticism.' The initial C of the department heading incloses a miniature medallion half-tone of Hon. R. L. Taylor, of the Michigan State Agricultural College [He is not connected with the Collego now.—Ed. REVIEW], by whose very able pen the criticisms are conducted. The REVIEW is indeed a unique publication—a credit to its editor and an honor to its supporters; and, in point of interest to advanced apiarists, its new department is second to none of those previously established. We are proud of our sprightly, artistic, and edifying exchange."

SPECIAL OFFERS.

The REVIEW is \$1.00 a year, but I am putting forth extra efforts for the sake of getting new subscribers, and to any one not now a subscriber I will, for only \$1.50, send the REVIEW one year and a fine tested Italian queen; or for \$3.00 I will send the REVIEW one year and 1,000 first-class one-piece sections. The sections will be shipped from any of the following points: Flint, Mich.; Chicago, Ill.; Jamestown, N. Y.; Higginsville, Mo.; Omaha, Neb.; or Medina, Ohio.

FLINT, MICH.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,
Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth.

Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages; bound in cloth and fully illustrated.

Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 175 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES OF HONEY. 10 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Poul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Poul Brood.—Gives the McEVOY Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Poul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Poul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p., illustrated. 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leather, calf finish. Price, 40 cts. No. 2 in the artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers. This book gives the latest, most approved methods of bee-keeping, in an easy, comprehensive style with illustrations to suit the subject. 50 pages, board cover. Price, 50c.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructors. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capon and Caponizing, by Dr. Sawyer, Faouy Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only ONE book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

Mr. Abbott sells our Hives and Sections at factory prices.

Please mention Bee Journal when writing.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apiarian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, snowy-white Sections, beautiful, straw-colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leahy Manufacturing Company, 1730 South 13th St., Omaha, Neb.**

Select-Tested Golden Adel Queens.

Each, \$1.00. A practically non-swarmling and non-stinging strain of golden bees. "How to Prevent Honey Candyng" given to each customer. Tested Queens, each, 75 cents.

HENRY ALLEY, Wenham, Mass.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, July 7.—A little of the new crop is coming, and it sells at 11 to 12c for the best grade of white comb. No ambers at present on the market. Extracted is coming freely from the south, and a little from the West; white brings 5 to 7c; ambers, 5 to 6c. Beeswax, 27 to 30c.

We do not look for a settled price on honey before September; meantime the offerings and demand will be limited to immediate wants. **R. A. BURNETT & Co.**

Kansas City, July 9.—New comb, No. 1, white, 11@12c; amber, 10@11c. Extracted, white, 5@5½c; amber, 4@4½c. Beeswax, 22 to 25c.

Old stock of honey all cleaned up. Few shipments of new in market. **C. C. CLEMENS & Co.**

New York, July 9.—Comb honey: We closed out all of our old crop some time ago. We have received several lots of new crop from the South, good, No. 1 white, which sells readily at 11c per pound.

Extracted: Receipts of new crop from the South are large. We quote: Common, 48 to 50c a gallon; good, 52 to 55c a gallon; choice, 5 to 5½c pound. Demand is good, especially for the better grades. Beeswax remains firm at 28 to 29c. **HILDRETH BROS. & SEGELKEN.**

Boston, July 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c.; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand.

BLAKE, SCOTT & LEE.

San Francisco, July 9.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5½@6c.; light amber, 4½ to 5½c. Beeswax, 23@25c

Small quantities of the new crop have been offered by sample, but nothing of consequence has been yet done in the same. There will be very little white sage honey this season, but a moderate amount from the alfalfa and tute districts. Values remain as previously noted.

Detroit, July 9.—Fancy white honey is lower and now quoted at 11c. No. 1, 9@10c.; fancy dark, 7@8c.; No. 1 dark, 6@7c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax 27@28c.

There are no changes in quotations, and very little desirable honey left. Sales are so slow that it is difficult to quote. The poor lots are being pushed at what they will bring.

M. H. HUNT.

Minneapolis, July 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½@6c.; amber, 5c.; dark, 4@4½c.

Outlook for honey much more encouraging. **S. H. HALL & Co.**

Indianapolis, July 9.—Fancy white honey 11 to 13c.; No. 1, 10 to 11c.; fancy amber, 9 to 10c. Extracted, white, 5 to 6c. Beeswax, 25 to 27c. Market appears to be well supplied and sales are rather slow for this time of the year. This is especially true of the amber and dark grades of comb honey. Beeswax is in good demand. **WALTER S. POWDER.**

Milwaukee, July 14.—Fancy 1-pound sections, 11@12c.; A No. 1, 10@11 cents.; No. 1, 8@10c.; amber, 7@7½c.; dark and old, 6@7c. Extracted, in barrels, kegs or pails, white, 6@6½c.; dark and amber, 4@5c. Beeswax, 26@28c.

Since our last the sales of honey have not been large, altho a fair demand has existed and continues, altho the fruit consumption makes some difference with eaters of honey. There is not a very large supply of old stock left, and we shall be in good order for new crop both extracted and comb. The outlook is good. **A. V. BISHOP & Co.**

Buffalo, July 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. **BATTERSON & Co.**

St. Louis, July 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. **WESTCOTT COM. CO.**

Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.

If you once try it you will have no other. Samples furnished FREE. Large Illustrated Catalog of all kinds of

PROFITABLE BEE-KEEPING, WITH HINTS TO BEGINNERS,

BY
C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 4.—SWARMING.

During the months of May, June and July the bees in all properly-managed hives become very numerous, and so crowded, particularly in hot weather, that they cluster around outside the hive, and hang in a large bunch from the entrance, unless more room is given by means of supers or by enlarging the brood-nest. This clustering outside is the usual and almost certain sign of swarming-time being near.

A swarm, composed of the queen and a few thousand workers and drones, leaves the hive, and, after filling the air for a few minutes generally forms a pear-shaped mass on the branch of a tree close by. Unless the bee-keeper happens to be at hand, the swarm may be lost to him, for in all probability scouts sent out previous to the swarm, lead the merry throng to a new home which they have prepared in a hollow of a tree or elsewhere. Should that be the case, if they do not go direct without clustering, they are almost certain to do so after becoming settled, unless they are quickly hived into a clean straw skep, preparatory to being put into a hive of more modern pattern. If the swarm is allowed to remain clustering for some hours, hiving becomes a difficult operation; for, altho when swarming, bees are good-tempered, they soon become irritable if left in the sun; therefore, hiving should take place as soon as possible after the cluster has been formed. Many bee-keepers suggest the advisability of hiving swarms in the evening: this advice must refer to the re-hiving, because unless the swarm is secured as advised above, it may, and most likely will, decamp. After it is safely hived it is immaterial whether it is put into a modern hive then or in the evening; but certainly to ensure success the latter is advisable, as during a hot summer day the swarm, after being disturbed, is more likely to take to flight than it is when hived, or rather re-hived in the evening.

Swarms leave the hive into which they are first placed either because they have chosen another home, because they are left in the hot sun, or because the hive is daubed inside with some vile concoction with the idea of inducing the bees to accept their new home. If a swarm leaves the hive into which it is placed in the evening, it must be from one or the other of the above-mentioned reasons, or it may, and most probably

is, due to the fact that it is a second swarm or cast. Casts are headed or accompanied by virgin queens, which must leave the hive to meet with the drone, and when they issue the bees often accompany them. Sometimes they all return with the queen from her wedding-trip, but it rarely happens that once a cast leaves the new hive it again returns to found a colony. The only satisfactory method of preventing this exodus and frequent loss of the swarm is to put into the hive, when introducing the bees, a frame of brood from another hive. Bees very rarely desert brood, and the presence in the hive of such a frame would doubtless keep the bulk of the bees at home when the queen left the hive.

NATURAL INCREASE.

As soon as the flowers begin to bloom early in the new year activity in the hive commences; and a slight examination of the center combs on a warm day will reveal patches of brood in the center of the combs. The queen commences laying slowly at first, but if the brood-chamber is not too large—that is, if there are not too many combs in it, and it is well protected from changes of outside temperature—a gradual increase in the number of eggs laid daily will be maintained. But if there is a scarcity of food, only a regular supply given by the bee-keeper will have this desirable effect.

The queen lays eggs for the first few months that produce workers only: then, as soon as the hive is becoming crowded, she lays eggs in the larger, or drone, cells from which issue in 25 days drones. The appearance of drones is the first sign of

Section Fitted with Foundation.

the busy season, and should be taken as the guide for the time when hives for swarms and supers for honey should be prepared.

When the bees in the hives have become so strong in numbers, it is almost certain that honey is coming in freely, and therefore, if it is honey and not swarms that is required, some kind of receptacle, that is, a super, must be put above the brood-chamber in which the surplus honey may be placed. If, however, room for the surplus honey gathered is not provided by giving extra chambers, the cells of the combs in the brood-chamber will be filled with honey instead of being used almost solely for brood-rearing. The effect of this is that if swarming is not thus caused the colony is spoiled, as the empty cells become less and less in number until the queen is crowded

out" altogether; that is, she has really hardly any cells in which to deposit her eggs. At the end of the season such a colony will contain a large quantity of honey, and a small lot of bees, most of them being then too old for many to be left for spring work. It is therefore of great advantage to give supers, for tho they do not at all times prevent swarming, the carrying of surplus above ensures that the combs in the brood-chamber are left for the use of the queen; consequently, the conditions enumerated above are reversed. The brood-chamber contains little honey, but a large colony of bees, most of which will be young ones, and just what are required for successful wintering and satisfactory work in the spring.

It is most desirable, if swarming is to be prevented, that laying-room should always be provided for the queen. This is usually secured by the giving of supers at the commencement of the honey-flow, so that the surplus honey is not stored in the brood-combs below. But if, after this precaution, swarms do issue, it is invariably due to the fact either that the formation of queen-cells in preparation for swarming had been commenced before the super was given; or that, tho the bees may have commenced to store honey in the super, they have been compelled by a change of weather to leave the super and crowd in the brood-chamber, thus producing the generally acknowledged cause of swarming. Certain it is that if from either of these causes crowding in the brood-chamber occurs either before or after the super has been given, the issue of the swarm is seldom prevented. If an increase of colonies is not desired, a thorough examination of the combs should be made, and the queen-cells, if any, removed. At the same time the exchange of combs for sheets of foundation may stop the inclination to swarm while the honey-flow commences, or until there is a recurrence of fine weather.

When an undesirable swarm has issued it should be hived and left until the evening, and then returned to the hive where, during the interval, a rearrangement of the brood-chamber has taken place, and additional supers if necessary have been added.

HIVING SWARMS.

Swarms settle in various places from which they are sometimes with ease dislodged, while on other occasions a little skill and some ingenuity must be exercised before they are safely settled in the hive.

All swarms should first be put into a clean straw skep. If a swarm has settled on the branch of a tree a sharp jerk will be sufficient to cause the cluster to fall into a skep held beneath. The bulk of the bees will fall into the skep, which must then be turned gently over and set on the ground, one side being raised by a brick, or something about that size. A good entrance will thus be given, and it is necessary, because at swarming-time the heat of the cluster is very great, and ample ventilation is essential.

Great care must be exercised in hiving, so as to avoid crushing a bee, for if the queen be killed the bees will return to the hive from which they issued, while if a worker be crushed, and the poison-bag ruptured, the smell of the poison will irritate the other bees, and cause them to sting. Sometimes after being put in the skep the bees again leave and return to the spot where they had clustered. In all probability this is due to the queen not being shaken with the bees into the skep. She may be remaining behind, or have dropt on the ground; if the latter, her presence will soon be ascertained by several bees clustering on the ground around her. If she is not on the ground, hiving must be repeated. Another reason for swarms deserting hives is that they are left in the sun. Being naturally in a high temperature, when under such excitement, they are unable to bear the great heat their exposure to the sun causes.

When a swarm has been hived the skep should be set down on the shady side of the tree upon which the hive clustered, or if that is not possible a white sheet should be thrown over it.

The hive may be moved as soon as the bees have clustered inside, to the spot where the swarm will remain for the rest of the season. Re-hiving—that is, the turning out of the swarm from the skep and running the bees into the hive they are permanently to occupy—had better take place later in the day; because if disturbed while the sun is hot they may refuse to enter the other hive, and fly away altogether.

Old-fashioned bee-keepers daub the inside of the skep, before hiving the swarm, with a vile concoction of beer and sugar, or some other sweet, sticky substance, with the idea of keeping the bees in the hive. Such an uncomfortable plan is more likely to cause the bees to desert the hive, as when they are shaken in their wings become sticky and many lives are sacrificed. Such a practice should be discontinued.

[Continued next week.]

Bee-Paralysis—Attempts at Curing It.

BY ADRIAN GETAZ.

In answer to Prof. Cook's inquiry on page 376, I will give a brief description of the result of my attempts at curing bee-paralysis.

In the first place, I want to state some of the peculiarities of the disease. Considering the individual bees, the disease develops very slowly; the first symptoms are the peculiar twitching so often mentioned, then a sort of slowness of movements. This increases gradually. By that time the affected bee begins to lose its hair, and finally becomes completely hairless and shiny, the stiffness gradually increasing until the affected bee leaves the hive, to drag itself on the ground until death terminates its existence. I will add that the twitching ceases about the time the falling of the hair begins. As to the duration of the disease, I cannot tell, it depends how badly the bee may be affected, and at what time of its life the disease was contracted. We may say, however, that several weeks elapse during the evolution of the disease.

As to the colony itself, it also depends how badly it is affected. The disease develops worse during the winter, and when the spring comes the majority of the bees composing the colony will have reached the hairless stage. In consequence of the weakness of the diseased bees, more or less spring dwindling follows. Nevertheless, in most cases a start at brood-rearing is made, and by and by young, healthy, or at least comparatively healthy, young bees appear in the hive and gradually take charge of the institution. Eventually they see that something is wrong with the old bees, and expel them. By that time the apiarist, not seeing any more shiny bees, thinks the disease is cured. Nevertheless it is not. A close inspection will reveal here and there a twitching bee, and now and then some sick bees expelled by the others. These are invariably thought to be robbers, unless the apiarist is fully posted. There is, however, a difference between the appearance and the quick movements of a robber-bee and those of a diseased bee.

During the summer very few bees, if any at all, reach the hairless stage, either because they are expelled before reaching that stage of the disease, or because they die of natural causes before the disease has fully developed.

In badly affected colonies it may happen that the young bees contract the disease so rapidly that they fail to expel the old ones, and carry out brood-rearing and other work. Such colony, as a rule, dies in the course of the year or during the following winter.

The queen does not seem to contract the disease very early in her life. The first effect seems to be a diminution of her laying powers; this leads to her superseding, which almost invariably occurs during the second year of her laying. If, however, the season is bad, and very little brood can be reared, she may become so diseased as to lay infested eggs. In such case trembling and twitching bees can be seen hardly more than a few days old. In the absence of a microscopic investigation, I cannot prove that the queen lays infested eggs, but the following case seems to show it conclusively:

I had a colony in that fix, that is, showing the disease in very young bees. The colony was pretty strong yet, the honey-flow and temperature favorable, so, as an experiment, I replaced the queen. Nothing else was done. By and by the progeny of the new queen hatch, but did not show the disease at all at the beginning. Eventually the young bees were numerous enough to expel all the old ones, and now the colony is neither worse nor better than the others.

I first tried to feed salicylic acid, but I could not feed it long enough to get satisfactory results. During a honey-flow the bees will not take it; during a dearth it is difficult to feed without starting robbing. I did not want any to go in the surplus. I thought of fumigating, and then of putting some medicated substances easily evaporated in the hive, so as to make the fumigation automatic.

I tried carbolic acid and camphor. I put them in the hives in the fall, and renewed them two or three times during the winter. The effect was marvelous. When the spring came not a shiny bee could be seen, and the colonies were strong and healthy. The diseased bees that went into winter quarters were probably dead. But to my sorrow, the diseased, twitching bees began to reappear about six or eight weeks after the use of the camphor or carbolic acid was discontinued. Applied in summer time the effect was the same. While the camphor is there the disease will not show itself, but will invariably reappear six or eight weeks after its use is discontinued. The inference is natural, that the fumes of the camphor or carbolic acid are strong enough to prevent the development of the spores of the disease, but not to destroy them.

During the last five years I have used camphor every win-

ter, and invariably with the above results. As a rule, I do not use it in the summer, because it gives the honey a slight taste and odor, enough to spoil the sale of it.

Sulphur is not good. In light doses it has no effect; in strong doses it kills a number of bees. The sick ones being the weakest are sure to die, and then the operator not seeing any more shiny bees, imagines that he has cured the disease.

Changing queens, introducing young bees, etc., all have the effect of increasing the number of young and comparatively healthy bees, and hastening the expelling of the old ones. At any rate, no queen should be allowed to get old enough to become seriously diseased herself, and a yearly requeening is considerable advantage.

It is not necessary to send for outside queens. The queen bought elsewhere will contract the disease before long, and will be disabled nearly as soon as one reared in the apiary.

Tobacco Smoke for Bee-Paralysis.

BY D. W. LIGHT.

On page 376 apiarists are asked to give their experience with bee-paralysis. I divided a colony about the last of May, last year, and in about two weeks afterward they began to die—first the old bees and then the younger ones, until in front of the hive there would be a handful or more every day. Finally I called an old bee-keeper's attention to them, who said it was the worst case he ever saw, and advised me to sprinkle the bees and comb with salt water. I applied the salt water about 4 o'clock in the afternoon. That night they were all over the ground for a rod or more around the hive, making a terrible noise. The next morning it looked as if they were all dead. The queens were very prolific, and there was plenty of nectar.

I waited two or three days, and the disease did not abate. Then I thought to experiment. I fixt up the smoker, put in plenty of leaf tobacco, and took out the frames one at a time, and held them in the air and sun for one minute each, and smoked them thoroughly once a day for a week, when it had entirely disappeared.

This last treatment began to check the disease from the start. I do not know which one did the work, or whether all were necessary. The next time I will try each one separately and be satisfied as to which to ascribe the curative properties.

I have noticed in the Bee Journal that the only remedy bee-men mention for the disease is to give a new queen. I think it would be wrong, as you would weaken the colony, and the queens never show any symptoms of the disease. The two cases I treated are as strong colonies as I have in my yard of 11; they are all doing finely, with a good flow of honey.

Lime and Salt-Water Cure for Bee-Paralysis.

BY J. A. GOLDEN.

On page 376 Prof. Cook asks for information on the treatment of bee-paralysis.

A few years ago I had an experience with the so-called "bee-paralysis" which I will never forget. That experience was published in Gleanings in 1893. I predicted that the time was near at hand, if the disease were not checked in its spread, bee-keepers would have cause to look for other occupations. That prediction is being verified throughout the milder climates, and is experienced to some extent in the colder as well.

I have never been able to give more than a guess, or supposition, as to the cause of the so-called bee-paralysis, and I have been successful in curing every colony treated by the chloride of sodium method, while others report a failure by this method. As it happens, I have two cases in hand that may have some bearing on the question, and for the information of others, I will give it here.

Having a queenless colony early in the spring, I sent South and procured a queen, introduced her, and in due time the colony became strong numerically. It may seem strange to the reader, but nevertheless true, I was glad to find those bees badly infected with bee-paralysis, many of the bees having a dirty, black, greasy, starved look. (What next?) Well, I just let them alone till hundreds were being dragged out of the hive by the bees, and then what did I do? Well, I want to say to Prof. Cook, that I lifted all those frames out and gave that hive a complete scrubbing with a strong brine; then, while damp, I put a handful of air-slackt lime in the smoker and gave the inside of that hive a complete dusting. I then took the atomizer and thoroughly sprayed the bees,

combs and all with a solution of salt water, tasting quite a little salty. I replaced the combs and bees, and in three days gave them another spraying, this time by lifting off the cover and spraying down between the combs. In five days I gave another spraying, this being June 18. That colony now has a super of 24 sections of honey nearly ready to come off, and I defy any bee-critic in this broad land to discover a bee in that colony infected with paralysis, or any signs that it ever had been infected.

The other case was a colony placed next to the colony above described, which was treated likewise, and bears the same recommendations. Those are the only cases in which the lime was used in connection with the brine—that is why I was glad, so as to test the lime in connection with the brine.

Morgan Co., Ohio, June 20.

A Rejoinder on Facing Comb Honey.

BY G. M. DOOLITTLE.

I have been much amused and somewhat surprised at the apparent general desire to "roast" Doolittle on the "gridiron of Christian opinion" regarding what he said on pages 174 and 175 of Gleanings for March 1, 1898, relative to facing comb honey. I have asked myself over and over again, why those quoting from that article withheld from the public the way Doolittle *did* crate honey, and advised others to crate it; also what he said or intimated would be the result if I crated in any other way, or by any other plan than the one given in that article.

It would be as easy to prove by the Bible that any and all men and women should hang themselves, as it was to prove that Doolittle believed in facing cases with fancy honey, white honey, and then fill up the center of each case with off grades of white or buckwheat honey. And yet the way it was put to the commission-men, and the way the quotation has been sent out before the world, would lead any reader of the matter who had not read the article in which it appeared in Gleanings, to think that Doolittle really did advise putting up comb honey in accord with the quotation, when the whole import of the article shows otherwise.

To be sure, I said it would not be "dishonest" to put up honey where it was *sent on commission*, with white facers and dark inside, and I note that only two out of the twelve commission-men who reply, attempt to make any claim to dishonesty, and one of the two does not say that *he* thinks such would be dishonest, but that some of his customers to whom he sold such honey as *white honey* "considered it dishonest," and that is just the claim I have made under like circumstances. Some of the commission-men took pains to say that such packing as the paragraph quoted allows, would be "right," and could not be considered "dishonest," thus perfectly agreeing with the position I took, and in all the discussion brought forth I have failed to find a single word of proof that would shake the position I took. Hildreth Bros. & Segelken come out frankly and say, "We admit that any bee-keeper has the right to crate his honey, face or mix it, just as he chooses," and it is conceded by all, that what any person has a right to do, cannot be *dishonest*, for there is nothing right in dishonesty.

Then these same commission-men hint at the great underlying point in the whole matter, where they say that people were not so much acquainted with comb honey a quarter of a century ago as they are to-day, in which they really admit that what might be considered by some dishonest to-day might not have been so considered when the older bee-keepers first began the pursuit and sold their crop as a *whole*, or just as it "came off the hives," as is so aptly put by R. A. Burnett & Co. And if it was not dishonest to put up honey just as it came from the hives 20 to 25 years ago, when did it cease to be honest and begin to be dishonest? This reminds me of some saintly persons who think it perfectly right to play croquet, but hold up their hands in holy horror where the same parties engage in a game of cards.

But on one point we all agree, and had the very next sentence of my Gleanings article been quoted there would have been no discussion, for immediately following the last words of the quotation—"and the producer thought it to his interest to do." As found on page 371, American Bee Journal, I tell every reader of that article that "I should doubt the wisdom of such a course;" which was the same as saying that it would not be desirable, financially or otherwise, for a man to ship his honey with No. 1 facers, and fill in the center with dark honey. In no way, except along the lines of honesty, when sent on commission, did I "defend facing or improper grading," as one party claims I did, and should never have

written the paragraph going the rounds of the press, only to combat the idea put forth by Mr. Snyder, that improper grading was the cause of the low prices of honey as compared with former years, during which years honey was rarely graded at all by the majority of bee-keepers.

My saying that I should doubt the wisdom of facing or improper grading of honey ought to have stopt all cavil at once. But, on the whole, I am very glad I wrote as I did, and that this discussion has followed; for, through the discussion, very much along the line of education regarding the crating of honey has been brought out which otherwise would never have seen the light. My shoulders are broad and strong, and if the pounding of me (or even vituperation, as indulged in by "Skylark") will bring out something of use to the world, I can but rejoice. Onondaga Co., N. Y.

[We notice in the foregoing that Mr. Doolittle thinks that if we had quoted all he wrote for Gleanings on the subject of facing comb honey, "there would have been no discussion." Then we wonder how it comes that in the very same paper where Mr. Doolittle's article appeared in full, there was such a hot discussion, and "roasting" of Doolittle, that the editor of Gleanings cut off discussion in that paper.

The weak point in Mr. Doolittle's defense is where he emphasizes the words "*sent on commission*," just as if that made any difference as to the honesty of the action. To our mind that makes it so much worse, for then the commission-man is made the scapegoat.

To face comb honey for market is *wrong*, every time and everywhere.—EDITOR.]

Management for Extracted Honey.

BY JOHN NEWTON.

In running an apiary as I do, partly for comb and partly for extracted honey, I usually select the strongest and best colonies for comb honey, and the rest are run for "extracted." When the spring work has been done—such as clipping queens' wings, etc, and before the honey season opens—I see that my extracting-combs and supers are clean and in proper condition for the honey season. My supers are the same size as the brood-chambers, only one comb less is used; eight combs $8\frac{1}{4} \times 16\frac{1}{4}$ comprising my extracting super.

As the season opens, my supers and queen-excluders are brought from the store-room, the smoker is lighted, and the bees smoked, the excluder placed over the brood-chamber, and one super is put over the excluder on all colonies to be run for extracting honey, and are strong enough to need room. After the honey-flow fairly opens I make it a rule to see what is being done in the supers, or colonies not yet having extra room, so that if more room is needed it may be given at once. I never allow a shortage of room for storing. In doing so, two objects are sought: One is to discourage swarming from over-loading, and the other is to receive the greatest amount of surplus honey. I run all colonies two stories high. When super No. 1 is about two-thirds full, it is raised and super No. 2 placed under it.

I might here say for those who have not so many spare combs, that it can be worked by extracting one-half of the combs at a time, always placing the combs with the most honey to the center of the hives. By doing this, you will get well-ripened honey, and it does not allow the bees to be overcrowded or in need of store-room.

As the season advances, and in four or five days after you have placed on the second super, super No. 1 will be ready for extracting, but here let us be sure that our honey is well ripened before extracting. We all know that nectar which the bees collect from the flowers is thin and watery, and must be fully evaporated to make the best honey. The bee-keeper should be equally wise and not extract his honey until it is cap over. This requires a little more labor of uncapping, but then we get honey far superior, and the wax for our trouble. We do not want honey that has been ripened artificially. All honey should be allowed to ripen in the hives; the honey will have a better body, and is superior in flavor.

Now we must see that our extracting and store rooms are in good order—everything clean and tidy. When visitors come to see me I never feel ashamed to show them into my extracting-room; I know they will not be disgusted and depart saying, "I do not want to eat any extracted honey if every bee-keeper is as dirty as Newton; it is not fit to eat."

I have seen extracting-rooms all daubed and sticky, and the bee-keeper also. Let us put a good, clean article on the

market and command a good price. Have our extracting and store-rooms in good order, the extractor placed in position on a box or bench in good order, and high enough to let a pall under the tap; the honey-cans the same in the store-room with the strainer secured around the top; uncapping-can placed in position, knife sharp, dish of warm water to place the knife in when not in use uncapping, which will assist much in the work.

My uncapping-can is just an oblong box with a bent tin so as to drain the honey to one end and run it in a dish. My screen for holding the cappings is one of the screens of my solar wax extractor. When the screen is full it is placed in the solar, and another one put in its place, and if it is a nice, sunny day the same night we will have no cappings to wash for vinegar, but they will be into nice yellow wax, and the honey which was in them can be placed in the store-can none the worse for going through the solar.

Now, when everything is ready—the comb-box, wheelbarrow, and the smoker going good—I proceed to the bee-yard and go around to those hives from which I wish to extract, placing the entrance-blocks on, and giving a few puffs of smoke. This will cause an excitement, and warm up the honey, and will greatly aid in extracting. We must be cautious not to give too much smoke, which injures the flavor of the honey. Now proceed to that part of the yard at which you wish to start, and after giving a few more puffs of smoke in the top, tear off the quilt and take out one comb, placing it at the entrance so as to give more room in the hive to shake and brush the bees from the combs, and prevent killing and making the bees angry, placing each comb as the bees are cleaned from them into the comb-box. After all combs are out, close down the hive, remove the entrance-blocks, and proceed to the extracting-room. Uncap and extract.

A little caution must be taken in turning the extractor: Start slow, gradually getting up speed, and there is not much danger of breaking the combs. After extracting, place the combs to one side until evening, then replace them on the hives. If I was working, as I mentioned before, extracting the half super at a time, I would carry a set of combs with me and replace them as soon as the full ones are taken out. After the day's extracting is over, and all honey is run into store-cans, cover up the extractor, uncapping-dish, etc., so as to keep them clean until needed again; and thus I work on until the honey season is over. During the last extracting the bee-tent is usually brought into use to prevent robbing.

After the extracting season is finally over, and all combs extracted, they are piled three high on hives, with a quilt between the brood-chamber and supers, with a corner turned back to allow the bees to clean them up, or, if placed in the yard some distance from the bees, tiered up, the combs spaced to allow bees access to them, they will soon clean them up. But I prefer the former way, as it does not cause the same excitement. After combs are clean and sweet, they are again placed in the store-room with a sheet of paper between each, until they are wanted again the following spring.—American Bee-Keeper. Ontario, Canada.

Shallow-Scalloped Sections in Tiering-Up.

BY EDWIN BEVINS.

Allow me to say to "Arkansas" (page 422) that his trouble about tiering-up arises from the fact that he uses sections which are not scalloped deep enough. When two sections such as I use are placed side by side, the scallops make an opening of $\frac{1}{2}$ inch. If separators are used that come up even with the tops of the sections and divide this passage there is, of course, a $\frac{1}{4}$ inch bee-space on each side of the separators; and this is ample for the bees to work through. With shallower scallops I have had some of the trouble that "Arkansas" complains of.

I cannot quite agree with Dr. Miller that it is no great matter if the bees cannot go up freely between the outside sections and the side of the super. It is a waste of time for bees to travel around to the other side of the section in order to get above, and there are times when time is honey as well as money. With a $\frac{1}{4}$ -inch space at the sides the bees seem to go up freely.

The Doctor's answer to "Arkansas'" second question shows that he misapprehended his meaning. It was not the space between supers that bothered "Arkansas," but the space between the upper edges of the separators and the scalloped edge of the section. "Arkansas" can get around his trouble by using sections with deeper scallops, and also by using separators scalloped on their upper edges.

Decatur Co., Iowa.

How to Prevent Swarming—And at the Same Time Get the Largest Yield of Honey.

BY J. E. CRANE.

Well, now! That heading looks like a good one. The only difficulty, so far as I am concerned, is that I do not know just how to do it; *i. e.*, with every colony. To be sure, I can remove the queen from every colony that I find preparing to swarm, remove queen-cells, etc., to the end, but I may not in this way get the largest yield of honey; besides, how about such colonies as swarm without so much as an egg in a queen-cell, and evidently without thinking about it more than 15 minutes?

Again, we may shake a colony from its combs and give it an empty hive; but this does not always work, as I have had them swarm under exactly these conditions; besides, our vision of final surplus grows less very rapidly with this treatment.

Another way is to produce a non-swarming strain, or breed, that we can depend upon, that will keep right on storing honey to the close of the season without a thought of swarming; but as it may take from 50 to 100 years, or perhaps much longer, to produce such a breed, it does not seem altogether practical, especially to us whose locks are turning gray. But this does not prevent us from doing what we can to develop such a strain of bees. If but partially developed, it would help in a degree. That some method is necessary is evident from the short time in which bees can gather surplus honey. In this section of country about four weeks is a full average. Now, if the brood-chamber is filled with honey at the end of the first week, and during the second week a swarm issues, it will be well on to the fourth week before this colony will be strong enough to go into boxes again to much purpose, and this leaves only a few days for filling our clean white sections. Our new swarm will require from one to two weeks to fill its hive; and will be ready to go into the surplus department just in time to start its combs, and then, as the flow is over, coat its sections with propolis.

