The theoretical examinations it is proposed to hold in public, the examiners, or jury, being members of the Syndicate, which numbers among its body many of the leading Paris and provincial photographers. The practical examination will be held in a laboratory under the supervision of the same jury, and this also is divivded into three parts. Of these, the Syndicate attach the greatest importance to (1) negative operations and all appertaining to the manipulation of collodion and gelatine, both wet and dry, and (2) printing in chloride of silver in its various forms.

The difficulty in examinations of this kind is to know where to draw the line, and the only objection that we see to the programme sketched out by the French Syndicate is that it draws the line a little too high up. Perhaps the difficulty might be met by giving two classes of diploma, a "junior" and "senior." Then the assistant who is modest about his attainments might proceed to the first examination, and, passing that, would gain courage to go on to the second. The main thing is to encourage the younger assistants to take an interest in their work, and if they foresee a possibility of passing by moderate exertion they will not object to work harder subsequently, to secure a second step after they have gained the first.

The French Syndicate is so firmly established, and already enjoys such influence among French photographers, that whatever it makes up its mind to, is likely to become law. Consequently, if the examination of assistants is seriously upheld, we may expect that there will be no alternative for the rising generation; but to enter for them. If the members of the Syndicate bind themselves to take no other assistants into their employ but those who hold a diploma or "brevet," then the competing for such honours will become an every-day matter. In this country there is no institution corresponding to the French Syndicate; the societies we have are supported as much by amateur photographers as by those professionally engaged, and consequently the members have no reason to institute tests of this kind. Still, assistants and operators at home should remember that we are now becoming so cosmopolitan in our dealings, that it matters very little what countryman you are, so long as you know your duty; and doubtless French assistants coming across the water armed with diplomas signed by a powerful body would get a more willing ear than those unprovided with any proof of scientific ability.

Of course the mere possession of a diploma does not prove that a man is a good photographer; and this is an argument that we are likely to hear very frequently as soon as photographic examinations are seriously talked about. In like manner, it may be advanced, that a man who has secured a B.A. degree is no more fitted to take up a tutorship or secretaryship than another gentleman who has not secured a degree. Granted; but supposing you know nothing about either candidate, and that they both prove equally eligible on a casual examination, then the chances are decidedly that the B.A. will be chosen, for he carries with him a proof that he has at any rate been thoroughly well educated: you are sure that he possesses knowledge which the other may or may not have. So, if two assistants were to present themselves whose abilities seemed equal at first sight, there is little doubt that the principal would prefer the one of whose knowledge he had a proof, furnished by independent and responsible persons, rather than the other whose abilities he has still to find out.

STRAY NOTES ON DRY PLATES.

BY J. PLENER.

Let us briefly examine the sensitometers with equal differences in size of apertures of any two contiguous divisions. This difference we will designate by c. If we expose under such a sensitometer two plates of different sensitiveness, but of the same kind, to the light of different intensity, then we obtain two equations corresponding to the densest and the faintest tints.

$$\alpha \mathrm{stimc} = \alpha \mathrm{s_1 ti_1 m_1 c}, \text{ and } \alpha \mathrm{sti}(m+n)\mathrm{c} = \alpha \mathrm{s_1 ti_1}(m_1+n_1)\mathrm{c}$$

where m and m_1 are the numbers of the densest tints, n and n_1, numbers of gradations, consequently $m+n$ and m_1+n_1 numbers of the faintest tints. From the above equations we receive—

$$\frac{m+n}{m} = \frac{m_1+n_1}{m_1}, \text{ or } \frac{m_1}{m} = \frac{m_1+n_1}{m+n}$$

This last equation is possible only when

$$m_1\chi = m_1+n_1 \text{ and } m\chi = m+n,$$

where χ is a variable. From this we have—

$$m_1(\chi-1) = n_1 \text{ and } m(\chi-1)n,$$

hence

$$\frac{m_1}{m} = \frac{n_1}{n} \ldots\ldots\ldots\ldots(1).$$

On the other band, from the equation—

$$\alpha \mathrm{sti}(m+n)c = \alpha \mathrm{s_1 ti_1}(m_1+n_1)\mathrm{c}$$

we receive

$$\frac{\mathrm{si}}{\mathrm{s_1 i_1}} = \frac{m_1+n_1}{m+n}$$

Uniting this with the equation (1), we obtain—

$$\frac{m_1+n_1}{m+n} = \frac{m_1}{m} = \frac{\mathrm{si}}{\mathrm{s_1 i_1}} = \frac{n_1}{n} \ldots\ldots\ldots\ldots(2).$$

This shows that for the above sensitometers the numbers of gradations on the plate stand in inverse ratio to the sensitiveness and the intensity of light, and are proportionate to the numbers of the faintest tints. When the intensity of light is the same same for both plates, then

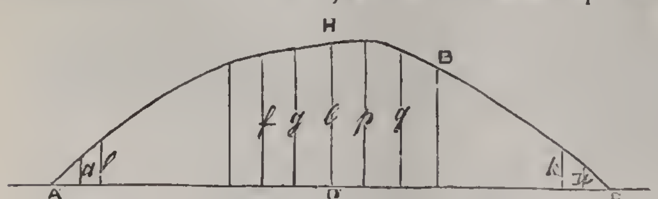
$$\frac{m_1+n_1}{m+n}=\frac{s}{s_1}$$

or the sensitiveness stands in inverse ratio to the numbers of the faintest tints. Therefore, if we were to compare the plates differing greatly in sensitiveness, we would have been obliged to use a sensitometer having a greater number of divisions. This constitutes the drawback of the sensitometers of this type.

When we know the sensitiveness and the number of gradations of any one good plate, then the quality of any other given plate may be easily known, because its sensitiveness and the number of gradations must satisfy the last above equation.

Till now we have compared the sensitiveness only of the plates of the same kind, viz., those in which the shades of spectral impression of a given light stood in the same relation between them. But we must consider the case of two plates of different kinds, such as, for instance, bromo-gelatine and bromo-iodo-gelatine plates. Supposing that two plates of different kinds when exposed under a sensitometer have n for their relative sensitiveness, the question arises, how will change the latter when the light will have been changed? For instance, if, having determined the relative sensitiveness with phosphorescent light, we wished to know how the former will change for the daylight, in order to be able to calculate the time of exposure? By simultaneous exposure of the above two plates to the daylight under two identical sensitomers we will receive the relative sensitiveness of the plates, and dividing it by that obtained beforehand we will have the relation of the relative sensitiveness. If we knew that this relation is constant for all the scale of sensitiveness, that it is the same for the slowest as for the quickest plates, then the calculation of the time of the exposure would be easy. We wish to find an algebraic expression for this relation, and to show that it is constant.

Let us take two different sources of light, and two plates of different kinds. At first we determine the sensitiveness of one plate to the different parts of the spectrum of one light. For this we divide the spectrum in as many equal parts h as we practically can. If the sensitometer of Macklow were accordingly arranged, we think there would be no difficulty in exact determination of the sensitiveness for each part. Suppose we have done this, then we are able to construct the curve A B C, whose ordinates represent



the sensitiveness of the plate to different rays, and at the same time the work done by each ray, because, all other conditions being equal, the work done is proportionate to the sensitiveness. Thus, the work done by all the light will be represented by the plain surface A B C D, which we will designate by Δ_1. To calculate the latter, we must make addition of all the trapeses of which is composed Δ_1. Thus:—

$$\Delta_1=\left(\frac{a}{2}+\frac{a+b}{2}+..+\frac{f+g}{2}+\frac{g+l}{2}+\frac{l+\rho}{2}+\frac{\rho+q}{2}+..+\frac{k+u}{2}+\frac{u}{2}\right)h$$

Or,

$$\Delta_1=(a+b+\ldots+f+g+l+\rho+q+\ldots+k+u)h.$$

For the same plate and the same light, the relations of shades remaining constant, let us designate them as follows:—

$$\frac{a}{6}=r_1\ldots\frac{f}{g}=r_{m-2},\frac{g}{l}=r_{m-1},\frac{l}{\rho}=r_m,\frac{\rho}{g}=r_{m+1},\ldots\frac{k}{u}=r_n$$

hence

$$a=l(r_{m-1}\ldots r_1),\ b=l(r_{m-1}\ldots r_2);\ f=l(r_{m-2}-r_{m-1});\ g=lr_{m-1}$$

$$\rho=\frac{l}{r_m};\ q=\frac{l}{r_m.r_{m+1}};\ u=\frac{l}{r_m\ldots r_n}$$

Substituting this in the above equation, we receive—

$$\Delta_1=lh\left[r_{m-1}\ldots r_1+\ldots r_{m-2}r_{m-1}+r_{m-1}+1+\frac{1}{r_m}+\frac{1}{r_m r_{m+1}}+\frac{1}{r_m\ldots r_n}\right]$$

The ray l being on the line H of the spectrum, therefore we can decompose the last factor into parts; one part,

$$r_{m-1}\ldots r_1+\ldots r_{m-2}r_{m-1}+r_{m-1}$$

which we will designate by γ_1, belongs to the ultra-violet rays; and the other, γ_2, to the luminous rays. Let us call the sum

$$\gamma_1+\gamma_2 \text{ by } \beta,$$

then

$$\Delta_1=l_1 h\beta_1$$

For the other plate, and the same light, we will receive in the same way

$$\Delta_2=l_2 h\rho_1$$

the work done being proportionate to the sensitiveness; consequently,

$$\frac{s_1}{s_2}=\frac{l_1 h\beta_1}{l_2 h\rho_1}=\frac{l_1\beta_1}{l_2\rho_1}$$

Now if we change the light we will obtain

$$\frac{s_3}{s_4}=\frac{l_3\beta_2}{l_4\rho_2}$$

and

$$\frac{s_1}{s_2}:\frac{s_3}{s_4}=\frac{l_1 l_4\beta_1\rho_2}{l_2 l_3\beta_2\rho_1}$$

Here l_1 l_2 l_3 l_4 represent the work done by the ray H of two sources in two plates; therefore

$$l_1=as_1 ti_1;\ l_2=as_2 ti_1;\ l_3=as_1 ti_2;\ l_4=as_2 ti_2$$

Where s_1 and s_2 are sensitiveness of two plates to the ray H, and i_1 and i_2 the intensity of the ray H in two lights. We observe that—

$$\frac{l_1 l_4}{l_2 l_3}$$

is equal to unity; consequently,

$$\frac{s_1}{s_2}:\frac{s_3}{s_4}=\frac{\beta_1\rho_2}{\beta_2\rho_1}=\frac{\beta_1}{\beta_2}:\frac{\rho_1}{\rho_2}$$

From this we see that the relation of the relative sensitiveness is constant, because β_1, β_2, ρ_1, and ρ_2 are constant.

The relations

$$\frac{\beta_1}{\beta_2} \text{ and } \frac{\rho_1}{\rho_2}$$

we have calculated from the spectral impression of two lights. Let us inquire in what relation they stand to the intensity of lights.

Again, we know that, all other conditions being equal, the work done is proportionate to the intensity of light. Then

$$\frac{I}{I_1}=\frac{\Delta}{\Delta_1}=\frac{l\beta}{l_1\beta_1}$$

If we take I_1, the intensity of one source, for unity, we will have—

$$I=\frac{l\beta}{l_1\beta_1}$$

where l_1 and β_1 belong to the source taken for unity. We observe that the expression for I contains two terms, one of which,

$$\frac{l}{l_1}$$

changes with the quantity of light, because had we doubled the luminous surface, the value of

$$\frac{l}{l_1}$$

would have been doubled; but the other

$$\frac{\beta}{\beta_1}$$

is constant for a given source, and changes only when the character of the light is changed; it constitutes the chemical characteristic of light. Of course this characteristic is related to certain kinds of plates. Thus it can be easily seen that the characteristics of the light giving s_3 and s_4 related to the two kinds of plates we had above under consideration will be

$$\frac{\beta_1}{\beta_2} \text{ and } \frac{\rho_1}{\rho_2}$$

respectively. In fact, the relation of the relative sensitiveness,

$$\frac{\beta_1}{\beta_2} : \frac{\rho_1}{\rho_2}$$

is the relation of the chemical characteristics of the light obtained in relation to two kinds of plates.

(*To be continued.*)

RECENT ADVANCES IN PHOTOGRAPHY.

BY CAPTAIN W. DE W. ABNEY, R.E. F.R.S.*

The next subject I wish to treat of is one which has been much misunderstood by many. The theory involved is not new to myself, but I think the results I shall show will be new as far as the audience is concerned. On this plate is pasted tin-foil, with various figures cut on it; first, there is a circle, then a line across, and so on. The image of these figures I now throw on a monster gelatine plate, the thickness of the glass being some $\frac{1}{4}$-inch. Now, I ask you to observe what you see on it. You see every figure surrounded by a halo. Thus, you see the circle is surrounded by a ring. You have a halo round every part of the images. If you come to analyse it, you will

Fig. 2.

find that the halo surrounding the bright cross is made up of a series of rings similar to that ring which surrounds the clot of light. Now, I have here some wonderful elixir to get rid of these haloes. I touch the back of the plate where the cross falls with asphaltum, and the halo vanishes. I move the plate a little, to get a fresh surface, and with red varnish I again touch the back of this plate, behind the cross, and now I have a white cross on a red background; to put the matter in words, according to the medium you place on the back of the plate, so is the reflection toned down. If I use a red varnish, this halation will have but little effect on the photographic plate, because it is red, and these red rays do not much affect the production of a change in the sensitive salt. The most perfect cure for halation is Brunswick black; there is no reflection from the back of

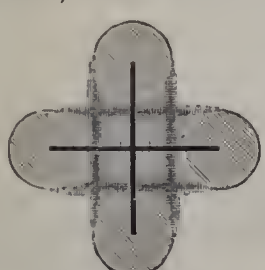


Fig. 3.

the plate, and by that means you get rid of any tendency to fuzziness of the image, which was often a disgrace to photographers' pictures. I will now throw on the screen one or two of the absolute photographs showing different halations. One is from an ordinary plate, the other from a thick glass plate; when the thick one comes on the screen, instead of the cross remaining where it was, it was spread considerably. [Shown.] When you come to analyse it mathematically, you will find the diameters of these rings depend on the thickness of the glass, together with the critical angle of reflection for the glass employed; the greatest intensity in the ring is fixed by the critical angle alone. That is a very important point, because there has been a good deal of controversy about it, which I will not enter into now. I think what you saw on the gelatine plate, and what you see on the screen now, ought to settle that point for ever. I will show you some plates taken with an asphaltum backing; it is of no use giving improper backing; if you have anything

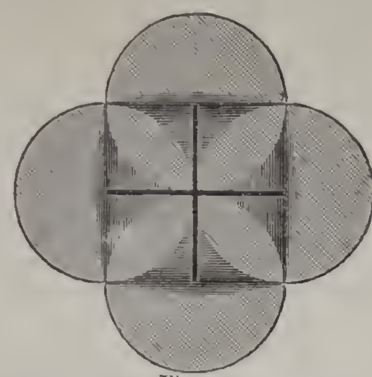

Fig. 4.

which will reflect blue light, you get this blurring of the image. With a plate prepared with a backing of asphaltum, you can even expose it to a bright image of the sun without getting a halo round it. An astronomer in Germany has recently deluded the French Meteorological Office into believing that he has photographed the corona in full sunlight; but when you come to inquire into the matter, this corona is nothing else than the halation; not only that, but he has found the most extraordinary

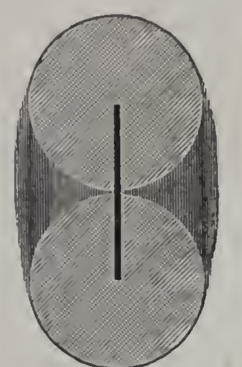

Fig. 5.

rays shooting out from it at certain times. When, however, you come to investigate the question, you will find that these wonderful rays, which are supposed to proceed from the sun, and thus to influence our earth, are nothing more than a certain reflection which the law of optics tell us ought to be there. Here is a simple method by which photographers can always be sure of seeing what amount of blurring they may get. If they take the trouble to place a gelatine plate, or any plate they wish to try, in contact with a slit cut in tinfoil, and then look through the back of the glass at a strong light, they will find it has more or less blurring round the slit.

Having so far digressed, I may say that the reason why you get apparently greater reversal in a photograph taken on a glass plate than you do in a paper negative, is because there is none of this halation to help it.

There is also another reason why reversal is more difficult to secure on paper, in that the bromine has two ways to escape, one through the paper, and the other through the surface of the bromide. I hold in my hand an example of reversal on paper.

Now I will show you how you can get rid of this reversal altogether. The film before you was exposed sixty seconds behind a negative to the full sunlight, yet there is no reversal on it. How is that? Simply because I gave it something which, instead of allowing the bromine to attack the bromide of silver, that had been altered by light, at once took it up. The substance employed was potassium nitrite. This shows that, if you want to get rid of the reversal of the image, you must give the plate something which will very rapidly absorb bromine, and I should say something, if possible, which is not organic, for the reason I have already stated to you. Now, is it possible that you can give a film something of that kind? I say it is quite possible to do so, and those photographers who are experimenters no doubt might turn their attention to this point. In the meanwhile, I may say that the addition of iodide to bromide in a plate is sufficient to a very large extent, because, as I showed you in a former lecture, the sub-iodide of silver acts as a sensitiser to the bromide of silver; the consequence is, that those films which

* Continued from page 525.

contain a large quantity, or even a small quantity of iodide, do not reverse in the same horrible manner as a pure bromine film will do. Perhaps a certain amount of anxiety may have been created in photographers' minds by a recent article in one of the photographic papers, in which a doubt was raised as to whether they can get iodide in their films. Let me once for all re-assure them. If you have iodide of potassium, and bromide of potassium to combine with silver nitrate, iodide of silver will always be present in your films; for the iodide is formed always long before the bromide, and, therefore, the scare as to whether you have iodide in your plates or not, is one which need not be seriously entertained. As far as chloride goes, I leave that for another occasion to remark upon; but once for all, if you have soluble iodide present when making an emulsion, you must have silver iodide in the film, and this will act as a sensitiser to prevent the reversal of the image.

I now come to a description of a most useful instrument introduced by Mr. Warnerke, which is known as a sensitometer; it consists of squares of coloured gelatine of different opacities through which light is allowed to fall on a sensitive plate. This sensitometer is meant to enable you to judge of the comparative rapidity of your plates. You have seen on the screen some of the images produced on glass, on paper, or on films, by the exposure of such a tablet as this, and it is a most useful instrument. To my mind, no photographer, be he amateur or professional, should be without one, or one similar to it. Mr. Warnerke has been the first to adapt this sensitometer to practical purposes. There are others in the field, of which we have a notable instance in that of Mr. Spurge; but for the time being I propose simply to call your attention to Warnerke's sensitometer. The method of operating is very much the way in which I operated just now. First, a phosphorescent tablet is exposed to magnesium light, and then allowed to rest a minute, placed in contact with the sensitometer plate, which is in front of the plate to be tried. The exposure lasts for half a minute, and the plate is then developed. The last distinct number seen upon the plate by reflected light, before fixing, is read off. By a simple table you are able to see the comparative sensitiveness of two particular plates of the same kind. Here, owing to Mr. Warnerke's kindness, I have an enlarged apparatus, showing the way in which you read off the sensitometer. Suppose, for instance, you find the last number on one plate to be 20 in the one case, and 16 on another, if you take two such plates out in the field in the same light, and you want to know how much exposure to give in the one that registers 16, knowing that necessary for the one reading 20, how are you to do it? You take Mr. Warnerke's instrument, such as we have here (but in miniature, of course), you place this opening at 20, you then cast your eye on the ring, look at 16, and find that the one that registers 20 is three times more rapid than the one that registers 16, and expose accordingly; so, in the same way, if you had one that registered 25, which is a very high degree of sensitiveness, and another 12, you would find that you would have to give the one 36 times more exposure than the other. I recommend this to the notice of practical photographers; I do not wish to act as an advertiser to Mr. Warnerke's sensitometer, but I merely advise them to get some sensitometer, so as to prevent groping about in the dark as to what exposure to give to plates of different degrees of sensitiveness. There is nothing like picking a hole in your friends, if you possibly can, and now I am going to pick a hole in Mr. Warnerke's sensitometer; it is not a very grave one, but still, one which ought to be noted; I want to show you what happens, supposing you measure all kinds of plates by such a sensitometer. First, let us examine what kind of light is emitted by this phosphorescent tablet. You will see, if I expose it to the light, it will phosphoresce, and the stronger the light the more it phosphoresces. Now, here we have a spectrum of the phosphorescent light, and when you come to examine it by the eye, it is found that there is one bright band in the indigo; there is a very faint light coming down as far as the red. When you photograph such light in the photo-spectroscope, nothing is indicated except the existence of the indigo band of light, and nothing in the violet or beyond; it is almost a monochromatic light which it emits, as far as photography is concerned. Supposing we have to try some plate, the composition of which is unknown, with such a sensitometer, it will be seen that we may fall into serious error. In fig. 6 the mountain represents the intensity of light which is painted by the phosphorescent light on a plate. Supposing the plate only contained iodide, you will really see that the little mountain, which only affects the iodide, is only $\frac{1}{30}$th part of the whole mountain which would be there if you are using white light. If you only use chloride, it would be showing one-third only; whereas, if you use bromide, it would be unity, or as giving the maximum. If you try a wet plate by the sensitometer, you will find that it indicates only about one-fourth of the true value; that is to say, you would be wrong supposing you went out with a wet plate and a gelatine plate,

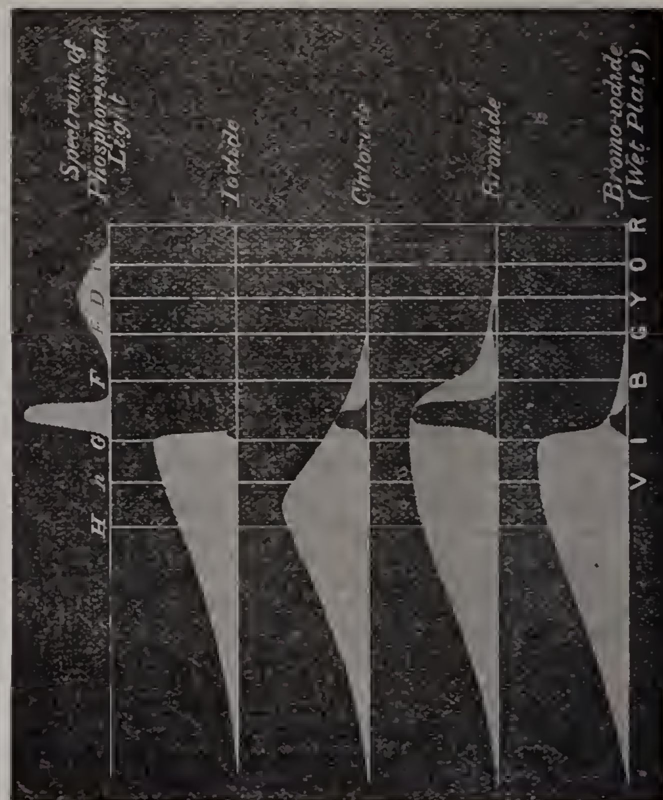

Fig. 6.

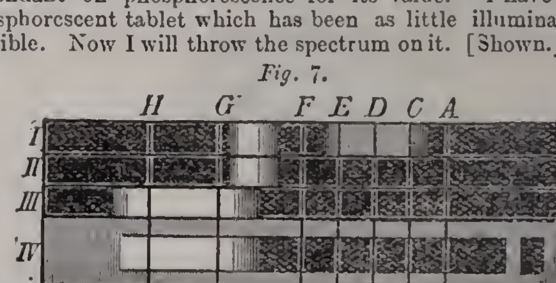
and exposed according to the sensitometer; you would find you had given five times too much exposure to the wet plate, simply because the bromo-iodide is most sensitive to those rays of light which are not present in the phosphorescent light. Hence, when using such a sensitometer with phosphorescent light, you must beware what you are about, and hesitate before you draw any exact conclusions.

This leads me on to the measurement of the intensity of light, for if we want to know anything about our plates, we must know what brightness of light we have. I again have to allude to Mr. Warnerke; he is a most facile inventor, and the photographic world is largely indebted to him for many ingenious contrivances. He has introduced an actinometer which is dependant on phosphorescence for its value. I have here a phosphorescent tablet which has been as little illuminated as possible. Now I will throw the spectrum on it. [Shown.] This

Fig. 7.



1. Visual spectrum of phosphorescent light. 2. Photographic spectrum of ditto. 3. Rays exciting phosphorescence. 4. Rays which extinguish phosphorescence.

bright spectrum of phosphorescent light extends into the ultra-violet, but stops short at the place in the indigo, where the phosphorescent light is emitted, that is to say, one spectrum ends where the other begins. Mr. Warnerke has shown us that by exposing such a phosphorescent tablet to the action of light, by an ingenious contrivance, such as you will see downstairs, he is able to tell the photographic value of the particular light. This is a most valuable discovery, because phosphorescence is induced by very nearly the same rays as those which affect bromide of silver. If I allow the spectrum to play on a fully excited phosphorescent tablet, we get another action. You will see that the phosphorescent light is diminished where the red and green have acted. These rays extinguish phosphorescence to a very large extent. With reference to this, there is a curious fact that below the red, as we know, there are rays which exist, and which to a certain extent "de-sensitise" the phosphorescent film, and we have a darkening going on in that region. I have shown you this experiment to demonstrate how you can de-sensitise this phosphorescent plate, viz.,—by allowing white light to pass through red or green glass, since they permit the passage of those particular rays which act as extinguishing rays. There is another very simple way, which I recommend to amateurs, of telling the amount of exposure to give to your plates, and that is by Mr. Woodbury's photometer, which is the

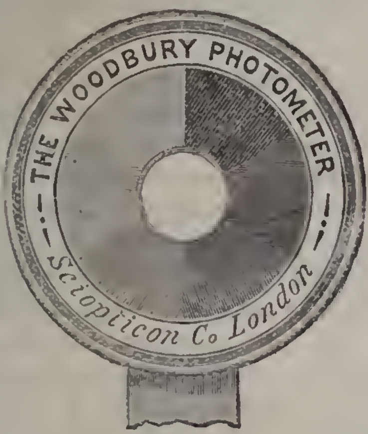


Fig. 8.

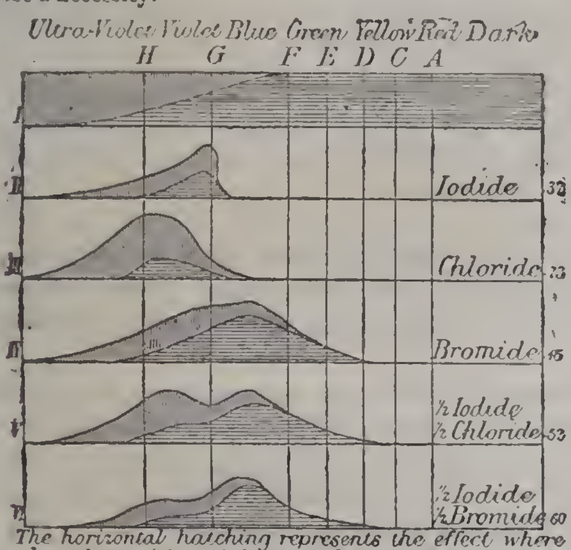
simplest thing in the world. Here we have a piece of bromide paper exposed to light for a minute, then read off against one of these tinted circles, according as to whichever tint it agrees with; you know what is the intensity of the light, and, therefore, what to give to a plate. A simple rule to remember is this, that if you use a bromide plate only, use a bromide paper for securing this tint; if you are using a chloride plate, use a chloride paper. Recent researches of mine have shown that the darkening intensity and the developing intensity go hand in hand; therefore, it will be found that when you have the number which gives the right tint, you may always be sure of getting the right exposure. If a tint requires two minutes to obtain, which corresponds with an exposure of a plate of two seconds, and you get that tint, and give two seconds, you will not be wrong. If it requires half a minute to obtain it, give the plate half a second's exposure, and you will be right. This is as useful an apparatus as you can have for the field. I do not know about the studio, but in the field some such device as this is almost a necessity.



The horizontal hatching represents the effect where the ultra violet light is deficient. The standard light is represented by the whole of the shaded figures.

Fig. 9.

I want to show you the theoretical as well as the practical necessity of using a photometer or actinometer of some description. Here we have these little mountains which signify the intensity of different parts of the spectrum. There are some bright days in summer, the light of which, when spread out in a spectrum, let us represent by a rectangle (1); that is to say, they are all of equal intensity. I do not say they are, but you can represent them as such. There are other days in autumn or winter in which the ultra-violets will very much decrease. If you judge the exposure by the eye, you may be entirely wrong, and if you are using an iodide plate, you may only give one-third of the exposure you ought to give; for chloride, only one-fourth; for bromide, about one-half. If you are using one-half iodide and one-half bromide, you would give only two-thirds of what you ought to give, so that the eye is no exact judge of the exposure you ought to give; it depends on the amount of rays which exist in the ultra-violet, and that can only be told by a photometer of some description.

The next thing I propose to show you is with regard to drop shutters. I could talk to you for a whole evening on drop shutters, and even I should not have finished, for there is a great deal in the philosophy of a drop shutter of which people have not dreamed. I am sure if I were to enter into the philosophy of the thing, I should carry you beyond any endurable limits of time. I therefore propose to show you one very easy plan of knowing what your drop shutter can do for you. We often hear said, "Oh, I exposed that plate with a drop shutter!" and if the exclaimer is asked what length of exposure that was, he will probable confess that he does not know, or will say anything from 1-5th to 1-50th of a second. Now that is a very untidy way of photographing. It is decidedly misleading to say 1-5th of a second when it may be 1-20th. I will show you a way in which you can tell whether it is 1-20th or 1-5th of a second of exposure you may have given with a drop shutter. I have here a monster lens, with which, had I time, I was going to show you some tricks. It is not very valuable; I think it cost 6s. In front of this gigantic lens I have a gigantic drop shutter, and attached to the sides of that drop shutter there is a tuning-fork which cost 1s. I claim no monopoly. You take a common iron clamp, and attach it to the side of the shutter. Then you blacken a piece of albumenised paper by the side, and make the tuning-fork vibrate. As the shutter drops, it traces its own vibrations, and tells you how many it has performed during the fall of the shutter. You know that an E turning-fork vibrates so many times per second, and by simple measurement you can tell at what speed your shutter is going at any part of its path. I dare say we shall be able to see that the tuning-fork leaves its mark on the smoked glass, which I have substituted for the albumenised paper above described. Here is another trace (fig. 10) made when gravity was aided by an elastic band. [The shutter fell, and the diagram was shown on the screen.]

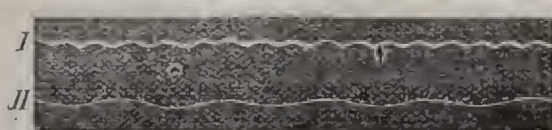


Fig. 10.

I find my time is more than up; but before I close I should like to show you one or two curiosities, as regards the scientific application of photography, and these are some composite photographs which were kindly lent to me by Mr. Galton, showing you what aid photography can give to anthropology. Here is a typical family composite portrait, composed of a mother and two daughters, all three faces being blended together. We thus get a likeness of the female branch of the family; then we have the father and mother, two sisters, and two brothers, giving the typical family group. Here we have another image, which is a typical group of Engineer officers, and I am glad to see that they are so good looking. Here is one more, which is a typical group of Sappers. I wish I had more time to go into the subject.

I cannot touch on printing processes at this late period of the evening, and therefore I must ask your permission to close. I feel that what I had done has been very imperfect, but I have done it to the best of my ability, so far as time would permit. I may have done things I ought not to have done, but I have certainly left undone a great many things which I ought to have done, but I hope for all my shortcomings you will excuse me. That this course of lectures has caused a certain amount of interest is evinced by the continued large audiences I have seen before me, and I hope some abler lecturer, at some future time, will be able to complete what I feel I have only commenced to do, viz., give a *resumé* of recent advances in photography.

Notes.

The establishment of a National Portrait Gallery of photographs is no nearer consummation, apparently, than when it was first mooted. The only way in which a commencement might be made, we think, would be for an amateur to begin the collection, which might afterwards be made semi-public property, or disposed of. We say an amateur for two reasons; first, because he is more likely to get others to part with copies of valuable portraits; and secondly, because an expense must be incurred for which no immediate return would be forthcoming.

That no time should be lost in commencing the work must be evident to all. Every day that passes makes the task of collection more difficult. Portraits that were easily obtainable twenty years ago are now rare, and in another twenty will be scarcely obtainable. It is not that the negatives perish, but that their original owners die out, or part with the plates to those who take no interest in the matter, and know not the value of them. Thus, there is probably a camera portrait of the Iron Duke extant, for he lived ten years after the discovery of Daguerre; but where it is to be found is another matter. Of Daguerre himself there were but two photographs in this country until we published the portrait in our Year-Book for 1881. Coming even to more recent times, to the portraits of such men as the Prince Consort, Thackeray, Macaulay, &c., good portraits of these are now-a-days not readily obtainable.

As an instance of photographic relics being lost sight of, we may mention the heliograph of Kew Church, produced by Nicephore Niepce when in this country in 1827. This, with other equally valuable pictures, was traced to the possession of the late Mr. Bauer, a former secretary of the Royal Society, and further to that gentleman's son-in-law. Subsequently they seem to have been regarded as worthless, and, mixed with lumber, passed into the limbo of the unknown. A few Niepcetypes are still in existence, but these, the first authentic photographs produced in this country, whose value is priceless, have been lost, simply because, instead of going into a collection, they passed into careless hands.

Captain Shaw, C.B., the chief of the London Fire Brigade, has a photographic portrait gallery at headquarters. It contains the portraits of all members of the Brigade who have distinguished themselves for bravery, and thus constitutes a pictorial roll of honour. The collection has, however, its melancholy side, for many of the brave fellows pourtrayed have lost their lives in the act that secured their admission to the gallery.

The desirability of taking a series of photographs after every fire was again forcibly illustrated in the case of the conflagration which nearly destroyed the Philharmonic Theatre on Wednesday morning; and it is tolerably certain that arrangements for the systematic use of photography by the Salvage Corps will be made before long.

Seeing is not always believing, and here is an example. When Mr. William England was in the United States, in 1857 and 1858 (for Mr. England makes pictures in every land except England itself), he happened to be at Niagara just when the redoubted Blondin made his trip across the Falls. The feat was made much of at the time, and has been made much of since; and Mr. England conceived the happy idea of taking a series of pictures showing Blondin on the rope, over the foaming water, to forward to England. This he did, posting off the packet of wonderful pictures to the *Illustrated London News.*

As Blondin's feat was the sensation of the day, Mr. England was rather anxious to see what use the journal made of his sketches: but, on searching, he could find no evidence of their having been used at all. So, naturally enough, on his return he called at the office to enquire if his photographs had been received. Yes, they had come to hand, he was told, with a smile. "Then why were they not used?" he rejoined. "Because," was the still smiling reply, "we knew they were only a joke." And to this day, indeed, the fact of Blondin having crossed the Niagara Falls on a rope is regarded as a myth by many people in this country. Certainly, the whole matter is not of very great moment; but when the *News* had the proof in hand, it is a pity it was not published. But in those days there was no *Graphic.*

Speaking of Mr. England's American photographs, it is well worth noting that he was the first to produce a series of views of that charming district hallowed by the romance of Washington Irving. The green-shored Hudson river and the craggy Kaatskills, world-famous as the home of Rip Van Winkle, where passed "the legend of Sleepy Hollow," and where Hendrick Hudson and his old-Dutch associates still live and move in spirit, carrying on in phantom-life their old sailor-smuggler adventures among the silvery crags and green forest land that overlook the winding river—these scenes were depicted with all Mr. England's art and skill during his stay in the New World.

Dr. F. Stolze appears to be quite at one with us as to the cause of halation, and he recommends backing with an aurine collodion.

One part of a saturated solution of aurine in absolute alcohol is mixed with three parts of plain collodion, and the addition of one per cent of castor oil is recommended.

Glycerine added to water constitutes a liquid that freezes with difficulty; in fact, if half as much glycerine as water is present, the mixture may be exposed to a temperature of 10° F. for a long time without being congealed by the cold. This fact is worth remembering, for it may be usefully applied in many ways, not the least important being in the charging of batteries with liquid in the winter time. By using glycerine, a non-freeable battery is at once secured in this country, a boon to all who propose to employ battery power for electric lighting.

Printing ink, and often printed matter, has frequently a bad odour because of the linseed oil varnish. Dr. Brackenbusch, of Berlin, proposes to overcome this disadvantage by using a solution of rosin in paraffin oil instead of linseed. He dissolves 45 parts of fine rosin in 25 parts of paraffin oil, heating the latter to 176° Fahr. to effect the solution. Fifteen parts of lampblack are subsequently mixed in, and the ink is made.

English authors who do not desire their books pirated in America should abstain from heavy type and smooth white paper. There is no difficulty about copying good print bodily by the sheet with the photo-etching process. The book is unstitched, the sheets stretched on a drawing board, and then a good black and white photograph is taken; an impression in fatty ink is transferred to a zinc plate, and this is then etched. The result is a block ready for the printing press; and the best of the process is, that if there are any engravings along with the letter-press, these are obviously copied at the same time.

The following results as to the penetration of coloured lights through darkness, which were obtained at Genoa some time back, are not without interest. White light, as might have been anticipated, could be observed the farthest. The penetrating power of red light came next in order, then green, and then blue. Green, before it actually fades from sight, appears white at a distance.

"They had made several dynamo machines, which had proved very good." Such is official report as to progress made during three months by one of the Electric Light Companies having a large capital. It is probable that many of the lighting companies may come to an end even before they have done this little.

It was in the Crimea that the first military application of photography was made, when, among other things, some very fine pictures of the Malakoff and the Redan were secured. These pictures, showing the nature of the earthwork defences thrown up by the Russians, how with huge baskets filled with earth our enemy was able to keep out the allied artillery fire, are still in existence, and mark a most important era in the history of ordnance. The photograph of the Redan—taken immediately after its evacuation by the Russians—exhibits traces everywhere of the terrible conflict, the floor of the battery being covered with dismounted guns, torn gabions, and shattered earth-works.

But the Redan picture has a story attached to it, too, which photographers will appreciate. Captain Lord, who was then serving in the Artillery in the Crimea, tells us that, like many other officers, he hastened into the Redan as soon as they learnt it had been abandoned by the enemy. Everything about the battery was naturally regarded with suspicion, for hidden mines were rife in the Crimea just then, and presently, in shadow of one of the angles, was found a machine that caused considerable distrust. It had evidently been left behind by the Russians, and might explode at any moment, so the officers forthwith called for assistance to help in its removal. So great was the scare, indeed, that when the photographer re-appeared with his collodion plate—he had left the apparatus and darkcloth after focussing—he had some difficulty in persuading the officers present that he was not a Russian spy, and that the unknown machine was nothing more than a photographic camera.

There are still people to be found who have but a vague idea of photographic portraiture. Here is a story we heard the other day. "I want you to take a portrait of our Sarah," was the request preferred on market-day by a country-woman, at a little studio on the confines of Wales. "Good, when can she come?" was the reply. "Oh, she can't come here, she is much too ill!" Then, when can I take over the camera to see her?" asked the photographer. "Take over the camera? Don't I tell you she is very ill, and she can't see nobody? But I can give you a description of her, quite as much as you'll want to make a portrait from."

If that photographer has many such customers, we advise him to follow the example of the heathen Chinee who took a studio at a sea-side resort in the Flowery Land, and whose stock-in-trade simply consisted of a collection of negatives of his pig-tailed brethren. When a customer came into the studio and wanted a portrait, he used to look over the stock of negatives for the same kind of face, with a pig-tail of the requisite length, and then print off as many portraits as the applicant asked for.

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

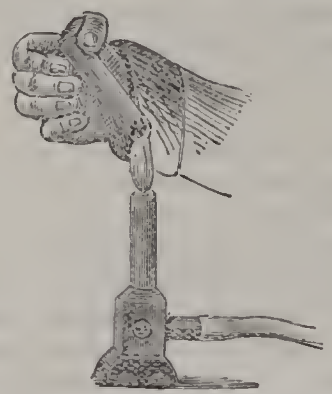
No. VI.—Qualitative Analysis of Photographic Chemicals.

It may, perhaps, be asked by some, "What is the use of knowing how to analyse chemicals?—why not leave it to the analytical chemist?" This question we can answer in a very few words, for, in the first place, the photographic student will always take more interest in his work if he knows the chemical properties of the substances with which he works; and secondly, everyone knows how provoking it is to find, when searching for a chemical, that the label has come off the bottle, and it is doubtful what its contents may be; while, if only the photographer knows the rudiments of qualitative analysis, he will determine by a few experiments with the test-tube the value of the substance under consideration.

It must be remembered that the following description is only intended for the separation of chemicals that are likely to be met with in the photographic laboratory, and consequently the description and manipulation are much shorter and simpler than that necessary for the analysis of all chemicals apart from any photographic use.

About twenty grains of the substance should be placed in a test-tube half filled with distilled water, and heat applied till the whole is dissolved (see fig.). The solution thus prepared is called the *original solution.* Pour about two drams of the solution into another test-tube, and add a few drops of hydrochloric acid. A white precipitate indicates the presence of *lead* or *silver*; add ammonia to the precipitate. If it dissolves, *silver* is present; but if unchanged, the substance is a compound of *lead.*

If no precipitate is formed with the hydrochloric acid, add to the *same* solution sulphuretted hydrogen water; a black precipitate indicates the presence of *copper*, *mercury*, or *gold.* To a fresh part of the original solution add ammonia. A yellow flocculent precipitate indicates *gold*,



greenish blue dissolving in excess of ammonia to a cobalt blue solution proves the presence of *copper*, white dissolving in excess to a colourless liquid indicates *mercury.*

If no precipitate is formed with sulphuretted hydrogen, add to the original solution about a dram of ammonium chloride and a few drops of ammonia and sulphide of ammonium. A black precipitate indicates *iron*, white shows the presence of *aluminium*, and yellow indicates *cadmium.*

If no precipitate is produced in the previous instance, add to a fresh part of the original solution ammonium chloride, ammonia, and ammonium carbonate. A white precipitate indicate *calcium.*

If there is no reaction, add to the *same* solution sodium phosphate; a white precipitate forming slowly when stirred proves the presence of *magnesium.*

If no precipitate is produced, even on stirring, add to the original solution potash, and warm gently; the odour of ammonia proves the presence of a compound of *ammonium.*

If no odour is produced, place a few drops of a *strong* solution of the original substance in a watch-glass with one or two drops of hydrochloric acid and platinic chloride; stir with a glass rod. A yellow precipitate formed in lines on the surface of the watch-glass indicates *potassium.* Heat a little of the substance on a platinum wire in the flame of of a spirit lamp or a Bunsen burner; a lilac-tinted flame confirms the presence of *potassium.*

If there is no reaction in either of the preceding experiments, repeat the watch-glass test, substituting potash and potassium antimoniate for the hydrochloric and platinic chloride. A white precipitate formed in lines proves the presence of *sodium.*

Having found the metal* or base, the next experiment is to determine what the acid is. Warm about ten grains of the substance with strong sulphuric acid in a test-tube.

Effervescence with inodorous gas indicates the presence of *carbonic acid*; confirm the experiment by passing the gas into lime-water (see Lesson II.).

Effervescence with pungent fumes, which form white clouds when brought near the stopper of the ammonia bottle, shows the presence of *hydrochloric acid.*

Yellow fumes which explode, when heated strongly, indicate *chloric acid.*

Brown fumes indicate *hydrobromic acid*, but slight brown fumes, which increase when metallic copper is placed in the liquid, indicate *nitric acid.*

Violet fumes prove the presence of *hydriodic acid.*

Yellow fumes of chlorine, which bleach moist litmus paper, indicate *hypochlorous acid* (the substance is probably chloride of lime).

* Of course, in the case of gallic, pyrogallic, and citric acids, no metal is present.

Effervescence, with odour of burning sulphur, indicates *sulphurous acid.*

Odour of burning sulphur and yellow precipitate indicates *hyposulphurous acid.*

Effervescence with inflammable gas which burns with a blue flame indicates the probable presence of *oxalic acid.*

Gradual blackening, with evolution of inflammable gas, proves the probable presence of *citric acid.*

Odour of vinegar indicates *acetic acid.*

To confirm some of the preceding tests, dissolve about twenty grains of the substance in water, to a small part of the solution add barium nitrate. A white precipitate, insoluble in nitric acid, indicates *sulphuric acid*; yellow, soluble in nitric acid, indicates *chromic acid.*

To another part of the solution add silver nitrate. A white precipitate, insoluble in nitric acid, indicates *hydrochloric acid*; yellow, insoluble in ammonia, proves the presence of *hydriodic acid*; cream-coloured, slightly soluble in ammonia, indicates *hydrobromic acid.*

A white precipitate, insoluble in cold nitric acid, but soluble on boiling, indicates *hydrocyanic acid.*

A white precipitate, which blackens on standing, indicates *hyposulphurous acid.*

To a small part of the solution add sulphate of iron, and then gradually pour down the sides of the tube strong sulphuric acid. A brown ring at the junction of the two liquids indicates *nitric acid*; a light blue precipitate with sulphate of iron indicates *ferrocyanic acid*; a dark blue precipitate proves the presence of *ferricyanic acid.*

To another part of the original solution add acetic acid, acetate of ammonia, and calcium chloride. A white precipitate, soluble in hydrochloric acid, indicates *oxalic acid.*

To a fresh part of the solution add potash, and shake. A red colour indicates the presence of *gallic acid*; a brown colour, *pyrogallic acid.*

The student should first take known photographic chemicals, and go through the above series of tests, in which way he will accustom himself to the various reactions; after finishing that task he should get a friend to supply him with unknown chemicals, and in that way test his knowledge of analysis. Suppose, for instance, the student is given potassium chloride, after going through a series of experiments according to the above description, he obtains a precipitate with platinic chloride, which proves to him that the compound contains potassium; he next tests for the acid, and finds the substance produces pungent fumes when heated with sulphuric acid, and that the solution forms a white precipitate with silver nitrate, insoluble in nitric acid, which indicates that the compound also contains hydrochloric acid: the substance is therefore potassium chloride.

After having tested the substance, the student is advised to read the description of it in the preceding lessons on "Photographic Chemicals," so as to confirm his results by performing any extra tests that may be described therein.

Review.

LIGHT: A Course of Experimental Optics, chiefly with the Lantern. By Lewis Wright. (*Macmillan and Co.*)

A HANDBOOK of the optical lantern, in which this instrument is rather put forward as a means of systematic scientific demonstration than as a means of exhibiting pictures, has long been wanted, and by publishing this work Mr. Wright has supplied an obvious requirement.

The opening chapter treats of the lantern itself, the various means of illumination which may be advantageously employed, and the various accessories required for ordinary scientific demonstration. Although the author remarks that a good Argand burner will serve for nearly all the experiments, provided that the demonstrations are carried out in a small apartment, he evidently thinks that the superior advantages of the lime light amply counterbalance the moderate amount of labour and expense involved by its use. The working instructions given by Mr. Lewis Wright for the management of the light are concise and practical, the precautions necessary to avoid accidents being clearly pointed out, while care is taken to indicate those details of adjustment on which the production of a maximum of light depends.

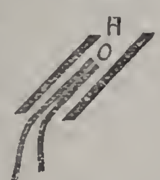
As regards preparation of oxygen, the author says :—

One must be sure that the pipe from the retort is disconnected from the first wash-bottle before the retort is taken off the fire or gas (otherwise water may be sucked back and cause an explosion), and to be sure no organic substances are in the mixture.

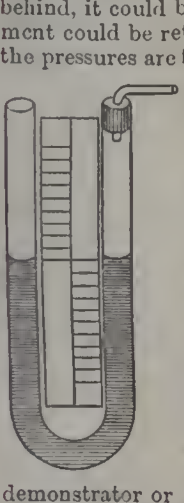
The safety tube will do the rest, and the india-rubber tops on the wash-bottles are additional safety-valves against a sudden rush of gas. The chlorate should be spread abroad on a sheet of cartridge paper to see if any small bits of straw, stick, or other matter have got in; and a small portion of the black oxide should be mixed with chlorate, and heated in a test-tube. Practically the only danger here is, lest a portion of soot or charcoal might be mixed with the sample; and if this is found pure, it is as well to lay in sufficient manganese from the same lot to last the winter.

The mixed jet is evidently regarded as best adapted for general use, as

No accident can occur if the pressure from each gas is fairly equal, and *no pressure is then altered* while the jet is alight. There is no practical danger in *adding* weight on a double pressure-board permanently. With the blow-through form, 28lbs. on the bag at first will be enough, gradually increased to 56lbs.; and many lose light as well as waste gas by commencing with too much; but the mixed jet gives the best results with high pressure. Unfortunately, however, the pressure does not remain uniform, but diminishes as the bags empty; the result of which is that a fresh adjustment of the taps is necessary every now and then. A valued correspondent found by experiment that a pressure equal to nine inches with full bags and taps closed, gradually diminished to little more than four inches as the gases exhausted; also that it was very difficult to get the same pressure with both gases, whatever arrangement was adopted. He therefore introduced between each bag and the lantern a simple gas regulator,* and then found that, provided there was only *sufficient* pressure behind, it could be kept uniformly steady, and the same adjustment could be retained throughout. In using these regulators, the pressures are first tested, as usual, by U-tubes (see fig.)



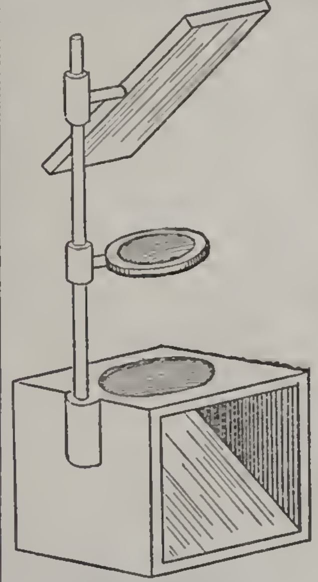
The tube is open at one end, while the gas to be tested is led to the other by a vulcanized stopper and small L-pipe.



Soft limes are often recommended for blow-through jets, but those known to opticians as "Excelsiors" are far the best; give at least equal, if not greater, brilliancy, with a smaller radiant spot; and with a "blow-through" require hardly any turning. With the mixed jet the lime should be turned a little, the same way, *with every experiment*. Finally, the best result will depend on the supply of each gas being carefully and deliberately adjusted; and the greatest advantage of the regulators referred to is, that when this has once been effected, it can be retained with certainty throughout the experiments, leaving the demonstrator or his assistant free (beyond turning the taps on and off as required) to give attention to other things.

In many cases, as when horizontal objects are to be represented, it is absolutely necessary to provide a vertical attachment, a very simple and convenient form being described.

A cubical wooden box is open on one of the perpendicular sides, and has a circular aperture cut in the top nearly extending to the edges of the square. The size of the box and of this aperture depend on the size of field to be projected; for magnetic curves or wave-ripples, a circle of less than five or six inches diameter is of little service. Opposite the open part, on strips of wood at each side, a piece of good plate looking-glass is supported at an angle of 45°, so as to throw the horizontal beam from the lantern up perpendicularly through the circular aperture. Owing to the larger size of this (the horizontal field), a *diverging* beam will generally be required, from any ordinary lantern, to cover it; and hence there *should* be a large plano-convex lens (costing about 15s. for one six inches in diameter) fixed to the under side of the aperture, so as to re-converge the rays on the focusing lens. Fair effects can, however, be procured without this with a good lime-light, in spite of what is then wasted. In any case, all but the condensers are removed from the lantern, and these are so adjusted, and the box so placed in front, that the field is just covered and no more. To one side of the box is fixed a stout perpendicular brass rod or tube, the same gauge as the pillar-stands already described, and furnished with two sockets. The lower socket bears a focusing lens, either plain or achromatic, and the upper socket the plane reflector, which reflects the image to the screen.



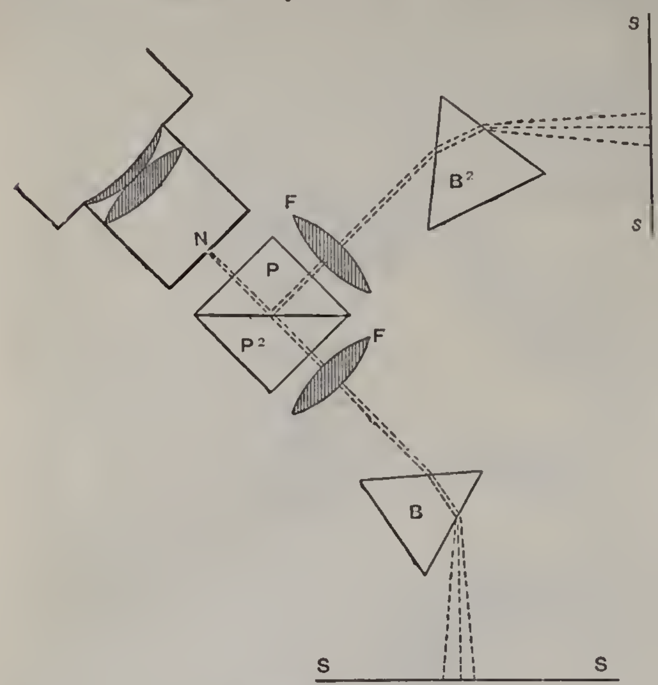
Vertical Attachment.

A selection of easily-performed experiments serves to demonstrate the laws of reflection and refraction, together with the production of real and virtual images; the pupils being thus placed in a position to understand any ordinary optical instrument which may be put before them. As an example of the thorough way in which Mr. Wright treats his subject, we may quote the description of an experiment to prove Newton's fundamental position of the special refrangibility of each colour.

It depends on the facts already noticed, that the angle of total reflection must vary with the index of refraction; the violet rays being totally reflected (because more refracted) at an angle which would allow the red rays to leave the denser medium. Newton therefore arranged an experiment (see fig.), except that he employed the parallel rays of the sun instead of those from the lime-light lantern. A perpendicular slit (N) is placed in the optical stage with the objective removed, or on the nozzle of the lantern if an adjustable slit is at command (see fig., which shows all the arrangements in plan). As close to the slit as convenient, on a table-stand, simply "stood up" on their ends, are two similar right-angled glass reflecting prisms (P and P2), with their reflecting sides together, kept together by an elastic band passed round near each end; they must not, however, quite touch, and may, if necessary, be kept apart by a narrow slip of paper at each end between them. In the direct path of the rays from the slit is a focussing lens (F), and beyond that, on another table-stand, is placed a bisulphide prism-bottle (B) in the usual position for throwing a spectrum on the screen S S. In the path of the rays totally reflected from the film of air between P and P2 is another focussing lens (F), and beyond that, on a third table-stand, a second bisulphide prism-bottle (B2), which throws its spectrum on the screen *s s*, adjusted at right angles to the other screen. All being thus arranged in the general, the double prisms, P and P2, can be turned round their common perpendicular axis from right to left in the figure, till nearly all the rays from the slit pass through both, and the prism B throws a spectrum on the screen S S as usual. Except for a little loss by reflection and absorption, all is just as if P and P2 were not there, the *refraction* of one being exactly neutralised by the other, and the rays passing as if through one square bar of glass. Let now the double prism be very

* Any efficient regulator ought to answer for this purpose; but the small and handy form used by my correspondent, and since by myself, with most satisfactory results, is manufactured by Messrs. Parkinson and Co., Cottage Lane, City Road. They cost 3s. to 6s. each.

carefully and slowly turned round in the direction of the hands of a watch. At one certain point of revolution, just when the film of air meets the rays from the slit at the critical angle



Newton's Experiment.

for violet, the violet *leaves the spectrum* on the screen S S, and being totally reflected, appears on the screen *s s*.* Continuing very slowly to turn the double prism, all the colours in succession leave the spectrum on S S to appear simultaneously on the screen *s s*, so that if we letter the screens with the conventional names, at the point when one screen has only left on it the colours Y O R, the other screen presents the missing colours, *v i b g*, which are "totally reflected."†

The course of demonstrations includes the principal phenomena of spectral analysis, phosphorescence, diffraction, polarisation, and all the ordinary phenomena of light as described in the usual text-books. No less than 190 woodcuts occur in the text, and there are in addition several coloured plates illustrative of the chromatic phenomena of light; while a copious index adds to the value of the book.

To the student, and more especially to the science teacher, Mr. Wright's work cannot fail to possess the greatest value, and we heartily congratulate Mr. Wright on the satisfactory manner in which he has struck out a new path in scientific literature.

THE VARIOUS MODIFICATIONS OF BROMIDE OF SILVER IN EMULSIONS.

BY DR. H. W. VOGEL.

Numerous investigations have been made in order to discover the relatively high sensitiveness of gelatine plates as compared with collodio-bromide plates, and these and other researches have brought to light the existence of several modifications of silver bromide.

The white silver bromide of Monckhoven appears, if we may judge from subsequent investigations, to change into the green modification by boiling, prolonged digestion, or treatment with ammonia; and at the same time its sensitiveness becomes exalted sometimes so much as fifteen-fold.

It will be remembered that in the year 1874, Stass studied the properties of the green silver bromide, and he recognised its high degree of sensitiveness, mention being made of the circumstance that an exposure of two minutes to the blue flame of a Bunsen burner served to blacken the bromide. This sensitive bromide he characterised as granular, as distinguished from the flocculent and pulverulent varieties; but how far these latter modifications are identical with the so-called white form is at present uncertain. There is no denying that I have been inclined to the view that the silver bromide of collodion emulsion and that of unripened gelatine emulsion are identical, as both are either white, or only possess a faint tint of yellow, and each of these modifications is unmistakably wanting as regards sensitiveness. There are, however, circumstances which have long been known which tend to contradict this view, as, for example, the fact that the sensitiveness of collodion emulsion cannot be exalted by warming or boiling; and although ammonia somewhat raises the sensitiveness, this increase is far less than in the case of gelatine. In addition to this I have made experiments which conclusively prove that the supposed identical silver bromides behave very differently in relation to the spectral light, the maximum of action for the collodion corresponding to the line G in the indigo; while in the case of the gelatine the maximum was found to be in the blue between G and F, but rather nearer to the former line—in fact, at a point corresponding to a wave length of 450.

It should be mentioned that the varying transparency of the atmosphere for the various spectral rays served to shift the position of the maximum to a certain extent; but the difference is always unmistakable when both bromides are simultaneously exposed; and the general reliability of my conclusions was further established by making considerable variations in the preparation of the emulsion.

Another point requires consideration. It is well known that the absorption of coloured light by a given material depends very materially on the solvent used, and the sensitiveness naturally depends on the absorption. I therefore attempted to separate the silver bromide from collodion emulsion and incorporate it with gelatine, but this experiment did not give a satisfactory result; still the converse experiment proved practicable, and it was found that collodion emulsion thus prepared with the bromide separated from gelatine, behaved exactly like the original gelatine emulsion when exposed to the solar spectrum. It is therefore evident that the difference between the point of maximum sensitiveness of the collodion emulsion and the unripened gelatine emulsion does not depend on the medium used, and it follows that a determinate difference exists between them. In fact, they are not identical, the former being indigo-sensitive, and the latter blue-sensitive.

It should be noted that the blue-sensitive silver bromide does not incorporate itself satisfactorily with collodion, and rapidly subsides, so as to render such a blue-sensitive collodion emulsion of but little practical value. The case is, however, quite different when the collodion contains gelatine, it being, as I have already pointed out, practicable to obtain a gelatino-collodion emulsion when a mixture of glacial acetic acid and alcohol is used as a solvent. Such a mixed medium can be readily obtained by mixing ordinary collodion and a solution of gelatine in glacial acetic acid. In a compound medium of this character the blue-sensitive silver bromide is maintained in a perfect state of subdivision, and such an emulsion is known in commerce as "Dr. Vogel's Emulsion."

The behaviour of the collodion gelatine emulsion in question towards the spectrum corresponds generally with the unripe gelatine emulsion, but the position of the maximum of action is a little nearer the line F, and corresponds to a wave length of 460, and it is, therefore, even more characteristically blue-sensitive.

If collodion emulsion is prepared in the usual way, and a solution of gelatine in glacial acetic acid is added, the resulting preparation is quite different from that obtained

* The effect is less visible on this screen, enough light being always reflected from the air surface to give a little spectrum. But it can be seen that the violet is strengthened.

† Only the sun, or the small radiant point of the electric light, will give the phenomena *perfectly* in these details. A large gas-burner will not answer for the experiment at all. A "mixed" jet will perform it fairly if the condenser will throw nearly parrallel rays. The "blow-through" form gives too large a radiant for a good parallel beam; but even with that, it is at least easily shown, by taking both prism-*bottles* away, and leaving the rest of the arrangement, that at a particular angle the direct image of the slit is reddish, and the reflected one bluish.

by first preparing a gelatine emulsion, and dissolving this in glacial acetic acid, the solution being next mixed with collodion. In the latter case, a blue-sensitive preparation results; while in the former instance the result is an indigo-sensitive emulsion, although the media are identical.

The green silver bromide of the ripened gelatine emulsion is ordinarily regarded as being distinct from the white bromide of the unripened emulsion, and the view taken by Stas would appear to lend support to this notion. Notwithstanding this, the fact that both are acted on to the maximum by the same spectral rays (wave length 450) appears to strongly indicate the identity of these bodies; but at the same time it must be admitted that the sensitiveness for all rays, and more especially for the ultra-violet, the indigo, and those of low refrangibility, is notably increased when the bromide becomes converted into the green modification. The green bromide must then be regarded as identical with the white, both being blue-sensitive; but I prefer to call the green bromide *high blue-sensitive*, and it appears to me that the greater sensitiveness of the green bromide is in reality due to the different state of aggregation of the molecule. As an illustration of a similar case in the domain of inorganic chemistry, it is merely necessary to call attention to the fact that many coloured metallic oxides—as that of chromium—vary extremely in colour according to their state of aggregation. The intensity of colour in such cases depends principally on the power of reflection for certain coloured rays, and the power of absorption for others. Doubtless something of the same kind holds good with the blue-sensitive bromides of silver.

The above considerations would lead us to believe that the blue-sensitive bromide of silver may be regarded as generally resulting when formed in the presence of gelatine, and the violet sensitive as being formed in the presence of collodion.

I had also previously stated that a minimum quantity of gelatine sufficed (I took 12 grammes of ammonium bromide, ½ of gelatine, and 100 of water) to form blue sensitive bromide of silver.

It afterwards appeared to me probable that the same modification would take place by the entire omission of gelatine, especially as Stas obtained his highly sensitive modification of bromide of silver by precipitation from aqueous solutions without gelatine.

My conjecture has been proved and established. Bromide of silver may be precipitated from aqueous solution of nitrate of silver, excess of silver being present, or from ammonium bromide, in the presence of excess of alkaline bromide, and both deposits, after washing with distilled water until every trace of soluble salt is removed, may be shaken up according to Abney's method in a warm solution of gelatine. Uniform emulsions resulted, and some plates were coated. The rest was allowed to stand in water at the temperature of 70° R. for an hour, in order that any increasing sensitiveness might be observed.

The plates were first tested by the action of the solar spectrum, and afterwards by trials on plaster models, backed up with black cloth.

The results are as follows:—1st. That the precipitated bromides of silver were each specially sensitive to the blue rays, the maximum point being about 450. That prepared with excess of bromide was almost free from fog, but the other emulsion was notably foggy. 2nd. The bromide of silver obtained from solutions containing silver in excess, after being digested for one hour, became more fogged, without increased sensitiveness; while the other bromide of silver became almost twice as sensitive by digestion. I here remark that Szekely, by allowing bromide of silver obtained by Abney's method with excess of silver to digest for a while, could not observe any increase in sensitiveness. I therefore believe that the formation of intensely blue-sensitive bromide of silver by heating only occurs with bromide of silver precipitated in the presence of an excess of alkaline bromide.

Abney, on page 70 of his book, says that the presence of great excess of bromide occasions greater sensitiveness. Eder is of the contrary opinion. Wilson, according to Abney's book, page 117, declares that the less bromide the longer it must be boiled. Were both present in equal proportions the conversion to the highly sensitive state would not take place, even by long boiling. In proof of this statement I made a gelatine emulsion with excess of bromide at 30° R., boiled one half for a quarter of an-hour, washed, and coated some plates. The other half was washed first, then boiled an equal length of time, and plates were prepared. The result was, that the emulsion not having free bromide, which was boiled after washing, was much more sensitive (nearly double) than the other. The Abney-Wilson theory, therefore, does not seem correct. Further, the emulsion not containing free bromide was quite free from fog, and on that account to be recommended. Although it is possible to obtain a silver bromide which is specially sensitive to the blue rays by precipitation from pure water, this proceeding is not to be recommended. The deposit without the presence of gelatine is too coarse for it to be fit for photographic purposes.

Stas certainly obtained highly sensitive bromide of silver in the finest state of division without using gelatine, but only after boiling for days, and using very weak solutions. Gelatine allows the bromide of silver, even in concentrated solutions, to deposit in the necessary state of fineness.

After these results, it was interesting to experiment on the bromide of silver precipitated from alcoholic solutions. The violet sensitive bromide formed in the presence of pyroxyline I have already considered; and the conjecture that the same modification may be arrived at without it is legitimate after the preceding.

Three grammes of ammonium bromide were dissolved in 100 c.c. of warm alcohol, and to this was added 5 grammes silver nitrate, first dissolved in 1 c.c. of water, and then mixed with 10 c.c. of alcohol. There is in this case a slight excess of bromide. The precipitate presents exactly the same appearance as that obtained under similar circumstances from an aqueous solution. It was next thoroughly washed in alcohol, then a portion was extracted with water, and shaken up with a solution of gelatine.

Here a distinct difference from the bromide deposited from the water is apparent. While this last was easily blended with the gelatine, and made a smooth emulsion, it was impossible to cause the bromide from the alcoholic solution to unite with the gelatine, either by shaking or warming for a long time. On the contrary, it mixed very readily with collodion, while the other precipitate did so with difficulty. With solutions of gelatine and pyroxyline in glacial acetic acid the same differences were observable. The preparation from alcohol would not unite with it, while that from water did so readily.

The alcoholic precipitate, when incorporated with collodion, did not produce as fine an emulsion as that obtained by the production of bromide of silver in collodion. The preparation was coarse, and only slightly sensitive. It was only after repeated trials with long exposure that it was found to be violet-sensitive, and that the maximum lay about G. Consequently, while it is proved that the precipitate from alcohol alone consists of violet sensitive bromide of silver, as a practical way, precipitation from collodion proves itself the better, as the bromide of silver is obtained in a finely divided state, which is necessary in the formation of a homogeneous picture, and to the attainment of the sensitiveness necessary for collodion emulsion.

Putting the results of these researches together, we have the following:—

1. Precipitation from aqueous solutions (either by excess of silver or bromine) gives blue-sensitive bromide of silver. Precipitation from alcoholic solution violet-sensitive.

2. The blue sensitive bromide of silver unites with diffi-

culty with collodion, and easily with gelatine; the violet sensitive acts in a contrary manner.

3. The presence of colloid substances (gelatine in aqueous solutions, collodion in alcoholic) practically effect only the fine division of the bromide of silver, without changing the spectral action.

4. The deposited bromide of silver resulting from excess of bromide in aqueous solutions becomes more sensitive by boiling, that prepared with excess of silver does not. Excess of bromide is unnecessary in adding to its sensitiveness. A great excess protracts it.

5. The various modifications of bromide of silver indicated by Stas, all obtained from aqueous solutions, namely, flakey, pulverulent, and granular bromide of silver, I believe to be varieties of the blue sensitive bromide of silver. I would rather distinguish them as different aggregations of the same body.*

* Stas has not experimented on precipitates with alcoholic solutions.

Correspondence.

DIRTY OPAL GLASS.

Sir,—In your last week's report of the meeting of the London and Provincial Photographic Association, I am made to appear in the ridiculous position of exhibiting as an object of interest an opal picture which was "not faded," but "much discoloured, as though with dirt."

If the definition of to fade, to become less vivid, be accepted, a picture the white parts of which darken is as much faded as one the dark parts of which become light. The fact that the surface of opal glass, especially when ground, is liable to change from white to a dirty brown is well-known; so much so that I have been informed by glass merchants that they will not keep it ground in stock, but grind it as required, as they have found it to become unsaleable from discolouration in a short time. This being the case, it is manifestly improper to use the material as a basis for expensive finished pictures issued as permanent, without some protection from the deterioration which it is liable to undergo.