There are some non-swarming devices, but as they have not seemed to me practical, I shall not speak of them. But what is to be done? Something must be done, or, in most seasons we shall get little surplus honey and much increase. We have all observed, or most of us have, that what will break up one "broody" hen will not another. You can frighten one from her nest and she will scarcely return to it again; while with others you can take them off and they will "set" on a board or on the floor, or even on their roost. You may imprison them for several days, and when you liberate them they will go back to "sitting" on sticks or stones with the most provoking stupidity. It is thus with our bees; what will cure the swarming-fever in one colony will have but little effect upon others. With one you can cut out the queen-cells nearly ready to seal and they will give it up; with another colony it is of no use whatever.

The presence of a large amount of brood in the hive appears to be the most exciting cause of swarming. This leads me to the first method of preventing swarming. I remove every brood-comb and replace them with empty combs, or at least those having no brood. While a little honey seems to do no harm, a little brood given them or left in their hive may upset our best intentions; for the colony is apt to start queen-cells upon it and then swarm. The brood-combs that are removed can be given early in the season to any weak colonies, and thus quickly bring them into a profitable condition, while the colony that would have swarmed, finding its brood gone, usually gives up swarming at once and goes to work with a will, quickly filling the brood-chamber with honey, and a moderate amount of brood, and is again at work in the boxes. This plan works well about nine times in ten, when perhaps the tenth time they will start brood and queen-cells at once, and out they swarm. This tenth time is apt to be where a swarm, or part of one, has gone into our colony before we operated on them. Strong colonies only should be treated in this way, as having no hatching brood in their hive they soon become weakened.

Another class of colonies, such as have a very moderate amount of brood, or an old queen, or one we wish to supersede, we open their hive and remove the queen, if we can find her, and cut out the queen-cells. Eight days later we again cut out queen-cells; and in from four to eight days more give them a young virgin queen. If she is young enough, she is usually accepted and soon laying, and as the brood from the old queen keeps hatching until near the close of the season, it remains strong and does quite a fair business. If we fail to find the queen we cut out all queen-cells every eight days to

the end of the season, and the queen usually disappears before that time, so we can give them a virgin queen.

But there are many colonies that have young, vigorous queens of the previous season that we do not wish to destroy, and we have not a sufficient number of dry combs to give them. These we treat in another way. Finding the queen, we remove her with a brood-comb, one from which the young bees are just hatching, if possible, and place the comb with another having considerable honey and one having a little honey and no brood in a new hive, and after shaking off bees enough from the combs of the hive from which the queen was removed to make a good nucleus, when the old bees have returned to the parent hive, we close it up, after making sure the comb of brood we gave it has no queen-cells. We remove all queen-cells from the hive from which we removed the queen, that are likely to hatch within eight days. Of course we return the partly-filled sections, and in eight or nine days we again cut out all queen-cells, and later give a virgin queen, the same as we did to the colonies whose queens we destroyed. This plan keeps us very well supplied with young queens.

In eight days we again go over our colonies, giving the strongest ones preparing to swarm a full set of dry combs in place of their brood-combs, and give these brood-combs to the nuclei formed the previous week, thus quickly building them up into profitable colonies that will sometimes give as much surplus as the colony from which they were started. Italian bees are at their best when placed in small nuclei; they give up all thoughts of swarming, and seem to store two or three times as fast in proportion to their numbers as when in full colonies.

I am apt to find some queenless colonies near the close of the season. My young queens are frequently several days old before I get around to introduce them, as I have several yards to look after. Then there are some that get mixt, and a part of the bees appear to want an old queen and a part a young virgin, and so, like some families that pull in different directions, neither get what they want. These I give two or three brood-combs, and they usually come out all right. Some apiarists return old queens to hives that have been unqueened, but I have never succeeded in returning them satisfactorily.

In removing queen-cells I select the best and place in nurseries to hatch, and thus keep myself well supplied with virgin queens of good quality.

While the plan above outlined does not wholly prevent swarming, it does prevent very much increase—enough to use all my old combs and keep my stock good; and while I do not get nearly as much honey as I believe I should if the bees would give up the foolish habit of swarming, I have reason to believe that I get more than I should by any other system with the same expense. Of course, it will be understood that I am working wholly for comb honey. Where a yard of bees is run for extracted honey, a modification of this view should be used.—Bee-Keepers' Review. Addison Co., Vt.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Several Questions by a Beginner.

1. I transferred a colony during apple-blossoming, from a box-hive to a dovetail. I became over-zealous and fixt up three frames with the old comb which had brood in and replaced in the hive. I find that the comb has sagged and sticks to one or two other frames. Would you cut them apart?

2. Will the bees be likely to swarm after transferring? They have not done so as yet.

3. I hived a swarm in what we call the "Lumber District," at Albany, some time ago. I looked for the queen but could not find one. I then took the hive with foundation comb, turned the bottom up, swept some of the bees into the hive, then turned it right side up and placed the edge above the remainder of the bees. They immediately began to run up in the hive, and I now have them here in the yard. They seem quite contented, and are working all right. Do you suppose the queen is among them?

1. From this same swarm I notice one drone-bee that goes

In the same as the workers. Does he carry nectar the same? If not, why should he act as he does, and remain away as long as if he were at work? And when he returns he remains in the hive about the same length of time as the workers do.

NEW YORK.

ANSWERS.—1. Yes, I'd cut them apart and straighten the combs in the frames. Don't have any frame that you can't lift out separate from every other frame.

2. They will do just about the same as if they had not been transferred, altho in some cases the transferring would have some effect toward preventing swarming.

3. The great probability is that the queen is in the hive with the bees. In hiving natural swarms, the queen is allowed to run in with the rest, and it is a rare thing that the queen is seen, and also a rare thing that she is lost.

3. A drone never gathers nectar from the flowers. He goes out and exercises to work up an appetite, then goes into the hive and takes a lunch. I don't know why that drone times his trips like a worker.

Shiny Bees—Honey-Dew for Winter.

1. I notice in two of my colonies a good many sleek, shiny-looking bees, usually about eight or ten about the entrance, and on lifting out the frames I find a good many on them. The healthy bees are hard at work all the time endeavoring to force these sleek looking ones out of the hive. They look as if they might have been dipped in oil, and seem to be smaller than other bees. I can detect nothing wrong inside of the hive.

2. Our crop so far has been almost altogether honey-dew, making a very dark honey of a disagreeable flavor. My crop will not exceed 800 pounds from 56 colonies, unless a good fall flow helps us out. The brood-chambers are full of this honey-dew. Will the bees winter well on it? VIRGINIA.

ANSWERS.—1. Occasionally one or more such bees as you describe may be found in different colonies, and no special importance need be attached to the fact. They have lost their plumage, and that makes them look black, and also smaller. A chicken looks smaller when all its feathers are plucked. If the number is large in a colony, and if the diseased bees have a tremulous motion, it is probably bee-paralysis. In the North this seldom amounts to much, but it becomes a very serious matter in the South. Very many remedies have been offered, each one saying his own remedy succeeds while the others fail, and that's about equivalent to saying that, as yet, no certain remedy has been found.

2. Some kinds of honey-dew will do well for wintering, but perhaps in most cases it is rather bad, especially if it is very dark.

Crost and Crooked Combs.

I have several colonies of bees in dovetail hives that have badly crost and crooked combs. Would you advise me to prepare new hives, by filling self-spacing frames with full sheets of foundation, and transfer all such colonies into new hives, and then put a queen-excluding zinc sheet on top of the new hive, and set the old hive with its unhatched brood on top of the new, in order that all the young bees may be hatched and reared, and not be destroyed?

Or, would it be best to place the old hive at the bottom, after the queen is secured in the new top hive, as then the bees might still hatch the young brood out, and remove all the honey in these crooked combs into the top story? and then, after all the brood is hatched in the lower story, and no eggs be deposited in it (the queen being at the top) I could remove the old lower story, and melt the crooked combs. VIRGINIA.

ANSWER.—The first question is, whether it may not be possible with a little cutting to get the combs, or at least part of them, separate and straightened in the frames. If the case is so bad that this is not possible, then perhaps you will find very little difference in the two ways you mention. If you put the old combs above, you'll find more honey in them. If you put them below, you'll find more pollen in them. If you don't object to having the honey in the old combs, perhaps it will suit the bees better to have the old combs above.

Labels on Sections.—Instead of having the very whitest sections, G. K. Hubbard favors using a cheaper grade and pasting labels on top of each section. Looks just as well on opening a case, gives as good satisfaction, and helps advertise.—Gleanings.

An Important Item in Moving Bees, the editor of the American Bee-Keeper says, is to have always a bit of cotton-batting ready to close promptly any leak that may occur. When bees are confined, he says they will take salt water more readily than fresh.

Activity of Italians.—H. Kuhn says, in L'Apiculteur, that he is convinced the Italians are more active than the blacks. In the evening he set the bees at work on some frames with a little honey not far from the apiary. His own bees (blacks) stooped work at sunset, but Italians that came from an apiary more than a quarter of a mile away kept at work till it was completely dark. The same thing was repeated the next day with the same result.

Top Ventilation in Summer.—Dr. Miller, in Gleanings, favors top ventilation in hot weather. It will not do to have an opening close to the sections, as that hinders the sealing of those nearest the openings, but he would at least have an opening to each story whenever a colony occupied with brood more than one story. The editor thinks that top ventilating, like spreading the brood in spring, is one of the fine arts that beginners may do well not to meddle with.

Skylark's Big Yield.—J. M. Hambaugh gives, in Gleanings, a sketch of J. P. Israel (Skylark,) who is now 75 and wide awake; and relates that in 1882, Mr. Israel increased 50 colonies to 101, and the next year decreased them to 16, a bad boy helping the decrease by robbing the bees and starting the bees to robbing. In 1884 he increased the 16 to 69, and harvested 10,592 pounds of comb honey in 2-pound sections—an average of 662 pounds to the colony, spring count!

Value of Unfnisht Sections.—W. Z. Hutchinson esteems them highly at the beginning of the honey harvest. If the harvest comes in a flood the difference is not so noticeable, but when it comes slowly the bees, especially if Italians, are loth to commence in the supers, crowding the brood-nest with honey. He says: "A super of partly-drawn combs at the opening of the harvest has proved nearly as valuable to me as a super of completed sections."—American Bee-Keeper.

When to Unite Weak Colonies.—G. M. Doolittle says he has found it not a good plan to unite weak colonies in spring. The excitement of uniting results in using up more rapidly the old bees, and the united colony gets through no better than either of the weaklings singly. So he lets them alone till some grow to five frames of brood. A frame of brood is taken from one of these and given, not to the weakest, but to one of those having four frames of brood. A week later he takes a frame from each five-brooder and gives to a three-brooder. When all are built up to five brood each, he takes four frames of brood with adhering bees from one colony and alternates it with the frames of another colony, thus making a strong colony with nine frames of brood, that will give a good account of itself in the supers.

How to Find Queens.—G. M. Doolittle gives, in Gleanings, the following specific instructions for finding a prolific queen, based on a theory that it may be interesting for others to confirm or refute:

"To find a prolific queen, look for her between the hours of 9 a.m. and 3 p.m., on one of the two outside combs of the brood-nest; for it is my belief, after 25 years of practical observation, that most queens have a certain route (there are a few exceptions,) which they go over every 24 hours, the queen being near the center of the brood-nest at midnight, when the temperature at the outside of the cluster of bees is coolest, and from there travels in her egg-laying toward the outside of the cluster till noon, when she commences to return, reaching

the center again at midnight. The next day she does the same thing again, only going in an opposite direction, or toward the opposite side of the hive, which brings her on one of the two outside combs of brood, between the hours above mentioned.

"Very early in the morning or late at night I rarely find a queen on either of the outside combs of brood, but midway between them and the center of the brood-nest, while at from 11 a. m. to 2 p. m. I find a queen on one of the outside combs of brood, nine times out of ten, providing the brood-nest is in a normal condition. If an empty comb is inserted anywhere in the brood-nest, the queen will be quite likely to be found on this comb 24 hours later; but in such a case the brood-nest would not be in a normal condition."

Consumption During Season of Repose.—M. Leon Dufour says that in his part of France this season lasts eight months—from Sept. 15 to May 15—and may be divided into three periods:

The first period is from Sept. 15 till Oct. 15. During this period there is still activity, brood is present, and altho there are some days when nectar is gathered, the consumption is considerable, varying from three to five pounds.

The second period is of four months, from about the middle of October till the middle of February. During this time there is no brood, no work, and the daily consumption is light, amounting to 11 to 13 pounds for the four months.

The third period includes the end of winter and the beginning of spring, the three months from Feb. 15 till May 15. Activity returns, flowers become increasingly abundant; some days the hives increase in weight; but the weather is very variable, the activity of the bees and the feeding of brood requires abundant nourishment, so on the whole there is heavy consumption, the loss in weight varying according to the colony from 16 to 20 pounds.

At least 33 pounds must be left for winter stores.—L'Apiculteur.

THE W. T. FALCONER MFG. CO., of New York State, for three months this season had an unprecedented rush of bee-supply orders. But it seems they were able to give their customers more prompt service than many of their competitors.

DR. A. B. MASON, of Lucas Co., Ohio, Secretary of the United States Bee-Keepers' Union, wrote us July 18:

"I never saw bees so busy on sweet clover, and still they are getting *very* little surplus honey."

MR. W. BOWLING, of Ontario, Canada, wrote us recently:

"The Bee Journal is a first-class bee-paper, that tells one where to get first-class bees and first-class honey; and also is a first-class kicker against adulterators. I wish you every success."

MR. O. O. POPPLETON, now in Brevard Co., Fla., writing us July 18, said:

"We are having another little spurt of honey-gathering, which may increase my average yield from 10 to 20 pounds over former estimate of 80 pounds (on page 441)—a good way to be disappointed; and I have, besides, 25 per cent. increase—a little the best I have done since the big freeze in 1895. Things are partially recovering from the effects of that freeze, but it will be many years before the phenomenal yield of 1894 can be repeated."

MR. W. A. PRYAL, of Alameda Co., Calif., writing us on July 14, reported:

"We did not have any rain to speak of since I wrote you previously. The rains then helped out some, but not enough to do any great amount of good. Aside from the dry weather the season is a nice one, tho it could be improved in a few particulars. But as man cannot improve the weather any, what is the use of complaining?"

"This city has had its wish gratified. We have a camp of

soldiers on this side of the bay. They are at Fruitvale, a suburb of the city, four miles to the East. I am four miles to the North, opposite the Golden Gate. So 'soger boys' are a common sight on the streets of Oakland. They are members of some of the California regiments, and we wanted some of the Eastern boys so as to show them some of the nice things hereabouts."

MR. W. L. COGGSHALL, of Tompkins Co., N. Y., writing us July 17, reported:

"A frost July 11th and 12th, when basswood is in full bloom, and no rain since, with North winds and cool nights, has the effect to make bee-keepers blue. We'll have the shortest white honey crop in eight years; so I helped the men (4 of us and a boy) put up 100 tons of hay in just 15 days."

MR. THOS. G. NEWMAN, of San Francisco, Calif., General Manager of the National Bee-Keepers' Union, writing us July 16, said:

"The high winds here, about nine out of the twelve months of the year, make bee-keeping almost impossible in, around and about San Francisco. It is all that the bees can do to gather enough to live on, altho we have pasturage for them in abundance. Further south and east they often do well, but here, never. The great drouth all over the southern part of the State will make this year's crop of honey very short."

MR. E. B. GLADISH, Secretary of the Leahy Mfg. Co., of Missouri, called on us July 21. He had been on a two weeks' vacation to Niagara Falls and then back again, calling on the A. I. Root Co., of Ohio, after which he crossed the State of Michigan, and Lake Michigan, and then visited several manufacturers of bee-supplies in Wisconsin.

It is surprising how some of the bee-supply manufacturers travel around. It almost tempts us to go into that line of business, for we have always had a great desire to travel, but are simply held down in our office all the time trying to get out a bee-paper every week. But "what can't be cured must be endured," we presume, and so we will have to be content to remain at home, and let others do the traveling around.

"H. E. HILL is now editor of the American Bee Journal," is the way the Australian Bee-Bulletin announced it when Mr. Hill took the tripod of the American Bee-Keeper. Editor Hill comments on the excusable error as follows:

"The similarity of names is doubtless responsible for the antipodal confusion. But we can stand it if Bro. York can."

Why, certainly, we can stand it. It's the truth generally that hurts. Whatever anyone says of or against us that isn't true always hurts the sayer more than it does us. Of course it is a little unfortunate that the American Bee-Keeper wasn't called by some other name, for, like the rose, if called by a different name it would be "just as sweet."

MR. PAUL VAN SYCKLE, of Porto Rico, has just lately been visiting Editor Hill, of the American Bee-Keeper, who says:

"Mr. Van Syckle was for a number of years located in Cuba, where we made his acquaintance and enjoyed his hospitalities. An apiary at San Juan, Porto Rico, constitutes a part of his present industrial interests, of which he expects to soon be in charge again. He relates a story of home markets, good prices, profusion of nectar-yielding flowers, and general favorable conditions, that makes us fairly 'homesick' for a Porto Rican bee-ranch."

Very likely by the time this number of the Bee Journal reaches its readers, Porto Rico will be under the flag of the United States.

MR. W. S. POWDER, of Marion Co., Ind., wrote us as follows July 18:

"I start for Atlantic City to-morrow morning for 10 days' rest. I never worked so hard in my life as I have this season, and I know you have worked hard, too. I wish you could join me on the trip."

Thank you, Mr. Powder. Indeed we would like to go with you, but we couldn't possibly get away, for the Bee Journal requires our constant attention. A weekly bee paper, and no helper that can bear the brunt of the work, ties us down pretty closely. Others will have to take the vacations, and we will remain home and report them.

GEORGE W. YORK, EDITOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY

118 Michigan Street, CHICAGO, ILL.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitecomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38.

JULY 28, 1898.

NO. 30.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The A B C of Marketing Honey is a very timely subject that will be discussed in a series of articles in the American Bee Journal by Mr. Herman F. Moore, who has had some 12 years' experience and is abundantly able to give something of interest and value to our readers. The first article will appear next week. Look out for it.

A Poor Honey-Year.—Gleanings thinks reports show a more general failure than ever known. Quite generally clover is a failure, but Vermont and Colorado have had a good season, and there are some good reports from West Virginia, Northern Carolina, Wisconsin and Michigan. But no remarkable upward tendency in prices appears as yet.

Honey in Cans vs. Barrels.—We are glad that most dealers in bee-keepers' supplies have stopped quoting barrels and kegs for honey in their annual catalogs. Tin cans holding 60 pounds each are so much more desirable in every way. They can be handled more easily, packed more closely, and then, best of all, when the honey in them is granulated it can be liquefied right in the cans, without first digging it out, as is necessarily the case when in barrels.

If we could have our way, no more extracted honey would be put into barrels. We have now on hand a number of barrels of honey, and would have paid half a cent more a pound for it if it had been put into 60-pound cans instead of the barrels. We doubt if we shall ever buy any more honey in barrels.

Of course, if a large bee-keeper has a certain demand for his honey that would prefer barrels, it would be different. But

we believe the cans are much more satisfactory in every way. Can your honey if you possibly can. If you can't can it, then bar'll it up.

Apiculture at Omaha.—On page 385 we presented a good picture of the Apiary Building at the Trans-Mississippi Exposition. This building is located on the North tract directly opposite the Transportation and Agricultural Implement Building. It belongs to what is familiarly known as the Swiss Farmhouse style of architecture, and is declared by experts to be the best arranged and most convenient building ever erected for bee-exhibits. It is built of wood and staff. All the exposed heavy timbers are painted a red brown color, while the roof is green, and has a skylight on each side of the ridge-pole that extends the length of the building. Every precaution has been taken to insure plenty of light, as it is an important adjunct in displaying a honey exhibit. In addition to the skylights there are numerous windows, and the show-cases have both glass sides and tops. The interior of the building has been prettily decorated with draperies of yellow and white, and the names of the counties exhibiting are shown in comb honey.

The Nebraska display is arranged in a case that extends along the south side of the building. The exhibit is very attractive and complete, and contains a large array of samples of honey both in the comb and extracted. A unique feature of the Douglas county exhibit is the bottled vinegar manufactured from honey.

In the center aisle a large collection of prest honey and pollen-producing flowers and plants are displayed in a large case. Nebraska is represented by 1,500 different specimens. There is also an attractive array of wax-flowers, the work of Mrs. E. Whitecomb. Other States exhibiting are: Iowa, Wisconsin, Minnesota, Kansas, Missouri, Ohio, Texas and Utah.

Two liquefying rooms fully equipped with utensils used by bee-keepers are located in the west end of the building for the convenience of exhibitors. There is also a very large assortment of hives and extractors and other articles.

A comfortable reception room has been fitted up for visitors in the gallery where three colonies of bees may be seen at work in glass hives, or passing back and forth from nearby gardens through holes made in the wall for their accommodation.

The United States Bee-Keepers' Union has decided to hold its next convention at Omaha, and an effort is being made to have it held Sept. 7, 8 and 9, which are the dates set for the National Pure Food Congress to be held at Omaha. Mr. E. Whitecomb, Superintendent of the Bureau of Bee-Industry, is in hopes that the convention may be held at that time, as it is believed that reduced railroad rates may be more easily obtained then.

Abbreviating the Names of Journals is the heading of a column and a quarter editorial by Editor Hutchinson in the July Bee-Keepers' Review. Of course it was written as a reply to our utterance on page 425, where we once more protested against the use in print of the letters "A. B. J." when referring to the American Bee Journal. But here is Mr. Hutchinson's editorial:

In a recent issue of his journal, Editor York objects to the use of A. B. J. as an abbreviation for American Bee Journal. I believe he has before now made the same objection. Out of deference to his feelings I always write it American Bee Journal in my editorials, but I always do it with a feeling that I wish that he didn't feel that way about it. He says that he is the highest authority as to what his journal shall be called; and I suppose that is true, but the next thing is to get people to call it by its whole name. I might request all my friends to call me William Zenas Hutchinson, but I doubt if they would do it. I am almost universally called "W. Z.;" not only by bee-keeping friends, but by my neighbors, and all those with whom I come in contact in a social way. And, say,

"Geo.," I don't feel badly about it. I look upon it as a mark of good fellowship, or comradeship or friendship. It's only to the fellow to whom you feel "chummy" that you ever give a nickname, or cut his name down to an abbreviation. American Bee Journal is a long name. It's almost as bad as William Zenas Hutchinson. Its editor may request us to spell it all out every time we write it, and we may do it because we like him and wish to please him, but when we get to talking one with another, it will slip out "A. B. J." in spite of all we can do. Wherever I go I always hear it referred to as "A. B. J." All orders and correspondence that come to me in reference to the American Bee Journal, call it the "A. B. J." Bro. York, himself, in his letters to me always uses this abbreviation. If we could simply contract it to the one word "Journal," as we can "Bee-Keepers' Review" to simply "Review," or "Gleanings in Bee-Culture" to "Gleanings," it wouldn't be so bad; but to have to write it all out each time—well, it shows that we have some regard for the feelings of its editor, and that is all it does show—in the Review. Of course, if I were writing an article for some paper outside of our special class organs, I should most assuredly refer to it as the American Bee Journal, and do it with pride, too, but right in our own family, where every one will know exactly which journal is meant, it seems as tho we might be indulged that much. Bro. York, won't you reconsider, and allow us, right here at home, when there isn't company, to use that short, chummy abbreviation that has slipped off our tongues and the points of our pens so many times—A. B. J.?

W. Z. HUTCHINSON.

Had Mr. Hutchinson read our remarks on page 425 more carefully, he wouldn't have written one-quarter of the above extract, for we plainly said that we objected to the use of the letters "A. B. J." when meaning the American Bee Journal, *in public print*. What do we care what people call it in their private correspondence or conversation? Why, they can call it "A. B. J.," "B. A. J.," "J. A. B.," or anything else they please, outside of public print, and we won't object at all.

Really, it is the editors of some of the bee-papers that need to learn that giving the initials of a paper from which they copy is no credit at all—neither to themselves nor to the papers they copy from.

"William Zenas Hutchinson" is not a parallel illustration at all, so need not be noticed further than to say that of course no editor would be guilty of copying an article that was written by Mr. Hutchinson, and then sign it "W. Z.," or "W. Z. H.," and call that a proper credit. But we are now talking about publications, and not about "chummy" names.

We said *we* were the highest authority as to how our journal should be referred to *in public print*. To this statement Mr. Hutchinson says: "I suppose that is true"—he isn't quite sure of it. If that isn't "cool" we don't know what is. If *we* are not the highest authority in this matter we think it is time we are finding out who *is*. Surely, not a man who hasn't a cent invested in the American Bee Journal.

Now, we don't want any editor to print in full the words "American Bee Journal" just because he regards our feelings, nor because he wishes to please us—those reasons are too weak to consider at all. We want him to do it because it is only simple *justice* so to do—because he has no *right* to copy original articles or ideas, and then not give full and intelligent credit for them.

On page 208 of the July Review, second column, after referring to something Mr. Dadant said in this paper about feeding, Mr. Hutchinson has "A. A. J., 162." That might mean "American Ant Journal," if there were one by that name; but of course he meant the American Bee Journal. Then why not say so, if Mr. Dadant's remark was worth mentioning in the Review?

We stand ready—as we have always stood—to credit other bee-papers for what we take from their columns in just the way their editors wish us to credit them; and we have a right to expect that the editors of the other papers will reciprocate that readiness.

In reply to Mr. Hutchinson's final question, we must say firmly, but kindly, *no*—if he refers to public print. And we

would say to any and all editors, whether of the apiarian or agricultural press, if you are not willing to give the American Bee Journal proper credit for what you consider worth taking from its columns, then don't take it. We are not begging editors to copy from our columns, but we are perfectly willing they shall take all they want, provided they always give credit therefor as they should—to the American Bee Journal.

The United States Bee-Keepers' Union

has a very nice bit of attention given it by way of a full-page engraving in the American Bee-Keeper, showing the nine officers, each one ingeniously set in a honey-comb cell. The likenesses are excellent. Two editorial articles, together with an article on "The Power of Association," by General Manager Secor, set forth the value of the organization and the wisdom of securing membership therein. The editor thus mentions the case of a Pennsylvania bee-keeper for whom trouble is brewing:

"He has kept bees for 15 years without a thought of any unpleasantness; but, like hundreds of others, his hour has come, and we regret sincerely to state he has no claim upon the Union's protection."

It is a good plan to get under shelter before the storm comes. Besser you jines der Union right away quick!

Asking Questions.

—A subscriber in Jamaica wants to know whether he can ask questions to be answered in the Bee Journal. Certainly. Any regular subscriber to this journal has the right, and is invited, to ask questions, which will be answered in print, unless they are such simple questions as can be answered by reading any of the many books devoted to bee-keeping. Of course, no one would begin to keep bees without getting a good book in addition to the American Bee Journal, or some other good bee-paper.

Actually, a year or two ago a subscriber asked if the queen lays her eggs in empty cells, or in those first filled with honey! Think of taking time and space to answer such a question in print!

After referring to your text-book on bees, and you find you are unable to solve any problem relating to your case, then send in your question, and our "special nut-cracker," Dr. C. C. Miller, will do his best to help you out of your difficulties.

The Names and Addresses of all your bee-friends, who are not now taking the Bee Journal, are wanted at this office. Send them in, please, when sample copies will be mailed to them. Then you can secure their subscriptions, and earn some of the premiums we are offering. The next few months will be just the time to easily get new subscribers. Try it earnestly, at least.

The Alsike Clover Leaflet consists of 2 pages, with illustrations, showing the value of Alsike clover, and telling how to grow it. This Leaflet is just the thing to hand to every farmer in your neighborhood. Send to the Bee Journal office for a quantity of them, and see that they are distributed where they will do the most good. Prices, postpaid, are as follows: 50 for 20 cents; 100 for 35 cents; or 200 for 60 cents.

Honey as Food is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey among should-be consumers. The forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 20 cents; 50 for 35 cents; 100 for 65 cents; 250 for \$1.50; 500 for \$2.75. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest aparies in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject to a

Series of Nine Illustrated Articles :

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This is a series of practical articles that bee-keepers of the United States will not want to miss reading. They will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Chesbire |
| 4 Poultry for Market—Fan Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan Field | 14 Muth's Practical Hints to Bee-keepers |
| 6 Our Poultry Doctor—Fan Field | 15 15 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse-Book | |

For Sending TWO New 40-cent Subscribers:

- | | |
|---|---|
| 1 Potato Culture—by T. B. Terry | 7 Hutchinson's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Blenen-Kultur—German |
| 4 Dr. Tinker's Bee-Keeping for Profit | 10 Bees and Honey—160 pages—by Newman |
| 5 40 "Honey as Food" Pamphlets | 11 People's Atlas of the World |
| 6 Winter Problem in Bee-Keeping—by Pierce | |

All New Subscriptions Begin July 1.

Please remember that all the above premiums are offered only to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Be It Known

To all Men, we are prepared to fill orders promptly for

CHOICE QUEENS of the best strains of Golden or Leather-Colored Italians....

Tested \$1.00; Untested—one, 75c; three, \$1.50. After July 1, 50c each. Remit by Express Money Order, payable at Barnum, Wis. One and two-cent stamps taken. Address,

Van Allen & Williams,
25Atf BARNUM, WIS.
Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases—everything used by bee-keepers. Orders filled promptly. Send for catalog. MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.

BEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, **E. L. CARRINGTON,**
11Atf De Funlak Springs, Fla.
Please mention Bee Journal when writing.

Whooping Up on Basswood.

Bees are booming. I have taken 4,000 pounds to date, and I am in the midst of the basswood flow. I have taken off 2,000 pounds the last 7 days from 100 colonies. J. MESSINGER.
Juneau Co., Wis., July 16.

Too Wet for Honey.

The honey crop so far is short. Like in all other localities, there was a profusion of white clover, but too wet to secrete nectar. We had a copious rain last night which will help the fall crop. B. FRANK HOOVER.
Whiteside Co., Ill., July 20.

Working on Acorns.

Clover bloomed well but did not yield much honey. I think it was too wet in the spring, and it is too dry at present, but there is still some white clover in bloom in the low places. Bees did not swarm much in this locality—had only six natural swarms from 65 colonies, spring count. They are storing some honey in the surplus departments, but it is dark in color. This dark honey must come from the acorns. Five years ago I got some dark honey that I thought came from flax. But it was awfully dark, and of peculiar flavor. Corn is

50c* Tested Queens *50c

For the next 30 days I will sell Tested Queens reared from the best Italian stock at

50c each—or \$5.50 per dozen. Untested, 40c.—or 3 for \$1.00. Safe arrival.

W. J. FOREHAND, Fort Deposit, Alabama.

Excursion to Saratoga, N.Y., and Return

via Nickel Plate Road, account Young People's Christian Union of United Presbyterian Church. Tickets to be sold Aug. 1 and 2, with return limit of Aug. 31, by depositing them with Joint Agent at Saratoga. Excellent dining-car service, smooth road-bed and luxurious sleeping cars. For full particulars address J. Y. Calahan, Gen'l Agent, 111 Adams St., Chicago. Van Buren St. Passenger Station. (54-30-1)

just beginning to bloom, and I think I will get better-looking honey from corn and black-heart weeds, which are very plentiful in this locality, and have not failed to yield nectar in six years. Golden-rod and Spanish-needle are very plentiful here, and always yields some honey. Will some one tell me something about honey from acorns?

I became interested in bees about a year ago, and have been attending to Jacob F. Wirth's bee-ranch. I like to work with bees. I have seven colonies of my own in fine condition.

ANNA MESSIER.

Henry Co., Ill., July 16.

Basswood Good While it Lasted.

Our honey harvest is over for this year, I think. Basswood opened July 2, and closed July 18. It was good while it lasted, and the honey secured will probably pay expenses and leave a margin of profit, especially if we get the better prices that we look for.

HARRY LATHROP.

Green Co., Wis., July 21.

No Swarms and No Honey.

There have been no swarms in this locality, and I have been examining my hives and find them all full of bees and sheets of brood, but no honey.

JOHN CRAIG.

Macoupin Co., Ill., July 18.

Seeded to White Clover.

Mr. Messinger, my neighbor, has taken over five barrels of honey, mostly white clover. Our country has come in freely to white clover this year; one would think the whole had been well seeded by some one. My bees are doing finely. Mr. Messinger never extracts any from the lower story. He wintered about 100 colonies.

GEO. H. LAWRENCE.

Juneau Co., Wis., July 12.

He Keeps in the Lead.

I have mailed a picture of my small apiary, which includes eight colonies, of which I am very proud, and hold the lead of all in my neighborhood for getting the largest quantity of honey, altho all the bees around have the same chance to gather it. All there is to gather from grows wild, and when the white clover is gone we take off the sections and apron them down. I believe I am the only one here who takes the Bee Journal, and that is what helps me to keep in the lead. This is only my second season with bees. CHAS. S. COCHRAN. Baltimore Co., Md., July 19.

[Thanks for the picture, Mr. C.—Ed.]

Not an Ounce of Surplus.

I began with 50 colonies in the spring, and up to date they have not stored an ounce of surplus honey. Too much rain. A. B. BATES. Franklin Co., Mo., July 16.

Failure of Alfalfa to Yield.

I see it stated that alfalfa does not produce any nectar in Iowa. Perhaps the land on which it is grown may have something to do with its failure to give out the nectar. I have in mind two pieces of alfalfa—the one is on first bottom land, and tho a creek runs along one side of the alfalfa and there is good

A Book Recommended by Dr. Gallup.

THE NEW METHOD

In Health and Disease.

By W. E. Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from Weakness to Strength so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings cannot be sick. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, not a drug treatment.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "New Methods" given here; even those who have been pronounced Consumptive have been entirely cured. While for Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "New Methods" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid; or club it with the Bee Journal for one year—both together for \$1.60.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

drainage, it does not give out any nectar. The other lot is on a ridge, the land a stiff clay, and with an incline to the southeast, the elevation about 30 feet above the bottom land, and on the ridge the alfalfa gives plenty of nectar.

WM. H. EAGERTY.

Republic Co., Kan., July 18.

Planting the Apple-Tree.

What plant we in the apple-tree? Sweets for a hundred flowery springs To load the May winds' restless wings, When from the orchard row he pours Its fragrance through our open doors.

A world of blossoms for the bee,
Flowers for the sick girl's silent room,
For the glad infant sprigs of bloom.

We plant with the apple-tree.
—Selected.

In the multitude of counsellors there is safety.—Prov. 11-14.

**Is a Swarm an Organism?—
Other Questions.**

Query 78.—What makes one colony, if left to itself, build more drone-comb than another? Or, what induces a colony to build drone-comb, and what to build worker-comb?

2. Is a swarm of bees one organism, or is it a crowd of organs—self-sufficient beings?

3. What do you think of the organic conception of the honey-bee?

4. As the larvae need different food during the time of their growth, how do the nurse-bees make the change, and how do they know to make it at the proper time?—German.

E. France—I don't know.

W. G. Larrabee—These questions are beyond me.

C. H. Dibbern—1. I don't know. 2. I should say a big crowd. 3. To fill a useful place in nature. 4. I don't know.

P. H. Elwood—I suspect the man who wrote this batch of questions is waiting to answer them, and I am willing that he should.

Jas. A. Stone—1. I know't know. 2. I think they are. 3. I don't have any idea on this point. 4. By the instinct God has given them—and in no other way.

Prof. A. J. Cook—1. Condition of hive, with probable character of queen and colony. 2. A multitude of individuals working together. Like a family. 3. ? 4. A great problem. Who can answer?

Dr. C. C. Miller—1. The strength of the colony, the age of the queen, the time of year, etc. 2 and 3. I don't believe we better fool with such things this side the water. Wait till they settle it in Germany. 4. Probably by instinct.

J. A. Green—1. A colony with a failing queen will build more drone-comb than one with a queen that is young and vigorous. Instinct, apparently, teaches them that drones are likely to be needed. 2. This is a question for the splitter of words rather than the bee-keeper. A single bee is an organism, viewed in one light. So is a single human being.

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **Two New Subscribers** to the Bee Journal (with \$2.00), and we will mail YOU a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

If you want the BEST... Honey Extractor

Get Williams' Automatic Reversible, And You Have It. Address,

VAN ALLEN & WILLIAMS, 10E1f Barnum, Wisconsin. Please mention Bee Journal when writing.

Viewed from another standpoint, nothing less than the colony can be considered an organism. In much the same sense the family, or in modern life the community, is required for a complete organism. 3. Tell us what you mean. 4. By means of the instinct which God has given them.

O. O. Poppleton—1. Several reasons: An old queen, a heavy flow of honey, a strong colony, etc., and sometimes pure contrariness. 2, 3 and 4. These are fine questions to theorize about.

R. C. Aikin—1. Conditions favoring prospective swarming or supersedure while the combs are being built on urgent need of store comb. Last sentence—need of drones, need of workers. 2, 3 and 4. I leave these to the scientists.

Mrs. L. Harrison—1. Where there are young queens more worker-comb will be built; if an old one, drone, as she contemplates abdicating the throne. 2. Crowd of organs. 3. I don't think. 4. By instinct; instructed by the God of nature.

D. W. Heise—1. Some strains of bees have far stronger inclinations in that direction than others. Much depends upon the rush with which a honey-flow may come, and the prolificness of a queen. 2, 3 and 4. I don't know. Ask Prof. Cook.

Eugene Secor—1. The age of the queen probably has some effect on drone-comb building. Bees also prefer drone-comb for storing honey, hence the outside frames in the brood-chamber are often filled with drone-comb. 2, 3 and 4. Excuse me, please.

G. M. Doolittle—1. An old or falling queen tends toward the building of drone-comb. 2. I incline to think one bee cannot "make a colony." 4. Instinct implanted in them tells the bees just how to accomplish the best results for the colony.

E. S. Lovesy—1. This is governed generally by the strength of the colony and the swarming impulse. 2. As I view it, a crowd of organs. 3. One of Nature's wonderful conceptions. 4. Bees, like other insect life, seem to know when and what to do in the matter of reproduction.

Mrs. J. M. Null—1. Age of queen and size of hive materially affect the building of drone-comb. 2. Of one organism when seized by the swarming impulse (apparently); at all other times each self-sufficient for its mission. 3 and 4. Beyond my reach. "Sour grapes," any way; don't want 'em.

Rev. M. Mabin—Several things have influence in this. The age of the queen has something to do with it. A strong colony will build more drone-comb in a large hive than in a small one. They will also build more drone-comb when forage is abundant. 2, 3 and 4. I cannot undertake to answer these questions here.

Dr. J. P. H. Brown—These questions more particularly concern the ethereal biological, metaphysical and theosophical minded bee-keeper than the real honey-producer. The latter is so held down to old mother earth by the "things of time and sense" that he has no time to give to the "ethereal" part of the business.

J. M. Hambaugh—1. The notion of swarming will strike one colony and the

Only 6 cts. per Pound in 4 Can Lots or Over.

Finest Alfalfa Honey!

IT SELLS ON TASTING.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,
Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 230 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarist's library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth.

Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages; bound in cloth and fully illustrated.

Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 175 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 800 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-keeping, by Dr. John Dzlerzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES OF HONEY. 10 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet.—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p., illustrated, 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2 in fine artificial leather, with pocket, elastic slate, and account-book. Price, 60 cts.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest, most approved methods of bee-keeping, in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50c.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages, fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Pinning and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks; wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Illinois.—The annual meeting of Northern Illinois Bee-Keepers' Association, will be held at the Court House, in Freeport, Ill., Tuesday and Wednesday, August 16 and 17, 1898. All interested in bees are invited to attend.

B. KENNEDY, Sec., New Milford, Ill.

instinct of nature prompts them to rear some of the opposite sex, while others are not so smitten. 2. I can't catch on, but it seems to me they are a crowd of organs, dependent upon one another. 3. Here I'm lost. Ask Dr. Miller. 4. That is their trade. Nature provided the instinct.

Emerson T. Abbott—1. What makes one man use tobacco and another let it alone? 2. Perhaps. Are two mud-turtles one? 3. I should like to have the writer explain what he means. 4. How does a pigeon know how to prepare the food for her young, and when to give it to them? How do you know anything?

S. T. Pettit—1. Various causes. Old or poor queens; dissatisfaction with their quarters; the thought of swarming. The opposite conditions conduce to the building of worker-comb. A strong colony will build proportionately more drone-comb than a weak one. 2. Yes, one organism. 3. I don't understand the question. 4. I don't know.

Dr. A. B. Mason—1. There are several reasons. A colony with an old queen is more liable to build drone-comb than is one with a young queen, and also more liable to do it under a strong honey-flow than when there is a moderate flow. 2. A crowd of organs. 3. I think it shows the wisdom of the Being who created it. 4. Perhaps Dr. Miller will tell you.

J. E. Pond—1. Who can tell? I can't. 2. A colony of bees consists of three parts, queen, drones, workers, all forming one distinct whole. 3. It would take pages to state an intelligent answer to the question, and then we could only theorize. Certain facts have been proved, why they are so is a guess. 4. Who can answer? I can't. We must fall back upon the idea that Nature governs well.

G. W. Dismaree—1. "German" has askt a whole book. All close observers know that very old queens induce large numbers of drones—it is a matter of instinct with the bees. A good season and too much drone-comb will usually give a big output of drones. 2. The honey-bee lives in colonies, and that condition with them is essential to existence. Is this true? 4. Don't have to make any change; Nature does that.

R. L. Taylor—1. The better the queen the greater the inclination to build worker-comb; the poorer or the older the queen the greater the inclination to build drone-comb. When a colony realizes that it may soon be necessary to rear a new queen, it is anxious first to provide drones and so build drone-comb. There is a limit to this, when comb is not needed for brood of any kind, but for honey only they are apt to build drone-comb because it is more economical. 2. Both—*E. pluribus unum*. 3. It's marvelous. 4. Instinct, I suppose.

One Fare to Saratoga, N. Y., and Return

via Nickel Plate Road, on Aug. 1 and 2, account of Young People's Christian Union of United Presbyterian Church, with return limit of Aug. 31, by depositing tickets with Joint Agent at Saratoga. Cheap rates to many other Eastern points. Communicate with this office, 111 Adams Street, Chicago, for further information. Van Buren Street Passenger Station, Chicago. (53-30-1)

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Bee-Hives, Sections, Etc.,

that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip't with best machinery, all combine to enable this firm to furnish the

Our 1898 Catalog

Send us your name and address and we will take pleasure in mailing you a copy

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polish, snowy-white Sections, beautiful, straw-

colored transparent Foundation, Improved Smokers and Honey Extractors, and all other first-class goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leahy Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

Select-Tested Golden Adel Queens.

Each, \$1.00. A practically non-swarming and non-stinging strain of golden bees. "How to Prevent Honey Canding" given to each customer. Tested Queens, each, 75 cents. 26Atf

HENRY ALLEY, Wenham, Mass.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, July 20.—Not any of the new crop of comb honey on the market this week; what little has come sold at 11@12c. Extracted brings 5@7c for the white, according to quality; ambers, 5@6c. Southern, fair to good grades, 4@5c. Beeswax, 27c. Market is in good shape for disposing of honey of all kinds. R. A. BURNETT & CO.

Kansas City, July 9.—New comb, No. 1, white, 11@12c; amber, 10@11c. Extracted, white, 5@5½c; amber, 4@4½c. Beeswax, 22 to 25c. Old stock of honey all cleaned up. Few shipments of new in market. C. O. OLEMONS & CO.

New York, July 9.—Comb honey: We closed out all of our old crop some time ago. We have received several lots of new crop from the South, good, No. 1 white, which sells readily at 11c per pound.

Extracted: Receipts of new crop from the South are large. We quote: Common, 48 to 50c a gallon; good, 52 to 55c a gallon; choice, 5 to 5½c pound. Demand is good, especially for the better grades. Beeswax remains firm at 28 to 29c. HILURETH BROS. & SEGELKEN.

Boston, July 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. BLAKE, SCOTT & LEE.

San Francisco, July 9.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5½@6c.; light amber, 4½ to 5½c. Beeswax, 25@25c

Small quantities of the new crop have been offered by sample, but nothing of consequence has been yet done in the same. There will be very little white sage honey this season, but a moderate amount from the alfalfa and tulie districts. Values remain as previously noted.

Detroit, July 21.—Fancy white, 11@12c; No. 1, white, 10@11c. Extracted, white, 5@6c; dark, 4@5c. Beeswax, 25@26c.

New honey is arriving, but prices are hardly establish. M. H. HUNT.

Minneapolis, July 9.—Honey much more encouraging. Fancy white clover comb is selling here now at 10½@11½c. Not advisable to ship darker than amber. Extracted fancy white clover, 5½@6c; amber, 5c; dark, 4@4½c.

Outlook for honey much more encouraging. S. H. HALL & CO.

Indianapolis, July 18.—Fancy white comb honey, 12@12½c; No. 1, 10@11c. Extracted, white, 6@7c. Beeswax, 25@27c.

Only a few arrivals of fancy white comb; market almost bare, and demand good. Quite a little comb honey from honey-dew is being offered, but there is simply no demand for the stuff. WALTER S. POWDER.

Milwaukee, July 14.—Fancy 1-pound sections, 11@12c; A No. 1, 10@11 cents; No. 1 8@10c; am er, 7@7½c; dark and old, 6@7c. Extracted, in barrels, kegs or pails, white, 6@6½c; dark and amber, 4@5c. Beeswax, 26@28c.

Since our last the sales of honey have not been large, altho a fair demand has existed and continues, altho the fruit consumption makes some difference with eaters of honey. There is not a very large supply of old stock left, and we shall be in good order for new crop both extracted and comb. The outlook is good. A. V. BISHOP & CO.

Buffalo, July 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & CO.

St. Louis, July 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. WESTCOTT Com. Co.

Cincinnati, July 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3½ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice ye low.

CHAS. F. MUTH & SON,

 Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.

If you once try it you will have no other. Samples furnished FREE. Large illustrated Catalog of all kinds of

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS, —BY— C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 5.—HIVES.

There is no royal road to success in bee-keeping any more than there is in any other industry; and as the time and attention given to bee-management must of necessity vary, it is only natural to expect that while some are successful others for want of success will give up bee-keeping in disgust. It is not always, however, the fault of the bee-keeper that success does not attend his efforts. He may have commenced with a style of hive that demands more time and attention to work successfully than he is in a position to give. Now, in endeavoring to give directions for managing the apiary properly there is one blot I must first notice. That the most improved system of bee-keeping should be extended to its fullest limits no one will deny to be an object worthy of every effort; but to the one bee-keeper who can manage the movable-comb system properly, there are, as far as my experience goes, at least ten who cannot, or at any rate do not. It is this latter class for whom I must write.

The fixt-comb principle is objected to simply because the combs cannot be moved about at the wish of the bee-keeper. If, however, a hive is adopted with fixt combs, but in which foundation can be used, that system will not be far behind the movable-comb system in point of honey returns, and it will be simplicity itself as far as management is concerned.

Years ago a hive, certainly in advance of the skep, termed the "Stewarton," and afterwards the "Carr-Stewarton," came much into favor among those bee-keepers who had not the time necessary to devote to bee-keeping on the movable-comb principle. Since the latter hive was introduced little or no effort has been made to bridge the gulf between the skep and the movable-comb systems, until the writer designed the hive now to be described.

This hive is known as the "Ivo" bar hive, and in appearance is very similar to the movable-comb or frame hive. The brood-chamber is simply four walls of substantial material, the front and back walls being rabbeted to receive the ends of the bars, which are $\frac{3}{8}$ inch thick and one and nine-twentieths inch wide at the ends, while out of each side a piece $\frac{1}{2}$ inch wide and 9 inches long is cut in order that when the ends are close together there will be a space of $\frac{1}{4}$ inch between the

combs. The width of the hive is such as will allow of 9 of these bars being placed close together side by side.

The supers are in all respects except depth like the brood-chamber, for while the latter is $7\frac{1}{2}$ inches deep the supers are only $4\frac{1}{2}$ inches in depth. This shallow depth is allowed for two reasons: First, because bees take much more readily to a shallow than to a deep super, and secondly because it may be used with slight alteration as a section-crate. The super is ordinarily fitted with wide bars about 2 inches in width, so that 7 bars occupy the space that accommodates 9 narrow bars.

If a start is to be made with a hive of this description, at least $1\frac{1}{2}$ pounds of brood foundation should be procured. The sheets of foundation are $7\frac{1}{2}$ inches in depth, and they should be cut so that one piece is $4\frac{3}{8}$ and the other $3\frac{3}{8}$ in depth. The top corners must next be cut off, also a small triangular piece out of the center of the top. Then open the saw-cut in the center of the bar with a small screw-driver and put in the sheet of foundation. The $4\frac{3}{8}$ sheets must be put into the narrow bars for the brood-chamber, and the $3\frac{3}{8}$ into the wide bars for the super.

When the bars are thus prepared and placed in position the hive is ready for the swarm. No swarm of less weight than 4 pounds should be expected to do much good the first season; therefore, a 4 or 5 pound swarm should always be secured whenever possible, the extra cost being trifling when the increased amount of surplus over what may be obtained from one of less weight is considered.

MOVABLE-COMB HIVES.

A movable-comb hive is the only shape that a bee-keeper who goes into the work of the apiary thoroughly can tolerate. By using such hives he has the bees and all parts of the hive

Super for Hive.

under complete control; but it is useless attempting this system unless with a determination to make it a success.

Accuracy in all its parts is essential in this hive if the bees are not to make movable parts immovable. A space of $\frac{1}{4}$ inch bees respect, but if any larger space is given (for instance between the two chambers when supering, or between the frame ends and the hive sides) it is almost certain that the bees will fill it with comb.

Those who construct their own hives will find the following instructions, if carefully kept to, all that is necessary in

making a good tiering hive of the style used most generally in England, and in America where bee-keeping on a large scale is carried on.

The hive consists of floor-board, brood-chamber, supers, lift and roof. The floor-board, with a slanting board in front, must be made to fit the brood-chamber, whose width will be determined by the thickness of the wood. The brood-chamber should be made of $\frac{3}{4}$ -inch wood, the outer walls $8\frac{1}{2}$ inches deep, and the inner front and back wall $8\frac{1}{2}$ inches. The inner dimensions are as follows: Side to side 15 inches to take 10 frames, $14\frac{1}{2}$ between the inner front and back walls, and 17 inches between the outer front walls, so that the 17-inch top-bar of the frame may rest on the inner walls and just fit in between the outer walls. When the frames are in the hive they will be level with the tops of the outer walls.

The supers may either contain frames or sections; if the former, they should be exactly like the brood-chamber except being 3 inches shorter, because super frames should be $5\frac{1}{2}$ instead of $8\frac{1}{2}$ inches in depth.

A "lift" is simply four walls with outer dimensions the same as the brood-chamber, and around the bottom to keep it in position are what are termed plinths. These plinths are also placed around the frame supers and around the brood-chamber except in front. The "lift" is for use upon the brood-chamber so that the frames may be better covered with quilts, but as supers are given the "lift" is raised so that it is always at the top. Over the "lift" is placed the roof, which should at all times be waterproof, and have a half or three-quarter inch hole in the middle of front and back for ventilation, and as a means of egress for bees through a cone escape.

FRAMES.

The size of the frame used is a very important matter; and as the sale of colonies may be one means of making the apiary a source of profit, it is absolutely necessary that the frame adopted should be of the British standard size, and therefore interchangeable with any hive in the same apiary, or in any part of the country, built to accommodate standard frames. [Of course in America the Langstroth frame, outside measure $9\frac{1}{8} \times 17\frac{1}{8}$ inches, has practically become the standard.—ERROR.] This frame in outward dimensions is 14 inches wide and $8\frac{1}{2}$ inches deep, but the top-bar, which is $\frac{3}{8}$ -inch thick, projects on each side $1\frac{1}{2}$ inches. The side-walls are $\frac{1}{4}$ inch, and the bottom-bar $\frac{1}{4}$ inch. The width of the frame is $\frac{5}{8}$ inch. If frames are made at home (which is not advisable), the outside dimensions and the thickness of the top-bar are imperative. This frame is intended to be used only in the brood-chamber where the production of bees is being carried on.

Shallow supers are at all times to be preferred to deep ones. As they are more readily entered by the bees, they are easier to handle when full, and shallow frames are more convenient than standard frames for extracting.

The shallow frame for extracting-supers is 3 inches shallower than the standard frame, and like it in every other respect.

SECTIONAL SUPERS.

Many people who eat honey prefer it in the comb, therefore it must be produced in a marketable form so as to be packed for transit. Big straw or wooden supers are altogether too bulky and too unsafe for traveling; consequently square or oblong boxes of thin wood have been devised to hold a certain weight of honey. These boxes are generally 2 pound and 1-pound sizes, but the latter are now almost universally used. The 1-pound section is imported, in the flat, from America, where suitable wood for its manufacture, soft and white, is grown. The section is grooved so that when bent at the grooves a square of $4\frac{1}{4}$ inches and $1\frac{1}{2}$ wide is obtained. The ends of the section are rabbetted so that when folded and tapt at the joint they become fairly rigid.

Before being used in crates or oblong boxes that hold 21, standing in 7 rows of 3 each, end to end, each section must have fitted in the center a piece or a full sheet of foundation. If only a piece called a "starter" is given, it should be fastened by heat or pressure to the middle of the top of the section to afford the bees a guide in building their comb, otherwise they might, and probably would, build it in any but what the bee-keeper considers the right way. The sections put in the crates without starters or foundation cannot be removed from the crate without much trouble and mess, as in literating the section the comb is broken and the honey made to run.

After the sections have been properly prepared and placed in the crate, a thin piece of wood known as the "separator" is placed between the rows of sections. The bees are thus compelled to keep their work confined to the space afforded by the section, and they usually finish off each side with a

nice, even surface, so that they may be packed without fear of damage.

How to get well filled sections and plenty of them will be fully dealt with under the heading of "Supering," and therefore it will be only necessary to say here that every hive should have supering capacity for 75 to 100 pounds of honey. If the hive is being worked for extracted honey, there certainly should be a brood-chamber of standard frames, and three shallow-frame supers to form a complete and satisfactory outfit.

A hive worked for sectional honey will require different super arrangements. There should be in addition to the brood-chamber two lifts 9 inches depth, or one of 11 inches and another of 6 inches. The lifts will be taken off the hive when the section crate is about to be placed upon the frames so that any openings around the crate, through which heat from the brood-chamber might escape, may be stopt with pieces of rag. The lift—only one will be required at first—is then placed again in position, the quilts are put upon the crate and packed around in the space between the crate and the sides of the lift so that when once the bees begin to work in the super they may not be driven down by cold nights lowering the temperature in this chamber. Each super crate should have a square of glass fitted in one end; the progress of the work can then be noticed without disturbing the colony. This is of great advantage, inasmuch as additional supers may be given at the right time which may not only be the means of preventing the issue of a swarm, but of the bee-keeper adding very considerably to the surplus from that hive, which would have been lost to him but for the additional room given. Bees invariably build combs from the brood-frames to the bottoms of the sections in the crate simply because there is a space of $\frac{1}{2}$ inch between the top-bars, and an additional $\frac{1}{4}$ inch beneath the sections, the rule of not giving a space of more than a $\frac{1}{4}$ inch is thus violated with the result that crates are moved with difficulty, and many sections spoiled. To obviate this nuisance, either an adapting-board must be used as a stand for the crate, or the frames must be made wider so that while the combs will be $1\frac{1}{2}$ inches barely from center to center, the frames will be only $\frac{1}{4}$ inch apart. All my hives in the future will be fitted with standard-sized frames made $1\frac{1}{5}$ inches wide instead of $\frac{3}{8}$. To keep the frames steady and at the correct distance apart, bell-staples will be driven into the shoulder, and a third down alternate ends of the frame.

[Continued next week]

No. 1.—The A B C of Marketing Honey.

BY HERMAN F. MOORE.

Twelve years ago the writer began at "A" in the above subject, and, while his advancement has been more or less rapid, he has not yet reached "Z" by a long shot.

It is undoubtedly true that the solution of the question of marketing honey, is for every bee-keeper who can to supply families within easy reach of his home. In this way vast amounts of honey can be kept from the city markets, and from overloading them. This matter of glutting the great centers of business with any produce is now well understood to be the cause of ruinous reduction in price, and not only of the particular lots of honey that happen to be sent to them, but in some degree reduces the price of all the honey in the land when offered for sale. Therefore, it should be strongly urged upon every producer of honey, to sell his product as near home as possible in actual miles.

There will be seen to be several cogent reasons for this, apart from the reason that heads this article. One reason for selling your honey near home is that strangers feel more confidence in you if you can say to them, "My county joins yours," or "Come over any day and I will give you a good time;" or any of the many friendly expressions that rise to the lips when meeting a fellow citizen of the same State, even tho 50 miles may separate your respective homes.

But you say, "I can't sell honey," "I am not built that way," "I haven't the gift of gab," etc. Now, with all respect to your opinion of your inability to sell honey, or to learn to sell honey, let me suggest that the main trouble with 75 per cent. of you is that you want to pronounce vwxyz the first day at school, forgetting that you started a-b, ab not many years ago. Of course, I mean by that you must learn to sell honey, and be satisfied with small profits at first, and small day's sales. Rome was not built in a day, neither can any man learn in one year all there is to learn about approaching the great public and finding the way to their pockets.

As we have decided to sell honey to our neighbors and

friends within 50 miles of the home apiary, let us not forget to start right. First, decide upon your package for your family trade, for I am proceeding on the supposition that catering to private families means the most in permanent results to the producers of honey.

By all means, adopt a size of package that sells for \$1.00, \$1.50, or \$2.00, and, if possible, have only one size of package, for that will greatly reduce your work and simplify your delivering. If any one desires more than your package, sell them two; and any person short of money, or for any reason wanting less, sell them half of your standard package, and this will be within reach of every one.

Be sure you know the exact net weight in pounds and ounces; also the capacity in pints and quarts, and when ask the weight or size answer freely, with no attempt to conceal or deceive. I want to bear down heavy on this point. Be absolutely open with your customers, for it is the best policy, and leads to the most lasting success—In fact, any other course leads to certain failure.

It seems to be a fact that the majority of men in trade in our great centers of business are not entirely candid with their trade. This causes an earnest seeking on the part of the customers for those whose word can be absolutely relied upon always, in quantity, quality and price; whose goods are *always* "all wool and a yard wide."

I feel sure that one of the greatest causes of the almost wholesale failures in business has been business dishonesty. There is no use trying to dodge the issue—it is *dishonest* to have on your shelves for sale to your customers, "pure black pepper," when you know, in fact were told by the drummer who sold it to you, that "it is half ground cocoanut-shells, so as to make the price more reasonable, and meet competition." In practice you will readily see the application—avoid even the appearance of evil.

There never was a time when dishonesty was more condoned than now, and fair dealing better or more liberally rewarded.

(Continued next week.)

Divider and Wedges in Honey-Production.

BY G. M. DOOLITTLE.

On page 401, I see Mr. Pettit has put a "coat" on that was not intended for him at all, and I am not even going to throw at him the old adage, "If the coat fits let him wear it," for when I wrote what I did on page 321, I did not have Mr. Pettit or his system in mind at all, for there are still scores of people who keep bees, some of whom live within 10 miles of me, who will believe nothing else, except that every bee which comes in from the field deposits her load of nectar directly into the cells, and unless forced in some way to go into the surplus apartment, they will deposit their loads in the brood-chamber. Therefore, Mr. Pettit will see that he failed to use the "charity which covereth a multitude of sins," when he said, regarding a sentence in my former article, "That assertion is based upon nothing at all."

No, Mr. P., that article was not intended for you at all; but since you call my attention to the matter I have something to tell you and the readers of the American Bee Journal, which I will try to make so plain that you will not call it even *theory*.

I took your case right out to the bees to decide. During the winter of 1896 I used my machinery in getting out some wedges according to your description of them, for the large entrance you were recommending at that time struck me very favorably. During 1897 there seemed no need for them, so they were allowed to remain stored away. But this season we have had extreme heat during the past three weeks, so the wedges were brought into effective use, under 25 hives.

Now I wish to say that you are just right in saying that where the bees hung out the day before the wedges were put under, after they were under they did not so hang out, even tho the next day was warmer than the first. But when taking the matter to the bees for settlement, and lying down right in front of the hives thus fixt, so I could ask them all about it, they thank me for raising their hive up from the bottom-board, for said they, "It is much more pleasant to cluster in the shade than out in the sun, as we had to do before you raised our hive."

Yes, I found about the same amount of bees hanging below the frames that there was clustered out on the hive the day before it was raised; and while thus looking at them and talking with them about Mr. Pettit's system, those from the field kept coming in right over my head. So I watcht to see them pass up at the "sides and rear end of the hive," as all

good bees should do when this system is used, but four-fifths of them did nothing of the kind. Just what they did do was to fly and alight right on the cluster hanging below the frames, or drop short of this cluster, when they would run till they reacht it, then climb up and into it, while only the few that happened to come close to the sides of the hive would run along there till they reacht the cluster. In no case did a single bee reach the "rear end" of the hive, for she could not do this except to crowd her way through 16 to 18 inches of clustered bees.

When we think of it, it seems very much more comfortable to the bees with these large entrances, but when we come to the practical part of the matter, it looks much as if we had the trouble and material for the wedges, for our thoughts and visions, with not a pound more honey.

The dividers I believe to be a good thing, that is, unless a few partly-filled sections, for "bait" sections the next year, are really of more value to us than to have all fully completed, as we are inclined to think is for "our best and highest good."

Onondaga Co., N. Y.

The Golden Method of Producing Comb Honey.

BY S. A. DEACON.

It goes without saying that altho an abundance of nectar-secreting flowers and strong colonies are the main requisites for securing a good honey harvest, unless these be supplemented by intelligent manipulation we can hardly expect to get the best results. And as we all know that (even as "trifles make the sum of human bliss") a few apparently very insignificant matters of detail in the management of colonies may favorably affect the "sum tottle" at the cessation of the flow, so we are not justified in lightly or contemptuously ignoring *any* suggestions calculated to work to the desired end which may, from time to time, be presented to our notice through the medium of these, or other bee-papers' columns; and the older and more experienced the propounder of any new suggestion, the more ready we should be to receive it with respect, and, analyzing it, endeavor to ascertain whether there may not perchance be something in it, or whether it be only fit to be past over with the laconic, and perhaps too frequently deserved comment—"only another fad!"

The foregoing rigmarole about represents the train of reflection that flitted through my cerebrum after reading (page 712, 1897) Mr. Hartzell's article on "Managing Swarms," in which he speaks very approvingly of the Golden method of producing comb honey, as set forth by Mr. Golden on pages 481 and 883 of 1896. I had read these articles cursorily at the time they appeared, but deeming the plan rather complex and fussy—incommensurately so with the probable extra gain—I past them out of mind; but Mr. Hartzell's commendatory statements thereon have caused me to go carefully over them again, with the result that, I cannot for the life of me see wherein Mr. Golden adduces the least proof of his system of management having any particular pull over the method or methods hitherto commonly adopted of returning swarms. Either Mr. Golden's style is not sufficiently explicit, or the obtuseness of my intellect makes me inaccessible to the obvious; and so, like the woman mentioned by Dr. Brown, who preferred the old-time process of getting babies to any new-fangled plan, Mr. Golden will need to adduce far more perspicuous proof of the superiority of his method ere I, with my limited intelligence, can see my way to admitting a preference for it over the old style of doing things.