My object, in addition to giving this caution, was to raise an enquiry as to what is the component of the glass which causes such a disastrous result, in order that, when known, the manufacturers may, if possible, be induced to prepare the material of a more permanent character.—I am, yours obediently, W. E. Debenham.

[When exposed to the action of dirt, all ground glass readily becomes dirty, and it is difficult to clean. This fact is pretty generally known.—Ed. P. N.]

PHOTOGRAPHY AND TRICYCLES.

Sir,—I read with interest your paragraph on "Photography and Tricycles." It has often struck me that amateurs taking advantage of all the scientific improvements in dry plates and apparatus do not utilize the tricycle more than they do in their rambles for artistic tit-bits. Journeys of forty, fifty, and even seventy miles are done in a day on good machines, and not by professional cyclists either, but by fair and square amateurs.

The best tricycle I have yet seen most suitable for the photographer, both for speed and hill climbing, is one made by a firm of engineers at Egham Hill, Surrey; I believe the name is Blenheim and Sons. I do not know the name of the machine, but there are peculiarities about it which are wonderful in their action, and though built extremely compact, leaves plenty of room for "packing traps," &c.

Fancy an amateur photographer getting on a tricycle in London in the morning, and in the afternoon quietly exposing his dry plates in some of the beautiful lanes and bye-ways in parts of Wilts and Oxfordshire! Or professionals even, like those your correspondent met in Guildford, running ten miles out, doing their business, and returning feeling not much the worse for twenty miles roadstering. It is really a triumph of mechanical science when we see such things accomplished, and they are now very frequently, and will be more so by-and-bye, when people get to understand the qualities of a thoroughly good machine. There is little doubt the firm to whom I refer would gladly supply particulars of their machines if applied to, and to amateurs or professionals who think of going in for photo-tricycling I would certainly recommend to have a look, if nothing more, at this machine.—Yours faithfully,

G. Emberson, Jun.

FERROUS OXALATE V. PYROGALLOL.

Sir,—Mr. Wilkinson says he is aware that some people cannot see the slightest merit in English work, simply because it is English; whilst they think that all foreign work is good, because it is foreign. I fear Mr. Wilkinson lays himself open to a similar charge of trusting to pyrogallol because it is pyrogallol. I read his article of August 4th with some surprise, but had not time to reply to it then. As far as my experience goes, I should say there is very little to choose between the two modes of development. I know some English photographers of good repute who, after long courses of experiment, have put aside pyrogallol altogether, and now only use iron.

I have seen work by Continental and American photographers, which, for brilliancy, could not be surpassed, and which in every respect was as fine as any English work I have seen. This foreign work was produced from negatives developed with ferrous oxalate. Mr. Wilkinson considers that with the ferrous developer a long exposure is necessary. With a properly prepared developing solution I have not found this to be the case—in fact, in some instantaneous work I did last winter, I found I got better results from the ferrous than from the pyrogallol developer. As to length of development, I find there is nothing to choose, the average time for both in my hands being three and a-half minutes, though I have often found that with the ferrous developer two minutes gave rather too much density. I am also at variance with Mr. Wilkinson in his opinion that it helps a poor plate. A good plate can, I believe, be equally well developed with pyrogallol or with ferrous oxalate, if the operator is equally familiar with the working of both methods; a bad plate may make an apparently better negative when developed with iron, but it will give just as poor a print as the pyrogallol-developed plate. In the one case the negative will print a little better than it looks, and in the other (the iron developer) it will print worse.

We should remember that the ferrous oxalate developer is very cleanly in use, that the smell of ammonia is avoided, that there is no pyrogallic poisoning or eruptions of the skin to be feared in using it, and that the negatives as a rule look better and print much more rapidly than negatives developed with pyrogallol.

I must leave it to some higher authority to decide which is the better developer, but I certainly do not agree with Mr. Wilkinson in thinking that with a really first-class plate it is not possible, under any circumstances, to get as good a negative with ferrous oxalate as with pyrogallol. I do not think the experiments given in his article are extended enough to draw a safe deduction from, and I regret to think that some beginner may have been discouraged or misled by his very positive assertions, which are not borne out by my experience.—Yours faithfully, John Doe.

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of the Association on the 31st inst., Mr. W. E. Debenham occupied the chair.

Mr. A. L. Henderson exhibited a gelatine negative which was taken with a small hole, the diameter of which Mr. Haddon had, by means of the micrometer, ascertained to be $\frac{1}{70}$ inch. The negative was exposed for seven seconds in the open air, and seemed much under-exposed and much red-fogged; but a collodion transparency from it was full of detail. Some curiosity was excited as to the *modus operandi* by which this result was obtained from such a poor negative, and he (Mr. Henderson) stated that he had copied the negative while wet by reflected light, and he was of opinion that if he had used caustic potash instead of ammonia in developing, he would have got more printable detail and less green fog. Two other negatives taken by Mr. Henderson without the aid of a lens (exposure twenty seconds), at Southampton, were shown, and also a lens picture of the same subject (the statue of the Prince Consort), the latter being but very little sharper than the others.

The Chairman said that having occasion to write to Dr. Eder, he had mentioned to him that he (Dr. Eder) had been elected an hon. member of the Association, and that gentleman had in his reply said he felt honoured by his election, and would in consequence be stimulated to further efforts in photographic science. The Chairman also stated that he had cleared the discoloured opal picture which he exhibited at the last meeting, by applying to the parts not covered with colour, strong hydrochloric acid, afterwards softening the edge of the vignette with colour.

In answer to Mr. Henderson, Mr. Cowan said he preferred clear varnish for protecting opal pictures.

In the course of a discussion which took place on emulsions, Mr. Henderson said he found it an advantage to add a small quantity of bromide (1 grain to the ounce) to the washed emulsion.

It was suggested that this would slow the plate, and Mr. J. Barker said he had published about five years ago the results of some experiments, and in which he stated "the addition of soluble bromide to the finished emulsion did not slow the exposure provided the plate was developed immediately after exposure, but that if kept for some time before developing, a longer exposure was necessitated, and that by long keeping a plate in which soluble bromide was present, the image became gradually obliterated." He was also of opinion that the relative degree of sensitiveness of gelatine and collodion plates was greatly exaggerated, and that in a good light the quickest gelatine plates were not more than five times quicker than collodion.

The Chairman thought that if Mr. Barker were correct, and that the presence of soluble bromide hardly had the effect he attributed to it, it would prove a valuable addition, as it would obviate whatever slight inevitable action of light the plates had received in preparation; and as the development need never be deferred when working in the studio, the slow obliterating action would not take place.

Talk in the Studio.

British Association Grants.—Among these, the following may be noted:—£20 to Professor Odling, for photographing the ultra-violet spark spectra; £10 to General Pitt-Rivers, for photographs of the races and crosses in the British Isles; £5 to Sir F. J. Bramwell, for Patent Legislation

Royal Cornwall Polytechnic Society.—We subjoin a list of the awards in the photographic department, and shall next week give a full report of the exhibition:—*Professional Photography*—H. M. King, 1st silver medal; G. H. Dew, 2nd silver; W. D. Sanderson, T. Hillingworth, F. M. Sutcliffe, and F. Argall, 1st bronze; E. Day and Son, and E. Gael, 2nd bronze; A. G. Tod, highly commended. *Amateur*—H. Stevens, 2nd silver; A. Pringle, 1st bronze; S. P. Jackson and H. Manfield, 2nd bronze. On the 12th inst., Mr. W. Brooks is to lecture on "The Rise and Progress of Photography."

Continental Rambles with a Camera.—Mr. D. Ireland, jun. forwards us a charming selection of views, and writes:—"I send you a few lines to let you know how much we enjoyed your two papers on Norway. They were especially interesting to us, as we had gone over the same ground as you, with a few slight variations. We had a smaller camera than usual this year, but got very poor results, thanks to the dealers, who, on our asking them what sort of plates to take, assured us that the instantaneous were the very thing for landscape. Had we then known as much about dry plates as we do now, we would not of course have taken them; but, relying on the manufacturers, and thinking they ought to know, we took the instantaneous, with only a dozen of ordinary. Of course, on developing, the instantaneous turned out very poor; indeed, we discovered afterwards, that the batch had been a faulty one. However, I send a few prints by the book post, hoping they will be recognisable. One of them is Fleischer's Hotel, which we found a first-class, even luxurious habitation, and famed as being one of the best in Norway."

The Production of Bank Notes by Photo-Reduction.—The Bank of France is about to strike off six million hundred-franc notes from a plate engraved by M. Robert, after a drawing by M. Baudry, the painter. The original drawing was about 4 feet long by 22 in. deep, and was photographed on a reduced scale to the size of a bank note. Robert was engaged engraving it for several weeks in the strictest seclusion, in an inner chamber of the Bank.—*The Artist.*

Flameless Combustion.—In reference to the leader on this subject which appeared in our issue of the 25th August, Mr. Fletcher writes, calling in question the existence of anything approximating to flame even around the heated body, and says:—"There is most certainly nothing, no flame and no heat at the mouth of the burner; no flame anywhere, and not a trace of heat or sign of combustion, except in contact with the hot surface. The only sign of combustion is the heat evolved by the surfaces, the gas and air being combined by contact with the hot surfaces. Further than this, thick black smoke and flame are both destroyed by passing the heated surfaces, provided air is present in sufficient quantity. If air is deficient, black smoke is converted into carbonic oxide." In the case of our own experiments, Mr. Fletcher's conditions, as described in his letter, were not completely realised; there was certainly no heat or combustion at the mouth of the burner, but round about it and in the immediate proximity of the heated body there was something which possessed a vague outline, and, as already stated, appeared to us to partake somewhat of the nature of flame. In order to verify this, a spectroscope was so adjusted as to clear the heated body, and sodium chloride was dusted around, when the sodium lines immediately became visible. There is, of course, a possibility that the experiment may be carried a stage farther than we took it; but we are inclined to think not.

Commercial Alcohol and its Purification.—Oxidation methods are subject to the disadvantage of giving rise to objectionable products, such as aldehyde, acetic acid, and acetic ether; but the reduction method of Naudin and Schneider, in which the copper-zinc couple (pieces of zinc partially covered with finely-divided copper) is used, appears to answer well, and electrolysis by means of a separate electric generator has also been proposed. Pictet has recently adopted distillation under a very low pressure, and the vapour is fractionally condensed at a temperature as low as —25°, or even— 50°. A considerable saving appears to be effected by this proceeding. Eismann's method of using ozone is under trial, and it is said that the results are likely to be better than was at first anticipated. The method proposed by Cayeneuve and Cotton for detecting methylic alcohol by testing freshly distilled fractions with potassium permanganate appears to be considerably influenced by certain oily impurities which are ordinarily present.

Influence of one Metal on the Surface of another Metal placed at a Short Distance. By H. Pellet (*Compt. Rend.*, 94, 1247—1249).—If two metallic surfaces are placed parallel to one another at a distance of a few millimeters or tenths of a millimeter, the properties of the superficial layer of each surface undergo a slight alteration, due to the proximity of the other metal, and depending on the nature of the latter. This change is produced slowly, and at first increases with the time, but afterwards tends to a limit. It is not permanent, for, if the influencing metal is removed, the metal influenced gradually assumes its original condition. The amount of change was measured by comparing the difference of potential between a gilded brass surface and that of the particular metal before and after the latter had been subjected to the influence of a second metal. Of the metals used, lead and iron produced the greatest effect, but the change was very distinct with copper, platinum, and gold. Zinc appears to cause no change in the surface of copper, gold, or zinc. The phenomenon is not purely electrical, but is of a material character. It is probably similar to the phenomenon of Moser's figures, and is possibly related to the fact that many metals have a slight but distinct odour. The influence of copper on zinc is perceptible, even when their surfaces are 10 mm. apart. It would appear as if the metals give off at the ordinary temperature a volatile substance which can be deposited on other bodies, producing chemical change. When the influencing body is removed, the volatile substance gradually leaves the influenced surface, which resumes its original condition.—*Journal of the Chemical Society.*

CRYSTALLIZED VEGETABLE ALBUMEN.—Ritthausen has communicated to the *Journal für Praktische Chemie* the results of his researches, and finds that the vegetable albumen from pumpkin seeds, &c., &c., always gave a higher percentage of carbon than in the case of albumen from hemp seed and castor-oil seed, but in no case were Grübler's numbers obtained, the latter finding 1·8 per cent. carbon and 0·2 per cent. hydrogen more than Ritthausen, whose analyses agree very well with those of Barbieri referring to amorphous albumen from pumpkin seeds.

To Correspondents.

All Communications connected with Advertisements and Business to be addressed to Messrs. PIPER & CARTER, "*Photographic News*" *Office, 5, Castle Street, Holborn, E.C. Advertisers are requested to make all Cheques payable to* Messrs. PIPER & CARTER, *and crossed* "*Union Bank, Photographic News Co. Account.*"

*** We cannot undertake to return rejected communications.

PERPLEXED AMATEUR.—1. Not if it is an ordinary view lens. 2. Probably not. 3. No, the length would remain precisely the same.

W. T. H.—We know nothing of the whereabouts of the gentleman in question.

C. HUME.—Thin light macintosh cloth.

D. A. (Cadix).—Soaking in a saturated solution of alum will answer the purpose.

R. O.—1. The deposition may be prevented by keeping the preparation very faintly acid by the occasional and cautious addition of a solution of oxalic acid. 2. Place them face downwards in the washing water, and move them about occasionally. 3. Pour it over your cuttings, and, when dry, burn altogether. 4 We are inclined to think that you either used crystallised calcium chloride, or, at any rate, an imperfectly dried sample. If this is the case, it is easy to understand the presence of excess of silver. With absolutely pure alcohol there is no blackening; but methylated spirit often contains impurities which cause a rapid reduction of the silver.

L.—Thanks for the suggestion. The deposit in question consists of metallic silver, and exists at the back of the film—that is to say, next the glass—and it can only be removed by stripping the film from its support; after which the loosely coherent silver may be dissolved away by means of metallic mercury.

HENRI GUICHARD.—We cannot say; but he is described in his advertisement as "*Professeur de Photographie.*"

W. H. P.—1. An excellent idea. 2. Friday, September 29th. If in packing cases, to care of Mr. J. Bourlet, 17, Nassau Street, Middlesex Hospital; or, if ready for hanging, at the Gallery, 5, Pall Mall East.

FEANER.—Washing in the ordinary sense is not sufficient, long soaking with several changes of water being necessary.

A. R. DRESSER.—The only way is to make use of a lens having double the focal length, but of course you will not then include so large an area of the surroundings.

AN OLD SUBSCRIBER.—You will find a list of them in the YEAR-BOOK, but this is now out of print. Perhaps you may pick up a stray copy at a stock dealer's, or you can call at our office to copy out what you require.

ED. DOBBS.—Thanks; it shall be done.

IVORY.—We cannot lay hands on the address at the moment, but will send it you by post.

ARIEL.—1. From 8 till 6. 2. Certainly not. 3. You had better commence with a systematic study of inorgannic chemistry.

BENTALL.—Level the plate, and cover it with as thick a layer of the solution as it will retain.

HABRON.—It consists of starch in a nearly pure state.

WATER.—1. It is difficult to say without examining a sample, but the fact of green vegetable growths appearing in the bottle certainly indicates the presence of a considerable proportion of organic matter. 2. Its solubility is increased to a remarkable extent when carbonic acid is present.

WESTMINSTER.—Such regulations are not law, and are almost invariably upset when brought before a superior court; still it is questionable whether it is worth your while to spend several hundred pounds over a matter which is of so little importance to you.

THE EVERY-DAY FORMULARY.

THE GELATINO-BROMIDE PROCESS.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ¾ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1⅜ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts. water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

THE WET COLLODION PROCESS.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ¼-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ¾ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

PRINTING PROCESSES.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chlor. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1¼ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Silk.—Remove all dressing from the fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

VARIOUS.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts. camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

FERROTYPES.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1254.—*September* 15, 1882.

CONTENTS.

TRUTH AND PHOTOGRAPHY.

There is a popular notion that a photograph affords conclusive and indisputable evidence as regards matters of fact, and there can be very little doubt that photography not only has done, but will continue to do, good service as a witness.

An illustration of the value of photographic records in connection with toxicological work is afforded by the paper of Mr. Jennings which is published in our present issue. Photography in this case gives us some kind of a permanent record of the appearances presented by sublimates consisting of one or two thousandths of a grain of arsenic, qualities far too small to be estimated by the ordinary methods of chemical analyses. In reference to the value of photographic evidence, Governor Porter, of Indiana, said, on a recent occasion:—

I have myself been a witness to some things exceedingly interesting in photography, in the course of legal investigations. In trials for forgery, important assistance has been rendered by it in showing erasures that the most skilful experts have been unable to detect in examining the papers copied. I recall that when I was first Comptroller to the Treasury, a young man came from Texas and paid a visit to my office to see if his father, who was dead, had become the security on a public bond. The family had persuaded themselves that he had not, and that his name on the instrument was forged. He asked me if he could not take the instrument from Washington to Texas, in order that it might undergo the inspection of those who were familiar with the handwriting of his father. I told him that it was impossible to allow any public paper to be taken off the official files, but that I would give him a photographic copy, and I thought from this they would be able to say whether the signature was forged or genuine. He took the photographic copy home, and in a few days he wrote to me that the family had examined the copy, and had no doubt that the signature was genuine. The Government was saved a lawsuit, and the family much expense, by a controversy being thus quietly settled.

Then again as affording valuable aid in relation to ethnological researches, we may mention that the anthropometric committee of the British Association reports as follows:—

The photographic portraits already collected have been handed over to the new committee, and will assist materially in determining the values of crosses in different parts of the country. Some, obtained under exceptionally favourable circumstances, and especially seventeen portraits of Shetland Islanders, well illustrating the Scandinavian element in the population, and presented by Dr. Muirhead, may be safely termed typical.

Not unfrequently is photographic evidence brought into courts of law, either with a view to deceive, or at any rate to give an exaggerated view of the case.

"I have lost my case all through one of you miserable photographers," said a lawyer to a friend of ours. "Serve you right," said our friend; "why did you not get another photographer to take pictures on your side?" The lawyer evidently profited by the lesson, for a few weeks afterwards he came into our friend's studio, and explained the necessity of having a series of pictures ready before the opening of court next morning. The nature of the work was explained, the widest of wide-angle lenses were sent for, windows were hastily knocked out, roofs were invaded, and pictures were taken which made a recently built wall look so far off that the jury could not possibly regard it as any obstruction to light reaching certain windows, which were also shown in the picture. Had the other side been ready with photographs taken by an objective of long focus the result would probably have been different.

Photographs illustrative of the remarkable powers of hair-restorers, fat-reducers, and other nostrums, may be occasionally seen, and no doubt influence the public in favour of the preparation in question; but a clever use of photography as an exponent of untruth was recently made at a fair in Paris, where the public were invited to look on the photographic portrait of a three-headed lady, and, moreover, to enter the booth and see the living original. The method by which the illusion was produced will be of interest to those of our readers who may wish to produce certain remarkable effects in combination photography, and we illustrate the matter by an engraving taken from *La Nature*.

An alcove on the stage is draped interiorly with black, and provided with a plain plate glass reflector placed at such an angle as to reflect any objects placed on an inclined bench, which is itself screened from public view by a high partition. Two of the models are draped in black, and so placed that the reflected image shows no trace excepting the heads. A good light thrown on them, and the abundant use of face powder, render it difficult to believe that one is not looking on a veritable three-headed lady, and a basket of flowers serves to break the line which might lead to a discovery of the trick. By employing sunlight it would be easy to produce a remarkable combination picture in the same manner. The trick depends on the fact that feeble radiations are entirely lost on striking the somewhat imperfect face of the plate glass.

THE CONVENTION OF AMERICAN PHOTOGRAPHERS.

THE third annual assembly, which has recently terminated, may be looked on as a partial success, although its value as compared with the efforts made as regards organisation, is a point open to question. In the present day subject matter of real value is, as a rule, placed before the public with considerable promptitude, and there is but a small probability of important papers being reserved for conventions or other similar gatherings. Proceedings under these circumstances tend, therefore, to take a conversational turn, and among other matters it is interesting to note how Mr. J. Traill Taylor refers to an evening spent in the company of Mr. H. P. Robinson. Mr. Taylor said :—

There is no one present who will not be interested in knowing the sentiments of that master of photographic art, H. P. Robinson, of England, respecting the value of extra sensitive gelatine plates to the artist. Having spent an evening within the past few weeks in Mr. Robinson's company, on the occasion of a recent visit to England, the Chairman of the Committee on Progress is enabled to reproduce in colloquial form the off-hand utterances of this able artist and art writer. Premising that your reporter had in course of conversation alluded to the fact of the paucity of those professional portraitists in New York City who made use of the gelatine process, Mr. Robinson said : "I am surprised to hear this, for here in England collodion is now seldom used, and that only for copying. Apart from the convenience of having your plates always ready, and the quickness of exposure, I consider that dry plates give artistic qualities that were seldom or never met with in the wet process. I do not know how to describe it except by the word 'quality' as used by painters. Then, if you can rely on your plate-maker, you have no faults in your plates—no pinholes, no comets, no streaks in the direction of the dip, and the other devilments that drove the wet-plater mad while he ought to be keeping himself cool so as to do the best with all the artistic gifts with which nature had endowed him. While you are posing your group for a gelatine plate," continued Mr. Robinson, "you need not fear that if you keep your plate waiting another minute it will be spoilt. Then you can do things it would be useless trying with the wet process. Few of these groups I now show you [and here it is of vital importance to observe that the speaker was so fortunate as (by the courtesy of Mr. Robinson) to secure copies of the pictures alluded to, and to have them here for exhibition] could have been possible in the old days ; but," observed our friend, "I say the *old* days by inadvertence ; I forgot that collodion was still used in America ; it seems to me to belong to the past ages. Then for convenience of work. I gave up outdoor photography eight or ten years ago because I was not equal to the physical exertion, but now I have taken to it again with large plates, and it is a delight to me. During my last holiday—photography is no longer hard work, but part of a holiday—of a fortnight, the wind and rain came on every day with great regularity, but there were two days on which I could get out with some hopes of success, and during these two days I exposed fifty-two 15 by 12 plates, all containing figures and all containing a subject—that is, some story is told. This would have been prodigious with collodion, but with dry plates it was only a sort of gentle exercise. But then, as you know, I think out my subjects before I make my pictures. I do not trust to accidents or the inspiration of the moment. Beside the fifty-two outdoor pictures, I exposed sixteen interiors, making sixty-eight in all." In reply to a question concerning the development of his negatives, Mr. Robinson said :—"I never develop away from home. I sometimes exposed two plates on a very good subject. Otherwise I trust to the negatives coming right, and am seldom disappointed. And the delight of developing at home! I never label my plates as I expose them, and as, perhaps, I ought to do, but mix them up recklessly ; so I never know what is coming. Perhaps it is one of your best subjects, or it might be one you were doubtful about, that comes out better than you expected. The 'Merry Tale' was done on a very windy morning. I posed the group, and said I would only throw away one plate on it as a sort of record for another time, and it turned out one of the best."

The foregoing is the gist of a conversation with Mr. Robinson just after he had returned from a fortnight's holiday, during which he took a number of pictures in the absolute sense of the word, not inferior in the slightest degree, however superior in many points they may be, to those by which his name has become known all over the world. It is not considered out of place to have quoted at such length the sentiments and expressions of this gentleman, seeing that, owing to his position as an artist and art teacher, they are so intimately entwined with photographic progress in a certain and all-important direction, not to speak of the fact of illustrations, never previously exhibited in public, being accessible to every one present.

By unanimous request the fine pictures by Mr. H. P. Robinson, which received so much attention on the first day, were placed in the exhibition room, where they were examined at leisure with a degree of interest that would have gratified the artist had he been present.

Mr. Carvalho's scheme of a Universal or International Photographer's Association was brought under consideration, but it did not seem to meet with the active support which might have been expected.

Several papers bearing on the gelatino-bromide process were read, but not one of them possess sufficient interest to be worth reproduction in our columns. A large number of every-day matters of photographic practice were discussed at considerable length.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

GLAZING PHOTOGRAPHIC STUDIOS—A PHOTO-ELECTRIC BATTERY—PHOTOGRAPHY AND TRICYCLES—THE USE OF BALLOONS IN WAR.

Glazing Photographic Studios.—At the last exhibition of "Domestic Labour Saving Appliances" at the Agricultural Exhibition were shown specimens of glazing for conservatories and photographic studios which were of interest to the photographer, and especially to those photographers who contemplate building studios. By using the old form of glazing with putty, the photographer has to contend with a life-long trouble. A perfectly water-tight studio roof is, when putty is employed, an impossibility, and the annual expense of re-painting, to say nothing of damaged apparatus, carpet, oil-cloth, and accessories, amounts to something enormous in a few years' time. The sections of roof glazed without putty, shown at the Agricultural Hall by various makers, indicate that this annoyance and expense are by no means necessary, nor does it appear that the cost of the new methods is very much greater. The three systems which particularly attracted our attention were those of Messrs. Tracey and Sons, of Ilford, Mr. B. Warhurst, of 33, Highgate Road, and Mr. S. Deards, of Harlow. The method of the first-named consists in the employment of a metallic tubular sash-bar. The edges of the glass are inserted in metal tubes, which thus act as gutters to conduct any moisture which may find its way in. Messrs. Tracey claim for their system that the most inexperienced person can glaze a conservatory, hot-house, &c , in a few hours without the assistance of a glazier ; while the squares can be taken out and replaced by any labourer without the risk of damaging the house or breaking the glass. Mr. Warhurst also uses metal bars, but on a different principle from that employed by Messrs. Tracey. In this plan gutters are entirely discarded, and by the adoption of strong lead connections the metal is pressed sufficiently close to the glass to prevent the oozing of any moisture. There is also no overlapping of glass, and consequently no accumulation of dirt between the panes. There is this advantage also with the use of lead bars, that curved roofs can be constructed as easily as flat ones. Mr. Deards uses a metal arrangement, which, placed on a wooden sash-bar, clips the glass tight, and prevents any moisture finding its way in. Of these three methods, that of Mr. Warhurst seemed the most suitable for photographic studios, on account of its lightness and freedom from obstructions. Whether it is sufficiently strong to be used for a large surface is another matter. Studios are, however, no longer the wildernesses of glass which they once were, and for all ordinary purposes the lead sash-bar should serve. There are certainly advantages in the endurance of lead and the non-necessity of paint, which recommend its use. It is singular that no horticultural manufacturer has tried the plan of making glass roofs water-tight by means of strips of vulcanized india-rubber. Last year we described in the News a cheap and effective method which, in the hands of a friend, had answered admirably.

A Photo-Electric Battery.—A series of experiments has led a French chemist (M. Saur) to the construction of an electric battery which gives a current only when exposed to light. The battery, which is described in *l'Ingenieur*, consists of a square glass vessel, with a solution of 15 parts of marine salt and 7 of sulphate of copper in 100 of water. This has an electrode of sulphide of silver. An inner porous vessel with mercury has an electrode of platinum. The electrodes are connected with a galvanometer, and the battery is placed in a box with light excluded. Closure of the circuit displaces the needle, the sulphide of silver being the negative. When the needle is at rest, exposure of the battery to solar light causes further deflection, the extreme sensitiveness of the battery being shown by the fact that the passage of a cloud causes a variation. The effect of the battery is due to the mercury being attacked by the bichloride of copper formed by the mixture of marine salt and sulphate of copper. The protochloride of copper formed reduces the silver sulphide; but this reduction requires the intervention of solar light, which produces the photo-electric current. We do not know whether this photo-electric battery has been tried as a recorder of sunshine, but if it is as sensitive as represented, it should be of some value in this direction.

Photography and Tricycles.—In view of the number of machines now in the market, it would be well if some photographer who has had practical acquaintance with tricycling would publish some details of his experience. We are inclined to think that a machine made for speed is not necessarily the best to carry baggage. For instance, a good pace can be got out of a tricycle with small wheels speeded up but at the expense of muscle and endurance. It is doubtful, too, whether a front steerer, which most authorities say is the best for hill climbing, would not be found rather awkward when loaded. The Premier, an admirable machine in most respects, requires one almost to stand on the treadles when going up a hill that is at all steep; if not, it tips backwards, and the addition of a weight would, we fancy, increase the tendency. The unexpected lifting of the front wheel from the ground, though not productive of absolute danger, is somewhat trying to the nerves. Whatever machine he selected, the most important factor is to have efficient break power. The sensation of being shot off through the machine turning over when going down hill is not at all a pleasant one—as we can testify from experience; and if to grazed elbows and barked shins be added smashed negatives and a shattered camera, you will be doubly urged to use strong language against both the tricycle and its maker for the want of means to regulate the speed properly. It is an error to suppose tricycles cannot turn over. They can and do, but invariably through inexperience or carelessness on the part of the rider, and in nine cases out of ten by reason of inefficient brakes.

The Use of Balloons in War.—The objection to the use of balloons in war time always has been the possibility of the enemy firing at and disabling them to the certain death of the unfortunate occupant. Mr. A. Cooper Key writes to a daily paper suggesting a plan by which this risk could be obviated. He proposes that a small captive balloon, from which four cameras fixed to a square frame are suspended, should ascend to a given height—say half or three-quarters of a mile; the four lenses, previously focussed, must be towards the earth, and closed with instantaneous shutters, capable of being moved by galvanic battery, the wires from which could be carried by the rope which tethers the balloon, and the frame in which cameras are fixed should have facing plates at an angle of 45 deg., and be prominently painted in different coloured symbols which could be clearly read off from the field of observation. The officer in charge should be provided with a field glass, mariner's compass, and a sheet of paper with symbols painted to correspond with those on the camera frame, so as to note the position of balloon the instant contact is made by means of the battery. Thus, when the balloon is brought to earth, the exact situation in which the photograph was taken can be ascertained.

By-the-Bye.

CONTINENTAL RAMBLES WITH THE CAMERA.

The Pyrenees.

There are two reasons why the tourist and the tourist-photographer are rarely found in the Pyrenees. The district is somewhat more distant than other playgrounds of Europe, and there is a wide-spread belief—certainly founded on fact—that the Pyrenean spas and spots of interest on the confines of France and Spain are expensive places. We are not going to deny this, but, despite the remoteness of the country and its costliness, we may state at the outset that we ourselves spent a month in the district, travelling, indeed, as far as Vittoria, to get a peep at Spain into the bargain, at a total cost of less than twenty pounds. That the journey cost us some fatigue as well—for third-class trains are very slow, both in France and in Spain—we readily admit; but, then, who would not undergo some little hardship to see the mighty forest-clad ranges, the snowy Vignemale and Maladetta, let alone the picturesque natives in their "berret" caps, broad red sashes, and white stockings, and the coquettish black-eyed maidens to be found on the borders of Don Quixote's country?

The way lies through Paris and Bordeaux, and at the latter town you may purchase a railway ticket, that makes the tour of much of the Pyrenean district, at seventy-five francs first class, and fifty, second class; but this ticket, naturally, only takes you into central spots, and, to get among the mountains, you must rely upon your legs, or hire a trap. The roads of the Pyrenees, we may here state, are very perfect of their kind—smooth and well paved; they pass through the most charming scenery of cliff and woodland, at times constituting a terrace-like promenade in face of a delightful out-look. Our journey was made on foot, with the knapsack, and so little is this mode of travelling understood, that, as often as not, you are taken for a pedlar. On one occasion, in the Val d'Ossau, we had thrown off the pack in front of a little auberge, the better to enjoy some red wine we had ordered. The landlady, after watching for some time, and mistaking our leisure for a hesitation to exhibit what we had in the knapsack, called out, by way of encouragement, "Eh, bien; qu'est que vous avez à vendre?"

One of the best starting points to visit the Pyrenees is Pau, journeying thence by diligence to Oléron at the foot of the valley of the Aspe, or Val d'Asaspe, as it is sometimes called. Oléron is a quaint town, where the camera may at once be brought into requisition, for it is one of those old-fashioned remote places where progress does not travel so fast as in big cities. Oléron, in fact, is a very good example of a Pyrenean town, and its streets and public buildings will make many an interesting picture. You may get into Spain by following the sequestered valley to its head, but the international traffic is not enough to wake up sleepy Oléron ; indeed, the road terminates at Urdos, and afterwards it is only a craggy ill-kept mule-path that leads over the border. A few miles beyond Oléron all traces of town-life vanish, and soon after the village of Asaspe is passed the lavish beauties of the valley become apparent. On both sides of the way are dense hedges of box, and upon the slopes on either side, which become more precipitous as we advance, are green fields in which the hay-makers are busy at work. It is not, however, till we cross the Gave, or stream, at the Pont d'Escot, that the most romantic part is reached, the mountains suddenly closing in upon you. In some places there is scarcely space for the road and the bright green torrent that runs beside it, so narrow is the defile, and the eye rests enchanted with the picturesque gorge that stretches many miles in front. The steep hill-sides present one vast expanse of soft green verdure, of various shades and tints, lawn-like meadows and cultivated fields being separated by hedges of leafy foliage. Not a barren spot, or a grey rock or boulder, is visible on the mountain side to mar the soft and peaceful aspect of the scene, which might be called with truth the Emerald Valley.

Presently the defile widens again, and we reach the busy little village of Sarance, the violet bloom of sunset making the cottages bright and splendrous with colour. It is a pretty sight of an evening to see the peasants hereabouts fetching water from a neighbouring rivulet, and carrying it away on their heads in tall wooden vessels, broader at the bottom somewhat than at the top, to allow of their being easily balanced. In most places it falls to the lot of the women to perform the office of water-carrier, but here it is the men of the household who do the duty. They set down their vessels, so white and clean as to be a marvel of scrubbing, at a spot where the little stream runs bright and clear over the pebbles, and proceed to bale the water into their tubs by means of bright copper ladles. The ladles are polished and rubbed till they shine like burnished gold, and the pure cold water is altogether treated with the most laudable care, to prevent contamination. At first we are under the impression that a party of water-carrying peasants, whom we meet, are on their way from the dairy with the milk-white utensils deftly poised upon their heads, and accordingly stop one of the men to beg a drink ; and great is our disappointment to be offered, instead of a sup of new milk, nothing but cold water, although we cannot resist the tempation of taking a sip from the golden ladle held out by the friendly hand.

The Pyrenees has not been photographed, like other mountainous districts, and even in the collection we have seen, no picture of the beautiful Val d'Aspe is included. The Pont d'Escot is one of the best points the photographer can select for a picture, and a second view may be secured above Sarance. Bédous, the next village, is rather dirty, and situated in the sole of the valley, where this is not so picturesque. But Bédous is a convenient halting place for the night, whence the rival valley, the Val d'Ossau, can be reached. It is a five hours' walk to reach the top of the col that separates the valleys, and the spa of the Eaux Chaudes is two hours further. Crossing the grassy peak, a charming glimpse of snow and forest scenery is before you, while on your lofty path, when other vegetation has ceased, may be gathered the red Alp rose, London pride, and the bright blue shepherd's looking-glass. The solitary Spanish shepherd and his dog we meet upon these lonely highlands deserve a few words to themselves, and a photographer nowadays, provided with gelatine plates, should not miss the chance of securing a photograph of the original aspect they present. He will have plenty of opportunities, for the type is to be met with throughout the Pyrenees. His swarthy figure seems covered with a sole garment, a big brown blanket with openings for the arms, quite a classic toga ; and instead of crook, he carries a long pole, at the end of which is a small spade or trowel, wherewith to dig up a bit of turf or earth to throw at an erring sheep. He precedes his flock, which is followed by a white dog, something like a Newfoundlander, but of more formidable proportions.

The hotels hereabouts—for we wish to make our paper as practical as we can—vary much in their prices and accommodation. In some parts the inns are homely and very reasonable, as in the case of the Val d'Aspe and that portion of the country between the valley and the Biscay coast ; in others, where fashionable spas exist, as at Eaux Bonnes and Eaux Chaudes, Cauterets, Luz, &c., the hotel charges are high, sometimes extortionate, but the accommodation is always of good character. Accordingly a pedestrian's expenses may vary from four to fourteen francs a day, if he travels continually across country without staying long in one place or another, and he can never estimate his day's expenses until he sees his night's quarters.

Eaux Chaudes—it takes its name from the warm springs here—makes a capital picture. It is not a village or even a hamlet, but a narrow defile or cleft in the rock in which a few houses are apparently firmly wedged. The mountain walls of the valley rise precipitately to a couple of thousand feet, and are not a hundred and fifty yards apart. The only difficulty in taking a photograph is how to display the full height of these cliffs ; as a matter of course, the lens must be raised above the centre of the camera, and if there is a swing-back, this must be adjusted with care.

Eaux Chaudes is a capital head-quarters for the tourist who wants to visit the wild scenery and magnificent torrents at the head of the valley, and a two days' excursion will take you to the primitive baths of Penticosa, situated up at the snow line in Spanish territory.

Eaux Bonnes, another spa, is close to Eaux Chaudes. This is a very fashionable place, and is filled with the élite of Paris in the season. There are fine gardens and pleasant promenades, together with easy mountain excursions in the neighbourhood. In fact, here you play at being at Switzerland ; the Parisian is not much of a mountaineer, but he likes to have his guide and his climbing suit, as if he were engaged on real hard work.

The guides, too, are a pretence. They know little of the district, and nothing of glaciers and crevasses. But as to costume and appearance they are perfect. Attired as if for the performance of an opera comique, with gorgeous red jackets and spotless white stockings, they invite visitors to avail themselves of their services in the most gentlemanly manner. Unfortunately, they are only men of promise, so far as their qualifications are concerned, and are not fitted for honest labour, any more than the theatrical costumes in which they are clad. One may safely trust oneself therefore in their hands, for they rarely venture off the beaten tract, and if they do, and lose their way, they are very frank about the matter.

"I beg pardon, sir, but do you happen to know where we are?" one of these guides is reported to have said on one occasion to his employer.

"That I certainly do not ; I was never here before!"

"Nor I either!" was the guide's unhesitating reply.

Frenchmen, as a rule, prefer to make their "ascents" on horseback rather than on foot ; and the guides we have mentioned are in reality horse-jobbers, rather than, as they are wont to describe themselves on their cards, and over their dwellings, "Guide de 1ère classe," "Chasseur des Izzards et des Ours," &c. No doubt chamois and bear are still to be found in the Pyrenees, but these Eaux Bonnes guides would make sorry hunters.

Another day's walk takes you to the valley of Argellez, over a steep col, whence a most charming view, when you once begin to descend, is secured of the valley below you.

It is the Val d'Arun you are looking at, and the tiny church and cluster of white cottages at your feet is the village of Arruns. If you can get a good photograph of this, you will have secured one of the most smiling features of the Pyrenees.

You may fancy you have gone back a couple of centuries as you lie lazily upon the grassy slope in the warm sun, and, half dozing the while, watch the objects passing along the road above you. Here come a couple of Spaniards with sunburnt faces and ragged beards, dressed in red berrets and sashes, white-stockinged and cross-gartered. Each carries a thing like a leg of mutton suspended from his shoulders, which turns out, as they come nearer, to be a skin of wine. The shaggy, picturesque characters come to a standstill, as a matter of course, on seeing travellers, and, in return for a coin or two, pour out some of the liquor into a travelling-cup, the red wine flowing out in a thin stream as soon as a wooden peg has been removed. Then labourers with agricultural tools of the most primitive kind pass by on their way to the village, and following them comes a cart drawn by oxen, such a one as our Anglo-Saxon ancestors might have used. It is a low wooden frame supported on wheels, which are simply wooden discs a foot in diameter, and altogether of the rudest aspect.

There is good accommodation at Argellez, and here we stop the night before proceeding on our way to Luz and Gavarni. (*To be continued.*)

PHOTOGRAPHING ONE-THOUSANDTH OF A GRAIN OF ARSENIC.

BY I. H. JENNINGS.

A few months ago Mr. Henry Carr sent me some micro-slides on which were deposited sublimates of ·001 grain and ·002 grain of arsenic, which had been obtained from definite solutions of arsenic; and he asked me if I could photograph them in a satisfactory manner, as he wished to have photographs of the whole deposit as seen under a low power, and also of a portion magnified 200 diameters. As I had been engaged in working with high powers upon diatoms for some time, and had obtained some very fair photographs of these difficult subjects, I had no hesitation in trying the crystals of arsenic. At first sight they appeared rather unpromising subjects for photography. In the centre of each slide was a misty-looking circular deposit of arsenious acid, about a quarter of an inch in diameter, looking like a film of moisture, and presenting to the eye no appearance of crystals. Under a two-inch objective, which took in most of the circle, one could discern tiny crystals, which were best seen by oblique light, but which were not defined properly by such a low power. I saw that I should have some difficulty in obtaining a satisfactory photograph of the whole area, for the nature of the object was such as to test the definition of the lens to the utmost, as well as its flatness of field. Added to this, a strong light at once "drowned" the transparent crystals; yet, without a strong light, it is almost impossible to work microscopic photography. Yellow or artificial light, which I always use, is so non-actinic, that, when transmitted too obliquely, or much modified, a thin washed-out negative alone is obtained. So I concluded that a rapid exposure with a strong illumination would be necessary to give the best results; and experiment proved this to be the case.

Under 250 to 400 diameters the crystals came out well; their forms, regular octahedrons, were clearly defined; and no unusual difficulty should be experienced in photographing them with a $\frac{1}{5}$-inch or $\frac{1}{8}$-inch objective. Viewed either by oblique, transmitted, or by reflected light, the crystals formed beautiful objects.

When I had made a complete examination of the slides, it occurred to me how useful, in certain cases, photography might be in quantitative analysis. The microscope has frequently done good service to the analyst; by its aid in discerning minute crystallized forms and chemical reactions invisible to the unaided eye, important facts have been revealed or confirmed; in qualitative analysis, the microscope has been invaluable, and the aid of the draughtsman has often been called in to give a record of permanence to certain results gained by its use—a record too often marred and nullified either by the inventive imagination or the lack of brains on the part of the limner. If photography could be successfully applied to record the results of a qualitative analysis, a step would be gained. But quantitative analysis is a different affair; no one at first sight would think the thing practicable.

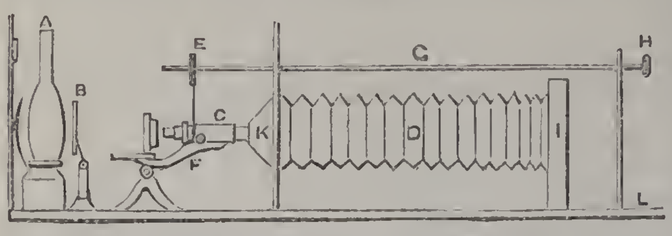
The results of my operations proved the truth of my conclusions. The slides which Mr. Carr had sent me were about twelve in number. On some were deposits of ·001 grain of arsenic, and on others ·002 grain. Under 250 diameters the difference between the two kinds of deposit was clearly marked. Taking up slides at random, and placing them on the stage of the microscope, after a little practice, one could not mistake the ·001 grain deposits for the ·002 grain deposits. On the ·002 grain slides the crystals were either much larger than the crystals on the ·001 slides, and more numerous, or, if the deposit of ·002 grain were a fine one, the crystals were crowded together thickly in the $\frac{3}{8}$-inch circle, presenting a strongly marked contrast to any of the ·001 grain deposits, in which the crystals were but sparsely distributed.

Now, in the photographs obtained, this difference is as clearly marked on the micro slides—perhaps more so. The photographs of the whole area of deposit, although neither attractive nor striking to the eye—being merely minute points, more or less thick, in a white circle—I consider of value for comparison; but those of a part of the deposit, as seen under a power of 300 to 400 diameters would probably be most useful. In these, the crystalline form of the arsenic crystals is clearly shown, while the amount of the deposit, whether ·001 grain, or ·002 grain, cannot be mistaken. Experience in photographing a number of these slides has shown me that no matter what portion of any deposit on any slide may be photographed, it is an easy matter to state at once whether the photograph be taken from a ·001 grain or ·002 grain deposit of arsenic. The forms of the crystals prove the deposit to be arsenic, while their number or size shows the quantity in a most unmistakable manner.

Doubtless, photographs taken from standard slides, such as these, would be of immense use to chemists and others in estimating the amount of arsenic obtained from an analysis. There are many chemists who rarely have to perform an analysis of any sort, and such would find themselves considerably aided by having recourse to reliable photographs, if they were required to pronounce an opinion on the quantity of arsenic contained in a wall-paper or fabric; while experienced analysts would often find it of use to call in the aid of photography to make a permanent record of an analysis, and in a mode that cannot be called in question—a mode in which imagination and the erring pencil have no part.

How far chemists may be disposed to use photography as a regular tool is a matter that time will decide; but there can be no doubt of the advantage to be gained from it. Suppose, for instance, that a chemist is called upon to prove that a poison (say arsenic) has been found to exist where it ought not; it would be inconvenient, to say the least, in most cases, to demonstrate the fact with microscope and slides, nor can everyone see and understand what the instrument reveals. But what difficulty would there be with photographs? They would be easily procured and easily carried about. Magnified 200 to 400 diameters, the forms of the crystals, and their quantity, could easily be seen and understood by anyone. The difference between a proper and improper quantity of arsenic in a dye could be pointed out to the most untechnical mind, and the photographs would most decidedly form evidence far weightier than any given by mere word of mouth.

To those unacquainted with the methods pursued in photographing minute objects, I may say that the microscope takes the place of the ordinary photographic lens; it is fitted to the front of a camera, and the image of the



A, lamp with reflector; B, bull's-eye condenser; C, microscope; D, camera; E, focussing wheel, attached to fine adjustment, F; G, focussing rod; H, milled-head, moving focussing rod, G; I, holder for dark slide; K, velvet hood to exclude light; L, base-board of camera.

object is thrown on the ground glass, this image being focussed by some motion of the microscope body. Motion of the camera is used only for the purpose of enlarging or diminishing the image.

I shall now describe the modes I employ usually in practising photo-micrography.

1. As to apparatus. Opinion is divided as to whether the eye-piece of the microscope should be used or not in photography. From my own experience, as well as that of several fellow-workers, I have come to the conclusion that while stronger illumination is gained without the eye-piece, the definition is not one whit better, while one has all the inconvenience which working with a long camera entails. My own practice, therefore, is to use the eye-piece with all lenses up to $\frac{1}{5}$ inch, and to omit it only with the higher powers, simply on account of the loss of light caused by its use, and the consequent long exposure required. Nevertheless, two of the best photographs that I have obtained with a $\frac{1}{16}$ inch objective were done with the eye-piece in place.

During the past winter, as I was engaged in photographing a number of diatoms, mostly new species, many of which were very small and finely marked, I constructed a special camera for working with high powers, which I have found very useful in all kinds of photo-micrographic work. A bellows body extending from about seven inches when closed, to about six feet when open, was made. The camera front is pierced with an aperture for the eyepiece of the microscope, and is fitted with a black hood for the more perfect exclusion of stray light rays. As the focussing is not performed by moving the camera, no rackwork was required, for it is only necessary to draw out the bellows by hand to any given distance to gain the desired enlargement; while the focussing, which is a delicate matter with high powers, is effected as follows. Along the top of the bellows body runs a brass rod, the extremity next the microscope carries a small wheel, and this is connected with the fine adjustment of the microscope by a narrow tape band; by first getting an approximate focus by means of the coarse adjustment, the final exact focus is easily obtained by gently turning the brass rod.

There has been much talk about the difficulty occasioned by the non-coincidence of the visual and actinic foci of microscopic objectives; but of this matter, practically, I know nothing. I have taken a good many hundred negatives of various subjects, using objectives chiefly by Swift, but also lenses by Ross, Zeiss, and Seibert, varying from five inches to $\frac{1}{16}$ inch focus, and I have never found it necessary to make any allowance. All I do is to obtain as sharp a visual focus as I possibly can; the results prove that the sharpness of outline and delicacy of detail in the best photographs produced in this way cannot be excelled. All the lenses that I use are of the most recent make, and slightly under-corrected, which would explain why no allowance for actinic focus is requisite. A lens that requires this allowance to be made must be a nuisance.

2. *Illumination.*—The illumination I generally prefer is that given by a broad-wick paraffin lamp (it matters not whether single, double, or triple); but I generally prefer a broad-wick duplex for all powers from five inches to $\frac{2}{3}$ inch. For $\frac{1}{12}$ inch and $\frac{1}{16}$ inch objectives, a good magic lantern will give the best results. Paraffin, unfortunately, varies much in light-giving powers, and bad samples are often dangerously explosive in a heated lamp; but, poor as it may be at times, it is far better than the uncertain flickering sunlight that we are usually favoured with. For low powers, I desire nothing better than a good paraffin lamp. When photographing the crystals of arsenic, I found I had too much light from my duplex, which fairly drowned the tiny crystals. Fortunately, I numbered amongst my apparatus an aperture shutter, which had very kindly been presented to me by its inventor, Mr. G. E. Davis. As this little piece of apparatus has been figured in the Photographic News, I need not now describe it; but I may mention, in passing, that some months ago I suggested to the inventor the adaptation of the aperture shutter to photographic lenses, in lieu of at least rotating diaphragms; but Mr. Davis did not agree with me that it would present any advantage over the diaphragms now in use. The object which Mr. Davis wished to attain by the use of his shutter was to give increased penetration to wide-angle objectives. This it does in a marvellous manner; and although I used it at first in photography chiefly as a light modifier, I found with the arsenic crystals, which severely tested the flatness of field of the objective, that I could only get the whole field in proper focus by using a suitable contraction of the aperture shutter. Some of the crystals would vary in size so considerably that, while I had the apex of a large crystal in good focus with a low angle $\frac{1}{5}$ inch, the smaller crystals in the field were completely blurred. Now, although the shutter is not supposed to be required with low-angle lenses, I found it invaluable in more cases than one.

For focussing, I find a fine ground-glass screen the best for all the lower powers; while for $\frac{1}{12}$ inch and $\frac{1}{16}$ inch objectives I always focus on plain glass, and examine the image with a Ramsden eye-piece. By this means there is no difficulty in obtaining an absolutely sharp focus.

3. *Exposures.*—This is one of the most uncertain and difficult matters in photo-micrography. Landscape photographers know how much judgment is required at times to estimate the correct exposure for varying light and subject; but in microscopic photography the difficulty is far greater. Only constant practice, using the *same* lenses, can make one expert in judging the time necessary for any given subject. With a five-inch, three-inch, or two-inch lens, and a moderately transparent subject, one or two seconds may be sufficient; while with the same powers, and a dark or thick rock-section as subject, half-an-hour may not be too much. Generally, I judge the exposure principally by the appearance of the image on the screen, and find I am usually correct with all the lower powers; but each lens must be carefully tested before it is brought into use for good work. High powers, owing chiefly to their small aperture, require much longer exposures than lenses of low power. Thus, with the camera extended four or five feet, as much as forty minutes may be necessary for a $\frac{1}{16}$ inch objective; but this inconvenient length may be much curtailed by a proper concentration of the light. Frequently I use magnesium ribbon, which is of great use with the higher powers, or where photographing very opaque objects, and find it almost as rapid as daylight. It gives splendidly dense negatives, but it is rather difficult to concentrate the light upon the exact point required. As I have not a lamp for the ribbon, I burn it in a holder, protruding about half-an-inch of ribbon at a time, and igniting it by a small spirit lamp. As each length is consumed, a fresh portion is thrust through, until sufficient flashes are given. Using a $\frac{1}{16}$ inch objective, and having a diatom as subject, I find from six to nine flashes sufficient.

With the arsenic crystals, one or two flashes were enough, using a $\frac{1}{5}$ inch lens; but all my best negatives were taken with the duplex lamp, *broad* side of flame towards the slide, and giving one minute or one minute and a-half.

The actual *modus operandi* followed with the arsenic crystals was as follows:—The slide of arsenic is placed on the stage of the microscope, and the crystals are brought into good focus; the stage is then moved about until a spot is found on the deposit, showing an average distribution of crystals, when the slide is clamped firmly, and the microscope is brought to a horizontal position. It is then fitted to the camera, and the velvet hood is fastened round the eye-piece by an elastic band. After this, the light of the lamp may be concentrated by means of a bull's-eye lens upon the slide; but I find it best to do this before attaching the microscope to the camera, as then the proper direction of the light can be more easily attained. This done, the camera front can be drawn forward and attached to the microscope, when the screen will be found to be fully illuminated.

I never use an achromatic condenser, even for high powers. It is advantageous to place before the lamp a large square of cardboard, preferably blackened, with a hole cut through the centre for the light to pass through. If some precaution of this nature be not taken, the heat from the lamp causes the expansion of the metal of the microscope, which will throw the objects out of focus. It is always best, when setting up the apparatus, to light the lamp, and leave the whole undisturbed for half-an-hour, to allow for expansion; in this way spoiling of plates from this cause can be avoided. It is an instructive experiment to focus an object with a high power correctly on the screen, and watch the image gradually grow dim through the expansion of the metal parts of the apparatus.

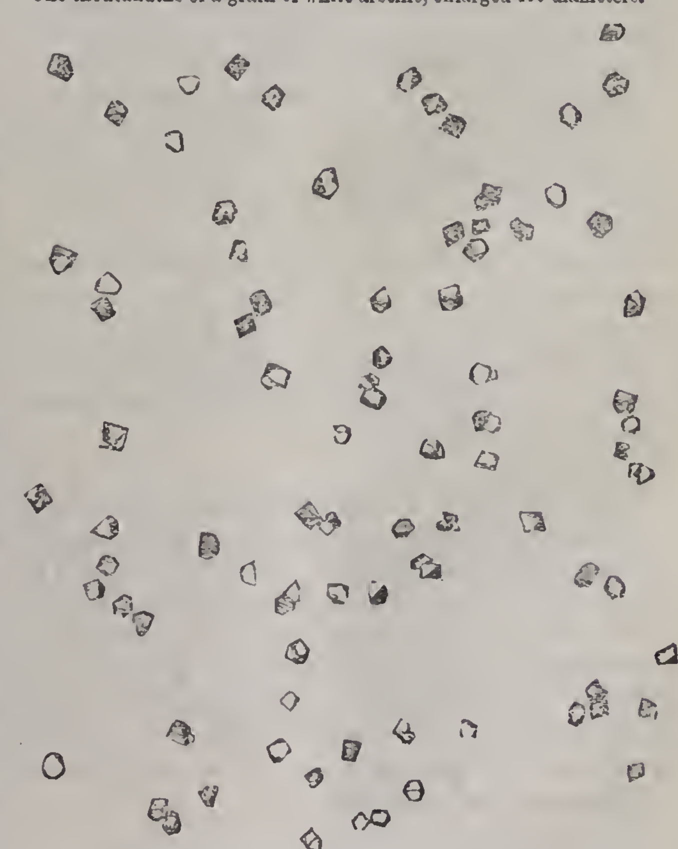
When sufficient time has been allowed for the apparatus to get warm, the coarse adjustment of the microscope, if within reach, is moved, so as to bring the object in focus; if it be too far from the hand, this must be done by the fine adjustment rod running along the top of the camera. If further enlargement be required, the camera is drawn out until the desired magnification is attained, when the slide must again be focussed on the screen. Then the light must be shut out, either by a screen in front of the lamp, or by a card fitting in front of the objective, or stage, as may suit best. The dark slide carrying the dry plate is then introduced into the camera, and the shutter drawn out. After waiting a few moments to allow all vibration to cease, the card is withdrawn from before the lamp, and the time of exposure marked. If several plates are to be exposed successively, the lamp must not be turned down between each exposure, or the alternate expansion and contraction of the apparatus will ruin good definition. When sufficient exposure is given, the light is again shut out, and the plate taken away to the developing room.

Now as to development. Photo-micrographic negatives require somewhat different treatment from ordinary negatives. As a rule, the image is a long time in making its appearance, no matter what developer is used, and comes out looking very much like an under-exposed plate. Patience and skill are often required to make a printable negative, especially if the operator have—as he should have—a wholesome horror of intensification. Ferrous oxalate is not well adapted for microscopic photography. The best developer, most decidedly, is Mr. Berkeley's sulpho-pyrogallol, if care be taken that the sodium sulphite is really neutral; or, if not, to make it so. Prolonged development being the rule in this work, the value of the sulphite developer cannot be over-estimated. Properly made, this developer does not slow the development, but allows all detail to be gradually brought out, without giving undue density.

I have used many makes of dry plates, and have got good results with all but one. Soft gelatine will not do for photo-micrography. It never gives the delicacy of detail that can be got from a good hard film, and prolonged development frequently brings on frilling. Latterly I have used the plates of Messrs. Mayfield, of this town, and find them all that can be desired for good qualities in microscopic work.

The woodcuts are taken from my photographs of ·001

One thousandths of a grain of white arsenic, enlarged 400 diameters.



Two thousandths of a grain of white arsenic, enlarged 400 diameters.

grain and ·002 grain deposits of arsenic. Each one gives about $\frac{1}{10}$ of the whole deposit, or roughly, the $\frac{1}{10000}$ or $\frac{2}{10000}$ of a grain. Much smaller quantities could easily be photographed by using higher powers.

Notes.

The late Mr. Fitz-Gibbon, the editor of the *St. Louis Practical Photographer*, was, it seems, born in London.

We have to acknowledge the receipt of the medal awarded to us last year by the Vienna Photographic Society for our Year-Book of Photography. It is a novelty in exhibitions to have a section for photographic publications, but one about which we are far from complaining.

Coblence has been chosen as the meeting-place next year for the German Photographic Association; and since it is situated on the Rhine, and easily got-at-able from England, it is not improbable that British photographers may give their presence to the gathering, which annually grows in importance.

Major Waterhouse has been busy at his photo-lithographic establishment at Calcutta producing maps for the Indian Contingent, now in Egypt. An army cannot move now-a-days without good maps and plans, and it has been the aim of the Indian Government to supply every British officer with a copy. Hence the services of Major Waterhouse's establishment has been largely drawn upon. "We have been hard at work making maps of Egypt," he writes us. "Easy work making maps now-a-days with the camera; but you must first catch your map, and maps of Egypt are scarce. However, we had some foreign maps, provided in anticipation of an emergency, and with English and French charts of Alexandria, Suez, and Suez Canal, we have managed very well." It is likely, indeed, that our army at this moment knows more about Egypt than do the Egyptians themselves, thanks to photo-lithography.

This week we bring our "Continental Rambles with a Camera" to an end with a short description of the Pyrenees. Next year we propose to describe some of the best-known European passes—the Stelvio, the Simplon, the Splügen, the Maloja, &c.—which present many interesting subjects to the tourist photographer.

Books illustrated by photography hang fire; one reason for this we discovered the other day, when we happened to be in Taunton, in Somersetshire. In the coffee-room of the hotel—next door, by the way, to Messrs. Chaffin's studio—was the *Illustrated Guide for Tourists*, and, as a tourist, we naturally turned to it for information. It told you where to purchase a hat at Brighton, and informed you on the subject of tradesmen in Warwick; but about Somerset and Devon it contained not a syllable. But it was illustrated by photography, and this is how.

In the Contents it told of four pictures; as a fact, we found but three—three dull, pigmy Woodburytypes. The first was Warwick Castle, the pigments of which had "run;" in a word, it was a spoilt print that ought never to have been issued, the lines being all swollen and unsharp. The second picture was that of a huge soot-beaten building of brick—"Washington Works, Sheffield"; the bleak, inhospitable walls, with not a soul near them, exhibited the most depressing, forsaken, wet-Sunday look it has ever been our lot to look upon. And yet it was considered an appropriate sketch for an *Illustrated Guide for Tourists!* The last picture, the best of a bad lot, was Shakepeare's birthplace; but here the quaint, old-fashioned house was much marred by the presence in the foreground of two young gentlemen dressed in modern town-cut suits. No wonder books illustrated by photography are not eagerly sought for.

Intending competitors at the Edinburgh Photographic Society's International Exhibition should remember that pictures, carriage paid, must reach Mr. J. M. Turnbull, 19, St. David Street, Edinburgh, by the 30th September. The conditions, which were published in our columns on the 10th of March, may be had on application to the secretary.

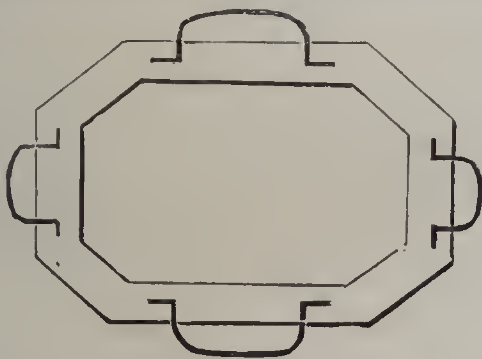
A photograph of a *Navicula Lyra*, taken with a $\frac{1}{16}$ immersion Siebert, and enlarged to the extent of 900 diameters, is a remarkable specimen of microscopic work sent to us by Mr. Jennings, of Nottingham, and the precaution which must be exercised in connection with the kind of work is well illustrated by the circumstance that if any considerable variation takes place in the size of flame used as a source of light, the definition of the resulting picture suffers, owing to the expansion or contraction of the brass work of the microscope. The above-mentioned gentleman says:—"It is an instructive experiment to focus an object with a high power correctly on the screen, and watch the image grow gradually dim through the expansion of the metal parts of the apparatus." All our readers should study Mr. Jennings' paper, as it embodies many points of interest to the general photographer.

The *Novelty*, the new theatre we have heard so much of lately, that is to have a photographic studio next the foyer, where portraits may be taken during the *entr'acte*, is to be opened next month. The photography will be done by the electric light, and the idea is that ladies and gentlemen attending the theatre will embrace the opportunity of being depicted in evening dress. Certainly few portraits are taken now-a-days in this costume.

The power of photography to confer popularity is very well understood. Some knowing ones in Constantinople have flooded the market with portraits of Arabi in order to create a diversion in favour of the rebel minister; but the step has not prospered very well, it seems, for, according to the *Daily News*, the Turkish police have seized and confiscated a great number of the photographs on sale in the shops. At the time of the downfall of President Macmahon, when the star of the late Prince Imperial was believed to be in the ascendant, some hundreds of thousands of the latter's portrait were sent into France to increase his popularity.

It is, perhaps, hardly in the power of any one firm of photographers in this country to render a man or woman popular by exhibiting portraits, in the same way as any lady whom Millais chooses to paint is said to become famous; but there is little doubt that if we had in Great Britain a syndicate of photographers, and such syndicate were to be of one mind about making a personage popular, this could well be done were the step worth while. As it is, we repeat, photography is already a power that politicians, patriots, play-actors, professional beauties, and others well understand.

Mr. Cowan's simple plate-holder is not so well known as it should be. While many photographers have been employing it for weeks past, others have never heard of it. It not only permits you to keep your fingers out of the developer—a matter of some moment to all who employ a pyrogallic solution—but it allows one to raise the negative out of the bath with ease, avoiding the sucking action of the developer which is so annoying. Here is a sketch of it.



Any tinman will make the apparatus for you. It should be constructed the size of your plate. The handles are of tinned iron wire, simply soldered on, and the cost of an eighth-inch holder would probably be a shilling. Tinned iron wire is used to prevent rust. The plate to be developed is placed upon the holder, and this is then put into the bath. After using, the holder should be rinsed in water and placed to drain.

One cannot dwell too much upon the importance of having the bromide solution convenient to hand in order to check development. The best plan we know is to have the solution in a corked bottle, a small wedge-shaped cut being made in the cork to allow the exit of the liquid. The cut should be so made that two or three drops only fall when the bottle is tilted, but when shaken with a jerk, a little stream is expelled. In a word, the bromide bottle cannot be better regulated than the well-known vinegar castor of the oyster-room.

Another hint for the dark-room is worth setting down. A ruby window alone cannot, as everybody knows, be relied upon in developing gelatine plates; but with a blind in front of stout yellow tammy, there is little fear of fog. Supposing you have the yellow fabric, you may fit up a most practical curtain of this sort for sixpence, by purchasing one of the American spring blinds, which, with roller complete, may be bought for this sum. The best of the American blind is that it is easily adjusted to any height, and requires only one hand.

"During this excursion I have exposed no less than three-quarters of a hundredweight of plates," writes a friend. The hundredweight is a unit of photographic work not quite calculated to comfort those who are just beginning to congratulate themselves on being released from the heavy burdens of wet plate operations afield.

Patent Intelligence.

Applications for Letters Patent.

4256. William Henry Reynell Toye, of Philadelphia, in the United States of America, and at present of 68, Fleet Street, in the city of London, for an invention of "Improvements in ornamenting or decorating glass, metals, and other materials or fabrics, and in means and apparatus to be employed therein."—Dated 7th September, 1882.

Grants of Provisional Protection.

3889. Edmund Edwards, of the firm of Edwards and Co., Patent Agents and Engineers, of 40, Southampton Buildings, Chancery Lane, in the county of Middlesex, for an invention of "Improvements in photographic cameras."—A communication to him from abroad by Paul Rouaix, of Paris, in the republic of France.—Dated 15th August, 1882.

Patents Sealed.

2403. Philip Middleton Justice, of 14, Southampton Buildings, in the county of Middlesex, Patent Agent, for an invention of "Improvements in frames employed for printing photographs, especially adapted for direct photography or 'blue printing.'"—A communication to him from abroad by George Stockton Street, of the town of Moncton, in the province of New Brunswick, in the dominion of Canada.—Dated 22nd May, 1882.

Patents Void through Non-payment of Duties.

3050. Henry Loewenberg, of Charlottenburg, near Berlin, in the empire of Germany, but at present of 20, Southampton Buildings, Chancery Lane, in the county of Middlesex, for an invention of "Improvements in apparatus for coating fabrics with gelatinous compounds for the production of imitation leather, fabrics, wood, and other embossed or figured surfaces."—Dated 31st August, 1875.

JUBILEE MEETING OF THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

[from a correspondent.]

For the town of Falmouth, September 5th was a red-letter day, owing to the 50th Annual Exhibition of The Royal Cornwall Polytechnic Society. The doors opened at noon, and the President's opening address was given at one o'clock p.m., by the Rev. Canon Rogers, M.A. (President). The hall was well filled with members and visitors, and there was scarcely standing room in any part, the platform being occupied by gentlemen of eminence in science and art. Among those present at the opening were Sir John St. Aubyn, Bart., M.P.; Lady Elizabeth St. Aubyn; C. C. Ross, M.P.; Rev. Sir Vyell Vyvyan, Bart.; Colonel Tremayne; Mr. A. Pendarves Vivian, M.P.; Mr. Wm. St. Aubyn, M.P.; Rev. H. A. Molesworth St. Aubyn; Admiral Borlase; General Aylmer; Professor Couch Adams, F.R.S.; W. Grylls Adams, F.R.S.; R. Taylor, F.G.S.; T. S. Bolitho, Esq.; Dr. Jago, F.R.S.; R. N. Worth, F.G.S.; W. Brooks; G. M. Whipple, B.Sc., F.M.S.; J. Laughrin, F.L.S.; E. Kitto (the Secretary), and a host of others too numerous to mention.

The galleries, as usual, were devoted to the oil and water-colour paintings, the body of the hall to works of art, &c., and the large committee room to the exhibition of photographs. The President commenced by saying that he congratulated the Society on the continued energy displayed by the various sub-committees which had been formed for the Jubilee Exhibition, and the way they had fulfilled their duty. So far as he knew, they had stuck to their work, into which they had thrown their whole hearts. In consequence of that he had to congratulate the committee on the success which had attended their efforts, the result of which was now to be seen in an exhibition which they might safely say was surpassed in no former year in general excellence and in the number and general quality of the exhibits. He further congratulated them on having a gathering which, as far as he could see, resembled some of the old gatherings of former years, when the country came forward to support the Society with one heart.

The President then referred to the various departments of the exhibition. In the art department especially—the photographic—there was no particularly new process, but he believed the display was second to none out of London, through the instrumentality of one of their members (Mr. W. Brooks), who had worked hard for the Society on many occasions, and this year the display was the largest the Society had ever had. He must not pass over this department without mentioning one or two of the exhibits—viz., the exhibits of Mr. King of the private apartments of Her Majesty the Queen, being a series of transparencies which were perfect gems of photographic art. Then, again, there were some of the finest specimens of floral photography, by Mr. H. Stevens, which were very fine and artistically arranged. There was also a curious as well as an interesting photograph taken from the car of a balloon of the earth at an altitude of 2,000 feet, and he was told that it was the only successful one that had ever been taken—this was by Mr. C. V. Shadbolt—and some careful instantaneous studies by Mr. S. P. Jackson, the eminent water-colour artist.