Neither he nor Mr. Hartzell, as far as I can see, make any comparison between swarms treated on the Golden plan and by any of the older or ordinary methods; they only contrast the results of the swarmed colonies treated by Mr. Golden's method with such as did *not* swarm. All they have seemingly attempted to prove, and of which every bee-keeper is well aware, is, that a swarmed colony, intelligently managed, can be made to produce more honey than a colony which has *not* swarmed; but nothing which either of these gentlemen have stated tends to prove that Mr. Golden's method of manipulation is superior to that generally in use under the same condition of things. Perhaps a further article from Mr. Golden's, or from Mr. Hartzell's, pen on this decidedly interesting matter may help to dispel the fog, and "make me sensible," as Paddy says, and enable me to see that there's more in it than I have so far been able to discover.

The way the matter presents itself to my sensorium is as follows: Mr. Golden claims that by hiving a swarm on his system, viz.: in a super of sections placed under the brood-chamber, he gets these sections rapidly filled with honey, and which would, he asserts, under the old order of management, "have gone into the brood-combs." Surely not, if the swarm

were hived on starters, and the supers put where their name plainly indicates they *should* be put—a top, he would then have had the same results, or I am greatly mistaken.

I have never tried Mr. Golden's plan, for the reason that I feel thoroughly convinced that were I to do so the result *with me* would be about as much pollen in the sections as honey. How Mr. Golden manages to keep pollen out of his sections is "a huckleberry quite beyond my persimmon;" I am sure I could not do it, nor will I attempt to guess how he does it. I am sorry he is so reserved on this rather important point.

Mr. Golden's plan, we are seemingly told, can only be adopted provided a colony swarms. But why not treat *every* colony in the same way, swarm or no swarm? All one would suppose to be necessary would be to cage the queen among the sections, as directed, and put the super underneath the brood body. But the pollen, Mr. Golden—pray what about the pollen? Will the bees go upstairs with that while leaving the honey down below?

Mr. Golden's statement that colonies manipulated by his method averaged 119 pounds as against 53 pounds obtained from those which *did not swarm*, furnishes no proof, that I can see, of the superiority of his system of returning and treating swarms over those long in vogue. I, for one, would esteem it a favor if Mr. Golden would kindly furnish us with comparisons between returned swarms managed by his method and a like number treated in the old way, setting forth clearly and seriatim each and every detail and operation, and not omitting to state how he overcomes the difficulty of the pollen; and if he succeeds in convincing me of the superiority of his plan I shall not hesitate to adopt it (if ever a honey-flow *should* by chance come my way—a thing I have not seen for the past four years!) and that with a feeling of gratitude towards its originator.

At the same time let me tell Mr. Golden right here that tho I may be induced upon clearer proof of its superiority than has been so far advanced to adopt his swarm-returning plan, I'll see him hang—I mean bothered, before I'll have any truck with that fussy old feeding arrangement of his; for I consider that my simple "Rapid Drawer Feeder" beats his all to fits—knocks it clean into a cockt hat! I hope he will try it and be convinced.

But as I am getting into "the sere and yellow"—verging on three score—and Mr. Golden's "picter" doesn't show that he can give me any points in this respect, I think it is time we old boys gave our inventive faculties a rest, and let the youngsters run the "Advance" department of the Show; and when I am afraid, will only be poking fun at us old fogies, and at what they will conceitedly call our "funny fads;" and, what with my chest of drawers in the basement, Mr. Golden's topsy-turvy ideas, so alarmingly subversive of the old order of things, they will be setting us down as getting doty. Well, it's a perplexing, bewildering, intellect-confusing pursuit, calculated to drive any one embarking in it crazy, and I am seriously thinking of leaving the bees to their own rude, primitive and senseless devices, and let 'em see how they get on, relinquishing all further attempts to reform them, and going on with that nap where Mr. Bevins' left off!

South Africa.

The Power of Association or Combination.

BY HON. EUGENE SECOR.

It ought not to be necessary, at this late date in the nineteenth century, to offer an extended argument to prove the power and value of organized effort.

There was a time in the history of mankind when the individual seemed to be a more potent factor in society and business than at present. There was a time when every man builded his own home and defended it by his own right arm. There was a time when every successful enterprise was projected and carried to completion by personal enterprise, personal valor, or personal wealth.

Even after tribal relations had been established and tribal protection guaranteed, success depended almost entirely on individual exertion. Cities were built, large mechanical transactions attempted, and cattle ranches established all without syndicates.

But the world is a little older than it was. Society has changed in some respects. Almost everything is done differently from what it used to be. Now, instead of every man being his own banker, and carrying his money in the sack when he goes down to Egypt to buy corn, he writes his check on New York or London. Business methods have so improved that a dollar goes farther in transacting the world's business than it did in the old time. This has been brought about

through organization and combination. A great many individual dollars brought together through associated effort may be made to produce effects which never could have been brought about by the same individuals acting each for himself and independently.

Organization has become the great fact of the age. No railroads are built by individual capital. No steamship lines are owned and controlled by one man. Great commercial enterprises are launched and sustained by combined capital and organized effort. Corporations have taken the place of the once single-handed manufacturer until it is hardly possible for one man, without capital, to compete with corporate wealth.

Since the business of the world is largely done by great corporations, the trade guilds have been a natural outgrowth, because the only way to meet organization is by counter organization. Men lay their heads together, form alliances for mutual protection, and thereby gain strength impossible to the single worker.

Men interested in a common purpose are enabled to unite on a common plan of action, and work to some effect. For instance, it is too large a job for one bee-keeper to attempt to fight adulteration of honey, but if he can combine his efforts with that of ten thousand other bee-keepers, all acting in unison, and that organization acting with other associations interested in the subject of pure food, together they may accomplish something.

As government in this country is constituted, the powers that be are ready to listen to any one who represents a considerable body of voters, if the said voters "mean business."

When a politician is asked to support a measure, he wants to know how many of his constituents are anxious about it.

All other trades and professions are organized for mutual help and protection. Bee-keepers should have one organization so strong in numbers and influence that their rights shall be respected. The object of the United States Bee-Keepers' Union is to fill this long-felt want. Its purpose is two-fold—to promote legislation helpful to bee-keepers, and to act as the guardian of their legal rights.—American Bee-Keeper.

Suggestions on Apiarian Exhibits at State Fairs.

BY W. Z. HUTCHINSON.

For at least a dozen years I have been making exhibitions of bees and honey at my own State Fairs, and this year (1897) I exhibited bees and honey at five State Fairs. It is from this experience that I wish to criticize some of the premium lists and to make some suggestions.

Perhaps I cannot begin better than by giving such a premium list as I would approve, and then proceeding to compare it with the lists of some of the State Fairs, and show *why* I would make the changes suggested:

| | 1st. | 2nd. |
|---|------|------|
| Single-comb nucleus Italian bees..... | \$10 | \$5 |
| Single-comb nucleus black bees..... | 10 | 5 |
| Single-comb nucleus Carniolan bees..... | 10 | 5 |
| Sweepstakes on bees, greatest number of different races of bees, in single-comb nuclei..... | 10 | 5 |
| Comb honey, most attractive display of 250 pounds, no more and no less..... | 25 | 15 |
| Sample case of comb honey, not less than 10 pounds, quality and manner of putting up for market considered..... | 5 | 3 |
| Extracted honey, most attractive display of 250 pounds, no more and no less..... | 20 | 10 |
| Specimen of extracted honey, not less than 10 pounds, quality and manner of putting up for market considered..... | 5 | 3 |
| Beeswax, most attractive display of 10 pounds, no more and no less, bright yellow wax to have preference..... | 10 | 5 |
| Largest and most attractive display of honey-producing plants, prest and mounted..... | 15 | 8 |
| Largest and best display of apiarian implements..... | 15 | 8 |
| Sweepstakes, the largest, best, most interesting and instructive exhibit, all things considered..... | 25 | 10 |

The foregoing foots up \$242, and it could be adopted by any Fair association by simply changing the amounts of the premiums, keeping the proportions between the sums the same.

I will now proceed with my criticisms, keeping in mind the fact that the object of a Fair is to encourage, stimulate and educate.

Turning to the premium list of the New York State Fair, I find that premiums are offered on the same kinds of bees as are mentioned in the foregoing list, but, while it says "in observatory hives," it does not specify that they shall be "single-comb hives," and the premiums are not liberal.

When I first began exhibiting bees they were always

shown as full colonies, and "numerical strength" was made one of the competing points. A populous colony bears confinement very poorly—practically it is ruined by the confinement of a week or ten days. The bees are quite likely to smother, and the combs to melt down from the heat. Beside this, a full colony does not really show so much as can be seen in a single-comb nucleus. The brood and queen are always in the center of the colony where they are out of sight. How often at Fairs we hear the expression, "I would like to see a queen-bee! I have never seen one, and I would be obliged if you would point her out to me." With a single comb this can always be done, as the queen can be found upon one side or the other. The few bees bear confinement very well, especially if they are young bees and given abundant room. There is nothing about an apiarian exhibit that attracts attention quicker than bees under glass. People will exclaim, "Oh, see the bees!"—and then rush up, and then rush off after others to bring them up. Bees always draw a crowd, and this allows the exhibitor to explain to an interested audience the wonders of bee-keeping, and the healthfulness and value of honey as a food.

Taking bees to a Fair is risky, laborious and expensive; they are something that requires much care in handling and in looking after, and for this reason the premiums ought to be liberal. I do not approve of offering premiums upon all of the different varieties of bees, as there are some varieties that are of no great value in this country, and in regard to which there are many different opinions. The three varieties mentioned might be called the standard varieties, and are recognized as such. If exhibitors have other varieties and wish to exhibit them, the "sweepstakes" offer will cover such displays.

In one respect the New York premium list is ahead of any list I have seen. In both comb and extracted honey, it specifies the *quantity* of honey that shall be shown. I have only one criticism to make. It says "best display." I would say "the most attractive display." Perhaps this is hypercritical, but there cannot be too much attention given to the wording of the list—have it so worded that it is *impossible* to be misunderstood.

The matter of quantity ought to be explicitly mentioned. The Indiana list simply says, "Comb honey, quality and manner of putting up for market to be considered." Not one word about the quantity. Had it said the "most attractive display" that would have been better, as quantity might have been considered *one* factor in attractiveness. As it was, one exhibitor went to the trouble to build up a pyramid of honey that reached to the roof, assuming that, if the honey was all equally good so far as "quality and manner of putting up for market was considered," the largest quantity would carry off the palm. The judge decided solely upon "quality and manner of putting up for market," in both comb and extracted honey, quantity cutting no figure whatever.

Hitherto, most of the premium lists have offered premiums for "the best display" of comb honey. Lately some of them have changed it to read the "most attractive." These offers are pretty good, but the objection is that the first prize usually goes to the largest display. Of course, size is *one* attraction, but it is not the only one by any means. As it is, most of the exhibitors bring in their honey in the regular shipping-cases and stack it up, and the largest pile gets the first premium. There is not much encouragement to make the exhibit attractive in other ways, such as by arrangement or ornamentation. This is why I recommend most heartily the New York premium list in this respect. It limits the quantity to 250 pounds, it must be that much, no more and no less. Now then, the exhibitor who can put up that amount of honey in the most attractive shape will win the prize.

There is a premium offered on tasteful arrangement and skillful display rather than upon quantity; 250 pounds of honey is really enough, if properly displayed; when we have seen that much, it is no great sight to see twice as much. Comb honey is fragile stuff, and the carting around of large quantities of it, and paying freight upon it, when better ends can be gained by working on different lines, is unwise. As there is a greater risk and expense in shipping and exhibiting comb honey than is the case with extracted, the premiums should be greater on the comb honey. Aside from the premium on the most attractive display, there ought to be a premium on a small quantity, so small that it can be furnished by *any* bee-keeper, and the offer should be for the best honey, that is, for "quality and manner of putting up for market."

Referring again to the matter of bees, I see that some of the Fair associations still offer premiums upon queen-bees caged. There is no place in which a queen can be shown to so good an advantage as in a single-comb nucleus, and the only judgment that can be pronounced upon a queen is that

made by looking at her workers. I have reference to purity of race, and that is the only point that can be decided at a Fair. Queens kept in cages in the cool weather that frequently comes during the fall are often chilled and die.

At the Illinois State Fair last year there was a premium offered on caged queens, and one of the competing points was that of quantity. The nights were cool, and one exhibitor lost nearly 20 queens (worth twice the premium offered). Another had 28 queens on exhibition. He took great pains to keep them as warm as he could nights, but many of them were worthless at the end of the Fair. The first premium was only \$10, and the exhibitor who won it had on exhibition 35 queens, and lost probably half of them after the Fair was over. Queen-bees ought to have no place on a premium list. The place for them to be shown is in the single-comb nuclei, where they can be kept warm and cared for.

There is one other premium that ought never be offered, and that is for the greatest number of samples of different kinds of honey. This offer would be all right if all men were honest, but, unfortunately, they are not, and the "manufacture" of different samples by mixing is so easy and so difficult of detection that many cannot withstand the temptation. There ought to be *nothing* for which the judge must take the exhibitor's word. Some lists contain such provisos as the following: "Honey must be of the present year's crop," "Must be the product of the exhibitor," etc. Such things are foolish, as there is no way of proving that they are lived up to.

While I am discussing the things that ought to be left out of a list, I may mention the offering of a premium on "honey extracted on the grounds;" also "comb foundation made on the grounds." These offers came about in this way: The managers of Fairs have about discontinued the offer of premiums on all kinds of implements and machines. When bee-keepers could no longer get a premium on a honey-extractor, they induced the managers to offer one on "honey extracted on the grounds," thus bringing in the honey-extractor. But this is no premium on the extractor, as the honey shows no characteristic of the machine that is used. It has been urged that the use of the machine on the grounds educates the public. As a rule, not two dozen people will see this operation—often it is done toward night, when the crowd is off out of the way. It is a mussy, disagreeable task when attempted away from the accessories of the honey-house.

The same objections apply to the manufacture of comb foundation on the grounds, with the exception that in this case the foundation *might* show the superiority of the machine in a slight degree, but it might also be a greater indication of the skill of the operator. I don't wonder that the managers have discontinued the offering of premiums on implements and machinery—that is, in the way of pitting one implement against another, as each implement is usually exhibited by the manufacturer or his agent, and the awarding of the premiums is very difficult, and the awards unsatisfactory. But there are premiums offered at many Fairs for the best display of furniture, clothing, musical merchandise, stoves, etc., and in this sense there might be a premium offered for the best display of apiarian implements that would bring no unpleasantness. The display of implements is of interest to bee-keepers, and aids them in giving information to the general public.

The display of honey-producing plants makes one of the most handsome backgrounds that can be used in connection with an apiarian exhibition, and interests and instructs the public.

A general sweepstake premium for the largest and best exhibition is a powerful incentive to the making of a large and attractive exhibition, and ought not to be omitted. Diplomas are "no good."

In all of the other departments of the different premium lists there is something approaching uniformity—that is, the horse department of the Michigan premium list does not differ materially from that department in the premium lists of other Fairs, and there is no reason why the same uniformity might not exist in the apiarian department of the different lists. I shall send a copy of this paper to the secretaries of the different Fairs, and to the premium-list committees when I can learn of them; also to those bee-keepers in each State who are interested and attend their State conventions. There is probably not a State Fair association that would not adopt the premium list recommended by their State association of bee-keepers. The managers have no interest in the matter except to please the bee-keepers; that is, if there is a give sum that can be used in the bee-keepers' department, the managers are perfectly willing that the bee-keepers shall make up their own list.—Country Gentleman.

Genesee Co., Mich.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, MARENGO, ILL.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Using Two-Story Brood-Chambers.

You advise for comb honey two-story S-frame dovetailed hives, or 16 frames, until the time to put on supers, then one story is to be taken off, reducing them to one story or eight frames. My experience is that in this locality the honey harvest opens and supers are to be put on somewhere near May 15; and up to that time the queen never occupies or fills more than eight frames with brood. In that case I should think it would not be necessary or practicable to put on the second story. Am I correct, or not? INDIANA.

ANSWER.—I don't know. If a single story gives all the room the queen will occupy, and if no more room is needed, then there can hardly be any advantage in giving a second story. But you can hardly be very sure about this if you've never tried it. Are you sure none of your queens will occupy more than eight frames if they have a chance? I think you'll find it true that, as a rule, bees don't like to use either of the two outside combs for brood, using them only for honey and pollen. If you find brood in either of the outside combs (and you may find it in both) you may feel pretty sure that they are somewhat crowded for brood-room; and if you find eight combs occupied with brood in an S-frame hive, the probability is that more than eight combs would be used if the bees had two stories. Keep a strong colony in one story of eight frames and it will have brood in not more than eight frames, if indeed it has more than six, whereas the same colony in two stories may have 9 to 14 frames with brood. Some colonies don't need the second story; some do. If you practice using two stories, you'll find a good many more of your colonies needing them than if you kept all of them constantly confined to one story. That is, by giving always all the room needed, you'll have stronger colonies.

A Quintet of Questions.

1. Do the bees store as much honey in the sections where only 21 are put on a hive as where there are 32?
2. Dr. Gallup told in this Journal of a man who made 108 colonies of bees out of one in two seasons. How did he get enough queens? and how did he get the colonies strong enough for winter?
3. How long should a good queen-cell be? Are natural queen-cells better than others?
4. Can you give me the address of a few bee-keepers that use the Quinby closed-end-frame hive, as shown in Beuton's book on bee-keeping? Are they better for wintering than the loose-frame hives?
5. Do Doolittle and Gallup answer questions in the American Bee Journal? WISCONSIN.

ANSWERS.—1. That depends somewhat upon how the matter is managed. If you put on one super at a time, and wait till all the sections are sealed before giving a second super, you'll probably get quite a little more honey by using the larger supers. If you use better management, and give room as fast as needed, never allowing the bees to be crowded for super room, you'll probably find no difference.

2. I don't know the particulars of the case, but he could follow the nucleus plan, rearing a queen in the nucleus, and then building up the nucleus. With a sufficiently long and good honey season, there would be no trouble in having the colonies stored for winter, the latest formed receiving aid from the earlier ones. Feeding might also be resorted to.

3. Perhaps something like $1\frac{1}{4}$ or $1\frac{1}{2}$ inches. But there are so many exceptions to the rule that it makes the rule of little account. Sometimes a cell two inches long will be a very poor affair, and sometimes a good queen will come out of a cell that hardly shows above the surface of the comb. So far as you can judge from appearances, the length of a cell is hardly so important as its appearance otherwise. A cell that is deeply pitted is more likely to be good than one that is smooth. That is true in the case of cells reared for natural swarming. If you take away the queen, and a cell is reared right in the middle of a comb with brood in every cell about it, the cell

may be perfectly smooth and of so little prominence as not to be noticed at a careless glance, and yet it may produce an excellent queen.

The average natural queen-cell is better than the average cell reared when the bees had no previous thought of swarming or superseding. For in making up the average, you must take into account a lot of very poor cells reared in weak and dispirited nuclei. Rightly managed, however, and reared in a strong colony—at least left in a strong colony till sealed—a cell reared artificially may be as good as the very best.

4. I'm not entirely sure of the address of a single bee-keeper who uses that frame, for altho many Quinby frames are used, I don't know which are closed-end. If any of the fraternity who use this particular kind of frame care to answer any questions that may be asked about them, perhaps they will make it known. As a rule, there is no other class of men more willing to divide their knowledge. Closed-end frames ought to be warmer for winter than others.

5. All the answers that appear in this particular department are written by the same person. When a question comes in, it goes into the general hopper, and is answered in this department. But both of the gentlemen named have answered many questions in this paper, and probably would do so at any time if so requested.

Honey in Mason Jars—Smothered Colony.

1. I have some extracted honey in Mason fruit jars. Would you advise one to put the covers on tight, the same as when canning fruit? About $\frac{2}{3}$ of it was unsealed when extracted. It is not for sale, but for my own use.

2. I was obliged to move a colony that was queenless, but had some sealed queen-cells. In the morning I stopt the entrance with wire-cloth before moving it, and at night on removing the cloth I found most of the bees smothered, and the two outside combs (heavy with honey) a little broken down, and some melted. The bees had turned almost black, and most of the brood was dead. What would you do with the combs having the dead brood?

For information, I would say that I found enough live bees to form a nucleus, and to sting (in fact, the sharpest and worst-feeling sting I ever received). I gave them some eggs from another colony in case the queen-cells did not hatch out, all in the same hive, and smoked them in after cleaning it out. I also extracted the two broken combs and have the honey in a jar by itself to find out how it acts. OREGON.

ANSWERS.—1. If you heat the honey as in putting up fruit, then seal it up tight, it is said to keep well and not granulate. But it's rather a dangerous thing to heat honey, for if you run it above 160° you are likely to darken it and hurt the flavor. If you leave the covers loose or entirely off, so as to give chance for evaporation, and then keep it in an airy place, a place where salt will keep dry, you will find it will keep well, altho it may granulate.

2. I would give the combs of dead brood to other colonies to clean up and take care of. It's only fair to say that some good authorities say there is danger of foul brood from rotting brood. I agree with those who think that if there is no foul brood present in any other hive you can't start foul brood without the seeds of foul brood, but knowing the two views you can act on your own judgment. If you are afraid the decayed brood will start foul brood, by all means burn it up. But if it was in my own apiary, I would give it to a strong colony, or to more than one colony.

You will very likely find that the honey extracted is not different from other honey.

Bee-Range, Shading Hives, Etc.

Being a new subscriber, I am not aware that the question of bee-range has been discussed before. Now that nectar is none too plentiful, the question of how far bees will range in search of food, might be taken up with profit. Also, the most improved manner of shading hives, which may be termed a burning question. ILLINOIS.

ANSWER.—At different times the question has been asked, "If I can have only one, shall I get a bee-paper or a bee-book?" I'm not sure but I have said a paper first, or at least have put them on equal footing. I wouldn't answer that way now. I'm older, and know more. By all means get the bee-book first. There are certain points that every bee-keeper—every beginner in bee-keeping—will need to know, and that he will be likely to want to ask about. These points are pretty well known to every experienced bee-keeper, and the text-

books take them up and answer them, in most cases more fully than they can be answered in a department like this. It is much better for the beginner to have all these questions answered in bulk in a book, available at any time, and more easily referred to than if scattered in the pages of a bee-paper, and after you've well mastered the contents of any or all of the best text-books, you will still find plenty of things to ask about.

The matter of the distance bees will go for stores has been very thoroughly discust, and it would be space wasted to have much room taken up with its discussion; but that you may not have to wait till you get your bee-book, I'll say that there are some differences of opinion as to the distance bees will go to gather stores. Some think that bees will go from choice three miles or more. Some think they do not often go more than $1\frac{1}{2}$ or two miles. There are cases on record in which bees have been known to go seven miles under favorable circumstances. So you see there is some chance for difference of opinion, and while the matter has been fully discust in the past, it is quite possible you may get some new light, and any facts that may come to your knowledge as helping to settle the question will be gladly welcomed. If you consult the actual practice of those who have out-apiaries, you will probably find that they are pretty well content to have their apiaries three or four miles apart, in which case they seem to think that bees do not work generally much more than two or three miles from their hives.

Looking at a text-book, I find that the question of shade and ventilation (it's hardly a "burning question," rather a cooling one), occupies as much as perhaps two pages like this. I may say in a nutshell that if you have trees for shade, you have the very best kind. If you have no trees, and must have shade without time to grow anything, one of the ways is to have any kind of a covering of boards with a space between the covering and the cover of the hive, and a big stone or something else by way of anchorage. An easy way, if tall grass is easily obtainable, is to put on top of a hive an armfull of green-cut slough grass or other tall-growing grass, and lay upon it two or three sticks of fire-wood. It dries to its place nicely, and will last throughout the season.

Use of Acid in Rendering Wax.

1. What kind of acid is sometimes used in rendering wax, and what is the process?
2. Is wax rendered with acid just as good for foundation-making?
3. Can acid be used to any advantage on residue from rendering old combs in a sun extractor?
4. Can any more wax be obtained from such combs by the use of acid? ARKANSAS.

ANSWERS.—1. Sulphuric acid is the kind used. I have no practical knowledge of the process, having never used acid in that way, but I believe the plan is to mix the acid with the wax while hot.

2. There seems to be a difference of opinion. Probably the wax does not have quite so much of its peculiar, agreeable odor after being subjected to the acid.

3. Yes, it is on that sort that it is used to the best advantage.

4. Yes, if I am not mistaken, you can get wax from remains that otherwise would be thrown away.

Keeping Down Increase.

If I do not desire any more increase of my apiary, and my bees are swarming, is it not a good way to prevent increase of colonies by returning the swarm to the old hive, provided I take all frames with sealed brood out of it, and divide this among weak colonies in the apiary, and give the new swarm empty combs or frames with full foundation? My idea is that I could leave the old queen with it, or if I do not want her, kill her, and leave one old comb with one or two sealed queen-cells in it. Of course, when I give the old combs with sealed brood to other colonies, I brush off all the bees to the old stand. What do you think about it? LOUISIANA.

ANSWER—Your plan will work all right. Leave the old queen with the colony, and you have the same as any natural swarm, with the added advantage that it is considerably stronger than when managed the usual way. You will hardly be so well satisfied with leaving them a comb with queen-cells. If you leave more than one cell they may trouble you with swarming. If you leave only one, that one may not be the very best one, and there is more possibility of its entire failure

than where the bees have several to choose from. Moreover, if there is only a queen-cell left, it will be, perhaps, two or three weeks longer before young workers will be emerging, than if you had left the old queen. Your colony will be badly depleted before recruits come on the field of action.

Uniting Colonies.

How would you unite two colonies without their fighting? I tried it and did not succeed very well, as they did a great deal of fighting. PENNSYLVANIA.

ANSWER.—There isn't room in this department to give all that should be known and is given in the text-books. In general, it may be said that much depends upon the condition of the bees, pasturage, etc. If one of the colonies to be united has its queen removed a day or more before uniting, there will be less trouble. Bees unite more peaceably at a time when pasturage is plentiful. If you shake all the bees off the combs, letting them run into an empty hive thoroughly mixt up, and afterward give them their combs, there will be little trouble. If you alternate the frames, putting into an empty hive a comb from one of the hives with its adhering bees, then a comb with its bees from the other hive, thus alternating throughout, there will generally be no trouble. If the colonies are so small that one of them can be put in one side of a hive and the other in the other side, with an empty comb between, they will generally unite peaceably.

Bees and Horticulture.—G. Kimbrell planted muskmelons close to his bees, and also $\frac{1}{4}$ mile distant, surrounded by timber, where no bee was ever seen to visit them. They grew alike, bloomed alike, but the vines near the bees set four melons to every one on the other vines.—Busy Bee.

Removing Honey from Hives.—Don't use much smoke in this process, as honey often has a slight, smoky tinge from injudicious smoking, says C. P. Dadant, in Busy Bee. An escape is a good thing, either for comb or extracted honey, but if the weather is very hot the combs may break down for lack of free ventilation if an escape is used.

Space Between Two Surfaces of Sealed Honey is a matter of dispute between J. E. Craue and the editor of Gleanings. The latter says he measured a number of lots coming from different parts of the country, and nine out of ten of the spaces would measure $\frac{1}{4}$ -inch. Some went $1/64$ under, some $1/16$ over. Mr. Crane found the spaces varying from $3/16$ to $1/4$, the average being somewhere from $20/96$ to $21/96$. Mr. Root thinks it may be that blacks make closer spacing, as Mr. Crane's honey was from blacks.

Specific Gravity of Different Honeys.—R. Wilkin had a glass tumbler $\frac{1}{4}$ full of white honey. He filled it with dark amber sun-extracted honey. In a few hours the white honey was on top. Then he filled the tumbler $\frac{1}{4}$ full of white honey, and put two tablespoonfuls of dark on top. The next morning the dark was in a distinct stratum at the bottom. He suggests having 12 pounds of honey specially colored, then a small quantity, by staying on top or sinking to the bottom, would show whether a lot of honey was above or below the 12-pound mark.—Gleanings.

Some Bee-Lore.—Editor Abbott quotes a paragraph from the Youth's Instructor, but some remarks he makes rather imply that he does not fully endorse it. The paragraph is as follows:

"After a time the grubs shut in the big cells turn into queen-bees, and they begin to sing a song. The queen-bee hears it, and she knows that more queen-bees will come out. That makes her angry. She runs at the cells to try to kill the new queens. The workers prevent her. But there can be only one queen in a hive at a time. So the old queen says, 'Come! I will go away!' Many of the old bees say, 'We will go with our queen.' Then with her they seek a new home."

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of beekeepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 38. AUGUST 4, 1898. NO. 31.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Langstroth Monument Fund is again brought up in Gleanings for July 15. It seems very strange that all the bee-keepers in America are unable to get together even \$200 for the purchase of a monument for Father Langstroth. Only about \$100 is now in sight for the purpose. We were hoping that by next fall the monument might be bought and erected.

Mr. P. H. Elwood, one of New York's greatest bee-keepers, says that he has just been buying a family monument for \$100, and thinks it good enough. Editor E. R. Root says that his idea is about a \$200 one for Langstroth. Well, suppose we all call it \$200, then, and go to work now in good earnest and raise the balance of about \$100 during the month of August. It can be done in one month just as well as in two years if bee-keepers will only think so.

Why not have four or five hundred 25 or 50 cent subscriptions right away? Send them in to us, if you prefer, and we will publish the list of names of contributors, and forward the money to the proper place.

Rough on Chicago Honey.—Mr. Stephen J. Harmeling, of South Dakota, recently had an article in the Northwestern Agriculturist, on "South Dakota as a Bee-Country," in which we find this paragraph:

"The home market for honey is good. There is no trouble in getting 12 to 15 cents for extracted. The flavor of Dakota honey is superior. That of wild mustard is delicious. Chicago has sent too much 'Rose Honey' and 'Bumble-Bee Honey' into these markets. Chicago is really the meanest hole of a city on the face of the earth. We expect all that comes from Chicago to be adulterated. It is so notorious here that people who have ever tasted real honey can notice something wrong,

and now they suspect everything that comes from the East, and will pay a good price for the home product, which they know to be pure."

We have shipped honey into South Dakota, and never sent any that was impure. There is plenty of pure honey in Chicago, or else the bee-keepers themselves are rank adulterators. And that we don't believe. The idea of any one saying that South Dakota people "expect all that comes from Chicago to be adulterated!" We don't swallow that at all. Any one with just ordinary sense ought to know that there is plenty of pure honey sent to Chicago—both comb and extracted—and that that same honey is often reshipped to purchasers in other parts of the country.

Goodness knows Chicago is not very Heavenly in many things, but we know there are lots of good people here, and pure honey, too. Mr. Harmeling will only harm himself by writing in the style indicated by the above quoted paragraph.

Organization for properly conducted self-defense seems to be necessary everywhere. The latest thing of the kind occurred among the daily papers of Chicago. At a time when every one was eager for war news, and immense numbers of papers were sold, the Stereotypers' Union made a peremptory demand for a very material increase of pay under threat that no papers could be issued unless their demands were granted. The dailies saw they were in a tight place, but concluded to meet organization with organization, deeming the demands entirely unwarranted, and entered into an organization agreeing to stand by each other. The great reading public were greatly surprised to receive no papers for a few days, then a small-sized paper rapidly increasing to its normal size, and the supposition is that the Stereotypers' Union has been left out in the cold.

If bee-keepers would have their rights defended, they, too, must organize.

Convention at Omaha, Sept. 13-15.—Finally the date of holding the next annual meeting of the United States Bee-keepers' Union has been fixed for Sept. 13, 14 and 15. The place—Omaha—was decided upon several weeks ago. Here is a notice from Secretary Mason:

STA. B, TOLEDO, OHIO, July 23, 1898.

EDITOR AMERICAN BEE JOURNAL:—I have just received from Mr. Whitcomb the following letter in regard to rates, etc., for the convention of the United States Bee-keepers' Union, which will explain itself:

OMAHA, NEBR., July 18, 1898.

MR. E. WHITCOMB—Dear Sir: Confirming our talk this afternoon, I wish to advise that the Western Passenger Association has put in a rate for the Annual National Encampment Sons of Veterans United States of America, Sept. 12 to 16, as follows:

One lowest first-class normal tariff fare for the round-trip, plus \$2.00, from Western Passenger Association territory, east of and including Utah, except that from points within a radius of 150 miles of Omaha rate of one fare for the round-trip will apply.

The following rates apply from the extreme terminals on the east: Chicago, \$14.75, Peoria, \$13.25, and St. Louis, \$13.50. Tickets on sale Sept. 10 and 11, and from points west of Colorado and Wyoming State lines, Sept. 9. From points within a radius of 150 miles of Omaha, Sept. 12. Tickets good to return Sept. 21.

We will endeavor to have these rates extended to cover all the United States, and would suggest that it would be a very good rate for the bee-keepers' meeting.

Yours truly,

W. N. BABCOCK,
Manager Department of Transportation.

It will be seen that the above rates are lower than those given in my previous notice of rates. Mr. Whitcomb writes:

"The above rate is the best in sight. . . . Hotel rates and place of meeting will be arranged a little later on, but it is thought that the members can be quartered in private families at \$1.00 per day, and that hotel rates can be secured at about \$2.00 per day."

This allows the Executive Committee to fix on Sept. 13,

14 and 15 as the time for holding the convention, commencing on the 13th at 10 o'clock in the forenoon, and closing the evening of the 15th.

The program for the convention is not yet quite completed, and will not be in time to be put in the monthly bee-papers before September, but will be in the American Bee Journal and Gleanings by Aug. 15. The program will be similar to the one prepared for the Buffalo convention last year, containing bee-keepers' music, and the first page of the cover will be occupied by an illustration containing the photographs of the Board of Directors and Executive Committee, with an appropriate background. Any one desiring one or more copies of the program can obtain the same by sending five cents in stamps to the Secretary, for each copy wanted.

If the place of meeting, hotel rates, etc., are not given in the bee-papers in time, those attending the convention will find a printed notice posted in each railroad depot in Omaha, on the days of the meeting.

Any one not a member of the United States Bee-Keepers' Union may become such by sending a dollar to the Secretary, or General Manager Secor, or the editor of any of the bee-papers. Don't send a dollar bill unless in a registered letter; and if you remit to me by post-office money order, have it drawn on Sta. B, Toledo, Ohio.

A. B. MASON, *Secretary.*

Now that the date of the convention is settled, everybody can begin to make plans for being present.

Remember the *date*—Sept. 13 to 15. And the *place*—Omaha, Nebr.

LATER.—Since the foregoing was put in type we have received the following letter that Mr. Whitcomb sent to Dr. Mason:

OMAHA, NEBR., July 22, 1898.

FRIEND MASON:—The Delone Hotel, corner of 14th street and Capitol avenue, is where the convention will be held, and which will also be the headquarters of the Union. Rates for rooms, on the European plan, \$1.00 a day; board \$1.00 a day. No one will be asked to double up, but each person will be given a bed, and be taken care of at this rate as long as there is a room in the house, even if it takes rooms that cost \$4.00 a day.

In order to reach the hotel from the Union Depot, take the Dodge street car and transfer at 14th street for the Sherman avenue line; 5 cents pays the entire bill for carfare.

Those who desire to take rooms and secure meals outside will be at liberty to do so. Rates for meals at restaurants and chop-houses from 10 to 50 cents.

The limit of tickets will give 10 days in which to see the Exposition and attend the meeting. E. WHITCOMB.

Getting New Subscribers.—Many of our regular subscribers have done good work in getting new subscribers for the American Bee Journal. We appreciate their efforts, and thank them besides sending them the premiums we have offered and they have earned.

But we want 1,000 more new subscribers by October 1—during August and September. That ought not to be a hard job when you consider the premiums we offer regular subscribers, on page 490, for the work of getting the new ones.

We are beginning all new subscriptions with July 1, as we have plenty of back numbers since that date, and as we want all the new readers to have a complete set of Mr. White's nine articles on "Profitable Bee-Keeping."

Perhaps some of our present subscribers would prefer to pay their own subscriptions instead of taking premiums for sending new subscribers. Well, we can accommodate them all right. Send us three new subscribers for a year, at \$1.00 each, or seven new subscribers for the last six months of 1898, at 40 cents each, and we will credit your subscription for one year; or send us four new six-months' subscriptions at 40 cents each, and we will credit your own subscription for six months.

Now it seems that with all the offers we are making in various places in this number of the Bee Journal, the 1,000 new subscribers ought to come very easily in the next two months.

EDITOR HUTCHINSON, of the Bee-Keepers' Review, in Genesee Co., Mich., reports the best honey-flow in years in his locality.

MR. J. W. KUHN, of Republic Co., Kan., has sent us a copy of his very neat catalog for 1898, offering improved golden Italian queens and bees for sale.

THIS INTERESTING (?) EDITORIAL paragraph we find in one of our apiarian exchanges:

"We are now out of Mason's fruit-jars, and as the price is nearly double what it was formerly, we will not purchase any more until they are lower."

MR. S. A. NIVER, of Tompkins Co., N. Y., writing us July 2, said:

"Clover was fine in looks, but yielded no honey. Basswood bloomed in great shape, but gives up but little surplus. Five pounds surplus per colony would be about my estimate. Buckwheat is our old stand-by."

MR. A. I. ROOT, of Gleanings in Bee-Culture, called on us last Friday, when on his way to Yellowstone Park, and other places in the great Northwest. Mr. Root seemed well and cheerful, and spent the day riding all over Chicago on our bicycle. We were glad we could furnish the "horse" for him to ride and put in a pleasant day. He rides like a boy and appears to enjoy life hugely.

MR. J. T. CALVERT, of the A. I. Root Co., spent about a half day with us July 22. He had been making a several-days' tour among some of the supply dealers in Michigan and Wisconsin, and found that they, like his own firm, had passed through a very busy season. Mr. Calvert was looking well, and seemed to be ready for another grand rush in the bee-supply business. They are contemplating the making of extensive improvements and additions to their present capacity for turning out implements for bee-keepers.

MR. E. M. STORER, who has 200 colonies in the vicinity of the great Okefinokee swamp of Southern Georgia, writes that while he has considerable stock of extracted honey of this year's crop on hand in 60-pound cans and 500-pound barrels, destructive forest fires are responsible for a much shorter crop than would otherwise have been obtained. Our Southern friends seem to be "catching it" all around from fires this year. Our own apiary in South Florida has been no exception.—Editorial in American Bee-Keeper.

YE EDITOR spent two most enjoyable days at the home of Dr. C. C. Miller last week—Wednesday and Thursday. It was 90° above zero while there, but pleasant nevertheless, for that home is in a cool place—"set on a hill, and can't be hid"—and is very restful and refreshing. At least we found it so. Next week we hope to tell more about our visit to the "Medicine Man of the Marengoes." We returned just about an hour ago (Thursday evening, July 28), and will not have room in this week's number of the American Bee Journal to speak further of our trip.

THE A. I. ROOT CO. give a few statistics in Gleanings for July 15, as follows:

"In the year beginning July 1, 1897, and ending June 30, 1898, we have made about 16 million sections of all kinds and sizes, besides buying about four million from other manufacturers, and turning away orders for many more. Our output of Weed process foundation in the same time was 55 tons, while Chas. Dadant & Son made 33 tons, or 88 tons in all, or 176,000 pounds of Weed process foundation sold in the United States within the 12 months. Several tons of what we made was exported. Since we have been making fences we have turned out half a million of the various styles."

We will be glad to give statistics from our other advertisers if they will forward them to us for publication.

FOR THE READERS OF THE
AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest apiaries in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles :

- | | | |
|------------------------------|----------------|---------------|
| 1. General and Introductory. | 4. Swarming. | 7. Supering. |
| 2. Bees. | 5. Hives. | 8. Diseases. |
| 3. Handling Bees. | 6. Foundation. | 9. Wintering. |

This is a series of practical articles that bee-keepers of the United States will not want to miss reading. They will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents—
To a NEW Subscriber—thus making it

SIX MONTHS FOR ONLY FORTY CENTS—

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send:

For Sending ONE New 40-cent Subscriber:

- | | |
|---|---|
| 1 Wood Binder for a Year's Bee Journals | 10 Foul Brood—by Dr. Howard |
| 2 Queen-Clipping Device | 11 Silo and Silage—by Prof. Cook |
| 3 Handbook of Health—Dr. Foote | 12 Foul Brood Treatment—by Prof. Cheshire |
| 4 Poultry for Market—Fan Field | 13 Foul Brood—by A. R. Kohnke |
| 5 Turkeys for Market—Fan Field | 14 Muth's Practical Hints to Bee-keepers |
| 6 Our Poultry Doctor—Fan Field | 15 15 "Honey as Food" Pamphlets |
| 7 Capons and Caponizing—Field | 16 Rural Life |
| 8 Kendall's Horse-Book | |
| 9 Mullen's Horse-Book | |

For Sending TWO New 40-cent Subscribers:

- | | |
|---|---|
| 1 Potato Culture—by T. B. Terry | 7 Hutchinson's "Advanced Bee-Culture" |
| 2 Green's Four Books | 8 Dr. Brown's "Bee-Keeping for Beginners" |
| 3 Ropp's Commercial Calculator | 9 Blenck-Kultur—German |
| 4 Dr. Tinker's Bee-Keeping for Profit | 10 Bees and Honey—160 pages—by Newman |
| 5 40 "Honey as Food" Pamphlets | 11 People's Atlas of the World |
| 6 Winter Problem in Bee-Keeping—by Pierce | |

All New Subscriptions Begin July 1.

Please remember that all the above premiums are offered **only** to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Be It Known

To all Men, we are prepared
to fill orders promptly for

CHOICE QUEENS of the best
Golden or Leather-Colored Italians....

Tested \$1.00; Untested—one, 75c; three, \$1.50. After July 1, 50c each. Remit by Express Money Order, payable at Barnum, Wis. One and two-cent stamps taken. Address,

Van Allen & Williams,
25 Atf BARNUM, WIS.

Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases—everything used by bee-keepers. Orders filled promptly. Send for catalog. MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.

Please mention Bee Journal when writing.

**ONE MAN WITH THE
UNION COMBINATION
SAW**

Can do the work of four men using hand tools, in Rippling, Cutting-off, Milling, Rabbeting, Grooving, Gaining, Dadoing, Edging-up, Jointing Stuff, etc. Full Line of Foot and Hand Power Machinery Sold on Trial. Catalogue Free.

SENECA FALLS MFG. CO.,
46 Water St SENECA FALLS, N. Y.

Please mention Bee Journal when writing.

BEEES! Florida Italian QUEENS!

Tested Queens, \$1.00 each; Untested, 50c. Prompt and satisfactory dealing.

Address, **E. L. CARRINGTON,**
11 Atf De Funiak Springs, Fla.

Please mention Bee Journal when writing.

In the multitude of counsellors there is
safety.—Prov. 11-14.

Bees Hived on All Drone-Combs

Query 79.—1. Suppose a prime swarm is hived on all fully-built frames of drone-comb, what kind of bees will they rear, drones or workers?

2. If worker-bees were the result, would this not be a good plan to follow to secure larger bees, and consequently longer tongues?—Illinois.

O. O. Poppleton—I don't know.

W. G. Larrabee—1. I should say they would rear drones.

E. France—1. I never tried it. 2. You try it and report.

R. L. Taylor—1. Both. 2. No, you can't fool Nature that way.

P. H. Elwood—I haven't observed any worker-bees reared in drone-comb.

R. C. Aikin—1. Drones, drones, drones. 2. I don't think it will work one bit.

Dr. A. B. Mason—1. Both drones and workers, but more workers than drones. 2. I think not.

Mrs. L. Harrison—1. Workers. When the levee broke in the South, and the water drove the bees into the surplus

Southern Home of the Honey-Bee

arrangement, bees reared workers in drone-comb. 2. The workers would not be any larger.

G. M. Doolittle—1. Both. 2. Worker-bees from drone-comb are no larger than other workers, according to my observation.

J. M. Hambaugh—1. Oh, goodness; try and see. I don't know. 2. This would be a broad stride. Let us hear the result.

Emerson T. Abbott—1. Workers, if they wish; if not, drones. 2. It is not always the largest egg that produces the biggest chicken.

C. H. Dibbern—1. I think they would be mostly drones. 2. Yes, but would the workers produced in drone-cells, if any, be really larger?

Dr. C. C. Miller—1. The only time I ever tried it they didn't do either. They left. 2. Perhaps, but if I wanted to try anything of the kind I'd go at it gradually.

D. W. Heise—1. If the swarm will remain I would expect them to rear drones until they had time to reconstruct the cells into worker, which I think they would do.

Jas. A. Stone—1 and 2. I think they would change the cells to worker-cells as far as necessary, so the result would be a loss of that much time in making the change.

Dr. J. P. H. Brown—Both these questions are premised upon a violation of the bee-"constitution." Before they could be carried out the constitution would have to be "amended."

J. E. Pond—1. Drones and workers both, in my opinion. 2. No; for many tests have been made in this direction, without making any perceptible increase in the size of the workers.

E. S. Lovesy—1. Both. With us as a rule the majority will be workers. 2. I doubt it. I have never perceived any difference. But I have never made any experiments along this line.

Prof. A. J. Cook—1. I don't know. Who would give them thus except for experiment? Try it, and you will know. 2. I doubt if it would work that way. May be they would leave in disgust.

Mrs. J. M. Null—1 and 2. I don't know. Personally speaking the boundary lines of practical, everyday bee-keeping are sufficiently extensive. "Might-be's" soar to inaccessible heights.

S. T. Pettit—1. Usually they will rear a fair proportion of both. 2. I could never see any difference in bees so reared from those bred in worker-combs. It might possibly add a little to the length of their tongues, but I doubt it.

Eugene Secor—1. They might try to reconstruct the cells so that workers could be reared, but I would not be surprised if they deserted the hive in disgust. 2. Do you think that the size of the cradle determines the size of the grown-up baby?

Chas. Dadant & Son—They will rear drones till they have managed to narrow down some of the cells. This experiment was tried by Drory, of Bordeaux, France, some 15 years ago, and the result was only a few eggs were laid that hatched as workers.

Rev. M. Mahin—1. I have never seen it tried, and do not know. It has been said that under some conditions queens will lay worker-eggs in drone-cells, but

Sweet Clover

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with order—

A Book Recommended by Dr. Gallup. THE NEW METHOD In Health and Disease.

By W. E. Forest, M. D., 12th Edition, Revised, Illustrated, and Enlarged. This is the greatest and best work ever published as a HOME PHYSICIAN, and as

A Guide to Health.

It makes the way from **Weakness to Strength** so plain that only those who are past recovery (the very few) need to be sick, and the well who will follow its teachings **cannot be sick**. It is now in many families the only counsellor in matters of health, saving the need of calling a physician and all expenses for medicines, as it teaches Hygiene and the use of Nature's remedies, **not a drug treatment**.

All Chronic Diseases

are considered, and there is not a curable disease that has not been helped by some of the "*New Methods*" given here; even those who have been pronounced **Consumptive** have been entirely cured. While for **Rheumatism, Indigestion, Dyspepsia, Constipation, Dysentery, Liver and Kidney Troubles, Catarrh, Emaciation, General Debility, Nervous Exhaustion, Diseases Peculiar to Women**, etc., the methods are sure, and can be carried out at one's own home and with little or no expense.

A Guarantee.

So confident are the publishers of the results, that they offer to refund the money to any one who will try "*New Methods*" thoroughly, if the book is returned in good condition.

The New Edition

is illustrated with a number of Anatomical plates from the best English work on Anatomy published, and others made expressly for this work; contains 300 pages, printed on fine calendered paper, and although the price of the first edition (much smaller in size and without illustrations) was \$2.50, we sell this at \$1.00, postpaid; or club it with the Bee Journal for one year—both together for \$1.60.

PREMIUM OFFERS.

For sending us two new subscribers to the Bee Journal for one year, we will mail you the book free as a premium, or we will mail it for sending your own advance renewal and one new yearly subscriber. This is a wonderful premium offer. Address all orders to—

I do not know that they will. 2. The size of the cell has very little influence, if any, on the size of the bee.

G. W. Demaree—1. Would they stay in a hive filled exclusively with drone-comb? Have you tried the experiment? I have not. If they could be induced to stay on drone-combs, no doubt but they would cut away at least a part of the drone-comb and build worker-comb in its place. 2. I have little faith in rearing big bees by any other process than that of selection in breeding.

J. A. Green—1. While I have never tried such a thing, I should suppose that both workers and drones would be reared, tho a larger percentage of drones than usual. 2. How could it have any effect on the succeeding generation? The queens would not be reared in larger cells than usual, neither would the drones. What have the workers to do with the succeeding generation further than to feed it and care for it, and what difference would their size make in these respects?

Grand Honey Season.

We have had a grand honey season in this locality this year—the best I ever knew. I like the old American Bee Journal. WM. AIKEN.
Ontario, Canada, July 23.

Wortman's Handy Tool.

The illustration of Wortman's handy tool for bee-keepers on page 451, makes it show the hammer on the edge. It is intended to be underneath to make it handy, as in raising brood-frames the hammer rests against a frame, answering for a fulcrum or stop. Otherwise the illustration is very good.

A. WORTMAN.

Bought Foul Brood.

I must tell what kind of a job a bee-keeper here has gotten into, only $\frac{3}{4}$ mile from my apiary, by not taking a bee-paper and keeping informed. He had about 40 colonies of bees, then bought 60 colonies the past spring that had foul brood in the worst form. I tried to get him to subscribe for the American Bee Journal, but he said he could get along just as well without a journal. My bees show no signs of the disease as yet. E. E. SMITH.
Lenawee Co., Mich., July 22.

Some Blunders—Bees Doing Nicely.

As usual, I have made a great many blunders this season, the greatest of which was to hive large swarms on starters. Heretofore I had used full sheets of wired foundation, and this season I wired my frames and put in a starter and hived large swarms. The result was drone-comb mixt in nearly all my frames. It is all right for young queens with a few bees, but it won't do in this locality.

I am becoming more convinced every season that large hives are the thing. I use from one to four S-frame hive-bodies to each colony. I supersede all worth-

THE BIGGEST OFFER YET!

Last year only about one per cent—only one subscriber to 100—ordered his Review discontinued. If the Review could secure 1,000 new subscribers the present year, there is an almost absolute certainty that at least 900 of them would remain; not only next year, but for several years—as long as they are interested in bees. Once a really good bee-journal visits a bee-keeper a whole year it usually becomes a permanent member of his family.

I would have no difficulty whatever in getting twice 1,000 new subscribers this year, if all of the bee-keepers in this country had read the Review the past year. I have sometimes thought that it might pay a publisher to give away his journal one year, simply for the sake of getting it into new hands. There are, of course, decided objections to such a course; but I am going to come as near to it as I dare. Here is my offer:

If you are not a subscriber to the Review, send me \$1.00, and I will send you twelve back numbers, the Review the rest of this year and all of next year.

Each issue of the Review, especially if devoted to the discussion of some special topic, is really a pamphlet containing the best thoughts and experience of the best men upon the topic under discussion. Twelve back numbers of the Review are, to a certain extent, so many little books devoted to as many different phases of bee-keeping. Some issues of the Review are now out of print; of others only a few are left; while of others there are several hundred. Of course, I shall send those of which I have the most, but no two alike.

Most people subscribe for a journal at the beginning of the year. In this case there is no use of waiting, as you will get the Review for next year just the same as the you waited until next January to subscribe, and you get all the rest of the numbers for this year FREE. The sooner you subscribe, the more free issues will you receive.

Let me tell it over once more. For \$1.00 you get twelve back numbers, the Review the rest of this year, and for all of 1899.

ELECTRIC WHEEL CO.

How About Your Wagon?

Does it stand up to the work? Don't the wheels get loose, the spokes rattle and the tires come off when the weather is hot? Don't the fellos and hubs rot and require much repair to keep the old thing in order during wet weather? These things are true at least of most wood wheel wagons. *Stop the expensive repairs. Buy a wagon that lasts.* There are two ways of doing this, one way is to buy

THE ELECTRIC HANDY WAGON

and the other way is to buy *The Electric Low Steel Wheels* and put them on your old wagon.

The Electric Handy Wagon will stand up under any load your team can haul. No rutting—light draft. Being low it is easy to load and saves much heavy lifting.

The Electric Steel Wheels will lengthen the life of your old wagon indefinitely. They fit any skein. Convert your old high wagon into a low-down easy-to-load farm wagon. Write for our Free Book, "Farm Savings." It tells the whole story.

ELECTRIC WHEEL CO., Box 16, Quincy, Illinois.

Please mention Bee Journal when writing.

less queens. I have some that keep 12 to 14 frames of brood through the spring and summer.

I give plenty of ventilation by raising the front of the hive on blocks, if needed. I never suffer the bees to hang out.

My bees are doing nicely this season. I have increased from 34 to 82, and have taken off some nice comb honey, and a lot on the hives now. We have a nice prospect for a fall flow.

J. T. HAIRSTON.
Cherokee Nation, Ind. T., July 20.

Comb Honey Breaking Down.

There has been some complaint of honey breaking down in the sections in shipment. I think it may be of some use to try the following plan:

In folding the sections, place them so that the part where they are match together will be on top, and in that end or side put the long sheet of foundation, and put the bottom starter in the other end. Now, when the bees fill the box with honey, reverse it, and have the match side or end down, so that the great weight of the honey will rest on the bottom of the box. The top of the box as it then stands will be smooth for any marking which one may wish to make on the box, and there will be very little breakdown. Wm. H. EAGERTY.
Republic Co., Kan., July 18.

Another Hive Tool.

Take an old horse-rasp, and draw it out wedge-shape 3 inches long by 1½ inches wide. Make the handle ¾ inches wide by ¾ inch thick, and bend it to an angle of 15 degrees. This will be found to be a very handy tool for prying supers loose, and also for loosening frames. The angle of 15 degrees makes the handiest part of the tool. It may also be used for a chisel, and will stand all the pry you wish to give it.

Kendall Co., Ill. H. C. GORTON.

Crop Will be Light.

I had 14 colonies of bees in the spring, and have increased to 26. I lost one on a Sunday while at church; but one came to me from one of our neighbors. I would have more colonies but I doubled up some of the late swarms. The bees have been storing some surplus honey, but not a great deal. The crop will be light.

J. RIDLEY.
Winneshek Co., Iowa, July 23.

Putty-Knife as a Hive Tool.

I frequently see in the Bee Journal something said about tools. I have been a bee-keeper for 10 years, and I have never found anything so handy as a common square-point putty knife. I don't think anything would take its place for cleaning supers, sections, scraping bottoms of hives, and hundreds of other things. If my bee-keeping friends have never used one, they should by all means get one and try it.

Mason Co., Ky. C. N. BOLINGER.

Illinois.—The annual meeting of Northern Illinois Bee-Keepers' Association, will be held at the Court House, in Freeport, Ill., Tuesday and Wednesday, August 16 and 17, 1898. All interested in bees are invited to attend.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.,
Chicago, Ills.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This edition has been largely re-written, thoroughly revised, and is "fully up with the times" in all the improvements and inventions in this rapidly-developing pursuit, and presents the material with everything that can aid in the successful management of an apiary, and at the same time produce the most honey in an attractive condition. It contains 250 pages, and 245 illustrations—is beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, \$1.00.

Langstroth on the Honey-Bee, revised by Dadant—This classic in bee-culture, has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages; bound in cloth. Price, postpaid, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages; bound in cloth and fully illustrated. Price, postpaid, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of Queen-Bees are reared in perfect accord with Nature's way. 175 pages, bound in cloth, and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedic of 400 pages, describing everything pertaining to the care of the honey-bees. It contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.25.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchison.—The author of this work is too well known to need further description of his book. He is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cts.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages; bound in paper covers, \$1.00.

Bienen-Kultur, by Thomas G. Newman.—This is a German translation of the principal portion of the book called BEES OF HONEY. 10 page pamphlet. Price, 40 cents.

Convention Hand-Book, for Bee-Keepers, by Thomas G. Newman.—It contains the parliamentary law and rules of order for Bee-Conventions—also Constitution and By-Laws, with subjects for discussion, etc. Cloth, gold-lettered. Price, 25 cts.

Practical Hints to Bee-Keepers—by CHAS. F. MUTH. Also contains a Foul Brood Cure and How to Winter Bees. 40 p.; 10 cts.

Why Eat Honey?—This Leaflet is intended for FREE distribution, to create a Local Market. 100 copies, by mail, 30 cts.; 500 for \$1.25; 1000, \$2.00.

How to Keep Honey and preserve its richness and flavor. Price same as Why Eat Honey.

Alsike Clover Leaflet—Full directions for growing. 50 for 25 cts.; 100 for 40 cts.; 200, 70c.

Apiary Register, by Thos. G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Preparation of Honey for the Market, including the production and care of comb and extracted honey. A chapter from BEES AND HONEY. Price, 10 cents.

Bee-Pasturage a Necessity.—This book suggests what and how to plant. It is a chapter from BEES AND HONEY. Price, 10 cents.

The Hive I Use, by G. M. Doolittle. It details his management of bees, and methods of producing comb honey. Price, 5 cents.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cts.

Silo and Silage, by Prof. A. J. Cook.—It gives the method in operation at the Michigan Agricultural College. Price, 25 cts.

Winter Problem in Bee-Keeping, by G. R. Pierce. Result of 25 years' experience. 30 cts.

History of Bee-Associations, and Brief Report of the first 20 conventions. Price, 10 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price 10 cts.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia. A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 p., illustrated, 25c.

Commercial Calculator, by C. Ropp.—A ready Calculator, Business Arithmetic and Account-Book combined in one. Every farmer and business man should have it. No. 1, bound in water proof leatherette, calf finish. Price, 40 cts. No. 2, in fine artificial leather, with pocket, silicate slate, and account-book. Price, 60 cts.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers. This book gives the latest, most approved methods of bee-keeping, in an easy, comprehensible style, with illustrations to suit the subject. 50 pages, board cover. Price, 50c.

Green's Four Books, by Chas. A. Green.—Devoted to, 1st, How We Made the Old Farm Pay; 2nd, Peach Culture; 3rd, How to Propagate Fruit-Plants, Vines and Trees; 4th, General Fruit Instructor. Nearly 120 pages. Fully illustrated. 25 cts.

Garden and Orchard, by Chas. A. Green.—Gives full instructions in Thinning and Marketing Fruits; Pruning, Planting and Cultivating; Spraying, Evaporation, Cold Storage, Etc. 94 pages, illustrated. Price, 25 cts.

Kendall's Horse-Book.—35 pictures, showing positions of sick horses, and treats on all their diseases. English or German. Price, 25 cts.

Lumber and Log-Book.—Gives measurements of lumber, logs, planks, wages, etc. 25c.

Maple Sugar and the Sugar Bush, by Prof. A. J. Cook.—Full instructions. Price, 35 cts.

Grain Tables, for casting up the price of grain, produce, hay, etc. Price, 25 cts.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 30 cts.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 30 cts.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about the Poultry Business. 64 pages. Price, 25 cts.

Turkeys for Market and Turkeys for Profit, by Fanny Field.—All about Turkey-Raising. 64 pages. Price, 25 cts.

Rural Life.—Bees, Poultry, Fruits, Vegetables, and Household Matters. 100 pages. 25 cts.

Potato Culture, by T. B. Terry.—It tells how to grow them profitably. Price, 40 cts.

Hand-Book of Health, by Dr. Foote.—Hints about eating, drinking, etc. Price, 25 cts.

Book Clubbing Offers.

(Read Carefully.)

The following clubbing prices include the American Bee Journal one year with each book named. Remember, that only one book can be taken in each case with the Bee Journal a year at the prices named. If more books are wanted, see postpaid prices given with the description of the books on this page. Following is the clubbing-list:

1. Langstroth on the Honey-Bee.....\$2.00
2. A B C of Bee-Culture.....2.00
3. Bee-Keepers' Guide.....1.75
4. Bees and Honey [Cloth bound].....1.65
5. Doolittle's Scientific Queen-Rearing.....1.75
6. Dr. Howard's Foul Brood Book.....1.10
7. Advanced Bee-Culture.....1.30
9. Bienen-Kultur [German].....1.20
11. Rational Bee-Keeping [Paper bound] 1.75
13. Bee-Keeping for Profit.....1.15
14. Convention Hand-Book.....1.15
15. Poultry for Market and Profit.....1.10
16. Turkeys for Market and Profit.....1.10
17. Capons and Caponizing.....1.10
18. Our Poultry Doctor.....1.15
19. Green's Four Books.....1.15
21. Garden and Orchard.....1.10
23. Rural Life.....1.25
25. Commercial Calculator, No. 1.....1.40
26. Commercial Calculator, No. 2.....1.10
27. Kendall's Horse-Book.....1.20
30. Potato Culture.....1.10
32. Hand-Book of Health.....1.10
34. Maple Sugar and the Sugar Bush.... 1.20
35. Silo and Silage.....1.10
36. Winter Problem in Bee-Keeping..... 1.30
37. A Apiary Register (for 50 colonies).... 1.75
38. Apiary Register (for 100 colonies).... 2.00

Page & Lyon Mfg. Co. New London, Wisconsin,

Operates two sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of

Bee-Keepers' Supplies.

They have also one **One of the Largest Factories** and the latest and most-improved machinery for the manufacture of

Send us your name and address and we will take pleasure in mailing you a copy

G. B. LEWIS CO., WATERTOWN, WIS.

Special Agent for the Southwest—

E. T. ABBOTT, St. Joseph, Mo.

Mr. Abbott sells our Hives and Sections at factory prices.

Ho, for Omaha!

AS we have many customers in the Northwest, and believing they will appreciate the low freight rates obtained by purchasing goods from a railroad center nearer to them than we are, getting a direct through-freight rate, thus cutting the freight in half, we have established a branch house at 1730 South 13th St., Omaha, Neb., where we will keep a complete line of all Apianian Supplies, the same as we do at Higginsville, Mo. With the quality of our goods, we believe most bee-keepers in the West are already acquainted, but to those who are not, we will say that our goods are par excellent. Polished, snowy-white Sections, beautiful, straw-colored transparent Foundation, improved Smokers and Honey Extractors, and all other fraternal goods, are what we sell. Kind and courteous treatment and honorable dealing our motto. On these bases, we solicit an order, feeling sure that if we sell you one bill of goods you will be our customer in the future.

PROGRESSIVE BEE-KEEPER, 50c per year. "Amateur Bee-Keeper," 25c. Both for 65c. postpaid. Sample copy of the PROGRESSIVE free, and a beautiful Catalog for the asking.

Address, **Leaky Manufacturing Company, Higginsville, Mo., or 1730 South 13th St., Omaha, Neb.**

Select-Tested Golden Adel Queens.

Each, \$1.00. A practically non-swarmling and non-stinging strain of golden bees. "How to Prevent Honey Candyng" given to each customer. Tested QUEENS, each, 75 cents. 26Att **HENRY ALLEY, Wenham, Mass.**

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, July 20.—Not any of the new crop of comb honey on the market this week; what little has come sold at 11@12c. Extracted brings 5@7c for the white, according to quality; ambers, 5@6c. Southern, fair to good grades, 4@5c. Beeswax, 27c. Market is in good shape for disposing of honey of all kinds. R. A. BURNETT & Co.

Kansas City, July 9.—New comb, No. 1, white, 11@12c; amber, 10@11c. Extracted, white, 5@5½c; amber, 4@4½c. Beeswax, 22 to 25c.

Old stock of honey all cleaned up. Few shipments of new in market. C. C. CLEMONS & Co.