In the loan collection were some very interesting exhibits of examples of the early processes of photography. There was an interesting collection of early Daguerreotypes, and an album of calotype prints and negatives—in it was one by Fox Talbot himself. There were also two specimens by Dr. Huggins, F.R.S., of stellar spectrum photography, which he had kindly lent; and he would finish his remarks by mentioning a series of early collodion negatives, taken by the inventor, Mr. Scott Archer. These were of very great interest from an historical point of view; but when Mr. Brooks gave his lecture, "The Rise and Progress of Photography," he would fully explain and enter into all the exhibits, as he knew more about them than he did. I must not omit to mention the presence of a certain lady who was on the platform, Miss A. M. Fox, the founder of the Society. On the mention of her name rounds of applause were given.

After the address several appropriate speeches were made by several gentlemen, when most of the company adjourned to the Royal Hotel, where about one hundred or more sat down to a capital luncheon. After the usual loyal toasts, the health of the founder of the Society was proposed, which, after being responded to, was succeeded by ringing cheers.

Thus ended the opening ceremony of the Jubilee of the Royal Cornwall Polytechnic Society of 1882.

ROYAL CORNWALL POLYTECHNIC JUBILEE EXHIBITION, 1882.

JUDGES' REPORT.

Section 1.—Professional Photography.

THE judges have great pleasure in being able to congratulate the Society on the unprecedented success of this year's display in this department. The number of exhibits far exceed those of previous years; and it has been with very great difficulty that the judges have been able to make the awards, as general excellence in all the exhibits is very marked. In previous years a great deal of inferior work used to form a large part of the display, with a few of great excellence, which contrasted greatly with the former. The days of want of judgment and slovenly manipulation happily seems to have passed, and, in many instances, the composition in productions of the higher branches of photography seems as good as, if not quite equal to, the work of well-known artists of the brush and pencil.

Mr. Julius A. Kay exhibits three frames of photographs (Nos. 840, 1, 2), two of portraits of examples of panel work, which possess great merit, and a small picture, "Waiting for my Lady," which show clean and careful manipulation. Mr. W. D. Sanderson sends some very fine examples of large size of interiors, and the chancel of Durham Cathedral (No. 850) has been awarded a first bronze medal, and it is one of the finest examples of interior work exhibited. Mr. Harris sends a frame of capital instantaneous work, similar to those exhibited by him some time ago. Messrs. John Chaffin and Sons are well represented by five exhibits, the best of which is "Sisterly Intercession," and would suggest that if Messrs. Chaffin and Sons would not have the same figures in their pictures year after year, they would possess more interest. A. G. Fox sends a pair of enlargements. Mr. F. York is well represented by a large series of magic lantern slides, which are very fine indeed, for which he has been awarded a first bronze medal. T. Hillingworth has also been awarded a first bronze medal for an enlargement—"Nurse and Children." Mr. G. H. Dew has a very fine series of pictures; No. 873—"The Old Mill, Guy's Cliff"—being the best, is awarded the second silver medal. It is very soft, delicate, and artistically treated. Mr. A. L. Henderson, of London, sends one frame of instantaneous views, taken at the Alexandra Palace, which are fairly good; also a frame of views of the course on the Derby Day, and a frame of his well-known enamels. Mr. F. M. Sutcliffe sends some splendid examples of instantaneous studies and effect subjects, No. 834 frame being the best, and has been awarded a first bronze medal. Mr. Lyddel Sawyer is represented by one enlargement on opal, "Supplication," which is very fine. Mr. J. Hubbard also sends one, evidently a composition picture—"A Mother's Love," a cottage interior, with the mother kneeling beside a cradle. The composition is well carried out artistically, but is a little too hard in the high-lights. Mr. E. Gale, of Falmouth, is awarded a second bronze medal for an enlargement, "Wesley Chapel," which is very successful. He also sends several well-selected views, notably one of Falmouth (panoramic) is the best, but being printed in platinum, is somewhat cold and unsuitable; if it had been printed in silver, it would have left but little to be desired. Mr. F. Thurston has a nice enlargement, "Frosted Trees," which is very effective. E. Denny and Co. send a few frames of small work, principally children, "Katie's First Ride" being the best. A series of twelve transparencies, by Mr. H. N. King, of interiors of Windsor Castle, are exceedingly fine, and are the most attractive in the Exhibition, and carrying off the first silver medal. Mr. J. P. Gibson sends some excellent examples, which are very soft and brilliant. A curious photograph is also exhibited by the same exhibitor—a flash of lightning. Mr. J. M. McLanachan has two frames of portraits, which are well treated. Mr. H. P. Robinson, of Tunbridge Wells, sends some half-a-dozen frames, and it is a general opinion that they are far below the average of this artist's work, and the tones are black, cold, and heavy. E. Day and Sons have been awarded a second bronze medal for a small vignette study, "Infant Meditation," which is very artistic, and they also send several other very creditable contributions. Mr. J. Milman Brown has several good landscapes, which show a marked improvement over his former work. Mr. F. Argall has also made great improvement since last year, and for his study portrait—"The

Skipper"—he receives a first bronze medal, and we hope to see in the future more of his work. Mr. Hendry is again represented by some very good productions.

Section 2.—Amateurs.

Mr. Henry Stevens sends several frames of the finest examples of floral photography ever seen of orchids, and too much cannot be said in praise of the delicate rendering of the pale tints of the bloom, the general arrangement of all the specimens sent being simple, graceful, and artistic; he has been awarded the second silver medal. Mr. F. S. Schwabe's exhibits of Egyptian views are very interesting; also an Autotype enlargement of an Atlantic swell. Our old contributor, Mr. J. M. Brownrigg, is this year well represented, and would have been awarded a medal had it not been that his having received an award last year precluded him from receiving one this year; there is a marked improvement in his productions this year to his former ones.

Mr. Andrew Pringle, we are pleased to see, is better represented than he was last time he exhibited. He sends a frame of Scottish scenery, for which he receives a first bronze medal.

Mr. S. P. Jackson sends four frames of artists' studies, which are very fine as rough sketches (sea pieces) which are well chosen, and has been awarded a second bronze medal. Mr. C. V. Shadbolt sends a very curious and interesting photograph taken from a balloon at an altitude of 2,000 feet above the earth. Mr. A. B. Thom sends a few examples of the animals in the Zoo. Mr. F. Beesley, Junr., sends some pretty little bits, which are soft, delicate, and brilliant. Mr. A. J. Grant is again represented by some of his well-known studies (Arctic subjects), and also some studies of horses, which might be improved in the printing.

Mr. M. Whiting sends some interesting small work. Mr. J. G. Horsey is again an exhibitor; his work is larger than last year. Some of his subjects are exceedingly good; but if he exposed a little more, his work would be improved, and we hope to see this suggestion carried out by him.

Photographic Appliances.

Messrs. W. Watson and Sons, of London, send a very clever instantaneous shutter by Addenbrooke, with clockwork arrangement for timing the exposure. The principle seems excellent, but the means for attaching to the lens is somewhat defective, as it has to be held by one hand while it is discharged by a trigger arrangement with the other; but as this is only a matter of detail it can be easily perfected. An instantaneous snap shutter, by the same firm, is also neat and clever; they also send two excellent cameras with several little improvements. S. P. Jackson's improved shutter is far more compact in form than it was in its last year's form, which is exhibited by Mr. J. G. Collins, of London. Mawdsley's tripod stand, by the same exhibitor, is a very clever arrangement, but the legs would be difficult to slide in damp weather; at the same time it is a very great improvement on the old form of tripod. Mr. Henry Husband, of Bristol, has several exhibits, which are well worthy of notice—viz., an instantaneous shutter, improved stereoscope, portable camera, and a portable lantern for changing plates.

Photographic Loan Collection.

This department is greatly indebted to the contributors for the loan of various objects of interest. Mr. Howard Fox lends a good collection of early Daguerreotypes, which are very interesting. Mr. W. Brooks, of Reigate, sends several objects of interest—viz., photographs of the caves at Reigate, taken by artificial light some few years since, some early specimens of the morphia and collodio-bromide process, &c. The stellar spectrum negatives of Dr. Huggins, F.R.S, are very interesting. Mr. J. Nicholson's (of Reigate, Surrey) collection of early calotype prints are of very great interest; the album contains one picture by Fox Talbot himself. There are also some calotype negatives of interest.

The most important exhibition in this department is a series of positives and negatives by the collodion process, by Scott Archer himself, sent by Mr. T. Barnes, of London. The above will be fully entered into and fully explained by Mr. William Brooks in his lecture, "The Rise and Progress of Photography." Mr. W. E. Foxlee sends some curious examples of the continuating action of light in carbon printing, which will also be explained.

MR. JENNINGS' PHOTO-MICROGRAPHS OF ARSENIC CRYSTALS.

BY HENRY CARR.

The publication of Mr. Jennings' paper on photographing crystals of arsenic will naturally give rise to the question, What is the object in view?

Some four years ago my attention was particularly called to the injurious effect of arsenical wall-paper, and so important did the question appear that I was induced to seriously take the matter in hand, in order to see whether some prohibitory legislation might not be carried out in this country as on the Continent.

The course adopted was to send a circular to about forty of the leading medical men and chemists, requesting them to state their experience and to give their opinions. Replies were given with a cordiality which was surprising, when it is considered that the application came from a stranger. Some few who did not reply at first did so on a further application made by my friends, the late Dr. Alfred Taylor and Mr. Jabez Hogg. One medical man, a leading scientist, who put my first communication into the waste-paper basket, soon after was found to have re-papered his consulting-room with a paper highly arsenical. A serious attack of dysentery, brought on, as he was satisfied, by this arsenical paper, at once induced him to join in the crusade against these poisonous decorations.

The information thus obtained was embodied in my pamphlet, "Our Domestic Poisons," which attracted a certain amount of attention. Mr. Jabez Hogg took the question up, and communicated a paper to the Medical Society of London. This led to a committee of that Society being appointed, with Mr. Malcolm Morris, M.R.C.S., acting as hon. sec., and this committee again sent out a large number of circulars to medical men asking for information. Much was obtained, a singular fact being that a large proportion of the cases of injurious effects occurred in the families of medical men. The fact is, that the profession are not yet fully alive to the question; but when a case occurs at home, the facts are more forcibly brought under their notice.

It was desired to bring the arsenical question forward at the Society of Arts, and Mr. Malcolm Morris was requested to write a paper; but his engagements would not allow of his giving the requisite time. I therefore undertook it myself in a paper dealing with "Poisons in Domestic Fabrics in Relation to Trade and Art." This was read January 21st, 1880, and a committee of the Society of Arts was appointed to work in conjunction with the committee of the Medical Society of London. The committee of the Society of Arts has taken up more especially the question as to the amount of arsenic permissible as "accidental contamination too slight to be injurious," and the framing of a "standard test" for arsenic which shall discriminate between *injurious* and *non-injurious* quantities.

A common standard test is essential, otherwise chemists have no means of comparing their results, a complete quantitative analysis being out of the question. The determination of whether a material be arsenical or not, depends finally on the obtaining octahedral crystals from certain quantities of fabric; these crystals are obtained, deposited on a microscopic slide, and the quantity of arsenic is determined with sufficient accuracy by comparison with the crystals obtained from certain small known quantities of a definite solution of arsenic. Representation standards are thus obtained of ·001, ·002, ·003 grains of arsenic, the ·001 grain and the ·002 grain being given in the photographs which have been reproduced as wood-cuts in illustration of Mr. Jennings' paper. Photography enables us to exhibit the crystals from definite quantities, thus realising a permanent definite scale or gamut of arsenic by which any chemist may compare his results with the results obtained by others.

As the Society of Arts have not yet published their report, I am precluded from giving details, which otherwise might have been of interest.

One word on the medical view of the question if not out of place in the Photographic News. The ordinary symptoms are irritation of the mucus membrane, debility, headache, dry cough, &c., running on to serious or even fatal illness, in the case of the physician before alluded to, to most serious dysentery. Chronic poisoning by arsenic simulates many other diseases, but there generally are some marked differences—as, for instance, in one case, that of apparent bronchitis in a child. The paper and the dust of the room were both found to be arsenical; but the child recovered permanently on removal of the poisonous paper. There are great facilities for determining whether unfavourable symptoms arise from exposure to arsenical fabrics, recovery on removal, recurrence on return, and this repeatedly, with final cure on the arsenical paper being taken down. Physicists may with propriety enquire how it is that such minute quantities of arsenic breathed as dust —or, perhaps, as gas—produce effects on the system vastly more powerful than far larger quantities taken into the stomach.

STRIPPING THE NEGATIVE FILM.

It has often been a matter of surprise to us that the stripping of the negative film was not more commonly practised, especially when we consider how much more safe a valuable negative is in this condition, where neither changes of temperature are to be dreaded on the badly-annealed glass so often met with, nor a sudden loud crack on fastening down the printing-frame door tell us so plainly what had happened that we do not have to turn over the frame to see; nor a fall on to a stone-floor or any hard surface mean destruction to something over which we had toiled and triumphed. We repeat, that it has seemed somewhat strange that photographers should go on accumulating housefuls of negatives in a perishable form, when it is not only possible, but quite easy to do otherwise. This we say having particularly in mind the exigencies of the ordinary portrait business. But it is even more true for the landscape and business photographer, who would gladly preserve all that he makes, especially if has invested capital and time in travelling to secure certain subjects; and the immense advantage to this class of photographers of being able to transport negatives for unlimited distances without the risk of accident is too obvious for further mention.

The stripping of a film is by no means the difficult and dangerous thing that it may appear to be to those who have not given it a trial; and although the re-application of a stripped film to glass is a little more difficult, yet it also becomes very easy and certain after a few trials.

Let us give a few directions, then, how to proceed; and let us begin with the standard wet collodion film, presuming that it is desired to make a pellicle negative, and preserve it in this condition, and not to re-apply it to glass, full directions for which will be given further on.

No special attention need be given to the collodion, any good sample succeeding if properly managed.

The glass must be well cleaned; and here let us say that it will be well worth while to use a good quality of thin plate, for as each piece may be used over and over again, the expense will not be very great, and the ease with which such glass can be cleaned, and its fine regular surface, make it most desirable for this class of work. Let it be soaked over night in weak nitric acid, then well washed, and, after draining, wiped dry with a roll of Joseph paper, finishing off with a second roll moistened with alcohol. With a tough and contractile collodion it would be possible to proceed at once to making the negative, merely brushing off the surface with a good stiff duster; but it is safer and better either to polish the surface with powdered French chalk, or to apply a rubber substratum. The text-books contain numerous formulæ for preparing a solution of india-rubber, but it will be found that some care and attention become necessary if such a solution is to be used as a substratum—*i.e.*, to cover the whole surface of the glass previous to coating with collodion. The directions usually given are simply to cut up pure india-rubber* into small pieces, and dissolve it in benzine. In our hands this has proved quite unsuccessful; such a solution is easily prepared, and answers perfectly for edging dry plates, so as to prevent the lifting of the film at the corners; but if an attempt be made to coat the plate with it, it will run off in oily streaks, and, in short, it will be found impossible to get an even coating.

The best method of preparing an india-rubber solution for this purpose is to use rhigolene as the solvent; and if the gum should not dissolve freely, it may be moistened with chloroform and allowed to stand until swollen up before the rhigolene is added. Nothing more is required except filtration through paper, taking care to cover the funnel tightly with a flat glass plate, inasmuch as rhigolene is one of the most volatile fluids known; and it is to this property, in fact, that it owes its power of producing intense cold, being used by surgeons for local anæthesia in some of the lesser operations. The solution when prepared should be slightly opalescent and very thin; not more than a grain or two per ounce of india-rubber should be added, and any thickening of the solution by use made up for by dilution with rhigolene. The plates are to be coated with the solution just as if it was collodion, and set up in a rack to dry, which will be effected in a few seconds. Plates so coated should be used within forty-eight hours, for the rubber film becomes brittle and loses its elasticity if kept longer.

Another method of preparing the glass is, as we mentioned above, to treat it with powdered French chalk. This can be bought at the drug stores in the form of an impalpable powder, and may be very conveniently kept in a small tin pepper-box, or one of the boxwood dredgers used by glove-makers. After the glass has been cleaned in acid and wiped dry, a little of the powder is to be shaken over its surface, and well rubbed in with a ball of clean cotton. A chamois skin is now to be applied, and the surface of the glass thoroughly polished until free from streaks. The powder will have been all carried off apparently, but enough will remain both to fix the collodion film firmly during the operations of making the negative, and to render the stripping easy and certain.

No directions need be given here for making the negative, all the manipulations being conducted as usual.

The negative, after having been dried, is laid on a levelling stand, and a solution of gelatine poured over it to the depth of about an eighth of an inch, taking care to avoid bubbles. If they form, they must be carefully removed with a bit of paper, without scratching the film.

The gelatine solution is prepared as follows:—

Gelatine	4 ounces
Glycerine	4 drachms
Water	32 ounces

After dissolving, add two ounces of alcohol, stirring briskly, and strain through muslin.

The proportions here given form a good standard solution; but it must be borne in mind that the proportion of the gelatine to the water, and of the glycerine to the gelatine, should vary with extremes of temperature or dampness of climate; less glycerine, for instance, being required when the weather is damp, and more when it is very dry and cold, the function of the glycerine being to modify the extreme contractility of the gelatine.

After the gelatine has set, the plate is to be dried in a place free from dust, and then, laying it flat on a table, the point of a knife guided by a ruler is to be carried through the film to the glass, about a quarter of an inch from the edge all round. The film may now be started by lifting it at one corner with the point of the knife, and by a steady and even pull it will leave the glass in one sheet. A suitable book, with the leaves made of blotting-paper, should be provided as a receptacle for the pellicle negatives.

The advantage of using plate-glass for the negative will be

* *Philadelphia Photographer.*

* Known to the trade as "virgin gum."

plainly seen if the surface of the film that was in contact with the glass be now examined. It ought to be perfectly smooth, even, and highly polished. If an inferior quality of glass has been used, the film will be found to have taken the impression of every bubble, scratch, or other irregularity.

The operations just described are in every respect applicable to the washed collodion emulsion film, or, indeed, to any dry collodion process where no albumen substratum has been employed. We have succeeded in making a transfer even where the glass had been albumenized, but do not advise the attempt, for the risk of sticking and tearing of the film becomes much increased by the presence of the albumen.

Before taking up the subject of the stripping of the gelatino-bromide film, let us say a word about the double transfer of a collodion negative. This is so invaluable to the travelling photographer that we feel that it ought to be as widely known and practised as possible. The negative is here stripped off the glass by means of gelatinized paper, *i.e.*, paper floated on a solution of gelatine, about $\frac{1}{15}$, and dried. A sufficient number of sheets of paper are thus prepared and cut to the proper size before leaving home. After the negative has been made and is quite dry, it is laid in a deep vessel of clean water, film-side up, and one of the sheets of gelatine paper with the film down is immersed in the water and held there for a few seconds until it has become thoroughly saturated and free from any tendency to roll up or cockle. It is now carefully brought down towards the negative film until it just touches; then, by lifting the glass, it will adhere to the film of itself. After draining off the superfluous water, the glass is to be laid flat on a table, and a soft India-rubber squeegee passed over the paper a few times. The glass is now left in its level position for about half-an-hour, or until the gelatine has had time to take firm hold of the collodion film without the paper drying. By passing the point of a pen-knife under the edge of the paper it may be lifted, and will carry the film with it, a little neat manipulation sufficing to strip the entire paper and film together off the glass. After drying, it may be trimmed and put away between the leaves of a book, and so carried home.

The only points requiring attention in this apparently risky procedure are not to force the wet paper roughly down on the negative film with the fingers, and to allow the proper time to elapse before attempting the stripping. An exact rule, of course, cannot be given, but it will generally be found that the paper should be allowed to become nearly surface-dry before starting the edge with the knife point. If the paper comes away and leaves the film behind, a longer time must be allowed; while if the paper gets dry, the film will be certain to crack when it is lifted, unless a sheet of wet blotting-paper be laid over the glass for a few minutes to restore the necessary moisture.

When it is desired to re-apply the negative to glass, a solution of gelatine is to be prepared of the strength of one ounce to ten or twelve of water. Add to this four grains of chrome alum dissolved in half an ounce of water; stir thoroughly and filter through muslin. Prepare the requisite number of glasses by coating them with this after having well cleaned them. After the insoluble gelatine coating has become quite dry, the glass is to be laid surface uppermost in water, and the negative on its paper support immersed in the water and made to adhere to the glass just as described above. The manipulations are identical, and after getting the paper smoothed down with the squeegee, the plate is to be thoroughly dried over night. The following day dip it into a vessel of hot water, and after a few moments the paper support will float off and leave the film firmly attached to the gelatine coating below, which becomes quite insoluble in water by the addition of the chrome alum. The plate may now be rinsed off in warm water, and after drying, varnish as usual.

Care is to be taken not to allow the negative on the paper to roll up, nor to get creased nor folded: and when it is first dipped into the water to re-apply it to the glass, hold it out straight and do not allow the sudden wetting to make it unmanageable.

The gelatino-bromide film may be stripped in much the same manner that we have already detailed for the wet collodion plate. If the plates, however, be bought ready prepared, an arrangement with the manufacturer had better be made beforehand, so as to enable him to prepare the glass specially for this purpose befor ecoating. The best method of doing this is to give the glass a rubber substratum after cleaning, in the manner already described, and then to give it a coat of plain collodion and dry it. The gelatine emulsion is flowed on the collodionized surface just as usual, taking care not to injure nor scratch it if a rod or any hard substance be used as a spreader to assist the free flowing of the emulsion. No directions need be given for any further manipulations, the drying of the plate and making of the negative being done in the routine manner, and the coating with gelatine, drying, and stripping off, being the same as for the wet collodion film.

Let us conclude, however, by hinting to those who prepare their own plates, that the film must be "hardened" before the warm gelatine is poured on, either by the proper additions to the emulsion, or by an alum bath, before drying, and so avoid the mortification of seeing the negative film dissolve.

THE RISE AND PROGRESS OF PHOTOGRAPHY.

Mr. W. Brooks, of Reigate, delivered a highly interesting lecture in connection with the Falmouth Polytechnic jubilee on "The Rise and Progress of Photography." The beautiful and fascinating art science of photography, with its various ramifications, had, he said, sprung into existence since the establishment of the Royal Cornwall Polytechnic Society, and as that Society had done so much for the advancement of photography, he thought a few historical notes would not be out of place that evening. That was the only Society that had offered awards for meritorious productions annually for so long a time. He was not aware when the first awards were given to photography, but he knew it was nearly twenty years since his productions received an award of a medal, and he was very pleased to acknowledge the satisfaction it gave him, and he believed it was owing to that medal, and the encouragement it gave him, that he had been so successful in photography.

In giving the history of the art, Mr. Brooks commenced with Pettit, who in 1722 noticed that certain salts of ammonia crystallized more readily in the light than they did in darkness. The illustrious Scheele, about 1777, published to the world how light changed the colour of certain salts of silver. Senebier repeated Scheele's experiments, and stated that he found chloride of silver darkened in the violet ray in fifteen seconds to a shade, which required the action of the red ray twenty minutes. In 1801 Ritter proved the existence of rays a considerable distance beyond the visible spectrum, which had the property of speedily blackening chloride of silver. The lecturer next referred to the discoveries of Dr. Wollaston, of the celebrated Cornish luminary, Sir Humphry Davy, and of Wedgwood, who undoubtedly was the first person who made the attempt to use the sunbeam for delineating the objects it illuminated, and therefore he must be considered the father of the photographic art. In 1802 Wedgwood published a paper in the journal of the Royal Institution under the following title, "An account of a method of copying paintings upon glass, and of making profiles by the agency of light upon nitrate of silver; with observations by Sir Humphry Davy." In his remarks, Sir Humphry Davy said: "In following these processes I have found that the images of small objects, produced by means of the solar microscope, may be copied without difficulty on prepared paper;" and Wedgwood said: "Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day is wanting, to render this process as useful as it is elegant." Seebeck, in, and subsequently to, 1810, made some important additions to our knowledge of the influence of the solar radiations. From the time when the difficulty of fixing the photographs which they obtained stopped the progress of Davy and Wedgwood, no more discoveries appeared to have been made until 1814, when M. Niepce, of Chalons on the Soane, appeared to have first directed his attention to the production of pictures by light. His early attempts were not very successful, and after pursuing the subject alone for ten years he, from an accidental disclosure, became acquainted with M. Daguerre, who had been by various chemical processes for some time endeavouring to fix the images obtained with the camera-obscura. In December, 1829, a deed of co-partnership was executed between them for mutually investigating the subject. In 1827, Niepce presented a paper to the Royal Society of London on the subject; but as he kept his process a secret it could not, agreeably with one of their laws, be received by that body. This memoir was accompanied with several heliographs on metal and glass, some of which are still in the British Museum. The substance M. Niepce used for producing these pictures was bitumen. That might be said to be the first carbon process, and a permanent one.

Mr. Brroks then described the further researches of Niepce, Daguerre, and Fox Talbot, who, it appeared, discovered the process of preparing a sensitive paper, ignorant of what had been done on the Continent by either of the former two. In 1841 Talbot took out a patent for an improved process, which he called calotype, but which, in compliment to the inventor, was called the Talbotype process. The experiments of Sir John Herschel were next spoken of by Mr. Brooks, examples of whose process he had with him, and which were taken in 1846 by Mr. Nicholson, an amateur, now residing in Reigate. On the 8th February, 1839, Mr. T. B. Jordan brought the subject of photographic registration before that Society. Mr. Jordan, who was still living, and residing in Reigate, was one of the first secretaries of the Society. Not many weeks ago he was in conversation with Mr. Jordan on the subject. He should have liked to see him present, and he was also sure they would all have been pleased at such an event. Mr. Brooks next gave an outline of Daguerre's process, and then referred to what Mongo Ponton had done for the art, and also mentioned M. Niepce de Saint Victor's method of applying albumen to glass plates, and Mr. Scott Archer's invention of the collodion process, which was also claimed by Mr. Fry. From 1850, the art of photography began to progress, and, very strange to say, the formula that Archer gave had been but very little altered to the present day. Robert Hunt was the first to call attention to sulphate of iron as a developer. He believed Mr. Hunt had done more for photographic chemistry than anyone else. The lecturer, having given a description of the collodion and dry-plate processes and the tannin process—a very popular one produced by Major Russel—and also of the experiments of Mr. W. B. Bolton of Liverpool, spoke of Dr. Maddox, Mr. Burgess, and Mr. Kennett, the last-mentioned being the first to put the gelatine emulsion process, introduced by Dr. Maddox, into commercial form. This process bids fair to eclipse all other processes. Mr. Brooks concluded his entertaining lecture by dealing with the most recent advances in the art, referring principally to the extraordinary achievements of instantaneous photography.—*Western Morning News.*

Proceedings of Societies.

BOLTON PHOTOGRAPHIC SOCIETY.

THE annual meeting was held at New Brighton, on Saturday, August 26th. The weather, though unfavourable on leaving Bolton, cleared up shortly after the party reached their destination, where about fifty instantaneous views were taken on the sands. The members were afterwards entertained to tea at the Royal Hotel by Mr. R. Harwood, at the conclusion of which a vote of thanks was passed to that gentleman for his hospitality, and suitably acknowledged. After another rough passage to Liverpool, the party returned to Bolton by the 8 p.m. train.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING was held on Thursday, the 7th inst.

Mr. E. J. GOLDING (the Chairman) stated that he found he could prepare an emulsion that developed with pyrogallic the same rich colour as an ordinary plate when ferrous oxalate was used, and further that plates prepared by this formula permitted great latitude of exposure. He had over-exposed a plate three times, and developed a good printing negative. The following was the formula for ten ounces :—

Silver nitrate	240 grains
Potassium bromide	sufficient to convert silver
Ammonium chloride	10 ,,
Ammonium iodide	4 ,,

The chloride and bromide were first added to the gelatine, then the silver. The emulsion was prepared by the boiling method, and gave a plate much quicker than commercial plates. There was scarcely any perceptible difference in the colour of the negatives, one of which was prepared according to this formula, developed with pyrogallic and sulphite ; the other was an ordinary bromide emulsion developed with ferrous oxalate.

Mr. GARRET exhibited a camera of very light construction by Hare, which gave rise to a discussion on swing backs, in the course of which Mr. Debenham said that he considered it preferable to use a swing back than to employ a lens of a very wide angle, and a front that could be raised much higher than usual, and he demonstrated by diagrams on the black board that with a lens having a flat field the plane of definition with a camera having rising front and rigid back was identical with the surface of the plate, but that when the camera was tilted and a swing back used, the planes were only coincident along one line.

Mr. COWAN exhibited some further improvements he had made to his cutting-board.

Mr. DEBENHAM stated that if a dense gelatine negative was first immersed in a solution of chrome alum, 20 grains to ½ ounce of water, then into ozone bleach, the density would be very successfully reduced, and that negatives which could not otherwise be printed, could by this method be reduced to good printing density.

Mr. HENDERSON said he had immersed gelatine in chrome alum, then washed free from the alum, and dried ; he then placed 2 drams of the gelatine so treated in 10 ounces of water, and boiled for two and a-half hours in a digester, when it was scarcely at all dissolved ; he then prepared an emulsion using half of the special and half ordinary gelatine, and found that a plate so prepared could be developed with a solution at 95° F., using the usual strength pyrogallic developer. The picture flashed up, and he then reduced the pyrogallic to $\frac{1}{10}$ strength, and still it developed too rapidly. He fixed with cold solution quicker than a wet plate with cyanide. He thought that this might prove of great use to those working in hot climates ; he also mentioned that the picture could be locally reduced by rubbing with the finger in the same manner as if treated with ozone bleach.

Mr. COWAN said he had placed a developed plate in chrome alum for half an-hour, then flooded with water at 125°, and the film washed off.

Mr. HENDERSON exhibited a drop shutter by Banks, of Bolton ; it was constructed of metal, the shutter being released by a spring catch on the saw-cut plan. He also mentioned that he had taken a transparency by transmitted light from the hole negative shown by him at the last meeting, and could not detect much difference between it and that taken by reflected light.

Mr. Trueman Wood was elected a member of the Association.

MEETING OF PHOTOGRAPHERS IN MELBOURNE.

A MEETING of photographers was held at Gunsler's Cafe, in Collins Street, when all the prominent firms were represented, and Mr. Stubbs, from Messrs. Batchelder and Co., was unanimously voted to the chair. Mr. Stubbs briefly explained that the object of the meeting was to consider an article dealing with the Tariff Commission which appeared in *The Argus*, stating, among other things, that several photographers desired the heavy duties at present imposed on many of their materials to be reduced, but that "one enterprising manufacturer of photographic materials made application for a duty to be placed on dry plates." The speaker then called upon Mr. Lindt, who had first noticed the matter, to give his views on the subject.

Mr. LINDT said it was the opinion of all photographers in the colony that as yet no trustworthy and uniform result had been obtained in the manufacture of dry plates in Victoria, and in his own opinion there was just about as much likelihood that anyone here would succeed in the manufacture of hair-springs for watches or steel pen-nibs as in making the modern dry gelatino-bromide of silver plates. He gave many reasons in support of this contention, and asked if any one present knew who the enterprising manufacturer alluded to was.

Mr. BURMAN stated that Mr. Perry, who was present, had informed him that it was his intention to apply for a protective duty to be placed upon dry plates which he purposed to manufacture here.

An irregular discussion followed, in the course of which Mr. Perry admitted that he had applied for a protective duty on dry plates, and spoke in justification of the action. It was argued by the other gentlemen present that the profession would be entirely opposed to an arrangement that would have been dependent on a manufacture which they regarded as being only in the experimental stage. It was urged that photographers were already handicapped with heavy duties on nearly all articles used in their business, and they intended to try and have the duty on nitrate of silver taken off, as the manufacture of that article was at present a monopoly, much to the photographer's detriment ; as well as to ask for a reduction of the duties on several other articles now heavily taxed.

The meeting then appointed Messrs. C. W. Foster, J. W. Lindt, and C. Nettleton as a committee, to place themselves in communication with the Tariff Commission, and to draw up a petition stating the grievances of the profession, to be offered for signature to every photographer in Victoria, and to be forwarded to the commissioners. The meeting terminated with a vote of thanks to the chairman.

Report of the Photographic Section of the American Institute.

President H. J. Newton in the chair.

Mr. Hallenbeck spoke of the merits of various developers used in dry plate photography, and gave some interesting details of recent experiments in photographing various spectra. He stated one instance in which it was believed that a hitherto unobserved line had been brought out on a negative of the spectra of iron, by the following developer :—

Water	1 ounce
Ferrocyanide of potash	60 grains
Carbonate of soda	50 „
Bromide of ammonium	1 grain
Pyrogallic acid	4 grains

This developer gave a more satisfactory image with an exposure of two and a-half seconds than was obtained with five seconds' exposure when other developers were used.

Mr. Partridge said that by the use of a small quantity of absolutely chemically pure sulphite of soda in his developer, he had been able to considerably reduce the time of exposure in the camera.

The President stated that the yellow and green stains often seen on gelatine plates could be removed by using a solution of perchloride of iron—two drops in one ounce of water. He would caution those who used it that unless all traces of the developer were removed before flowing this solution of the perchloride of iron on the plate, the action would produce the well known Prussian blue tint. If properly used, however, the resulting tint would be a rich chocolate, so much admired by all photographic printers. He also stated that he had continued his experiments upon the production of gelatine plates without using the somewhat tedious process of washing the emulsion, and exhibited several negatives and positives on glass, in producing which such unwashed emulsion had been used. These, he believed, gave sufficient proof of the correctness of his theory that the washing was quite unnecessary. He stated that all the instantaneous views recently exhibited by him had been made on unwashed emulsion plates ; yet his limited experience with gelatine had been such that he always felt more confident of success in field work when using collodio-bromide plates. With the latter he felt sure of getting twelve good negatives on each dozen plates taken out.

Mr. Partridge had believed that the washing of gelatine emulsion was solely for the purpose of removing any uncombined silver or bromide, together with such other soluble matter as might prove objectionable if left in the film.

The President exhibited negatives by the collodio-chloride process, and a gelatine positive from such negative. The work was much admired by those present ; a negative thus reproduced had all the fine printing qualities of the original. In using the oxalate developer, he recommended adding the iron in the form of a dry powder, and then rendering the developer quite acid by citric acid. He believed that the ammonia-sulphate was preferable to the protosulphate of iron, but in using it one-third more was required, as the combining proportion of iron in the former was less than in the last named. Thirty grains of the ammonia-sulphate should be added to each ounce of the oxalate solution just before use, while twenty grains of protosulphate would be sufficient. In speaking of various methods for increasing the density of gelatine negatives, he said that even very thin negatives could be made to yield good prints by treatment with the following intensifier :—

Water	5 ounces
Hyposulphite of soda	$\frac{1}{2}$ ounce
Carbonate of soda	100 grains
Pyrogallic acid...	3 „
Aqua ammonia...	1 drop

In discussing some of the common errors in working gelatine plate negatives by amateurs, Mr. Hallenbeck stated that the most usual mistake made was the lack of sufficiently long development ; many plates which would yield good printing negatives were discarded by the impatient operator, merely because the image did not appear to become dense enough in a few minutes. He believed that many of the failures, even by professional photographers who had always used the more rapidly developed wet plates, might be charged to the same lack of patience.

Association of Operative Photographers of New York.

The minutes of last meeting were read, and, after modification, approved.

Mr. H. J. Newton. I am not prepared to take up a special subject, but am always loaded with many subjects pertaining to photography. My experiments may not be of any advantage to practical photographers of this Association, though it is a great satisfaction to know many things ; they may be useful at times. If you have any special subject, or select any branch of the business, I shall be very happy to answer any questions. I have prepared chemicals for different persons, but in my experience they never succeeded. No two persons with the same chemicals attain the same results ; why it should be so we do not know. In the action of light upon mineral salts we know the effect, but not the cause. Take some of the most simple articles ; for instance, cane sugar, or glucose. The constituents of the two are nearly alike ; still they are different—why, we don't know ; but the facts we do know ; the same conditions and circumstances produce the same result. I have brought some transparencies and negatives to show the Association. If you have a fine negative, and you break it, it is lost. Quite a number of years ago I got up a process for duplicating negatives and making transparencies. If you had the collodio-chloride emulsion you would not be liable to make a picture such as I show you. I could not call to mind the quantities, but it was published in the various journals.

Mr. Atwood. I had two negatives from Mr. Newton ; one was an original, the other a duplicate from it. The duplicate made as fine prints as the original.

Mr. Newton. Anyone working collodio-chloride knows that it tones very quickly. The present transparencies were toned with gold in hyposulphite ; any colour from wine to deep black may be made. My method is to coat the plate with collodio-chloride and dry with heat ; now warm the negative, and, while both are heated, place together. The heating prevents condensation of moisture. There is another way to duplicate negatives : expose this sensitive film for a particular time to the action of light, and it turns into chloride of silver ; what the relations of light and the minerals are, we are not permitted to know. If you have a sensitive film and expose it to gaslight you get a positive ; now expose to sunlight and you get a negative.

Mr. Buehler could not get the collodio-chloride emulsion to work ; he changed everything, but it would not work. Some time after he tried again, and worked with ease.

Mr. Newton. Some of the chemicals (corrosive sublimate), two atoms of chlorine and one of mercury, form a deadly poison ; now the same ingredients under different relations form a harmless compound.

Mr. Hallenbeck : You were once trying to turn a transparency into a negative, Mr. Newton ; did you succeed ?

Mr. Newton thought he did not. He had used plumbago for the dusting-in process. He said, I use precipitated chalk and lamp-black, and make a dark lead colour, more to the colour of a negative.

Mr. Buehler thought plumbago was not good to use, as it often went on in patches.

Mr. Hallenbeck. I would like to hear some of Mr. Newton's ideas on printing.

Mr. Newton had been experimenting a great many years. It used to be thought you could not make a print on a bath of less than 80 or 100 grains to the ounce. It was thought if it was less than 60 grains it would take off the albumen. If you have 25 grains of silver, 25 grains of nitrate of magnesium, and 25 grains of nitrate of ammonium—a solution made in this way makes fine prints. I always make my bath 40 grains of silver and 30 grains of ammonium. You can work this down to 25 grains. You must have your solution alkaline, at least two drops of ammonia to the ounce. There is always a tendency to become acid. Fume with half ammonia, half water, thirty minutes in winter ; in summer fifteen minutes. The gold I dissolve with four parts of hydrochloric acid to one of nitric acid ; when dissolved, add bicarbonate of soda till just neutral. Now your copper (speaking of coin gold) turns to nitrate of copper ; now add aqua-regia to make it acid. I add borax to make alkaline ; add two or three grains of salt, and use the same toning bath over all the time.

Mr. Atwood thought the copper was very good. Mr. Newton made some prints in a combination bath to imitate the celebrated Salomon prints, and was so successful that experts could not tell the difference. He was sure he used chromic acid in it. Mr. Newton experimented in fifty different ways with collodion. You have four grains of bromide, five grains of iodide ; now go on increasing your bromide, and you come to the same point. In emulsion you get different results from the way you mix them. Mr. Black, of Boston, used an exceedingly acid bath. He found that by adding two or three ounces of acid to his bath it made the action very sensitive.

Mr. Buehler had fog from acid.

Mr. Newton. You can remedy that by adding tincture of iodine to your collodion. I have had silver crystals exposed to light for three months. When he used it, it was neutral.

Mr. Coonley had tested one of Mr. Black's baths, and it was no more acid than what he used; did not think Mr. Black used so much acid as was thought.

Mr. Newton. When you make up a bath it should be neutral. The bath is supposed to become acid with use.

Mr. Coonley: In the West Indies a bath becomes neutral, and you have to add acid twice a week.

Mr. Buehler said, if his bath had an excess of acid the bath held organic matter in suspension, and the negatives came out thin.

Mr. Newton was never troubled with discolouration of bath; he always had it neutral, and set it in the sun.

Mr. Coonley: I have used nitric and acetic acid apart and together, but never saw any difference; he preferred nitric acid.

Mr. Newton: For many years acetic acid was used before nitric acid, but nitric acid is most used at present.

Mr. Coonley: It does not matter whether the bath is acid or alkaline, if your collodion harmonizes with it.

Mr. Newton. Acetic acid is not as reliable as nitric acid.

Mr. Schaidner: Which is the safest way to neutralize a silver bath—with ammonia or bicarbonate of soda?

Mr. Newton. Throw down your bath with bicarbonate of soda to form carbonate of silver, wash it out well, then redissolve, and your bath is pure.

Talk in the Studio.

The Late John H. Fitzgibbon.—Mr. J. Traill Taylor, in writing to us of the sudden decease of Mr. Fitzgibbon, the founder of the St. Louis *Practical Photographer*, writes:—"Fitzgibbon was exceedingly jolly up to the last. A stout, fat, heavy man, with no neck (to speak of), one would have unhesitatingly pronounced him a subject for apoplexy at first sight. He was a Londoner."

A Photographic Lawsuit.—An action was commenced last week, in which a Lieut. Loring is plaintiff, and Captain Kerr, of the Artists' Co-operative Society, defendant, touching a money dispute. After the examination of one witness, the case was adjourned until the 19th inst.

Fire Caused by the Sun's Rays.—Quite recently a shop in the Avenue de l'Opera was kindled by the heat of the solar radiation; but the phenomena became easy to understand when it was found that some kind of reflecting arrangement exposed on an opposite roof by a photographer served to partially concentrate the rays.

Photogrametry, or Surveying by Photography.—Our readers will be interested to hear that the practical value of Meydenbauer's photogrametric methods has been practically demonstrated by the ease, rapidity, and accuracy with which a set of plans—representing the actual condition of the Tower of the Halberstadt Cathedral—have been prepared. We shall give some details regarding this matter before long.

A Photographer as a Candidate for Matrimony.—The following is translated from the last number of the *Notizen*, and any of our fair readers who care to respond should write in German, as perhaps the advertiser does not understand English:—"A widower, 34 years of age, and having a boy who is now five years of age, possesses a business in a provincial town, and this business, which is partly photographic, brings in from 1,300 to 1,500 florins yearly. He wishes to make the acquaintance either of a young good-looking widow without children, or of a spinster. The lady must be the possessor of 2,000 florins. Serious applications should be sent to "Aufrichtigkeit 1,500," care of Herr A. Moll, Vienna.

Trapped by a Photograph.—On Saturday a labourer was charged at Woolwich with stealing clothing and jewellery. Samuel Gaskin, a groom, living at Albert Road, North Woolwich, said that the prisoner engaged a lodging at his house, and stayed there three days, representing that he was employed on the river. On the third night witness met him leaving the house, carrying a large bundle, and he then stated that he was going to his home at Stratford. Witness walked with him to the railway station, and then, suspecting something, hurried home, and found that a portmanteau had been broken open in the prisoner's bed-room, and property stolen to the value of £6 6s. In his room, however, he left his photograph, and, this being sent round the police stations, led to his identification and apprehension. Some articles of clothing which he left behind were also recognised as the proceeds of a robbery from a barge. Mr. Marsham committed him to Maidstone for trial.—*Daily Chronicle.*

To Correspondents.

All Communications connected with Advertisements and Business to be addressed to Messrs. Piper & Carter, "*Photographic News" Office, 5, Castle Street, Holborn, E.C. Advertisers are requested to make all Cheques payable to* Messrs. Piper & Carter, *and crossed "Union Bank, Photographic News Co. Account."*

⁂ We cannot undertake to return rejected communications.

Dirty Opal Glass.—Mr. Debenham writes to say that he is still of the opinion that opal glass is liable to special chemical discolouration, and we shall be glad to receive particulars of any experiments or observations tending to support this view.

E. Davey.—1. The non-ammoniacal emulsion, if not boiled or digested, gives bright brown tones a little inclining to red; but by digesting for twenty-four hours at 35° to 40° much darker images—in fact, almost violet—result. A short digestion, say about six hours, leads to the production of good dark brown. Try the gallic developer. You had better use a somewhat harder gelatine, such as Coignet's.

South-Easter.—Judging from your description, the premises are most desirable ones, and the south-easterly aspect will occasion you but little inconvenience if you provide screens of tissue paper. During the summer the tissue paper may be permanently fixed to the glass as regards a greater part. Ground-glass is very undesirable, as it holds dirt, and becomes very opaque to the actinic rays. 2. It is generally considered better to adopt a shade rather inclining towards darkness, and to use white reflectors as required. 3. Either No. 1 or No. 2 will answer your purpose admirably; but you had better have one extremely rapid lens for difficult work in bad light. Although work can now be done much more quickly than formerly, the public expect more, and are likely to be impatient of long sittings.

A. M. K.—They are, in ordinary cases, hand-work, and they are usually painted to order.

G.—Apply to Messrs. Van Voorst and Co., publishers, Paternoster Row.

C. P. Chapple.—See the Formulary in our last issue.

E. J. S.—1. On or before September 29th. 2. Send them to Mr. Bourlet, 17, Nassau Street, Middlesex Hospital.

J. Streatfield Cox.—Its insertion would be calculated to create an ill feeling between the parties concerned.

Novice.—"The A B C of Photography," by W. K. Burton, price 6d., published at our office.

F. Cowley.—2. The apparatus is a very convenient one for use in the field; but after you have had some amount of practical experience as regards exposing, you will prefer to work without anything of the kind. Directions are sent with it. 2. No; ordinary sensitive albumenised paper. 3. By the judicious use of a paper mask and cotton wool.

C. N. D.—The Balmain phosphorescent paint is sold wholesale by Iblee and Horne, of 31, Aldermanbury, E.C.

Pyro.—1. You have evidently been very successful, not only in the production of the photographs, but also as regards colouring and retouching. You ought not to have any difficulty in obtaining a situation as all-round assistant. 2. The terms vary extremely; say from 30s. to 50s.

Lex.—1. Use a thin hard paper, and roll it very carefully. 2. It is due to the presence of the sizing material, which is likely to be either starch or gelatine. 3. Thin with lithographic varnish; that sold as "middle varnish" will probably suit you best.

C. Thirlow.—Only when the water is hard, or, in other words, contains soluble compounds of lime or magnesia.

Nitrate.—1. It consists of sesquioxide of iron in a hydrated condition; but if you heat it to redness for half an hour or so, the water will be driven off, and the colour will deepen considerably. 2. Preferably not; but when the gelatine has become partially deteriorated by a prolonged heating, you will find the proposed modification desirable.

C. Murdock.—Direct enlargements on bromo-iodised paper can be easily made with the appliances you describe, but you will find it advantageous to replace the white paper reflector by a square of looking-glass.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1255.—September 22, 1882.

CONTENTS.

FERROUS OXALATE AND ALKALINE PYROGALLIC DEVELOPERS.

The discussion which has recently been going on in our columns on the subject of the properties, defects, and excellencies of the two rival dry plate developers will have been read with unusual interest, as the point involved is one of vital importance to photographers.

The discussion has died a natural death, the champions of each of the developers being probably of much the same mind as he was before it commenced, for there is no truer saying than that "a man convinced against his will is of the same opinion still."

That this should hold of subjects which are ordinarily ranked as matters of opinion is natural: but that it should be equally true of scientific subjects, which are, it might be supposed, capable of definite demonstration one way or another, is remarkable. In photographic questions it probably arises from the fact that the first conditions are far more numerous and variable than is supposed.

Probably no better example of this could be found than the discussion in question, where quite insufficient account seems to be taken of the vast differences which exist in plates, subjects, and methods of treatment. Each side, whilst stating emphatically the defective nature of one of the developers, proves that the other is capable of giving the highest results by pointing out where these same results are to be seen.

This being the case, namely, that it is at least possible to obtain by the use of either the ferrous oxalate developer, or the alkaline pyrogallic, the very highest results under favourable conditions, it may be well to glance at the circumstances which favour each developer, and should lead to its adoption.

The great advantage of the ferrous oxalate lies in its cleanliness and simplicity. The manipulations are devoid of all complexity, and the greater or less mess which results at every turning with pyrogallic is entirely avoided, the resulting negative being the chief item which escapes the various stains due to pyrogallol. The desirability of this cleanliness can scarcely be over-estimated, especially where work is carried on in a large scale; but, on the other hand, it must be recollected that the difference between the two developers is much less than it was before the introduction by Mr. Herbert Berkeley of sulphite of soda in the pyrogallic, for by this addition, not only is the negative in many cases rendered indistinguishable from any oxalate one, but the developing solution is rendered much less liable to stain the fingers, or whatever it may come in contact with.

The objections urged against oxalate are, that it registers a shorter scale of light gradations than pyrogallic, thus giving an unharmonious print, and also that it permits a less latitude of exposure. That there is truth in both these accusations, under certain circumstances, we are quite satisfied; but both the defects mentioned are greatly reduced by the discovery recently made by Captain Abney of the effect of the addition of a small quantity of hyposulphite of soda to the oxalate developer. By this addition the gradation of shades is greatly improved, the appearance of a print hard without brilliancy, or feeble without softness, being avoided. It is still probable, however, that subjects including a very great range of light are best rendered by the alkaline developer. We have been able to get with it a difference of density between each two of a greater number of the tints of the sensitometer than by oxalate, even when this latter had some hyposulphite mixed with it.

In affording latitude of exposure, the hyposulphite shows to a great advantage. It gives a means of accelerating, to a certain extent, in a manner somewhat analogous to that of ammonia with pyrogallic.

The method of using three or more baths, either flat or vertical, the first of which may contain concentrated oxalate developer with an addition of hyposulphite, whilst the last contains a dilute developer restrained with bromide, is now pretty well known, and affords much greater latitude than would be believed by those who have not given it a trial. There are three objections to the method. It is not suited for work on a small scale, or for developing an occasional negative. The time of development necessary to get density with the weak and restrained solution in the case of an over-exposed negative is excessive, and, if the hyposulphite be adopted merely as an accelerator, to be used in the event of under-exposure, the benefit of it in giving a soft yet brilliant negative is lost in the case of normal exposures. This last difficulty is overcome, however, by placing in the second dish a developer similar to that in the first—that is to say, containing hyposulphite, but somewhat weaker in ferrous oxalate. This will then be the developer which will come into play for cases of normal exposure.

There can be little doubt that, given a plate which has been exposed for an unknown length of time, the chances of getting a good negative from it would be far greater were the pyrogallic developer used than with the oxalate. On the other hand, in the case of an extensive business in portrait photography, where the exposures are pretty fairly uniform, and where a number of negatives may be developed one after the other, it is probable that about equally good final results—that is, finished pictures—would be turned out, whichever developer was used; whilst greater cleanliness would reign when oxalate was the agent than when pyrogallic was; and, moreover, the printing operations would be considerably easier, although the difference in rapidity of printing between negatives developed by oxalate and pyrogallic need not be nearly so great as it generally is if full advantage be taken of the properties of sulphite of soda and of alum and acid.

So far we have not considered the differences in plates which, apart from subject and treatment, render one or other developer most suitable. In the first place, there are a number of evils which arise only when pyrogallic is used, and which, therefore, constitute oxalate the best developer for such plates as exhibit them. These are chiefly fogs and stains of various kinds. On the other hand, there are plates which are not suited to oxalate development insomuch that density is not be got at all, or only after a very prolonged development. These are plates which have been too thinly coated, or in the manufacture of which a very repellent gelatine has been used. They are difficult to work, even with pyrogallic, the usual strength of developer being insufficient to give density. A limit to the strength of the iron developer is very soon reached, but the alkaline may be almost indifinitely increased, the ammonia being, of course, increased in a less ratio than the pyrogallic and bromide; otherwise fog will ensue.

Amongst the properties of pyrogallic which may be of use must not be forgotten that of "flashing out" an image. The proceeding is not, as a rule, a desirable one, but it may be performed with advantage at times.

To sum up, it is generally believed that the alkaline pyrogallic developer has, on the whole, the wider range of usefulness. It is specially suited for landscape or any work in which the exposures are uncertain, and for all operations on a small scale, whilst it has the farther advantage of cheapness.

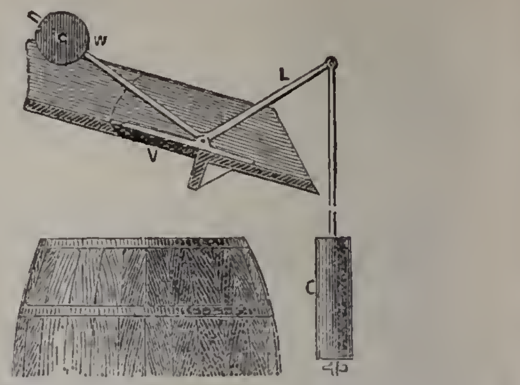
On the other hand, there is little to choose as far as results are concerned between the rivals for any work where the exposures are even fairly certain, and where it is possible to develop a number of negatives at one time, and here oxalate has the advantage of cleanliness.

PURE WATER FOR PHOTOGRAPHIC USE.

Our readers are well aware that water as found naturally is never absolutely free from dissolved impurities; and in ordinary cases it contains solid impurities derived both from the inorganic and organic kingdoms, together with gaseous substances; these latter being generally derived from the atmosphere.

By far the purest water which occurs in nature is rainwater, and if this be collected in a secluded district, and after the air has been well washed by previous rain, its purity is remarkable; the extraneous matter consisting of little else than a trace of carbonic acid and other gases dissolved from the air. In fact, such water is far purer than any distilled water to be obtained in commerce. The case is very different when the rain-water is collected in a town or densely-populated district, more especially if the water has been allowed to flow over dirty roofs. The black and foully-smelling liquid popularly known as soft water is so rich in carbonaceous and organic constituents as to be of very limited use to the photographer; but by taking the precaution of fitting up a simple automatic shunt for diverting the stream until the roofs have been thoroughly washed, it becomes possible to ensure a good supply of clean and serviceable soft water, even in London. Several forms of shunt have been devised, some of these being so complex as to offer every prospect of speedy disorganisation; but a simple and efficient apparatus is figured in the current number of *Engineering* by a correspondent who signs himself "Millwright," and as we have thoroughly proved the value of an apparatus which is practically identical, we reproduce the substance of his communication.

A gentleman of Newcastle, a retired banker, having tried various filters to purify the rain-water collected on the roof of his house, at length had the idea to allow no water to run into the cistern until the roof had been well washed. After first putting up a hand-worked valve, the arrangement as sketched below has been hit upon. Now Newcastle is a very smoky place, and yet my friend gets water as pure as gin, and almost absolutely free from any smack of soot.

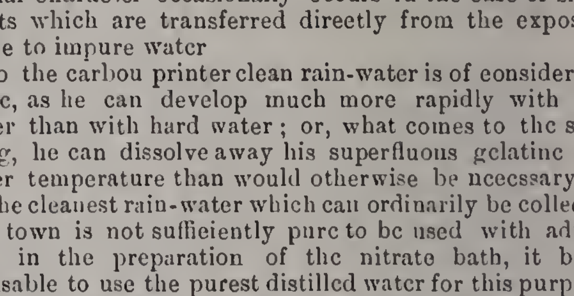


The sketch explains itself. The weight W and the angle of the lever L are such that when the valve V is once opened it goes full open. A small hole in the can C acts like a cataract, and brings matters to a normal state very soon after the rain ceases.

The proper action of the apparatus can only be insured by a careful adjustment of the weight W, the angle through which the valve opens, and the magnitude of the vessel C. It is an advantage to make the vessel C somewhat broader in proportion to its height than represented, and to provide it with a moveable strainer placed about half way down. This tends to protect the cataract hole, and any accumulation of leaves and dirt can be removed once in six months or so. Clean soft water is valuable to the photographer in very many cases. Iron developer (wet plate) free from chlorides will ordinarily remain effective on the plate much longer than when chlorides are present, and the pyrogallic solution for dry-plate work will keep good for a long time if made with soft water, while the lime which is present in hard water causes the pyrogallic acid to oxidise with considerable rapidity. Negatives that have been developed with oxalate developer often become covered with a very unsightly veil of calcium oxalate when rinsed with hard water, and something of a similar character occasionally occurs in the case of silver prints which are transferred directly from the exposure frame to impure water

To the carbon printer clean rain-water is of considerable value, as he can develop much more rapidly with soft water than with hard water; or, what comes to the same thing, he can dissolve away his superfluous gelatine at a lower temperature than would otherwise be necessary.

The cleanest rain-water which can ordinarily be collected in a town is not sufficiently pure to be used with advantage in the preparation of the nitrate bath, it being advisable to use the purest distilled water for this purpose; and in many cases it is well to carefully distil water for the bath in a glass apparatus of the kind figured below, which we take from the fourth edition of Captain Abney's "Instruction in Photography."



A. Thin glass flask serving as a retort. The tube T is fitted air-tight to the flask by a cork, C.

B. Receiver into which the tube T fits quite loosely.

D. Water vessel intended to keep the spiral of lamp wick, which is shown as surrounding T, in a moist condition.

This wick acts as a syphon, and water is gradually drawn over into the lower receptacle, E.

L. Spirit lamp, which may, in many cases, be advantageously replaced by a Bunsen burner.

A small metal still, provided with a tin condensing worm, is, however, a more generally servicable arrangement, and if ordinary precautions are taken to make sure that the worm tube is clean, the resulting distilled water will be nearly as pure as that distilled in glass vessels.

Such a still as that figured below can be heated conveniently over an ordinary kitchen fire, and should find a place among the appliances of every photographer.

Distilled water should always be used in the preparation of emulsion, as the impurities of ordinary water may often introduce disturbing conditions.

By-the-Bye.

CONTINENTAL RAMBLES WITH THE CAMERA.

The Pyrenees.*

Quitting the emerald vale of Azun, at the mouth of which Argellez stands—a sylvan paradise where the luxuriant foliage of Spanish chestnut trees, the grass-green leaves of the walnut, and the freshness of the verdure are "beyond compare," and all in lovely contrast to the frosted peaks and snow slopes that bar the end of the vale—we pass on to Pierrefitte. This little village—three miles from Argellez—is at the foot of the gorge of Pierrefitte, a magnificent mountain defile. The photographer will find plenty to do here, if he loves wild and rocky pictures. Grey cliffs rise precipitately several hundreds of feet above the torrent, which is little else but foam. On the wayside, too, are mighty boulders—picturesque masses of rock—which, if lighted from behind, make a magnificent feature in a landscape picture with their heavy shadows. The path is very steep for our destination. Cauterets is upward of three thousand feet above the sea, but well within a day's walk from Argellez.

Cauterets itself has little to attract, being rather cold and desolate; it is, however, a fashionable spa, its nasty lukewarm springs being considered very efficacious in disease. In the neighbourhood is the peerless Lac de Gaube, situated at the foot of the snowy Vignemale, and as the way thither leads by some magnificent cascades—masses of white foam tumbling out of mighty chasms in the depths of a black pine wood—the excursion is one which must be undertaken by every able-bodied visitor. You pass on your way the "Pont d' Espagne"—a few pine planks thrown over the torrent, and scarcely enough to make a picture in the camera—reaching the tiny mountain lake in about three hours from Cauterets. Of a greenish hue, its clear, still waters reflect upon their surface the towering Vignemale, whose sparkling glaciers rise from the further shore of the lake. We have never seen any photograph that has done justice to the Lac de Gaube; the pictures are too cold and hard, and have none of the warmth of sunlight about them, a quality very necessary to the full appreciation of the scene.

You may get over the snows of the Vignemale to Luz, but we prefer retracing our steps to Pierrefitte, which is a convenient spot to leave one's heavy baggage. Luz is quite a romantic spot. Of the two old castles you certainly must get a picture, for these were invested by Edward the Black Prince, during the prolonged wars in the reigns of the Edwards. The old church will also attract the photographer's attention, and he should include in his picture the little doorway, now bricked up, by which the crétins or cagots used to enter the divine edifice. Like the lepers of old, they were forbidden to mix with their fellow-creatures, and were permitted only to marry among themselves. At the present day, fortunately, whether these poor creatures are more properly cared for in hospitals, or whether the disease is gradually dying out before the progress of civilization, it is very rare indeed to meet with afflicted in the villages and hamlets, and, unlike in Switzerland and Savoy, cases of goitre or idiocy are rarely to be seen.

Opposite Luz, on the slope of a smoothly-turfed hill, and consisting of a street of tall white houses, stands St. Sauveur, one of the favourite and most cheerful spas of the Pyrenees. The prettiest view is obtained from the hill at the foot of the Pic de Bergons, whence the bright little place is seen, partly hidden among leafy foliage, its church of fine white stone being the most conspicuous object. An elegant iron bridge, spanning an abyss of upwards of two hundred feet, connects the spa with the valley of Gavarni.

The lawn-like meadows, the fresh green foliage, the dog-roses in the hedges, the stone church with its tapering steeple, the odour of new-mown hay, the cool atmosphere, all remind one somehow of Old England; while some of the thatched farmhouses about, with their straw-littered folds, help materially to heighten the illusion.

All this smiling country is soon left behind, and then you begin to climb the steep road to Barèges Barèges has a familiar sound to us, because of the fabric of that name which is made, not in the mountain town itself, but in the district. Barèges itself is reputed for its healing waters, which are said to cure old wounds, but it is such a woe-begone spot, and the way there is so difficult and steep—the road making its way through a bleak wilderness of stones and rocks—that, as M. Taine once remarked, an invalid must have lots of strength if he is to be cured.

Composed of tall, gaunt houses and wooden booths, the place has a temporary, half-built appearance, the wet and mountain fogs that never seem to desert the place making it still more dismal and depressing. Still the place is full of invalids, and especially with the crippled and diseased of the lower classes. Soldiers are also numerous, for the French Government has established a military hospital in the village.

From Barèges by the Tourmalet Pass to Bagnères de Bigorre is a day's walk, the photographer securing a picture of the Lac Bleu and the grand waterfalls at Grip on his way. Thence we cross the Hourquette d'Aspin—the farm buildings hereabouts make you think you are back again in Old England, they are so much like our Kentish homesteads—and reach Arreau, in the Val d'Aure. The outlook from the Hourquette d'Aspin is one of the finest and most extensive in the Pyrenees. In front, stretching from east to west, is a continuous chain of verdure-clad mountains, behind which rise others more lofty—some of a pure white, some merely tipped with snow, and others grey and craggy. The monarch of the Pyrenees, and highest mountain in Spain, the famous Maladetta, may be seen, and far beyond, at the blue line of the horizon, are the broad plains of Arragon. Down in the valley at our feet are tiny villages, with fields and streamlets on the same microscopic scale, the miniature town just under us—so near, apparently, as to be within stone's-throw—being Arreau, which is, however, still a dozen kilometres distant. A more beautiful picture can scarcely be imagined, combining as it does the snowy

* Continued from page 549.

scenery of the Alps with the luxuriant vegetatiou of a southern climate.

Quarters are to be found at Arreau, and then we march along the sequestered Vale d'Aure. At Cadéac, the first village, is a capital subject for the camera. It is an old church of the most original construction, and if you take your picture from the roadway, you show at once its chief features. For the church is literally built upou the highway; the road runs right through the building, the altar and pulpit being on one side of the thoroughfare, and rows of stone seats arranged in tiers on the other. A cart driven along the road during service would therefore find itself all at once in the middle of a devout congregation, driving up the aisle, or rather across the central pathway in front of the altar. Farmers coming to mass on a Sunday might remain in their vehicles during service, and have no need to dismount and to put up their horses at a neighbouring hostelry.

It is only the pedestrian who can penetrate this lovely valley beyoud the picturesque village of Tramesaigues, for here the roadway ceases, and there is no outlet except that over the Col de Cambiel into Gédre. This col, although not nine thousand feet in height, is an arduous climb, as the snow usually is very deep, but it may be attempted by any good walker accompanied by a guide from Arragnouet. It is a comb between two mighty peaks, and a couple of hours' tramp through soft snow is generally necessary to reach the summit, whence it is easy to reach Gédre in the Gavarni valley.

From Gédre, where the accommodation is good, although rather simple, we proceed to Gavarni and the Cirque, oue of the most wonderful spots in the whole of the Pyrenees. The famous French artist, Gavarni, took his name—for it was only a *nom de plume*, or rather *de crayon*—from this spot, where he lived many years. It is but a four mile walk to the village; but the Cirque is twice as far, so that it is well to sleep a night at Gavarni, where the inn, if not first-class, is very tolerable. The photographer must not fail to secure a photograph or two on the road, for there are pictures at every turn. Imagine the green sward of the valley as trim as a gentlemau's lawn, with graceful silver birch trees here aud there, and a backgrouud of dazzling snow peaks. The smooth road runs through this sunny Eden, but not in a straight line, for big masses of black rock, that have become detached from the bare mountain walls on either side, and have rolled headlong into the valley, lie about in glorious confusiou. In and out among these mighty obstacles your way leads to the valley, sometimes broad and spacious, and sometimes only a narrow rocky defile scarcely allowing room for the road and the torrent that runs beside it.

The Cirque of Gavarni is a mighty amphitheatre of rock and glacier, bringing the valley to a sudden end: it would be called a Corrie in Skye. A waterfall, said to be the highest in Europe, falls over the face of the cliff; but it is generally only a thread of water. The Cirque is a difficult subject to photograph; all the pictures we have seen give no idea of its height aud grandeur. They look like the representation of a big marble quarry more than anything else. So here is a problem for the tourist photographer which he may set about solving.

A steep climb from Gavarni will bring the hardy pedestrian to the snow-fields above the Cirque, and if he is a mountaineer, he may reach the Brêche de Roland, whence a path leads into Spain. But this is a difficult tour. For most tourists it is best to turn back to Gédre, and then visit the lower part of the Gavarni Valley between that village and Luz.

Coming homewards, it is well to pay a visit to Biarritz, a delightful watering place in the Bay of Biscay, and most picturesque with its shelving rocks, natural arches, and corralled bay. Thence the traiu may be conveniently taken into Spain—the frontier is but a dozen miles off—either to St. Sebastian, Saragossa, or Vittoria. A few days are sufficient to visit any of these interesting towns, to glean something of Spanish life, and to take a peep at the Pyrenees from the south.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,

Assistant Surveyor-General of India.

CHAP. II.—APPARATUS AND GENERAL ARRANGEMENTS.

BEFORE proceeding to the consideration of the practical details of the various manipulations, it will be as well to describe the special photographic apparatus and appliances required for producing negatives suitable for photo-lithography, leaving the description of the process and material for transferring and printing to be considered afterwards, when treating of the manipulations connected with that branch of the subject.

Apparatus.—The essential points to be observed in regard to the apparatus for copying by photography are absolute rigidity and freedom from vibration, together with accurate parallelism between the plan board aud sensitive plate. Without rigidity it will be difficult to secure and retain squareness and freedom from distortion; vibration will destroy sharpness; want of parallelism will produce distortion; and though, in copying a subject within the compass of a single negative, a slight want of sharpness or squareness is of uo great consequence beyond its unsightliness and unworkmanlike appearance, it is otherwise with large maps and plans that must be taken in several sections to be joined up together afterwards. Unless each sectiou corresponds accurately with the other, distortions and discrepancies will arise which will make it impossible to produce a satisfactory result.

The camera must, therefore, be of the best construction, supported ou a firm, solidly-constructed stand. The plan-board must be fastened to a wall, or carried on a strong stand free from vibration. When possible, it is an advantage to have the copying-studio on the ground, there being always more or less vibration on an upper floor, especially in a town with vehicles constantly passing. By using the electric light, cellars and other underground rooms may be utilized for this purpose.

Camera.—The camera may be either of the rigid or bellows pattern; the latter has many conveniences, but a camera of this form must be thoroughly well made, so that the front and back parts may remain perfectly rigid and square. The size will, of course, depend on the work to be done; but, if required to be used for copying to scale, it must be of at least sufficient length to draw out to twice the equivalent focal length of the longest focus lens it is to be used with, and may be furnished with cone fronts to give this a further extension if necessary. A conical front has also the advantage, especially with large cameras, of diminishing the shadow thrown by the front of the camera. In making enlargements this is especially desirable.

The front and back of the camera should, in all cases, be quite firm when fixed, and be truly parallel. A swing back may, however, sometimes be convenient, and gives the power of correcting slight differences of parallelism between the plan-board and sensitive plate.

The lens should be accurately fitted, so that in its normal position its axis may correspond with the centre of the focussing-screen. Sliding fronts will, however, be useful for adjusting slight differences of position of the image of the plan on the focussing-screen.

It will be found convenient to have the focussing screen marked with one-inch squares round the centre; four inches or sixteen squares will be sufficient. Their use is, in conjunction with similar squares on the plan board, to test the squareness of the copy, and also to furnish an aid in setting the camera for reduction to any given scale

Lines passing through the centre of the focussing screen at right angles to one another, and marked off in inches, will also be found useful for measuring the size of the copy. Where much work of the same size, such as reductions of the sheets of a map, or a standard scale to any uniform smaller scale, has to be done, it is convenient to have one or more rectangles drawn on the ground glass to correspond exactly with the size the copy should be photographed. When the image of the subject exactly fills this rectangle, the adjustments of focus and parallelism will be correct.

It is a good plan to have a scale on the camera, by which it may be set to any desired focus at once.

The camera stand for copying should be constructed to run on rails fixed truly level in the ground, at right angles to the plan-board, in order to retain parallelism between

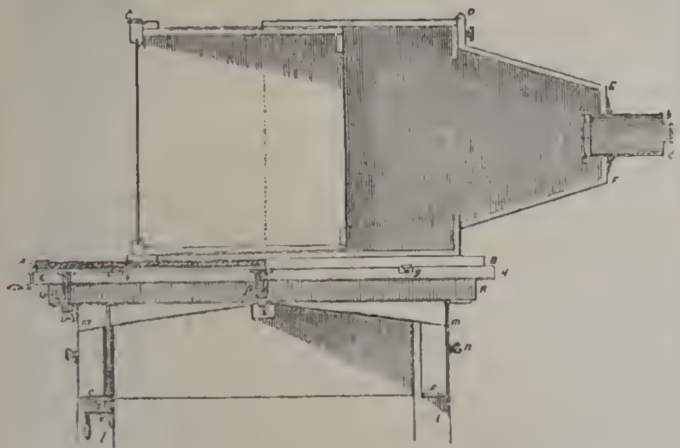


Fig. 1. Section and Elevation of Camera and Stand.
A B C D E F, the camera; G H Q R, top of stand; G H, upper board; Q R, lower board; a b c d, lens and mounting; g g, V-shaped runners working in V grooves; k, circular arc cut through the lower board; l, portion of legs of stand; m m, hinged plates; n n, screws for clamping plates; p, centre pin on which upper board works; r, screw passing through circular arc clamping upper to lower board; s s, endless screw for focussing; v, elevating screw for giving top of stand motion on axis x; x, axis of top of stand.

the camera and plan-board, and allow for easy adjustment to focus. It should be furnished with adjustments for moving the camera horizontally right or left, for turning it round on a central axis, and for tilting it up and down so as to make it perfectly level or give it a slight inclination so as to correct any want of verticality of the plan board or inclination of the floor. I know of no better pattern of camera stand for the purpose than that used at the Ordnance Survey Office, Southampton, of which a description was given in the News, vol. iii., p. 380; but as this description will not be available to many present readers of the News, a repetition of it may not be out of place.

The top of the stand (see fig.) consists of two separate portions; the lower, a strong board working on a transverse axis which rests on the frame of the stand, and is clamped at any required altitude by four screws, biting four hinged plates, which connect the top of the stand with the frame. The amount of motion is regulated by an elevating screw.

The upper board on which the camera is placed is connected with the lower one by a central pin, which passes through the top, and works in a socket in the lower board.

Through the latter an arc of a circle is cut, and a screw passing upwards through the arc, and fastened to the lower surface of the upper board, gives the means of clamping the top board in any portion of the azimuthal arc it describes on the central pin, its motion being of course limited by the length of the arc cut in the lower board.

V-shaped grooved plates of brass are let transversely into the top surface of the stand, and to the bottom of the camera are screwed similarly shaped brass runners, so that when the runners are fitted into the grooves, the camera lies symmetrically on the stand, and can be made to slide with an easy motion in a transverse direction, the motion being given by a small screw likewise let into the surface of the stand, and working in a small female screw-socket attached to the bottom of the camera. Each of the legs of

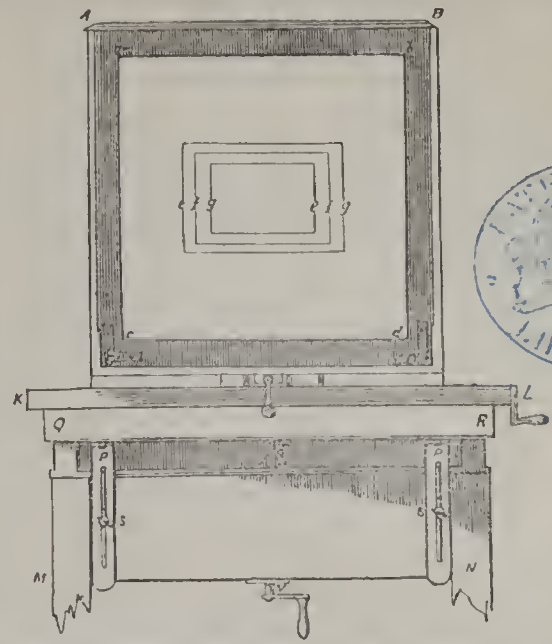

Fig. 2. Elevation of Back of Camera and Stand.
A B C D, movable slide, containing focussing glass; a b c d, ground-glass plate for focussing; e f g, rectangles ruled on ground glass to be made to coincide with margin line of plan according to nature of reduction, e 1-2500th to 6 inches, f 1-500th to 1-2500th, g 6 inch to 1 inch; K L M N, stand for camera; P P, plates to allow motion in altitude; s s, clamping screws for ditto; Q R, lower board; r, screw passing through circular arc clamping upper to lower board; V, screw for giving top of stand motion in altitude on axis.

the stand has a groove at the bottom to fit the convex surface of the rails on which it slides. I may mention that the above stand has been supplied to various offices by Mr. Dallmeyer.

Plan-Stand.—Very many forms of plan-stand are in use in different establishments devoted to photographic copying, and differ according to the work to be done. Nearly all of them are on the same principle as the ordinary vertical easel, and are fitted with adjustments for moving the plan-board vertically up and down and laterally right and left. In some forms the plan-board has a slight movement of rotation round a horizontal axis, so that if the plan is not quite straight on the board, its image may be made straight in the camera. If desired, the feet may be grooved or be fitted with runners for moving it easily on rails.

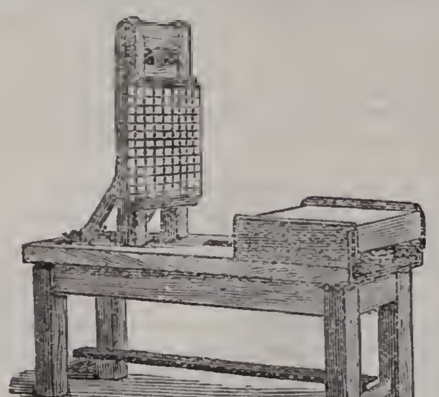
A convenient form of this kind of stand is one I had made up by Mr. Dallmeyer for the Surveyor-General's Office, Calcutta. It was specially constructed to enable maps drawn on a sheet of double elephant paper (40 by 27) to be copied in two sections. It consists of a rectangular iron frame about 5 feet long and 2½ feet wide, travelling in two vertical grooves cut in the side standards, its height being regulated by parallel rack work, with a detent to stop it at any required height. This frame has two horizontal parallel rods, about an inch thick, fixed in it, at about a foot apart, on which slides a glazed frame containing the original drawing. This frame is fixed on a pivot in the centre of two diagonal arms, the ends of which terminate in four arcs with circular slots cut in them, through which screws are attached to the frame, and serve to clamp it in any position. Between these arcs and the centre pivot are fixed tubular slides which run upon the parallel rods. These slides are attached to the back of the glazed frame, and support it on the rods. The plan board can thus be moved about half its length to the left or right, and may be raised or lowered about half its width, and thus any part of the plan can be readily brought in front of the lens.

Another very good form of stand of the same kind is used in the Deposit de la Guerre at Brussels, and is figured and described in Maes and Hannot's *Traite de Topographie et de Reproduction des Cartes.* Stands of this kind are very well adapted for subjects of moderate size, but in cases where work is varied, and plans and drawings of all sizes are received for reproduction or reduction, it is convenient to have a large vertical wooden screen, made of well seasoned wood, fixed permanently in a truly vertical position against a wall, and upon which plans of any reasonable size may be fixed.

When the work of a camera is confined to the constant reproduction of maps or drawings of the same size, I have found it convenient to make up a glazed frame on the same principle as the pr nting frames supplied by the Autotype Company for pigment printing, being fitted with a spring-back, which presses the plan closely and evenly against the glass. This frame is supported on a framework let into the wall, and allowing of a little vertical adjustment, so that the centre of the map frame may be on a level with the axis of the lens. Once fixed it requires no further adjustment. The map is held inside the frame by two thin brass clips, and the change is made at once. While making the change, the glass is supported by side props, and the frame is kept closed by hooks or spring catches.

For all ordinary small work it is most convenient to have camera stand and plan-board all combined in one piece of apparatus. This is usually made in the form of a table six or eight feet long, which can be moved about into any desired position, and on which the plan-board is fixed at one end, and the camera made to slide at right angles to it from the other, as shown in the annexed diagram of an apparatus of this kind made by Romain Talbot, of Berlin.

Sometimes it is convenient to have the plan-board fixed

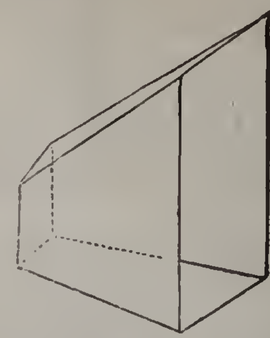


on a slider, so as to gain greater extension if necessary; and it is an improvement to have the top part of the apparatus working on a transverse axis, so that the camera and plan-board may be inclined to any desired angle in order to get the light of the sky falling direct on the plan. In some American studios this form of apparatus is suspended from the roof of the glass room, and can thus be very readily shifted into any position or light that may be desired.

For taking reversed negatives, the part carrying the camera should be moveable, and fitted transversely with sliders, so that its position on the stand can be changed. The plan-board should also have motion right and left to allow the drawing to be in front of the lens.

It is convenient to have the plan-board marked off in one-inch squares, which, as already noticed, with the lines and squares drawn on the focussing-screen, will be a great aid in ascertaining that the image is perfectly square and of the proper size, according to the scale of reproduction.

In order to prevent the *grain* of the paper showing up, Monckhoven recommends that the original should be placed within a square cone of white cardboard. The light reflected in all directions on to the white sides of the cone, and thence on to the original to be copied, will render the grain invisible.



Captain Abney recommends a similar arrangement, made of tissue paper stretched on laths.

When taking reversed negatives with a reversing mirror or prism, it is sometimes convenient and advisable to have an arrangement for laying the plan horizontally underneath the lens at any convenient distance from it. The grain of rough paper will be very much reduced by this mode of operating.

Lens.—In order to produce perfect copies, a lens must be used which will give a sharp clear image all over the field, and perfectly free from all distortion or curvature of the marginal lines of a rectangle. In practice, the most suitable forms have been found to be the triplets, rectilinears, and symmetricals of Dallmeyer and Ross; especially Dallmeyer's rapid rectilinear, and Ross' portable symmetrical, or a new lens specially made by the latter firm for copying. The aplanatics of Steinheil, and other lenses made on the principle of giving straight marginal lines, are also useful.

The lens should be worked well within its power, so as to use the most central rays with as large an opening as possible. The image should generally be focussed about midway between the centre and margin, with the full aperture, and then stopped down as may be necessary to secure perfect sharpness all over the plate; and for this a comparatively small stop will be required.

In order to prevent extraneous light entering the lens and fogging the lines, it is very desirable to put a long cone, an open box, telescopic sliding tube, or some similar protection in front of the lens—the opening should just admit the subject being seen.

For enlarging directly from a drawing or print, it is desirable to mount the lens so that the front part of it may point inwards towards the sensitive plate, and not outwards as usual. With lenses of symmetrical form, *i.e.*, those in which two exactly similar components are combined, this is unnecessary.

(*To be continued.*)

THE EXHIBITION OF 1882.

This annual event of importance to the photographic world will open with a *conversazione* to members and friends on the 7th of October.

The last day for reception of exhibits is rigorously fixed for Friday, the 29th of September. Till nine o'clock in the evening of that day the rooms in Pall Mall will be open for this purpose, and exhibits arriving after that hour will be "too late." This rule is established to enable the Hanging Committee to utilize their labour with the least delay and the greatest effect, to give time for the preparation of a correct catalogue, and opportunity for the judges to decide in comfort and at leisure on the merit of the show. It is a rule manifestly judicious, equitable to als exhibitors, and in the interest of the public and the Society.

There can be no doubt that the influence of the Exhibitions of the Photographic Society of Great Britain is favourable to the advance of photography as an art, and is commercially and socially useful to the profession. The best work of each season is gathered to a focus in an admirable gallery in Pall Mall, and year by year the interest shown by the public increases. Due prominence is given to new developments of the art, the public is made to appreciate its progress, and to utilize its advantages; while excellent work brings into prominence the names of leading professionals and amateurs. There is no work done by the Society more useful than the successful organisation of these Exhibitions, and many noted photographers whose names are yet absent from the list of members might gracefully recognize the good work by repairing that omission.

The award of medals is certainly an inducement to exhibitors abroad and at home to contribute. No one is indifferent to the recognition of merit in himself or in others. A medal is an outward and visible sign of distinction, gratifying to self-consciousness, and useful in business. The commercial instinct may innocently interpenetrate the artistic, when one's living is concerned; and photography is of more vital interest to the professional, than to the amateur.

Doubtless there is always some dissatisfaction when awards are announced, a dissatisfaction that may arise from interested, disinterested, or blended feelings; but it has never in the Photographic Society been deep or wide. The election of the jury is on a popular basis, and its composition includes each year the most trusted names. Some murmurs have been heard the last two years to the effect that portraiture has been neglected by the judges; that charming lucky bits of landscape caught on a dry plate have swept off the medals; while the higher-class portraiture, involving much greater skill and labour, has received no official recognition. The distinguished painters who have honoured the Photographic Society by joining the staff of judges have been supposed to wield an undue influence, to underrate technical difficulties, and to neglect the merits of portrait work.

On the other hand, competent observers who have closely watched the portraits exhibited of late years have thought the progress made so slight as to acquiesce complacently in the decisions which left this branch of the art without judicial recognition.

Two things may be said in support of this view: first, that during the evolutionary stages of the bromide gelatine emulsion process, when the wet plate was giving place to the dry, a noticeable degradation of quality was observable in studio work generally; and secondly, that it was both natural and desirable that the results of the new process, full of fresh powers and possibilities, should receive marked attention from the judges, and that the successful workers should receive the distinction of a medal. These awards are certainly justified by the event, for in every branch of photography the new process is superseding the old.

Nevertheless, the social and commercial importance of portraiture is so paramount, and its artistic progress so desirable, that its just claims are not likely to be neglected by the leading Photographic Society; it is, indeed, settled that portraiture will certainly receive prizes this year if the work rises to the level of desert. The bromide emulsion process offers its advantages equally for portrait and for landscape work. Varieties of graceful pose, charms of expression, and life-like spontaniety of subjects, can be rendered with a fidelity to nature impossible with prolonged exposures. Studio work has been less bold than that in the field; but how much more difficult! Given a spot well chosen, light and conditions favourable, a landscape will yield all of its beauty to the camera that photography is able to seize. But to seek in a humble way to approach in portraiture the masters of painting, to follow such guides as Reynolds, Gainsborough, Millais, is a task demanding superior skill and ability.

Consider for a moment the difficulties with which the photographer has to contend; the brief time allotted to him, time quite insufficient to enable him to give anything like artistic study to his subject; consider the intractable nature of the means at his disposal, the lens taking actually what it sees, neither more nor less. No one knows better than a photographer how common-place-looking most people are when the character and expression is not stimulated into life and activity. How often do people wish to be taken as they are, in their natural way; and, as a rule, how awkward and ugly they look when the photographer gratifies their whim! And yet, in the short space of ten minutes or so, a photographer is expected to make an artistic picture and a good likeness, to seize salient excellency of feature, attitude, and expression, to modify and hide whatever is commonplace, to harmonize figure and background, and to have light and shade duly and favourably proportioned to the subject. All this, when done well—and it is done well by very many able, educated, and talented professional photographers all over the kingdom—demands a feeling for art, a social tact, an insight into character, and a rapid decision that enter very largely into the true artistic element, and deserves more recognition from artists than has hitherto been accorded.

It is expected that the forthcoming Exhibition will show marked progress in portrait studies, and great improvement in the general excellence of dry-plate work.—*Autotype Notes.*

THE BLUE PROCESS OF COPYING TRACINGS.

As we have had several inquiries recently in regard to the best method of copying tracings by what is known as the "blue printing process," we will give a brief description of the method employed by us; we do not say it is the best, but it certainly is as simple as any other, and has always given us perfect satisfaction.

The materials required are as follows:

1st. A board a little larger than the tracing to be copied. The drawing-board on which the drawing and tracing are made can always be used.

2nd. Two or three thicknesses of flannel or other soft white cloth, which is to be smoothly tacked to the above board to form a good smooth surface, on which to lay the sensitized paper and tracing while printing.

3rd. A plate of common double-thick window glass of good quality, slightly larger than the tracing which it is wished to copy. The function of the glass is to keep tracing and sensitized paper closely and smoothly pressed together while printing.

4th. The chemicals for sensitizing the paper. These consist simply of equal parts, by weight, of citrate of iron and ammonia, and red prussiate of potash. These can be obtained at any drug store. The price should not be over 8 or 10 cents per ounce for each.

5th. A stone or yellow glass bottle to keep the solution of the above chemicals in. If there is but little copying to do, an ordinary glass bottle will do, and the solution made fresh whenever it it wanted for immediate use.

6th. A shallow earthen dish in which to place the solution when using it. A common dinner-plate is as good as anything for this purpose.

7th. A brush, a soft paste-brush about four inches wide, is the best thing we know of.

8th. Plenty of cold water in which to wash the copies after they have been exposed to the sunlight. The outlet of an ordinary sink may be closed, by placing a piece of paper over it with a weight on top to keep the paper down, and the sink filled with water, if the sink is large enough to lay the copy in. If it is not, it would be better to make a water-tight box about five or six inches deep, and six inches wider and longer than the drawing to be copied.

9th. A good quality of white book paper.

Dissolve the chemicals in cold water in the following proportions: 1 ounce of citrate of iron and ammonia, 1 ounce of red prussiate of potash, 8 ounces of water. They may all be put into a bottle together and shaken up. Ten minutes will suffice to dissolve them.

Lay a sheet of the paper to be sensitized on a smooth table or board; pour a little of the solution into the earthen dish or plate, and apply a good even coating of it to the paper with the brush; then tack the paper to a board by two adjacent corners, and set it in a dark place to dry; one hour is sufficient for the drying; then place it, sensitized side up, on the board on which you have smoothly tacked the white flannel cloth; lay your tracing which you wish to copy on top of it; on top of all lay the glass plate, being careful that paper and tracing are both smooth and in perfect contact with each other, and lay the whole thing out in the sunlight. Between eleven and two o'clock in the summer time, on a clear day, from six to ten minutes will be sufficiently long to expose it; at other seasons a longer time will be required. If your location does not admit of direct sunlight, the printing may be done in the shade, or even on a cloudy day; but from one to two hours and a-half will be required for exposure. A little experience will soon enable any one to judge of the proper time for exposure on different days. After exposure, place your print in the sink or trough of water before mentioned, and wash thoroughly, letting it soak from three to five minutes. Upon immersion in the water, the drawing, hardly visible before, will appear in clear white lines on a dark blue ground. After washing, tack up against the wall, or other convenient place, by the corners to dry. This finishes the operation, which is very simple throughout.—*The Locomotive.*

Notes.

Next Friday, the 29th, is the *last day* for sending in pictures for the Annual Exhibition of Pall Mall.

The Honorary President of the Vienna Society, Herr Anton Martin, is dead. He was the first Austrian to practise the Daguerreotype process, and the first to make experiment with the Petzval-Voigtländer lens. Herr Martin was also the first to issue a photographic manual in the German language.

"The A B C of Dry Plate Photography," by W. K. Burton, C.E., which recently appeared in these columns, is shortly to be published in French by M. Gauthier-Villars, of Paris.

Writes a correspondent: "I develop with ferrous oxalate, and I always find my second plate (I work duplicates, to be sure of my result) is more successful than my first. The reason is, that I employ the same developer for the second plate, which comes out more slowly and evenly, and is consequently under better control. To tell the truth, I hardly like using a fresh and vigorous developer."

Mr. Durrant's yacht pictures are well known, for there are few photographers so successful in depicting the delicate rigging and snowy sheets of those trim craft as he is. We were privileged the other day, at Torquay, to examine a whole collection of these clever pictures at Mr. Durrant's little studio; and the various shapes and forms of the beautiful vessels, as they spread their "white wings" to the breeze, or drooped their tired pinions at the journey's end, reminded you of huge and graceful sea-birds, and for the moment you almost forgot they were but structures of wood and canvas.

Following the footsteps of their sailor-uncle, the Royal midshipmen seem to take particular interest in all things photographic. They have a large collection of pictures of the places visited during their recent voyage round the world. The Duke of Edinburgh, it will be remembered, became an expert photographer on his early voyages, thanks to the tuition of Mr. Frederick York, who accompanied His Royal Highness during his cruise in the *Euryalus.* The pictures, by-the-bye, produced jointly by the Duke of Edinburgh and Mr. York were never published, having been produced, indeed, for the Queen's private album—a great pity, we think, for they would add one more to the many interesting series of "slides" which Mr. York has given to the public.

In these advanced days, when it is not uncommon to hear the names of princes taken in vain, it is something to know that our royal family do not forget old companions. Mr. Francis Bedford, who accompanied the Prince of Wales to the Holy Land twenty years ago, is always sure of a friendly greeting when they meet, and same may be said of the Duke of Edinburgh, who still chats pleasantly with Mr. York of the times when the former was a midshipman, and the latter a member of the ward-room mess on board the *Euryalus.*

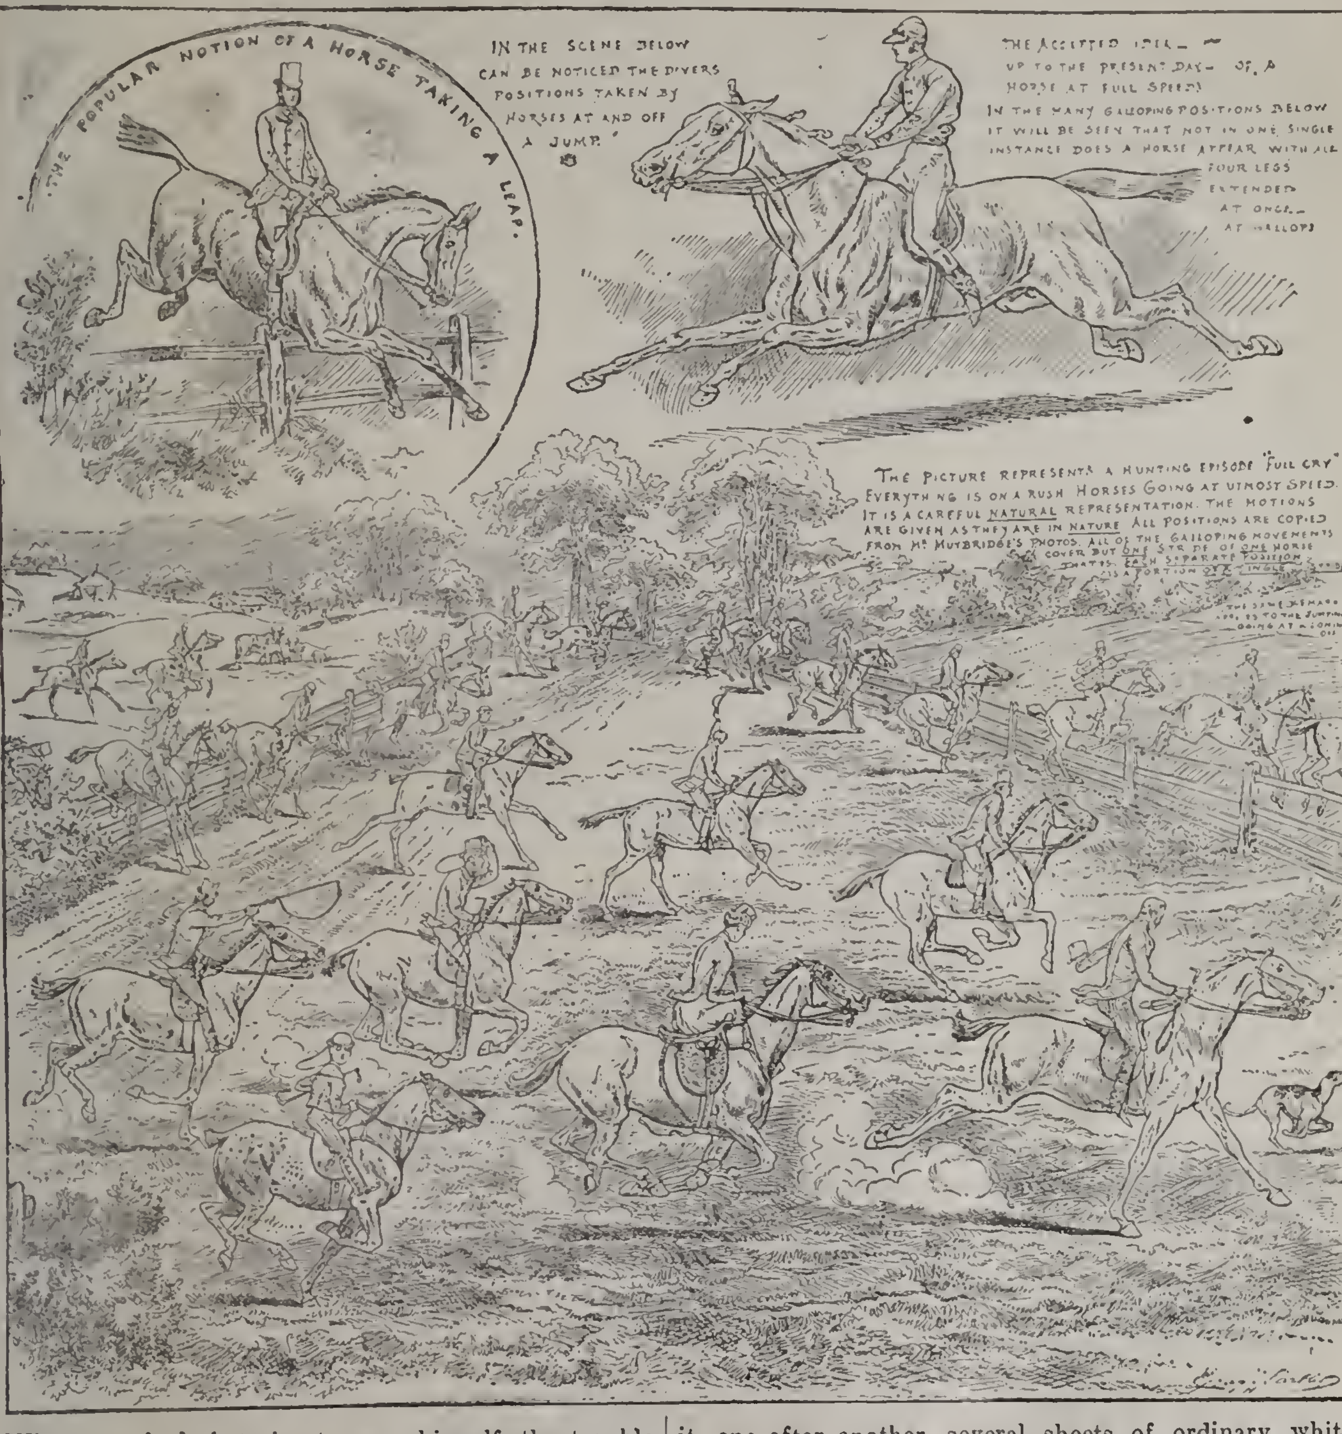
Messrs. Liesegang and Co., of Düsseldorf, have sent us the *Ateliers von Europa*, being the German edition of our "Studios of Europe." The German publishers have conceived the happy idea of issuing, by way of supplement to the book, a portfolio containing specimen pictures emanating from the principal studios described. The price of the portfolio is twenty marks (shillings), and no doubt Messrs. Liesegang would forward it to any of our readers in this country on receipt of a postal order to that amount.

We have already called attention to the singular perverseness of nations in declining to adopt a thermometer scale suggested by one of themselves, and we notice that a contemporary last week returns to the subject in proof that no man is a prophet in his own country. Thus, while we in England adopt the system of Fahrenheit, who was a German, the Great Fatherland on their part use the Réaumur scale, Réaumur being a Frenchman. The French, again, use the scale of a Swede, Celsius, or the Centigrade, as it is now generally called; while to complete the chain, the Swedes themselves adopt the thermometer scale of Leslie, a native of Great Britain.

We gave the other day the prices of cartes and cabinet portraits in the first-class studios of Europe; here are the prices charged for the next larger size, the panel or promenade. In Paris 120 francs per dozen (£4 16s.) is the highest charge we have met with, while in England £6 6s. is quoted by several studios, or at any rate £3 3s. for the half-dozen. In Germany the average charge in high-class houses is about fifty shillings; while in Austria, and also in Hungary, it is but forty-five shillings. In the above instance, therefore, England leads the way; but, on the whole, it may be said that Paris and London prices are about on a par, while those of Vienna and Berlin are a trifle lower.

It is only the other day that we mentioned Blondin in these columns in connection with photography; now the *Mittheilungen* gives us something more to say about him. Blondin has become a photographer—a high-art photographer, indeed, for he takes pictures on a rope stretched at a height of seventy feet from the ground. On the 27th of last month, at the "Neue Welt," in Berlin, he went through the whole operation of photographing upon the tight-rope; he put up his camera-stand, fixed his camera, and actually focussed in the approved manner with his head underneath the dark-cloth. Imagine this, balanced at a height of seventy feet, and in the teeth of a stiff breeze. Then he introduced the dark slide, held up his hand as a signal for the spectators to remain quiet, and coolly exposed. What Blondin's success was in these conditions is not recorded.

We take from the *American Queen* an illustration which will be of considerable interest to our readers. It represents the ideal and the real of the horse in the hunting field. It is needless to say that the horse-pictures are taken from Mr. Muybridge's instantaneous photographs; and it would have been well, indeed, if his riders had also been copied. These, however, have been supplied by the American artist.



When everybody is trying to save himself the trouble of sensitizing paper every day, it may be well to remind our readers of the old-fashioned but very effective plan of preserving it by means of carbonate of soda blotting-paper. Sensitized albumen paper will keep good a week—nay, even a fortnight in cold weather—by taking the precaution to roll it between carbonate of soda pads, and the ordinary operations of toning and fixing need not be modified.

The best plan is to make a strong solution of bicarbonate of soda—a saturated solution, if you will—and immerse in it, one after another, several sheets of ordinary white blotting-paper. The blotting-paper, when wet, is so tender that it cannot be lifted without much risk, and therefore it is well to lay sheet after sheet in the solution, until a dozen or a score are immersed one above the other. The sheets are then taken out *en bloc*, squeegeed, and, when tolerably dry, separated and most perfectly desiccated. Sensitized albumen paper packed sandwich-wise in these soda sheets will be preserved from brownness.

Another use for this bicarbonate of soda paper arises in winter time, when a slow-printing negative remains in the frame for two or three days together. If you put a sheet of the soda paper in the printing-frame next the sensitized paper, the latter neither becomes yellow nor discoloured. The soda paper, we may add, will keep indefinitely.

Although Mr. Robinson, of Tunbridge Wells, employs nothing but gelatine plates for his studies, he still finds room for a dipping bath in his laboratory; the reason is that he prefers wet plates for taking sky pictures, lack of sensitiveness in this case being in most circumstances a considerable advantage.

Tracings of designs, especially if made upon cloth, are not easily copied with the camera, even when made with Indian ink. In these circumstances, the *Moniteur Industriel* recommends the addition of raw sienna to the Indian ink, as this colour unites very intimately, besides intercepting the greatest amount of light.

Black mounts with bevelled gold edges have hitherto been generally employed for portraiture, but they are still more pleasing when small landscapes, say of cabinet size, are mounted on them. The prints should be cut so as to leave a quarter of an inch margin of black all round, and then, if the gold bevel is broad, the effect is that of a bijou picture tastefully framed. The mounting in this fashion is especially suitable for small landscapes exposed for sale, for a most finished look is thus imparted to the little productions. We recommend those of our readers who have not seen the effect of a cabinet landscape mounted in this way to make trial of the plan.

The *Pall Mall Gazette* is exercised in mind on the subject of the word "scientist," which it pronounces to be very objectionable. Instead, our contemporary proposes that scientific men should be called "scientiates" for short, in the same way as we have licentiates and potentates. We suspect that in this everyday world, the more simple word will always be preferred; telegraphême was said to be more correct than telegram, and yet it never had a chance; while to quote a more recent instance, the Zulu battlefield where we suffered disaster having in the first instance been misprinted Isandula, was ever after called by that convenient name, in preference to the unpronounceable Isandhlwana.

On the principle of setting a thief to catch a thief, the authorities of the Bank of France, so the *Archiv* tells us, have taken advantage of photography in producing their bank notes to prevent photographic forgeries. The famous painter Baudry has been pressed into the service to design the new note, and this he has done on a monster scale The original bank note is, indeed, no less than thirteen feet long and four feet broad. In this condition it has been handed over to the photographer, who having reduced it, with all its fine detail, to the ordinary dimensions of a bank note, the design has been etched on metal. By securing the aid of photography in this way, the Bank of France hopes to suffer immunity from evil-doers in future.

Patent Intelligence.

Notice to Proceed.

2277. Herbert John Haddan, of Kensington, Middlesex, for an invention of "A new or improved process for producing pictures on glass, stone, metal, and other materials."—A communication to him from abroad by Edouard Godard, of Paris, France.—Dated 15th May, 1882.

Specification issued during the Week.

565. A. Cowan.—"Packing photographic glass plates automatically." Price 2d.

A rectangular box has in the lid an opening half an inch larger each way than the size of the plates to be packed, and on each side of this opening are placed sliding pieces having their top edges bevelled off at an angle of 45°. These pieces are made to close over the opening in box by springs, and when in their normal position are about one quarter of an inch nearer together than the width of the plate to be packed. Above these sliding pieces is placed a strip of paper which is held in position by a hinged frame with frictional rollers to regulate the paper, and having also on each side a hinged plunger which drives the plate through the opening. Inside the box below the opening is a rising platform kept in position by a spring. In use, the plate to be packed is placed in the hinged frame, and the side plungers made to push it past the sliding pieces, which, directly it has passed them, close together and make a corrugation in the paper all along each edge; on removing the plungers the lower platform rises and flattens the bent edge of the paper ready to receive another plate. *Provisional protection only.*

Specifications may be obtained by addressing an order, with the price and postage, to Mr. H. Reader Lack, Office of the Commissioners of Patents, London.

Patent Void through Non-payment of Duties.

3541. Frank Wirth, of the firm of Wirth and Company, Patent Solicitors, at Frankfort-on-the-Main, in the empire of Germany, for an invention of "Improvements in apparatus for holding photographs and showing the same."—A communication from Friedrich Wilhelm Schwarz, manufacturer, a person resident at Offenbach-on-the-Main, in the empire of Germany.—Dated 3rd September, 1879.

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. VII.—Preparation of Pyrogallic Acid, Gallic Acid, and Hydrokinone.

There are several methods of preparing gallic acid, but the one which is simplest to carry out on the small scale is by heating an infusion of gall-nuts with a dilute solution of sulphuric acid. Take about a quarter of a pound of powdered gall-nuts, place it in a pint beaker, and pour about half a pint of boiling water into it and allow the mixture to stand for an hour. Place over a large funnel a piece of calico about a foot square, and turn the contents of the beaker into the calico, but of course allowing the liquid which passes through the funnel to drop into a suitable vessel. When all has drained through, the calico is held by the corners, and thoroughly squeegeed in order to press out the adherent liquid; this is then mixed with the liquid which drained through, and the whole is filtered through bibulous paper. Now pour the filtered solution into a pint flask, with half an ounce of dilute sulphuric acid (1 : 4), and boil over a sand-bath for a quarter of an hour; then let the solution cool down, when beautiful needle-like crystals of gallic acid will separate out. The gallic acid thus prepared is somewhat impure, so to purify it, the crystals, after draining, are placed in a flask with about five ounces of water, and boiled till all is dissolved; the solution is filtered, while still hot, through bibulous paper, and the filtered liquid will deposit, on cooling, gallic acid which is moderately pure; the crystals are finally dried by pressing between two or three thicknesses of bibulous paper.

In preparing pyrogallic acid, one has the choice of several methods, viz., heating gallic acid alone, heating a mixture of gallic acid and powdered pumice-stone in an atmosphere of carbonic acid, and heating a solution of gallic acid in glycerine. The method which is most conveniently worked by the photographer is that of heating a solution of gallic acid in glycerine, but we give details of the other processes, so that the student may experiment with them.

In order to prepare pyrogallic acid by the first-named process, about half an ounce of gallic acid is placed in a large porcelain crucible, a piece of thin cardboard perforated with several small holes is tied over the top of the vessel, and a cone of stout paper is placed over it. The crucible is placed in a sand-bath heated by a Bunsen burner fitted with a rose. The temperature should be kept at about 180° C. or 185° C. for some hours, when the gallic will gradually decompose into carbonic dioxide, various secondary products and pyrogallic acid, the latter compound condensing in the paper cone. The great objection to this process is, that there is a great difficulty in maintaining the right temperature, for should it exceed 185° C., the gallic acid is converted into meta-gallic acid and water; consequently, the above process does not yield more than twenty per cent. of the original weight of the gallic acid.

The second method is a modification of the preceding process, and was proposed by Liebig. About half an ounce of gallic acid is mixed with one ounce of coarsely-powdered pumice, and placed in a six-ounce tubulated glass retort; the latter is placed on a sand-bath heated with a Bunsen burner to the same temperature as is necessary in the first method. In the tubulure of the retort is fitted a perforated cork, and a tube connected with a carbonic acid apparatus (the sulphuretted hydrogen generator containing lumps of white marble and hydrochloric acid will answer very well). The pyrogallic will gradually form on the inside of the neck of the retort, and can be easily removed by a glass rod. If the latter process be carried out correctly, about thirty per cent. of the original weight of gallic acid is formed. The reason why a greater yield is produced than in the former method is that the carbonic dioxide carries away the pyrogallic acid as soon as it is formed, and consequently prevents it being decomposed to a certain extent by a rise of temperature.

The next method is that of heating an aqueous solution of gallic in a sealed vessel to about 200° C.; after about half an hour the solution is boiled with animal charcoal, filtered, and evaporated to dryness, the residue being afterwards distilled under diminished pressure. In this process almost the theoretical yield is produced; but the process is not easily worked on the small scale, as a special apparatus is required for heating the solution of gallic acid and for distilling the impure pyrogallic acid under pressure. The process of heating a solution of gallic acid in glycerine has lately been suggested by Professor Thorpe, and is certainly the simplest and most economical method for working on the small scale. Place in a four-ounce hard glass flask 300 grains of gallic acid and two ounces of Price's glycerine; fit in the neck of the flask a cork perforated with two holes, one being left open for the escape of gas, and through the other place a thermometer capable of registering 200° C. or 400° F., the bulb of which must dip into the liquid. Now heat the flask on a sand-bath to about 190° C. or 200° C. (400° F.), till the evolution of carbonic dioxide stops, which operation generally takes about an hour. The solution can now be preserved in a stoppered bottle for months without any apparent change. Each ounce of the liquid will contain about 100 grains of pyrogallic acid, but Professor Thorpe prefers to pour the solution into 66 ounces of water, and in that way he obtains a solution which contains rather more than three grains to the ounce; the pyrogallic acid in so dilute a solution will not keep more than a month.

Hydroquinone or hydrokinone, which substance has lately been proposed as a developing agent, may be prepared by distilling an extract of the cinchona bark or the coffee-berry with a mixture of sulphuric acid and manganic dioxide, and finally reducing the quinone thus obtained by dissolving it in water containing sulphurous acid, and evaporating the solution. A simpler and more economical process, which has been suggested by Nietzki, is that of oxidizing aniline by means of potassium bichromate and sulphuric acid.

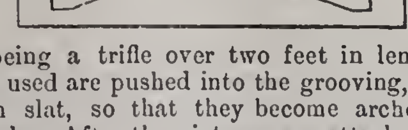
For preparing it on a small scale, pour into a quart flask a pint and a half of water, and then gradually add five fluid ounces of sulphuric acid and allow to stand till quite cool. When ready, place the flask in a basin of water with a few lumps of ice floating in it, and pour an ounce of aniline into the dilute acid; then very slowly add powdered potassium bichromate till the dark green precipitate first formed is dissolved. From two to three ounces of the salt is required. When the operation is finished, place about ten ounces of methylated ether in a Winchester quart stoppered bottle, and then pour the contents of the flask into the bottle, replace the stopper, and briskly shake the vessel for ten or fifteen minutes, and allow to stand. When the two liquids have separated, draw the top ethereal solution off into an evaporating-basin by means of a syphon, and place the dish in the open air (if possible in the sun) for two or three hours, when the ether will evaporate, leaving crystals of quinone. While the evaporation of the ether is proceeding, a solution of sulphurous acid in water should be made. An apparatus must be fitted up similar to the sulphuretted hydrogen generator, the bottle being replaced by a four-ounce flask; into the latter vessel about an ounce and a half of copper turnings is placed, together with a fluid ounce of strong sulphuric acid, and the cork replaced, the delivery tube being conducted into a vessel containing six ounces of distilled water. The flask is gently heated on a sand-bath, when in a short time action commences, and will continue for about twenty minutes. When the operation has finished, the delivery tube should be withdrawn from the water before taking the lamp away, otherwise the water will run up the tube into the flask, and cause an explosion.

When the greater part of the ether has evaporated, pour into the dish the six ounces of the aqueous solution of sulphurous acid made in the previous experiment, and place the evaporating basin on a saucepan of boiling water, continuing the boiling till all the water has evaporated, leaving a crystalline mass of hydrokinone.

A SIMPLE APPLIANCE FOR USE IN MOUNTING CARTE PICTURES.

BY C. KEUCHEL.*

It is my opinion that the convenient and easily constructed apparatus about to be described will prove of real practical utility to the photographic printer. The tendency of recently mounted pictures to curl inwards on drying causes considerable inconvenience in several ways, but more especially during burnishing or rolling; and in order to overcome this, I construct grooved wooden slats or strips of moulding having a section as shown in the diagram



each slat being a trifle over two feet in length. The cards to be used are pushed into the grooving, six end to end in each slat, so that they become arched with the face outwards. After the pictures are attached, the cards are once more slid into the grooves, and allowed to remain until nearly or quite dry. The set or curve thus given to the cards quite counterbalances the tendency of the print to distort the mount; but if the pictures are allowed to become quite dry in the grooves, it sometimes happens that a permanent curvature is given in a contrary direction to that usually taken.

ODD JOBS.

BY THE AUTHOR OF "LOOKING BACK."

No. 11.—THE PARVENU!

EVERY profession has its annoyances, no doubt. Lawyers have queer clients that expect them to buy justice in the face of a bare unvarnished truth; doctors have patients that want to be healthy and intemperate at the same time. Each, more or less, in his business routine, beholds the seamy side of humanity; but I fancy photographers see more petty meannesses and pitiable littlenesses than any other. The tailor is told of the high shoulder, and has to hide it; the shoemaker has to make large feet small, and knobby toes symmetrical; but what is that compared to the multitude of weaknesses displayed in all nakedness to the photographer in the studio? Every day almost, we pass one or other of the seven cardinal sins through our hands. We are not told of them as the tailor and shoemaker is; experience or intuition points us out the cloven foot. No one can mistake the noodle, full of empty pride; the common—not to say ugly—looking girl so puffed with vanity; the penurious purse-drawn face of avarice; the filthy breath and blotched face of the drunkard; the bloated cheeks and sensual lips of the glutton, or the bitter withering look of old maid envy as she looks upon the budding charms of sweet seventeen. Occasionally we meet with flaming anger; but, in my experience, that sin displays its proportions to more advantage in the dark room than in the studio.

In this paper you will only find a sample of a class that tries the patience of operators until they find themselves hovering on the verge of raving lunacy. When one of this class drops into the studio, quote Shakespere's "Patience on a monument," &c., and think of Job. A good plan is to have a few engravings from the Book of Job handy, so as to refresh your memory with that exemplary man's sufferings.

The yahoo, as usual when he deemed something nice in store for me, was on the broad grin when he informed me that F. Midas, Esq., who drove the four-in-hand creams, and had run away with Methusalah Smith's wife, and got turned out of the assembly rooms, and kicked out of the club, was coming to be "nicked off (Yahoo's vernacular) in various poses and divers garbs."

F. Midas, Esq., was a fair, good-looking little man with a jaunty, impudent, over-bearing air about him; he gave one the idea that he was for ever trying to impress the public that he was a "good man and tall"—six feet at least—the only party deceived with the fraud being himself. When F. Midas, Esq., entered the studio, I politely bade him good morning; but, instead of answering, he fixed up his eye-glass, and, with the utmost coolness, impertinently scanned me slowly from head to heel. I daresay he wondered at the assurance of a photographer daring to address even a good morning to his greatness.

"A—ah! What country du yu come from?" he asked. The stare would have been enough to raise some people's dander, and, backed up with a question given in the same tone as if he were asking into the antecedents of a footman, I'm sure you will not blame me when I lied and coolly answered, "Africa."

Up went the eye-glass again, while the yahoo spluttered and knocked about the bottles in the dark-room in a very suggestive manner. "Jove!" quoth F. Midas, Esq., "that accounts for your curly hair!" I could hear the yahoo going into fits in the dark-room at the deduction of F. Midas, Esq.

"I want cabinets taken in this coat," explained my sitter, the coat in question being a brown silk velvet; "but I must have it open so as to show this chain." And he displayed an enormous gold albert, made of long square solid links, and the side of each link studded with a diamond. "Never saw anything like that before—eh?" he continued, as he fondled at the heavy links." This is my own design—pretty, ain't it? The diamonds alone cost me £7,000. What do ye think o' that? No wonder if I want it to come out well—eh! Ha, Ha! You should see the ladies how they look at it! Why, the Prince has nothink equal to't! By-the-bye, I'm told you photographed the Prince. Now, honestly, don't yu think him a very common, podgy sort of a chap?"

With such vain, vulgar twaddle did F. Midas, Esq., with an income of £60,000 per annum, pass the intervals of posing and arranging the lighting. Of course, the posing was the great trouble. "I want something gentlemanly. I don't care whether I sit or stand, but I must have it gentlemanly." I first tried a three-quarter figure, sitting at a reading-desk with some books. "Demmit! I shan't have that! Looks like a schoolmaster." I then took away the books, and as he stuck his legs in form as if they were made of wood, I got him to cross them. "Oh, oh, this won't work! every demmed tailor sits cross-legged! How will this do?" And, bringing up one foot over one knee, he flung himself back in his chair, taking care to put aside his coat, so as to display his chain. He had several suits with him, and as all my suggestions as to posing were met with such expressions as—"Oh, that's frightful common! Awfully stagey! Quite vulgar; suit a tradesman!" I was really put to my wits' end to please him. I have a dislike to scenic backgrounds, especially interiors. There was one in the studio—a complicated affair, with a half-open window, a distant view, a curtain, and some elaborate wainscoting that was my particular abomination. F. Midas, Esq., while looking over some specimens, dropped upon one of it, and immediately went into ecstacies over it. It was so like a picture in itself, nothing stiff or formal, and everything came out so distinct. Believe me, the only picture that he really liked and praised was the one taken with that hideous interior.

I had a whole day about with him, and, to help make the thing worse, he was the veriest fidget I ever saw: three seconds' exposure with the head-rest, and he would move as if he were doing it on purpose, and, when charged with it, swear you some good round oaths, that he was—"Demmit! steady as a rock! Demmit!" Independently of this, I succeeded in making some very good pictures of him, the best being a large head (that he never ordered from) and the three-quarter in velvet. I was agreeably surprised at the rich effect produced by the velvet on the gelatine: it far surpassed anything I could obtain with collodion. An enlargement made from it retained the shimmer so well that one would fancy it quite easy to lay hold of the folds.

The last *gentlemanly* action of F. Midas, Esq., prior to leaving the studio, was to offer me a shilling for being so attentive. I was asked in the evening by the guv'nor what I had done that F. Midas, Esq., set me down as a "demmed proud sort of a fellow."

While he was leaving orders in the reception room about his portmanteau and dressing case, the yahoo had impaled the guv'nor's little boy in a corner, and evidently had been teaching him a lesson. During a pause in the talk the yahoo exclaimed:

"What did Joe Jolliffe's ducks say, Tommy?"

"Quack! Quack! Quack!" answered Tommy.

Everyone laughed with the solitary exception of F. Midas, Esq., and he looked angrily and suspiciously at the smiling and placid face of the yahoo, while his face flushed most painfully. The yahoo knew the secret of F. Midas, Esq.'s wealth. The elder Midas was originally a bird catcher, but lately had discovered that quackery paid better. Thus, the elder Midas, with a wonderful pill that cured all the ills that flesh is heir to, made a fortune, and only failed in his last undertaking—*videlicit*, to make his son a gentleman.

THE DEVELOPMENT OF GELATINE PLATES.

There is no doubt but that certain makes of plates develop better with pyrogallic developer than with ferrous oxalate; and it is equally a fact that certain other makes develop quite as well, if not better, with ferrous oxalate than with pyrogallic. This is not only true of plates made by different makers, but even of plates made by the same maker, and is probably due to an alteration of texture in the gelatine, produced by some slight variation of the treatment during the process of manufacture.

It is therefore impossible to say that one mode of development is superior to the other, and that is practically admitted when the instructions sent out with the plates include both modes. In the ferrous oxalate development there is a clearness and brilliancy, and an appearance, which remind one strongly of a fine collodion negative, and if the absence of yellow stain is considered advisable in plates developed by ferrous oxalate, this stain is conspicuously absent.

It has been urged against ferrous oxalate that it does not permit of any coaxing of the negative as the pyrogallic development is supposed to do. This is a mistake; the normal condition of ferrous oxalate is about the same as that of pyrogallic with its full dose of ammonia; if the exposure has been too long, or it is wished to proceed very cautiously in the development, the addition of bromide will retard and control the action of the ferrous oxalate just as it does the pyrogallic.

As a practical matter, if one ounce of a one-grain solution of bromide of potassium solution be added to each five ounces of ferrous oxalate developer, it will be at once apparent that it puts the development of the picture quite under the control of the operator. It is true that it is impossible to force up the picture with ammonia, as it is attempted to be done with the pyrogallic mode of development, but is this ever of any value? Does it not simply intensify the yellow veil over the picture, without in the least helping to bring out the desired detail?

In employing the ferrous oxalate developer, it should always be used as strong as possible. It is best to have saturated solutions, and with the aid of a couple of good large jugs this condition can readily be secured. It may be urged that the saturation point depends upon temperature, and that more is taken up at one time than another. That is very true; but in any case the solutions balance each other, are as strong as they can be made, and in the winter, care should be taken to keep them in a room or in some place where the temperature does not fall very low.

The following is an easy and simple mode of making saturated solutions, the important point being to always have a quantity of the undissolved salts in the bags. Procure two large common jugs; over the tops put two pieces of common coarse muslin, or strainer, so that they bag into the jug; now put a quantity of neutral potassium oxalate into the one, and a quantity of protosulphate of iron into the other; fill the jugs up with warm water, leave them to get quite cold, and the two are ready for use. Keep the jugs filled up with water, and take care to have always some undissolved crystals left in the bags. Before commencing to develop, mix a sufficient quantity for the day's work, in the proportion of one part of the iron solution, stirred into four parts of the oxalate.—*Autotype Notes.*

LIGHT AND COLOUR.

BY ALFRED DANIELL, M.A., BS.C.

Light is a form of wave-motion in the all-pervading ether; and it scarcely needs, nor does space allow, a lengthened discussion of the varieties of converging proofs which aid one another in forcing us to this conclusion. If we throw a couple of stones on the surface of water, we find a couple of systems of rings produced, which at their points of crossing present the appearance of engine-turning. Where the crest of one coincides with the crest of the other, there is double upheaval; where the trough of one coincides with the trough of the other, there is double depression. Where, however, the crest of one coincides with the trough of the other, what do we find? Neutralization of effects—no effect, no motion; for the instant a state of rest. This is exactly what happens when two beams of light coming, or appearing to come from two points exceedingly near to one another, are allowed to shine upon the same spot. The phenomena of interference of light are phenomena in which light added to light produces darkness in some places, and extra brightness in others—darkness when the same spot is affected by waves which are in opposite places, and increased brilliancy when the waves are in accord with one another. This is a matter capable of easy explanation when the phenomena of light are considered as due to wave-motion; but under the old corpuscular material theory of light it was very difficult to explain, as, indeed, it was to understand or believe the explanation offered.

The phenomena of colour are again due to waves of different lengths. Each colour and shade of colour, provided that it is in the spectrum, is due to a special wave-length. The waves of light which produce in our eyes the impression of deep red have a length of about the 37,640th part of an inch; and since the ripples of 192,000 miles of space break upon the eye in a second, we learn that during each second we spend in contemplating the planet Mars, or any red star, the prodigious number of 458,000,000,000,000 break upon the eye; and if the red object we look at be terrestrial, it must be in a state of continued vibration, which enables it during each second to start this enormous number of waves travelling through the ether and striking the eye. The other extreme in colour is produced by certain violet rays, which have a wave-length of the 60,000th part of an inch, and of which more than 700,000,000,000,000 strike the eye during every second. But there are still more rapid vibrations, propagated by the ether, to which our eyes are not sensitive, but to which our photographic plates do respond; and there are vibrations, slower than those of the extreme red, to which our eyes are not specially sensitive, but which our skin and general bodily organisms perceive as heat rays. The slower waves are thus the cause of radiant heat, the more rapid ones cause the sensation of light, and the most rapid produce the chemical effects upon which photography depends. Yet there is no broad line of demarcation between these departments of energy-bearing waves. The red rays are felt to be warm by the hand, and seen by the eye to be red; the violet rays are seen by the eye to be violet, and are also found to be active in relation to photographic plates. What lies beyond these we do not know. There is no probable reason, in the nature of things, for such a limitation of vibrations in the ether to one or two octaves; but whether there be or be not any radiations through space which are slower or more rapid than those with which we are acquainted as heat waves, light-waves, or actinic waves, it remains that we do not know anything about them, for we have no senses which perceive them, and we have as yet discovered no instrumental means for their detection. Yet we suspect their existence. Many of the vibrations of luminous bodies are connected with one another in the same way as the harmonies of a low musical note are related; and thus we may, without any material call upon our imagination, suppose ourselves to be in relation to the vibrations of light in much the same position as we can easily suppose a grasshopper to be on listening to the boom of a church organ. The grasshopper can hear sounds which are beyond our hearing, sounds high and keen edged, sounds like those which he himself makes; but it is probable that we in our turn can hear low tones which the grasshopper cannot hear, and that on listening to a full-chorded combination of sounds, the insect would be deaf to the lower notes, and would hear simply a crowd of harmonics, which would seem at first to bear no relation to one another. In the same way, we can suppose ourselves to be blind and devoid of sensation in respect of those long fundamental waves in the ether, of which these light rays and heat rays are some of the harmonies. Too much stress must not be laid on this, however, because our knowledge (though growing) is not yet very great in this regard; and there is not much evidence that there is any material loss of recognizable or perceptible energy in the shape of unrecognizable or imperceptible radiations.

Colour in the theory of light resembles pitch in the theory of sound. Both depend upon the length of wave which strikes upon the appropriate organ of sense after travelling through the appropriate medium. Yet, though they depend upon the length of wave, the length of wave does not explain the sensations of colour or pitch. The theory of light and that of sound are both, in the most rigid sense, sciences of calculation, of applied mathematics, mechanical sciences. They have nothing to do with the emotional effect of the harmony of colours or of sound; or with the relation between beauty of colour or of sound, and the admiration which this calls forth from a sensitive mind. They have to deal with vibrations alone, and a transversal vibration in the ether, having a wave-length of the 51,110th of an inch, and falling on the retina of the eye, may or may not rouse the enthusiasm of the mind which is behind the eye that perceives the blue of heaven; but physical science, concerning itself with the vibration as such, and as such only, stops short where physiology and psychology take up the burden of discovery and of explanation.

White light, such as that which comes to us from the sun, is composed of almost all the vibrations within the limits of visibility, simultaneously travelling through space, and simultaneously striking our eyes. When a ray of bright white light strikes the eye, we have no sense of any special colour in the mixture, and this is the sensation of white light; the mixed sensation of all colours, of which none preponderates, is the sensation of uncoloured or white light. If an orchestra sounded forth every imaginable note within the compass of our hearing, the blinding flare would not produce in our ears the effect of any particular pitch; the result would simply be an indescribable Wagneresque ocean of pitchless sound. So it is, and as wonderful, but that we are more accustomed to it, every time we behold white light; and our object when we endeavour to procure what we call pure white light is to procure light which is due to all possible vibrations, of which no one preponderates over the other so as to impress the aggregate result with its own coloured individuality.—*Journal of Gas Lighting.*

THEORY AND PRACTICE.

Theory and practice, says the *Chemiker Zeitung*, will involuntarily strike the ear of some of our readers like shrill discord.

"All theory, dear friend, is hoary," perhaps one will say, while the theorist, wrapping his toga proudly about him, will draw aside from the practician with a sympathetic smile and express his ideas. The contradiction herein expressed has become so customary that one rarely meets with any other conception than this, which is decidedly false. For this reason we may be permitted to state in a few words what is the real relation between theory and practice.

We do not see in it any contradiction, any "master and servants," or "head and hand;" nay, we look on them as two perfectly equal factors, through the harmonious co-operation of which the acquisitions of science are first made to serve mankind. If we admire the learned who live only for science, pondering on the highest problems for their own sake alone, unconcerned as to whether their thoughts can find any practical use, we do not honour less the man who is quick to see which thoughts of that savant promises a rich return if carried into practice, and then with an iron energy carries it out, and impresses upon it its best form.

And where is there any discovery which owes its origin to the mind of a theorist, that has not found its first complete application in the efforts of a diligent practician?

We have seen a whole series of discoveries, which seemed originally to have merely a scientific value, but they soon celebrated unexpected practical triumphs; we have seen how flourishing industries have been built on small and unseemly experiments made only for scientific purposes in the laboratory of the investigator, not only without regard to their practical utility, but very frequently without any suspicion of it. About two decades ago Bunsen and Kirchhoff astonished the world by their discovery of spectrum analysis, but at that time no one imagined that it would so soon find an eminently practical and genial use in the manufacture of Bessemer steel.

The insignificant observation that the legs of a frog hanging on a copper wire would jerk whenever they touched the iron, was the foundation of the electric telegraph, and there is scarcely another domain in which practical men have attained such brilliant results as in electricity.

Marggraf's ever memorable isolation of the "sweet salt" in the beet was the corner stone of one of the most flourishing industries of Germany, which to-day supports very many chemists and technical men who are continually striving to advance the higher development of this branch of industry.

What a wide step from Ziuin's conversion of nitro compounds into amides to the present state of the coal tar colour industry!

We could give an enormous number of examples of how small theoretical beginnings have risen to important practical results. But these few may suffice to show how everything of importance which has been accomplished in our profession owes its results to the circumstance that theory and practice have mutually supplied each other's deficiencies.—*Scientific American.*

Correspondence.

PHOTOGRAPHIC SOCIETY EXHIBITION.

Dear Sir,—Permit me to remind intending exhibitors that packing cases can be despatched any day, addressed to Mr. Bourlet, 17, Nassau Street, Middlesex Hospital; but the very latest sent must reach London on Friday morning, September 29th; also that the *only* day for receiving exhibits (sent by hand) at the Gallery, 5a, Pall Mall East, will be Friday next, September 29th, up to nine o'clock in the evening, after which time no picture will be received (by order of the Council). Any information respecting the exhibition can be obtained from—Yours, &c.,

57, Queen's Road Peckham, S.E. Edwin Cocking.

USE OF BALLOONS IN WAR.

Sir,—We have noticed in your last week's issue a paragraph on "The Use of Balloons in War," suggesting that for photographic purposes no person should require to ascend in the balloon, but that the camera being fixed in position, and fitted with a shutter capable of being discharged by electricity, the exposure might be made from below through a wire.

It may be interesting to your readers to know that the Royal Engineers were, by the War Office, provided with such an apparatus.

We, a short time since, made for Captain Abney one of our Addenbrooke's shutters fitted with an electrical discharge to expose by a wire at a distance from the apparatus; this having been seen, we were requested to supply a similar one for the use of the proposed balloon expedition, which we therefore did. The Addenbrooke shutter was particularly well adapted for the requirements, as by its construction any definite exposure required can be exactly given.

We might also mention that we presume the above was for occasional use, and that ordinarily the balloon would have occupants, as for the same order was supplied, together with other apparatus, three of our new snap shutters to be discharged by hand only; but in places of danger, the ability to get accurate record of the proceedings of the foe, without risk to life, would of course be of great service.—We are, dear sir, your obedient servants,

W. Watson & Sons.

[We did not suggest employing balloons without occupants, but described Mr. Cooper Key's suggestion. The originator of the plan is, as our readers know very well, Mr. Woodbury, who has taken out a patent in connection with it.—Ed. P.N.]

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of this Association held on Thursday, the 14th inst., Mr. A. Haddon occupied the chair.

The Chairman stated that he had measured the aperture of the hole with which the pictures of the statue of the Prince Consort, exhibited by Mr. Henderson at a previous meeting, were taken, and he found it was $\frac{1}{150}$ inch.

Mr. Debenham said this would represent No. 2,300 on the uniform system.

Mr. W. K. Burton passed round some 12 by 10 negatives, in which both sky and foreground were fully exposed; this result was obtained by shading the lens with a cabinet mount, the foreground receiving five seconds, and the sky three seconds exposure.

Mr. Collins said that Mr. England used a somewhat similar arrangement inside the camera.

Referring to the plates exhibited by the Chairman of the previous meeting, Mr. Debenham said he had prepared plates with an emulsion containing chloride, and did not find any perceptible change in colour.

Mr. Burton thought the colour of the plate depended more on the gelatine than the salts.

Mr. J. Traill Taylor was elected an hon. member of the Association.

Sheffield Photographic Society.

The ordinary meeting was held at Freemasons' Hall, on Sept. 5th, Dr. Thos. H. Morton presiding. The minutes were read and approved. It being near the close of the financial year, Messrs. Yeomans and Davy were appointed auditors.

The Society's excursions, owing to unfavourable weather, have not been very successful, but the members are making amends for it by work on their summer holiday tours. Several good prints were shown by Messrs. Taylor (hon. sec.), Seaman, Fonon, Amley, and others. The instantaneous views by Mr. Taylor, taken at Morecambe Beech, were much commended.

Mr. Dakin exhibited a useful combination of pocket-knife and glaziers' diamond.

In reference to the subject of mounting photographs, Mr. Taylor thought that fading was sometimes due to the presence of soda salts, and questioned the utility of cheap mounts.

It was decided to have the usual supper at the Annual Meeting on Tuesday, Oct. 3rd, members of the Society and friends being cordially invited.

Talk in the Studio.

Photographic Society of Great Britain.—The next Technical Meeting of this Society will be held at the Gallery, 5a, Pall Mall East, on Tuesday next, September 26th, at 8 p.m.

Royal Cornwall Polytechnic "Art Union."—Among the successful numbers drawn this year are the names of Mr. W. Brooks, Reigate, £5; and Mr. E. Gael, Falmouth, £1, the amounts to be selected in pictures exhibited in the exhibition by professional artists.

Developing and Fixing Dry Plates.—"I find it very convenient," says a correspondent, "to lay a piece of thin string or thread in the developing dish under the plate, extending a few inches each way beyond it. This enables me to lift the plate out of the solution without putting my fingers in, and prevents the adhesion of the plate to the dish by suction. I should have thought this expedient so obvious as to suggest itself to every worker, were it not that the various more or less elaborate contrivances described from time to time in the News for lifting the plate seem to show that there are many to whom it has never occurred that 12 inches of thread would be just as efficacious, without raising the plate sufficiently to require more solution for covering it." Some of our readers will find this, which is one of the earliest devices of the kind, to be more convenient than the rather elaborate arrangements recently proposed.

The Arctic Yacht "Kara."—Our readers will be glad to learn of the safety of this little craft, in which Mr. W. J. A. Grant accompanied Sir Henry Booth to the Arctic regions. According to the following telegram, the little ship has safely got back to Norway:—"The Arctic Sloop *Kara*, Hammerfest, Sept. 16.—Met the ice on August 12, in lat. 75 deg. 45 min. north, long. 58 deg. east. On the 13th anchored at Berg Island. Driven by ice into Lystina Bay. On the 16th lost anchor, cable, and boat. Driven ashore on Tern Island, so called by Markham. Lightened ship, and got off on Sept. 2 uninjured. Up to this time beset by ice. On the 3rd got free and sailed southward. Met snow and very bad weather." Sir H. G. Booth left England this spring in his sloop *Kara*, with the object of following up his researches in Nova Zembla, and of co-operating with Sir A. Young as far as possible in the search for and relief of the missing crew of the *Eira*. The *Kara* was in Matochkin Straits when Sir Allen and the *Hope* rescued the *Eira* crew. The *Hope* returned to England with the long-lost explorers, and Sir Henry Gore Booth and Mr. Grant remained on the coast of Nova Zembla. The *Kara* has shared in the usual risks attending Arctic navigation, and has narrowly escaped the fate of the Austrian exploration ship *Tegetthoff*, which was beset in the same locality, and which had eventually to be abandoned by her crew.

The Late Dr. Pusey.—Mr. Samuel A. Walker has photographed, from an original drawing in his own possession, the portrait of Dr. Pusey, sketched from life, eight or nine years ago. The venerable churchman would never consent to sit for a photographic picture. As a contrast to this, we may mention that Queen Emma, of the Sandwich Islands, is possessed by a mania for being photographed in different costumes and attitudes. At Montano's, the grand photographers of Honolulu, she is seen in no less than twenty-five different photographs, and no two of them in the same dress.

Balloon Photography.—The Academy of Aërostation will try on September 22nd the system of aërial panoramic photography, for which they have received a subvention from the city of Paris. This scientific experiment, which, it is expected, will bear interesting results, will take place on the occasion of the *fete* of the "Defence National" round the Lion of Belfort, at a very little distance from the Observatory.—*Nature.*

Separation of Silver from Alloys.—The silver-holding alloy of metals are dissolved in the least possible quantity of crude nitric acid. The solution is mixed with a strong excess of ammonia, and filtered into a high cylinder, provided with a stopper. A bright strip of copper, long enough to project beyond the liquid, is next introduced, which quickly causes separation of pure metallic silver. The reduction is completed in a short time, and the reduced silver is washed, first with some ammoniacal and then with distilled water. The more ammoniacal and concentrated the solution was, the more rapid is the reduction. The strip of copper should not be too thin, as it is considerably attacked, and any little particles which might separate from a thin sheet would contaminate the silver. The operation is so simple that it seems preferable to all others for such operations as the preparation of nitrate of silver from old coins, &c. Any accompanying gold remains behind during the treatment of the metal or alloy with nitric acid, chloride of silver (produced by the impurities [HCl] in the nitric acid) is taken up by the ammoniacal solution, like the copper, and is also reduced to the metallic state; and whatever other metal was not left behind, oxidized by the nitric acid, is separated as hydrate (as lead, bismuth) on treating with ammonia. Any arsenate which may have passed into the ammoniacal solution is not decomposed by the copper.—Mr. Solthien, in *Arch. d. Pharm.*

The Photographic Money Dispute.—At Clerkenwell, on Tuesday, Captain Herbert Kerr, late of the 17th Regiment of Foot, of 22, Bushey Place, Clarendon Road, Hampstead, appeared before Mr. Hosack to answer the sworn information and complaint of Lieutenant Arthur Henry Loringe, R.N., for having, on the 20 April last, obtained from him the sum of £2,070. Mr. Besley, barrister, appeared for the prosecution, and Mr. Grain, barrister, for the defence. The plaintiff stated that he had been induced to embark the sum specified, in the Photographic Artists' Co-operative Association, on the presentation of certain statements of account, showing that the Association was in a satisfactory condition. He had taken up the appointment of Assistant Manager, and since then found that the affairs of the Association were not so flourishing as he believed them to be. After detailing his evidence as to the payment of money to Captain Kerr, &c., Mr. Hosack said he should have to remand the case at this point. As far as he understood it, the case for the complainant was that if he had known the real state of the accounts between the defendant and the Company, he should not have parted with his money. Mr. Grain said he was anxious that the case should be taken at the earliest possible opportunity, as it would collapse as soon as he had asked the prosecutor one question. The fact was that the prosecutor did not know or did not remember what was the effect of the affidavit which he had sworn in the Court of Chancery. The case was then adjourned.