New York, July 30.—There is some little new Southern comb honey on the market, mostly irregular quality and selling at from 9 to 11c. Extracted of all kinds is in good demand. Common grade Southern, 50 to 52c per gallon; good, 55 to 57c.; choice, 5 to 5½c. per pound; some exceptionally fine lots sell at 6c. Beeswax is very quiet at 26 to 27c. HILDRETH BROS. & SEGELKEN.

Boston, July 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. BLAKE, SCOTT & LEE.

San Francisco, July 20.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5¼@6c.; light amber, 4¾ to 5¼c. Beeswax, 23@25c.

The ship Roanoke, clearing from this port for New York on the 16th inst., carried 179 cases of extracted honey of 1897 crop. There is some new crop honey on the market, both comb and extracted, but no large quantity of either. New comb of fairly choice quality is offering in 1-pound sections, and in a small jobbing way at 10c. per pound. Quotable values for extracted show no change.

Detroit, July 21.—Fancy white, 11@12c; No. 1, white, 10@11c. Extracted, white, 5@6c; dark, 4@5c. Beeswax, 25@26c.

New honey is arriving, but prices are hardly established. M. H. HUNT.

Minneapolis, July 26.—Fancy white clover comb is now selling at 11@12c.; amber, 10½c. Extracted fancy white clover, 5½c.; amber, 4¾@5c. Dark grades, both comb and extracted, not wanted at low prices. S. H. HALL & Co.

Indianapolis, July 18.—Fancy white comb honey, 12@12½c; No. 1, 10@11c. Extracted, white, 6@7c. Beeswax, 25@27c.

Only a few arrivals of fancy white comb; market almost bare, and demand good. Quite a little comb honey from honey-dew is being offered, but there is simply no demand for the stuff. WALTER S. POWDER.

Milwaukee, July 14.—Fancy 1-pound sections, 11@12c; A No. 1, 10@11 cents; No. 1, 8@10c; amber, 7@7½c; dark and old, 6@7c. Extracted, in barrels, kegs or pails, white, 6@6½c; dark and amber, 4@5c. Beeswax, 26@28c.

Since our last sales of honey have not been large, altho a fair demand has existed and continues, altho the fruit consumption makes some difference with eaters of honey. There is not a very large supply of old stock left, and we shall be in good order for new crop both extracted and comb. The outlook is good, A. V. BISHOP & Co.

Buffalo, July 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. BATTERSON & Co.

St. Louis, July 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. WESTCOTT COM. Co.

Cincinnati, July 9.—Demand is slow for all kinds of honey, especially comb. Prices for best white comb honey, 10 to 13 cents. Extracted honey brings 3½ to 6c, according to quality. Beeswax in good demand at 25 to 28c for good to choice yellow. CHAS. F. MUTH & SON.

Talk about
... Comb Foundation

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

It is always Pure and Sweet.

No. 32.

Mr. and Mrs. Thos. Wm. Cowan.

It will be remembered by our readers that Mr. and Mrs. Cowan called on us last May, when on their way back to England from California, where they had spent the previous 18 months. In Gleanings for July 15 appeared the picture which we show on this page, and which that paper has kindly loaned us.

As our opinion of Mr. and Mrs. Cowan is so well echoed in an editorial written by Ernest R. Root, that was printed in

the same number of Gleanings in which the picture was shown, we reproduce it almost entire, as follows:

Some of our readers will remember that Mr. Thomas Wm. Cowan, Mrs. Cowan, and their son, an electrical engineer, have been sojourning in California for several months past for their health. The condition of all three has greatly improved. While Mr. Cowan, Jr., remains, Mr. and Mrs. Cowan left there a few weeks ago, stopping on their way at the homes of some of the bee-keepers of the United States. They called on Mr. York, of the American Bee Journal, and on Dr. C. C. Miller. In writing to Dr. Miller recently, I mentioned

Mr. and Mrs. Cowan, and Mrs. E. R. and Master Leland Root.

the fact that I was enjoying a visit from Mr. and Mrs. Cowan, and in reply he writes this, which I give to our readers :

DEAR ERNEST:—I congratulate you heartily on the opportunity of a visit from Mr. Cowan and his wife. I do so with some intelligence after having enjoyed the treat myself. They came just at a time when work was in such shape that I couldn't stop for anybody—just couldn't stop. But I did stop for three days, and gave myself up to the abandon of thinking there was no work to be done while they were here; and altho it may take two weeks to catch up, I'm not worrying over it.

Along with a strong desire there was also just a shade of dread of the coming of two such prominent people; but they brought with them a large stock of common sense and loving kindness, and immediately we were at ease. Mr. Cowan impresses one as a man with a wonderful fund of information, but who has hardly discovered yet that he is any better off in that respect than the ordinary mortal. It so happened that while he was here I had sent me a letter and a newspaper clipping in a foreign language. I didn't even know what was the language—thought by the looks of the printed part that possibly it might be modern Greek. But Mr. Cowan read it off at sight. It was Russian. It made me feel I'd like to begin life over again and be a linguist.

Mrs. Cowan is so simple and unassuming in her manners that just at first one is hardly ready to recognize in her a woman of unusual intellectual attainments; but gradually the fact appears, and, along with very clear perceptions of the truth, she is possessed with an intense zeal that others shall see the truth as she has learned to see it. My wife, who had more opportunity than I to become acquainted with her, gave as her verdict, "Mrs. Cowan is a woman that lives to do good."

The present war seems bringing closer together a good many people. At the close there will be no gap between the North and the South; and England and America, mother and daughter, will be closer than ever before. "We be brethren."

C. C. MILLER.

The Doctor's impressions of the two were exactly my own—in fact, of all Rooddom. Notwithstanding Mr. Cowan is the most talented and best informed bee-keeper living to-day, I believe, having traveled over nearly all of the civilized world; notwithstanding he reads eleven different languages, and speaks perhaps half as many; notwithstanding honors of various kinds have been conferred upon him by different societies for the advancement of science; notwithstanding he is editor of the British Bee Journal, and president of the British Bee-Keepers' Association, he is one of the most modest men I ever met. Unassuming and quiet in his manner, one cannot fail to be impressed that he is in the presence of a master of our pursuit.

Without doubt he has the most extensive library relating to bees of any man in the world. He has been all his life gathering together rare and old volumes pertaining to bees; and it does not make any difference what language they are printed in, he reads them just the same. He pronounced some of the bee-books we have, dating back two and three centuries, as being exceedingly rare and valuable—such as, for instance, Butler's *Feminine Monarchy*, printed in 1609, or two years before the publication of the common version of the Bible; also Hill's treatise on bees, printed in London in 1608.

When Mr. Cowan was here in 1887 he had with him his big microscope with which he has made some of his exhaustive researches. This instrument is one of the finest in the world, and was made by Mr. Cowan himself. Father once pronounced it the finest piece of handwork he ever saw.

I found Mr. Cowan to be well versed in all the modern and ancient practices of bee-keeping. It seemed to amuse him that so many ideas were being discovered in these latter days that have been fully described in former works. For instance, the modern starvation cure for foul brood is fully described in Della Rocca's works, written over a century ago, and printed in 1790. He was also amused at the way we Yankees have of inventing things that his countrymen invented and afterward discarded.

On the afternoon of one of the days he was here, Mr. and Mrs. Cowan, Mrs. Root, Master Leland, and myself, took a drive down to our basswood apiary. I felt that when so distinguished a personage was here I must not fail to take along my camera, and so I requested the privilege of a "shot" or two, which was kindly granted; and I also asked if I might present the result of that shot to our readers. With some reservation this privilege was also granted. Mrs. Cowan is shown in the back of the buggy, Mrs. Root in front holding the dog Trix, and Master Leland in front of Mrs. R. From the picture one would think it impossible to go between the trees, but such is not the case. Of course, we do not need to point out Mr. Cowan.

Mrs. Cowan is as simple and unassuming in her manners as her husband; and the fact gradually begins to dawn on one, when he begins to know her better, that she is a woman of more than usual intellectual attainments, as Dr. Miller well

says. She is a very earnest and able advocate of the doctrine that the ten tribes of Israel, after their carrying away to Assyria, 133 years before the sacking of Jerusalem (when Judah and Benjamin were taken to Babylon) were not lost by absorption into other nations. She claims that the Bible justifies us in believing that those Israelites migrated to Central Europe and became the Anglo-Saxon nation; that England is Ephraim in prophecy, and the United States represents Manasseh; that the religion and principles of these two nations will spread all over the world and become dominant.

It is not necessary for me to refer to the members of my own family, unless it is to the dog Trix (I count her) that eats more honey than any other canine living. The other day she showed she was very fond of raw bananas and raw tomatoes; and for taffy she has a "sweet tooth." I have not tried her yet on a chunk of comb honey, but I have no doubt she would whine for that as she does for everything else in the sweet line.

ERNEST R. ROOT.

Mr. and Mrs. Cowan anticipate returning to this country the coming fall, as their health is much better when on the Pacific Coast. We shall hope at that time to have more time to spend with them. Like Dr. Miller, when they came here, it was in the busiest time of the year—it required all our time to look after the mail orders for bee-supplies, so that we were really ashamed that we could not devote more time to our distinguished visitors. But being a wise man, and acquainted with the requirements of bee-keepers at that particular time of the year, of course Mr. Cowan was able to take in the situation, and we hope he made due allowance for our apparent inappreciation of our English friends.

Neither Dr. Miller nor Mr. Root have spoken too highly of Mr. and Mrs. Cowan. We feel that they indeed merit every good word that has been said concerning them.

PROFITABLE BEE-KEEPING, —WITH— HINTS TO BEGINNERS, —BY— C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 6.—FOUNDATION.

Those who keep bees in skeps and boxes are at a serious disadvantage when compared with their more fortunate brethren in the craft who use a modern style of hive. The latter are aids to success which prove of very great importance. If we compare two swarms, one in a skep or box and the other in a modern pattern hive in which is a provision for saving the bees many days' labor, we can't fail to see that for several days the bees in the skep are busy making combs of wax which they secrete from the honey they are gathering daily, while bees in the wooden hive, if of the same capacity, will have converted the sheets of foundation into combs in from 24 to 48 hours, and during the remainder of the time the other bees are laboriously building combs below, they are rapidly filling their supers. In many cases, owing to the waste of the honey-flow, or change of weather, the days thus saved make the difference between full and empty supers.

The foundation referred to as an aid to success is wax in sheets that have been past through a machine somewhat like a small mangle, the rollers of which have been cut in such a manner that they impress on both sides of the sheet the shapes of worker-cells. Foundation is undoubtedly one, if not the most valuable, of the many devices the modern bee-keeper makes use of in the profitable management of the apiary. A

frame fitted with a full sheet of foundation and put into a good colony during the summer will on the following day not only contain a partly-workt-out comb, but the newly-built cells will in all probability each contain a tiny egg. The great value of foundation cannot well be over-estimated, and therefore I strongly advise its use on all occasions when practicable. The cost—2s. per pound (less in quantity)—is a really small item when the amount of extra surplus resulting from its use in the brood-chamber, as well as supers, is taken into consideration.

As generally made there are about six sheets the size of standard frames to the pound, tho seven to ten for wiring are sold. It is not, however, advisable to have a sheet of less thickness than seven sheets, at the most, to the pound will give, even for wiring; as thin sheets are apt to sag and spoil the appearance and usefulness of the combs.

The fixing of the sheets of foundation in the saw-cut of top-bars of frames has been explained in a previous article, but tho the foundation is by this method expeditiously fixt in the frames, the latter must be handled very carefully, otherwise the new combs will fall out. Then again the least move of the hive from a horizontal position by accident, or the settling of the ground after rain, will throw the combs, which are being built together, out of the frames; neither can colonies with such combs be moved without fear of the combs collapsing, except when they become tough by usage.

All these disadvantages disappear by wiring the sheet of foundation into the middle of the frame. The foundation

Fixing Foundation in Frames.

is not only placed in the right place and kept there, but the saw-cut in which the wax-grub is often found may be done away with, by using a plain top-bar.

To wire a sheet of foundation into a frame proceed as follows: Put through the side-bars towards the inside of the frame, a thin French nail about an inch in length, half an inch from the top, and an inch from the bottom, and turn the ends with a pair of small pliers to form hooks; then lay the frame down to be better able to follow the instructions. Let the bottom-bar be near and the top-bar away from the operator. Now take about two yards of No. 30 tinned wire, make a noose on one end and hook it on the nail near the bottom of the side-bar on the left hand, run it across to the other bottom nail, pass it through the loop, and thence through the hook at the top of the same side-bar; then carry it across under the top-bar and pass it through the top hook on the other side-bar. The nails, as we have come to them so far, we will number from starting, 1, 2, 3, 4. We have now to run the wire along near the bottom of the frame up to the top and across under the top-bar to the left hand side. Now draw the wire tightly and take it back to No. 3, which gives two wires under the top-bar. From 3 pass the wire under the middle of the bottom strand that runs from 1 to 2; pull tight and carry it over No. 4, and then down the left hand side to No. 1. From No. 1 pass it over the middle of the lower of the two strands under the top-bar, finally drawing it tightly and fastening it off at No. 2. If the wire has been drawn taut during the process of wiring the bottom strand, one of the top strands will be drawn inwards, and by the crossing of the wires a diamond will be formed in the center of the frame.

Next procure a piece of board to just fit inside the frame while being only half as thick. Tack onto the back of this board laths top and bottom to project beyond the side-bars, so that when a wired frame is laid upon the board these projections hold the frame with the wires just resting upon the board. The frame is then raised while a sheet of foundation is placed upon the board and then returned. The wires, which are now lying upon the foundation, are ready for embedding. The next step is to press the wires down until they are embedded in the middle of the sheet of foundation. Various devices are employed to do this work properly, but there is not one worthy of mention save the "Woiblet" spur embedder. This is a tooth wheel, and if it is placed in hot water, and when hot run along the wires, they will sink down and remain in the foundation, while the bees build their comb

upon it. When the combs are completed the wires will be seen running along the mid-rib at the bottoms of the cells.

Tho the saw-cut in the top-bar of the brood-frames may be dispensed with, it should be retained in the shallow frame top-bar, for wiring in this frame is not necessary, and the use of a saw-cut for fixing the foundation will be simple and effective.

The foundation to be used in sections must, as the honey therein stored is eaten with the wax, be very thin and irreplaceable as regards color. In dipping the boards in the wax-tank only thin sheets are taken, and these when set are past through the rollers of the foundation-mill adjusted so that the thinnest sheet possible may be produced. The best super foundation will give nearly 100 sheets, four inches square, to the pound; and therefore the sections in five crates may be fitted with full sheets of foundation for 3s., the price of a pound of super foundation. Full sheets are not really necessary, tho they are an advantage, and consequently triangular pieces may be used. Whether full sheets or "starters"—as small pieces are called—are used, they must be fixt in the middle of the section and firmly attach to the top. This may be done by bending the edge of the sheet or starter and pressing it firmly upon the part to which it is to be fixt; or while held in position a little melted wax should be run along the edge of the sheet which will attach it securely to the middle of the top of the section.

A simpler and most satisfactory way of fixing is to procure sections that have a slanting saw-cut through the middle of the end which, when the section is placed in the crate, will be the top. In putting the section together it is completed except that the half of the top is left unfastened until the edge of the foundation is placed upon the level, when it is closed, thus completing the section and holding the foundation securely in the middle.

FEEDING BEES.

The second, and by no means the least in importance of the aids to success is feeding. Food given judiciously is of immense advantage, for without it many bee-keepers would undoubtedly have empty instead of full supers. Food in some form may be required in the spring to help on a colony to its full strength in readiness for the honey-flow; it is none the less needful during the summer, when through a continuance of unfavorable weather loss by death is otherwise inevitable; but it is often of supreme importance at the end of the season, so that there shall be surrounding the bees food enough to serve not only for the daily wants but also through the early part of the year, when the new honey is not being gathered the stores are drawn upon largely for brood-rearing.

The best bee-food at all times, if it could be given, is certainly honey, but in its place the only substitute admissible is *pure cane-sugar* either in its dry state or in the form of syrup.

Syrup is best used when a supply must be given quickly, as in the case of a colony on the verge of starvation, or at the end of the season when making up the necessary quantity of food for wintering. There must, however, be a difference in the consistency in the spring and autumn syrups—in fact the latter should be about twice that of the former. The reason for this difference is that in the spring the bees leave the hive for water with which to thin the food they, in their capacity of nurse-bees, prepare for the queen and grubs; and when syrup is given with a good proportion of water, these journeys to the pump or drains are rendered unnecessary, while in the autumn, unless syrup about the consistency of honey is supplied, the bees will have considerable trouble in getting rid of the superfluous moisture in order to seal it over; and if they could not do this the syrup remaining exposed might, and probably would ferment and cause dysentery.

Syrup is made by melting (boiling is not necessary) three pounds of cane loaf or white crystallized sugar in a quart of hot water, for spring food; and six pounds to the quart of water for autumn feeding.

If syrup is given from the close of the honey-flow to induce a continuance of egg-laying, much of it will be stored in the cells. To prevent this and at the same time save trouble, dry sugar feeding may be adopted. For this purpose the best kind of sugar is Porto Rico, because it is a fine-grained, pure cane-sugar. Demarara is not recommended, for two reasons: chemicals are used in the manufacture of some samples, and the grains are too large for satisfactory work. The Porto Rico may be given in any manner so that it does not get wasted, and is in a position to receive the moisture from the brood-nest.

A simple method is to fill a basin with the sugar and press it level; then place upon it a thin board, in the middle of which two or three holes have been bored or burnt with a red-hot poker, about the size of a finger-end. If then the basin with the board under it be inverted, and placed on a hive immediately over a hole in the center of the brood nest—that is

over a hole in the quilts—the moisture arising from the brood-chamber below would be absorbed by the sugar and thus provide a food that the bees would be able to take. But it would be exactly what they require for brood-rearing, a slow but continual supply. If this simple method of feeding is used up to the middle of September, an examination of the hive then will reveal an extensive brood-nest, a large quantity of bees, but most likely, as must be expected, not sufficient food stored to carry the colony through the winter. Then is the time when there are plenty of bees, young and old, and mild weather, to give quickly as much syrup as will make their future safe. The bees will have time to ripen and seal it over, and will then go into winter quarters in a thoroughly satisfactory condition.

No. 2.—The A B C of Marketing Honey.

BY HERMAN F. MOORE.

[Continued from page 483.]

Before going any further in this A B C school, let me exhort you all to remember that this is no play school; that the walls of our school-room are decorated with pictures of the Patriarch Jacob (Gen. 43-11), Solomon (Prov. 24-13), Aristomachus, the celebrated Sicilian apiarist; Dzierzon, Von Berlepsch, Adam Grimm, Samuel Wagner, L. L. Langstroth—men of deepest, broadest thought and culture—men who gave their lives to work and study and scientific investigation among their beloved bees—men who found a long, peaceful life among the hives all too short to fathom all the mysteries, to solve all the problems.

In the spirit of deepest seriousness, then, let us approach our study, realizing that only by years of constant application can we hope to approach perfection, in even the simplest forms of human industry.

Look at shoes, dry goods, cloaks, hats, woollens, etc.; in all these lines men are required to put in two to five years' work in the factory or counting-house before they are considered worthy to sell a dollar's worth of goods from a grip or sample trunk. Why? Because an inexperienced man, ever so innocently, might damage their business thousands of dollars. Let us learn from these great lines of merchandise, that control the world's business, that it is no slight thing to go among the people and ask for their trade; that no amount of education, investigation, culture and labor is too great to bring to your aid in this work.

In order to succeed you must be everlastingly at it. Don't go at it by fits and starts, for remember the people eat three times a day, and 365 days in the year, and sometimes more.

Don't be satisfied with anything less than calling on every family in your county, and if possible in every adjoining county.

Now as to the kind of honey we are going to sell. Decide on the start always to sell the best only; we need not dwell on the question of purity, for I take it for granted that no bee-keeper will ever sell anything but pure honey.

Let me beseech you, if any case of adulteration comes to your notice, when a bee-keeper is guilty of such practices, go to him first in private, talking with you a neighbor who is also a bee-keeper; ask him to "quit his meanness" at once and forever. If he goes on doing wrong, and injuring our vocation—one of the most honorable—prosecute him without fear or favor, and call down upon his head, by legal process, the utmost penalties of the law.

By the best honey is meant clear, well-ripened honey, of flavor agreeable to the trade that will consume it. This is, of course, a relative term. In the Middle States white clover and basswood are the best, tho they allow of a small percent of honey from golden-rod and buckwheat without detracting from the fine flavor that most pleases the people. In the rainless, irrigated districts of the West and Southwest, honey from the alfalfa clover takes first place, tho a small mixture of say 5 per cent. of clover or other honey will not condemn it if otherwise good.

In California black and white sage lead, very likely more or less mixt with other flowers that happen to bloom at the same time. Now here is the point: Use the greatest care in importing honey from one of these districts to another. People were never more suspicious of anything they don't understand than at the present day, and if you follow your own fine clover product of one year with sage or alfalfa the next year you may need to be deep in the confidence of your customers, or use lots of persuasion and explanation to avoid having the cry of adulteration raised against you.

The writer has been all through this experience. In the

80's he sold thousands of pounds of California honey in Toledo and Cleveland, Ohio, under its proper name, and a fairly good grade as well. At first the name was popular, no doubt from the well known excellence of California fruits. But the difference between Ohio white clover, and sage from California was so marked that no permanent demand for the sage could be worked up among people accustomed from childhood to clover honey; and even to this day, in certain localities, California honey is considered another name for adulterated honey.

Any of the very mild flavors of honey must be condemned for use in any other locality than their own. The majority of consumers desire a deep, strong honey-flavor, and one-third buckwheat or golden-rod will often correct a too-mild flavor. I go into this matter because if you have a good trade in honey you must sell them honey 12 months in the year, and you will have good years and poor years for honey-production, and in poor years you must of necessity buy some honey of your near and far neighbors, and even from friends in other States.

Be sure to keep the quality of your liquid honey right up to the top, for by so doing you will find that your sales of extracted honey will be far greater than in comb honey, your profit will be the greater, and the certainty of your making a lasting success of selling honey will be all the more sure. Remember that any lasting success always must mean good profits and increasing sales.

The matter of deciding upon the size of package and price per pound of comb and extracted honey is one that must receive our careful attention. If you are able to call upon each customer in your route, once in three months, your standard size of package should be such that it will last an average family of five persons for two months, leaving them some time to get hungry for more before you call again. The average family will buy honey only four times a year, if you can sell them 5 to 15 pounds at each sale. This manner of selling will add greatly to your profits by lessening the expense of handling, for it will cost you as much to sell one pound to a private family on your route as 10 pounds.

Some may say, "My trade will not buy 5 to 15 pounds at a time." In this you are in error. The average customer will buy anything that is offered to him, if he is satisfied about quality and price. The quantity is entirely secondary. To prove this, the writer has sold honey in large-sized packages (\$1.00 to \$2.50) for years, when at the same time people could go to a grocery and buy one pound or less almost everywhere. This may seem like a puzzle, but the reason is near. Families everywhere are always glad to buy their produce of whatever kind from the one who raises it, because they get fresher stuff and better quality than when purchase of the ordinary dealer. Instances: A friend once purchased 12 dozen fresh-laid eggs of the writer, that his brother had sent him, with no objection, when six eggs could have been purchased at any grocery. Many families, that are favorably situated, are accustomed to buying five to twenty dollars worth at a time, especially in the fall, of potatoes, apples, meat—in fact anything that the farmers raise and offer for sale from their wagons.

In deciding upon the price per pound to ask for our honey, several things must be considered. Your expenses in any business are usually two times as much as you have estimated that they will be. You must pay expenses and have a small or large profit for yourself out of every pound of honey you sell. This is the way business is conducted all over the world. Any other method leads to certain failure.

In selling to the consumer we are entitled to the highest market price in our locality, for our labor and expense is much greater in proportion than when selling the same goods at wholesale.

In determining the price in your locality, go to the best and highest-priced retail grocery-houses and inquire their selling price without letting them know you are a producer of honey. You are sure then to receive a truthful answer. If you sell to families in their town, do not cut their price, for people who want the best goods will be more certain to buy if you charge a good price. Of course, you must use your judgment about small fractions of difference, but this is a good general rule.

If you should begin by cutting prices you can't afford to keep it up, and you will wish you never had sold your honey too low when you undertake the task of putting back the price up to where it should have started. If you don't lose half or more of your customers I miss my guess. One of the greatest advantages you will find in selling to the consumer is that the quality and not so much the price is his great desideratum.

[Continued next week.]

Selling Comb Honey to the Grocery Trade.

BY G. K. HUBBARD.

Altho there have been published a number of articles on the subject of selling honey, I thought it possible that I could contribute something on this that would be helpful, and that might encourage some one to make an effort in this line who has dreaded to undertake it. The object of this article is to encourage those who have a crop of honey to dispose of to sell it at the groceries in neighboring towns, thus accomplishing the desired result of getting better prices and keeping the small shipments from going to the city commission-men.

We Californians are doubly interested in keeping honey from going into the city markets, for the reason that we are compelled to sell our product there. There is no escape from it except for those who have small amounts to sell. Our honey must of necessity go to market in carload lots of 1,000 or more cases, and it is only the large cities that can handle it in such quantities. The smaller cities and flourishing towns offer a splendid market at fair prices, and ought, in nearly every case, to be supplied without the grocers having it shipped in from the wholesale cities. The cost of getting a pound of comb honey to the Eastern market, counting the loss from having to pay the freight on the cases, is about 2½ cents for freight, if shipped in car lots. Less carload, if we care to take the risk of breakage, the cost per pound, with the extra crating necessary, is 4½ cents. This extra 2 cents, with the accompanying risk, shuts us out of any markets except those that can handle honey in car lots, and this leads me to emphasize the point that the smaller cities should be supplied from the surrounding territory, and the city markets largely left to those who are of necessity compelled to use them.

Now, my reader, if you have a crop of comb honey of from 20 cases anywhere up to 200 or so, I suggest that you sell it to the grocers in your surrounding territory. You may answer that you are not a salesman; that it takes time and ability to push off your crop a few cases at a time; that you would prefer to take less for it and see it all go at once than to get more in smaller sales. Of course, you would if the difference were not too great; but the difference is too great for you to afford if you wish to make the best success from your pursuit. Suppose it does take time to sell a crop; if it pays you well for your time, can you not afford to take it? I wish to urge you strenuously to make a brave trial and see if you do not get along better than you expected.

I am going to give some experiences and suggestions, and will say at first that you might make a score of calls and not use many of the ideas; but if I give you the idea of how it can be done, your tact and good sense will suit your talk to the right person. I cannot map out a minute program for you, but I can give you some insight of a plan that has proved very profitable to me, and incidentally you will learn something about my ideas of having a crop in such readiness for market that it will command the highest price the grade will bring.

You probably know all that is to be known about your own home market. You often go to town to do your trading, and know as well as any man in the community about how much honey your grocers have on hand, and what the possibilities are for business. As an almost invariable rule you will never make a large sale in the town you are best acquainted. Your merchant will say, "I might take one case of you. You are in town often, and I can get more of you almost any time." Therefore, I urge you to make a longer drive, get out of your own immediate community, where you will have a fighting chance of selling several cases to one customer.

Start with a load of 10 to 20 cases, according to the size of the place you are going to visit. Put on the best suit you have; collar and necktie; if you ever wear cuffs, do not leave them off this time; give your shoes an extra good shine, and look just as neat as possible. You are not a farmer or bee-keeper now; you are a business man, and are going out to do business in a businesslike way. Take along your horse-feed if you wish; but go to a modest hotel where you can get a meal for 25 cents, and have the almost as desirable point of being able to wash and to brush the dust thoroughly from you, from hat to shoe-sole. I do not think I overestimate the value of your personal appearance. While clothes do not make the man, they do, very largely, make the estimate that people place upon you, especially among strangers. You will walk with a firmer tread, and feel more like business, if your appearance is not being criticised, but, instead, is helping you to appear as if you meant business. I trust my reader's good sense to understand me aright, and do not think I advocate unreasonable extremes.

You know what your honey is worth, and the price you ought to get, which should be enough above the price at which

you hold the entire crop to pay for the time you put in distributing it. Adopt your prices for your different grades, and stick to them, treating all alike. It is all right to miss a sale occasionally on this account, as it will save you so much time, and be such a help in making sales to these parties in the future.

Being all in readiness to be your own "drummer," go to the leading grocer, and be as pleasant and polite as possible. Make your business known at once, for busy men do not care to talk much with strangers about the weather, crops, condition of roads, etc.

"I have driven over from Blankville with comb honey, and this case is a fair sample of my best grade. I take a great deal of care in producing a good article, and casing it up fair, and I think, if I could sell my load to you, you would find it to give good satisfaction to yourself and to your customers."

Of course, he will look at the honey, and likely pass his opinion upon it, comparing it with the honey he has handled. You will soon know whether he is at all interested or not, whether he is well stocked, whether or not he is supplied regularly, as his trade demands, by some home bee-keeper who is his regular customer, and who may put an article on the market that compares favorably with yours. If there is no chance at all for a sale, bid him a pleasant good-day, and tell him you will probably see him again some time when he is nearer ready to buy. Then if he wants to visit a little with you, and start an acquaintance, meet him half way, letting him make the advances; but make it short, and leave him with the impression that you are out for business, and that your business is just as important to you as any other man's business can possibly be to him. The next grocery you call at the man you take to be the proprietor is busy. After waiting a little, and you see he is not apt to be through with his customer very soon, you start out. Likely he or one of the clerks will inquire if you wish to get anything; but you reply that you have a little business with the proprietor, and that you will call again in a little while. Thus you save your own time, and impress the grocer that you are a man of business, and too much of a hustler to waste your time waiting for some independent chap to give you a little of the time he wants you to think is so extremely precious.

At another grocery you see at once that the proprietor is interested in what you have. He has but little honey, or none at all; and when you see there is probably a chance to sell him some you say, "I have just come to town, and have talked to but one man. I am very sure you could do well with the honey I have if I could sell it to you. I have only 15 cases with me—7 of the fancy grade and 8 of the dark; and if I could sell you my load, I am confident you would realize well on the purchase."

He looks at you with eyes wide open; he thinks to himself, "Fifteen cases of honey at one purchase? Gracious! wonder if he thinks I sell all the groceries used in this county." But all the same you have made a favorable impression. You have flattered him by assuming that he is one great big merchant, and you have impressed him with the idea you are to do business on a big scale.

"Fifteen cases? oh! I couldn't use that much. You see, the grocery business is terribly cut up here. There are many stores, and of course every man has his friends. We never buy very heavily. We keep pretty close to the shore, as the saying is; but then I don't mind buying a few cases of you if I can get it right."

If you had taken in a case and asked him to buy it he would hardly have thought of asking for more; but now that you put the idea into his head of buying the load, he feels safe in risking a few cases. Likely you sell him three of each grade. You set the cases in a conspicuous place, and he remarks that it looks like enough to run his trade for three months; but you thank him for the money, and wish him better luck in moving it than he imagines. You certainly would not have sold him six cases if you had tried to sell him one, and it is almost as certain you would not have sold him six if you had not first talked up the sale of your load.

Now, you go back to the man who was too busy at your first call. You tell him your business, and where you are from, and that, as he will be soon out of honey, he is interested in what you have to say; but he is one of those men who always wants to cut and slash prices; and to do this he begins to talk hard times and low prices.

"I have only nine cases of this left, and I should like to sell you the lot."

"But your price is too high."

"I do not think so, considering the quality I furnish."

"But I can get it shipped in from the wholesale houses and commission-men in Blank City for at least a cent, and likely a

cent and a half, less than your prices, and get my business discounts besides."