Photographic and Political Meetings.—It appears, according to a statement in a daily contemporary, that one of the meetings of Zulus alleged by Sir Henry Bulwer to have been held for political purposes was in reality for no other purpose than that of being photographed. The Bishop of Natal, alluding to this meeting, asserted that a photographer from Maritzburg had arranged to take the likenesses of the principal members of the deputation at Bishopstowe on the Wednesday, but the weather being very inclement, the Princes sent a messenger to excuse themselves from coming. So much for the first "meeting." Sir H. Bulwer, however, stated that on the Thursday there was a second meeting of Zulus at Bishopstowe, but the Bishop explained that this report—to which the attention of the Secretary of State was gravely called—was simply based on the fact that the Princes, having disappointed the photographer on the Wednesday, returned on the following day to keep their engagement with him.

To Correspondents.

*** We cannot undertake to return rejected communications.

H. E. P.—1. The black powder is metallic gold, and after it has been deposited the bath has no longer any toning properties. Add the chloride of gold just before you use the solution. 2. As the varnish is too soft, reduce the proportion of castor oil and Venice turpentine.

Bertani Oreste.—Use the usual India-rubber solution or paste; we have bought it in tins at Hancock's Rubber Works in the Goswell Road.

Perplexed.—This takes place as the iron oxidises, and depends on the fact that a highly oxygenated oxide requires more acid to neutralize it than a lower oxide.

Printer.—The formula is one of those curious burlesques which, after circulating through family magazines and provincial newspapers, are occasionally quoted in technical or semi-technical journals. Although it is impossible to make up the solution according to the directions, as these will bear no definite interpretation; you may succeed in utterly ruining your burnishing rollers.

W. E. Davis.—Write to the Secretary of the City and Guilds Institute, Gresham College, London, E.C., asking for a syllabus of the Photographic Course.

William V. Morris.—Both are first-class, and far ahead of most continental makers.

Richard Nicholson.—You probably allude to Mr. Ashman's article on "Coloured Photographs on Glass." It appeared in our issue of August 11.

E. S. K. (Amsterdam).—Mr. G. F. Williams, who is an authority on glass, gives us the following particulars:—"Stained red is nothing more nor less than what it is called. It is distinct from 'flashed' red (or, as it is called, flashed ruby), inasmuch as it is made by taking ordinary sheet glass made with *kelp*, and covering this with a layer of 'stain' containing silver as a principal ingredient. This is fired, and gives a *rich yellow*, intense according to the richness in silver, and the conditions of the glass, and the temperature of the fire. The glass is then cleaned off, and another coating is put on and fired in again, which has the effect of doubling the intensity of the colour; this being said to soak in. Two thicknesses of yellow will give a deep orange, and so a third firing will deepen into *red*. I send you a small sample of stained red; you will see it is very much brighter than 'ruby,' and the facility with which you can abrade the stained side will show you that the colour is extremely thin. Sometimes the plain glass is flashed with a thin skin of 'kelp' metal, which is very soft, and readily absorbs stain at a low temperature. In such cases the flash can be detected, as it is greener than the body of the glass, due doubtless to iron in the kelp salts. Stained red is very dear, four or six times the price of ruby, and is only made perfectly in England by one firm, Messrs. Chance Bros. and Co., whereas flashed ruby is made from copper. Stained red is made by silver, at the same time there are secret formulæ in existence for making red stain, the components of which are doubtless well known to the firm named. Red stain can be bought ready made from Hancock and Co., Worcester." Let us know your exact address, and we will post you the small sample which Mr. Williams sent us.

A. R.—Dissolve it in dilute nitric acid, and nitrate of silver will be formed; carbonic acid being evolved. If you employ excess of the carbonate, the resulting nitrate will be neutral, or nearly so.

N. I.—The process given in the Everyday Formulary can be carried out on calico, silk, or linen. There is no patent covering the method as we give it.

South Devon.—See Mr. Ashman's paper, as referred to in answer to "Richard Nicholson."

Alexandria.—Only a small salary would be expected at first, with a provision for an increase when facility in the work might be attained.

S. Bowley.—1. It will boil at a much lower temperature when the pressure is lowered. 2. Yes, if the pressure is not considerably reduced. 3. Add a small proportion of Epsom salts to the water—say a salt spoonful to each quart. 4. They consist of nearly pure silica. 5. Give at least three times the exposure.

PHOTOGRAPHS REGISTERED.

Mr. J. W. Walmsley (Liverpool)—Photo. of Rev. J. Reacher. Photo. from Painting entitled "The First Prisoner."

Mr. Palmer (Harrow Road)—Photo. of Steamer in the North Sea.

Mr. F. Downer (Watford)—Two Photos. of two Girls of Watford Free School. Two Photos. of two Boys of ditto.

Mr. W. F. Anckorn (Arbroath, N.B.)—Photo. of Mr. G. Deakin.

Messrs. Adams & Stilliard (Southampton)—Two Photos. each of Prof. Leone Levi; Thos. Hawkesby, Esq., C.E.; Richard A. Proctor, Esq. Six Photos. of Mr. C. W. Siemens. One Photo. each of Capt. Abney and Capt. Bedford Pim.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ¾ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1¾ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ¼-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ¾ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chlor. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1¼ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Silk.—Remove all dressing from the fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.
collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1256.—September 29, 1882.

CONTENTS.

VIGNETTES AND VIGNETTING.

The vignette style, although more generally adopted for head and shoulder portraits, may be employed with advantage in many other instances; as, for example, in the case of small landscapes and seascapes, and occasionally for three-quarter and full-length portraits.

It is not a rare thing to enter a reception-room and to find the general work excellent, good examples of all the usual styles of picture being shown, vignettes alone excepted. This doubtless arises in many cases from the circumstance of vignetted pictures being occasionally required from a negative altogether unsuited for this style of work; and it is seldom that results of the highest merit can be obtained unless the original was specially taken with a view to the production of vignette pictures. We shall not be wrong if we say that the London photographers who can be depended on to produce artistic vignettes might be counted up on the fingers of one hand.

A very general fault is the use of a background which is too dark, the result of this being generally noticeable either as a black halo around the head, or in the loss of all outline by attempts to cut this off close to the figure.

When the subject is a lady clothed in light garments, a uniformly tinted background of a faint cream colour may generally be used with advantage; but even in such a case it is often desirable that the lower part of the background should be a shade darker than the top. When the sitter is dressed in a material of more sombre hue, this condition of things becomes almost essential, as otherwise the requisite gradation of shades around the dress cannot be satisfactorily obtained without occasioning considerable difficulty in shading off the surroundings of the head.

An excellent background for general use, when vignettes are required, is a large square one graduated uniformly from a nearly pure white to a faint tint corresponding approximately to the colour of ordinary brown bread. This, when arranged so that the light tint is on one side of the sitter, and the dark tint on the other, can be so shifted as to give a light or dark tint as required; but in most cases it will be advisable to so tilt it over as to bring the lighter portion either towards the top, or towards the diagonal of the general field. In order to employ such a background to full advantage, it will be necessary to provide a slot or groove in the floor, so that the background can be partially lowered when required; but as this is not always practicable, it will frequently be necessary for the portraitist to provide several smaller graduated backgrounds. Such points as the adjustment of the shades of the background to the special requirements of each sitter can only be learned by careful observation and study, and much can be gathered regarding this matter by a careful observation of the works of good portrait painters, more especially those of the Flemish school.

Before passing from the production of the negative to the operations incident to printing, we may refer to a process of making a vignetted negative which was practised with success by one of the earliest portraitists. A series of white paper screens were provided, each having an oval hole cut in it, and these were so placed between the lens and the sitter as to produce the required gradation. The screens were generally much nearer to the lens than to the sitter, this being essential for obtaining the required gradation of tints, and by overlapping the oval masks any required shape could readily be obtained. Our friend used to urge in favour of this system that he could carry out his ideal of a vignette more thoroughly by this method than by any other, and he was sure of having all his prints uniformly graduated.

In actual practice most are contented with the less perfect, but much easier method, of graduating by a mask placed in front of the printing frame, this mask being generally attached to the outer glass of the frame by strips of gummed paper. When one is pressed for time, an ordinary vignetting glass, such as can be purchased from any stock dealer, may be useful as a basis of operations, the final adaptations to the requirements of the picture being made by pulling out cotton-wool into extremely light flocks, and attaching these by gum where required. Another method is to sandwich a quantity of cotton-wool between two perforated cardboards, and then to pull out the wool with a point until the required graduation and shape are produced. As cotton-wool is very liable to be deranged in discharging and re-charging the frames, many prefer to use paper screens, these being best built up out of a series of thin tissue paper masks, cut as shown in fig. 1.

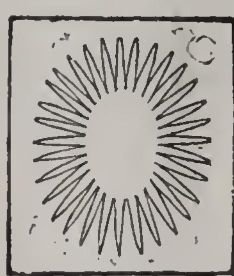

Fig. 1.

These sheets are next piled on each other so as to produce the requisite number of steps and the required shape, the whole now resembling the arrangement shown in figs. 2 and 3. The distance between the vignetting-screen and the glass of the printing-frame often requires some adjustment, this either being effected by distance pieces of cork, or other similar arrangement. It is often an advantage to place the frames on a large square board, suspended scale-pan fashion, from an ordinary roasting-jack. Direct sunlight should be avoided in ordinary cases.

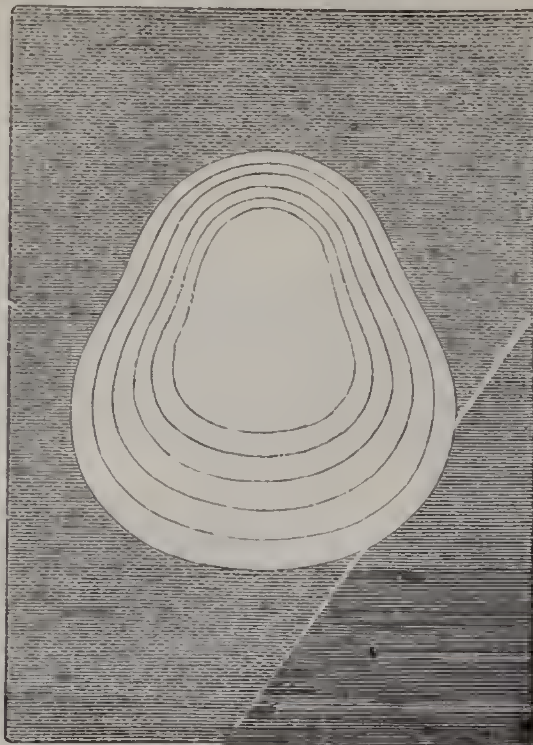

Fig. 2.

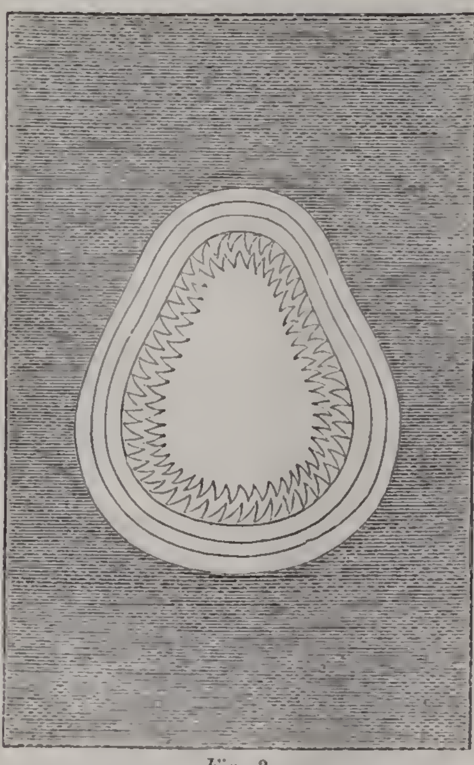

Fig. 3.

More difficulty is experienced in producing good vignettes in carbon than in silver, as the feebler radiations appear to possess less effect on tissue than on the usual sensitive silver paper; and many very successful carbon printers merely use a rough hole cut in a piece of cardboard, this being fixed at a distance of from half-an-inch to two inches from the glass of the printing-frame. In such a case, constant attention must be given to the frame, as frequent changes of position are required.

The carbon printer may, however, work successfully with an ordinary compound mask made of tissue paper, but the graduation must be less rapid as regards the central steps. Let the following diagram (fig. 4) represent a

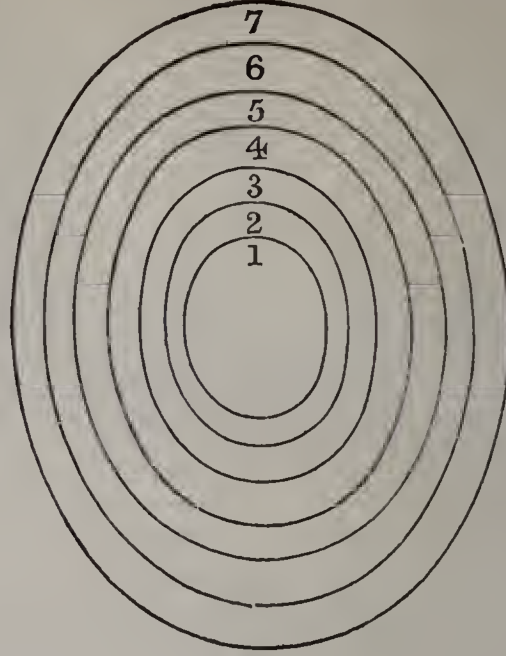

Fig. 4.

vignetting mask, and if it is intended for silver the steps 2, 3, 4, 5, 6, and 7 may all be equal; but for carbon printing the steps 2, 3, and 4 should be much more transparent, this being compensated for by the more rapidly advancing opacity of 5, 6, and 7.

The old-fashioned method of striking an oval by using two pins and a piece of string, as represented by fig. 5, holds its ground. The pencil is moved round at the

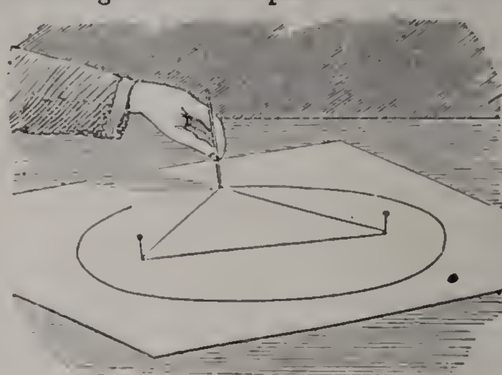

Fig. 5.

extreme limit which the length of the string permits.

THE CONDITIONS OF CHEMICAL ACTION IN PHOTOGRAPHY.

BY J. VINCENT ELSDEN, B.SC., F.C.S.

The photographer who has the advantage of even a little chemical knowledge cannot but feel the superiority of an ability to understand chemical reactions over a blind rule-of-thumb method of working. Not only is he in a better position to investigate the causes of his failures, but he can also, in many cases, so improve his results that the highest pitch of excellence is within his easy reach.

But in photographic chemistry, as in other branches of science, a little knowledge is sometimes, if not a dangerous thing, at least misleading; for those chemical reactions which are the most delicate are also usually the most dependent upon circumstances, and varying conditions will often produce the most unexpected results. This is especially the case with those reactions which enter most prominently into the chemistry of photography. The extreme care and the minute attention to detail which are necessary for success, alike point to the deranging influence of external circumstances, and to the multiplicity of the causes which combine to defeat the best efforts of the photographer.

In examining the chief of those causes which modify chemical action and their influence in photography, it will perhaps be best to refer them to the following heads—viz., *cohesion*, *pressure*, *mass*, *motion*, *catalysis*, and *temperature*. Cohesion, it is well known, is of immense importance in many ways. The state of minute subdivision into which silver bromide must be reduced in an emulsion is a most important element in the successful working of the gelatino-bromide process. The coarse, granular condition of the silver salt, which makes some gelatine plates so gritty to the touch, is always antagonistic both to delicacy of detail and to extreme sensitiveness, and doubtless some kinds of spots may be traced to the aggregation of minute particles of bromide into compact insensitive masses.

But if different degrees of cohesion have an important influence on chemical reactions, even so apparently slight a cause as *pressure* is not without a considerable effect in changing the photographic condition of many substances. Thus, if any metallic substance be placed upon a piece of clean mirror glass, and heat be gently applied, on cooling and removing the substance it will be found that by breathing upon the glass an image is developed. An analogous result has been shown to be produced in gelatine films by pressure, and doubtless many of the streaks and other unaccountable markings which sometimes appear during development may be due to an alteration in the molecular condition of the gelatine by accidental pressure, such as might easily be applied while changing plates in darkness.

But far more striking variations are produced in photography by the influence of *mass*. From earliest times it has been known that very different results are often obtained according to the amount of material present. The quality of collodion made in small quantities is known to be far inferior to that made on a larger scale, and it is not improbable that a similar fact may apply to the manufacture of gelatine emulsions. It would be interesting to know by actual experiment what difference there is in the sensibility and excellence of gelatine emulsions made in both small and large quantities. There can be but little doubt but that the coarseness of the precipitate of silver salt is to a very large extent influenced by the degree of concentration of the solutions of the soluble haloids employed. Many emulsion formulæ seem to aim at dissolving both silver and haloid salts in a minimum quantity of water, and also in cooking an extremely concentrated emulsion with an exceedingly small quantity of gelatine. A very simple experiment will illustrate the influence of strength of solutions upon the characters of precipitates. If silver nitrate be mixed with an equal or larger quantity of soluble chloride, it will remain for a long time milky; but if excess of the nitrate is used, on shaking, the whole of the silver chloride collects into dense flocks, and leaves the liquid clear. If, then, the condition of the silver, when first precipitated in an emulsion, is as important as seems to be indicated by the numerous devices which have been invented for its introduction, of no less importance must be the degree of concentration of the solutions which are employed. This influence of mass, however, is perceived not only in emulsion making, but also in the equally important process of development. Perhaps in no case is so little care taken in photography as in adjusting the quantities in pyrogallic development. Even where the relative proportions of ammonia and bromide are carefully taken, the quantity of pyrogallic used, the amount of water added, the quantity of developer employed, are so often regulated by mere guess work, that we are convinced that the effects of mass and of rapidity of development upon the character of a negative are not by any means universally appreciated.

The influence of *motion* is seen in many chemical and physical reactions. Water may be cooled down far below freezing point so long as it remains perfectly still, but solidifies immediately when agitated. Many well-defined chemical reactions refuse entirely to manifest themselves without violent agitation or constant stirring. A good example is seen in the formation of the bi-tartrate of potash, or of the double chloride of potassium and platinum. Similarly in photography, agitation is often beneficial during certain processes, such as the introduction of the silver into an emulsion.

A very great deal might be said upon those numerous and scarcely-understood phenomena, which are included under the term *catalysis*. Catalysis may be defined as a determination of chemical action by the mere presence of another substance which does not of itself undergo any perceptible change. Thus chlorine, when in the presence of ignited charcoal, can decompose silica; but neither alone can effect this decomposition. Gaseous ammonia is only partially decomposed when passed through a hot porcelain tube; still less when a platinum tube is used, and not at all in a glass tube; but the presence of finely-divided copper or iron in the porcelain tube renders its decomposition easy at a low temperature. Similarly, every photographer remembers the attempt, not long ago, to ascribe certain defects in gelatine emulsions to the use of glazed porcelain vessels in which the cooking was done. Few also have not had experience of the influence of dust particles, which not only prevent development immediately beneath them, but exert a sort of repellent action on the developer for some distance around them. These and many other obscure chemical and physical actions, which may be classed under the head of catalysis, render it a matter of no small astonishment that photography should have reached such a high state of perfection in the face of the multitudinous circumstances, known and unknown, controllable and uncontrollable, which at every step beset the photographer, and combine to produce the most perplexing and unlooked-for results.

So much may be said upon the influence of *temperature* on chemical affinity, that its treatment must of necessity form the subject of a future article.

THE TRIESTE ART EXHIBITION.

A correspondent who has recently visited the Exhibition writes:—

The exhibition at Trieste is well worth visiting, more perhaps by reason of its beautiful site on the shore of the blue Mediterranean, than the intrinsic value of the collection. Most of the Austrian photographers have preferred *not* to exhibit; they are probably tired of exhibitions.

The exhibition, nevertheless, contains much to interest the photographer, and one point observable is, that the gelatino-bromide process is making its way, if rather slowly, into the Austrian provinces. The most important exhibitors in portraiture are Messrs. Benque et Cie, of Trieste, who have a branch house in Paris. Benque produces most of his work on Monckhoven plates, and he employs the oxalate developer. Some very beautiful enlargements of Benque are also to be seen.

The Pesth photographers make a brave show. Koller—whose atelier you described in "The Studios of Europe"—as also Kloesz, have a fine collection of portraits, Koller, moreover, attracting considerable attention by his pictures of Hungarian life. Ellinger, of Pesth, sends a collection of oil paintings and crayon sketches upon canvas, the groundwork of which is photography.

One of the most attractive exhibits is that of Konkoly. Konkoly is a Hungarian nobleman, who spends much of his time and money in astronomical research. In a word, he is a man of fortune, like your Dr. Huggins in England, who spares nothing to advance the science of astronomy. He has built his own observatory, furnished it with the best of apparatus, and is now occupied in applying photography to recording the wonders of the heavens. His beautiful star pictures, as also his photograph of the eclipse taken at O'Gyalla, shows that he is a most successful photo-astronomer.

Just, of Vienna, exhibits a collection of albumenized pictures, and also a beautiful assortment of platinotype prints, which he has produced by the method of Captain Pizzighelli and Herr Hübl. Knoll, of Bozen, is distinguished for his interesting studies of heads; Burato, of Zara, shows some infant photographs, as does also Ortolani, of Trieste.

At first the exhibition was not very largely patronised. For one reason, there was a good deal of bad feeling shown by the Italians, and at the opening, it may be remembered, some miscreant threw bombs among the crowd, and several people were killed. The exhibition, I should mention, was to celebrate the 500th anniversary of the union of Trieste with Austria, and hence some Italian partisans have felt aggrieved. Since, however, the Emperor of Austria visited the exhibition on the 16th of this month, it has become popular, and visitors have been abundant. Indeed, any one travelling to Trieste, or to neighbouring Venice, will find it well worth his while paying a visit to the art exhibition.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

Instantaneous Photographs of London—Spiritualistic Photographs — Awarding Medals — Pictorial Notoriety.

Instantaneous Photographs of London.—Looking over a number of photographs of London the other day, we could not help thinking that the great city has not been done justice to. The majority of the pictures are cold and colourless in the extreme. They have been secured in the early morning when there is no traffic, and, apart from the flatness which somehow generally marks photographs taken in a light of feeble actinic power, the deserted and desolate aspects of the streets give them a most woebegone appearance. There are, it is true, a few specimens of instantaneous work, but it is by no means of the highest kind. Nothing that has been done in the present day at all approaches the instantaneous views of Mr. Valentine Blanchard taken some twenty years ago. Wet collodion was of course employed, yet for graphic representations of street life in London as it really is, these views could not easily be surpassed. It is a mistake to suppose that any time of the day will do for photographing streets and street architecture. The shadows falling on one side or the other will make all the difference between an artistic and an inartistic effect. We believe it will be found that each street looks its best at one particular time of the day, and it is the business of the photographer who wishes for the best result to find out this particular time. The ground, in fact, wants carefully going over two or three times before the picture is taken; and, if this is done, it will be found that the trouble has been well bestowed. With gelatine plates the enormous labour of twenty years ago has disappeared, and the time has come when a series of really good instantaneous pictures should be produced. At present nothing of the kind exists. The public appreciate something which is really artistic; witness, for instance, the enormous sale of a series of charming little etchings, illustrating the Thames below and above bridge. Most of the photographs of London are neither artistic nor truthful; that is, they do not show the streets or the buildings as we are accustomed to see them.

Spiritualistic Photographs.—The exposure of an unhappy medium at Peterborough recalls to one's memory the excitment which the "spiritualistic" photographs caused some years ago. We can remember two photographers whose names we need not mention, but who are well known, interesting themselves greatly in the subject. One, if we did not misjudge him, was always hovering between the extremes of scepticism and belief; the other was a most ardent supporter of the spiritualistic theory, though he was rather shy in talking about it. What have become of all these "spiritualistic" photographs, and do those who were so enthusiastic over their production believe still that it is possible to take the portrait of immaterial beings? With the ultra-sensitive gelatine plates something more definite than the shadowy outlines of former years, which might have been intended for persons in white robes, but which generally looked like "fog," ought to result. But spiritualism is now at a very low ebb, and perhaps the spirits, disgusted at the little interest taken in their table rappings and concertina fantasias, have also deserted photographic studios.

Awarding Medals.—A professional photographer, we take it, has a perfect right to make use of any medal he may gain as a means of advertising his superior skill, though it may be doubted whether this is exactly the object intended by those who confer the award. Some years ago an odd incident happened to a gentleman who was the chief actor in the scene, and who happened to be one of the judges in the selection of the competitors for certain prize medals, which must certainly have led him to this train of thought. Immediately after the awards being decided, the gentleman in question started on a tour abroad. It so chanced that he went to a town in which a photographer resided who had competed in the exhibition where the visitor had been a judge. The photographer had gained a medal, but was not aware of his good fortune until the tourist called upon him and acquainted him with the fact. The recipient of the prize was, of course, overjoyed, and anxiously pressed the visitor to come again the following day, when he would have a number of specimens ready for his inspection, and delicately hinting that he should like to present him with a *souvenir*. Our friend accordingly paid the studio a second visit, and, sure enough, there was a grand display of photographs, and exceedingly good photographs too. Wandering about was an unconcerned-looking young man who occasionally made a note in a memorandum-book, but the visitor took him to be an assistant, and, engrossed in examining the specimens, forgot his very existence. The photographer, who was all smiles and graces, made himself agreeable to his guest, who, nothing suspecting, talked freely about the merits of the photographer's work, what the other judges had said about it, and so on. The interview over, the photographer bowed the visitor out, but had apparently forgotten all about the *souvenir*, for he never referred to it, and away went our friend, if not disappointed, at least surprised. But his surprise changed to astonishment when the next morning he opened the local paper, and discovered the entire conversation he had had with the photographer reported verbatim, together with some glowing remarks of the editor on the honours which had been showered on "our fellow townsman," who had not only carried off a medal in London, but had also received a visit from one of the judges, who had come over on purpose to congratulate him. The unconcerned looking young man was of course the reporter, whom the artist photographer had taken the precaution to invite, and for this purpose had asked his visitor to come a second time. The gentleman who was thus entrapped has not the implicit faith in medals he once had. We hope, however, that this story, which is perfectly true, will not deter the Council of the Photographic Society from offering these awards, as very few photographers are to be found who would make *this* use of them.

Pictorial Notoriety.—The *Globe* has been discoursing learnedly on "Pictorial Notoriety," and has expressed inability to understand why it is persons are so anxious to have their photographs exposed in shop windows for sale, remarking that "there are really so few who can show portraits to be proud of, that few, it might be supposed, would care to go to the trouble and expense of having them distributed about for scrutiny and criticism." It further observes that very often it is a monetary inducement that leads to this publicity, but that "it is impossible to suppose this is always the case, and there can, it is to be feared, be little doubt that hosts of photographs issued every week, and numberless printed portraits in cheap serials, are merely the manifestations of a silly vanity and a paltry desire for cheap notoriety." It is odd how the *Globe* has in these remarks entirely missed the point. The reason of the exhibition and sale of portraits is a very simple matter. It is entirely based on the law of supply and demand. The public are anxious to see persons of whom they have heard much, and in whom they are interested, and are willing to pay for their portraits. The photographer and the photographic dealer do their best to supply the demand. In very many cases the person whose portrait is exhibited is indifferent on the subject, and consents simply to get rid of a pertinacious petitioner. All the vanity in the world will not get publicity for an uninteresting nobody. As for the pictures of the young ladies whose names are so ostentatiously displayed together with their features, we may presume that they have their admirers, although they may be unknown to the general public. At all events, the majority have the excuse of a pretty face, which is certainly a reasonable justification for publicity.

At Home.

M. GERUZET IN THE RUE DE L'ECUYER, BRUSSELS.*

M. Géruzet enjoys a distinction of which he may well be proud. Of all portraitists on the Continent of Europe, he is the only one who prints his work in carbon, and in carbon alone. "I made a vow, two years ago, to produce only permanent portraits," says M. Géruzet to us, "and I have since kept to it. If a better process than the carbon is brought forward, I shall be quite ready to adopt it, for printing in pigments is not unattended with difficulty; meanwhile I take the best process I can that will give me durable work."

All the prints, then, we see around us—from tiny carte to life-size pictures—are printed in permanent pigments. "What of their quality?" it will be asked. Our reply is that M. Géruzet, five years ago, was in the first rank of portraitists in the Belgian capital, and in that position he is still as firm as ever. It may be that in small work the impressions are less bright and pretty, occasionally, than might be produced from highly-albumenized paper of roseate hue, as M. Géruzet himself readily admits; but, among the many prints we critically examined at the studio, there were none that were anything but satisfactory, while, in many cases, it would have puzzled an expert to say whether silver or pigment constituted the impression.

We shall say but little of M. Géruzet's studio, into which we were first invited, for the simple reason that we desire to do justice to the carbon operations in progress at the establishment. Suffice it to say that M. Géruzet employs now only the gelatino-bromide process. He purchases the dried pellicle always, and dissolves it for use as required; and he uses none other than oxalate development. For carbon printing he thinks, indeed, that oxalate development is imperative; but a daily experience of eighteen months has proved to him its superiority over the pyrogallic developer in many ways. In this respect, by-the-bye, M. Géruzet does not differ from his brethren in Brussels and in Paris, for, at the chief ateliers in the French capital—Benque, Van Bosch, Lejeune, Walery, Nadar—the oxalate developer is also in favour. It is so difficult to judge the printing density of a pyrogallic negative, and, since the whole success of a carbon print depends upon this, it is naturally a matter of the first importance. "Non, non," says M. Géruzet, emphatically, "pas de pyro."

The sensitizing of the tissue is conducted in the cool domain of the cellar. The solution of bichromate varies from 3 to 5 per cent. in strength, the tissue, as it comes from the bath, being gently squeegeed on a glass plate to remove the superfluous liquid. It is contact with the bichromate solution that is one of the most vexatious drawbacks of the carbon process, for one cannot but admit it is injurious to health. To take care that the skin is touched by the solution as seldom as possible is one of the standing precautions; but it is not so easy for a principal to get his assistants to carry out even regulations provided for their benefit. The temperature at Brussels in the summer, and also in spring, is often so warm that the sensitizing of the tissue cannot be carried on uninterruptedly in an ordinary room, for gelatine runs when the thermometer points to 90° F. or thereabouts. At the same time, after thoroughly draining and squeegeeing, the tissue is found to set so quickly, that within ten minutes or a quarter-of-an-hour of its being sensitized it can be carried into one of the upper rooms to dry. Heat is now a matter of little consequence, so long as there is a good current of air; and M. Géruzet allows the drying to go on as quickly as possible. Keeping the tissue for twenty-four hours after sensitizing, instead of being hurtful, is, in some conditions of the tissue, a positive advantage. But this question is a matter in which experience is the only guide.

We now proceed to the printing-shed on the roof, and here a singular sight presents itself. There are probably five hundred small negatives printing, and yet not a single printing-frame. The printing is conducted in the open, but in the shade. "Many talk of the comparative rapidity of carbon printing," says M. Géruzet; "but, practically speaking, owing to the care necessary in the operation, the work does not go on more quickly than the production of good silver prints."

We have said that no printing-frames are used. Each carte or cabinet is simply made fast to an under glass by means of two or three American clips. A piece of pigment tissue is put under the negative; this is backed up by half-a-dozen pieces of red blotting-paper to act as a pad, and the whole clamped between the two glasses. It is the simplest arrangement conceivable. Since it is never necessary to look at an impression in course of printing, the whole *raison d'etre* of a complicated pressure-frame disappears, the negatives can be closely packed in rows on the printing-board, and, when printed, the process of changing the tissue of a hundred negatives or so is but the work of a few minutes.

Every negative has gummed round it a paper margin or mask, so that an unexposed border of tissue is round every print. The negatives are examined by the printer before the printing commences, and he estimates their density; they are then put in closely-serried rows upon the printing-board, according to the density they present. Thus one row will remain exposed to light until the photometer—Marion's photometer is employed—records five degrees, another row until six is recorded, and so on. M. Géruzet, by means of the oxalate developer, can now control the density of his negatives so well that they all range between five and eight degrees.

We will now follow a batch of exposed pieces of tissue to the developing room. This is a sombre apartment with plenty of water, warm and cold, laid on. The development of the prints takes place on sheets of opal glass measuring about 12 by 10 inches. The surface of the opal is polished, and this first receives a preliminary coating of white wax, which is simply rubbed on and off again; afterwards thin normal collodion is poured on, and the plate put into cold water until the greasiness of the surface has disappeared. Here in a shallow bath of cold water are

* From Pritchard's "Studios of Europe."

half-a-dozen such prepared plates ready at hand for development.

Six or eight small pieces of the printed tissue are now thrown into cold water,* and, when thoroughly soaked, say in two minutes, they are pressed, of course face downwards, upon a wet opal plate. A little while elapses, to permit the tissue to become firmly adherent to the glass, and then immersion in warm water follows. The temperature of this water, as most of our readers know, must depend to some extent on the tissue, whether it is fresh or stale, but 90° to 95° F. is the usual warmth. All the pieces of tissue are supposed to have received the same amount of printing, and should, therefore, develop simultaneously, but this does not happen in practice. It becomes necessary to hasten the washing of the more tardy images, and this is done by using ammonia. A coffee-pot-looking utensil stands close at hand containing warm water to which a little ammonia has been added. and this mixture is carefully poured over the surface of those prints from which the superfluous pigment refuses to wash away. In this way the development is at once accelerated, and the manipulation of half-a-dozen impressions can be proceeded with at the same time.

The white opal surface, of course, permits one to judge of the success of the print on development, and we need scarcely say that this part of the process is the most difficult and crucial of all. Besides skill and experience, the carbon printer must have an inexhaustible amount of patience. "If you will only wait, you will get what you want," is a proverb that the carbon worker must have closely at heart, for it may happen that he has to develop half-a-dozen impressions before securing that pitch of perfection he desires. Fifty per cent. of failures M. Géruzet would probably take as a low estimate; in any case, however frequent failure may arise, he pushes on until success at last attends his efforts.

The application of gelatined paper to the developed prints when dry, and stripping the latter from the glass surface, are matters of less moment. M. Géruzet employs fresh paste for mounting; but with carbon prints, obviously, this operation plays a far less important rôle than when silver impressions are under consideration.

We have only referred to the printing of small work, for it is in this that so many photographers have failed. M. Géruzet succeeds where others do not, for the simple reason that he has a larger stock of patience, and has the courage to condemn all but first-class work. As we have said, among the vast collection of prints we saw, there was not one picture that was unsatisfactory; but this was due to the fact that he destroys all mediocre pictures. In saying this, we do not desire to underrate M. Géruzet's experience, skill, and keen judgment on points connected with carbon printing, but we are sure that these would never have led him to success unless he had possessed much courage and patience into the bargain.

The "By-the-Bye" next week will be "About Rapid Exposures"; the following "At Home" will be "Mr. Frederick York at Bridgwater."

THE CHEMISTRY OF PHOTOGRAPHY.

BY DR. GARRISON, OF CHICAGO.†

I probably have the honour of being the only amateur present, and am probably the only person present who has practised photography for three or four years without ever making a cent by it. On the contrary, I have invested several hundred dollars in this unprofitable work. Nevertheless, it has given me a great deal of pleasure, and that is all the use I have for money—to buy pleasure; and I think that I have procured as much of it in this way as in any other direction in which I could have turned my energies. I feel somewhat acquainted with you here from these signs just before me. I happened to be born in this old State of Indiana, was educated in the State of Ohio, began to practise medicine in the State of Iowa, and finally drifted to Illinois, where I now hold forth. These signs stand before me in the order in which I have progressed, going on, like the good old Methodist, from one degree of grace to another. I have now nearly got to the state of perfection, I believe.

Now, I hardly know what it is expected that I shall say. Your President intimated to me last evening that the subject of chemistry is one not generally understood by the craft, and that it is a subject of which they wish to know more. Now, I consider that a very difficult subject, although a very profitable one. I may, perhaps, if I attempt to elucidate anything of this kind, fall into the common course, and partially fail, as do most scientific gentlemen, because of abstruseness and abstraction. They pitch their notes entirely above the capacity of their audiences, and then wonder that their utterances are so little appreciated.

You know, as to sound, according to the laws and theories of acoustics, it is believed that there are many sounds that we cannot hear. It is believed that insects make many sounds audible to each other, but inaudible to us. I know scientific men often have good ideas, but when they attempt to put them before an audience they present them invested in a technical nomenclature above the comprehension of their audience. Now, I make this explanation preparatory to saying some things in very common language.

Perhaps, if I ask a question or two, the matter will come up to you in a more interesting form. Many of you wish to make oxalate of potash for your ferrous oxalate developer, and you at once ask the question, how much oxalic acid should I use to a given quantity of carbonate of potash? Or, if you have a certain quantity of oxalic acid, how much carbonate of potash shall be used? Now, how many of you can figure that out? Suppose that you have two ounces of oxalic acid, how much carbonate of potash shall you purchase or weigh out to neutralize that? The common way would be to add little by little until you have got enough; but you are almost sure to get in too much, and then, if you have no reserve of oxalic acid, you are in a fix. You have made your solution alkaline, and cannot correct it. There is a way to determine these questions chemically. Let me put an example before you. You are going to make dry plates by the new process, and you have a certain quantity of nitrate of silver. Take a case that occurred in my own practice. I was going to make some dry plates the other day, and weighed out my entire stock of silver, and found the amount to be one that would astonish you by its smallness—only 464 grains; that is all I could scrape up. Now, how much bromide of ammonium would that require? This was not a quantity—464 grains—that could be found in any formula, but I was able by a very simple calculation, which I think I can explain so that you can make it, to determine how much bromide of ammonium to use, or, if bromide of potassium was preferred, how much of that salt would be necessary.

In order to get this matter before you properly, I must call your attention to the old and hackneyed question of atoms for just a minute or two. We know that all matter of every kind is composed of atoms. These are extremely small bodies, as you have probably heard before. How small they are no one can tell you, but they are, as all agree, extremely small. Now, they have another quality which I want you to bear well in mind. Whether these atoms are of the same diameter or not, no one can tell you! but it is absolutely certain that they are not of the same weight. They are not of the same weight any more than the different individuals before me are of the same weight. You all have your special weights, each one of you. That weight is somewhat characteristic of you. It may increase a little, as it has in my case, in the course of time, from a good conscience and plenty of food, and a little beer occasionally. Your weight may also increase or diminish; not so with the atoms, however. They always retain the same weight. Each atom has its special weight. Now, we cannot weigh one of them, because we cannot even see them, but we can take masses of them and let them act upon other masses, and considering them in that way find, after many trials, how they compare with each other.

Now, for instance, we find the hydrogen atom has the least weight of any. We do not know how heavy it is. It is the lightest of all, at all events, and we therefore take that as a

* With very fine work, it is well to coat the printed tissue also with collodion, prior to its immersion in cold water for development.

† Read before the Annual Convention of the Photographers' Association of America.

starting point, and compare all the rest with it, and we call it 1. Now, you say, one what? Well, one anything you please.

If you have enough of them you have one grain; if you have enough hydrogen atoms you will have one pound—or, of course, you can have a ton of them. No matter what the actual weight is, you may consider the hydrogen atom alone, and you can say the weight is 1. Now, you compare the other atoms with it, and you will find that they have different weights. The atom of potassium, for instance, is 39 times as heavy. The atom of sodium is 23 times as heavy; iodine, 127 times as heavy; silver, 108 times as heavy; bismuth, 210 times as heavy—210 times as heavy as that little atom of hydrogen! You will find this table of atomic weights in the rear part of most of the works on photography—at least, you will find it in all of the works on chemistry. It is a part, though, like the preface, that a great many never read. You don't need to read it, but you have it there for reference. That is the way with most knowledge; it is available and valuable when we know where to lay our hands on it when we want it, and know how to use it when we find it. Now, looking at this table, what does it all mean? Suppose that I unite together one atom of hydrogen and one atom, we will say, of chlorine. I may state that the atom of chlorine is $35\frac{1}{2}$. Upon uniting these atoms together they make what we call a molecule, which is simply a compound of two or more atoms. I think you can all remember that, so when I use the word molecule you will know just what I mean. I mean the combination of two or more atoms—not a mixture, but a compound of two or more atoms in which the atoms have united chemically. Now, suppose that we unite hydrogen with chlorine, what will be the weight of the molecule? The hydrogen atom is 1, and the chlorine is $35\frac{1}{2}$. I expect that you are all mathematicians enough to solve this problem. We add these together, and the result is $36\frac{1}{2}$. That is the molecular weight of hydrochloric acid. Let us take another example. We will say that we wish to find the molecular weight of bromide of silver. Let us represent it by symbols—we have those outlandish symbols that were invented originally to keep folks from understanding the science. Now that we have got them we have to make the best of them that we can. We have Ag representing silver. The old Latin name was argentum. Then we have Br for bromine. Now, what are the weights severally of these atoms? The weight of the bromine atom is 80; the weight of the atom of silver is 108. Now, it does not require much of a mathematician to add them together. We see the result to be 188, and that is the molecular weight of bromide of silver. I think that you could calculate the molecular weight of anything in that way. But let us take a more difficult example. Let us take the nitrate of silver, of which the following is the formula expressed in symbols:

Ag (silver)	108
N (nitrogen)	14
O_3 (oxygen, 3 atoms)	48
	170

We will add these up. It is just as simple as before: 108 for the silver; then the nitrogen, and as the nitrogen atom is fourteen times as heavy as the hydrogen atom, you put down its weight, 14; and lastly, the oxygen atom is sixteen times as heavy as the hydrogen—in other words, 17 is its actomic weight, and, as we have three of it, we must multiply the 16 by 3, of which the result is 48; then, adding these together, we get 170 as the molecular weight of the nitrate of silver.

Now, again, let us find the molecular weight of bromide of ammonium. These are the two substances we are going to use, and we want to know how they will balance, so that each molecule will be decomposed, and there will be no excess on either side. Let us, therefore, examine the bromine of ammonium critically. You will see, by referring to your works on chemistry, that this is the formula for bromide of ammonium: NH_4Br. Let us consider the weight of this molecule: Nitrogen 14, hydrogen 4 (because there are four atoms present), and bromine 80, the total being 98, which is the molecular weight. Now, that means just this, that 98 grains of bromide of ammonium are exactly equivalent to 170 grains of nitrate of silver; and, if you put those two compounds together in this proportion, they will exactly decompose each other—double decomposition will take place, so that there will not be a single atom left on either side.

What occurs when we have put the bromide of ammonium and the nitrate of silver together? You know what occurs in the dance. You change partners. That is all that happens here. There is a change of partners, the ammonium evinces an affinity for the acid radical with the silver, and the bromine and silver unite—a "cross over," as they used to call it. Now, that is a case of decomposition, and it is about as difficult as any example that you may expect to encounter. You will see that there is just enough of each element. Now, the question is, after this is accomplished, what have we formed? Well, in the first place, the silver and the bromine have united together. How much bromide of silver has been formed? That is a question you usually do not wish to determine in the practice of making dry plates. But suppose that you do care. Just think a moment! We have 108 of silver and 80 of bromine, which, added together, give 188, which is the amount of bromide of silver formed. Now, then, what else has been formed? Well, nitrate of ammonia. You see that we could plainly tell how much has been formed if we wished to stop and do it; and now I think that any of you could tell that just as well as I can.

We found that 170 is the molecular weight of nitrate of silver. That is the weight of all the different atoms, and we found that the molecular weight of the bromide of ammonium is 98; very well, now these are the quantities that act upon each other without any excess being left upon either side. Now this serves as a ratio or a proportion by which we can determine in what quantities to add these agents to each other in order to effect complete double decomposition. 170 of silver are to 98 bromide of ammonium as any given quantity of silver is to the quantity of bromide of ammonium to be used. Well, let us try an example. We will take the example here: 170 (of silver) is to 98 (that is the bromide of ammonium) as the amount of silver which I have, 464 grains, is to the quantity of bromide of ammonium which I must use. I have made the calculation and find that 267 grains are necessary. I know, then, just the amount to add to make these gelatine plates, but, as you know, if you have tried it, you must use some excess of the bromide of ammonium. I used a very small excess, much less than the books said was necessary, and yet obtained good plates. Now we will leave that and come back to the oxalate of potash.

In the first place, we have the oxalic acid. Let us see if we can write the formula for that. It is a rather hard formula. I may get something wrong. You had better watch me. Here it is: $H_2C_2O_42H_2O$. Now let us find the molecular weight. Two of hydrogen is 2, 2 of carbon (1 of carbon is 12, 2 would be 24), 4 of oxygen (4 times 16 are 64), and now we add to this water, and we must always take that into account, because it weighs—it has a definite weight on our balance. We buy it when we buy the oxalic acid. You cannot get rid of it, and when you buy a good many salts you buy more water than anything else—a good deal more sometimes. Carbonate of sodium has 10, alum 24 equivalents of water of crystallization. They weigh very heavily. Let us try 1 equivalent of water and see what it weighs. One equivalent of water is 2 of hydrogen and 1 of oxygen = 16, that would be 18 altogether. Here we have two of them, this big figure 2 [pointing to 2 in the formula] shows that whatever follows it is taken twice. So we have twice 18, which is 36. Now perhaps I have confused you in this. Perhaps I had better do it in another way, by which we may arrive at the same result. I told you that whatever follows the figure is to be taken as many times as the figure indicates; if 2, it is taken twice; if 3, three times; if 10, ten times. Here are 2 of hydrogen; if you take those 2 twice, that will be 4, and we will set that down 4, then we have it. There is 1 of oxygen, that will be 16 by itself, but you take it twice, which will be 32, so that you see that we get the same result whichever way we calculate. Now we are prepared, having added up this combination, to find out what the whole of it weighs—here we have it, 126. Now, that is the molecular weight of oxalic acid—that is the weight of the formula, if you please. It is just like the firm of Brown, Thompson, and Smith, each one has his own special weight. One weighs, say, 100 pounds, another 150 pounds, and another 200 pounds; you add these weights together and you get the firm's weight, which is analogous to molecular weight, the latter being the joint weight of a firm of atoms of different kinds, the former of men. Very well, having now illustrated that, let us turn to carbonate of potash. To understand carbonate of potash, we will have to write out its formula. K is the heiroglyphic that stands for potash. It used to be called kalium; we have retained the K, but dropped the balance of the name. Two of potash, 1 of carbon, and 3 of oxygen (K_2CO_3). Now, let us add these weights up, and see what the amount will be. Twice 39 for the potash, 12 for the carbon, and three times 16 for the oxygen will be, altogether, 138.

Now, then, the facts brought before you simply lead to this conclusion, that for every 126 parts of oxalic acid you must use 138 parts of carbonate of potash, or the reverse.

You must remember that carbonate of potash is not absolutely pure, and it sometimes happens that oxalic acid is not absolutely pure, so with ordinary articles you do not arrive at such absolute precision as you may arrive at theoretically, but practically you are near enough right. Now, you might inquire, how can these facts be utilized? We do not wish to weigh out 126 grains of oxalic acid and 138 grains of carbonate of potash each time, but we take that as a ratio, and say as 126 of oxalic acid is to 138 of carbonate of potash, so is the amount of oxalic acid which I propose to use to the amount of carbonate of potash which I must use with it. If we have three members of a proportion, we can get the fourth; so we can turn this problem backward and forward, and work everything out that we wish, and in that way.

Notes.

The Sheffield Photographic Society loses its President for a while; Dr. Thomas Morton proceeds to India this week.

The *conversazione*, open to members and their friends, with which the Exhibition of the Photographic Society will be inaugurated, takes place to-morrow week at 8 p.m.; it will be held, as usual, at 5A, Pall Mall East.

The Photographic Exhibition will be open to the public daily, from Monday, the 9th October, until Thursday, the 16th November, and on Mondays, Wednesdays, and Saturdays in the evening.

"It just reminds one of the queer attitudes in which pedestrians appear in ordinary instantaneous pictures," said a friend, on looking at the illustration after Muybridge, which we issued last week.

Mr. E. Leader Williams, C.E., the president of the Manchester Photographic Society, is the author of a scheme to make Manchester into a seaport, by cutting a canal navigable to ocean-going vessels. There is every probability of Mr. Williams' proposal being adopted by Cottonopolis.

Dr. Eder suggests, as a method of measuring the length of exposure in the case of certain shutters, to get an assistant to make circles in the air with lighted magnesium wire. After a little practice he would have little difficulty in describing a circle in the space of a second, and then the portion of circle shown by the image would demonstrate the period of exposure. As burning magnesium is easily extinguished, a glass shade of some sort would be necessary. Another plan we would suggest, as possibly more accurate, would be to fasten the burning magnesium to a long pendulum, and then expose. The rate of the pendulum could be measured by a scale, and the length of the image on the plate would demonstrate the rapidity of the shutter.

Everybody has been buying a pocket spectroscope lately to examine the "rain-band," and see if it is going to rain; and some of our observatories have been making arrangements to have the spectrum photographed daily, so that the state of the "rain-band" from day to day may be recorded. Suddenly, we are told to place no reliance upon the "band" as a forecast of weather. Mr. Abercromby and the Duke of Argyll both say that after much watching, the "rain-band" is not to be relied upon, although the latter admits that Professor Piazzi Smyth, who brought the subject forward, "has certainly made a good shot" in his prognostications about the weather.

Here is a brief explanation of what the "rain-band" is If we look through a spectroscope directed to any portion of the sky we see a spectrum-tinted riband, crossed with thin black lines. One of the strongest of these, situate in the orange, is technically known as the D line. When the instrument is directed to a pure blue sky this line is thin and faint, but in certain conditions of cloud or sky the red side of the line has a dark shadow, as if it had been shaded down with a bit of rough black chalk. This shading is the "rain-band" of Professor P. Smyth, who maintains that the relative darkness of this band is a measure of the nearness or quantity of rain.

Mr. York's little room for changing the paper of his printing frames deserves to be described, it is so simple. It is a little erection in a corner of the printing yard, measuring, perhaps, nine feet each way, and lighted in front by a large window having a tammy blind. An assistant sits herein as in a pay-place, and through a large pigeon-hole on the shadow side of the building receives and gives out printing frames. In fact, the little room reminds you of an office where you take tickets; while the paper is kept well screened from the light, it is still very handy for use, for the printers have but to stretch forth their hands to thrust the frames through the pigeon-hole.

There has been an early fall of snow in Switzerland—rather a heavy one, too—and Dr. Tyndall, who happens to be there just now, has deemed it his duty to write about it and about himself to the *Times*. We should like to reprint the whole of his beautiful letter, for the Tyndallian style is never commonplace. Dr. Tyndall does not say the storm abated, but "the flakes dwindled to flocculi;" and instead of vulgarly putting it that they melted a pot full of snow to get water, he tells us that firewood was "expended in rendering its own heat latent in the indispensable fluid." All this is very gratifying, and when Dr. Tyndall, *à propos* of our Egyptian success, winds up with, "Thank God, we are a people yet," we feel constrained to add on our part, that, despite the snowstorm, "Thank God, too, we have our Tyndall yet!"

The *Times* is acquiring quite a reputation for being behindhand with its news. Photographing from a train in motion is a feat it has just heard of, and probably next year we shall be told the operation can be performed on board a steamer as well. Our contemporary also speaks of a shutter moving so rapidly that "only 1-100th of a second" exposure is given by it. Apparently the *Times* is incapable of conceiving anything faster than itself just now.

An interesting experiment in signalling by sunshine has been made by our army in Egypt. Colonel Keyser ascended one of the Pyramids near Cairo, and setting up a heliographic mirror, reflected a ray of sunshine all the way to Alexandria, a distance of some 120 miles. The signals, appearing like pin-points of brightness, were distinctly readable on the coast, and took the form of a message from Sir Garnet Wolseley to the Khedive.

"How do you print a cracked negative?" asks a correspondent. We reply that there are two very good ways: one is to put the printing frame at the bottom of a narrow box some two feet deep, with blackened sides, a sheet of light tissue paper being dropped upon the face of the frame; the other, which is quite as efficient, is to place the printing frame on a board suspended from a roasting-jack, which is kept going during the process of printing. There should be no trace of the crack upon the paper print if the plans are properly carried out.

"Don't you think that there is as much pride in refusing to sit for your portrait as in consenting?" asked Dassier of Montesquieu; and this query we would beg all to bear in mind who hesitate on the subject. The man who loudly vaunts he has never been photographed is really more vain than he who has been depicted in the camera a score of times. We hold that the Queen, who so frequently allows herself to be pourtrayed, is far more modest withal, and far more considerate, than the Empress of Germany, who will not allow such a liberty to be taken. Her Majesty's subjects are gratified in the possession of her portrait, while photographers and shopkeepers derive no small pecuniary benefit from the circumstance. It is difficult, indeed, to assign any other reason than pride, nine times out of ten, to a refusal to sit for one's portrait.

A guinea a dozen—or rather a guinea for ten cartes-de-visite—is the highest price charged in any photographic establishment in London at this moment, or indeed anywhere. But it is not so long since that two guineas was the price, while one firm, we remember—that of Messrs. Williams and Mayland, of Regent Street—were wont to charge £1 11s. 6d. for half-a-dozen cartes. This, however, was in the palmy days when cartes-de-visite were a novelty, and when unmounted copies of the same were usually charged half-a-crown a-piece at West End studios.

The *Graphic* not so long ago organised a gallery of beauties, to which some of our best painters contributed; each picture was supposed to represent the particular painter's idea of beauty, both in respect to model and treatment. It seems to us that in any competition in photographic portraiture, the same principle might well be adopted; that is to say, the palm given for the most charming type of beauty, both in respect to model and treatment. As everyone knows, the most beautiful may be marred by photography, just as by tasteful lighting and posing, a plain face may be rendered pleasing. In a "type of beauty" competition, the photographer would be able to distinguish himself by the choice of his model and by his art in displaying her to the best advantage.

"Impersonal" studies, such as these, would no longer be called portraits, and here we repeat our opinion that the sooner medals for portraiture, as portraiture, are discontinued, the better. Unless the individuals whose portraits are exhibited are known to the jurors, how can these tell if the portrait is good or the reverse? You can judge of the lighting, the posing, and skill in manipulation, but that is all; you cannot say if it is a speaking likeness, or whether the expression is foreign to the individual or not. "By Jove! what a good portrait that is of Brown—you know Brown, of course"—suddenly exclaims one of the jury, coming upon the picture of a man he knows; and the chances are that the photographer of Brown will get the medal, not because the portrait he sends is so much better than all the rest, but because it happens to be a good picture of a model who is known.

Frederick Woehler—certainly the most celebrated of our recent chemists—died on Saturday last at the age of eighty-two. For nearly fifty years he was Professor of Chemistry at the University of Gottingen, and his name is connected with some of the most brilliant discoveries of the century. He it was who first produced the beautiful metal aluminium, and another element—boron—he likewise isolated. But, perhaps, his most important investigation was that in which he was able to connect organic with inorganic chemistry. Before his researches it was supposed that organic substances could only be evolved from the animal and vegetable kingdom; but Woehler showed—as in the production of urea, for instance—that so-called organic matter could be prepared from inorganic substances. The result of this investigation was to Woehler so startling, and so opposed to preconceived notions on the subject, that for a long time he hesitated to make it known, and did not, indeed, do so until three years after he had completed it.

Patent Intelligence.

Grant of Provisional Protection.

4071. William Christopher Haigh, of the city of Manchester, Artist, for an invention of "Improvements in apparatus for printing."—Dated 25th August, 1882.

German Patents Granted.

19,395. J. W. Muchall, of Berlin, for "An instrument for multiplying, enlarging, or reducing drawings."—Dated 24th January, 1882. Class 42.

19,499. C. Frank, of Leipzig, for "An instrument for measuring and recording profiles of bodies."—Dated 7th March, 1882. Class 42.

Specifications issued during the Week.

775. R. T. Wall—"Improvements in photography." Price 4d.
The improvements consist in making a new sensitizing solution from white pepper and its analogues macerated with and in

ether, turpentine, alcohol, naphtha, chloroform, or spirit of tar and such like; or by essential and volatile oils; acetic, carbolic, or other acids; or with diluted mastic, crystal copal, sandrac, photographic spirit, or other varnishes; a ready way being to take one pound weight of freshly-ground white pepper and macerate it in one to two pints of ether or alcohol for some days, then press the tincture through one or more filtering media. Also, in using, a little mastic varnish or oil of turpentine is added to the resultant solution if ether is used, a little spirit varnish is used when alcohol is used, and the resultant solution is spread on the surface to be sensitized and exposed in the usual way; and in the use of powdered pigments, cold or warm, brushed or dusted over the surface for the purpose of developing the image. The improvements also consist in the manufacture of transparent sheets of collodion and collodion emulsions, and elastic media for printing on uneven or other surfaces. For making a clear transparent sheet of collodion, a thick preparation of collodion is made, consisting of acetic acid or formic acid, gun-cotton, and castor oil. Canada balsam may be used also. This composition is poured upon waxed glass edged with strips of paper by means of glue so as to form a dish; being placed in a box, the lid is closed, and then left a day or two to dry. On this layer a film of prepared gelatine emulsion or rapid collodion emulsion is poured, and the negative or transparent picture taken thereon suitably varnished and protected, when the whole may be stripped from the glass together. A thick ordinary collodion and a little of castor oil added may be used instead of the above, but the result will be a light yellow colour. The sensitive gelatine emulsion sold in the market may be used. If my extra rapid collodion emulsion is used, the above collodion sheet must contain gelatine, or gum, or india-rubber coating before the application of the emulsion. The following description will show how this emulsion is prepared. The collodion is thus made:—

Ammonia bromide	27 grains
Distilled water as little as possible.	

When dissolved, add 2 or 3 drops of gelatined hydro-bromic acid.

Alcohol...	$2\frac{1}{2}$ ounces
Pyroxyline	32 grains
Ether	$2\frac{1}{2}$ ounces.

The emulsion with silver is formed by adding 120 grains of silver nitrate which has been dissolved in a little distilled water, and then $\frac{1}{2}$ ounce of alcohol. It is poured out into a dish of sufficient capacity in order for the solvent to evaporate, and in a day and night it is ready for further treatment. This consists in breaking up the mass into pieces with a piece of glass or a bone spoon, and covering it with water for some time, and pouring the whole into a calico bag which has previously been washed in carbonate of soda and then well rinsed and dried; the bag and its contents are put into an enamelled saucepan, or in a stone jar covered with gelatine solution, 20 grain No. 1 gelatine in one ounce of water, when the whole is boiled for thirty minutes, and then taken out and put into clean warm water, twisting and washing several times till all traces of acid are removed, which can be tested by litmus paper. When all water is wrung out, the emulsion is dried on a hot-water bath, or spread out in a warm room on blotting-paper; the result is mixed in $2\frac{1}{2}$ ounces of alcohol and $2\frac{1}{2}$ ounces ether. I also make a collodion emulsion as follows:—Bromide of ammonia, 27 grains; distilled water, as little as possible; and when dissolved add 2 or 3 drops of hydrobromic acid containing gelatine, and then blend; glacial acetic acid, 3 ounces; pyroxline, 32 or 35 grains. The emulsion with silver is formed by adding the silver nitrate solution prepared as before, but instead of evaporating I pour the whole into a large jar filled with clean water, and then pour it into a calico bag, and wring, and put it into gelatine solution and then boil for thirty minutes, dry as before, dissolve in 4 ounces of equal parts of ether and alcohol. I find it convenient to use a box for regulating the evaporation having both sides covered with several pieces of calico, holland, or linen, which must be soaked in alumized gelatine, whipped, and then dried; or fine perforated zinc sheet, fine horsehair, or fine wire gauze may be used. This box will keep down the too rapid evaporation, and prevent honeycombs or other irregular marking. To wax the glass plate I warm the glass and rub it with a piece of wax, and warm it again sufficiently to melt the wax, and immediately rub with a piece of flannel until a thin coating is left. I make also a preparation of an elastic medium for printing on uneven surfaces, of gelatine, sugar, glycerine, chrome alum, spirit, thymole or boricic acid, or any preservative agent. A glass plate is prepared by gluing a strip of paper around the edge of the plate so as to form it into a dish. I pour the mixture into this dish and leave it to set, and then place a negative tissue on it, and then place it on a dried pepper sensitized surface; print by light as usual; and for this purpose I find the following proportions useful:—

Water	4 ounces
Sugar	1 ounce
Gelatine	1 ,,
Glycerine	6 ounces
Thymole	some drops
Alcohol	$\frac{1}{2}$ ounce
Saturated chrome alum	some drops

Hand-drawings may be used for my process by using the collodion sheet, coated with matted varnish, then draw any picture on the matted sheet with soft lead pencil, charcoal, or chalk, and print on by my process as before; coloured prints may be used by it. I claim:—1. The sensitizing solution formed from white pepper and its analogues. The manufacture of elastic media for uneven surface printing. 3. Also the mode of treatment for regulating the evaporation and manufacture of transparent sheets of collodion.

820. T. VICKERS—"Improvements in photographic camera shutters." Price 2d.

My invention relates to means or apparatus whereby the light may be quickly or instantaneously excluded or shut out from cameras in photographic operations; such improvements may be employed in photographing generally, but are particularly applicable for the instantaneous processes. For the above purpose I employ a box or casing so constructed as to readily fit on to the outer end of the lens of the camera. Within the case or box is arranged the means for shutting out the light, and for this purpose I prefer employing two slides or shutters of sufficient size together to cover the opening in the lens. These shutters or slides are retained in front of the opening by elastic bands or springs; but for the purpose of photographing any object, they are pulled away from the front thereof, in opposite directions, by the operator, a cord being attached thereto for the purpose. After the required length of exposure, and when the operator lets go the cord, the shutters instantaneously close over the opening and entirely exclude the light. In some cases, one shutter only may be employed in this arrangement; the opening and closing operations are similar to the above described. The shutters in some cases may be of a flexible nature, and passed on to rollers. The shutters may be worked backwards and forwards by a cord, or by mechanical, electrical, or pneumatic means. (*Provisional protection only.*)

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. VIII.—PREPARATION OF SILVER NITRATE, GOLD AND PLATINUM CHLORIDE.

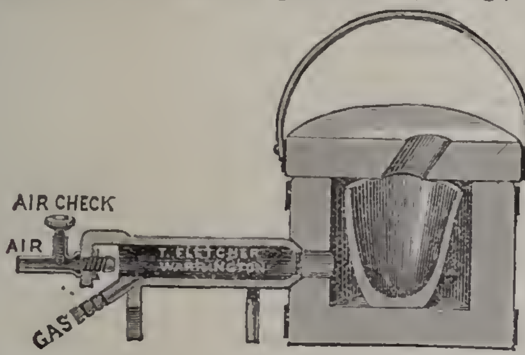
IN preparing silver nitrate, the first operation is to obtain pure silver. Of course different processes are used, according to whether the silver is in the form of an alloy or as a residue; but the precipitation as chloride is the method which is best adapted to the requirements of the photographer.

The impure silver, whether it be silver plate or precipitated from hyposulphite solutions, is placed in a beaker, and for every ounce of the metal pour into the vessel an ounce of strong nitric acid, and warm the mixture till all the metal is dissolved. If old-fashioned plate be treated with nitric acid, very often a slight residue of gold is left undissolved, the reason being that the separation of gold from silver was not so perfect in former days as at the present time.

When the solution of the metal is complete, the liquid is diluted with an equal volume of water, and common salt is added till no further precipitate is produced; rather more than half the weight of the original metal is generally required to ensure the perfect precipitation of the silver chloride. After allowing the mixture to stand for a few minutes till the precipitate has settled, the top liquid containing the impurities should be carefully decanted off, and the beaker refilled with water, the operation of washing by decantation being repeated. Having obtained the silver chloride, the next operation is to reduce it to the metallic state, which may be accomplished in several ways—viz., fusing the chloride with a mixture of potassium and sodium carbonate, reducing the precipitated chloride with metallic zinc suspended in a dilute acid, or by gently fusing the chloride, and placing a piece of pure zinc in the fused mass, and, when cool, pouring dilute acid over it.

These methods are equally successful in bringing about the desired result; but it depends entirely upon the apparatus which the student happens to have at his disposal. Thus, if he possesses a good furnace, we should advise him to work with the first-named process, while if not, he must content himself with using either of the other processes.

When working by the first-named process, a good blast furnace is required, either of the form known as the Sefström, fed with coke, or, where gas is attainable, a Fletcher's injector furnace is preferable (see fig). The



dried silver chloride, mixed with rather more than half its weight of an equal mixture of potassium and sodium carbonate, and about one-fourth its weight of borax, is put into a clay crucible, fitted with a loose lid, and placed in the furnace for about twenty minutes. The crucible should be examined from time to time during the operation, and after the mixture has been in a complete fusion for five or six minutes, the liquid must be poured into a dry tile and allowed to cool down. The button of silver is best separated from the slag by treating it with hot water, thus leaving pure metallic silver ready for conversion into the nitrate.

For reducing by zinc, the silver chloride should be placed in a beaker and covered with a ten per cent. solution of sulphuric acid, about an equal weight of chip zinc being mixed with the silver compound. In a very short time the white chloride of silver nearest to the zinc will be seen to turn to a grey substance consisting of spongy metallic silver; every few minutes the mixture should be stirred, so that a fresh quantity of the chloride may come in closer contact with the zinc, and after two or three hours the whole of the chloride will be reduced. All that is necessary in order to obtain pure silver is to wash the spongy metal by decantation with three or four changes of water. The disadvantage of the process is, that a small amount of the chloride is apt to escape reduction; but if the silver compound be melted first, it forms one compact mass, and consequently does not require stirring. The silver chloride, after being thoroughly dried, is placed in a porcelain crucible, and heat applied till the whole is melted; the lamp is then taken away, and a piece of zinc placed in the acid is poured into the crucible, and left for about half an hour till the grey mass has changed to brown spongy metallic silver. Any zinc remaining after the action is complete should be taken out, the acid liquor poured off, and the spongy silver thoroughly stirred up with water, to wash away the adhering impurities. Having obtained the pure silver, the remaining operation is very simple; the silver is placed in a beaker, and strong nitric acid poured into it, about three-quarters of a fluid ounce of the acid, sp. gr. 1·4, for every ounce of the metal is sufficient; the beaker is heated till the whole of the silver dissolves, the solution is then poured into an evaporating basin, and the excess of acid driven off by boiling, The operations of dissolving the metal and evaporating the acid solution should be conducted in the open air, as the acid fumes are very objectionable if inhaled. In order to recrystallize the salt, dissolve it in the smallest possible quantity of boiling water, and, on cooling, the solution will deposit beautiful crystals of pure silver nitrate. Of course the salt remaining in the mother liquor may be recovered by evaporation, and preserved as a less pure sample.

When preparing gold chloride from coins or jewellery, one meets with the same impurity as in making silver nitrate—viz., copper; thus it is necessary to purify the gold before converting it into a chloride. The gold is put into a beaker, and a mixture of three parts of hydrochloric and one of nitric acid (*aqua regia*) is poured into it, and heat applied till the metal is dissolved; the excess of acid is then expelled by evaporation. The impure gold chloride, when free from acid, is dissolved in *boiling* water, and a cold saturated solution of protosulphate of iron added till a dark precipitate of pure gold is no longer produced—about two ounces of the crystallised sulphate of liquid. When cold, a ten per cent. solution of sulphuric iron being sufficient to reduce one ounce of gold chloride. The precipitate of gold must be poured on a filter and washed by pouring boiling water constantly over it till the wash-water no longer produces a precipitate with a solution of barium chloride, proving that the gold is free from the excess of sulphate of iron. The gold is redissolved in *aqua regia*, and the solution evaporated to dryness, the latter part of the operation being carried on slowly on a sand-bath, to prevent spurting. The yellow crystalline chloride of gold thus prepared should be preserved in a well-stoppered bottle or in a sealed tube, as the salt is very deliquescent.

Perchloride of platinum, or platinic chloride, a substance sometimes used for toning, is prepared in a similar manner to chloride of gold, the same precaution to expelg the last traces of acid at a gentle heat being observed.

Bichloride of platinum, or platinous chloride, may be prepared by gently heating the platinic chloride; but if the temperature rises beyond a certain point, the platinous salt is reduced to the metallic state. The best method of reducing the plantinic chloride is to add a saturated solution of sulphurous acid (as described in the previous chapter) to an aqueous solution of the salt, when a yellow precipitate of platinous chloride is produced; this is washed and dried, and, if required for photographic purposes, must be converted into the double chloride of potassium and platinum, which is soluble in water.

To prepare this salt, mix twenty-seven parts of platinous chloride with eight parts of potassium chloride, dissolve in a small quantity of hot water, and evaporate to dryness; the residue being chloroplatinite of potassium, the substance used in the platinotype process.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,

Assistant Surveyor-General of India.

Chap. II.—Apparatus and General Arrangements.*

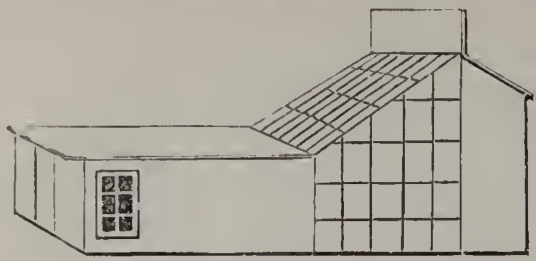
Studio.—In fine weather a good deal of copying work may conveniently be done out of doors, provided that all the apparatus connected with the camera and plan-board is firmly fixed and sheltered so as to be free from vibration, which would destroy the perfect sharpness of the image; but when work is constant and must be carried through regardless of weather, a glazed studio will be necessary.

As regards the best position of the studio for copying, it is difficult to know what to recommend, especially as so much depends on local circumstances of position, aspect, and climate.

Monckhoven recommends for reproductions a studio of what is called the "tunnel" form, having the glass roof to

* Continued from page 566.

the north, and I think there is no doubt that on the whole a steady, bright diffused light from the north coming through clear glass is to be preferred to sunshine filtered, as it must



be, through ground glass, which cuts off an enormous proportion of the light.

In my own case, having a certain amount of open ground towards the south of the office building, and none to the north, I built the glass house for the photographic branch of the Surveyor-General's Office, in Calcutta, on the ground level in something of the same kind of tunnel shape as Monckhoven's, but facing the south. The sloping glass roof and the side sashes under it are glazed with ground glass, so that a strong diffused light is thrown upon the plan-boards. In order to lessen vibration as much as possible, the plan-boards are fixed on a separate wall, quite isolated from the walls of the buildings; and each camera stands by itself on a block of masonry resting on a bed of sand, and is thus isolated from adjoining blocks, and from the walls and floor of the rest of the building. The house is roofed in over the cameras, and the dark-rooms are conveniently placed just behind the cameras, the dark-slides being passed in and out of the dark room through wooden boxes let into the wall.

This arrangement is found to answer very well for copying of maps, though sometimes, when the sun is high, the grain of the paper is apt to show too much, and it is possible that a similar arrangement facing the north might have been better.

For out-door work in places where there is little wind and dust, I have found it a good plan to have the camera and plan-board, both Southampton pattern, mounted on a firm traversing carriage about twenty feet long, running on trucks and working on a vertical pivot, so that as the day wears on, the position of the plan-board may be changed so as always to face the sun. This can also easily be done with the combined table-stand and plan-board described above.

It is of course much easier to make suitable arrangements for copying the small subjects generally required for book illutration than for large maps and plans, which require considerable space and large apparatus.

Lighting.—A strong diffused light coming in a horizontal direction at nearly the same angle and strength upon every point of the picture, so as to give an even light over the whole surface, is generally to be recommended for copying, as the grain and other unevenness of the paper is least shown by such a light. In a vertical or strong side light the rough points of the grain, creases and waves of the paper, throw shadows which interfere with other details, and render it difficult to get a clear ground of the transfers. Indian ink or sepia drawings and plans and engravings, or prints that have been stained and yellow with age, are better copied in sunlight or strong diffused light.

A good deal may be done to remedy defects of lighting, and shorten exposures in dull weather, by means of reflectors suitably placed below or at the sides of the subject. These reflectors may be made of clean white paper or of silvered glass. An ordinary looking-glass placed in the sun outside the studio is often useful to brighten up a piece of dark work.

Arrangement of the Plan and Focussing.—The subject to be copied must lie quite flat and free from ridges on the plan-board or other support. This is best attained when drawings are made specially for copying, and can be left strained on the drawing-board. Another effective way, especially if the original is creased or cockled, is to cover it with a sheet of glass rather larger than the negative, and in which holes have been drilled at the corners, through which drawing pins may be passed to fasten glass and paper to the board; or, better, if the subject is not too large, to put it into an ordinary printing-frame or the especial glazed frame before described, in which the paper will be sufficiently pressed to lie quite flat against the glass.

Engravings and prints, &c., which will not be injured by wetting, may be soaked in water for a few minutes, and laid face downwards, perfectly flat and evenly, on a glass plate, or strained on to it by gumming round the edges. In either of these cases, when using glass over the original, care must be taken to avoid any reflection from light objects directly in front of the plan-board, and which may be reflected back into the lens. The camera will require a black cover, and any light coming in from behind it must be cut off with a dark screen placed at the back, and large enough to cut off all reflections. These reflections can best be detected by looking at the subject with the eye in the position of the lens. The tunnel form of studio is advantageous for this kind of work, because everything at the back of the camera is in comparative darkness.

In the Military Geographical Institute at Vienna, the drawing to be copied is placed in an iron frame, the sides of which can be drawn out by means of screws, and thus the drawing can be stretched quite tight and smooth all over. A somewhat similar arrangement is used in the Military Topographical Institute at Florence.

We have already stated that in order to prevent distortion, the ground glass and the subject to be copied must be perfectly parallel, and it is necessary to have some ready means of ascertaining that they are so when focussing the camera. The squares and rectangles ruled on the plan-board and focussing-screen will generally be sufficient, and will also serve at the same time for adjusting the camera to scale. Thus, supposing it is desired to produce a copy half the scale of the original, the camera and plan-board must be first adjusted, so that the image of the centre of the board may coincide with the centre of the focussing-screen, which in a properly constructed camera will occupy the same position as the centre of the sensitive plate. The position of the camera must then be altered till the image of a square eight inches in the side on the plan-board exactly occupies the square of four inches in the side marked on the focussing-screen. Should any one of the lines forming the sides of the square on the plan-board be longer or shorter than the others, it will show that the two surfaces are not strictly parallel, and either the plan-board or camera must be slightly slewed round or tilted a little up or down, till both sets of lines correspond exactly. If the sides of the test-square on the plan-board are marked with a number, a simple inspection will at once show the nature of the adjustment required to bring any particular side of the square to its proper length. With properly constructed apparatus once put into true adjustment, there will be very little trouble in setting the camera for different subjects; but it is advisable to see at least once a day that the adjustments are true.

Captain Abney (*Instruction in Photography*, p. 96) recommends the following method:—On the centre of the board on which the drawing, &c., are to be fixed, a small mirror may be fixed temporarily, or may be let in flush and strictly parallel with the board, thus obviating the necessity of its removal for fixing up the drawing. The point corresponding to the centre of the lens should be accurately marked on the ground glass. On the lens itself an open cap should be fitted, furnished with two cross-threads intersecting on the prolongation of the axis of the lens. The image of these cross-threads will be reflected by the mirror, and should be focussed. The board should then be tilted or screwed round till the image of their intersection coincides with the point marked on the ground glass;

the board will now be parallel to the ground glass, and the drawing may be fixed on it and focussed as usual.

In Vogel's *Hand-book of Photography* another simple method is given, which consists in using a black board with a white stick fastened to it perpendicularly. This is fastened on the copying-board, the camera pointed towards it, and focussed. If the camera and plan-board are parallel, the stick should appear as a white circle on the ground glass.

Dark-Room Arrangements.—The arrangements in the negative dark-room will be much the same as usual, and require no special remark. When working large plates, a horizontal well-bath for the silver solution, on the system recommended by the Autotype Company, will be found most convenient. It is made to tilt up, so as to thoroughly drain the plate, the latter being protected from light meanwhile by a hinged cover.

Large troughs will be required for the bichloride of mercury solution. These may be made of good wood, well coated with black varnish, over which a layer of canvas or cotton-cloth is laid very evenly all over, and then coated again with two coats more of the varnish.

If hydrosulphate of ammonia is used for intensifying, care should be taken to perform this operation in an open place, if possible over a drain, so that the fumes may be carried off at once, and not allowed to get into the other work-rooms.

For the preparation of the photo-transfer prints two special dark-rooms will be required—one for preparing and drying the paper, and the other for inking and washing the transfers. For drying the transfer-paper a drying-box will be useful. It may be made of sheet iron, and furnished with apertures at the bottom and top, for allowing a current of heated air to pass through the box without admitting light. The sheets of paper are suspended from wooden slips resting on wooden supports at the sides of the box.

It will be convenient to have a range of shallow zinc troughs running along one side of the washing-room, under the windows, and to have hot and cold water laid on to each trough. *(To be continued.)*

Review.

Die Fortschritte der Photographie Seit dem Jahre 1879 (Photographic Progress since the year 1879). By Professor Dr. H. W. Vogel. (*Berlin: Robert Oppenheim.*)

Dr. Vogel has been good enough to forward us his new book on photographic progress since 1879, forming a kind of supplement to his well-known *Lehrbuch der Photographie.* The author has done well in confining himself to a description of photographic science for the past three years, for although his volume is a goodly one, comprising 176 closely-printed pages, the importance of the period is such that a record of it, to be complete, must necessarily be somewhat lengthy. And Dr. Vogel has given us a most complete history, as the reader at once discovers on opening the volume. Not only are the physics and chemistry of our art duly recognised, but Dr. Vogel has wisely commented upon all the important practical improvements a well, which have been so numerous during the past few years. He even adds a chapter especially for amateurs, which we make bold to assert will not be found the least attractive portion of the volume.

Dr. Vogel's work, complete and thorough as it invariably is, has always one other important and attractive feature. Whatever he writes is interesting, and this is a great point with nine readers out of ten. His present book is, moreover, capitally illustrated, not the least attractive among the illustrations being pictures and diagrams relative to the employment of electricity in the studio.

Of course the principal feature of the book is the history and description of the gelatine process, the manner of preparing the emulsion, and the different formulæ that have been suggested for development. Dr. Vogel has put this forward in a most clear and succinct manner, detailing the modifications and improvements that have been suggested up to the moment of going to press.

New apparatus—and there has been much novel apparatus in the form of shutters and dark-slides lately—are summarised, and, in many cases, pictorially described; while the new lenses that have recently come into favour on the Continent are shown and discussed. Finally, the new positive printing processes are carefully considered, not forgetting platinotype, to which several pages are devoted. Altogether, we may pronounce Dr. Vogel's new book a most valuable and interesting one, and one likely to attract many students, not only in the great Fatherland, but in this country and in America.

THE LIMITATIONS OF PHOTOGRAPHY.

BY J. E. BEEBE.*

Did you ever think, brother photographers, in the hurry and excitement of money making, that in this beautiful art of ours there are many things well worth thinking about that are of themselves quiet and restful? That the philosophy of the art-science contained within its range many problems that in no wise touched the vexed questions of prices, Sunday work, unwise competitions, troublesome customers and the like? If you have thought this matter over, it will be helpful to know that others are awake to the fact; and if you have not, it will not be unprofitable to reason awhile together and see if we cannot find food for thought outside of formulas and technicalities.

Have any of you ever read that splendid work by England's first art writer, Philip Gilbert Hammerton, called the "Graphic Arts?" If you have not, get it and study it. In this work he says of photography: "It is supposed by many, that since photography gives very minute details, and is in some sort the fixed reflection of nature in a mirror, any one who desires a true record can get it much better by making use of a photographic apparatus than by the careful study with a pencil. This is one of those cases in which a really well-founded opinion cannot possibly be a simple opinion easily transmitted to those who have not studied the subject.

"Photography does in some respects give more delicate truth than any draughtsman can, but from its incapacity for selection, there are many truths which it cannot state in drawing, and it often happens that even if the photograph could give them separately, it could not give them together.

"Again, notwithstanding all the really wonderful ingenuity which has been employed in making the photographic apparatus portable and convenient, it is still far from being so ready and handy as a pocket sketch-book. But there is one fatal objection to photography in comparison with drawing—an objection that far *outweighs* all others—and that is, *the necessity for an actual existing model.*

"You cannot photograph an intention, while you can draw an intention, even in the minutest details, as we constantly see by the drawings made by architects of buildings not yet in existence. This settles the question in favour of drawing, because all constructors require to be able to represent ideas and conceptions which have not yet become realities. Even in the representation of realities photography is less explicit than a good drawing by a person who thoroughly understands his business."

The photographer, then, is not to be compared with the painter, who generally attempts to render something of the mystery and effect of nature. This, then, is the idea of a careful thinker, a lover of all the arts and art-sciences, as to one of the limitations of photography; and I think I can safely say that in all the range of art literature you will find no truer, fairer statement than this. Photography is the helpful assistant, the patient fact collector for the higher arts of printing and illustration. Let her rest content with these honours, and waste no time in reaching for laurels that she can never attain.

Let us analyse a little further, and try and get a few more of the weak spots in our defences in sight before we go into the much easier strain of self-congratulation.

* *Photographic Times.*

Our lenses are eyes of brass and glass, but, unfortunately, they have not behind them a powerful brain. Our plates will accept one set of facts at a time, but no more. When the slide is pushed in, no beating heart or busy thoughts are placing the coming image among the stores of memory. Photography fails woefully when she attempts to depict any of the higher or holier emotions; so guard yourselves carefully, ye modern geniuses who attempt the copying of great paintings—or, worse yet, who attempt arrangements that touch the bounds of the tragic or soulful—for ridicule is your just reward.

Realise well the fact, my friends, that no matter how magnificent your chemical effects, no matter how perfect your workmanship, you are hedged and bounded in the range of subjects you can depict with your cameras; you are limited in the class of expressions you can attempt with safety; you, and subjects whose effect is dependent on colour, are without affinity; your chemicals can bear but a certain strain; your lenses cover but a limited space at one time; your professional life has its boundaries, and you waste your energies in attempting heights your wings were never made to reach. A skilful artilleryman will not use his ammunition in firing at an object beyond the range of his cannon, and a skilful workman will profit by his example. A thoughtful photographer will carefully study his resources, will dull his faculties in certain directions, will use his tools with cool judgment, will polish, refine, beautify his work within certain limits—will, to put it technically, not make 14 by 17 heads with a greater size tube. Many of my hearers must take to heart this lesson. Their art knowledge is limited, their studios are small, their opportunities for culture and training are of a meagre character. If they climb, it must be but slowly and painfully; they must pocket their pride, not fret their lives out over what they would like to do, but use every means to do perfectly what they have to do. See what a field opens before you, my dissatisfied friend. That you are dissatisfied is a sure sign of growth; that you are hungry for formulas, ravenous for information, anxious to meet this man and that man whose work you admire, points straight to the fact that you are improving, and will improve in your work; perhaps not, however, in your prices. A year ago I led my hobby before you, and I will once more ride him across the stage. Art study is not limited; culture will end only when you yourself desire it; a sturdy, honest desire to improve will take the form of studious perusal of art books, a subscription to art journals, of humble, loving study of the work of the master painters and photographers, of drawing, of an endeavour to understand composition, arrangement, light and shade. You forget that your study of chemicals and the management of your light and instruments is but the means by which the great end is to be obtained—namely, beautiful, artistic work. Now for one word of encouragement, and I am done. You may think, as I myself have done, of what benefit is all this, if the worst of all limitations continually surround us? What satisfaction in beautiful, artistic work, expensive studios, or loving devotion, if cabinets are to be made for two dollars a dozen? Let me give you the answer; it is the only one: the love of a true workman is for his work. This has helped many of us over the roughest places; and without it the journey of life would be well nigh intolerable. Courage, therefore. Life is short, art is long; love your work for its own sake, and the result will be satisfaction to your soul without limit.

Correspondence.

BALOON PHOTOGRAPHY FOR WAR PURPOSES.

DEAR SIR,—I am much obliged to you for having called attention to the fact of my being the original inventor of the system of photographing from a captive balloon by means of electricity, as notwithstanding the numerous press articles, together with a paper read at the Balloon Society, my endeavours, which cost me much time and money, seem, during the late war balloon furor, to have been entirely ignored. I patented the system in 1877, but as I found no signs of a likelihood of its being taken up, abandoned it at the three years' stage. I must do Mr. Cooper Key the credit to say that he had not heard of my endeavours prior to his writing the article in the *Daily Telegraph*.

In my original patent I describe a method of causing a band of tissue "à la Warnerke," worked by clockwork, to be detached by the electric current, thus exposing a fresh surface at each connection of the wires, but found this less practical than the simple cube holding four plates, and caused to make a quarter of a revolution at each contact. This was exhibited by me at the Crystal Palace during the late exhibition, and formed an illustration in the *Graphic*.

In conclusion, let me assure Captain Abney and the other gentleman who, I note, are said to be working in this direction, that nothing will give me greater pleasure than hearing of success attending their endeavours.—Yours truly, WALTER B. WOODBURY.

MR. HENDERSON'S COLD EMULSIFICATION PROCESS.

DEAR SIR,—It appears to me that Mr. Henderson's method of preparing gelatine emulsion as described in the NEWS a few weeks ago gives a key to the long-sought problem of uniformity. Although I am only a worker on a very small scale, I have proved its value, and have been much more successful in attaining the proper exposure of my plates than has ever been the case previously. I have found the sensitiveness to be somewhat exalted when the carbonate of ammonia is increased to 30 grains, and I, for one, would be glad to learn more about this process.

SAM. LAUDNER.

[We have received several letters of a similar character, and would be glad if Mr. Henderson would let us have an account of his more recent experiments.—ED. P. N.]

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The monthly meetings of the above Society will be resumed on Thursday evening next, October 5th, at eight o'clock, at the Rooms of the Society of Arts, Adelphi. Papers have been promised on "Notes from the Royal Cromwall Polytechnic Society's Exhibition," by Mr. W. Brooks; and "The Past Season," by Mr. E. Dunmore.

PORTRAITS OF SIR GARNET WOLSELEY AND THE ARCHBISHOP OF CANTERBURY.—Mr. Luks, of Bedford Street, is good enough to forward us portraits of the above, belonging to a "new series" of celebrities he is publishing.

THE A B C OF MODERN PHOTOGRAPHY.—The *Journal of the Society of Arts*, in noticing this work, says:—"This little book is a reprint of a series of articles in the PHOTOGRAPHIC NEWS, by Mr. Burton, whose paper read before the Society last Session will be remembered by those who take an interest in photography. The recent advances which photography has made have brought within its powers results which a few years ago were unattainable; and it is not one of the least remarkable points about the progress of the science, that it has rendered the production of these results comparatively easy. The would-be photographer can have the first and most difficult of his processes done for him. He can purchase his plates ready made, and if he will only attend carefully to the directions which accompany his purchase, he can hardly fail, even at a first attempt, to produce something more or less resembling a picture. An amateur, at the end of his first season, has even been known to boast that his first attempt was quite as good as any of his later efforts—and perhaps it was. This facility in picture-making is raising up a host of amateurs, who may be expected to be anxious to acquire a mastery of their art with the smallest expenditure of time and trouble. For these Mr. Burton writes. He assumes no previous knowledge. He begins at the beginning, giving minute and detailed instructions for every stage of the process, from the time when the plate is placed in the dark slide, to the completion of a print from the finished negative. The little book only deals with the gelatine process, but to the extent to which it goes it is complete, and so far as manipulation can be taught by written instructions it is taught. In spite of the simplicity of the processes to be carried out, the learner will, doubtless, soon discover that there is abundant scope for dexterity in manipulation as well as for judgment. That this is so is sufficiently evident from the different degrees of excellence to be observed in the productions of our best photographers, professional and amateur; and it will be found that while, thanks to the manufacturers of apparatus and gelatine plates, a certain low standard of excellence is rapidly attained, to pass beyond this level is far from easy. Were it not so, the only interest left for the photographer would be the arrangement and treatment of his subject, so that his pictures may really be pictures, and not mere transcripts of the scene towards which his camera happens to be pointed. Artistic merit will always be the quality most sought, but there is still room for many different degrees of technical excellence."

Technical Classes at Preston.—We notice that Mr. Parkinson, who obtained the Guilds' Special Silver Medal for proficiency in the technology of printing, is about to commence a class in Preston. The course will include lithography, plate-printing, and some of the photo-mechanical methods. Considering that photographers usually fail in phototypic work just where the skill of the practical printer is required, rather than on the photographic side, we shall not be surprised to hear of a large proportion of the Preston photographers joining Mr. Parkinson's class, especially as it is to be held in the evening.

The Photographic Money Dispute.—At the Clerkenwell Police Court, on Tuesday, Captain Herbert Kerr, late of the 17th Regiment of Foot, 22, Bushey Place, Clarendon Road, Hampstead, appeared on an adjourned summons to answer the complaint of Lieutenant Arthur Henry Loringe, R.N., of having, on the 20th April last, obtained from him by fraudulent pretences the sum of £2,074, with intent to defraud. Mr. Besley appeared for the prosecution, and Mr. Grain for the defence. The fraud complained of is alleged to have been committed by the defendant as Managing Director of the Photographic Artists' Co-operative Supply Association. The prosecutor, recalled, said that, in addition to the premises at 43, Charterhouse Square, the Association had offices in Carthusian Street connected by speaking tubes with the main premises. The book from which he had obtained the information as to the account between Captain Kerr and the Company was found by him amongst some old books at the offices in Carthusian Street. There was nothing in any of the current books to show that the Company owed Captain Kerr in 1881 more than £202 4s. 6d. He first saw this book when he was making out a balance-sheet for the half-year ending June, 1882. At that time the balance sheet for 1881 had not been completed. He had asked Captain Kerr at least three times when that balance-sheet would be ready. Cross-examined by Mr. Grain.—When he commenced active duties he took charge of the books in use. After the middle of May the books from which he had taken the figures showing the account between Captain Kerr and the Association was on a shelf in his office. He had applied for the winding-up of the Company in Chancery, and he then swore an affidavit. Mr. Grain (reading from the affidavit)—Is it true that you "inspected the books of the Association on several occasions before contracting for the purchase of any shares from H. Kerr?" Witness—Some of them; not all of them. It was true that he had the opportunity of inspecting the books before contracting for the purchase of the shares. His brother suggested that he should have a separate accountant to examine the books. He knew that at the time that the negotiations for the purchase of the shares were proceeding, Mr. Steel was solicitor to the Company. Captain Kerr told him that he had a large number of shares; that he had invested a large sum of money in the Company. The defendant did not say that he had worked up the business himself, and in effect was the Company. What Captain Kerr said was, that he had been engaged for some years in the manufacture of dry plates, and it had been suggested to him that he should start a co-operative company for the manufacture of photographic materials; that he had adopted this suggestion, and had invested largely in shares. Before the interview with Mr. Covell, he had seen a statement of accounts which Captain Kerr guaranteed as correct, and the defendant had promised that the balance-sheet for 1881 should soon be ready. Mr. Grain.—What do you say is the false pretence made by Captain Kerr which induced you to part with your money? Witness.—Captain Kerr gave me a statement of assets and liabilities, stating that he guaranteed it as correct. In this there was a sum of £201 4s. 6d., instead of £1,456, which was standing to Captain Kerr's credit at the time. Mr. Hosack.—Would you have parted with your money if you known that the Company owed Captain Kerr £1,456? Witness.—No. Mr. Grain.—Is that £201 4s. 6d. carried out at all? Witness.—No. It does not affect the totals carried out. Mr. Grain.—Is that the only false pretence you allege? Witness.—No; on the statement of liabilities there is an omission of a liability of the Company of £315, owing to Mr. Gerald Vanderlin. Continuing, he said that before he had anything to do with the Company they took large sums in cash every day. The sums during the first half of this year varied from £12 to £50 or £60 a day. The sales for the first half of this year amounted to £8,600. Last year the sales, according to the books, were £20,000; but after inspecting the books he had even reason to doubt that this was correct. He believed the prices had been raised this year. Witness was not satisfied with the receipts this year, as they showed a falling off as compared with last year. In July, he did not think the business was at all satisfactory, but he thought it was a business to put further money in, and he lent £500 to the Company. He had also lent £500 to the Company in June. That was probably after he had seen the difference in the receipts for May, 1882, as compared with those of the corresponding month of 1881. The second £500 was certainly lent after he had compared the figures. By the Magistrate.—It was before he knew that the Company owed Captain Kerr £1,456. Cross-examination continued.—Captain Kerr did not tell him at any time during the negotiations that he had never drawn the salary due to him. He had not searched the books to see whether he had drawn any salary. Captain Kerr had said that he had such faith in the undertaking that he intended to regularly invest a portion of his salary in the Company. After some further cross-examination the case was again adjourned.

The Photographic Artists' Co-operative Supply Association, Limited, in Chancery.—On Wednesday, a petition was filed by Mr. A. H. Irving for the winding-up of this Company, and for the appointment of a provisional liquidator. The Company objected to the validity of the petition on two grounds. The first was that the petitioner had not held his shares for six months, and that his debenture stock for £1,000 was not ripe for payment. Mr. Eddis, Q.C., for the petitioner, and Mr. W. Barber, Q.C., for the Company. His Lordship said that since the case was last before him he had looked into all the facts and gone over the whole of the affidavits, and for his own part he thought it would be much better that this Company was put out of its misery. It was clear that the two parties—the managing director and the assistant manager—had quarrelled, and hence these proceedings. These two parties held the largest number of shares, and the petitioner knew when he took his shares that the Company was being carried on at a loss. It would be much better that some agreement was come to between the parties. Mr. Eddis said that he had to suggest that a provisional liquidator should be appointed. Mr. W. Barber did not object to such an appointment. His Lordship appointed a provisional liquidator.

Photography from Trains.—Instantaneous photography, in its more familiar aspect, supposes motion of the objects photographed; but another form of it is that in which it is the camera, more especially, that has motion of translation, as in photographing from balloons or trains. The practicability of photographing landscapes from the window of a train running at a rate of even forty miles an hour has been recently proved by Dr. Caudéze, who uses what he calls a gyrograph for the purpose. The apparatus comprises a copper tube similar to that which carries the lenses in ordinary cameras, but the lenses are placed on opposite sides parallel to the axis. Within is a shutter similar to the box of a stopcock; it presents two quadrangular apertures, which, according to the position of the shutter, do or do not let pass the light-rays in making a quarter of a turn. This rotatory movement is obtained by means of a spring liberated from a catch. An exposure of only 1-100th of a second may be had. With a little practice wonderfully distinct views, it is said, can be obtained with the apparatus.—*The Times.*

The Progress of Electric Lighting.—The enormous difficulty of keeping an extensive system of electric lighting conductors in a proper state of insulation can only be appreciated by those who have had experience in working with currents of moderately high potential, and it is a question whether even an area of a square quarter of a mile can be efficiently covered by one generating station for any length of time. The recent attempt to light up a considerable area of New York from a single source led to curious results, horses being frightened by electric shocks traffic stopped, and something like a general consternation existing over the district. On cutting off the current the manifestations ceased, and peace was restored. It seems to us that incandescent lighting will show at its best when a terrace, small square, or similar group of houses, is alone supplied from the same dynamo room.

To Correspondents.

Specimens and Testimonials.—The grievance is an old one, and has often been adverted to in our columns. Although, of course, any honourable man will return specimens when stamps are enclosed for that purpose, correspondents forward their samples at their own risk, the publishers not holding themselves accountable from the simple fact of their consent to receive replies. In the case of testimonials, it is always advisable in the first instance to forward copies, producing the originals only at a personal interview if desired.

Registration.—You would have saved yourself much trouble had you simply signed your name *in full* on the registration form as desired, leaving the description to be filled in from the prints forwarded. What is wanted is the name and address of the photographer, the name of the person or thing photographed, and such a description of the photograph, briefly given, as will enable it to be identified.

Toner.—1. Do not be alarmed, as there is no danger. Such a catastrophe has never yet occurred; neither will it ever happen. 2. The whole matter was fully discussed in the News rather more than a year ago.

T. C. Johnson.—It is all very well for those who have plenty of time to waste; but business men will generally prefer to adopt the usual method.

Lex.—A short series of articles on the subject will appear in the Photographic News before long.

F. Cowley.—The bitumenous film left on drying the varnish tends to become insoluble by long exposure to light, and the best solvent you can employ is chloroform. As the next best, we should recommend benzole; but take care that you do not get light petroleum, or the so-called "benzolene," by mistake. It is probable that if you had devoted less time to elaborate studies as regards photometry, and a correspondingly longer period to careful observation in the field, your progress would have been more rapid. The appearance of the image on the focussing-screen will generally serve to enable a fair estimate to be made; but you must not forget that the actinic intensity of the light falls off very much towards the evening. As good a practical method as any is the following. Set aside a few sheets of albumenized paper as a store, and before going into the field sensitise a small slip on a standard solution of silver nitrate, say 40 grains to the ounce. The times required to produce a standard darkening on a small slip exposed in the direction of the landscape will have approximately the same relations among themselves as the exposures required for camera work. Let us suppose that when you first expose your paper it requires 30 seconds to darken it until it corresponds to a standard tint, and that a gelatine plate with a given lens and stop requires 1-17th of a second, it is obvious that with similar plates, lens, and stop the exposure in the camera should always be 1-510th (or, say, 1-500th) of that required to darken the paper to the arbitrary point selected. There are many circumstances which render this method somewhat incorrect, but you may find it practically useful, for all that. Still the fact remains that the most successful out-door workers do not practise photometry in the field. As regards the other matter, see our leader.

Laboratory Boy.—1. Your supposition that Mr. Verbum Sap. is a well-known authority on photographic matters is somewhat erroneous. Just study through a list of abbreviated Latin quotation, such as you will find in an ordinary dictionary, and you will find the real meaning of the mystic ending. 2. Your method is the correct one, and far preferable.

W. G.—Fasten up screens made of the thinnest and whitest tissue paper which you can obtain.

Lux.—Probably because of the white fumes of magnesia. You had better employ a very large number of paraffin lamps, and give a long exposure. If you possess the means of producing an electric light of sufficient power, you will be able to work with greater rapidity.

O. S.—1. Mr. A. L. Henderson, of King William Street, London Bridge, is undoubtedly one of the best enamel photographers in this country. We do not know the cost. 2. No doubt you can obtain it from the stock dealers. 3. Unless the reduction of weight is a matter of exceptional importance, it is better to use glass. 4. They must be cleaned occasionally, and for this purpose there is no alternative but to unscrew them. 5. Very nearly, but not quite. 6. Quite the reverse, as it enables the photographer to depict nature in its most interesting aspects.

W. E. Craig.—On page 487 of the present volume (issue of August 18th).

Perplexed.—1. Try the formula of Dr. Eder as given in the Year-Book. 2. Judging from the appearance, you have used too large a proportion of silver in relation to the chloride. Perhaps your chloride was not quite free from moisture.

W. B. Funnell.—1. You will find much more extended information in "The Studios" than we can possibly give you in this column. 2. No absolute preference can be expressed, as special circumstances must be considered.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water $1\frac{1}{2}$ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water $\frac{1}{2}$ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add $\frac{3}{4}$ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia $1\frac{3}{4}$ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts. water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge $\frac{1}{4}$-oz., liquid ammonia $\frac{1}{2}$-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol $\frac{1}{2}$ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron $\frac{1}{2}$ oz., glacial acetic acid $\frac{1}{2}$ oz., alcohol $\frac{3}{4}$ oz. The amount of proto-sulphate iron may be diminished to $\frac{1}{4}$ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to $\frac{1}{4}$ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz

Painting Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. $\frac{1}{2}$ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash $1\frac{1}{2}$ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash $\frac{1}{2}$ oz., gelatine $2\frac{1}{2}$ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste. Best white wax, in shreds, 1 oz., turpentine 5 oz.; dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1257.—*October* 6, 1882.

CONTENTS.

OBERNETTER'S NEW GELATINE EMULSION.

News comes to us from Germany of a further improvement in the preparation of gelatino-bromide emulsion. Herr Obernetter, of Munich, whose name is well known as a practical photographic chemist, and as the projector of more than one successful method of importance, has put forward a manifesto among his countrymen to the effect that he has succeeded in devising a more satisfactory and simple plan of preparing gelatine emulsion than that in general use. How far Herr Obernetter is justified in making his statement we know not, but shall content ourselves with placing before our readers all that has so far been communicated on the subject, adding that, in a letter just to hand from our friend Dr. Vogel, of Berlin, that gentleman informs us he has witnessed the process of emulsion making in the Obernetter laboratory—the preparation from first to last taking but six hours—and that he was much impressed by the simplicity and success of the operations.

Herr Oberuetter produces his emulsion in the form of a cake. All the details, he tells us, up to the coating of the plates, are undertaken in daylight, and the tedious operations of mixing and washing are in effect done away with. But the great advantage claimed is, that the proportion of gelatine to sensitive silver salt is only half that usually employed, and yet the salts remain perfectly in suspension. The reason given for this is, that the silver bromide is in a finer state of division than formerly; it is not precipitated in a liquid solution, but is formed in the set gelatine cake, and hence, we are told, the bromide of silver particles have no opportunity of balling together.

Herr Obernetter thus describes his process. "It is a general rule to mix the bromine salt with the gelatine, and then add the silver salt. I reverse the process. I maintain, as the result of many hundred experiments, that gelatine may be for days in contact with nitrate of silver solution without any trace of red fog showing itself, if only on the preparation of the emulsion, a short time before washing, there is an excess of soluble bromide salt present. On this account, in my process, I take the gelatine mixed with nitrate of silver and treat it with a bromine salt; but I do not have the gelatine mixture in solution; I effect the treatment with set gelatine.

"In ordinary daylight, I dissolve the gelatine and the nitrate of silver in water, filter the solution into a shallow vessel, and let it set. At an ordinary temperature, but taking meanwhile certain simple precautions, I can in a few hours obtain a hard gelatine cake, which contains as much as 200 per cent. of nitrate of silver. This cake is not so hard but that I can easily cut it to pieces with a bone spatula, the fragments being one to two centimetres broad, and of convenient length. These are put into a large glass, which is enclosed in a washing apparatus that can be effectively screened from light. Afterwards, I carry the gelatine fragments into the dark-room, and pour upon them a solution of a bromide salt, shut up the apparatus, and allow the whole to remain for a few hours.

"The solution of bromide penetrates the set gelatine, and produces in a most perfect and equal manner the finest bromide of silver, while the greater part of the nitrate salt remains in the mother liquor. In a short time the whole of the silver salt has undergone change, and then ordinary water is allowed to run through the washing apparatus, in order to free the gelatine fragments completely from any soluble salts. Finally, the wash water is permitted to run off, and the sensitive emulsion is at hand in the apparatus, without the least chance of any injurious light rays having penetrated to it. When required for use, the cake emulsion is dissolved, and plates coated therewith; or it may be kept for years by pouring over it a little alcohol."

Herr Obenetter, we may say, in conclusion, estimates the cost of his emulsion at about two marks, or shillings, per square metre of film.

No doubt the indications given above will scarcely suffice to produce the emulsion by anyone except, perhaps, a skilled chemist; more detailed information will be necessary, but still many of our readers will be glad to make experiment on the lines we have indicated. What measures Herr Obernetter will take to make his emulsion known in this country, we are not informed; but we see that photographers of the Great Fatherland may receive further instruction in the process on payment of a certain fee to Herr Obernetter, fixed, we believe, at one hundred marks. All, however, we are concerned with, at present, is to place before our readers what we have learnt respecting the manipulations involved in Herr Obernetter's new method of making sensitive emulsion, and this we have done to the best of our ability.

PHOTOGRAPHY AT THE PARIS EXHIBITION OF DECORATIVE ARTS.

The position of photography as an instrument of art culture appears to be more fully recognised in Paris than in London, a circumstance which may perhaps arise from the fact that a Frenchman judges in such matters rather from his own impression than from a consideration as to what view is likely to be taken by others. For this reason a gem of photographic art is less likely to be hastily passed over as "only a photograph" in Paris than in London.

Photography holds a very good position in the exhibition of decorative arts which was opened a few weeks ago in the Champs Elysées. The gallery upon which one sees the names Daguerre and Niepce emblazoned contains a principal portion of the photographic exhibits, but some objects of notable interest to the photographer are to be found in other parts of the building. The enlarged groups of children shown by Braatz, of Settin, are extremely good and rich in those intermediate grades of tone which are often lost in the case of enlargements, while the arrangement is also good from an artistic point of view. A characteristic collection of portraits from the Reutlinger studio, and comprising promenade, cabinet, and carte-de-visite work, may be taken as typical of the high class portraiture of the present time; and the effect of many of these pictures is much improved by the selection of suitable frames, solid bronze, and greenish-yellow satin, bordered with metal, producing an admirable contrast to the pictures in some instances. Perhaps those mounted with surroundings of dark brown-red satin are the most striking.

Among the Rhine views of Lévy, we were struck by the excellence of some of the old churches of Cologne, these being in most cases very difficult subjects, owing to the proximity of other buildings; the picture of the quaint and heavy-looking St. Gereon being especially worth notice. Lévy has also an interesting series of views of Portugal.

Photo-mechanical processes are so well represented as to make the collection well worthy of a visit from any person specially interested in this branch of photographic work; and the phototypic process, or so-called similiogravure of Messrs. C. P. Petit and Co., is well illustrated from beginning to end. The negative to be reproduced in block form is first somewhat enlarged, and from the reproduction a gelatine relief is made; this relief being next subjected to enormous pressure in contact with a grained paper, more or less resembling emery paper in its nature. The half-tones of the relief are thus broken up into a grain or stipple, and by photographing this relief, so as to reduce it to the original scale, a translation of the first negative into stipple or grain is produced. The further steps consist merely in exposing a zinc plate, coated with a thin film of bitumen, under the stipple negative; and after the unexposed or still soluble portions of the bitumen have been dissolved away by turpentine, the zinc plate is etched into relief. This appears to us to be one of the most promising methods of making photographic blocks for printing in the ordinary typographic press, and we are informed that in most cases the cost is not likely to exceed one-half of that of wood engraving. Photolyptic blocks are also shown by Michelet of Paris, Monchou, and others; zinc, copper, celluloid, brass, and steel being the materials most used. Woodburytype, collotype, and intaglio plate engraving are well illustrated in their various stages by several well-known firms; the collection of the old-established house of Lemercier and Co. being, however, one of the most interesting and complete.

Microscopic photography is not so extensively represented as one might expect from the extent to which it is practised in France; but the enlargements of diatoms shown by Ravet are so sharp and clear as to be remarkable; but they are certainly not such good examples of work as some which have been recently executed by Mr. Jennings, of Nottingham.

The extensive collection sent by Mr. Carlos Relvas, and his daughter, Miss Margaret Relvas, is a large photographic museum in itself, comprising collotypes, and several other photo-mechanical productions. Messrs. Braun and Co.'s well known carbon enlargements cannot fail to attract attention, owing to their notable size and general excellence; but besides these there are but few examples of carbon work on view.

Instantaneous photography is by no means well represented; but the excellence of the street and marine views contributed by Grassin, of Boulogne, compensates for this to some extent.

Ceramic photographs, both plain and coloured, are shown by Gougenheim and Forest, of Paris, and for delicacy of tone, combined with vigorous depth, these reproductions stand high.

By-the-Bye.

ABOUT RAPID EXPOSURES.

We are not about to describe some new form of shutter that accurately times an exposure to the millionth of a second, nor do we intend discussing the intricacies of mechanism of some of the more elaborate instruments now before photographers; our intention is simply to look at the matter from a practical photographer's point of view, and to discover what it is he generally wants to carry on his work. Whether his wants are met by any of the hundred and one shutters that have been described in these columns and elsewhere, is a matter that must be left to his decision alone.

One of the most important points in connection with rapid exposures is not unfrequently overlooked by the shutter designer. The exposure may be of the briefest, and the vibration reduced to a minimum, and yet the invention, when it comes to be handled practically, lacks perfection. For the advantages we have enumerated go for nothing if the exposure does not happen to take place at precisely the right moment. A shutter may act very rapidly and very accurately, giving an exposure of precisely one-hundredth or one-thousandth of a second, but if it does not act at the proper time, its very rapidity mars success. It is for this reason that most photographers still prefer to employ an ordinary apparatus—such as the drop shutter before the lens or behind it—in their work. It so rarely happens that an exposure of but a very small fraction of a second is called for; while, in nine cases out of ten, it is of the utmost importance that the exposure should be so under control that the photographer can effect it any instant he desires.

We have had experience in rapid exposures, but have never yet required to employ one less than one-tenth—or, say, one-twentieth—of a second. There are occasions, of course, when exposures of almost lightning celerity are absolutely essential—to wit, in such experiments as the clever French photo-astronomer, M. Janssen, is wont to conduct. When a direct view of the sun itself is to be taken, it stands to reason that the briefest of exposures is desirable, for a so-called *solarised* image is pretty sure to result. For this reason it is M. Janssen employs a rapidly revolving disc, which is said to open and close the lens in an interval estimated to be as small as $\frac{1}{2000}$ of a second, and even less. In this way M. Janssen was able to achieve the result which set the astronomical world talking two or three years ago; he obtained upon his plate, not merely a round white disc, such as we are wont to see in a sun photograph, but a disc that contained veritable half-tones all over its surface, showing oval grain-like markings, which changed their form in succeeding photographs, one taken rapidly after the other. In M. Janssen's work, it is not of so much importance to secure a picture at any precise instant—although he is quite capable of doing this with his *revolver*—as to secure rapid exposures, and obtain them quickly one after another. In ordinary photographic work, on the other hand, we hold that excessive rapidity of exposure is a matter of secondary importance, while the means to expose at the proper instant is most essential; while, if it were possible to obtain a *revolver* which was something more than a scientific instrument, so that the photographer at will could give three or four exposures, following rapidly one after the other for brief intervals, such a *revolver* would certainly be a most useful instrument.

We will give our experience of instantaneous work by quoting two instances. The first happened long before drop-shutters were christened, or gelatino-bromide thought of. It was in May, 1866, that we first gained experience in the taking of a torpedo explosion—or, rather, of the effect made upon the surface of water by the firing of a submarine charge. These photographs were taken by means of a stereoscopic camera fitted with a pair of No. 1B Dallmeyer's, and furnished with a simple flap-shutter. Doubts that had been entertained about a short-enough exposure were found quite uncalled for, and the upheaving of the water against the *America* hulk was shown crisp and sharp by an exposure that resulted from a simple turn of the wrist. Indeed, in the securing of torpedo photographs in which a body of water appears in the form of a cascade or fountain, rapidity of exposure is, as we have before said, a secondary consideration. The main point is not to expose too soon. It behoves one to wait patiently until the water is thrown to its full height, and as it remains suspended in the air—it is surprising what a long time this really is—to expose then, and not till then. To expose at the time of the explosion would be to get no picture at all. Standing on shore, we have felt through our feet the shock of concussion some time before the time proper for exposing. This, one might almost say, cannot be done too leisurely, for as the American Engineers have demonstrated by actual experiment, it takes sometimes no less than two and a-third seconds before the column of water reaches its full height.

In the case of a torpedo explosion, half a second's exposure may sometimes be given—certainly one quarter; but whether it is of the longest or briefest, this, we repeat, is not so important as the time at which the operation is performed. In landscape photography, the same thing holds good. It is but the other day that Mr. England pointed out how necessary it was to be able to expose at the right moment. "One can never tell," he said, "when the particular instant for exposing may arrive. It may be in five minutes, or five seconds. It all depends upon a puff of wind or a gleam of sunshine." Mr. England, we believe, employs nothing but a small drop-shutter behind his lens, and this, albeit we have a battery of shutters at our disposal, is the one that we, too, usually employ. We made use of it in the other instance we wish to bring forward, and although the problem we desired to solve is not likely to present itself in the every-day work of photographers at large, it contained conditions which, in these days of experiment, will require to be fulfilled again and again. The event we speak of was the destruction of a small building by dynamite—an explosive, as most of our readers know, much more sudden in its action than gunpowder. We desired to secure a picture, if possible, at the moment of explosion, and to do this naturally required a little forethought. In the first place, it was necessary to avoid the fall of brickbats and splinters likely to follow the catastrophe, a measure effected by erecting an iron mantelet, such as is employed by volunteers at the firing butts, in front of the building, at a distance of some forty or fifty yards. Two cameras were set up, their lenses valiantly peeping forth from the mantelet, and their shutters weighted with a few ounces of metal to render the fall rather quicker than usual. The flexible tube, or rather bulb, was, in each case, held by an observer in the mantelet, who could judge in safety ofthe time of exposure by looking at a mirror overhead, reflecting the building. In this case, if the exposure had been made at the time of depressing the electric key to fire the charge, the exposure would have been all too soon. A sharp vibration was felt, the building quivered, and then the four walls fell like a house of cards. The bulbs had been pressed intuitively at the first visible motion of the house, and some excitement naturally attended the development of the plates, all being anxious to know what phase of the explosion would be depicted. In the end, it was found that nothing the observers had remarked was photographed; the four walls that had been seen falling outwards were still erect in the picture; but a space of six feet intervened between them and the roof, showing clearly that the first phase of the explosion had been to send this into the air. It was a very good proof, if any were wanted, that dynamite does not explode downwards only, as some wiseacres will keep on insisting. A curious point in the photograph was the circumstance that both observers had exposed at precisely the same period of time, for in each picture was shown a huge splinter in mid-air, flying in the direction of the mantelet. M. Charpentier has told us that a human being can repeat a signal within thirteen-hundredths of a second, and these two negatives bear out that gentleman's statement, for both photographers exposed at the first visible movement, and were equally successful in securing the roof in mid-air and a flying splinter.

The sharpness of the shaken brickwork, as also the débris flying in all directions, proved very plainly that the exposure was a brief one; although we doubt if it were less than one-twentieth of a second. At any rate, it was quite short enough to capture the results of a dynamite explosion, and yet, we repeat, it was secured by a simple wooden shutter, the fall of which was merely accelerated by being weighted. The experiment only wanted one thing to make it perfect: if a revolver of some sort could have been used, capable of firing off a series of exposures quickly one after the other, it would have been possible to depict not only the first phase of the explosion, but every succeeding one, during the second or two of time that the operation lasted.

There are, no doubt, occasions when photographers desire to work more quickly than in the cases we have cited; but these are exceptional. As a rule, we think their rapid exposures do not include conditions more severe than those of our own experience, and for this reason we shall be surprised if the simplest apparatus for quickly uncapping and capping the lens is not, after all, preferred by practical men.

The "At Home" next week will be "Mr. Frederick York at Bridgwater;" the following "By-the-Bye" will be "A New Scientific Study by Photography."

ABSORPTION OF LIGHT BY THE ATMOSPHERE.*

M. Egoroff, who was deputed by Admiral Mouchez to carry on experiments at the Paris Observatory on the absorption of light by the terrestrial atmosphere, has communicated his latest results to the French Academy of Sciences. In previous experiments he had proved that the electric light when sent from Mont Valerieu to the observatory, lost many of its rays, as was evident from the absorption bands in the spectrum of the beam. The greater part of these rays had also been identified by him with corresponding rays in the solar spectrum. It still remained, however, to study the order of their disappearance in proportion as the layer of air decreased in thickness, and to find for that thickness the limit at which they all ceased to be visible. All the observations were made in company with M. Thollon, who placed his delicate apparatus at the disposal of M. Egoroff. The first series of experiments were made with the electric light sent from Mont Valerien, a distance of about six miles. Between D_1 and D_2 of the spectrum obtained, there were four plain absorption rays. To the left of D on the red side, the rays were exceedingly numerous and distinct; the group *a* being almost complete. The region C was also very rich in absorption rays, as was the region B. Lastly, A was easily distinguished by putting a cobalt blue glass before the eye-piece to absorb diffused light. A second series of experiments was made with a petroleum lamp and reflector stationed at Montsouris, about a mile distant. The spectrum in this case was quite luminous, but only extended in the red to beyond B. When a Drummond limelight was substituted for the petroleum B, *a* and A could be seen. Between B and *a* there were two feeble absorption rays, but *a* could hardly be distinguished, and in the regions D and C some traces of absorption rays were visible. When the Drummond lamp was placed in the Ecole Arago, 264 yards distant, the spectrum showed two absortion rays *a* and A, the

* *Engineering.*

former being very feeble. When a Drummond light was placed in the garden of the observatory, 90 yards distant, the absorption ray at A could be seen with difficulty, but all the rest had disappeared. To determine the elements of the atmosphere which produce absorption rays, a number of experiments on different gases such as nitrogen, oxygen, vapour of water, &c, are still required, and M. Egoroff intends to perform these. Experiments of the kind are desired not only by spectroscopists, but by electricians, as the electric light loses much of its power in passing through the atmosphere, especially if the air is moist. M. Janssen's experiments on the absorption of bodies made in 1866 at Villette would be very valuable, but they are not yet published.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Chapter III.—The Preparation of the Negative.

The production of a suitable negative is the most important part of the whole photo-lithographic process, because upon it depends the entire success of the after operations. With a good original drawing or print, in which the lines are strong, black, and well separated, and the paper clean and white, there is no great difficulty in securing a good negative, and all will work well towards obtaining a successful result; but with originals in which the lines are pale, very fine and close together, and the paper tinted or dirty and yellow from age, difficulties will arise which will require considerable skill to overcome. At the same time, a good deal may be done with the most unpromising originals by the exercise of a little care and trouble in retouching.

Putting aside the few cases in which photo-lithography may be used for reproducing subjects in half tones, and for which any good ordinary negative, direct or reversed, will answer, we may confine ourselves to the consideration of negatives of subjects in line or dot from pen and ink drawings, lithographs, and engravings.

The characteristics of a negative from such a subject, suitable for photo-lithography, are the following:—

1. Perfect sharpness of the lines in every part. This is secured by proper focussing, and by using a suitable lens well within its power.

2. Exact squareness and freedom from optical distortion, which would alter the proportions of the copy relatively to the original. To secure this a suitable lens of the rectilinear type must be used, and the apparatus must be carefully adjusted for parallelism, as described in the last chapter.

3. There must be the greatest possible contrast between the lines and the ground of the negative. As in the original the lines should be black, on an even clean white ground, so on the negative there should be perfectly clear glass on a black or opaque ground. The nearer these conditions are realised, the easier will be the work, and the better the result.

The process by which negatives for photo-lithographic work are generally obtained is the usual wet collodion process, modified and extended by an after-process of intensification, in order to secure the desired transparency of the lines with an intensely opaque ground.

Recently, however, in this as in other branches of photography, this old and useful process seems likely to be supplanted by gelatine bromide dry plates, which have many conveniences and advantages in their favour.

The manipulations and formulæ for copying by the wet collodion process do not differ very much from those in ordinary use as described in the text-books. It may, however, be useful to describe some modes of working, the utility of which has been proved in large government offices; and we shall assume that our readers are familiar with ordinary photographic manipulations.

Glass.—Any good photographic glass may be used, but for large sizes patent plate is to be recommended, as giving better contact, and being less liable to break in the printing frame. The surface is also better and more free from blemishes—a point of considerable importance in taking reversed negatives through the glass.

The glass should be cleaned in the usual way with a mixture of tripoli, ammonia, and spirit of wine, or any of the other mixtures recommended for this purpose.

The films may be removed from old glasses by boiling or soaking them in a solution of washing soda, quarter of a pound to a gallon of water, and if they are stained with mercury they may be steeped in a solution of iodine and iodide of potassium.

A very effective way of treating old glasses stained with mercury is to rub them over with Eder and Toth's lead intensifier, viz.:—

Nitrate of lead	4	parts
Ferridcyanide of potassium ...	6	,,
Distilled water	100	,,

This is allowed to remain on for some days, then rubbed off, and the glass cleaned as usual.

Solutions of bichromate of potash containing nitric, muriatic, or sulphuric acid are also very useful for cleaning old glass. A good formula is:—

Bichromate of potash	30	parts
Nitric acid	300	,,
Water	700	,,

Or,

Bichromate of potash	60	parts
Sulphuric acid	60	,,
Water	1,000	,,

It is very convenient to have a bottle of the nitric acid mixture handy for washing out bottles and dishes. It will clean off and remove very obstinate stains.

Before use, the glasses should be coated with a substratum of albumen, to prevent stripping or lifting of the film in the after-processes. If the glasses are old and stained, the solution of albumen may be tolerably thick (1 part of albumen to 4 of water).

Collodion.—The collodion should be of a kind yielding clear, intense negatives, and should not be too new. Sometimes a plain iodised collodion is recommended as giving more intensity and a harder image; but it will generally be better to use a collodion containing a small quantity of bromide. Captain Abney recommends the addition to an ordinary collodion of a grain or two of pyroxylin—or, better, papyroxyline—which has been washed in dilute ammonia, the alkaline solution favouring intensity, which is further increased by the addition of the pyroxyline.

The formula generally used in the Surveyor-General's Office, Calcutta, for large plates, is—

Plain Collodion.

Pyroxyline	60	parts
Ether	2,000	,,
Alcohol	1,000	,,

It is sometimes found necessary to increase the quantity of pyroxyline to seventy-two parts.

Iodiser.

Iodide of ammonium	20	parts
Iodide of cadmium	12	,,
Bromide of cadmium	8	,,
Iodine	0·3	,,
Alcohol	1,000	,,

In the Military Geographical Institute at Vienna, the following is used. It contains the usual iodides and some chlorides, but no bromide:—

Plain Co lodion.

Pyroxyline	15·6	parts
Ether	500	,,
Alcohol	400	,,

Iodiser.

Iodide of cadmium	7·8 parts
Iodide of ammonium	4·7 ,,
Chloride of calcium	1·6 ,,
Absolute alcohol	100 ,,

This is used with a strong nitrate bath at 10 per cent., acidified with nitric acid.

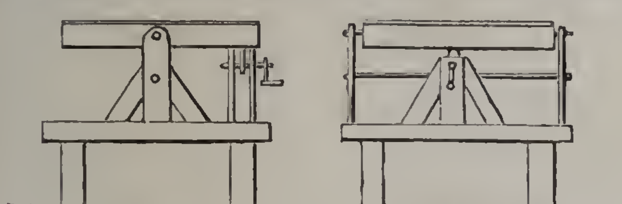
Senhor Rodriquez gives the following as used in the Photographic Section of the Geographical Department at Lisbon:—

Alcohol	500 parts
Ether	500 parts
Pyroxyline	11 ,,
Iodide of cadmium	6 ,,
Iodide of ammonium	5 ,,
Bromide ammonium	2 ,,

Nitrate Bath.—The nitrate bath is made up in the usual manner, at about thirty-five grains to the ounce of water, and should be rather more acid with nitric acid than is usual for portrait or landscape work. As noted before, for large plates, horizontal troughs will be found more convenient and economical than the usual vertical dipping-bath. They will be found useful for many other operations when using large plates, and may be made up of well-seasoned wood carefully put together to avoid leakages. The inside is varnished and covered with cotton-cloth or canvas, then varnished again with two coats of Bates' black strong shellac varnish, or the following composition recommended by Mr. W. K. Burton:—

Asphaltum	7 lbs.
Beeswax...	2 ,,
Linseed oil	1 pint

The trough containing the nitrate bath should be constructed with a well at one end for the reception of the silver solution when the bath is in an upright position for draining, &c. It should have a cover, which may be fastened to it with hinges, or be loose, and should be mounted on a wooden stand so that it may be raised up in a slanting position to allow the plates to drain, and may be given a slight rocking motion on an horizontal axis by the addition of some simple mechanism, such as an excentric turned by a handle and acting at one end of the trough, so that it rises and falls as the excentric is turned (see figs.)



Side View. Back View.

It is a good plan to have two baths working alternately, so as to keep them in good working order; the one out of use being sunned to drive off ether and alcohol and precipitate impurities.

Developer.—With bromo-iodised collodion an iron developer is generally used, but pyrogallic acid is sometimes substituted for it, especially with simply iodised collodion.

The following is the formula in general use in the Surveyor-General's Office, Calcutta:—

Protosulphate of iron	50 parts
Glacial acetic acid	33 ,,
Spirits of wine	40 ,,
Water	1,000 ,,

The addition of a little gelatine in the proportion of $\frac{1}{61}$th part per 1,000 has been found useful in giving intensity, and at the same time keeping the lines clear. The gelatine is kept dissolved in the acetic acid.

A very good developer for line work is—

Protosulphate of iron	1 ounce
Acetic acid	1 ,,
Spirits of wine	½ ,,
Water	1 pint

To 40 ounces of this are added 8 ounces of a solution of glycerine prepared by dissolving 2½ drachms of gelatine in 1 ounce of sulphuric acid—neutralising with ammonia—and then adding 7 drachms of acetic acid, 500 grains of protosulphate of iron, and sufficient water to make up 25 ounces.

At the Ordnance Survey Office, Southampton, the developer is—

Protosulphate of iron	1 ounce
Glacial acetic acid	6 drachms
Alcohol	6 ,,
Distilled water	20 ounces

In the Military Geographical Institute at Vienna the following is in ordinary use, but I do not like it quite so well as the above:—

Protosulphate of iron	210 parts
Sulphate of copper	105 ,,
Glacial acetic acid	210 ,,
Water	6,720 ,,

also—

1.—Solution of protosulphate of iron at 10 per cent.	350 ,,
Glacial acetic acid	70 ,,
2.—Nitrate of lead	21·9 ,,
Water	350 ,,

(1) and (2) are mixed, filtered, and diluted with 350 to 700 parts of water. It is weaker than the first formula, and requires a longer exposure, but is said to keep the fine lines very open and free from fog.

Captain Abney recommends rather a weak developer:—

Protosulphate of iron	5 grains
Glacial acetic acid	10 minims
Alcohol	*quant. suff.*
Water	1 ounce

In developing negatives of line work, the action of the developer should be arrested before any traces of deposit show themselves on the lines, and the negatives should also be slightly under-exposed.

Fixing.—As a rule, it is better to fix immediately after development, and before intensifying; but in copying large maps with long-focus lenses we have found it useful to wash the plate well after development, and then apply a 20-grain solution of nitrate of silver, followed by a second application of the iron developer, in order to give the requisite density for the after mercurial intensification.

For fixing, a solution of cyanide of potassium of 6 per cent. is generally used, and it is an economical plan to keep it in a vertical dipping-trough lined with lead.

Redevelopment.—The first development with iron will not, as a rule, give enough deposit of silver to obtain perfect opacity by the after-treatment with bichloride of mercury. It is necessary, therefore, to slightly intensify or redevelop with pyrogallic acid or iron, and this may be done either before fixing, as described above, or after. To make sure of the lines being clear, I prefer to do all intensification after fixing.

If the lines appear slightly clouded after fixing and washing, the *clearing* process recommended by Mr. Osborne may be used with advantage before proceeding to intensify. The plate is covered with a solution of—

Iodine	20 grains
Iodide of potassium	40 ,,
Water	20 ounces

This is allowed to act for about a minute, and then washed off. A very weak solution of cyanide of potassium is now applied, and should take off all deposit from the lines. If it does not do so, it will be better to reject the negative and take another.

The negative, being free from deposit in the lines, is again covered with the above solution, which is washed off almost immediately, and the plate exposed to daylight for a few moments. It is then intensified with the usual pyrogallic acid and silver or iron intensifier containing citric acid, but, as a rule, only a very slight increase of density is given. The plate is then well washed, and is ready for further treatment with bichloride of mercury, &c.

One of the simplest methods of obtaining the necessary density with suitable subjects, showing perfectly clear lines, is to allow the fixed and cleared negative to remain in Davanne's solution of iodine—

Iodine	1 part
Iodide of potassium	4 parts
Water	200 ,,

until the film becomes yellow throughout. It is then well washed, and re-developed in daylight with the ordinary pyrogallic and silver solutions restrained with citric acid. Any amount of density may thus be obtained, and the intensification may be stopped at any desired point.

As a rule, it is better, however, to re-develop slightly, and obtain the requisite opacity by changing the colour of the deposit rather than by increasing its thickness.

(*To be continued.*)

SOME EXPERIENCES WITH THE EMULSION PLATES NOT SO PLEASANT.

BY EDWARD L. WILSON.

I have said so much in favour of emulsion plates within the last year or two that I believe myself to be entitled now to find a little fault with them. But I do not wish the remarks which I make to be taken as referring to every kind of plate under all circumstances, or as in any way harsh. I am personally acquainted, I believe, with nearly all of our emulsion plate manufacturers. I do not think a set of men exist who are more devoted and earnest in the desire to produce faultless plates than they are. I believe they all want to do the very best possible, and are constantly striving to make more valuable plates. Therefore I relate a few of the experiences I have had lately, more to clear up in the minds of the photographers who are using them the doubts as to what are the causes of certain experiences which they have had as well as myself, than to suggest to dry plate manufacturers how they may improve; for I am sure they know as well as I do what the faults of their plates are, if any. I ought to say, too, that my experiments have been confined to only a few brands of the plates offered in the market, though they have been quite extensive. One of the first things I saw, which I did not like, upon developing the plates exposed from two to six months ago, was the irregular coating of the emulsion upon the plate. It is very evident that some of these had had a puddle of emulsion applied in the centre of the plate *à la* collodion, which had been allowed to spread itself toward the sides and ends, thus making the centre of the plate more thickly coated than the other parts. The consequence is a difference in intensity of the various parts of the plate; this would be apparent when developing. Two 5 by 8 plates, following each other, showed that they had once formed parts of an 8 by 10 plate which had been cut in the middle, leaving a sort of half disc of intensity in the middle of each plate, with a weakness of image at each end.

Moreover, a second experience, which was not pleasant, was found in the 5 by 8 plates, which seemed to have been coated separately, one end giving a much stronger and better image than the other. This is undoubtedly due to irregular coating. Doubtless carelessness in the same direction causes some plates to make no show of an image whatever.

But it is a different sort of carelessness which displays ruthless finger and thumb-marks through the latitude and the longitude of the film in various directions. I have either lost a number of excellent results from this cause, or had to resort to a great deal of labour to save them.

Another unpleasant thing is the manner in which some plate manufacturers pack their plates. The most of those which were used by me during my tour were packed in cases, and I cannot speak too loudly in praise of such a method. I have found since my return scarcely a single plate broken when packed in this way. But I used some plates that were packed with a frame of card-board or straw-board (I do not know which) between them, and they have caused me a great deal of trouble. Some chemical effect seems to have taken place which causes an insensitiveness around the whole border of the plate to the extent of from half to three-quarters of an inch, sometimes giving me on a 5 by 8 plate only 3½ inches of image the narrow way. This is a most unpardonable blunder, and should be remedied by any one who makes it. There is a machine made for packing plates by Mr. Cowan, which I found in use in England and France. It should be adopted everywhere, and would avoid all trouble in the direction I have just described.

I have been asked many times whether I have been troubled with fogging during the development of my plates. I have been blessed with a great deal of freedom from fogging, having had none of the "green" or "red" varieties which are described so graphically by many; but I have had fog, and sometimes it was very annoying. I find the addition of a few drops of citric acid to the developer disposes of the trouble altogether.

Another disagreeable effect which I noticed, was that plates which would develop rapidly and with good strength would be reduced in the hyposulphite solution considerably, rendering them almost useless unless intensified. This trouble was overcome by the addition of a little protosulphate of iron to the fixing solution. I have tried the use of alum in the hyposulphite bath for the hardening of the film and the prevention of frilling, and I cannot say that I altogether like it. It causes the solution to be milky, while it hardens the film, and leaves a deposit on the plates which must be brushed off, thus causing extra trouble. I prefer rather the use of the dipping bath of alum, and then the hyposulphite separately. There may be other experiences which will come up from time to time as I go on with my work, and, if so, I will mention them. Some results have been obtained thus far fully equal to those obtained with the wet method, and I consider part of my journey would have been impossible without emulsion plates, on account of the scarcity of water. I feel that, with all the drawbacks, emulsion plates are a great thing for the photographer of to-day; but we have a great deal to learn about them.—*Photographic Times.*

IMPROVEMENTS IN COLD EMULSIFICATION.

BY A. L. HENDERSON.*

Since I gave the formula for emulsification in the cold a few weeks since, some exceptions have been taken to it as being an expensive way of making emulsion, in consequence of the value of the alcohol used. I believe that anyone trying both methods—that is, washing and precipitating—and taking the number of plates coated into consideration, will find the advantage on the side of the alcoholic method. No matter how carefully you may wash emulsion, some of the bromide gets washed away, and, as a rule, you have greater bulk than you desire, necessitating thicker coating. Let us compare the price of each. The alcohol for ten ounces of emulsion will cost about eightpence, and with precipitated emulsion about two dozen more quarter-plates may be coated than with the same quantity of the washed. I do not advocate my method purely on commercial grounds, but on that of quality. Since I published the cold method I have made an improvement, namely, to utilise some of the waste products to make the next batch. If you recollect, I used one ounce of water to three of alcohol, then two ounces of water with the silver. This gives a compound containing three ounces of alcohol and three ounces of water; when I add the twelve ounces more alcohol to precipitate I have 80 per cent. of alcohol and 20 per cent. of water in the so-called waste product. Of course the solution contains sufficient gelatine for emulsification, as well as some of the soluble salts which help to act as restrainers. This solution must be allowed to cool, and be filtered before using again. If I take three ounces of this compound and add the bromide, then the silver, I save at least two ounces of alcohol; and, moreover, what is of much greater importance, is the fact that all the gelatine in this batch is soluble in alcohol, and consequently removed by the next precipitation. One thing I must mention, namely, that the bromide of potassium is not all soluble in this quantity of alcohol, &c., and it is as well to add half the solution of silver first, stirring all the time, and in a few seconds the water from the silver will go towards the solution of the bromide. In conclusion, I am glad to say that my last formula seems to have made some

* Read before the London and Provincial Photographic Association.

impression on our Continental brethren. I have received several communications on the subject, and have also been informed that one of the largest professional plate makers in this country has adopted the cold method. He has personally expressed his opinion that the rapidity obtained is due to the alcohol.

ILLUMINATION OF THE DEVELOPING ROOM.

BY W. HORSMAN KIRKBY.*

To many present my present remarks will be an oft-told tale. When gelatine plates first came into vogue they were found to fog in the light then used in the preparation and development of collodio-bromide, although this was much nearer the red end of the spectrum than was requisite for wet collodion. There was a general cry that not only must the light be more confined to red, but that little—in fact, almost none—of even that must be used; consequently there resulted a regular groping in the dark, and many a negative has been spoilt thereby. Ruby glass was generally employed, and that of the darkest; and even several thicknesses were used by many.

It is due to Captain Abney to state that, in connection with his investigations with the spectroscope, the use of ruby and orange combined was recommended, and this when properly selected is perfectly non-actinic; but still many photographers, unable to get out of the groove, were afraid to use much light with it. I have always held the opinion that, provided we could obtain a *perfectly* non-actinic light, we might use *any* quantity of it, and thus be enabled to see clearly what we are doing. I see that in a lately published book by Captain Abney he says that "if the quality of the light be correct, the quantity may be unlimited."

I am induced to make these remarks from reading the labels on a packet of extra-sensitive plates received from a well-known maker. One label recommended filtering the light through the "deepest ruby glass," and the other spoke of the importance of using a "very *subdued* red light." Now, to show the fallacy of this, I developed one of these extra-sensitive plates within a foot of my lantern, and fully exposed to it, without any trace of fog; and when I tell you that by the same light I could read the above-named labels at a distance of six feet from the lantern, and even see the seconds hand of my watch at sixteen feet distance, you will understand that I do not work in a very subdued light. My lantern is an ordinary square petroleum stable lantern, the air-holes being carefully shaded to prevent the exit of white light, and the flat glass sides are covered with (Thomas's) commercial ruby paper, which, I have no doubt, is stained with both ruby and orange dyes, either separately or combined.

HOW TO MIX THE DEVELOPER.

BY J. DIXON.†

I have been working dry plates for one year, and I have had no trouble. I never saw a dry plate before one year ago. In New York I saw them working—Mr. Scholten and others—three times, and actually developed some of Mr. Cramer's plates. I have been since then living myself in a small city where there are about five thousand people. Remember that I only saw him develop five or six different plates. I saw how they were worked. I went right home and commenced trying them; the first two or three were failures. I kept on, however, and kept at work at it. I picked up a receipt, and I saw it was good, and I was bound to do it. So I kept on. I first worked the oxalate for three months. I worked it until I understood it. I worked it at three different degrees of strength. Whenever I came upon a formula that was better than the one I was using, I adopted it, and at last I struck Edwards' receipt, and for the last six months I have been working that steadily, and I have no desire to change. You can use any strength you wish. It is always ready, and there is no spoiling of plates. I have tried the different grades of plates of different makers. I work altogether the Swan plate, made in England, with from one to three seconds' exposure, and from seven to twelve by electric light at night. I take these plates and I take this same developer, and I never make an exposure of more than one second. I can produce as fine results as I wish in my pictures. As I said before, I always use the Swan plate, made in England.