"It is barely possible that you can do as well; but I very much doubt about your getting as good value for the money as I offer you. There is the risk of your not getting as good an article as you expect when you place an order, and also risk of breakage in transit. I am right here with the honey; every section of it is in first-class condition; you can see exactly what you are buying, and if any case I sell you is not as represented I will take it off your hands next time I come over, without any hard feelings on the part of any one, or a lot of unpleasant correspondence over such a matter. I sell to every one alike; and while it is natural for every buyer to want to do a little better, and have a small advantage over his competitor (and I do not blame you for it), at the same time I know by experience that it is more satisfactory all around to treat all alike. You can make 25 percent easily enough on my honey at the prices I offer; and the rebate of the cases when empty, if you will let me have them back in good condition, will more than equal the business discount you mention. If you had these nine cases standing up front here, I do not doubt it would attract as much attention, and make as fine a show as any lot of honey you ever handled."

He tries to beat you down on the price, but you are firm, tho very gentlemanly, and, as a result, he concludes to take two cases of fancy and two of dark, after you have reassured him that you will be over again in 60 days or so, and will pay him 10 cents each for the empty cases if he keeps them in good condition.—Gleanings in Bee-Culture.

[Concluded next week.]

Foul Brood in the San Joaquin Valley, Calif.

Some pertinent and interesting facts are brought out by the county inspection for the purpose of stamping out foul brood, a bacterial disease of great virulence and destructive ability.

IN FRESNO COUNTY.—J. A. Roberts worked at inspection from April 11 to May 28. He lost his first two weeks' record, but in five weeks he visited 150 places, inspected 2,038 colonies, and found 196 infected with foul brood. He says he found none of the disease west of the West Park colony, but two north of Fresno, and they had been moved from a diseased district. He found nothing east of Malaga, north or south of Easton. He confined his work principally to that section of the country where the disease existed.

NOTES ON THE DISEASE.—Foul brood is a disease that kills the young bee in the larva state, after it has been captured. The dead larva becomes a shapeless mass, of a coffee color, and, by running a straw into it, you will find it thick and stringy. It will stretch out, and, when it pulls in two, will fly back like rubber. Brood that dies from any other cause is watery and generally of a lighter color. The young bee retains its shape, and will not string out, as in foul brood. Any one who will watch can soon learn to take care of his bees and stop the disease should it get started.

HOW THE DISEASE SPREADS.—He finds a great many people who have only a few colonies, who take no care of them, and do not see the brood, and when one colony dies from the disease the other bees in the neighborhood carry off the honey, and so the disease is scattered; and it goes on until it will destroy the bee-industry if not checked. He is confident that a good bee-inspector can eradicate the disease in two years more by working two or three months each year. It has been done in other places, and can be done here. He thinks, as he has quit the work, that the disease will not spread much before next spring, when he thinks some one ought to be appointed to look after it as soon as the spring will justify.

IN TULARE COUNTY.—Josiah Gregg was inspector, and he worked from April 18 to June 4. He inspected 4,478 colonies—an average of 127 colonies per day. He found nine colonies infected with foul brood, and took the proper measures to have them properly attended to.

THE COUNTY BEE INTEREST.—There are about 10,000 colonies of bees in Tulare county. Among the larger apiaries are the following: J. F. Boldau, 430 colonies; R. H. Fray, 343; Richard Hyde, 233; J. C. McCubbin, 278; S. B. Halton, 180; Henry Miles, 150; Carmichael & Thompson, 175; Hunsaker & Nelson, 140; William Wilkinson, 126; Clark Decker, 104. The average amount of honey extracted from each colony for the year 1897 he finds to be about 100 pounds.

INSTANCES OF HONEY-YIELD.—Clark Decker, who lives near the Lamberson ranch on the west edge of the county,

near Waukena, had 84 colonies last year. From these he got six tons of extracted honey, and one ton of comb honey, or 14,000 pounds altogether. This year he has 104 colonies, an increase of 20. Most of this large amount of honey is shipped away to San Francisco and eastern points. Some of it realized 5 cents a pound the past spring, tho most of it sold at less than 4 cents.—Pacific Rural Press.

CONVENTION PROCEEDINGS

Report of the Utah Bee-Keepers' Convention.

The Utah Bee-Keepers' Association held their semi-annual meeting April 5, 1898, in Salt Lake City.

Pres. Lovesy called the meeting to order, the minutes of the October meeting were read and approved, and also the financial report.

The election of officers resulted as follows: President, E. S. Lovesy; Vice-President-at-large, George Hone; Secretary and Treasurer, John B. Fagg, of East Mill; Assistant Secretary, G. E. Garrett.

The following county vice-presidents were chosen: Salt Lake county, Frederick Schach; Utah, William Peay; Wasatch, J. A. Smith; Davis, Wm. C. Smith; Boxelder, J. Hansen; Weber, C. O. Falkman; Juab, Thomas Bilston; Sevier, C. Canutesen; Washington, Mrs. Woodbury; Tooele, Benjamin Barrows; Cache, Henry Bullock, and Morgan, T. R. G. Welch.

Pres. Lovesy spoke in part as follows:

"I can congratulate our bee-keepers that in some respects we meet under more favorable conditions; still there are other conditions that we would very much like to see improved. We now have a good foul brood law, and we should get it in force all over the State, especially where there is any danger of disease. This law can be made a practical success for the benefit of our bee-keepers and for the protection of the bee-industry, so that if there is any failure in the matter the fault will lie with the bee-keepers.

"The Langstroth monument fund—some of our bee-keepers are interested in this matter. Out of 100,000 or more bee-keepers in the United States, one would think that something handsome should be done to mark the last resting place of our departed friend, the greatest of all American bee-keepers.

"Co-operation in the purchasing of supplies and in the marketing of our products are questions which I hope this convention will take into consideration.

"Adulteration by middle-men, and the getting of our products on the markets at a reasonable price, are the most interesting and difficult problems that confront the whole of the agricultural pursuits of the United States to-day. Some claim that over-production is the cause of the trouble; while I admit this to be true to some extent, there are other vital questions that seem to be lying out beyond this in obscurity, which the people seem slow to grasp or grapple with.

"For the general benefit of the bee-industry of our State I hope to see a good exhibit of our products sent to the Trans-Mississippi Exposition at Omaha."

Mr. Welch said that foul brood inspectors were needed to look after the bees of those that do not make a business of bee-keeping. He cited a case through which the disease was scattered all over a neighborhood. Messrs. Butler, Corwall and Johnson also discuss this question at length.

Mr. Smith spoke in regard to buying sections and other supplies. He said that bee-keepers should buy them in car-load lots. The subject of supplies in general were discussed by Messrs. Peay, Woodmansee and Schach, the prevailing opinion being that nearly all supplies except sections are as good and cheaper at home.

J. B. Fagg spoke on the adulteration of honey, and said that all packages should be labeled exactly what they contained; that an effort was now being made to get a National law passed on this subject. Mr. Lovesy and others also spoke on this subject. It was shown that a law of this kind would be of much benefit to the bee-industry, as the practice of mixing glucose with the best grades of honey was carried on in Eastern cities.

Mr. Terry spoke on the marketing of our bee-products. A general discussion followed, and while it was shown that

much good could be accomplished in this matter if a strong combination in the interest of bee-keepers could be formed, no definite conclusions were reached.

J. B. Fagg, Reporter.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. O. MILLER, MARENGO, ILL.

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Getting Bees Into the Sections.

My bees are doing very poorly this season. I have taken but 10 pounds of honey from 4 of them so far. I also have one colony that does not go into the super—only sit around and will not work in it. What can I do about it? Would it be a good plan to take out brood-frames to extract, and give them empty ones in such a case?

ILLINOIS.

ANSWER.—Thousands of bee-keepers are in the same predicament. The season is a poor one, and altho there may be plenty of flowers, the flowers do not yield honey. There's nothing in the world for you to do but to bear it patiently and hope for a better season next year—unless, indeed, the situation is so desperate that you must feed to get them through the winter. Of course, in some localities, the season is excellent, but according to reports in general, this is probably as poor a season all over the country as was ever known.

Rearing Drones in the Fall.

How can I rear drones in the fall to mate with late queens?

SUBSCRIBER.

ANSWER.—After the close of the harvest, the workers usually set earnestly to work to kill off all useless consumers, and it's a difficult thing to get them to start a fresh lot. You may do something toward it by feeding a colony regularly for some time, thus inducing them to believe a harvest is on again. An old queen in a strong colony promises more of success than a young queen, or an old queen in a weak colony. An unusual amount of drone-comb in the center of the brood-nest will be an additional inducement.

Better not depend on rearing late drones, but rather depend on saving the lives of those now on hand. That's a comparatively easy matter. Give any drone-brood you may now find in any hive to a queenless colony, and the drones will be respected till they have a fertilized queen. Postpone that time by taking away from them their queen-cells, giving them a fresh frame of unsealed brood once a week.

Wintering in a Building—Wax in a Brood-Chamber—Value of Foundation, Etc.

1. Would you advise putting 19 colonies of bees (for winter) in a frame building 8x10x7 feet high, built of stock boards and battened, with a tight floor six inches from the ground? Chaff cushions to be put over the bees and straw packed between the hives; ventilation to be provided at the roof.

2. Or, would it be better to fill up with earth to the floor?

3. Is it a good plan to bore a small hole in the end of the telescope-cover to provide ventilation?

4. In melting up the combs of the brood-chamber, how much wax ought there to be?

5. How much do you consider foundation in full sheets worth in the brood-chamber? That is, in time and honey.

6. The bees have stored something in with the clover honey this year, that is as dark as buckwheat. Is it honey-dew?

ILLINOIS.

ANSWERS.—1. Buildings above ground for wintering bees have not generally been very successful. For your locality, if a good cellar can be had, you may do well to try that.

2. Probably it would make little difference.

3. Yes, altho generally the fit is not so close as to make it necessary.

4. That depends something on the manner of melting. If the combs are very old, the cocoons in the cells are like so many little sponges, and will soak up a large part of the wax.

If the combs are broken up fine and thoroughly soaked with water, you will get out most of the wax. At a guess, I should say that an average brood-chamber might yield a pound or a pound and a half of wax. But I really know nothing positive about it, and will be glad if any one who has positive knowledge from experience would correct my figures.

5. I don't know. Probably the chief value is in getting straight combs with no drone-cells. Good authorities tell us that there is very much more gain in having foundation for the last half of the combs built by a swarm than for the first half. That is, that they will build the first half of their combs very nearly as soon without foundation as with it, and yet it is so important to have combs that are to last a life-time just right, that it may be better to use foundation for all.

6. Most likely. It seems to be a somewhat general complaint.

Feeding to Finish Sections.

I would like to know how to feed bees to finish the sections?

IOWA.

ANSWER.—Use a strong colony with a young queen, preferably of black blood, dilute the honey to be fed—I think those are the principal points to be looked after—using a feeder that contains a goodly amount. W. Z. Hutchinson is one of the few who say they can practice it profitably. I confess I can't, and I very much doubt if you will find it advisable.

Candy for Queen-Cages.

How is the candy made that is used in queen-cages?

TEXAS.

ANSWER.—The Schultz or Good candy, such as is used in queen-cages, is not difficult to make. The materials used are powdered sugar and the best quality of liquid honey. Better have the honey heated—perhaps it is better to say warmed—for if you scorch it the candy will be bad. It can be more quickly made if well warmed. Start with very little honey mixed in with the sugar, for if you're not careful you'll have it so soft that you'll have to mix in so much more sugar to get it stiff enough that you'll have a larger batch of candy than you desire. Add a little sugar at a time, stirring it and kneading it, till you get it into a stiff dough. After it stands a day or so, you may find it thinner than you supposed, and you can knead in more sugar. When you get it stiff enough so it will lie for a day in a dough-like lump without running, it's all right for use.

Why Did the Colony Leave?

How can I manage a colony of bees when they will not stay in the hive with plenty of honey and young brood? I had a colony that would leave the hive and go off. It first went to a neighbor's bees, in with a colony, then came out and settled on an apple tree. Then I brought them back and clipped the queen's wings. They then would come out every day and go back and leave the queen crawling around on the ground. They kept on for several weeks, going out and staying about ½ of an hour every day, then I would get the queen, and when they were returning I would let her out and she would go in. What was the trouble?

NORTH CAROLINA.

ANSWERS.—Altho you don't say so, the fair supposition is that this was a swarm that refused to stay in the comfortable quarters provided for it. You say there was plenty of honey and brood. That was probably what made the whole trouble. When a colony swarms, if you return it to its own hive it will swarm out again. The bees want a place to commence house-keeping afresh. You gave them "plenty of honey and young brood," and they thought it was just about the same as they had left, so they would have none of it. If the supposition is correct, the remedy is plain. Don't give them a "hive full of honey." Give them a clean empty hive. Bees are freaky creatures. Sometimes they might not object to quite an amount of honey and brood, and again they may object seriously, and the more times you put them back the more determined they are not to stay. If the hive is in a hot place, that makes it all the worse.

The McEvoy Foul Brood Treatment is given in Dr. Howard's pamphlet on "Foul Brood; Its Natural History and Rational Treatment." It is the latest publication on the subject, and should be in the hands of every bee-keeper. Price, 25 cents; or clubbed with the Bee Journal for one year—both for \$1.10.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

UNITED STATES BEE-KEEPERS' UNION

Organized to advance the pursuit of Apiculture; to promote the interests of bee keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., George W. York; Vice-Pres., W. Z. Hutchinson; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GENERAL MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Omaha, Nebr., Sept. 13, 14 and 15, at the Delone Hotel, Cor. 14th Street and Capitol Avenue.

VOL. 38. AUGUST 11, 1898. NO. 32.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

A Mistake is made by a few subscribers every year in asking that their paper be discontinued on account of the poor season. This is a very short-sighted policy. Surely any bee-keeper can spare one dollar a year for a bee-paper, whether he has a honey crop or not. He really cannot afford to do without the paper, even if he has no crop, for during the year he fails to get the paper he will likely miss enough good advice, short cuts described, new things brought out, etc., to pay for many years' subscription when a good crop of honey comes his way.

We always dislike to discontinue a subscription for any cause except when a subscriber goes into some other business requiring all his time; and yet there are some who are so interested in reading about bees that they will have a bee-paper even if not keeping any.

In many localities this year there is a failure of the honey crop. Such failures come no matter how careful and diligent the bee-keeper has been. Of course the only thing to do is to "grin and bear it," hoping that next year the bees will be able to do better. In the meantime prepare for doing better work, by reading and planning.

If you are fortunate enough to have honey to sell this year, study to get the most out of it financially. Much good advice on marketing is published every year.

Omaha Exposition and Convention.—Mr. Louis R. Lighton might appropriately be called a "Lightoning" shorthand writer. He it was who reported the national

convention of bee-keepers at St. Joseph, Mo., in 1894—the report that the Secretary of that year failed to turn over for publication. We presume he has it yet safely tucked away somewhere. But Mr. Lighton did his part all right. He has been engaged again, this time to report the convention at Omaha, Sept. 13, 14 and 15. From a letter Mr. Lighton wrote us July 26, we take the following, which is of interest just now:

The apiary building at the Exposition is one of the finest buildings on the grounds, and the exhibits are *superb*. Messrs. E. Whitcomb, L. D. Stilson, and August Davidson—all of Nebraska—are putting forth every effort to make the exhibit a splendid success, and they are succeeding.

Too much cannot be said in the way of inducing bee-keepers to attend the convention of the United States Bee-Keepers' Union. Nebraska will send at least 500 delegates.

Dr. Miller and Mr. A. I. Root will be interested to know there are "talking seals" in connection with the Exposition. Now keep them away, if you can!

LOUIS R. LIGHTON.

The last paragraph settles it—Dr. Miller and A. I. Root will be there. And we shouldn't wonder if Editor Abbott will be found "s(t)earing" around somewhere near to "talk" with those seals.

Our Visit to Dr. Miller's, July 27 and 28, we promised last week to tell something about in this number. For the benefit of the new readers we will say that the Doctor lives in McHenry Co., Ill., about 65 miles northwest of Chicago. He has three apiaries—one at home, one three miles north, and the other five miles south. In all there are some 300 colonies, 120 being at the home apiary.

Last year the Doctor's crop was over 17,000 pounds of comb honey; this year—well, it will likely not reach 1,000 pounds. Tho there was a profusion of white clover bloom—which is his main dependence—it seemed to yield no nectar, or at least the bees failed to work on the blossoms to any great extent.

We saw in the Doctor's shop a pile of 24,000 sections all in supers, with foundation, ready to set right on the hives when needed. But they will likely wait until another year to be used.

Many of the Doctor's hives are very old, and weather-beaten, warped, etc., and the frames in them are just a little different in size from the standard Langstroth— $9\frac{1}{8} \times 17\frac{1}{2}$. Desiring to have all on the regular size frame, he was changing them over on thick-top frames, both end and side spaced—at the ends staples being used, and at the sides nails driven in to within $\frac{1}{4}$ inch. The bottom-bars of his new frames are the same width as the top and end bars, and heavier than usually made. In them he had full sheets of foundation, not wired, but with four or five perpendicular splints of wood sunk into the foundation after first being boiled in beeswax to prevent the bees gnawing them out.

He was using a new ventilated cover of his own invention. It is made of $\frac{3}{8}$ -inch stuff, the under pieces being crosswise of the hive, and the upper lengthwise, with a $\frac{3}{8}$ strip nailed between them around the edges, thus leaving a hollow space. The whole top is then covered with tin, and painted white. The upper lengthwise pieces extend beyond the lower crosswise pieces about an inch at one end, which serves for a handhold to lift the cover from the hive. The whole thing, nailed and painted at the factory, costs 25 cents. But as such a cover cannot possibly warp or leak, and will last a lifetime, it is quite inexpensive.

The forenoon of the first day we spent in the apiary clipping queens' wings and in other manipulations, indicated as necessary by the Doctor's annual record book. In this book he has a complete record of each colony in connection with its number. It is his constant guide and companion during the season, and materially aids him in his work with the bees. He

has saved these books for the past 25 years, and they form an interesting library of themselves.

Miss Emma Wilson, the Doctor's sister-in-law, has been his chief helper in the apiary for many years. She was formerly a school-teacher, is thoroughly informed on all matters pertaining to bees and their management, and could write most helpfully out of her large experience—if only she could be induced to take up her pen.

Mrs. Miller is in every way the Doctor's equal in goodness and general goodness. But we almost incurred her displeasure by suggesting that she allow us to put her picture in the Bee Journal with that of the Doctor, as they appeared one day when Editor E. R. Root was there and took several snap shots at them.

We might write further of our pleasant two days' stay at the home of the apiarian "Sage of Marengo," but will close with a reference to one of the worst cases of robbing the Doctor ever had, and of which he was heartily ashamed.

It occurred the first day we were there. We had helped the Doctor put more hive-bodies with combs containing some brood and honey on a pile that he had already placed in the care of a colony—perhaps six stories high. But the colony was not sufficiently strong to care for so many combs, especially when some of the old hives had ample cracks and holes that it was somewhat difficult to close up.

Well, the robbing began about noon, and it was a sight. From top to bottom of the pile the robber-bees just swarmed. The Doctor soon got a sprinkling-can and several pails of water and began to put it on the pile of hives and the robbers most thoroughly. They had a complete and continuous bath for quite awhile. Then a large armful of straw was brought, and thrown on the hive-entrance and wet down.

Well, the shower-bath was kept up almost all the afternoon, and by night the insurrection was pretty well put down. The next morning all was lovely again.

Strange as it may seem, tho' all the other hives in the apiary were raised up on inch blocks, not one of them was attacked by the persistent robber-bees, and that with no honey coming in.

What the Union Ought to Do?—Some time ago this question was asked in the Question-Box department of this journal:

"What would you advise in order that the membership in the United States Bee-Keepers' Union may be so increased as to make it of the greatest possible good to the bee-keeping pursuit?"

In reply to the foregoing, Hon. R. L. Taylor said:

"You have the cart before the horse. 'Make it the greatest possible good' to its membership, then its membership will be sufficiently increased."

Editor Hill, in the American Bee-Keeper, in referring to Mr. Taylor's answer, wrote thus:

"Mr. Taylor is not in the habit of vocalizing his thoughts without due consideration, and we are, therefore, led to cherish the hope that his full ideas in this connection were not expressed in the Bee Journal. Hence we beg to propound a supplemental question: How can the Union be made of any possible good (not to say 'the greatest') to its members without an increased membership?"

Whereupon Mr. Taylor replies to Mr. Hill's "supplemental question" as follows, in the Bee-Keepers' Review:

"I answer, the membership of the Union is already large, and its resources abundant. Let its officers make a determined and effective campaign, offensive and defensive, against the evils and dangers that threaten bee-keepers and bee-keeping, and doubters will fall in rapidly enough."

We beg to correct Mr. Taylor in his first sentence above. The Union's membership is not large, nor has it abundant resources. There are not yet 500 members, so there can't be \$500 in the treasury. As one of the Union's

officers, we do not think it worth while to begin much warfare with so little ammunition on hand. Adulteration of honey is the great evil threatening bee-keepers most, and that should be attacked next, but surely Mr. Taylor would hardly begin a fight against such an enemy without more than \$500 in the treasury. In our opinion there should be \$1,000 to begin with, and a possible \$1,000 more to draw upon when needed.

Mr. Taylor is an able lawyer. He knows how expensive is efficient legal talent. We think he would hardly want to commence the prosecution of even one big adulterator here in Chicago, and expect to win, with less than \$500 at his command. Why, we could name several large honey-adulterating firms here that would simply laugh at the presumption of an organization that numbers only a few hundred members, with an equal number of dollars, attempting to fight their millions of dollars!

"A determined and effective campaign" can hardly be waged "against the evils and dangers that threaten bee-keepers and bee-keeping" until the United States Bee-Keepers' Union is in a position to back up its efforts with the same kind of shot and shells as the foe can hurl—dollars, dollars, dollars. It takes money to conduct a war, as the United States is finding out very fast these days. The Union might as well learn that from observation, as it would be compelled to learn it by actual experience.

As Mr. Taylor is not a member of the United States Bee-Keepers' Union, we must conclude that he is one of the "doubters" he mentions in his last sentence. It seems to us that it would be far better for him to "fall in" and help increase the membership and treasury by sending his dollar to General Manager Secor, instead of staying on the outside and "doubting."

Against Ants in Hives, Le Progres Apicole advises the use of chloride of lime in little dishes in which stand the feet of the bench that supports the hives.

The Department of Criticism in the Bee-Keepers' Review seems to be given up almost entirely to controversy between the critic and Dr. Miller. Both the men might be better employed.

Do Bees Move Eggs?—H. Rohrs, on page 381, thinks he has a case that proves they do, but R. L. Taylor, in the Bee-Keepers' Review, thinks the eggs found in that case were the work of an enterprising worker.

Guarding Against Foul Brood.—Editor Holtermann thinks there is no danger of getting foul brood through a queen, but that there may be danger through the food that comes in the queen-cage. So he would not let the bees have the food that comes with a queen.—Canadian Bee Journal.

Contraction of the Brood-Nest.—The editor of the Bee-Keepers' Review, with characteristic frankness, says he was wrong in thinking contraction of the brood-nest had never been practiced with established colonies at the time of putting on supers. He doesn't believe in such contraction, but he does believe, as do many others, in contraction at the time of hiving swarms.

A Conundrum.—The July Canadian Bee Journal quotes the item from page 330 in "Beedom Bolled Down," and remarks, "Friend York is attacking a man of straw. Where did Holtermann ever say that Root said so? In reply to that conundrum another may be asked: 'Where did York ever say that Holtermann ever said that Root said so?' And how can York be attacking a man of straw, when no attack whatever

is made? If Mr. Holtermann will again read carefully the item he has quoted, he will find that it is not an attack, but merely an effort briefly to chronicle some of the thrusts and parries in the engagement between Messrs. Holtermann and Root.

Wintering Bees on Solid Combs of Honey. D. W. Heise says, in the Canadian Bee Journal, he has seen practiced with entire success, altho formerly he was an utter disbeliever in the practice. In that connection he takes occasion to call this department of this paper "Bee-Doom." If that young man finds this Boiler after him with his little stirring-stick, he will think it will "Bee-Doom" enough for him.

Making Bees Fly in Winter.—D. W. Heise says it sometimes happens that on a day in winter when the temperature rises to 50°, one colony will rush out and have a good flight, while another sitting beside it, apparently like it in every respect, remains dormant. In such case he thinks it good practice to stir the latter to action by removing the cap and top packing, letting the sun shine directly on the quilt.—Canadian Bee Journal.

Systematic Pilfering.—The item under that head on page 394 of this journal is quoted by Editor Holtermann, of the Canadian Bee Journal, the item ending by saying, "But by all means, Mr. Holtermann, be sure you first follow the instruction given by the Great Teacher, in Matthew xviii, 18." To this the editor replies:

"Did it hit. When the editor of the Canadian Bee Journal transgresses as per above, he will be obliged if you will let him know it."

No wonder Editor Holtermann felt guiltless of any charge on reading Matthew xviii, 18, but if he had read the verse intended—the 15th verse of the same chapter—he would have found these words:

"Moreover, if thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother."

That remark, "Did it hit," (by the way, Mr. Holtermann, you ought to use an interrogation point after "Did it hit," also after another question in the same column)—that remark makes this Boiler feel sure he is the guilty party. He confesses the crime, is sorry for it, promises never to do so again, asks pardon of the editor of the Canadian Bee Journal, and will anxiously watch the editorial columns of that paper to see that pardon duly proclaimed.

HON. EUGENE SECOR, of Winnebago Co., Iowa, wrote us July 27: "Honey is going to be a light crop."

HAHNEMANN, a German tailor still living in South America, was the inventor of the queen-excluder.—Gleanings.

MESSRS. R. H. SCHMIDT & Co. wrote as follows, Aug. 4, regarding their trade this year:

"We have had a very large rush of business this season, exceeding that of previous years, and we are now making plans for enlarging our plant."

MR. JOHN CLINE, of Lafayette Co., Wis., is an old bee-keeper. He wrote us thus when sending in a new subscriber lately:

"I am taking the Bee Journal—can't do without it. I have been tending bees for 66 years, and think I know something about how to get along with them, but I find something new and valuable in the Bee Journal."

DR. PEIRO, as we announced his intention some time ago, started for the Pacific Coast last month. After reaching Salt Lake City, Utah, and seeing Mr. E. S. Lovesy, the President of the Utah Bee-Keepers' Association, he wrote us from there as follows, July 28:

DEAR FRIEND YORK:—You see where I've come to. Just arrived this afternoon. I lookt much like the chimney sweeps

of old, so begrimed with the sweat and dust of travel. But a fine bath and fresh linen soon improved my personal feelings. It was after so exhilarating a performance that I called on Mr. Lovesy. I found him very cordial and up to his ears in honey. He states the flow has been very good, and the evidence shown me quite proves the statement. I never saw nicer, whiter alfalfa comb honey anywhere. I got a pointer or two regarding the prevention of swarming, which I will tell you about when we meet again.

I am glad to have met Mr. Lovesy, and only regret I could not avail myself of his generous invitation to visit his apiary, some 15 miles distant, among fields of sweet clover and alfalfa.

So far on my journey I have had a fine trip, but I have reasons to believe that henceforth I'll strike it dry and hot.

Kindest regards to you, Mrs. Y., and office force.

Fraternally yours,

PEIRO.

As many of our readers know, Dr. Peiro is a good neighbor of ours. He expects to be gone about a month, and will likely call on other bee-keepers. We shall expect quite an interesting report from him when he gets back from his "tower" through the great Western country.

MR. A. I. ROOT'S CHICAGO VISIT we mentioned last week. The following is a little description of what he saw in one or two places in this great city:

On account of the rain when arriving I stopt at the Great Northern Hotel, near the depot. It is 18 stories high, and things are in fine style, I tell you. I should like to show you an electrical device that turns out the electrical lamps when you take the key out of the door of your room. If you remove the key from the door when you are on the *inside*, the lights don't go out.

When you go into the bathroom it is lighted up and stays lighted until you go out; as soon as you go out and shut the door the lights are out. This modern hotel has many similar surprises.

I am writing these notes on a shady seat in Lincoln Park, close beside the Aquatic Garden. Water-lilies of gorgeous hues, and as large as dinner-plates, are all about me. Yes, and the celebrated Victoria Regia is near, and in full bloom, too. Almost all the water-plants are in bloom. The water-puppy is a pretty plant, and seems to thrive at common temperature. Some water hyacinths of immense size, far larger than those in Florida, are making a beautiful show just now.

I came over here on a wheel that the editor of the American Bee Journal was kind enough to loan me. Very early in the day I asked a policeman (near the big hotel) if he could tell me where I could rent a wheel this early. He thought awhile and then said, "Oh, yes! I can fix you out exactly; there is a fellow that sleeps in that place right over there, just to catch such trade, but you will have to make a racket to get him up." Now this policeman was very kind and gentlemanly with the exception of that blank word. Would it be too great a thing to expect of the Chicago police, or would it be too great a task for them to consider that the stranger asking for information *might be a christian*, and that he *might be greatly pained to hear talk like that?*

I am afraid I have said it before, but I *must* say it again, never before in my life have I seen such entrancing, gorgeous beauty as the scene before my eyes, as I sit contemplating an acre or two of bedding plants in Lincoln Park. The flowers and plants are not new, but their grouping and contrast form a harmony of colors that I did not before know was possible. Several things perhaps combine to give me this *thrill* of joy and pleasure.

You see it rained last night, and the warm rain was just what the plants "thirsted" for. I have had a wheel ride and then a delicious nap here in the shade of a tree, with the lake breezes "fanning my brow." Then there are boys and girls all about me. Little ones are trudging along delightedly with their pails and mas, lunch baskets, tin pails, etc., for they have come out on the street cars and are to have a picnic in this beautiful place. Besides the flowers there are animals and birds; birds of plumage that rivals the flowers, and beautiful fountains are playing and splashing on this warm July day.

I don't know what this great and beautiful park cost, but say what you choose of Chicago she has done a grand and noble thing for her people, especially for her *children*, in making this beautiful spot where they can get pure air, exercise and health. I have visited the parks of nearly all of our great cities, and I would put Chicago ahead of them all.

A. I. ROOT.

FOR THE READERS OF THE AMERICAN BEE JOURNAL.

PROFITABLE BEE-KEEPING, WITH HINTS TO BEGINNERS.....

By Mr. C. N. White, of England,

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

Mr. White is owner of one of the largest aparies in the country where he lives, and has made a life study of the subject. He is also lecturer, under the Technical Education Scheme, to several County Councils in England. He will treat the subject in a

Series of Nine Illustrated Articles :

- 1. General and Introductory. 2. Bees. 3. Handling Bees. 4. Swarming. 5. Hives. 6. Foundation. 7. Supering. 8. Diseases. 9. Wintering.

This is a series of practical articles that bee-keepers of the United States will not want to miss reading. They will appear only in the AMERICAN BEE JOURNAL.

We want our present readers to begin at once to get their neighbor bee-keepers to subscribe for the Bee Journal for the last six months of 1898, and thus read the articles by Mr. White. In order that all may be able to take advantage of this rare opportunity to learn from a successful and practical English authority on bee-keeping, we will send the American Bee Journal for

The balance of 1898 for only 40 cents-- To a NEW Subscriber--thus making it

SIX MONTHS FOR ONLY FORTY CENTS--

Which can be sent in stamps or silver. If you are a subscriber already, show the offer to your bee-keeping neighbors, or get their subscriptions, and we will give you, for your trouble, your choice of ONE of the following list, for each NEW 40-cent subscriber you send :

For Sending ONE New 40-cent Subscriber :

- 1 Wood Binder for a Year's Bee Journals. 2 Queen-Clipping Device. 3 Handbook of Health--Dr. Foote. 4 Poultry for Market--Fan. Field. 5 Turkeys for Market--Fan. Field. 6 Our Poultry Doctor--Fan. Field. 7 Capons and Caponizing--Field. 8 Kendall's Horse-Book. 9 Mullen's Horse-Book. 10 Foul Brood--by Dr. Howard. 11 Silo and Silage--by Prof. Cook. 12 Foul Brood Treatment--by Prof. Cheshire. 13 Foul Brood--by A. R. Kohnke. 14 Muth's Practical Hints to Bee-Keepers. 15 15 "Honey as Food" Pamphlets. 16 Rural Life.