Now the developer is the pyrogallic. The first few times I mixed it up I used to take it out with a stick on paper, and put the paper into the stand or holder, and then put it into a smaller bottle, all of which took considerable time. (Mr. Dixon now proceeded to mix his developer.) Now here is the pyrogallic—there are six ounces of alcohol which you pour right in—one ounce of pyrogallic acid to six ounces of alcohol. Now there is a great deal of it; pour it in a stoppered bottle, then you put what you want to use in another bottle, put it away for half-an-hour until it is all dissolved—put very little in the bottle. That is what I call the pyrogallic and the alcohol. Here are two ounces of glycerine; one ounce we will put into that. I will tell you in a few minutes what they are put in there for; they are all for a purpose. If you should see it on paper, you would say it was "all bosh." There is one ounce of pyrogallic, six ounces of alcohol, one ounce of glycerine. The pyrogallic is put there for strength, the alcohol is put there to keep it better. I have got stuff enough here to last six months. You can mix it up better in water; let it stay twenty-four hours in warm water. The glycerine is put there for a restrainer, and also for its keeping qualities. Use good alcohol. Here I have sixty grains of bromide of ammonium; we will take six ounces of water, and it will keep just as well as with the alcohol. Now there are sixty grains of ammonium. Instead of adding six ounces of water, I put eight ounces in. Now we will put in one ounce of glycerine and one ounce of liquid ammonia. I want you all to understand this. In this bottle there are sixty grains of ammonium, six ounces of water, one ounce of glycerine, and one ounce of strong liquid ammonia (concentrated). Label that bottle "ammonia." Now, then, with the pyrogallic mixed up and the ammonia mixed up, there is enough to make over one hundred dollars' worth of work, and I think it cost me in this town one dollar and ten cents. Now we will take one ounce of either one of these, just one ounce of stock to fifteen ounces of water. Now take one ounce of ammmonia. When I say ammonia, I mean the mixture of bromide of ammonium, glycerine, and all—I mean the stock solution. Then I fill the second bottle up. Now supposing we have an over-exposed plate, I fill the second bottle up and develop it quickly, just as quickly as I can. Suppose we have here an over-exposed plate, what shall we do with it? We first take one ounce of the pyrogallic, and then put in one ounce of the ammonia. Now you have a two-ounce solution. Instead of laying the plate in there and letting the solution flow over it, I put several into the dish—otherwise you would get a nice crop of air-bubbles—the glycerine will give air-bubbles. Now you must take heed to my description. If you will take a bit of paper, and lay the plate under it all at once with one sweep, it will go right over in a wave. You will commence to see it come up. It will come up in one minute. If you go to work shaking it pouring it in, you will have water-bubbles, and you will not improve the plate.

Now, suppose that the plate is coming up nicely, in one minute it will appear fairly developed. Supposing it does not—suppose that it is coming up slowly—the developer works slowly—you will then use the pyrogallic. The pyrogallic gives strength, ammonia gives detail; the bromide of ammonium is put in there as a reducer or retarder, the same as citric acid in the iron developer; the pyrogallic is put in to build it up and give strength; the alcohol to keep it up; the glycerine to give body; the liquid ammonia is put in there for an object also. So you have your mixture. Supposing that the developer is working too slowly, and you want it to work quicker. You pour ammonia into your graduate, and pour it into the pyrogallic. Now you have more ammonia than pyrogallic. The ammonia will give more detail, and the pyrogallic will give more strength. I heard a gentleman say yesterday, while giving a receipt, "Suppose it is going too slowly, you then add so many grains more of the pyrogallic. If you add more of the pyrogallic, you want to bring in something. Ammonia will do. Suppose that it is acting too quickly, what will you do? Then you want to add more pyrogallic." This is the way you should work with your plates, by which way you can add more pyrogallic, or less, whichever way you want to, according to the kind of plate you are using.

† A communication to the Photographers' Association of America.

Notes.

The Photographic Exhibition at Pall Mall opens to-morrow, to members of the Society and their friends, at eight p.m.; to the public, on Monday, at ten a.m.

The Royal Victoria Music Hall, in the Waterloo Road, yclept "The Vic'," is to be the scene of a series of popular scientific lectures, undertaken after the plan of the Polytechnic demonstrations. The admission is to be one penny.

It will be noted that an important point in connection with the Obernetter emulsion process, which we describe in another column, is the absence of all boiling or cooking of the emulsion.

Events cast their shadows before, and we must not be surprised, therefore, to find many shadows of Mrs. Langtry being cast before her visit to America. Indeed, no less than 25,000 shadows, in the form of photographic portraits of Mrs. Langtry, have been ordered from one firm alone for the United States.

A well-known "model" to painters and photographers died last week. He was an old man, tall of stature, and with long, grey hair blowing over his face, to be usually met with in the Strand, and generally known as a vendor of evening papers, and by his never wearing a hat. One of Mr. Valentine Blanchard's finest studies, exhibited some years ago, at Pall Mall, was obtained with this "model," who has probably represented more "holy men" on canvas than any of his brethren.

A communication made last week to the Academy of Sciences shows how inadequate an observatory unprovided with photographic apparatus is to secure trustworthy records of astronomical phenomena. A beautiful comet has been discovered by MM. Thollon and Gouy at Nice, in the immediate neighbourhood of the sun. Apart from its brilliant head, there was nothing very noteworthy, except this salient fact: on examination through the spectroscope two lines were seen very close to D′ and D″ of sodium, but not perfectly agreeing with the Frauenhofer lines. If it is sodium, this is the first time the metal has been discovered in a comet. Unfortunately, the latter has disappeared, and as the lines have not been recorded in a photograph, the momentous question is still involved in doubt, and will be for some time to come a subject of many deliberations in astronomical circles.

A new use has been found for micro-photography. It is employed to demonstrate the structure of wood, a glance at the photograph serving to show whether the wood is strong or weak. At the Franklin Institute, on a recent occasion, a series of micro-photographs of timber were exhibited, and it was stated by Mr. Grimshaw that practical tests bore out the indications of the micro-photographs. Thus, in strong timber, the concentric rings were close in texture and of slight width, and the radial plates frequent, wide, long, and thick; while in the case of weak timber these characteristics were reversed.

Shortly before his death, Dr. Van Monckhoven resumed the photo-spectroscopic researches which had been put aside for some years, owing to the calls made on his time by the commercial preparation of gelatino-bromide; and only a fortnight since we received a memoir which had been presented by him to the French Academy of Sciences. In this memoir he sets at rest a dispute as to the cause of the broadening of hydrogen lines in the spectrum. Dr. Van Monckhoven secured several photographic observations of the spectrum of hydrogen under different pressures and at different temperatures, and these he submitted, in proof of his deductions, to the French Academy through M. Janssen.

We may thus briefly summarise the investigation. While many astronomers attribute the broadening of the hydrogen lines in certain spectra to the influence of pressure alone, others—among whom may be cited Cecchi—believe the phenomena to be caused jointly by pressure and change of temperature. Dr. Van Monckhoven secured photographs of the hydrogen lines under varying conditions, and the pictures were so conclusive as to lead him to state at the end of his memoir: "The broadening of the hydrogen lines is, therefore, absolutely independent of temperature, and solely due to pressure."

The out-door portraitist must be careful in future how he pushes his business, as the magistrates of Ramsgate have fined a member of the photographic fraternity 2s. 6d. for pertinaciously soliciting one of the holiday folk to have his portrait taken.

A fine of half-a-crown often covers a much more serious offence, and, considering that visitors to Ramsgate are seldom engaged in any serious or important work on the sands, we are inclined to think the prosecutor may have been the greater offender against society. If the photographer deserved a fine of 2s. 6d., what punishment would suffice for him who knocks at a door and brings you from the top of the house to explain that no water-cresses are required to-day? Still worse is the offence of the circular sender, who often occasions the loss of moments far more valuable than those spent in sunning oneself by the sea-side. Magistrates generally hit little boys hardest.

The Prince of Wales took considerable interest in Mr. Muybridge's instantaneous photographs, and, it may be remembered, occupied the chair on the occasion of that photographer's lecture at the Royal Institution. We have just now received a note from His Royal Highness' private Secretary, stating that the Prince has been much interested in our illustration of a fortnight since, in which the Muybridge results were for the first time applied to picture-making.

Mr. Mayall's studio in Bond Street may be added to the list of those lit up with the Swan electric lamp, only Mr. Mayall does not employ battery power for the purpose, as photographers have hitherto done. Having a ten-horse engine on the premises, and a powerful dynamo machine, which is used for taking portraits by the electric light, he has at his disposal a magnificent source of electricity, available for ordinary lighting purposes. Each window of the Bond Street establishment is fitted with six Swan lamps of twenty-five-candle power, there being thirty lamps in all, and these illuminate the pictures and show-cases in the most brilliant manner.

There are not many who would care to light up their windows on this grand scale, but if photographers only understood how comparatively inexpensive, and how easy of application, the incandescent lamp is, we feel sure that its use would be more general. A pair of five-candle Swan lamps should not cost more than from ninepence to a shilling per evening, and they suffice to light up a show-case in a most effective manner. No doubt this is dearer than gaslight, but then the novelty and attractive character of the light go for something. We shall next week explain the matter fully, and give such plain directions as will enable any intelligent being to fit up a battery and lamp without difficulty.

Here is a hint from the *Engineer* on the subject of making cheap and easy moulds for metal castings. If ten per cent. of alum is used in the water employed for mixing plaster of Paris, and a mould made from this, it is, our contemporary says, hard enough to resist molten metal.

The time is not far distant, we think, when the formation of a Photographers' Defence Association will be necessary to protect photographic copyright. Every day the hawking of pirated photographs, both portraits and landscapes, becomes more common, and every day do the pirates exhibit greater impudence. They know very well it is not worth the while of any single photographer to prosecute, and the consequence is they fearlessly exhibit in the open thoroughfares whole barrows full of pirated pictures. We have seen cabinet pictures by Downey, Van Bosch, Reutlinger, Mayall, &c., selling for twopence a-piece in the streets, and it is very certain that if the public can purchase pictures at this low rate, they will soon cease to buy from the authorized vendors at all.

Some time ago Messrs. W. and D. Downey did join hands with the Stereoscopic Company with a view to prosecuting the hawking of piracies, but the expense involved was so large that the firms in the end deemed it wiser to withdraw. But if photographers banded themselves together in the form of an Association or Syndicate to protect their commercial interests, there would be funds in plenty for such prosecutions, and piracies would soon become rare. Whether photographers have yet suffered sufficiently to bestir themselves we know not, but the creation of a Defence Association is only a matter of time.

We referred recently to the advantages which would accrue to the Insurance and Salvage offices if they adopted the plan of photographing the scene of a fire; the picture would be valuable not only as a record, but as an illustration of the amount of damage done, and possibly of the origin of the disaster. We can now furnish a paralle example which supports our view. The Home Office, as our readers may know, exercise control over all gunpowder works and manufactories of explosive compounds, and a periodical visit is made to these by the inspectors of explo sives. When an accident happens—and, thanks to the excellent supervision, these are now rare—the first thing the Government Inspector does, on arriving on the scene, is to order a photograph to be taken of the results of the catastrophe. Afterwards, when he comes to make his report upon the affair, the photograph serves as an excellent illustration.

Dorber: "Strange thing that photographers never can paint, isn't it?" *Foatow*: "I don't know; there's Doublet You know Doublet's fine photographs; well, he paints, and so does Aplanatic; I have seen them both at work with the brush." *Dorber*: "Oh, yes; I've no doubt they are tolerable, but they are not, of course, well-known exhibitors at the Academy. Look at some of our men who handle the camera. Take Bretcep, R.A., for instance; now, he is an excellent painter." *Foatow*: "Yes, but then he is a very bad photographer."

Patent Intelligence.

Applications for Letters Patent.

4605. John Henry Johnson, of 47, Lincoln's Inn Fields, in the county of Middlesex, Gentleman, for an invention of "Improvements in the manufacture of paper applicable especially for bank notes, share certificates, state documents, and the like."—A communication to him from abroad by Edward Musil, Manager of the Paper-making Company of Neusiedl, near Vienna, in the empire of Austria.—Dated 28th September, 1882.

4651. John Young McLellan, of Glasgow, in the county of Lanark, North Britain, Analytical Chemist, for an invention of "Improvements in artificial-light apparatus for photographing, and applicable otherwise."—Dated 30th September, 1882.

4671. Charles Picton Evans, of Birmingham, in the county of Warwick, Gentleman, for an invention of "Improvements in the art of photography."—Dated 2nd October, 1882.

Patents Sealed.

3232. Jean Frederic Plucker, Capitaine D'Artillerie, of Antwerp, in the kingdom of Belgium, for an invention of "An improved stand for photographic cameras."—Dated 7th July, 1882.

3329. William Patrick Bruce, of Kinleith Currie, Midlothian, for an invention of "A new process for the reproduction of designs applicable to the illustration of books and the like."—Dated 13th July, 1882.

Patent Void through Non-payment of Duties.

3818. Ralph Augustine Jones, of Brill, in the county of Bucks, Gentleman, for an invention of "A new or improved apparatus for applying pressure suitable for taking copies of letters or other documents and drawings, and for mounting photographs and drawings, or for similar purposes."—Dated 23rd September, 1882.

My said invention relates to a simple and effective hand apparatus for applying a rolling pressure when taking copies of letters or other documents, and drawings or designs, applicable also to the mounting of photographs and drawings, and for similar purposes, and consists of a frame or holder of any convenient construction, and of any suitable material, such, for example, as wood, *papier maché*, metal, porcelain, or glass, the said frame or holder carrying two or more rollers placed side by side, and working loose within such frame, which rollers rest upon the surface intended to receive the pressure, and project slightly beyond or below the under-side or surface of the said frame or holder. One or more handles or bearing surfaces are provided in or on the frame, or the frame itself and the handle or bearing surface may be formed in one for the purpose of receiving through the hand or hands of the operator the direct pressure required for the purpose, such pressure being imparted by the two or more lines of contact of the rollers acting in the same direction and upon the same plane at the same time. Having now described and particularly ascertained the nature of my said invention, and the manner in which the same is or may be used or carried into effect, I would observe, in conclusion, that what I consider to be novel and original, and therefore claim as the invention secured to me by the hereinbefore in part recited Letters Patent is,—First. The peculiar construction and arrangement of hand-pressure apparatus wherein a rolling pressure is applied along two or more parallel lines of rolling contact, acting simultaneously in the same direction and upon the same plane, substantially as and for the purposes hereinbefore described and illustrated by my drawings. Second. The application and use of the said hand-pressure apparatus to and for the taking of copies or impressions of letters, or other documents or drawings, and mounting photographs or drawings, substantially in the manner hereinbefore described.

Specifications issued during the Week.

959. T. Singleton—"Improvements in the construction of paper wrappers for photographic purposes." Price 2d.

This invention is designed for the purpose of utilizing and extending the use of paper wrappers for post purposes, and modes for preventing their contents from slipping out during transit, at the same time allowing them to be examined as under the present system by simply pressing them in the hand. In making the paper wrappers I make them taper or otherwise, thereby making a saving in the amount of paper from which they are produced of about twenty per cent., being of great commercial value, both as regards economy and cost. The various modes of securing the contents I accomplish in the following manner. The wrappers are provided with openings, holes, or slots on the address side, against which the contents to be sent are placed, being fastened by placing the ordinary stamps over the aforesaid openings, holes, or slots, the gum on the back of the stamps adhering to the wrapper round the sides of the openings, holes, or slots, the part of the stamps lying over the openings, holes, or slots adhering to the contents, thus securing them to the wrapper, and thus preventing them from slipping out. In another method the wrapper is made taper, the small or narrow end when folded is placed inside, after which the paper or other content is wrapped up, thus causing the large end of the wrapper to extend or project beyond the part over which it laps; this end being gummed, causes the part folding on the wrapper to secure itself, the extreme or projecting ends falling on the papor or contents enclosed, thereby securing both together. In another method I place the openings, holes, or slots on the back side of the wrappers, the gummed edges lapping over them, securing the contents hy the gummed part sticking to them through the aforesaid openings, holes, or slots. I also make the wrapper so that when it is folded, the gummed edge laps on half the opposite edge of the wrapper, the other half on the contents, or both ends may be gummed, the inner edge being secured to the contents.

1000. E. C. Hancock—"A process for rapidly etching and matting patterns, letters, &c., on glass."—A communication from Dr. W. Grüne. Price 4d.

This invention relates to a new or improved process of rapidly etching and "matting" or "deadening" patterns, designs, or ornamental effects, letters, and the like, on glass or other vitreous surfaces. Aqueous fluoric acid dissolves glass without exercising a visible influence upon the remaining surface, leaving it approximately bright. Profiting by this peculiarity in its corroding power, I avail myself of reserving materials which have before been thought comparatively useless in consequence of their feeble resisting capacity. These substances, if placed upon glass in very thin layers, and even dried and hard, will yield in a few seconds to a solution of fluoric acid in water if the solution is concentrated. Being simply used for the above purpose, very faintly marked and bright results will be seen; but if I powder them when placed upon the surface of the glass with very finely divided metal, copal, or other substances, resisting the action of the acid for a longer time, and allow them to dry on after treating them with the acid, I obtain at once a more or less matted result. The practical advantage of this invention is that the corrosive action being very quickly performed, those parts of the pattern required to be bright need not be covered by any resists whatever. Only feebly resisting substances being required, which would be useless for the ordinary method of procedure, not only all the well known methods of drawing with a brush, pen, stylus, &c., can be used for putting the drawing on, but impressions by all available methods of mechanical printing, typography, lithography, glass, zinc, and copper-plate printing, &c., as well as elastic stamping. I also take advantage of thin and thick resists, using sometimes fine and coarse materials for powdering, obtaining thereby a matted appearance of different density or grain. In a drawing one can therefore obtain different and variegated shading by the simple use of various materials in the same drawing. In describing the *modus operandi*, I shall divide the process into two parts—firstly, the simple process, by which a matted pattern or drawing is put upon the glass; and, secondly, the double process, by which a bright pattern may be reserved upon the glass, the ground work of the glass being matted or deadened.

Simple Process.—First, I put the drawing upon the object either by hand, transfer, or direct printing, with almost any oil or varnish mixed with a little colour to render it visible. I then powder it by means of a brush or a tuft of cotton-wool, or in other suitable manner, with pulverized metal, copal, or such similar substances. I find what is known commercially as "bronze powder" very suitable for the purpose. After having dried it, I dip it into fluoric acid; or this may also be put on with a brush if desirable. After a few seconds the powder begins to shale off. I then wash it in water. It is not necessary to remove the greasy printing colour. The fluoric acid destroying it, it comes off in the water.

Double Process.—First, I either paint, draw, or print the pattern in a material resisting fluoric acid, such materials being well known. When dry, I oil over the whole surface by means of an ordinary printer's composition roller with a greasy printing colour or oil varnish, powder, treat with acid, and wash, as described in the simple process. I then remove the resist pattern either with an alkaline solution, benzine, alcohol, or like solvent. Instead of applying the acid as a bath or by brush, I may apply it in the form of fine spray. It will be understood that the word "glass" through this Specification must also be taken to mean vitreous surfaces in general. A very important feature of my invention is this, that whereas other patterns or designs in vitreous etching with which I am acquainted are depressed below the surface, my "deadened" or "matted" portion is raised above the surface, as may be tested by running the finger-nail thereover.

The invention may be summed up as follows:—The powdered materials allow the acid to flow between the particles, thus leaving a series of minute spots or holes between each particle, caused by the acid directly attacking the minute uncovered portions, and indirectly attacking the particles forming the resist (leaving them deadened), and thus a series of minute and imperceptible holes or depressions produce the deadened effect. I may arrange the pattern to be bright and incised, while the groundwork is dead and intaglio; or the pattern may be intaglio, and the groundwork bright and incised. If desired, I may print in a drying oil, powder with asphaltum, warm, so as to reserve the part under it, oil again, dust with the powder, and treat with acid. Having now described the nature of the said invention as communicated to me from abroad, and the manner of performing the same, I would have it understood that what I believe to be novel and original, and desire to claim on behalf of the said Dr. Wilhelm Grüne, is:—Firstly. In vitreous etching the direct result of a "matted" pattern by the corrosion of fluoric acid, substantially as described. Secondly. The process of vitreous etching, or any mere modification or variation thereof, substantially as described.

ELIMINATION OF HYPOSULPHITE FROM GELATINE PLATES.

BY JAMES WATKINS.

When a gelatine plate has been fixed, a long protracted washing is required to remove every trace of hyposulphite, with all the risk of frilling, starting the film, injuring the image, and uncertainty as to whether the object sought is gained; any safe process, therefore, that shortens the work, and at the same time makes assurance doubly sure, must be a boon to dry plate workers.

After a fixed plate has been in the alum bath, had even a lengthy washing under a tap, and is partially drained, it will be found to be covered with innumerable little protuberances, like minute grains of sand. On examining these with a powerful magnifying glass, they are seen to be salt crystals. Further, if the plate be of no value, and at the risk of obliterating the image, it may be warmed over a spirit lamp or gas jet, till evaporation begins to take place; with the magnifying lens crystallization may be seen rapidly going on; and the same effect, though in a less degree, may often be noticed even after prolonged washings.

Some time back, and late in the evening, I had fixed a plate and given it its preliminary or "little go," when, according to custom, before proceeding further, I was scraping some of the gelatine, with which manufacturers almost invariably and unsolicited adorn or disfigure the backs of the plate, and which, if not removed at an early stage, is apt to be more troublesome further on. On this occasion, this secondary layer was larger and denser than usual, and to assist in its denudation, I vigorously applied the jack towel for some minutes; but I soon discovered, or suspected, that I was operating on the wrong side, which proved to be the case, from one or two scratches on the picture; but I was surprised to see how thoroughly free the gelatine was from any specks, and was satisfied that the hyposulphite was removed.

A few days after, I exposed a plate, cut it in halves, and treated one half to the usual washing of two or three hours, and the other I submitted to a similar experiment, using a clean pocket handkerchief. The result was the same, and on testing for hyposulphite, no trace was discernible; the handkerchief, however, left behind fragments of its own material, difficult to remove, which would leave spots on the print. I tried various other materials, such as silk, india rubber, but after many trials, the most satisfactory and safest, and at the same time thoroughly effective plan, was as follows. Immediately after development, wash off developer, and place the plate in a solution of alum, rather stronger than is ordinarily used, say a 20-grain, and leave it there for fully ten minutes, then fix as usual. After fixing and a good preliminary wash to get rid of the surface hyposulphite, place it in a 40-grain solution of alum (an addition of a little citric acid does no harm), leave it therein for at least another ten minutes (half-an-hour would not hurt), to harden the film. Remove any extra coating from the back previously, and then give it a good washing, and let it stand in water (face downwards, if possible) for a short time, say fifteen minutes, while another plate is proceeded with. The face of the film will be found full of protuberances. Now thoroughly wash the hands to remove any chemicals, and taking the plate in left hand, face upwards, flow a good stream of water from the tap, while with the front joints of the fingers of the right hand, with a circular quick motion and a fairly firm pressure, you well rub the plate all over for at least five minutes. On examination it will be found the gelatine is more or less a wholly smooth surface, or perhaps a few specks still linger in the corners, or here or there. At any rate, proceed as before, only rubbing the fingers from near the top down to the bottom, then reverse the plate and proceed as before, until all specks disappear. The plate will dry as fast again as it would after a lengthened soaking, and either a chemical or optical test will show the plate to be safe. No one who once tries this method will revert to the old tedious and doubtful washings.

ODD JOBS.

BY THE AUTHOR OF "LOOKING BACK."

No. 12.—Bath and Landsdown Races.

Bath! That world-renowned *rendezvous* of idle people; that home of the lame and "'arf dead;" that resort of old misses and half-pay officers; that El Dorado of doctors and hair-dressers; that hot-bed of flirting, scandal, hot springs, assemblies, and debt—that wonderful, historical, and picturesque city of Bath! It breathes of romance to its very foundation. When Beecham Cliff, Camden View, Sham Castle, and Coombe Down were unnamed, and when the Borough walls and Milsom Street were tracts of rotting herbage, overhung with gnarled oaks, and the sites of the Grand Hotel and Pump Room were muddy puddles, steaming away in the open air like the boiling wells in Iceland—then did history and romance touch it with their magic finger. Everyone knows how Prince Bladud and his pigs took to the order of the *Bath*—how they wallowed in the steaming waters, and walked away rejoicing in renewed health and the proud knowledge that they had discovered a boon for the unfortunate "bloated ones" that were doomed to follow after them. Everyone knows that Prince Bladud and his pigs were the making of Bath, just the same as Lady Godiva, when she threw a glamour of poetry and romance over the antique gables of Coventry by her extraordinary feat of horsemanship. Strange to say, artists and poets, as a rule, fail to extol the prognosticating faculties of the Prince and his grunters, while Coventry's lady seems to make slaves of them all. "Human natur' *is* rum," quoth Squeers. I wonder if Bill Stumps and his pigs had been the happy discoverers of the virtues of Bath waters, if it would have become the fashionable resort of the bearded nobles of Saxon Athelstane's court, or been patronized by the hybrid horde that came over with William the Conqueror? In such case, I hardly think you would, after a lapse of hundreds of years, have found the elegant Beau Nash doing the honours of the Pump and Assembly Rooms to the *élite* of "society."

Apart from all joking, Bath, at the present date, is a pretty place, and a rare one to amaze and tire out a stranger in. If a country cousin drops upon you in Bath, and wishes to see the lions, you must be a ninny if you do not manage to make him nearly break his neck coming down a hill, or burst a blood vessel climbing up one. The knowing ones in photography will see in a minute that Bath is the very *ne plus ultra* for a holiday. I take it that most photographers, when enjoying a holiday, would rather leave "shop" behind them—they would for the nonce forget all about cameras and dark-rooms, and whistle dry plates and instantaneous shutters down the winds. The city-bound worker rushes to the "briny," or to "bosky dells, lovely glens, and heath-clad mountains," and quaffs great doses of that clear nepenthe that blots out the worry of the past year. Then our pro's from the provinces, whose lives are passed within easy or every-day reach of maritime or rural beauties, vary the monotony by seeking relaxation in the roar and rattle of the busy city. Yet, I firmly believe, there is a larger number of photographers—both professional and amateurs—who, loving their art or their hobby, would fain go to some place where they could bring back some *souvenir* worth showing their friends, and at the same time give themselves an opportunity of proving how clever they are in doing work out of the routine of their every-day grooves. To this set, whether they toil in the city, or labour in the "country," I say emphatically, "Go to Bath!" If they are hale and hearty, and up for some fun, "Go to Bath!" If they want to recuperate, "Go to Bath!" If they want the excitement of a city commingled with the verdant delights of a rural life, "Go to Bath!" Whatever may be the matter with you (always excepting an empty purse), "Go to Bath," and you will get what will set you straight. It is really a wonderful place—a remarkable place—a celebrated place! Bath chairs, Bath bricks, and Bath buns are world-renowned.

But these are not the *souvenirs* my brethren would care about fetching home with them. They want to go, in the first place, to Orange Grove—just in front of the "Cross Keys"—and point their lenses at the grand old Cathedral. Let them do this about nine o'clock in the morning, when the sun has just come round, and sparkles all over the venerable pile; then will they get one of the prettiest pictures that ever an architectural antiquary gloated over. The Abbey (by-the-bye, it is called Bath Abbey). from the Green, is worthy of a plate, if it were only to reproduce the two "Jacob's ladders" on each side of the ancient doorway, with their load of delapidated angels hanging on their time-worn rounds. For those who love little bits of woodland, there is the Victoria Park, and the Avon side by Bathampton and Batheaston, both within easy walk of any part of the city. Bath is peculiarly situated for being photographed as a whole, being built in a valley and surrounded by hills. Splendid views of the city can be obtained from either Sion Hill, Claremont, Camden, Beecham, or Bathwick; but I fancy the best of all can be got at the base of Sham Castle, or Pope's Folly, as it is sometimes called. Behind Claremont there is one of the smallest churches and graveyards in England (the church all but hidden by a huge yew of dismal black), that well deserves a visit: it is called Charlecoombe. To those who love climbing, and wish to see miles and miles of a rich and fertile country, dotted all over with undulating hills and woodlands, and streams gleaming in the sunlight as they meander iu their midst, I advise au ascent of Salisbury Hill. Then, my fellow-workers, who may visit Bath, be sure you go aud pass a day among the green meadows at Limpley Stoke, refresh at the Viaduct, and come home over Coombe Down, and I think you will do me the justice to say I have not exaggerated the beauties of Bath and its environs.

Easter, or the Race Week in June, are very favourable times to see Bath at its best. At Easter it is "full," and fancy balls, amateur theatricals, and everything of that sort, are in full swing; while in June, the Grand, the Yorke, and the Castle, are seething with "swells," whose talk is all of dogs aud horses. During the latter excitement the resident photographer gets little or nothing to do, compared with the fancy balls at Easter; thus it was that two years since we were all surprised at being ordered to make sundry groups and single portraits of all the jockeys that rode at Landsdown. The ferment in the establishment at this news was great indeed. All the young fellows wanted me to get "the straight tip" for them, so that they might make sure bets with their shillings and half-crowns. Would you believe it, sir, each one of those sixteen jockeys, under a deep vow of secrecy, gave me "the tip," and each "tip" was to back the individual jockey who had for the time button-holed me? Was it any wonder that under these circumstances the young fellows should become rather mixed in their betting? There had been heavy falls of rain during the fortnight prior to the great event, so that the usually dry and breezy Course of Landsdown was completely soddened. By-the-bye, there are some spleudid woodland bits out in that direction; besides, the view from any part of the Course is glorious, and will well repay a trudge up the steep road, or a walk through the greeu lanes.

It was a bright, breezy, sunshiny day, and the Course was more than usually crowded. I need not describe the race (I allude to the principal event of the day's performance—the Duke of Beaufort's Cup, or something); all that I shall say is, that the result astonished even a good many of the knowing ones, for a short-hocked, heavy-boned outsider came thundering in, leaving the favourite nowhere. The soft state of the Course made it a matter of endurance instead of swiftness, so this strong-limbed steeple-chaser carried the bell. I had to photograph this horse under peculiar circumstances, so my next paper will be a sequel to this, entitled "At a Veterinary Surgeon's."

IMPROVEMENTS IN DEVELOPERS FOR DRY PLATES.

So far as we at present remember, there has been no systematic attempt made, writes the Editor of the *Photographic Times*, to notice the special effects produced by the use of different kinds of acids in the developer.

In an iron developer with wet collodion, when citric or tartaric acids are employed instead of acetic, the colour of the deposited silver is darker. This is much more noticeable with dry plates and acid pyrogallic development, in which case almost any quality of tone required may be got by varying the acids in the developer. In a less marked degree this is also the case when intensifying an iron-developed wet plate with pyrogallic acid and silver, acetic acid giving a somewhat warm brown colour; that yielded by citric acid being cold and black.

To discover in what manner the quality of gelatine negatives is influenced by the presence of acids of different kinds in the alkaline developer, Mr. Henry J. Newton is at present making a series of trials, with results which are quite interesting. The various acids hitherto tried by him have been citric, acetic, sulphuric, phosphoric, formic, boracic, oxalic, together with alum.

The following will afford some idea of the results obtained from such trials as have yet been made.

Citric acid gave a precipitate on the plate in the form of a fine powder.

Acetic acid, whether glacial or No. 8, gave a perfectly clear picture.

Sulphuric acid behaved very much like the acetic, only the colour of the film was rather yellow.

Phosphoric acid, concentrated (sp. gr. 1437), yielded a beautiful negative of a rich brown colour, and in every respect satisfactory. The proportion present iu the developer was five minims to the ounce.

Formic acid, when used in the proportion of from three to five minims per ounce, produces a negative having a fine colour.

Boracic acid was tried in the proportion of three grains to the ounce. When speaking of the effects produced by this acid, Mr. Newton said: "This is the most powerful restrainer I have ever used." Had the same quantity of this as of other acids been used in the developer, the exposure would require to be prolonged ten times in order to obtain a good negative.

Oxalic acid, three grains to the ounce, was quite satisfactory, and almost identical in its actions with the formic.

Alum, when present in proportion of three grains, entirely prevented the development of the image.

Now what, it will be asked, is the practical outcome of these experiments? We reply, that it is a formula for a developer which, in the estimation of Mr. Newton, is the best that has yet been brought before the public, and which we here give:—

I.

Carbonate (washing) soda	500 grains
Water	10 ounces

II.

Oxalic acid	30 grains
Pyrogallic acid	20 ,,
Bromide of ammonium	10 ,,
Water	10 ounces

The above are mixed in equal proportions immediately before developing, which is best effected in a flat tray. It will be observed that this is one of the most economical developers that can be employed, as there is only one grain of pyrogallic acid to each ounce of the solution.

There are certain brands of plates, such as those of the Cramer and Norden, and Beebe make, which do not require the addition of the bromide of ammonium in the developer; indeed, they work much better without it, while for those of other make the formula is recommended as here given.

Under some circumstances full printing intensity will be obtained with even one-half of the quantity of the pyrogallic in the formula, while it may, on the other hand, sometimes be necessary to increase the proportion of the bromide if great density be required.

A substitution of the carbonate of potash for that of soda in the formula just given has also been tried, the potash salt in question being that form of carbonate known in commerce as salts of tartar, but it has not been found to possess any advantage over the soda. Not only so, but it is inferior in its action; therefore, as between these two alkaline carbonates, that of the soda must be conceded to stand unrivalled.

The solutions Nos. 1 and 2 keep indefinitely, and are ready for use at any time. The pyrogallic solution, keeping pure and white, is in every respect to be preferred to the ordinary alcoholic solution. Mr. Newton recommends that at least two bottles of this solution be made, one containing two grains of bromide to the ounce, and the other no bromide. These can be mixed to produce such effects as may be required. Ordinarily, however, no bromide will be required, unless in case of over-exposure.

In the use of this developer great latitude is allowable; the quantities given in the above formula are not arbitrary, and may be varied to suit any kind of work. The soda present will be, when used, twenty-five grains to the ounce; a much smaller quantity can be successfully used for ordinary work. A developer with ten or fifteen grains makes an excellent one. If ammonia is used, let the solution be *water* four ounces, *ammonia* one dram. This will give thinner negatives, and cannot be used without a bromide. Its developing power is also much sooner exhausted.

TONING FOR YOUNG AMATEURS.

BY HENRY CLAY PRICE.*

One difficulty the young amateur frequently encounters in his photographic manipulations is that of toning. To give any definite rule for the accomplishment of this in a satisfactory manner is not easy. Toning can only be learned by practice.

It is necessary that the student proceed in a systematic manner to work it out, and the following plan is suggested by which a vast amount of information on toning may be obtained.

Select a strong, vigorous negative, and from it make a proof on sensitized paper, printing deeper than the finished print should be. Cut this proof into four equal parts, and on the back of each put a number, as 1, 2, 3, 4. Make a toning bath according to the formula in use; four pieces are washed in several changes of water, and then placed in the toning bath.

Watch the prints closely, and as soon as No. 1 assumes a very slight approach to the purple, remove it and place in a dish of clean water. Allow No. 2 to show more of the purple; No. 3 should be carried further; and No. 4 will receive the longest immersion in the toning solution. Wash well the four pieces in several changes of water, and fix in hyposulphite of soda (say four ounces soda to pint of water). After fixing, wash in five or six changes of water, and then transfer to a solution of acetate of lead. Again wash and dry the prints; then study each well.

Correspondence.

A PHOTOGRAPHIC NUISANCE.

Sir,—Is there any reason why dry plates cannot be cut true to size? A short time back, having a day's holiday, I packed my dark tent, camera, dark slides, and an unopened box of 5 by 4 by a leading maker. Arrived at the farm, and lunched, I proceeded to set up my tent in a barn, and load my three slides ready for the campaign. Out of the dozen, only four would go into my slides, and one by pressure. No diamond to be had within three or four miles, only one of those American glass cutters. With this instrument, in the narrow compass of a tent, I managed to cut, or rather boggle, two, and split two more, so gave it up, and confined myself, *nolens volens*, to six views, instead of a dozen. It is not the first time I have thus been served; nor was this manufacturer the only one, for I hear complaints frequently of the same nuisance from others. When I buy 5 by 4 plates, I do not want $5\frac{1}{8}$ by $4\frac{1}{16}$. To cut off a quarter of an inch requires some dexterity in a regular glazier; if the plates were an inch over, it would be better. Often the plates are anything but on the square, sometimes an additional corner. I think makers ought to pass every plate through a guage before sending out. I may say my carriers are rather over than close to measure. It is bad enough in the studio to have to cut and trim, but when out for a day's run, it really amounts to a photographic nuisance.—Yours obediently,

Exact Measure.

Proceedings of Societies.

London Provincial Photographic Association.

At the meeting of the above Association, held at Ashley's Hotel, Covent Garden, on Thursday, the 28th ult., Mr. R. J. Palmer occupied the chair.

Mr. W. E. Debenham showed a drying-rack for gelatine plates.

Mr. Henderson mentioned that a hundred quarter-plates could be drained on a piece of board 18 by 8 inches by standing them in rows against small French nails.

Mr. W. K. Burton showed a negative of a sea and landscape; it had been shaded as suggested by him at a previous meeting, so as to give one side an exposure of twenty seconds, while the other only received half a second.

Mr. Henderson mentioned that it had been suggested, during the recent discussions on varnishes, that if the plate were coated with albumen (coagulated) previous to varnishing, the gelatine would not swell if any damp got through the varnish, and he had coated several strips of a gelatine negative, when almost half dry, with a solution of albumen, and then dried; one half of these strips had been placed in a saturated solution of alum. These being now placed in boiling water for some time, it was found that the part that had been placed in alum was but little swollen, much less than a film that had been subjected to a chrome alum solution would have done.

Mr. Brown said that the breaking up did not occur when an oil varnish was used; he found copal varnish thinned with turps answered well, the only drawback being the time occupied by drying.

Mr. Cowan passed round the result of some experimental exposures in daylight, under a very dense sensitometer, of two makes of plates, one containing a large quantity of iodide, and the other but a very small percentage. The reversal of the image commenced much earlier in the first plate, and the experiment seemed to show that iodide tends to cause reversal.

Mr. Burton said he had removed silver stains from negatives by a weak solution of alum and cyanide.

Mr. Henderson then read a paper on "Cold Emulsification" (see page 598).

Mr. Debenham said he should like to see it established that more plates could be coated with a precipitated emulsion, than with the same quantity of a washed emulsion.

Mr. Cowan said he always found a great waste of bromide in a washed emulsion.

Liverpool Amateur Photographic Association.

The usual monthly meeting of this Society took place on Thursday, the 28th ult., Dr. Kenyon, in the absence of the President, being in the chair.

The minutes of the August meeting having been read and confirmed, the Rev. J. Bruster was elected a member of the Society.

The Hon. Secretary read a letter from the Librarian of the Free Library, specifying the conditions under which the Liverpool Amateur Photographic Association would be allowed the use of the room in future.

The Rev. G. J. Banner proposed the acceptance of the terms, with many thanks to the Corporation for their liberality and courtesy.

Mr. J. A. Forrest seconded the proposal, and it was carried unanimously.

The Hon. Secretary laid upon the table the reports of the annual proceedings of the Philomathic Society, and the Liverpool Naturalists' Field Club, for which votes of thanks were accorded.

The Hon. Secretary wished to remind members of the approaching *soirée* of the Associated Scientific Societies of Liverpool. He thought it most desirable that the Liverpool Amateur Photographic Association should continue to fill the important share it had hitherto taken in providing the instruction and entertainment of the visitors to St. George's Hall, and hoped that members would have ready for exhibition a goodly number of their productions of the past season.

Mr. Forrest urged the members to make a special effort, so that the Society might be well and numerously represented this year by exhibitors. He reminded the meeting that, although last year's exhibition of pictures was certainly a very fine one, it had been mainly contributed from the collections of Messrs. J. W. H. Watling and Ellerbeck.

Mr. E. Twigge said that members whose cameras were small were often deterred from exhibiting prints, under the impression that small pictures were monotonous and ineffective.

Mr. J. H. T. Ellerbeck thought that the great interest of these annual exhibitions should lie in the fact that the bulk of the exhibits were the work of members of the Society.

Mr. Forrest deprecated any discouragement of the producers of small pictures. All good work of every size should be wel-

* *Photographic Times.*

comed and exhibited, and, above all, the exhibits should be sent to the Hon. Secretary in good time.

The Committee appointed last year to receive and arrange the exhibits in the hall was then re-appointed, with the addition of the names of Messrs. Forrest and Rutter.

Mr. Ellerbeck wished to know if the Tuesday evening meetings, which had been held last winter at his house, should be resumed.

The Chairman thought that the Society were greatly indebted to Mr. Ellerbeck for his hospitality and kindness in giving the use of his house for these meetings last year, and that they should certainly be continued, inasmuch as very valuable information and assistance had been obtained by means of them.

It was, therefore, decided that Mr. Ellerbeck's kind offer to continue these social meetings during the coming winter should be accepted, and the Hon. Secretary was requested to give intimation to the members of the fact.

The Rev. H. J. Palmer (Hon. Sec.) passed round a very beautiful specimen of crystallization from a saturated solution of oxalate of potash, from which all the liquid had evaporated.

Mr. H. N. Atkins passed round a portfolio of prints on platinotype paper, and said that the process had given him the greatest satisfaction from its simplicity and the rapidity with which finished prints could be produced. He greatly admired the pure blacks and whites of the prints, and referred the members to the small portfolio of photographs done during a recent holiday, which would speak for themselves. He had printed and developed about a dozen prints in half-an-hour, and found that a proof under-printed, which would be absolutely worthless in silver, was more like a sketch in pure black and white than an imperfect print. He (Mr. Atkins) exhibited a camera of his own construction, which he commenced in June and had in working order on the last bank holiday. It was almost item for item, a *facsimile* of one afterwards extensively advertised by a London maker a fortnight later. It permitted him to take out and expose any number of plates, dispensing altogether with dark-slides, the plates being carried in a light-tight tin box, each box being made to carry ten plates. He had with it escaped all fog and imperfect registration of ground glass and sensitive plates. The camera—which was half-plate size—when closed and carrying ten 5 by 4 plates, measured 8 by $6\frac{1}{4}$ by 6 inches, and was very light. At first his greatest difficulty had been from over-exposure; but he had recently found the greatest ease in overcoming this by developing with the following formula:—

Saturated solution of oxalate of potash	1 ounce
,, ,, ferrous sulphate	$\frac{1}{4}$,,
Bromide of potassium, 20-grain solution	4 to 6 drops
Water ...	$1\frac{1}{4}$ ounces

This developer was placed in one dish, and the plates placed there in until all details were out. They were then transferred to another dish containing strong developer—

Saturated solution of oxalate of potassium	4 parts
,, ,, ferrous sulphate...	1 part

and in this they acquired density rapidly. The plates were clear glass in the margin, and printed remarkably quickly, with full half-tone and pure whites.

The Chairman expressed his thanks to Mr. Atkins for his interesting exhibit and communication. He thought that it was in the direction in which Mr. Atkins was leading by this contrivance that heavily-burdened amateurs must look for relief from the load of their cameras, dark slides, and plate-boxes. He suggested the exertion of further ingenuity on Mr. Atkins' part to increase the range of focus.

Mr. W. H. Kirkby thought that silver printing would soon die out in favour of platinotype.

Mr. Ellerbeck had found difficulty in obtaining pure white high-lights with deep shadows and satisfactory contrast.

Mr. J. H. Day remarked that details of weak negatives came out much more crisply and clearly in platinotype prints than in silver.

Mr. Atkins corroborated this.

The Chairman said that he had kept sensitive silver paper in a platinotype box, and had found a difficulty in toning in consequence.

Mr. Kirkby read a short paper on the "Illumination of the Developing Room" (see page 599).

Mr. Ellerbeck said that he had recently visited the studio of a well-known professional firm, and found them developing gelatine plates in a much brighter light than that usually used by amateurs.

Mr. Day had developed seven plates recently by bare gas-light without a trace of fog; but he found that a serious absence of detail resulted.

The Rev. H. J. Palmer (Hon. Secretary) then gave an account of some experiments upon heat-haze which he had recently made in Switzerland. In July of 1881 he had noticed from the Rigi that, on looking at distant Alps and glaciers (which were but dimly seen as to details through white glass owing to heat-haze) through ruby and orange glass, every crevasse on the snows and shadow on the precipices and mountain slopes became visible with amazing clearness. This year he had taken with him variously-tinted sheets of gelatine, and had made many exposures upon distance, interposing the clear gelatine in front of the lens. He had used violet, orange, green, and ruby films, and found that the result was an equalisation of the necessary exposure on distance and foreground, and a most amazing obliteration of haze, without a very serious increase in the duration of exposure. He had been unable to perfect his experiments in this direction, owing to the failure of his supply of plates; but he was certain that here was a most important field for future experiment and investigation.

Mr. Ellerbeck exhibited a very fine series of views of scenes on the river; Mr. J. Guyton a plate-box of great usefulness and ingenuity; the Hon. Secretary some negatives of Louvain, the Abbey of Villiers, and the old town of Laufenburg; Mr. Day some good prints of his recent work in Wales; and Mr. A. K. Bean some views of the interiors of St. Mark's, Rock Ferry, and Chester Cathedral.

Mr. Kirkby gave a description of a visit to the studio of Mr. Schenkenhofer, where he had seen a new and very clever apparatus, devised by that gentleman, for expediting the processes of toning, fixing, washing, and drying of silver prints. The apparatus seemed to be very effective for the purposes for which it was intended, and could also be used for rapidly drying the films of gelatine plates.

Votes of thanks having been passed to Messrs. Kirkby and Atkins, the meeting, which was well attended, was adjourned.

Halifax Photographic Club.

The annual meeting of this Club was held on Tuesday evening, the vice-president (Mr. W. C. Williams) taking the chair.

After the Secretary had read the minutes of last meeting held in June, the report was submitted, and showed a balance in hand of £3 14s. 7d., which was considered very satisfactory. Ten meetings of the Club had been held, and five papers read, with practical and experimental demonstrations; viz., "Emulsion Making" (two papers), Mr. John Smith; "Photo. Lens," Mr. W. C. Williams; "Photography, Past and Present," Mr. E. Gledhill; "Carbon Process," Mr. W. C. Williams.

The intervening meetings had been devoted to discussion on the various incidents, experiments, successes, and disappointments photographers—more especially amateurs—are heirs to.

The election of officers for the next session then took place, and after thanks for their past services, the following gentlemen were reelected:—

President—Captain J. B. Holroyd.

Vice-Presidents—Mr. T. Birtwhistle and Mr. W. C. Williams.

Treasurer—Mr. W. H. Bulmer.

Secretary—Mr. E. Gledhill, 15, New Bond Street, Halifax.

It was then resolved that an exhibition of work of the past and succeeding years should be held, and that in future three orders of competition, and three prizes in each order, should be given for the best photographs, &c., the exhibition to be held in the first week in January, 1883, at which exhibits from optical and photographic instrument makers will be gladly received.

The following papers were then promised:—Mr. Williams, on "Photo. Enlargements;" Mr. Illingworth, "Emulsion Making," and also "A Test on Exposure of Photo. Plates." Mr. Jones, who also promised a paper, then showed instantaneous prints of Scarboro', Filey, and the late Agricultural Show.

Mr. E. Gledhill showed thirty stereo prints of Scotland, Ireland, Bedford, and Buckinghamshire, taken during the last month.

Talk in the Studio.

The Late Dr. Van Monckhoven.—The photographic world will learn with deep regret the death of Dr. Desiré Charles Emanual Van Monckhoven, which took place on the 25th ult., at Ghent. Dr. Van Monckhoven was in his forty-eighth year, having been born in 1834, and during a busy lifetime had occupied himself with well-nigh every branch of photography. Thirteen years ago he occupied himself a great deal with enlarging apparatus, and it will be remembered that in 1869 he came to this country and read a paper before the Photographic Society, "On a New Artificial Light Suitable for the Production of Photographic Enlargements." His light was a species of oxy-hydrogen lamp, and was adopted by several gentlemen in this country. Afterwards Dr. Van Monckhoven proceeded to Vienna, when he entered into partnership with Herr Rabending, a firm much noted for its fine cabinet pictures. The partnership lasted, however, but a short time, and Dr. Van Monckhoven returned to Belgium, where he occupied himself jointly with photo-spectroscopic research, and in the manufacture of photographic requisites. He applied himself with some success to the preparation of carbon tissue, and of late the production of gelatine plates engrossed much of his attention. Indeed, he was for a long time the most successful Continental manufacturer of gelatino-bromide, the Monckhoven plates acquiring a high reputation. He steadfastly recommended the employment of the ferrous oxalate developer, and it is due to his teaching in a great measure that ferrous oxalate is so much in favour with our Continental brethren. Dr. Van Monckhoven was a most energetic photographic chemist, and it is some consolation to know that of late years his labours were successful in placing him in affluent circumstances.

Crayons in Vitrifiable Colours.—A French publication says:—"M. Lacroix, a Parisian chemist, has introduced crayons similar to the ordinary lead pencils, the lead being replaced by vitrifiable colours. The coloured designs which are executed with these crayons, on slightly roughened glass, bear the heat of a muffle, and are fixed like a painting upon glass; the greys especially give excellent results. A similar process which was tried upon porcelain some years ago was unsuccessful, probably because enamelled surfaces were used. On biscuit it is likely that good results might have been obtained." We happen to know, however, that Mr. F. J. Emery, of Burslem, who exhibited such an interesting series of photo-engraved copper plates at the last meeting of the Photographic Club, manufactured and patented crayons of a similar kind more than sixteen years ago; and excellent work was done on biscuit plaques with Mr. Emery's crayons. In the laboratory we have used these crayons for marking crucibles and other vessels of a similar nature. It is strange that M. Lacroix should be so much behind the time with his invention.

A Mathematical Calculation.—Miss Fanny Davenport is said to be the "most photographed" in America, as Mrs. Langtry is undoubtedly the "most photographed" lady in this country. Messrs. W. and D. Downey have now, it appears, taken a picture of the pair together, thus producing a mathematical problem, to be worked out by multiplying into one another the two "most photographed" English-speaking individuals.

Photographic Instruction at Liverpool.—We note that on Tuesday last (3rd October) a weekly class for photographic instruction assembled under the superintendence of Mr. Edwin Banks, at 9, Hackin's Hey, Liverpool. The course is to be thoroughly practical as well as theoretical, and deserves, therefore, to be well supported; we feel sure that if a similar undertaking were commenced in the metropolis, there would be many glad to avail themselves of it.

The Photographic Money Dispute.—At Clerkenwell, Captain Herbert Kerr, late of the 17th Regiment of Foot, of 22, Bushey Place, Clarendon Road, Hampstead, appeared on an adjourned summons to answer the complaint of Lieutenant Arthur Henry Loring, R.N., of Montague Place, Portman Square, of having, on April 20th last, he being managing director of the Photographic Artists' Co-operative Supply Association, obtained from him by fraudulent pretences the sum of £2,074, with intent to defraud. Mr. Besley appeared for the prosecution, and Mr. Grain for the defence. The latter gentleman proceeded with his cross-examination of the prosecutor. Mr. Arthur Vandeleur, an accountant, who had been bookkeeper of the company, was also examined, and said there was a balance due to the defendant at the beginning of 1881 of £2,000 odd, but that entered in the book as due to him on January 1st, 1882, was £1,400 odd. So far as he knew, that did not include any salary. Mr. Hosack further adjourned the hearing for a week.

"Truth" on Illustrations.—If, as *Truth*, says, the merit of illustrated papers is in proportion to their accuracy, we may speedily hope for the appearance of camera sketches or photo-engravings therein. Here is a piece of sharp criticism. "The aim of illustrated newspapers ought to be to give pictorial realisations of passing events. Their merit is in proportion to their accuracy. Of late they have, however, taken to fancy sketches. In this week's *Illustrated News* there is a huge drawing of the battle of Tel-el-Kebir, 'from sketches by our special artists.' It represents a number of our soldiers fighting with Egyptian soldiers on the earthworks. There is no smoke, in order that the faces of the warriors may be distinguished. The men are all crowded together. An English officer points his revolver at an Egyptian officer of singularly mild appearance, who replies by offering him the handle of his sword. Behind him, on a horse that is wedged in, is another Egyptian officer, endeavouring to conceal his head in his shoulders, and with his sword almost falling from his hand. In the foreground is a black soldier. He has a musket with a bayonet fixed to it, firmly grasped. The bayonet of one invading Briton is already stuck in his breast, and the end of another bayonet is a few inches off. The black man seems to like being spitted. He does not drop his musket—he does not parry—he does not fall, and he does not apparently even perceive that he is in danger; but he fiercely, and with grim determination, attacks some sand-bags. I should like to know where and when 'our special artists' drew the sketches from which this remarkable battle scene is drawn. Anything more silly—indeed, more absurd—I never gazed on."

Experiments with the Heliograph.—A detachment of nineteen men of the Sixth Cavalry and Twelfth Infantry, near Fort Grant, Arizona, under command of First Lieutenant M. P. Mans, First Infantry, has been testing the practicability of heliographic signalling since July 1, and it is pronounced a grand success. Lieutenant Mans has signalled messages from the top of Dos Cabezas Mountain to Fort Grant, a distance of forty miles, which were read at once by his party at Grant. Messages can be sent with the heliograph at the rate of from six to twelve words per minute, according to the ability of the operator, and it is a splendid substitute for the telegraph, should the Indians cut the lines, which they have been doing, and always can do, when on the war-path, while they cannot cut a sun flash. It is understood that heliograph lines are about to be established by Lieutenant Mans, and partly under direction of Colonel Bracket, commanding scouting operations connecting Bowie, Grant, Thomas, Apache, and points along the Gila River, in the vicinity of Solomonville and Clifton, enabling troops in the field to be in constant communication with one another, without waiting for couriers or the proximity of a telegraph office. The signalmen, on account of their elevated positions, are enabled to observe with their glasses the movements of the hostiles, and in a few minutes to communicate it to any command in the field, each of which is always to be accompanied by one or two heliographic signalmen. The great advantages of this system of transmitting messages in a mountainous and hostile country are self-evident.

Manufacture of Iodine in Peru.—The British Institution of Civil Engineers has just published a brief paper by Mr. Robert Harvey, of Tarapacá, Peru, descriptive of the method and plant used by him in manufacturing iodine from the mother liquor of the refining of nitrate of soda. This *aqua vieja*, or mother liquor, at the works in question, contains 28 per cent. of nitrate of soda, 11 per cent. of chloride of sodium, 3 per cent. of sulphate of soda, 3 per cent. of sulphate of magnesia, 22 per cent. of iodate of soda, and 33 per cent. of water. It is run into precipitators of lead-lined wooden tanks, which are provided with wings or fans for agitating the liquor by hand power. The precipitant consists of acid sulphite of soda, formed by saturating the aqueous solution of saleratus or impure carbonate of soda with fumes of burning sulphur. It contains an excess of sulphurous acid. The agitation of the liquor causes a part of the precipitated iodine to fall to the bottom, while some of it rises to the surface. The latter skimmed off, the iodine is put into clarifying tanks and washed with water, while the mother liquor is returned to the nitrate of soda department, when it is again used and again becomes impregnated with iodine. The washed iodine is partially dried in a filter-press, and is then pressed into forms eight inches in diameter and six inches thick. These cakes of crude iodine, containing from 80 to 85 per cent. of iodine and from 6 to 10 per cent. of non-volatile matter, are subjected to sublimation in a cast-iron retort, to which are attached eight earthenware receivers, each 3 feet long by 2·5 feet in diameter. The cost of the plant, drawings of which are given in the original paper, was $23,000, Chilian currency. It produced in two months 7,560 pounds of sublimated iodine.—*Engineering and Mining Journal.*

To Correspondents.

E. Dubois.—In by far the greater number of cases white is decidedly best, but the pink and mauve papers may occasionally be used with advantage. Very often these are tinted with colours so fugitive that a few weeks' exposure in a shop window will serve to bleach the colour.

A. A. Campbell Swinton.—Becquerel's treatise on light contains the information you require; but little has been done in recent times.

Godfrey C. Harkness.—Do not attempt to photograph them direct, but make plaster casts, and work from these. A trace of rose-pink may be added to the plaster with advantage.

B. Hannah.—1. The design round the photograph can be registered, but this will not in any way prevent other persons building up something of a similar character. You can, however, patent the general method of working, and if no one has done anything of the kind previously, your patent will be valid. 2. We can see no connection between them.

M. Stinton.—There is no way of preventing it in the case of albumenized paper; but if you use plain salted paper, the difficulty will not arise.

M. D. Jones.—There is nothing of the kind at present, but we hope that something may be organised. See paragraph in "Talk."

Studio.—The inside of the loaf, not the crust.

Mr. A. Ram (India).—Subscription duly received.

T. W.—Our Year-Book for 1882 has been out of print for over three months.

W. W.—Next week.

R. M. G.—It is obviously a matter for private arrangement, and if we were to do as you suggest, much unpleasant and personal discussion would be likely to arise.

Carl Kammerhauer.—The addition of a small proportion of chrome alum is advantageous in most cases, but the proportion must depend altogether on the quality of the gelatine and the season of the year. We have found it convenient to keep a twenty-grain solution of chrome alum in stock, and to add more or less of this as indicated by circumstances. When a plate shows signs of softness, you may moisten it with the standard solution of chrome diluted with a tenfold quantity of water, and allow it to become nearly dry before working from it. 2. We only know of one collotypic power press which has been used commercially in this country, and we believe that it could now be bought for a little over the price of old iron. There is certainly a strange lack of enterprise as regards this matter.

Vera.—1. Rather use the former, as only one-sixth of the exposure will be required. 2. Add enough of an alcoholic solution of iodine to give the fluid a pale sherry colour. 3. Ordinarily on a quarter-plate, or a glass $3\frac{1}{4}$ inches square. 4. It contains nothing but carbon, hydrogen, and oxygen. 5. A simple solution of shellac in alcohol will answer very well, and you had better shake up with a little dry kaolin and allow it to settle before using it. 6. Yes, a waxy constituent insoluble in alcohol.

C. Brookland.—Hardly good enough for commercial work. Study Major Waterhouse's articles on photo-lithography.

F. Stolt.—The markings are probably due to floating particles in the bath. Filter carefully through clean white blotting-paper

Master Builder.—We cannot imagine that you have any power to prevent the circulation or sale of the pictures. If it were otherwise, no street view could be sold without obtaining an authority from a large number of persons.

C. J. Timmins.—The gelatine you have been using is of far too soft a quality. Try the effect of replacing one half of it by the gold label gelatine of Coignet.

Iron.—1. There is no advantage in increasing the strength under the circumstances; indeed, you might reduce it somewhat. 2. Not at present.

PHOTOGRAPHS REGISTERED.

Messrs. Adams & Stilliard (Southampton)—Photos. of Sir Wm. Thomson and Dr. Acland.

Messrs. J. & A. McLeod (Newark)—Photos. of Mr. W. E. Gladstone, and Mr. and Mrs. Gladstone.

Mr. H. Robins (Landport, Hants)—Photos. of H.M.S. *Serapis*, *Jumna* and *Bacchante*.

Mr. Henges (Lytham)—Photo. of Ascent of Balloon, "The Colonel," at Preston Guild, 1882.

Mr. J. Shannon (Rawtenstall)—Four Photos. of late Mr. Thomas Kay Whitehead.

Mr. J. Whittaker (Oswaldtwhistle)—Photo. of Rev. Geo. H. Smith.

Mr. E. A. Maxwell (Barnet)—Photo. of Group, including Photographer.

Mr. W. Watts (Staines)—Photo. of Tomb of Miss Byng, designed and given by H R.H. Princess Royal.

Mr. W. V. Amey (Landport)—Photo. of Coombes and Co.'s Establishment.

Mr. J. D. Hannah (Shrewsbury)—Eight Photos. of Bishop Crowther.

Messrs. W. Norman & Sons (Haltwhistle)—Three Photos. of Featherstone Castle, one Photo. of Lambley Viaduct.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water $1\frac{1}{2}$ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water $\frac{1}{2}$ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add $\frac{3}{4}$ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia $1\frac{1}{2}$ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge $\frac{1}{4}$-oz., liquid ammonia $\frac{1}{2}$-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol $\frac{1}{2}$ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron $\frac{1}{2}$ oz., glacial acetic acid $\frac{1}{2}$ oz., alcohol $\frac{3}{4}$ oz. The amount of proto-sulphate iron may be diminished to $\frac{1}{4}$ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to $\frac{1}{4}$ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. $\frac{1}{2}$ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash $1\frac{1}{4}$ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash $\frac{1}{2}$ oz., gelatine $2\frac{1}{2}$ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz.; dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1258.—October 13, 1882.

CONTENTS.

THE PHOTOGRAPHIC EXHIBITION.

Whatever the opinion entertained as to the progress of our art in recent years, certainly there is a marked increase in the interest taken in the practice of photography. For some time past it has been evident that the Gallery at Pall Mall, spacious as it is, would soon be all too small to contain the gathering which, year by year, has attended the opening *soirée* in increasing numbers; and on Saturday evening last, about nine o'clock, when the atteudance of visitors was greatest, there was neither moving room nor breathing room to spare. Every attractive picture on the walls caused a dead block, and at one period of the evening the only "loose" space was towards the centre of the hall. To convoy a visitor from one end of the room to the other, in order to point out a noteworthy exhibit, was at once a task of patience and difficulty, while even with the aid of a catalogue it required no small enterprize to search out any given picture.

It is so seldom that the hanging committee and a jury of awards obtain anything beyond a grudging word of thauks, that we cannot help expressing a belief that on this occasion there has been less dissatisfaction expressed on their shortcomings than for some years past. The "horizon-line" is certainly lower this year than last, and if a little more discretion still as to the keeping back of works below mediocrity were exercised, it would be of considerable advantage to the Exhibition. The hard-working president, Mr. Glaisher, was as untiring as usual in his endeavours to make the Exhibition a success, and was present betimes at the *soirée* to welcome members and their friends. The hanging committee had completed their laborious task at an unusually early hour, and consequently plenty of time was at hand for the printing and issue of the catalogue; while by Saturday at noon, when the press critics were admitted, the green labels attached to the medal pictures showed that the awards had been duly considered and conferred.

Of the collection of pictures as a whole we must leave every visitor to form his own estimate. That it includes many charming and clever productions few will gainsay; but it is difficult to point to any pictures that indicate progress, either in the way of art or technical excellence. Indeed, to speak frankly, the Exhibition is curiously devoid of any surprises, aud seeing that we are still at the begining of the "new era," and have not yet fully developed "the new power" in our hands, it is not to be wondered at that many visitors on Saturday evening evinced disappointment. Whether there was any reason for it we do not pretend to say.

The medals bestowed were eleven in number, and, bowing with deference to the opinion of the gentlemen who made the selection, and of whose undoubted good faith and qualifications there can be no question, we shall begin by considering the works exhibited by the medallists. Taking these in alphabetical order—we will begin at the end of the alphabet for a change—they are Mr. Frank M. Sutcliffe, of Whitby; Mr. Henry Stevens, of Addleston Lodge, Surrey; Mr. Robert Slingsby, of Lincoln; Mr. H. P. Robinson, of Tunbridge Wells; Mr. Abel Lewis, of Douglas, Isle of Man; Mr. G. E. Horsey, of The Elms, Perry Hill, Catford; Mr. W. J. A. Grant (the Arctic explorer), of Cullompton, Devon; Mr. J. Gale, of Long Lane, Bermondsey; Mr. Adam Diston, of Leven, Fife; Messrs. John Chaffin and Sons, of Taunton; aud Messrs. W. J. Byrne and Co., of Richmond.

Mr. Frank Sutcliffe well earns his medal by a series of marine studies. There is a sadness and weirdness about many of the pictures—darkness falliug upon a lonesome fisherboat is a favorite subject—that approaches pathos; aud yet that Mr. Sutcliffe can thoroughly appreciate humour is evident from "Limpets" (67), which represents a couple of laughing fisher-lasses leaning against a wave-beaten bit of rock to which the tangled sea-weed clings. The life and gaiety of "Limpets" is no doubt heightened by contrast with other of Mr. Sutcliffe's pictures, none of which touch mediocrity. "Morning" (464) is au effective bit of lighting that young photographers will do well to study.

Mr. Henry Steveus is a large exhibitor, and takes his medal in that branch of photography which Mr. Frank Good and Mrs. Glen Payne have for some time past made their own, namely the depiction of flowers. Mr. Stevens' pictures are the embodiments of technical excellence, and denote high skill and tact in lighting and development. A tiger lily (323) is superb, and so, too, are orchids and pansies in china jar (325); whether it is a wax-like camelia or verdant maiden-hair fern, Mr. Stevens is equally successful in depicting them. He also shows in another part of the room some very good examples of portraiture.

Mr. Robert Slingsby's name among the medallists will be cordially welcomed. He exhibits several most excellent portraits, also one or two pleasing groups, such as "Brambling" (289), a group of youngsters out with mama blackberrying. But the picture for which Mr. Slingsby secures his medal is "Homeward" (239), an ambitious study, that bids fair to become as popular as the well-known "Alone." It is a twenty-inch picture, showing a three-quarter portrait of a girl, who with filled pitcher is returning homeward. The girl, if not handsome, is decidedly comely, and the pose of her figure is a most agreeable one. The draping, too, is graceful and artistic, the tone being smooth and even, while yet there is plenty of vigour. But the most pleasiug part about the picture is the contrast between figure and background, a grassy slope, fringed with trees; the shadows of the tall tree-trunks cast across the sun-lit landscape have a very telling effect; yet the whole is so soft and subdued, that, the sweet country scene notwithstanding, the eye is firmly rivetted upon the buxom damsel before us.

Mr. H. P. Robinson, of Tunbridge Wells, makes a brave show this year, and although his pictures are not so favourably hung as heretofore, they nevertheless set their mark upon the Exhibition. It must have been somewhat bewildering to a jury where to fix the green label bearing the word medal, for Mr. Robinson certainly sends half-a-dozen studies all of which are entitled to the distinction. "Wayside Gossip" (135), with the silver sunshine beaming through a wealth of foliage, a broad sheet of still water, and a picturesque group of wayfarers in the foreground, seems to have been the favoured one with the jury; but if "A Merry Tale" (128) had been hung a little lower, the verdict would probably have been different. The life and humour of this last have never been surpassed in photography; the interest of the story-teller and the effect of story on the different listeners—every countenance betraying humour, but in a different degree—from a tardy smile in the standing figure, to screaming delight in the recumbent model, who is lying back on the moss fairly overcome with laughter—make up together an *ensemble* which has the rare quality of being a picture complete in itself, with details, every one of which tells the spectator something. "Artist and Model" (133), again, is pregnant with humour—a rare quality hitherto in pictorial photographs—and so, too, is "Her Ladyship" (132), the groups lending an additional charm to the bright scenes of lake and woodland that no one renders so sweetly as Mr. Robinson. Another phase of this artist's work is shown in "Lady Mary" (241), a dainty miss in white ringlets and mittens, powder and patches, a belle of those days when our great grandmothers were belles; one can almost detect an odour of satinwood and lavender about the picture.

Mr. Abel Lewis, of the Isle of Man, sends only one frame of "Portrait Studies" (220) containing three pictures. Of these, the left-hand one is most to our liking—a little maid seated on a sofa in a most unconventional yet quiet and simple pose. Apparently quite unstudied, the portrait cannot fail to please; and the same may be said of the right-hand picture, where we have the same little woman standing with violin in hand at the "attaque." The draping and lighting of these are most effective. The central picture is not quite so successful, the two little girls taking little interest apparently in the butterfly on the window pane which occupies so prominent a position.

The medal given to Mr. Horsey, of the Elms, Catford, is awarded for a series of harvesting sketches, several of which indicate high ability on the part of the photographer. The reapers at work in "Near Betchworth" (60), standing in the half-cut cornfield, is a delightful photograph, with the waving crop beyond; and so, too, is "Near Shere," also a harvest picture, in which a group of stately trees are seen, their soft shadowy foliage bordering the rich cornfield, and affording a delightful contrast to the dark sheaves in the foreground.