For Sending TWO New 40-cent Subscribers :

- 1 Potato Culture--by T. B. Terry. 2 Green's Four Books. 3 Ropp's Commercial Calculator. 4 Dr. Tinker's Bee-Keeping for Profit. 5 40 "Honey as Food" Pamphlets. 6 Winter Problem in Bee-Keeping--by Pierce. 7 Hutchinson's "Advanced Bee-Culture. 8 Dr. Brown's "Bee-Keeping for Beginners". 9 Blenc-Kultur--German. 10 Bees and Honey--160 pages--by Newman. 11 People's Atlas of the World.

All New Subscriptions Begin July 1.

Please remember that all the above premiums are offered only to those who are now subscribers, and who will send in new ones. A new subscriber at 40 cents cannot also claim a premium.

Now, let every one go to work, and help roll up the largest list of subscribers the old American Bee Journal ever had. It can easily be done if ALL who possibly can get a few new subscribers will kindly do so.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Be It Known

To all Men, we are prepared to fill orders promptly for

CHOICE QUEENS of the best strains of Golden or Leather-Colored Italian.....

Tested \$1.00; Untested--one, 75c; three, \$1.50. After July 1, 50c each. Remit by Express Money Order, payable at Barnum, Wis. One and two-cent stamps taken. Address,

Van Allen & Williams, BARNUM, WIS. Please mention Bee Journal when writing.

Bee-Hives, Sections, Shipping-Cases--everything used by bee-keepers. Orders filled promptly. Send for catalog. MINNESOTA BEE-KEEPERS' SUPPLY MFG. CO., Nicollet Island, Minneapolis, Minn.

Short Crop of Honey.

The honey crop will be short here this year--not half as much as last. Bees are in good condition, very little swarming this year, as well as little honey. What honey I have taken is very fine, all white clover. We may get some honey in September and October from asters, but it will be dark.

W. S. FEEBACK. Nicholas Co., Ky., July 26.

Clipping Device--Wired Frames.

The Monette queen-clipping device is a good thing for catching and clipping queens. At times, however, a number of bees are caged with the queen, which often go up the cone before the queen, and delay work somewhat. The wooden stopper could not be pulled out to let those bees out, as the tin strips coming from the tin bottom are fastened to it. I therefore made an improvement on mine. I unwound some of the top of the cone and bent it on two sides at right angles with the cone, forming a T; to these I fastened the strips of tin. In this way the wooden stopper is free to be removed when letting out bees that run up the cone before the queen. If the device is made this way I think it is twice as good.

When wiring frames having somewhat

soft end-bars, the wire will cut the wood. I have never tried putting in books around which to stretch the wire, as I don't like them. I prevent such cutting by driving a 3/4-inch brad into the end-bar from the side, either just above or below the hole, according to which side the wire will cut. This practically prevents all unnecessary cutting.

A small staple or a large-headed tack driven on the outside of the end-bar where the wire will cut, will also prevent cutting the wood; but I like the first plan the best. **F. ADELBERT.**

Flathead Co., Mont.

Honey Crop a Failure.

The honey crop is a failure in this part of Missouri; the severe drouth of last season killed the clover. We look for a big crop next year, as the rains have caused the clover to spring up everywhere—I never saw so much. I could not very well do without the American Bee Journal. **W. N. KING.**
Greene Co., Mo., July 25.

Very Light Crop of Honey.

The honey crop is very light in this part of the country. I have only 2/4 of a crop as yet, and the prospects are poor at present, on account of no rain. If we don't get rain soon we will have no fall flow. **N. RICHARDSON.**
Steele Co., Minn., July 26.

Bee-Keepers in Hard Luck.

I have been all over Onondaga County and several other counties, and the bee-keepers are in hard luck—no honey is the cry. Last year was about half a crop. Basswood failed, and very little sweet clover in some localities, makes bad luck. Where sweet clover is plentiful they have a pretty good crop. These people can get good prices if they try, as there have been two short crops in succession. There are lots of bee-keepers who never take a bee-paper. This part of the county is overstocked with bees; some of the apiaries will be empty of bees next spring. My bees are in good condition and gathered some surplus—good bee-paper and good queens, you see. **J. MUNROE QUICK.**
Onondaga Co., N. Y., July 26.

Season Disappointing.

The season here has been very disappointing. There was an abundance of clover bloom, but the weather was too unsteady and too cool. The basswood was very late in blooming, and as there was the promise of a great bloom, we had big hopes of large returns from that source, but on the night of July 10 there was a heavy frost, causing ice to form on water as thick as glass. The basswood was just then beginning to open, but the bees worked only a few days on it, and quit it when it was in full bloom, so that we got but very light returns from that source. Whether the failure was caused by the frost, or the severe drought that followed, it is hard to determine.

My yield per colony, spring count, will not reach 75 pounds, but the honey is much thicker than it was last year.

Swarming was not excessive, but the bees were very cross, and no work could be done in the yard without a veil, and my man refused to work without gloves. I put on a quantity of sections at the commencement of the basswood season,

Sweet Clover

And Several Other Clover Seeds.

Meeting of Sovereign Grand Lodge, I.O.O.F., Boston, Mass., Sept. 19 to 24, Inclusive.

For this occasion the Nickel Plate Road will sell tickets at rate of one fare for the round-trip. Tickets on sale Sept. 16 to 18, inclusive, good returning until Sept. 30, inclusive. For particulars, address **J. Y. Calaban,** General Agent, 111 Adams Street, Chicago, Ill. Telephone Main 3389. (59-32-6)

and now have hundreds of them partly filled, or just begun, and I am about disgusted with that feature of the business.

To prevent after-swarming, I cut out the queen-cells 8 days after the swarm issued, and now find the majority of these colonies queenless.

The demand for honey here is very limited, and is difficult of sale at 8 cents for extracted and 12½ cents for comb.

A. BOOMER.

Ontario, Canada, Aug. 1.

Leveling Unfinish Sections, Etc.

Will you allow me to help Dr. Miller to answer "Iowa," on page 454? "What should be done when the melter forms a cap over the comb?" I answer, make it hotter, so it will melt the comb on touching it, then lift it up quickly.

Also "Arkansas," on page 422. To his first question, it seems to me that Dr. Miller doesn't "catch on." I was in the same trouble, provided I am right. Cut strips of sections ⅜ of an inch wide—tack them on the side of the super where the sections meet; tack them on to stay, which will give more bee-space.

J. H. STEPHENS.

Fremont Co., Iowa.

Basswood and Sweet Clover Yield.

Our yield from basswood and sweet clover has been quite heavy, in fact somewhat beyond expectations. Sweet clover is still yielding, but the honey is colored quite dark with wild verbena (*V. stricta*), so much so as to render it unfit for sale. The sweet clover taste has been killed in it, leaving only a heavy, dead, sweet taste.

Fall flowers are blooming quite plentifully, even though it is early in the season.

I have had but two swarms this season, and feel confident the reason is because I gave every colony plenty of room and kept the hives well ventilated.

I sold all of my honey to the Douglas County and State Exhibits in connection with the Trans-Mississippi and International Exposition.

LEWIS R. LIGHTON.

Florence Co., Neb., July 26.

Report for 1897.

Last year I had 8 colonies, and got something over 400 pounds of comb honey. I had 100 pounds from my best colony. This year I have 10 colonies, and they are working in the supers.

W. H. DUNLAP.

Crawford Co., Ark., July 25.

Bees Doing Little—Swarming.

I have eight colonies of bees which were wintered on the summer stands. They came through the winter all right. Bees are doing but very little here this summer. During fruit-bloom it was too wet and cold; then after the white clover came it turned so dry and hot that the clover all burned out. There was not very much basswood bloom. There was a week or ten days during which the bees did not do anything but loaf. The last few days since the rains began to come they have been bringing in some pollen during the forepart of the day.

On page 3, G. M. Doolittle says: "If more swarms are allowed, they come forth two days after, or from the 8th to the 9th day after the first, and never later than the 16th." Now, I do not

Excursion to Boston.

The Nickel Plate Road will sell excursion tickets from Chicago to Boston and return for trains of Sept. 16, 17 and 18, at rate of \$19.00 for the round trip. Tickets will be valid returning until Sept. 30, inclusive. On account of heavy travel at this particular time, those desiring sleeping-car accommodations should apply early to J. Y. Calahan, General Agent, 111 Adams St., Chicago. Telephone Main 3389. (58-32-6)

know whether I understand him or not, but I will give my experience with one colony last year. In the early part of June, 1897, a colony sent out a swarm, and on the 16th day afterwards they sent out a second swarm, which returned to the parent colony without clustering. Then on the morning of the 17th they came out again, clustered, were hived, and went to work all right. And then on the 18th day after the first swarm, there came off a third swarm from the same colony from which the first and second swarms came. That is, the third swarm came off on the 18th after the first swarm.

A. J. JOHNSON.

Logan Co., Ohio, July 26.

Poor Season—Brown Honey.

There is no honey here this season—the poorest season in my experience. I have had only 34 one-pound sections of honey from 24 colonies. I had no trouble to get them in the supers. There was no honey to be had, and what they did gather was very poor quality—the comb and honey being very brown. I hope next season will be better. Honey like what I have this year will hurt one's trade.

C. C. YOST.

Berks Co., Pa., July 25.

Scheme for Ventilating Hives.

We see a good deal now in the bee-papers about ventilation. There are a great many people who use blocks of wood under each corner of the hive. That is all very well in a strong flow, but if it slacks up suddenly, what about robber-bees?

Now, we give permanent ventilation, and have no fear of robbers. It is not our idea, but that of Mr. Digby Roberts, of this State, and he told us we could make use of it, and also give it to the rest of the fraternity.

We take two pieces of drest white pine 14x1½x1, and at each end of the 2 pieces cut down on each side to ⅜ inch by 1 by 1½; also in one bore one-inch holes about 1½ inches from each shoulder, and cut out the part between.

Now, take four pieces of drest white pine, 20x1½x¼, and nail on to the other pieces at the shoulder so as to make an oblong frame. Cover the open sides and rear end with wire gauze, inside and outside, and if you have made it right you will have lots of ventilation on two sides and the rear of the hive, while the entrance is just exactly the same as it was before.

We found that gauze just on the outside was no protection against robbers, as they would get inside and then pass the honey through the gauze to their chums outside.

Bees here have only been making a living, up to within the last week, as mesquite was an utter failure, but now as cotton has started to open, they are beginning to put white frills on top of the brood-nest.

ALDER BROS.

Callahan Co., Tex., July 15.

[We took the foregoing letter to Dr. Miller when we went to visit him, and ask him what he thought of that plan of ventilating hives? He said he preferred a one-inch block at each corner of the hive, as he had, perhaps, 100 hives so ventilated at the time we were there. And there wasn't a bit of robbing going

ELECTRIC WHEEL CO.
The Farmer's Wagon....
 If any man needs a reliable wagon more than another it is the farmer. He does not use a wagon every day, but when he does use it he wants its use badly. At such times it is a great misfortune to have a tire come off, a hub split, a felloe break and the wheel "go to spokes"—a general break down. The disuse of a wagon for a few days may mean the loss of a crop. **THE REMEDY?** Buy a wagon that won't break down. The wheel is the vital part of a wagon.

THE ELECTRIC HANDY WAGON
 with its Loud faced, stagger spoke, low, steel wheels is clearly the safe thing for the farmer to buy. It is low and easy to load—no high lift. Will stand any load you wish to haul. Don't cut in or rut in the fields or on the road—runs easy. **ELECTRIC LOW STEEL WHEELS** make the old wagon new. Fit any skien. Stand anything and last indefinitely. Get our **FREE BOOK**, "Farm Savings" and read all about them and other things of interest.

GEORGE W. YORK & CO.,
 118 Michigan Street, - CHICAGO, ILL.

on at any of the hives so elevated, notwithstanding there was a great honey-dearth existing at the time, and not a super on the hives.

The idea of robber-bees getting inside and "handing out" honey to their "pals" through the single wire-cloth didn't strike the Doctor as being anything very serious, for if the robbers were allowed to pass into the hives, they certainly would get out again with their loads, especially as the plan of ventilation as proposed by Alder Brothers does not contemplate much reduction of the ordinary hive-entrance.—EDITOR.]

Bees Doing Well.

Bees are doing well in this locality, especially those that did not swarm. But the new swarms are very slow, as I have 10 or 12 that are not up in the supers as yet.
 H. S. HUBBARD.
 Arapahoe Co., Colo., July 30.

Another Hive-Tool.

I see a tool is called for that will beat the screw-driver in prying off hive-covers, supers, etc. I will send you one of the kind that I have used for years. It is made of steel. A blacksmith can make one for 10 cents, except the handle. If you have use for it, keep it. If not, pass it on to Dr. C. C. Miller.
 Olmsted Co., Minn. N. STAPLE.

[Thank you, Mr. Staple. The sample tool came all right, and we took it along out to Dr. Miller's to give it a good trial, which was done. It works very well, tho in some respects we prefer an ordinary screw-driver.

Mr. Staple's tool is about ¼-inch wide and 4 inches long, with a wooden handle. About an inch from the end it is bent to an angle of perhaps 45 degrees. The end is then made quite sharp and tapered back to the bend. It is a handy tool. But Dr. Miller thinks the ideal tool will have one end made for loosening frames, and the other end for prying up the hive, supers, etc.—EDITOR.]

Short Crop of Honey.

Bees have not done much in this part of the country. There was white clover in abundance, but it did not seem to yield much nectar. They did pretty well while the basswood was in bloom, but that did not last long. I have taken off only about 400 pounds of comb honey from about 30 colonies. Unless the fall season turns out pretty good there will not be honey enough to supply the home market. **SAMUEL FLORY.**
 Keokuk Co., Iowa, July 30.

Don't Forget

the excursion to Boston over the Nickel Plate Road, Sept. 16 to 18, inclusive, at rate of \$19.00 for the round trip. Good returning until Sept. 30, 1898, inclusive. Tel. Main 3389. (61-32-6)

MARKET QUOTATIONS.

Chicago, July 20.—Not any of the new crop of comb honey on the market this week; what little has come sold at 11@12c. Extracted brings 5@7c for the white, according to quality; ambers, 5@6c. Southern, fair to good grades, 4@5c. Beeswax, 27c. Market is in good shape for disposing of honey of all kinds. **R. A. BURNETT & Co.**

Kansas City, July 9.—New comb, No. 1, white, 11@12c; amber, 10@11c. Extracted, white, 5@5½c; amber, 4@4½c. Beeswax, 22 to 25c.

Old stock of honey all cleaned up. Few shipments of new in market. **C. U. CLEMONS & Co.**

New York, July 30.—There is some little new Southern comb honey on the market, mostly irregular quality and selling at from 9 to 11c. Extracted of all kinds is in good demand. Common grade Southern, 50 to 52c per gallon; good, 55 to 57c.; choice, 5 to 5½c. per pound; some exceptionally fine lots sell at 6c. Beeswax is very quiet at 26 to 27c. **HILDRETH BROS. & SEGELKEN.**

Boston, July 9.—Fancy white in cartons, 13c.; A No. 1 white in glass-front cases, 11 to 12c.; No. 1, 10 to 11c.; No. 2, 8 to 9c. Extracted, white, 6 to 7c.; light amber, 5 to 6c. Beeswax, pure, in good demand with very light supply, 30c.

At the present time the demand for both comb and extracted honey is very light with but little stock on hand. **BLAKE, SCOTT & LEE.**

San Francisco, July 20.—White comb, 8½ to 10c; amber, 6½ to 7½c. Extracted, white, 5½@6c.; light amber, 4½ to 5½c. Beeswax, 23@25c.

The ship Roanoke, clearing from this port for New York on the 16th inst., carried 179 cases of extracted honey of 1897 crop. There is some new crop honey on the market, both comb and extracted, but no large quantity of either. New comb of fairly choice quality is offering in 1-pound sections, and in a small jobbing way at 10c. per pound. Quotable values for extracted show no change.

Detroit, July 21.—Fancy white, 11@12c; No. 1, white, 10@11c. Extracted, white, 5@6c.; dark, 4@5c. Beeswax, 25@26c.

New honey is arriving, but prices are hardly establish. **M. H. HUNT.**

Minneapolis, July 26.—Fancy white clover comb is now selling at 11@12c.; amber, 10½c. Extracted fancy white clover, 5½c.; amber, 4½@5c. Dark grades, both comb and extracted, not wanted at low prices. **S. H. HALL & Co.**

Indianapolis, July 18.—Fancy white comb honey, 12@12½c; No. 1, 10@11c. Extracted, white, 6@7c. Beeswax, 25@27c.

Only a few arrivals of fancy white comb; market almost bare, and demand good. Quite a little comb honey from honey-dew is being offered, but there is simply no demand for the stuff. **WALTER S. POWDER.**

Milwaukee, July 14.—Fancy 1-pound sections, 11@12c; A No. 1, 10@11 cents; No. 1, 8@10c; amber, 7@7½c; dark and old, 6@7c. Extracted, in barrels, kegs or pails, white, 6@6½c; dark and amber, 4@5c. Beeswax, 26@28c.

Since our last the sales of honey have not been large, altho a fair demand has existed and continues, altho the fruit consumption makes some difference with eaters of honey. There is not a very large supply of old stock left, and we shall be in good order for new crop both extracted and comb. The outlook is good. **A. V. BISHOP & Co.**

Buffalo, July 9.—There is a very good demand for strictly fancy 1-pound comb, at 10 to 11c.; other grades, however, range from 9 to 7c., and even 6c. when poor enough. Quite an amount of honey can be sold at this range. Extracted ranges from 4 to 6c., with a moderate demand. **BATTERSON & Co.**

St. Louis, July 9.—Fancy white comb, 10 to 11c.; No. 1, 10c.; amber, 9 to 10c.; dark, 8 to 9c. Extracted, white, 5½ to 6c.; amber, 5 to 5½c.; dark, 4 to 4½c. Beeswax, 20 to 22c. **WESTCOTT COM. CO.**

Cleveland, Aug. 3.—Fancy white, 13@14c; No. 1, white, 12@12½c; light amber, 11c; buckwheat, 9c. Extracted, white, 7c.; light amber, 6c.

The demand for honey is exceptionally good, owing to the crop in this vicinity being very light. **A. B. WILLIAMS & Co.**

 **Talk about
... Comb Foundation**

WE can now furnish the very best that can be made from pure wax. Our New Process of Milling enables us to surpass the previous efforts of ourselves and others in the manufacture of Comb Foundation.

**It is always Pure and Sweet.
It is the kind that does not sag.
It is the kind you want.**

If you once try it you will have no other. Samples furnish **FREE**. Large illustrated Catalog of all kinds of

Bee-Keepers' Supplies,

And a copy of the American Bee-Keeper, sent upon application. Address,

**THE W. T. FALCONER MFG. CO.,
JAMESTOWN, N. Y.**

Please mention Bee Journal when writing.

**I. J. STRINGHAM,
105 Park Place,
NEW YORK,**

KEEPS IN STOCK A FULL LINE OF

APIARIAN SUPPLIES

1-pound Square Jars, \$4.60 gross. Labels, 60c gross; disc. on quantities. Italian Queens, 65c each. Catalog **FREE**.

Please mention Bee Journal when writing.

CARLOADS

Of Bee-Hives, Sections, Shipping-Cases, Comb Foundation, and Everything used in the Bee-Industry.

We want the name and address of every Bee-Keeper in America. We supply Dealers as well as consumers. We have Dry Kiln, Improved Machinery, 40,000 feet of floor space, and all modern appliances. We make prompt shipment.

I ARISE

TO SAY to the readers of the **BEE JOURNAL** that **DOOLITTLE**

has concluded to sell **BEEES** and **QUEENS**—in their season, during 1898, at the following prices:

One Colony of Italians on 9 Gallip frames, in light shipping-box \$6.00
Five Colonies..... 25.00
Ten Colonies..... 45.00
1 untested queen. 1.00
6 " queens 5.50
12 " " 10.00
1 tested Queen... \$1.50
3 " Queens. 3.50
1 select tested queen 2.00
3 " " Queens 4.00

Select tested queen, previous season's rearing. . 3.00
Extra Selected for breeding, THE VERY BEST. . 5.00
About a Pound of BEEES in a Two-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding the Bees and each class of Queens.

PROFITABLE BEE-KEEPING,

—WITH—

HINTS TO BEGINNERS,

—BY—

C. N. WHITE, OF ENGLAND.

Author of "Bees and Bee-Keeping," "Pleasurable Bee-Keeping," etc.

No. 7.—SUPERING.

The amount of success that a bee-keeper achieves depends, as has already been stated, upon surrounding circumstances, such as nearness of honey-producing crops to the apiary, and the state of the weather during the time they are in bloom; but with these necessary conditions in his favor, there remains another item without which the fullest advantage possible cannot be obtained; his energies must be directed by thought and applied to the work of the apiary at the right time.

It is utterly useless expecting full supers if bees are left to themselves; it is equally foolish not to give supers when colonies are strong and honey is being gathered rapidly. I have known many cases where, for want of supers, 40 or 50 pounds of honey per hive have been lost. For instance, in my own apiary I had three swarms as nearly as possible of the same weight, I hived them on the same day in exactly similar hives, and gave exactly the same treatment to all except in one respect. Two were supered a few days after hiving, the other was left entirely alone, the consequence being that while the bees of the two supered lots were working vigorously day after day filling their supers, the bees in the third hive were lounging about the entrance doing nothing simply because they had nowhere to put the honey if they gathered it. This resulted in a positive loss of over 20s., as the other two lots stored honey to more than that value.

It may be asked, "What is supering?" This term, tho sometimes wrongly applied, is understood to mean the giving of bell-glasses, sections, shallow-frames, or, in fact, any receptacle in which the bees may store their honey when they are gathering considerably more than is required for the daily wants of the colony.

Supering really should be applied only to the giving of room for surplus honey above the brood-chamber, as must be the case when the tiering hive is used. This is the style of hive recommended, and the supers used in connection with them may be either Ivo bar supers, shallow-frame, or sectional supers.

The style of super adopted should be determined by the market for honey, and the time that can be spared for the

work. Being a busy man I have used some Ivo bar supers on several movable-comb hives for some years past, and I find I can get as much honey, if not more, by using such supers than I can by using either shallow frames or sections, and by spending not a quarter of the time. Sheets of foundation, three inches in depth, are put into the bars, and then the super is ready, but between this or the shallow-frame super and the brood-chamber there should always be placed a sheet of queen-excluding zinc.

When full of honey the super must be cleared of bees by one of the methods given in this article. The combs are attached to the front and back walls of the hive, and therefore before they can be moved the attachments must be cut by raising each end of the super alternately and running a knife from end to end close to the inside walls. The combs will then hang from the bars, and are removed by raising the latter. The combs are next cut from the bars and allowed to drop into a pan, to be afterwards sliced so that when put into

Dr. H. Besse—See page 519.

some kind of a strainer or honey cistern the honey may drain away free from any contamination whatever. Before the bars can be used again fresh pieces of foundation must be fitted in them, but this need not be looked upon as an expense, as the wax produced by melting the sliced combs will more than compensate for the outlay.

EXTRACTING FROM SHALLOW-FRAME SUPERS.

Extracting honey from the combs is now a very general practice, and one that is to be strongly recommended in working colonies for large returns, for much work is saved the bees, and more honey is obtained seeing that much that would

otherwise be used in the production of wax for building the combs, is carried up into the super, thus adding considerably to the surplus.

The $\frac{5}{8}$ -inch shallow-frame super should in all cases be used if the object is extracted honey, for not only is it more convenient in handling, but the bees enter it more readily than they do the larger, and, for extracting purposes rather unwieldy standard-frame super.

On removing the super it should be placed in a warm room, and if the work of extracting can be carried on at once, while the honey is warm, it will be an advantage, as it will flow more freely than if allowed to get cold by standing a day or two in a cold room. The cappings, or cell-covers, should be shaved off with a sharp knife, warmed by standing it in a pitcher of hot water, and if cut from the bottom with a saw-like motion while the top of the frame is held forward, the cappings will remain in a sheet and fall into the pan held below. When the uncapped combs are put into the cages of the extractor, they should be so placed that the bottom-bars go around first, for thus the honey is more easily thrown out as it leaves the cells in the direction of the pitch given to them by the bees when they are building their combs. The dripping combs should be allowed to stand to drain for a few hours: otherwise honey might be dropt about in the apiary and cause robbing.

It is always advisable to return combs wet with honey in the evening so that the excitement they cause may be over by the morning. Returning such combs at unsuitable times, and placing scraps of comb about for the bees to clean, are undoubtedly the cause of much robbing, and, if in a foul-broody district, the spread of the disease.

SECTIONAL SUPERS.

The style of sectional super to be chosen, and the mode of preparation, have already been explained under "Hives," and therefore advice will only now be needed in order that good sectional work may be produced. It is by no means an easy task to obtain really well-filled sections, tho' if the sections are properly prepared and placed upon strong colonies or swarms standing near fields of white or Alsike clover, or similarly good honey-producing crop, the bulk of the sections will generally be well finished.

The great secret of obtaining well filled sections is to crowd the bees. This is done in two ways, either by removing the outer frames from a strong colony and substituting dummies at the commencement of the honey-flow, or by giving a very strong swarm limited room in the brood-chamber when hived. By adopting the former method, the crowding has a tendency to cause swarming, but so long as fine weather continues, and the bees have ample, but not too much, super room, so long will swarming, as a rule, be averted. It is when there comes a change in the weather, compelling the bees to leave the super and further crowd in the brood chamber that swarming is practically certain, unless during the time they are so crowded, work in the form of comb-building is given by substituting empty for full frames in the brood-chamber. To succeed in the production and sale of sections requires much more skill and patience than many bee-keepers are in a position to give; it is therefore advisable that they should adopt either the shallow-frame or the "Ivo" supers.

REMOVING SUPERS.

Until very recently the most difficult and not the least dangerous of operations in the apiary was the removal of supers: but with accurately fitting parts, and the avoidance of all incentive to the building of brace-combs, the difficulty is removed, while, by the use of bee-escapes, the bees leave the supers without disturbance.

The two super-clearers in most general use are the *cone* and "Porter" escape. The cone is made of finely-perforated zinc: it is 3 inches long, 2 inches wide at the end attach to the hive, and $\frac{3}{4}$ inch at the narrow end. It is fastened over a hole in the front of the roof, or fixt on the side of a box to be used for clearing of bees all kinds of supers after removing them from the hives. If the cone is fixt on the roof the super to be moved is gently raised while a cloth or newspaper is placed beneath it to imprison the bees in the super. The quilts are next removed, so that when the bees leave the super, which they will do as soon as they find they are cut off from the brood chamber, they can get into the roof, from which, if bee-proof all around, they can leave only by the cone.

The box clearer must be of a size to allow the super to rest evenly upon it. The straw, box, or other super is then gently raised, lifted across to the box, and placed in the same position upon the top of the box in which a hole 6 or 9 inches in diameter is made. The bees are in this case prevented from leaving the super except by passing down into the box below,

and then, being attracted by the light, they pass through the cone first over an inch hole in the side. If the supers do not fit evenly upon the top of the box, any holes through which bees can pass should be stoppt with rag or paper, otherwise the sweets will be found by bees of other hives, and carried off rapidly, so that in a few hours a grand super may contain nothing but empty combs.

By using the cone escape the bees are compelled to pass through the air on their way back to the brood chamber, and this fact no doubt, inasmuch as it may lead to a disturbance in the apiary, led the inventive mind to seek for a more satisfactory method of emptying supers of bees. The best ever designed is known as the "Porter" escape, named after the inventor, an American bee keeper. It is fixt in the center of a board made the same size as the super. If all supers, therefore, are of the same pattern, one or two boards will be ample for most apiaries. When the super is raised this board is placed beneath it and both are then returned: but in order to prevent the crushing of bees, when replacing the super, the board is fitted with a $\frac{3}{8}$ inch ledge running around above. By placing this clearer beneath the super to be removed, the bees

Honey-Extractor.

Queen-Excluding Zinc.

are prisoners until they find connection with the brood-chamber. There is then some commotion until a passage through the escape or trap in the center of the board is found. By listening at the side of the super for a few minutes a continual clicking of the fine brass springs which form the trap will be distinctly heard, and it will tell of the stream of bees passing down into brood-chamber or super below.

This method of clearing supers of bees is strongly recommended because the bees simply pass downwards from the top super or supers leaving the super work there intact. If the clearer has been put into position with care and without jarring the hive, there is no disturbance caused, as the bees do not leave the hive, and the super may be left on the hive a few hours, or longer if desired without the bee-keeper being anxious as to the safety of the contents. This clearer is really indispensable if show sections are being removed, for on the least disturbance of the super crates the bees, according to their natural inclination, commence uncaping the sealed comb. If the sections are thus treated by the bees, they are not only spoiled for the show table, but weep and become sticky and therefore unfit for market.

(Continued next week.)

The Eucalyptus—Varieties and Value.

BY PROF. A. J. COOK.

The attention of all visitors to California is at once attracted to the numerous groves of eucalyptus which form a most conspicuous feature of our landscape. Their habit of growth, reaching as they do away up to cloud regions, gives them special prominence. As is well known, they are natives of arid Australia, and so are peculiarly well fitted to our own arid clime of Southern California. When I say that there are well toward 200 species of eucalyptus, it need hardly be

added that one can find attractive variety for tree-planting and not go beyond this single species. The common blue-gum—*eucalyptus globulus*—the one so generally seen in California, is very tall and slender, while some of the red-gums, like *eucalyptus citriodora* and *eucalyptus robusta*, have a fine spreading habit, and are very graceful in habit and form.

The bloom of all is attractive and beautiful, and the deep crimson blossoms of *eucalyptus ficifolia* always elicit praise and admiration. While the most common period of bloom is from September to May, there is no month in the year that bloom may not be found in a park of eucalyptus trees, with well selected varieties. The top-shape fruit of all species is interesting, while the peculiar form and habit of bloom of such species as *eucalyptus corynocalyx* must ever win admiration, and create interest.

The oil of eucalyptus is so peculiar that crushed leaves give a very marked odor, and the air near a grove gives unmistakable evidence of the near proximity of the trees. Eucalyptus essence and oil is used not a little in pharmacy.

Of late I have secured some honey which undoubtedly is eucalyptus. Of course there is no reason to suspect that the peculiar flavor of the juice would be reproduced in the honey. The nectar-glands make or form nectar from elements obtained from the juice, and do not draw it all formed from the juice. I was glad to find that this honey was light in color and delicious of flavor. To be sure, this honey will always be secured in the season when it will be useful for stimulation and food of bees, yet in favorable seasons it may come in such profusion as to be a generous supplement to the season's crop, and it is good to know that in such case no harm will result. Indeed, the common planting of these trees will add another point to California's fame as the great honey-region of the world.

That the range of bloom makes the tree more desirable will appear from the following data of a few species now most in favor:

The common blue-gum, *E. globulus*, is in bloom from December to February; *E. robusta*, which is also much in favor, has the same period of bloom. The honey I have come from these species, I think. *E. rostrata* blooms in April and May; *E. citriodora* from August to December; the curious-blossomed *E. corynocalyx*, from June to September; the brilliant *ficifolia* blooms in August and September.

Mr. Barber, foreman of the Forestry Experiment Station, at Santa Monica, speaks in special praise of the following species for honey, which he says are swarming with bees on all pleasant days while in blossom: *E. calophylla*, July to October; *E. corymbosa*, August to December; *E. globulus*, December to February; *E. robusta*, December to February; *E. polyanthemos*, December to April. He also praises the dwarf *E. alpina*, September to November, which will endure some considerable frost, and has a peculiar habit of growth which will make it more attractive.