Mr. W. J. A. Grant sends several frames, including some fine studies of trees and animals; but the medal is awarded to him for a collection of Arctic pictures taken on board the ill-fated *Eira*, in 1880. "The *Eira* anchored off a floe at Spitzbergen," and another picture showing "Furthest point reached," where a massive crust of translucent ice bars all further progress of the ship, are rare examples of Polar scenery; the still, limpid water bearing aloft huge frozen bergs, the stretches of desolate ice-bound coast, the streaming glaciers of congealed snow and ice, their glittering masses in high contrast with the black rocks that surround them—all these features of the frozen deep, Mr. Grant depicts as no other Arctic traveller has yet shown them to us.

It is no surprise to find Mr. Gale again among the medallists. His work is always refined and artistic, and this year he has imparted life into many of his pictures by including in them groups of fisher folk and cottagers. "Cornish Fishermen" (309), and "A Doorway Group at St. Ives" (308), are excellent little pictures. Mr. Gale has been visiting the Cornish coast, and has gathered a whole string of pearls; here is "Polpero" (221), the quaint little fisher village, renowned for its smugglers, where passes the action of Mrs. Parr's delightful novel "Adam and Eve;" here is a little sketch from Newlyn (359), the fishertown beyond Penzance; and here a "Caul of Pilchards" (293). Mr. Gale has earned his medal well.

A solitary picture comes from Mr. Diston, of Leven, but it has found favour in the eyes of jurors, and receives a medal. It is entitled "Gloміn" (391), and contains just that "touch of nature" which is so difficult to realise in a picture. In a humble cottage, a solitary old woman seared by time and bent with years busies herself over a lamp which she is about to trim and light; it is, in truth, eventide with her. Mr. Diston has produced many more ambitious works, but never one so full of pathos and meaning.

Messrs. Chaffin and Sons, of Taunton, are also among that small number who desire that photography shall reflect something more than a pretty face or a bright landscape, and if they are not always successful in carrying out an idea, it is not for want of trying. "Cherry Ripe" (231) gives Messrs. Chaffin their medal; two ladies in a garden are regaling themselves with cherries, thrown to them by a neighbour who is seen above the wall. But there is more ambitious work in "Sisterly Intercession" (240), which is very near a big success. A lady kneels at the feet of her father; the latter, with his hard unforgiving expression, is very well conceived and represented, and so, too, is the sister on her knees. The weak point is in the standing figure of a man, who stands by awaiting the result of the intercession; it would have been better, we think, to have placed the last more in shadow, say at a half-opened door.

Messrs. Byrne and Co. of Richmond, secure their medals with a frame of panel portraits (182) representing children. The collection includes some very good work, and the work, moreover, possesses qualities which, unfortunately, are rare in gelatine plates. Brightness and brilliancy are the characteristics of Messrs. Byrne's pictures, and it would be well if our portraitists would give up a little of the monotonous softness so often seen in these days of gelatine, to attain these desirable results. We do not say that Messrs. Byrne's pictures in this respect have our unqualified approval, for in some instances the high lights are too extensive to please us; still, briliancy is now-a-days not so often met with in portraiture as in the collodion days.

Mr. Payne Jennings' work was "not for competition," and therefore had no chance for a medal. Mr. Jennings, indeed, only sends three pictures, but they fully sustain his high reputation as a sun-painter of landscapes. A shadowy pathway beside a pebbly stream (436) is a delightful scene, and so, too, is a group of graceful trees, their trunks in deep shadow, through which the sun-lit water beyond sparkles with all the merriment of summer. We desire, too, in this first notice to mention the pictures of the two other exhibitors whose work we consider of a very high order. The first is a "Misty Morning on the Wear" (23), by Mr. McLeish, of Northgate, Darlington, which, on the score of its beauty, no less than its originality, deserves high commendation. The graceful boughs of a tree, its supple twigs and delicate foliage sharply limned, compose an artistic foreground, beyond which, clothed in the silvery mist, is seen the magnificent pile of Durham Cathedral. There is no middle distance; we see simply the grand proportions of the north country cathedral in a most delightful and tasteful setting. The other exhibit to which we desire to call special attention is the frame of lake pictures by Mr. Alfred Pettit, of Keswick (52). These sweet sketches from our English lakeland are superb, the two central pictures representing very fine work indeed. The soft, shadowy hills, the placid water, the dappled sunshine, all exhibit rare taste and exquisite skill on the part of the artist.

Next week we propose to consider the exhibition in detail, but meanwhile append a complete list of exhibitors.

Captain W. de W. Abney, 3, St. Alban's Road, Kensington, W.; Messrs. Adams and Stilliard, Southampton; Mr. W. Adcock, Melton Mowbray; Mr. G. E. Alder, Croydon; Mr. Charles Andrea, Clapham Common; The Autotype Company, 74, New Oxford Street; the Rev. W. Barlee, Norwich; Mr. F. Beasley, jun., 30, Hamilton Terrace, N.W.; Mr. W. John Belton, 26, St. Paul's Crescent, Camden Square, N.W.; Mr. L. Berry, Chorley; Mr. F. Bills, 8, Peckham Grove, Camberwell; Mr. J. W. Boord, M.P., 14, Berkeley Square; Mr. Julius Braats, Stettin; Mr. J. A. C. Branfill, 137, Chadwick Road, Peckham; Mr. Edward Brightman, Redland House, Bristol; Mr. J. Milman Brown, Shanklin, Isle of Wight; Mr. T. M. Brownrigg, Artington House, Guildford; Mr. George Bruce, Dunse, N.B.; Mr. Peter Burges, The Ridge, Chipping Sodbury; Mr. W. K. Burton, Adelphi Chambers, 7, John Street, W.C.; Messrs. W. J. Byrne and Co., Richmond; Mr. J. S. Catford, Ilfracombe; Messrs. John Chaffin and Sons, Taunton; Mr. Archer Clarke, 8, Plough Lane, W.; Mr. Seymour Conway, Inglecroft, Beckenham, Kent; Mr. G. Christopher Davies, Orwell House, Town Close, Norwich; Mr. W. Davies, Rose Villa Studio, Greaves Street, Ripley, Derby; Messrs. E. Day and Son, Bournemouth; Mr. Arthur Debenham, 28, Union Street, Ryde; Mr. W. E. Debenham, 158, Regent Street; Mr. George F. Dew, Norton Street, Coventry; Mr. Adam Diston, Leven, Fife; Messrs. Henry and T. J. Dixon, 112, Albany Road, Regent's Park, N.W.; Mr. W. F. Donkin, Malvern Lodge, Upper Tulse Hill; Mr. F. Downer, Watford; Mr. John Duncuft; Mr. Edward Dunmore, 28, Oseney Crescent, Camden Road; Mr. G. Selwyn Edwards, Crick Road, Oxford; Mr. B. J. Edwards, The Grove, Hackney; Mr. P. H. Emerson, 4, Park Side, Cambridge; Mr. Robert Faulkner, 21, Baker Street; Mr. C. A. Ferneley, Reigate; Mr. Edward Fox, 44, Market Street, Brighton; Mr. Joseph Gale, 225, Long Lane, Bermondsey; Mr. G. T. Garrett, 60, Doughty Street, Mecklenburgh Square; Mr. J. T. Glossop, Silver Hall, Isleworth; Mr. Ernest H. Goold, 4, Danes Inn, Strand, W.C.; Mr. W. J. A. Grant, Hillersdon, Cullompton, Devonshire; Mr. David Green, 39, Circus Road, St. John's Wood; Major J. E. Gubbins, R.A., Yarmouth, Isle of Wight; Mr. R. V. Harman, Bromley, Kent; Mr. Robert Harris, Port Elizabeth, South Africa; Messrs. Heath and Bullingham, 24, George Street, Plymouth; Mr. Alfred Hendry, Godmanchester; Mr. T. C. Hepworth, 32, Cantlowes Road, Camden Square; Mr. J. B. Hilditch, Asgill House, Richmond; Mr. W. J. Hollebone, Linwood, St. John's Road, Putney Hill; Mr. Fred. Hollyer, 9, Pembroke Square, Kensington; Mr. S. G. Hooker, Sevenoaks, Kent; Mr. John G. Horsey, The Elms, Perry Hill, Catford, Kent; Mr. J. Hubert, 39, Lauriston Road, South Hackney; Mr. Edmund Hyde, Hill Crest, Castle Bar, Ealing; Mr. D. Ireland, Jun., Rockhill, Broughton Ferry, Dundee; Mr. Payne Jennings, Elm Grove, Rosendale Road, West Dulwich; Mr. A. Johnson, Wick; Mr. J. A. Kay, 160, St. George's Road, Bolton; Mr. H. N. King, 4, Avenue Road Villas, Goldhawk Road; Messrs. W. J. Lancaster and Sons, Colmore Row, Birmingham; Mr. J. A. Langton, 309, Euston Road, N.W.; Mr. Charles R. Lenthall, Wray Park Studio, Reigate; Mr Abel Lewis, Douglas, Isle of Man; Messrs. Lombardi and Co., 13, Pall Mall East; Mr. Fred. G. Lupson, 9, Church Street, Stoke Newington; Mr. H. Manfield, Campbell Square, Northampton; Mr. W. P. Marsh, Bognor; Mr. Peter Mawdesley, 363, Portobello Road, Notting Hill; Mr. E. A. Maxwell, Barnet; Mr. McLanagan, Douglas, Isle of Man; Mr. W. McLeish, 71, Northgate, Darlington; Mr. McLellan, Glasgow; Military School, School of Engineering, Chatham; Messrs. Morgan and Kidd, Greenwich; Mr. William Muller, 194, Aldersgate Street; Mr. Arthur H. Mure, Hill House, Greenhill Road, Hampstead; Messrs. Murray and Heath, Jermyn Street, W.; Mr. John Nesbit, 18, Lancaster Road, Finsbury Park; Messrs. Neustadt and Co., 25, Mincing Lane; Mr. Simeon Norman, Burgess Hill; Mr. Joseph Paget, Stuffynwood, Mansfield, Notts; Mr. C. J. Palmer, Harrow, Paddington; Mr. E. R. Palmer, Lawn House, 135, Dulwich Road, S.E.; Mr. Silvester Parry, The Cathedral Studios, Chester; Mrs. S. Glen Payne, Aylesbury; Mr. S. Glen Payne, Aylesbury; Mr. Alfred Pettitt, Keswick; Mr. W. H. Plaster, M.R.C.S., F.R.G.S., Pembury, Tottenham; Mr. H. Waterhouse Pope, West Holme, Alderley Edge; Mr. Andrew Pringle, Craigcleuch, Langholm, N.B.; Mr. Clive F. Pritchard, 2, Alwyne Place, Canonbury; Mr. Charles Reid, Wishaw, N.B.; Mr. George Renwick, 20, Station Street, Burton-on-Trent; Mr. J. H. Ritchie, Cedar Band, Hyde Vale, Greenwich; Mr. H. P. Robinson, Tunbridge Wells; Mr. J. B. Robinson, Jun., 6, Gladstone Terrace, Gateshead; Mr. W. D. Saunderson, Dean's Gate, Manchester; Mr. Frederick S. Schwabe; The Sciopticon Co., 26, Colebrook Row, N.; Mons. Emil Seelig, 6, Standplatz, Cassel; Mr. Cecil V. Shadbolt, Beechcroft, Chislehurst; Messrs. Shew and Co., 89, Newman Street; Messrs. Skill Bros., 62, Vail Gate, Lincoln; Mr. Robert Slingsby, Lincoln; Mr. Arnold Spiller, 2, St. Mary's Road, Canonbury; Mr. H. Stanley, Spital Street, Guildford; Mr. C. S. Stephens, 8, Woodley Hill, Early, Reading; Mr. Henry Stephens, Addleston Lodge, Addleston, Surrey; Mr. F. M. Sutcliffe, Whitby; Mr. A. Bisset Thom, 49, Torrington Square; Mr. John M. Thompson, King's College; Mr. F. Thurston, Luton; Mr. W. Trenemen, 7, Great Sutton Street, Goswell Road; Mr. George Tuohy, Richmond; Mr. W. Wainwright, Jun., Hoe Place, Woking; Messrs. Watson and Sons, 313, High Holborn; Mr. John Werge, 11A, Berners Street, Oxford Street; Messrs. G. West and Sons, 97, High Street, Gosport; Mr. H. E. White, Tangier, Africa; Mr. G. Sydney Whitfield, 14, Sandringham Gardens, Ealing, W.; Mr. Matthew Whiting, Lavender Hill, Wandsworth; Mr. Charles F. Wing, Tunbridge Wells; Mr. H. Trueman Wood, Society of Arts, Adelphi; The Woodbury Co., 157, Great Portland Street; Mr. Alfred Youngman, Sidcup, Kent.

DR. SZEKELY'S METHOD OF PREPARING GELATINO-BROMIDE WITHOUT WASHING.

The late Dr. Van Monckhoven, it may be remembered, published a method of preparing gelatine emulsion without washing. He dissolved carbonate of silver in hydrobromic acid, and thus prepared his silver bromide; unfortunately, the resulting emulsion generally contained the silver particles in a coarse and unsatisfactory condition.

Dr. Szekely has proposed another plan of working. He precipitates nitrate of silver with carbonate of soda, washes the residue with water, and then dissolves it in ammonia. The solution of silver thus obtained he adds to warm gelatine, with which a soluble bromide has previously been mixed, and digests the whole at a temperature of 40° C., or 86° Fahrenheit. The resulting emulsion is at first rather insensitive, but after a few hours, this quality rapidly improves, and in the end a product is at hand endowed with a high degree of sensitiveness. The ripening of the emulsion is slower than in the case of ammonio-nitrate of silver.

The emulsion of Dr. Szekely is applied to the glass plate without undergoing any process of washing, and gives vigorous negatives free from fog. But it is found that if the emulsion is permitted to remain warm for too long a time, fogged plates are the result.

It is a remarkable point in the process, that emulsion produced in this way does not stand washing very well. If the preparation is treated with water, the particles of bromide of silver, curiously enough, become coarse, notwithstanding the circumstance that the emulsion is in a set condition, or in the form of jelly. Negatives produced with the washed emulsion exhibit a granular character of a decidedly objectionable nature.

ALUM AND CHROME ALUM IN THE DEVELOPER.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.

It has been so often asserted as to almost have become an axiom, that alum destroys the photographic image when applied to gelatine plates. Now, on no theoretical grounds should this be the case, and for that reason I had always intended to try its action, or, rather, to investigate the cause of its refusing to allow the development of an image. In all my experiments, plates were exposed behind a negative to obtain a developable image. My first trial was to place the exposed plate in the alum bath for five minutes, and then, after a wash, to develop with ferrous-oxalate developer. My astonishment was great to find that not only was there no destruction of the image, but, on the contrary, an increased rapidity of development, and a denser image than usual. Here, then, was a plate seemingly behaving quite contrary to all established rules. It ought to have refused to develop at all, according to what we have so often read in the journals. A second plate was then taken, and half of it immersed in a cell containing a saturated solution of alum, and left for a quarter of an hour, after which, without washing, it was placed in a dish, and ferrous oxalate developer applied. Here we had the result that the print immersed in the alum showed more detail and was denser than the other half. It struck me that this might be due to the soaking of the film first, and thus allowing the developer more ready access to the image, as I have already shown is the case in dry and warm weather. A parallel experiment made with pure water seems to have almost confirmed the idea.

Treating a plate, however, with ferrous oxalate was not everything; the alkaline developer remained to be tried. A plate was exposed and placed in the alum as before, with the result that the half which had been placed in the alum solution *refused to show the least signs of any image whatever.* Here, then, we meet with the phenomenon described by so many photographers, who, finding no image appearing on application of the developer, naturally conclude that the image is destroyed. It certainly looked very much as if such were the case, and yet when ferrous oxalate was employed the image remained intact. The question then arose as to whether the alkaline developer plus the alum had not destroyed the image. How was this to be ascertained?

Taking the plate the half of which had been developed by the alkaline developer, and the other half of which was blank—the blank being caused by the alum—it was washed under the tap, and again placed in the alum bath, and left for five minutes. It was then taken straight to the dish containing ferrous-oxalate, and watched. The image rapidly appeared on the blank space, and after a couple of minutes nearly caught up in density the half already developed, though it, too, increased in intensity. This demonstrated the fact that alum is no destroyer of the image, neither is alum plus the alkaline developer, and theory again was proved to be right.

The same series of experiments were conducted with chrome alum instead of alum, with precisely the same results, excepting so far I am inclined to think that density was given to the image by its use with ferrous-oxalate. This will form the subject of more deliberate experiment before it can be seriously announced as a fact.

The question arises as to what is the cause of this remarkable difference in the behaviour of the two developers, and here, for the moment, I do not wish to commit myself. One thing we know, that alum is acted on by ammonia; but even when the solution was strong with ammonia, and after thorough washing, the same result was found to hold good. Hydrokinone behaved like pyrogallic acid, and both are complex organic bodies, with which alum might form a compound. Whether it is that the gelatine is altered in character, or what, I am not certain; but most probably a more simple explanation will be found for its behaviour. Be the cause what it may, the facts remain, and whether they may prove to be of use where plates which frill are to be developed, remains to be seen. One fact that should be noticed is, that the brown dye which shows so markedly when no sulphite is used with the pyrogallic acid disappears entirely when the ferrous-oxalate is applied to the washed image; in fact, the deposited silver is similar in character to that obtained by using the ferrous-oxalate alone. This, too, may be of use, and I hope photographers will not grudge the time to look into the matter.

THE DECORATION OF POTTERY BY PHOTOGRAPHY.

BY F. J. EMERY.*

I was last night privileged to be present at the weekly meeting of the Photographic Club. I had, indeed, left home specially to avail myself of the opportunity, and with the object of proposing a comparatively new departure in photography to gentlemen who, guided by the laborious researches of their predecessors in the art of photography, have, so to speak, put the "bit" in the mouth of the great Sun itself. I say "comparatively," because, although photography has been applied to pottery, it has generally, I think, been confined to the production of works of advanced art.

It will at the outset be desirable, for the better understanding of each other, that I attempt to do for you in five minutes what I have failed to do for myself in thirty years, and that is, to make you accomplished potters. I will endeavour to convey my lesson in narrative form—one that I engage shall have as much truth in it as the famous story of the willow-pattern plate, while it shall convey an eminently salutary moral.

Know, then, that "once upon a time," there were two earthen vessels, both made of the same clay, and both fashioned on the same wheel. The curves and lines of both differed only in degree, and yet the fancy of the thrower had destined them to very different ends; for the sloping shoulders and slim form of the one clearly indicated an easy future, while the matter-of-fact proportions of the other as clearly shadowed a bustling, busy existence. They went through the same training at the hands of the turner, were fitted with the necessary appendages by the handler, and together had mutually "a very warm time of it" preparatory to their emerging from the saggar in the biscuit stage of life. But here their companionship came to an end—the vase to go into the hands of an artist of note, there to receive the direct impress of genius, and in due time to find an honoured retreat at South Kensington.

As a maker of every-day crockery my sympathy goes with the companion of the vase—the homely teapot. Remembering that the biscuit of the vase is no more susceptible of tender impression than the humble teapot, it is no matter of wonderment that, even with a foreknowledge of its ultimate retreat being the ash-pit, it yearned for at least a modest adornment. To be brief, it coveted the engraved design of a copperplate. The prospect of this ambition being achieved was not promising, for nothing could well exceed the rigidity of the teapot nature, while it was perfectly certain that the copper would never accommodate itself to the curved whim of the thrower. At last a go-between was found in a sheet of tissue paper, which was not above accommodating itself to the curvature of crock. Mark, however, how its good-nature was rewarded. No sooner did the teapot find itself decorated with the coveted design, than, remembering that further companionship with the paper would militate against the acquiring of that lustrous covering which was necessary to fit her for the world, she availed herself of the knowledge of an old standing feud between oil and water, and, plunging herself into a bath of the latter, got rid for ever of the simple-hearted tissue to which she owed the success of her scheme for self-advancement. Moral: Could anything be more human?

Forgetting that moral as though it never existed, I propose the industry which I presume to represent shall be the teapot, your art the copperplate, and I myself the paper, premising that the courtesy with which I have been received last night and to-night is the return for my interposition; for if any of you think well to experiment in the direction I shall indicate, you will always find me ready to bring your experiments to a practical test.

I would here observe that, had I anticipated the kindly interest which manifested itself last night at the Photographic Club, and which has led to this courteous invitation to appear before you this evening, I would have been at some trouble to prepare a paper worthy of your kindness, and illustrated by examples much more complete than those which I am able to put before you to-night. You are doubtless aware that the exports of our staple to lands beyond sea are very extensive—notably to North America. Up to forty years ago, the demand for pottery consisted mainly of printed and common goods. About the time indicated there came a change in taste, the printed goods giving place to a superior white ware. Consequent on this, an important artistic department of our business suffered considerably. Able men found their profession waning, and abandoned it for other pursuits. No apprentices (or scarcely any) were put to pottery engraving, and consequently it is not at all surprising

* A communication to the South London Photographic Society.

that, both in quantity and in quality, the engravings for potters' use have seriously fallen off. And yet our potteries' district has furnished the art-world with some of its best men, among whom may be honourably mentioned Greatbach, Lightfoot, and notably Bourne.

As an evidence of what has been done for pottery I call your attention to an engraving by Mr. William Bourne, of Fenton, which is so delicate and artistic, as almost to be too good for the necessarily rough usage of the pottery printer. I also show an impression from a copper engraved some years back, and beneath it another average modern one, in which the decadence is painfully apparent.

Anticipating a possible return of the demand for printed pottery, and foreseeing that in that event the demand for skilled work would exceed the supply, I have for years looked to your profession to supply the want. I, therefore, as closely as my opportunities allowed, watched the wonderful progress which photography was making; and a further study of the subject has enabled me to prosecute my experiments to a point which has warranted my asking for protection of a modification of the Niépce bitumen process, specimen of which I now exhibit. On examining the copper you will see that the graver has been used for supplementing some portions, about three hours' hand-work having been given it.

I have had the privilege of making the acquaintance some year or two back of Mr. Whitfield and Mr. Fry, of the Woodburytype Photographic Printing Company, and their kindly aid —which I take this public opportunity of gratefully acknowledging—enables me to show two very beautiful specimens of prints from metal plates, wanting only greater depth to render them suitable for potters' use.

Thus far I have considered the application of photography to potters' engravings; but there is still another opening for its usefulness, and that is in the obtaining of low reliefs in the clay itself, to be afterwards developed by a coloured glaze. I show specimens—a view of Chiswick Church—reproduced from a plaster cast taken by the swelled gelatine process, and two portraits made from Woodburytype blocks kindly supplied to me by Mr. Whitfield and Mr. Fry. Had I had time before coming to London to cover these with a coloured glaze, the delicacy of the details would, I am sure, have surprised you.

To bring these desultory observations to a practical point, let me say that copperplates made on the principle of heliogravure or electrotype (provided that the lines or indentations are of depth sufficient to carry colour to the extent of the prints I have produced) are all applicable to pottery printing.

There is, I am satisfied, a good opening for the profitable extension of photographic processes in the direction I have endeavoured to indicate, and its successful prosecution can be best effected by interfering in no way with the existing methods of taking off and transfer.

THE PAST SEASON.

BY EDWARD DUNMORE.*

At the urgent request of our esteemed Treasurer, I have attempted to provide a paper for this evening, choosing a title that leaves little to be found fault with on the score of elasticity. The extreme difficulty, as I have frequently remarked, of writing papers that will be fairly interesting to the majority of members is a task much more exacting than might be expected by those who have never tried to produce one; for it is not now, as in the early days of photography, when the knowledge of it was but partially understood, and any day or any hour might give birth to some astounding and unexpected revelation indicating lines of research before undreamed of, and fraught with germs of a new knowledge whose ultimate value it was impossible to estimate. But now year after year passes, and only occasionally some new process crops up, or an old one revived for new applications.

The photographic world has of late been occupied in revolutionising the practice of photography by substituting a dry gelatine film for a wet collodion one, and with, it is allowed on all sides, remarkable success. At present it is, however, barely understood. Numerous faults occur that the users of the process are at a loss to understand, and I do not think that I am far wrong in saying that many of the makers of commercial plates are themselves in the same fix. Until such faults and shortcomings can be fairly traced to their source, understood, and remedied, the average of gelatine work must, of necessity, be below that of our tried and thoroughly-comprehended friend wet collodion. In all probability, however, some considerable time will elapse before this desirable end is attained, and it is now incumbent on those who adopt the process to freely communicate their failures and successes—the means by which difficulties have been overcome, the conditions under which their failures occurred, and the plans pursued that have scored them a success. Mutual confidences are the most practical and expeditious means of gaining a thorough mastery of the process.

From my own experience I have drawn certain conclusions which, though adverse to the dictum of some experimentalists in the matter, have been in a measure supported by repeated experiments of my own, and by the examination of numbers of negatives by various photographers. It is that for general landscape work (not isolated cases) very rapid plates are unsuitable, the slower plates being infinitely preferable. The principal care of manufacturers of commercial dry plates has, I believe, been that of producing as sensitive a film as can possibly be produced—plates that will work in the fraction of a second; and, looking on this quality as the quality a dry plate should possess, they are somewhat careless of another very important factor in the production of a good printing negative—that of quality of image. More than either rapidity, ease of development, or brilliancy of image is the quality of giving a regular and distinctly-graduated series of tones from the light to the deepest shadow—a quality more frequently absent than otherwise, although on it depends the solidity and atmosphere in the resultant print. In the majority of cases, supposing the subject be a trying one—deep shadows in the foreground and with a bright, open distance—a proof from the gelatine negative will either show the distance blurred and indistinct, or the foreground flat and deficient in detail, which is so very different from our old collodion wet-plate work, where all would be atmosphere and harmony. This I do not mean to say is, of necessity, the case, as similar subjects have been most successfully rendered by the gelatine process. I am talking of the average of work.

There is no doubt whatever that much depends on development—very much; also, much depends on the film to be developed. At the same time there are many plates upon which no skill in development could produce a good result, the condition of the emulsion itself entirely precluding the development of satisfactory images. It seems to me that the temptation of doing "a good stroke of business" has induced many, after having just mastered the difficulties of the manipulations of mixing and coating, or scarcely that, to commence supplying the public with gelatine plates, aided by puffing advertisements, which plates are profitable only to the vendor, but to the confiding purchaser a source of irritating loss and disappointment. After the novelty has worn off this sort of thing will rectify itself, and the conscientious, careful, and scientific manufacturer will be the only source of supply to those who take pride in their work. We have not yet emerged from the experimental stage; but I anticipate every year will bring improvements, and the time may not be far distant when we shall cease to hold up the wet-plate negative as a model for imitation.

I would suggest, as a test of the qualities of a gelatine plate, that two large cylindrical objects—one perfectly white and one of some non-actinic colour—should be photographed in the open air with one exposure. We know what a wet collodion plate would do. The white cylinder would be represented with one line of high light and a multitude of pearly half-tones over the remainder, and a roundness and modelling be common to both dark and light objects. If we could obtain the same results with a gelatine plate we might fairly infer that a landscape taken on similar plates would have the same equality and the same range of tone. Unless the plates were equal to this test it would be hoping against hope to expect a perfectly printing landscape negative result from the plates used. This deficiency in scale of tints is, in my opinion, the greatest drawback to the (I was about to say the process, but I think the process is not to blame) use of a vast number of gelatine plates now on their trial. If, on the other hand, great rapidity be added to other good qualities, my objections would in some measure be removed, and it would resolve itself into convenience of practice. The question is—Whether any operator could as accurately time the exposure when working in fractions of seconds as in seconds—with all the varying lights and subjects with which he may have to deal, and with the certain amount of uncertainty in the actinism of the light that is always an important factor in the case? Speaking for myself, I do not think I could; but this is an open point, and a matter of practice and skill.

* Read before the South London Photographic Society.

Since we last met, one of our members has succeeded in practically demonstrating a method of photography without camera or lens. The idea is old, but I believe had never before been illustrated with anything like the completeness or perfectness it now has. I need scarcely say that the success of the experiment was facilitated, if not suggested, by the exalted sensitiveness of our gelatine plates, which, being placed in position behind a minute perforation in a piece of thin metal, received the image formed, and by a somewhat protracted exposure it was found possible to develop a good negative. The result is, anyway, exceedingly interesting, and points out that in an emergency, no lens or camera being available, dexterity and a good and rapid dry plate will enable one to secure a picture.

Another matter affecting the social status of the photographer has recently been brought home to me in an unpleasant manner. As a householder of some three or four and twenty years' standing, only within the last few years have I been summoned, as a loyal subject of Her Majesty, to act as a common juryman. I inquired the cause of one of the officials, and was informed chemists were considered more as professionals and were passed over, but photographers were classed with shoemakers and greengrocers, *et id genus omne*, and were selected to serve. This, then, is the enviable position a photographer holds, and that members of a profession requiring varied scientific and chemical knowledge to successfully carry out a profession which is, perhaps, one of the most useful scientific helps of modern times, are considered only on a par with the butterman, whose scientific knowledge is probably limited to distinguishing between "bosh and Dorset." I certainly think photographers should agitate for a position in the social scale somewhat better than this.

During the past season some few improvements have been introduced into our working plant, in the direction of lightness and portability, by an exceedingly light and rigid tripod stand for tourists, an additional stay to each leg imparting the extra rigidity. A camera, also, about half the weight of the usual make, and with few or no loose pieces, commends itself to the peripatetic photographer, the weight of whose *impedimenta* is an important consideration.

A simple velvet cap, secured with elastic round the lens, is one of those trifles that lead to make the life of the wandering photographer happy. A portable changing-box, contrived to carry the spare and exposed plates, and folding into camparatively little compass, has been designed and made; also a small wire frame for use in development of plates by those who object to soil their fingers, together with some few other useful and simple matters which, I have no doubt, will find a place at our technical meeting. Several instantaneous shutters have been added to an already long list. The drop shutter is, however, still able to hold its own, and for real, simple, inexpensive, and practical utility perhaps is as good as any. An improvement in it has been made by causing a flexible shutter with an elongated opening and working on small spring rollers, thus obviating the necessary bulk of the ordinary drop arrangement.

Sulphite of soda has been fought over considerably during the past six months, the advocates and opponents to its use being pretty equally divided. The charge made against it as a restrainer of development depends a good deal on circumstances. If kept in solution with citric acid and pyrogallic there is no doubt it has considerable restraining action; but omit the citric acid and the conditions will be altered, and very little slowing effect perceived.

I have now exhausted the topics that have occurred to me as providing something to talk about, and leave it to the members to continue the discussion.

A VISIT TO WEST CORNWALL.

BY WM. BROOKS.*

During my stay in Cornwall I received a letter from the Secretary asking me to give a few notes on the Royal Cornwall Polytechnic Society, to which I consented. In addition I give a few notes of my trip to the Lizard, which I hope will be of interest; therefore, I give the title "A Visit to West Cornwall."

The Royal Cornwall Polytechnic Society was first established in the year 1833, by Miss Anne Maria Fox, of Penjerick, near Falmouth, who is still living, and was present at the opening ceremony of the recent meeting—the jubilee year. A Miss Caroline Fox was the authoress of the name "Polytechnic," which has since been adopted by a number of kindred institutions, and the Royal Cornwall Polytechnic Society can fairly claim to have been the pioneer.

The first exhibition of this Society took place on Monday, the 23rd of December, 1833, and was kept open for two days only. This first exhibition was held at the Falmouth Classical School. The first patron was the Right Hon. Lord de Dunstanville, and the first president was Sir Charles Lemon, Bart., M P., F.R.S. In 1835 His Most Gracious Majesty King William IV. became the illustrious patron of the Society, and the Society was thenceforth called "The Royal Cornwall Polytechnic Society." In the year 1837 Her Most Gracious Majesty Queen Victoria became patroness, and H.R.H. the Duchess of Kent remained vice-patroness until her death. I must not omit to mention that Her Majesty this year gave a donation of £25 in aid of the funds to meet the extra expenses of the jubilee year.

In the year 1841 H.R.H. Prince Albert was elected vice-patron. In 1850 the freehold of the Polytechnic Hall and premises was purchased. The funds were raised by donations and the proceeds of a bazaar, so that it should not encroach on the general funds of the Society. In the year 1852 the Art-Union of Cornwall was established in connection with the Society, and has been continued ever since. It is a great feature in the annual exhibitions that all the prizes are selected by the winners from the works of professional artists and photographers whose works are in the exhibition, and by this means many works are disposed of annually. This year I was informed by the Secretary that one of my tickets in the Art-Union had been successful in drawing a prize of £5, and I selected a water-colour drawing, value £7 7s., paying the difference. The subject was "St. Michael's Mount—Sunset," by my friend Mr. T. Hart.

Photography from its earliest days has been a feature at the exhibitions. The year 1863 appears to have been the first year that awards were made by the Society to photography. Mr. H. P. Robinson and Colonel Stuart Wortley received first silver medals, and from this date the photographic art has received a very large amount of patronage and encouragement from the Society. In 1864 I received my first award from the Society. From this year to the present, full reports have been published in the journals of the doings of the photographic department.

It has often been a matter of wonder to me why photographers had never personally put in an appearance from a distance at these meetings, now that tourist tickets for two months or more are so reasonable; and those who take an annual holiday (and I suppose that there are many who do) could not do better than pay a visit to the west. The best way is to book through by the Great Western Railway to Falmouth, which will be found a very good centre for the surrounding country after visiting the exhibition. Although the journey is rather a long one, the price is not. The above company issues tickets for the double journey—first-class, £4; second-class, £2 15s.; and third class, £2 4s. Accommodation in the way of apartments and living is far below the average of the watering-places near London. If any should feel inclined to pay the exhibition a visit next year, I shall be pleased to give all possible information that I can.

This year's exhibition was a decided success in every department. During the opening ceremony an excellent photograph was taken of the platform by Mr. E. Gael, of Falmouth, which I hand round for inspection. In the Photographic Department a very notable feature was the even technical excellence. There was not, so far as I could see, a single bad specimen of the photographic art. The greatest novelty was Mr Henry Stevens' flower studies. All the photographs of flowers that I have previously seen have been bouquets, but in Mr Stevens' examples he photographs a single specimen, and by so doing there is a great charm in the result he obtains. In some the only addition that he makes is the introduction of a single specimen of fern, such as the maiden-hair, which in no way detracts from the beauty flower above. Mr. King's transparencies of the private apartments of Windsor Castle were very fine indeed. Mr. York's admirable collections of lantern slides were also greatly admired. For the rest of the exhibits I must refer you to the reports as published in the journals a week or two since.

Leaving Falmouth, I drove out to the Lizard, a distance of twenty-four miles, on a visit to my friend, Mr. T Hart, the marine artist. At the present time there is a great attraction at the Lizard, namely, the wreck of the steamship *Mosel.* She struck on the morning of August 9th, at 8.30 a.m., in a fog. She was a North German Lloyd's bound for New York, having on board 650 passengers and a valuable general cargo. When she struck, the second mate informed me, she was going at the

* A communication to the South London Photographic Society.

rate of fourteen knots an hour. The steamer *Rosetta*, of Falmouth, was near at hand when she struck, and took off the specie and mail to Falmouth. The reason I introduce this disaster is because wrecks at all times make good subjects for the camera and the incidents connected therewith. I have three pictures of this wreck. The first one I hand round is a woodcut from the *Illustrated London News* from a photograph taken from the sea a few days after she struck, by Mr. Moir, of Falmouth. The reason I put in this print is, that it is perfectly correct in every detail. On the top of the cliff it shows the signal station and a private residence. At this station is the telegraph office. The signalmen are on the watch night and day, their duty being to signal vessels and telegraph immediately to their owners as having passed the Lizard. In the daytime the signals are by flags; at night by signal lights of different colours. The *Mosel* was the vessel that some infernal machines were to be shipped on board at Bremerhaven; but, owing to one of them exploding on the quay, the design was frustrated.

I have omitted to mention where this vessel struck. It is to the east of the headland, Penolver, and just under the signal station, about two miles east of the Lizard headland. It was quite calm when she struck, and all lives were saved without any great difficulty. The Church Cove lifeboat, I believe, rendered the greatest assistance.

The second photograph I now hand round was taken from the land, by Mr. Gael, of Falmouth (this was produced about a fortnight after the vessel struck); and the third one was taken by myself in a gale of wind, on September 9th, the wind blowing from the east, and everything in the ship shaking violently as the sea struck her. This picture is a faithful representation of a wreck on a rock-bound coast. The photograph was taken about three hours before the ship's funnel went over the side, on September 9th. Any amount of pictures could have been taken at different times with the divers at work trying to save the cargo, and a lot of small boats dredging by the villagers, and all sorts of things were landed, too numerous to mention.

A FEW PRACTICAL HINTS TO BEGINNERS.

WITH PRACTICAL ILLUSTRATIONS.

BY WILLIAM CROOKE.*

My subject to-night, as you are all aware, is "A Few Practical Hints to Beginners." Now, to begin photography aright, there are certain qualifications necessary, viz., an abundance of patience, presence of mind, dexterity in manipulating, a slight knowledge of chemistry, a little artistic taste, and a quick eye for the beautiful. A sense of order, "a place for everything, and everything in its place," will be found useful in enabling you to put your hand upon any chemical or appliance at any moment, even in the deep ruby light of the dark room during development.

It is not my intention to enter into the manufacture of gelatine plates, for it is my opinion that you will make better progress by practising first on plates by some known maker until you get satisfactory results. Some believe in this maker, and some in that. I use chiefly Wratten and Wainwright's, a few of which I shall develop this evening. With regard to size, $6\frac{1}{2}$ by $4\frac{3}{4}$ will be found convenient, the camera for this size being portable, the prints fitting into ordinary albums also being suitable for framing.

After camera and lens have been considered, a drop shutter is a necessary commodity, but I would here warn you to avoid a certain make of shutter, with a spring to be pushed either towards or from the camera, as this is sure to move the instrument during exposure, unless great care is exercised. The shutter cannot drop too easily; any concussion that may take place once the opening has passed the lens is not detrimental.

For out-door work a fishing-basket to hold camera, lens, and slides, and legs in the form of a rod, is a convenient arrangement. I have found the cape of an overcoat to make an useful focussing cloth; the opening for the neck round the lens, and fastened underneath between the legs, holds the entire thing light and water-tight, leaving plenty of room behind for drawing the slide, and keeping it covered while drawn, a most important point.

Being equipped, we will imagine you start on a short trip. The day is all that could be desired—fleecy clouds abound, and spots of sunshine adorn the landscape. You climb a hill, from which an extensive view is to be obtained. A fine old mansion occupies the foreground, with plantations sloping down to the river, the windings of which can be seen for miles. The point of sight is chosen, and all ready for exposure. Now you must be careful. Don't take off the cap as soon as you have drawn the slide, but wait until the conditions are favourable for a good and pleasing picture. Get the distance a little shaded if possible, and a spark of sun on the thickly-wooded foreground. Previous to this you should have determined the exposure. Supposing it to be two seconds, you lift off the cap and simultaneously commence to count one, two, three seconds, putting on the cap as you say three. If you have drawn the slide next the lens the plate has received two seconds.

Rambling on in search of another "nice bit," you come across a friend on horseback, and thinking they would make a good picture, you thereupon plant your camera, and focus, while the animal stands in a beautiful attitude. Just as you draw the slide he moves his legs, and instead of four, only two are visible, which would look bad in the picture. To alter this the horse must go forward, making it necessary to focus again. If you had first taken the precaution to mark the spot where he stood, you could trot him round till all his points were shown. Suppose your next subject to be a few swans on the margin of a lake, take care that the sun does not shine from behind the camera too flatly on their plumage, as rotundity in this class of picture is desirable.

If you exposed many plates during the day, there would be a likelihood of getting confused when you proceeded to develop. You would find it a great assistance to enter in a little book, published for the purpose, the number of plate, size of stop, subject, and exposure.

To those who use larger cameras and various sizes of plates, I would relate the experience of two professional photographers who travelled a good many miles to photograph a detachment of Her Majesty's auxiliary forces. All the necessary preliminary was gone through, and two plates exposed. Then the detachment received orders to "right about turn, quick march." Pushing home the slide, one of the professionals exclaimed, "We're in luck," but lo! a change came over his countenance, and thoughts of the shortest way to the banks of the Clyde rushed into his mind (by this time the detachment had retired half-a-mile), when he reluctantly broke the tidings to his companion that he had used the wrong slide. A preventive for a similar blunder would be to stick a small gummed ticket on the slide, upon which you can write the size of plate.

I would like to say something to-night about indoor photography, there being such great facility for the production of really pleasing portraits of one's friends, with the same exposure, or even less, than in the studio. I shall give my opinion as to the best position of sitter and camera. For instance, at an oriel window; the sitter should be placed against the shutter, the camera close to the opposite one, a little more in the room, and well shaded from the light with a screen acting as a reflector towards the sitter, to carry the light as much to the front as possible; on the shadow-side a semi-circular reflector, well in front of the sitter, in fact until the edge of it appears on the ground glass; a clothes-horse with a blanket over it answers the purpose very well. The portion of window immediately beside the sitter should be darkened. When the sun is shining, a very rapid light is produced by fixing some sheets of tissue paper, slightly moistened at the corners, on glass.

In a room with two ordinary windows, not too far apart, the sitter might be placed about the centre of the room, on a line with the first and facing the second window, the camera shaded from the latter; the same system of reflectors answers in this case. Where there is only one window, the sitter should be placed close to and slightly facing it; here tissue paper will be found an advantage if judiciously used. The camera should be a few feet into the room. The least under-exposure in this branch is very detrimental, as it produces still greater contrasts. A weak solution of pyrogallic should be used on this account, and the development not carried too far. I shall not enter upon the subject of posing to-night, but just point out a very common error, viz., giving sitters a certain point to fix their eyes on, thereby to get mesmerised. Now nothing relieves the eye so much as a little motion during the exposure. This can be attained by placing a circular object, twelve inches in diameter, and about twelve feet distant, with a series of pretty faces round the edge, to be looked at consecutively.

A word about interiors. First see your camera is level (this applies also to exteriors). If the ceiling happens to be high,

* Read before the Edinburgh Photographic Society.

and something of importance in it, raise the front a little, but do not tilt the camera if you can possibly avoid it. The illumination on the ground glass in most instances being poor, makes it difficult to focus. In most cases a piece of white paper will be found sufficient, but if very dark, a light must be carried about from place to place to enable you to get the image sharp. Plates for this class of work should be thickly coated, and backed with some non-actinic substance. As our most worthy president can tell you, some very great obstacles present themselves in this his favourite hobby.

Notes.

Dr. Eder has written us on the subject of Obernetter's new emulsion process, of which the former seems to think very highly. There is little doubt that if we can thus avoid the chemical difficulties hitherto so inherent to the process, and can prepare an emulsion in half a dozen hours without the painful glare of ruby light, the Obernetter process will be received on all sides with open arms. But it seems almost too much to hope for the Gordian knot to be severed in this simple fashion.

Professor Piazzi Smyth has made a good defence of the "rain-band."

> "A rain-band captain eke was he,
> Of famous Ed'nbro' town."

He does not deny that a mere observation of the "band" alone will tell us if it is going to rain, but that if the observation is made by an intelligent man, who will place the records side by side with those of the "barometer, thermometer, and wet-bulb hygrometer, not forgetting both wind and cloud," he is likely to learn something of the condition of the atmosphere. It must not be forgotten that Piazzi Smyth has already made several meteorological suggestions of value, which entitle his opinion to respect; one of them—that of taking photographs of the clouds, in order to prognosticate the weather—being likely to be generally adopted in our observatories.

It is not very nice to be awarded a gold medal, and yet get none of the glory and none of the gold. But this is precisely what has happened to Mr. G. F. Williams, whose picture entitled him to the highest award in the Alexandra Park Competition. In the first place he received none of the honour, for his name was not mentioned in connection with the gold medal when the result of the competition was first published; and in the next place, when the time came for giving the medal, the givers were in the Bankruptcy Court. Nor is this all; for, so far from being able to get his medal, Mr. Williams cannot even get his pictures back again. Who would be a gold medallist in these circumstances?

Mr. Arthur Debenham, who has just returned from a tour in Italy, confirms Mr. Robinson in his view that many plates are spoilt by the diaphragm slit in the lens. Mr. Debenham tells us that nearly all his spoilt plates were spoilt by light entering his camera in this way; and as the Italian skies are very bright, the gelatine plates suffered accordingly. Mr. Debenham informed us, too, that he knows no better plan of remedying matters than the one given in the News—namely, to sew an elastic band on one margin of the dark cloth, so that the latter clasps the lens tightly during exposure.

The *Times* criticism on the Exhibition is in keeping with its usual slow and solemn utterances. The writer gravely commences with a dull account of the early history of photography, which takes up a whole column, and then devotes a short half-column to a notice of the pictures. Still, he tells us several bits of gossip, which, if not actually criticism, are nevertheless very gratifying to hear. "We should have had some illustrations of the new St. Gothardt route to notice," we are told, "only that the collection was not completed in time for the Exhibition." And again, he says of one medallist, that he had "only taken up the active practice of photography within the last year." This is capital small talk, but we think exhibitors would have been better pleased with a few remarks upon their pictures.

The American system of phototyping English books, and issuing them in the New World without permission, is being met by the simple expedient of performing the operation here and forwarding the plates. "Skeat's Etymological Dictionary," recently printed at the Clarendon Press, Oxford, is an example, the whole having been phototyped on a reduced scale in England, and sent off in advance. The phototypic process is of especial value in the case of such a work as this, owing to the number of "peculiars" and foreign quotations.

A second name, well known in photographic circles, has become associated with electric discovery, and, as in the case of Mr. Swan, the discovery relates to the problem of domestic lighting. A son of Mr. Ferranti, of Liverpool, has come forward with a process which from the very first seems to have inspired confidence. "Without pretending to have pitched upon the very best system," says the *Daily News*, "we may confidently assert that the sample of estimates for supplying light by the new Ferranti process is far from being the worst." In a word, Mr. Ferranti, Junior, who is, by the way, but eighteen years of age, has devised a house-to-house electric system that compares favourably with the price of gas.

A good deal of fuss has been made over the appearance of an electric launch on the Thames—that is to say, a launch worked by engines set in motion by a number of secondary batteries. The secondary batteries were charged ashore, and subsequently were made to part with their electricity to turn an electric machine which worked the screw of the little craft. As a practical experiment, no doubt the matter deserves record, but the public should have been fairly informed at what expenditure of force the boat was sent on its journey. Thus, very few readers of the daily papers imagined that not ten per cent. of the force originally employed was available to make the screw revolve, the other ninety per cent. being lost over the experiment. Loss of power resulted in every operation, the burning of the coal to heat the boiler, the boiler in setting the steam-engine to work, the steam-engine in turning the dynamo-machine, the dynamo-machine in charging the batteries, and the batteries in discharging their electricity to set the machine on board in action; indeed, we believe it would not be far wrong to set down the power put forth in the last operation as equal only to three or four per cent. of the original energy at hand at the beginning.

Attention has been recently called to the danger of acidity in papers, many descriptions having a marked acid reaction when tested. No doubt acid paper is to be deprecated in photography, and therefore it is well to have a ready method of testing at hand. The best plan is to moisten a piece of blue litmus paper with distilled water. and lay it between the sheets for twenty-four hours; its tint at the end of that time establishes the absence or presence of acid.

It will not be the fault of scientific societies if we learn nothing of the next transit of Venus. France alone sends out eight different observing parties, and England six. Germany, Russia, and America are also to be represented. The phenomenon takes place on the 6th December next, and Lieutenant Darwin, R.E., late Honorary Secretary of the Photographic Society, is already in Australia making arrangements for an English observing party in that part of the world.

The Germans are becoming alive to the advantages to be derived from photographing the scene of a railway accident. It is necessary, of course, to put the line in order as quickly as possible after a breakdown, but still, if the "breakdown gang" that is sent to repair damages included among them a photographer with his apparatus, evidence might be collected on the spot without delay. The state of affairs immediately after an accident teaches much, both as to its "cause" and "effect," and we feel sure the day is not far distant when our Home Office will make it a stringent rule that a photograph be secured of the débris before any step is taken to set matters straight. The Germans adopted this plan on the occasion of the serious accident at Hugstetten, and the position of the locomotives, and of the wrecked trains, have materially helped to demonstrate how the catastrophe was brought about.

It is a moot question among scientists how far an investigation may be undertaken by deputy—that is to say, how far a principal may claim a discovery made by his assistant. If we were to read of the defeat of the Egyptians and taking of Cairo by the Duke of Cambridge, most of us would regard it as a joke; and yet, among the papers presented to the Academy of Sciences a little while ago, there is one entitled, "On an Observation of the great Comet of 1882, seen from a balloon, by M. de Fonville." This would be all very well if it were not followed by, "M. Mallet made the ascent at his (Fonville's) request, having keener vision, and took measurements."

"We meet at Ashley's Hotel, Henrietta Street, Covent Garden, on Wednesday evenings, at eight o'clock, and shall be glad to welcome among us any photographic brethren who may be in London during the Exhibition time." So writes the Secretary of the Photographic Club. The agreeable air of non-formality and good fellowship which characterise the Club gatherings, altogether distinguish them from the meetings of the photographic societies.

Heard in the crowd on Saturday night. Said one visitor at the Exhibition, as he hustled another: "Fearful crush, is'nt it? I hear three instantaneous shutters have been smashed already."

Another fragment of conversation at the same time and place. "Yes; he is growing quite a man, isn't he? We all wish him to marry, but he says he wants to save up his money and buy a camera."

Patent Intelligence.

Application for Letters Patent.

4747. Francis Joseph Emery, of Burslem, Staffordshire, Earthenware Manufacturer, for an invention of "Improvements in photographic engravings."—Dated 5th October, 1882.

Notice to Proceed.

3190. John Henry Johnson, of 47, Lincoln's Inn Fields, in the county of Middlesex, Gentleman, for an invention of "Improvements in the manufacture of cardboard, pasteboard, and the like, and in the machinery or apparatus employed therein, and for cutting the same into sheets, and for coating sheets of paper or cardboard, or the like, with adhesive material."—A communication to him from abroad by Jean Müller, of Schaffhausen, in the republic of Switzerland, Card Manufacturer.—Dated 6th July, 1882.

Patent Void through Non-payment of Duties.

3352. Robert Slingsby, of the town and county of Lincoln, for an invention of "Improvements in the construction of photographic studios."—Dated 24th September, 1875.

This invention consists "in constructing the 'sky-light' as well as the 'side light' of a photographic studio with a double pitch or inclination inwards from the two ends to the middle of its length, where the two inclined or sloping surfaces meet at an angle of about 120 degrees." Thus advantage is secured at whichever end of the studio the sitter may be placed. Instead of the sky and side lights meeting at an angle, they may be separated a few feet by an unglazed or darkened portion of straight roof and side, under which the camera may be placed in comparative obscurity. Instead of the side light being vertical, it may be sloped outwards from top to bottom, the sky light being at one slope and the side light at another slope. Or, they may both be at the same slope, and combined in one in the form of a "Mansard" roof, but with the double pitch or inclination inwards at the centre. The inward pitch or inclination of the sky and side lights may be adapted, in a single form, to studios in which the sittings are made at one end only.

Patents Granted in France.

147,655. Enjalbert, of Montpellier, for "A photographic apparatus for the pocket, called 'photo-revolver.'"—Dated 14th February, 1882. Class 17.

Certificates of Addition (French).

116,533. Perier, for "Reproducing photographs, drawings, &c., by means of the camera lucida, &c."—Dated 6th March, 1882. Class 17.

146,702. Olive, for "A funeral frame for photographs."—Dated 22nd February, 1882. Class 20.

THE PHOTOGRAPHIC EXHIBITION.

[*From the* Times.]

Just thirty years ago (in December, 1852) the first exhibition of photographs over held was opened by the Society of Arts at their house in the Adelphi. In the following year the Photographic Society was founded, that Society whose annual exhibition opened on Monday last at the Gallery of the Society of Painters in Water Colours, Pall Mall. It would be hardly too much to say that between the dates of these two exhibitions, the art of photography as we know it has grown up. In 1852 photography was passing from the range of scientific experiment to practical use. Fox Talbot, at the request of the Earl of Rosse and the President of the Royal Academy (Sir Charles Eastlake), had just consented to forego, for the benefit of amateurs, the patented rights in his "calotype" process, of which an unsuccessful action at law a year later entirely deprived him. Collodion, introduced by Archer a year before, was coming into use, but principally for portraits, for most of the pictures shown at the Society of Arts Exhibition were produced by the transparent paper negatives of the calotype process. But Archer's beautiful discovery soon drove the waxed paper from the field, and for long all photographs were taken on a film of moist collodion. Still, there were drawbacks. The necessity that the film should be fresh and moist, in order that it might absorb into itself the sensitive salts of silver from which the picture was to be built up, obliged the landscape photographer to carry with him a cumbrous appurtenance of chemicals and apparatus, together with a dark chamber or tent, in the recesses of which the various manipulations had to be performed. Hence arose a demand for a sensitive plate which could be prepared at home, taken to the spot where the picture was to be produced, exposed, and brought back after exposure for the final operations, by which the invisible or latent image is made visible and permanent. Various applications of collodion and albumen were tried, with considerable success, the only drawback being that the plates were "insensitive." They required a prolonged exposure to the rays of light before the picture was formed. Exposures were measured in fractions of the hour, instead of in fractions of the minute, or, as is now frequently the case, in fractions of the second. At last the idea occurred of employing gelatine as the vehicle for the haloid salt of silver, and the result was the production—after many experimentalists had expended much trouble and time in the research—of the wonderfully sensitive plates now in the hands of every photographer. It was some time before the photographic world would trust itself to gelatine, but when the change once began it was very rapidly completed. This is clearly shown by a single fact. In the exhibition catalogue of two years back a special note was added to the entry of any picture produced by a process other than wet collodion. Now it is assumed, unless otherwise stated, that the negatives of all the pictures shown were taken on gelatine dry plates.

By the introduction of the new process, the powers of the photographer have—as is sufficiently well known—been very largely increased. The portraitist can catch fleeting expressions. He can render with some approach to truth the mobile features of infancy. He may even dispense with that appalling, if harmless, implement with which he was wont to clamp his victim's head into a fixed position. The landscape photographer can render effects once entirely out of his reach. He can truthfully represent the clouds of a stormy sky, or the foam of a breaking wave. He can introduce figures without much risk of their spoiling his picture by walking out of it in the middle of the exposure. The photographer who cares neither for portraits nor landscapes can, if he so pleases, invade the domain of the painter and depict for us, more or less faithfully, according to the skill of his models, scenes of domestic, rural, or sea-faring life. Even objects in rapid movement can be caught. In so short a time can an image be impressed on the sensitive gelatine, that the displacement of moving objects during that time may be insufficient to affect the sharpness of the picture, and we got representations of express trains, flying birds, race-horses at full speed, and the like.

The present exhibition affords a good test of the manner in which these increased powers have been employed, and it is a most interesting and important point to consider whether, while the scientific processes of photography have been so greatly and so rapidly improved, there has been any corresponding advance in the actual results. That artistic progress should keep pace with technical is no more possible in photography than in any other art, but some advance might have been expected. It is, however, difficult to find evidence of such improvement, at all events as regards pictures of the highest class. That the general average has been considerably raised is, on the other hand, equally certain. There are now in the Pall Mall Gallery very few pictures that do not possess considerable merit, either technical or artistic; there are many showing evidence of both qualities. This is doubtless to a large extent due to the fact that modern inventions have smoothed the photographer's path for him. The manufacture of photographic plates has become a commercial business. They are made on a large scale, with regularity and uniformity, so that, despite occasional disappointments, the purchaser from a respectable dealer can rely on getting an article varying as to excellence at all events within not very wide limits. The manipulation, too, is by no means difficult, and, indeed, a fair amount of success may be attained by mere rule-of-thumb work. This is the case with very many amateur photographers. They work away, spoiling a good many plates, getting a good many average pictures, and every now and again turning out a perfectly successful one. The successes are shown, the failures are forgotten. Like a bad shot, who forgets how many cartridges he started with, our photographer neglects to count the number of plates his maker has supplied him with. More than this, the amateur may, if he chooses, send the exposed plates back to the maker to develop and print from, his share in the production of the finished picture being confined to the choice of a suitable subject and a good point of view. The natural result is that the process of picture-making is considerably simplified, and an average standard of excellence, such as may be expected in an extended manufacture, is secured.

But, turning to the finest specimens of photography now on the walls of the Gallery, it is hardly possible to avoid the opinion that, while recent progress has rendered more easy the attainment of good results, it has not improved the results themselves. There is no special new feature among the pictures of this year, nor are the best of them better than their predecessors of any year for some time back. Two years ago, when "instantaneous" work was more or less of a novelty, the walls were hung with pictures of express trains and other objects in motion, only less violent. The interest attaching to the first of such pictures was very great; the scientific value of the power they demonstrate is considerable, but their artistic value is nothing. The human eye is not so constituted that it can follow rapid changes of position in the object observed. The image formed on the retina is retained for a certain interval, and is blended with the images of the previous and following instants. This generalized impression is what we see, and this it is or should be the effort of every artist, painter, or photographer to represent. The attitudes of a galloping horse as shown by the camera are not the same as those the eye perceives. The photographic lens does not see in the same way as the eye. For artistic purposes, it is no more true to present us with a picture of a horse which the eye cannot recognize, than it would be to give us a likeness of a friend whose skin should be represented as it appears under the microscope. As actual facts, both are equally true; as representations of what we see, both are equally false. This is now evidently recognized by photographers, for there appears to be nothing in the exhibition moving faster than a yacht or a steamer. Here the waves, the wake of the vessel, the broken water from the paddles, sufficiently convey the idea of motion, and we get what is at once a good picture, and a true representation of fact. Few more beautiful examples of what can be done in photography are to be found than some of the sea pieces with yachts and shipping sent to the present exhibition by Messrs. Sutcliffe, A. Johnson, S. Conway, M. Whiting, and others.

Another class of subjects which cannot well be treated, except by the use of gelatine plates, is that comprising groups of fishermen, reapers, haymakers, and the like—pictures, that is to say, in which living figures form a principal part. It is true that to a limited degree such subjects have always been capable of photographic treatment. Mr. H. P. Robinson has long enjoyed a well-earned reputation for his rustic groups and scenery. But, truth to tell, there is always a terribly artificial look about Mr. Robinson's groups of picturesquely-attired maidens in more or less conventional attitudes; and clever as the groups are, they always seem to carry with them a taint of the theatre into the woods and fields, where we find them planted. This objectionable feature is emphasized when, as in the present exhibition, half-a-dozen such pictures are placed together showing, apparently, the same girls in the same dresses, enacting different little rustic dramas in different scenes. Decidedly the best of these is the one to which the judges have awarded a medal, and it is just the one in which the figures are most carefully subordinated to the surroundings, seeming, as they do, to give life to a scene which, without them, would have lost half its interest. No such fault can be found with the pictures of the other exhibitor of this class, who has received a medal, Mr. Gale. He has taken his subjects where he found them; a little judicious grouping and a quick plate have done the rest. Those who deny the artistic capabilities of photography should be made, before again expressing an opinion, to study carefully the pictures sent to the exhibition by Mr. Gale.

The landscapes are as good and as interesting as ever. They come, as usual, from all parts of the world. From India, New Zealand, Palestine, South Africa, the far North, and elsewhere, we get views which have more than a photographic or pictorial interest. Mr. Donkin sends several of his well-known Swiss views. He seems as yet to be the only member of the Alpine Club who regularly carries a camera among the higher Alps. Another series of Swiss views expected from one of our cleverest professional landscape photographers, Mr. England, was not completed in time for the exhibition, or we should have had some illustrations of the new St. Gothard route to notice.

Among the portraits there is really nothing calling for special remark. It was announced that the judges would have placed at their disposal three medals to be awarded for portraiture, but of these only one has been given. It has been taken by Mr. Byrne for an excellent case of children's portraits.

A medal has been deservedly awarded to Mr. H. Stevens for a singularly fine series of flower studies, a reward to which the greater interest attaches from the fact that its winner has, if we are not misinformed, only taken up the active practice of photography within the last year.

There are many other pictures to which it might be desirable to draw attention, but they must be left for visitors to the exhibition to discover for themselves. Some few, however, cannot be passed over without mention. First among these may be placed Mr. Grant's photographs taken on board Mr. Leigh Smith's yacht *Eira*, during her cruise to Franz Josef Land in 1880. Then come some views of Captain Abney's, taken in the Alps, near Zermatt, and showing the enormous difference in the photographic quality of the light reflected from the sky at considerable altitudes (nine to ten thousand feet), and that reflected at lower levels, the photographic power of the former being only a twentieth part of that of the latter. A photograph taken by Mr. Shadbolt from the car of a balloon at the height of 2,000 feet, showing the streets and houses below, is also curious, though to those who do not know the difficulties attending this class of work it is a little disappointing.

[*From the* Daily News.]

The Exhibition of the Photographic Society of Great Britain, now open at the Gallery of the Royal Society of Painters in Water Colours, marks, as distinctly as such things can be marked, an epoch in the history of sun-printing. Without dilating on technicalities, it may be briefly observed that a great advance has been made during the last two years in the process of photography. Ever since photography became popular, the main conditions of the operation have remained almost identical. Whatever the subsequent treatment might be, whether silver printing, autotype, heliotype, or Woodburytype, the primary operation depended on the figure received on a plate of glass coated with collodion, and rendered sensitive by a bath in salts of silver at the last moment. This process is now known as that of the "wet plate," and required an appreciable time for exposure and development, causing a certain difficulty in the case of ships crossing each other, of irritable sitters, and of breezy landscapes. When collodion was well established as the medium by which nitrate of silver could be made to produce a sun-picture, gelatine appeared as a rival medium or vehicle for the employment of silver salts. No sooner was this found out than gelatine displayed qualities not possessed, so far as experience has demonstrated, by collodion. It was found to be in sensitiveness, and consequent speed of work, when compared with collodion, as a racer to a common cab-horse. This extreme sensitiveness made the gelatine process very difficult at first, but all drawbacks are more than compensated by the faculty of a properly prepared gelatine plate taking its impressions while dry, a condition invaluable in field work or on a voyage. The dry plate, being already sensitive, only requires to be kept carefully from the light, and will do its work at any moment without preparation. This convenient portability, and the speed with which pictures may be taken, drew attention strongly to the dry plate method, which at length seems to have proved so far satisfactory to the general body of photographers, as to secure adoption for everything but studio work under exceptionally favourable circumstances. The result of this revolution in the ordinary practice of photographers is displayed this year, and shows some striking results, especially in the department of marine photography. Perhaps the council of the Photographic Society may be said to err in the direction of hanging too many works, but it must be conceded that a large proportion of the photographs of this year are remarkable for the evidence they bear of rapid work. There is a prominent exception in the case of the School of Military Engineering, which contributes some fine views of "Lynmouth and the Valley of the Lynn," taken by the wet collodion process; but the great majority are "dry plates," and some like those taken on board Mr. Leigh Smith's yacht, the *Eira*, by Mr. Grant, impossible by any other plan. A medal has been assigned to Mr. Grant, also to Mr. J. G. Horsey for some beautiful views in Surrey and Berks, and to Mr. H. P. Robinson for his fine series of figure subjects taken by the gelatine and collodion processes. Some views in Tahiti by Colonel H. Stuart Wortley have been well produced by the Autotype Company, whose enlargement-pictures in permanent carbon also possess great merit. Particular mention is also due to Mr. Henry Stevens' pictures of orchids and other flowers, and to a charming piece, "Gloamin," by Mr. Adam Diston.

[*From the* Morning Advertiser.]

It would be unreasonable to expect a pronounced development in the province of photography at each of the annual exhibitions of the Photographic Society of Great Britain. A few years ago the gelatine or dry-plate process was introduced, and it is worthy of remark that nearly all the original negatives of the pictures exhibited this year were taken on gelatine plates, the exceptions being so few that they alone are noted in the catalogue. The period of transition having reached its fulness, for a time there is little to indicate any new departure, although naturally certain modifications in the now almost universally adopted method of procedure are presented by the photographic manipulator. The exhibition, is remarkable for its large proportion of amateur productions, and it is satisfactory to find that these are by no means deficient in artistic merit. The non-professional photographers particularly excel in landscape work, of which there is a large variety; while the professional likeness-takers have fewer exhibits than usual. This is not altogether to be regretted, for there is at best a wearisome monotony about their productions, and in many examples the negatives have undergone so much artistic sleight-of-hand in the shape of "touching up," that they are as much the product of the pencil as of the camera. In other examples the sitters are apt to look like lay-figures, wanting in freedom, and painfully suggestive of their cognizance of the fact that they are undergoing some kind of operation. This sort of work has happily been almost weeded out, so far as this exhibition goes, and what of portraiture remains shows high artistic training and the acme of chemical manipulation. It may be noted that the specimens embracing the grouping of figures in selected landscapes are remarkably successful, for the most part eclipsing previous efforts in this direction. This improvement is unquestionably the natural result of the process of instantaneity. Formerly the figures in a landscape or piece of architecture would be gazing in one direction, and that towards the photographer; but now they need not trouble themselves to pose, but may pursue their labours, while by means of the instantaneous shutter the operator is effigiating them as with a lightning flash on his sensitive plate. A capital example of this is afforded in Mr. John G. Horsey's "Views in Surrey and Berks" (60), in one of which the natural attitude of the reapers in the harvest field is specially commendable, while the extent of country beyond forms a charming feature of the picture. For general excellence this series of views is unsurpassed. Mr. Horsey has been awarded a medal, as also has Mr. Frank M. Sutcliffe, of Whitby, for studies of fisher folk and fishing boats, all of which are natural in the extreme, and could only have been limned by the instantaneous process in skilful hands. Mr. A. Johnson, of Wick, has been similarly successful in his frame of "Studies of Fishing-boats from the Pier-head, Wick" (80), in which the movement of the sea has been caught with the happiest results.

Another interesting series of photographs, taken under circumstances of the utmost difficulty, is exhibited by Mr. W. J. A. Grant, Hillersdon, Devonshire, and brings vividly before us reminiscences of the Arctic regions during the cruise of 1880 to Franz Josef Land, the views being taken from Mr. Leigh Smith's yacht *Eira*. These also have been awarded one of the Society's medals. They are numbered 53 in the catalogue. Mr. H. P. Robinson, of Tunbridge Wells, contributes, too, some remarkably good work, showing thoroughly artistic grouping of appropriate figures in well-chosen landscape views, on 15in. plates, by the gelatine and collodion processes, the superadded skies being clear, and harmonising both in tint and form with the more material parts of the subjects. No one but a real artist could have produced examples of such surpassing loveliness. Skies are usually printed separately from the landscape, and it is not always that the particular cloud-form or effect of atmosphere selected adapts itself kindly to the foreground objects and distance; but Mr. Robinson is too appreciative and refined an artist to err in this respect. His compositions are unified, and only an expert would imagine that they have been built up by separate printings, so perfect is the arrangement, so complete the amalgamated parts, whether of sky, landscape, buildings, or figures. A medal has been very properly adjudged for these triumphs of photography.

The Autotype Company, 74, New Oxford Street, are as usual large contributors, and amongst the most noteworthy of their exhibits are the reproductions by Mr. Sawyer's collotype process, by means of which drawings in monochrome and engravings are printed in *fac simile* from a press, without any necessity for sunlight. They show in this process a frame of elaborately designed fans from the cabinet of Mr. Robert Walker, of Uffington, in which the most delicate tracery is clearly brought out (97). They also exhibit a *fac simile* of the "Codex Alexandrius," containing the New Testament and the Clementine Epistles, the original of which is in the Royal Library of the British Museum; also a copy of Magna Charta, and other ancient manuscripts published by the Palæographical Society; and a frame of "Views in Tahiti" (147), from negatives by Colonel H. Stuart Wortley, for the book on Tahiti, by Lady Brassey, now in the press. The collotype process seems eminently adapted for illustrations, the design being printed direct on the paper, leaving margins for binding. The Autotype Company has long been celebrated for its carbon enlargements, and they display in this exhibition a view, "Near the Dargle Rock, County Wicklow" (125), from a 12 by 10 negative by Mr. Payne Jennings, the enlargement being of the size known as antiquarian, and untouched. They have also good examples of portrait enlargements from cabinet negatives, showing how completely the process is under control.

Mr. Edmund Hyde is the exhibitor of two pretty views in Devonshire, "Rushford Mill" and "Lustleigh Village" (157 and 158), which are enlargements from negatives, the prints of which are exhibited on the screen (426). The panel and cabinet portraits of children by Messrs. W. J. Byrne and Co., of Richmond, have been awarded a medal which they richly deserve, for anything more exquisitely beautiful as photographs could not be conceived.

Mr. Robert Faulkner, Baker Street, exhibits a number of instantaneous photographs of children (184), the like of which, however, has been seen before; and the same observation will apply to the portraits printed in carbon, soft and charming as they are, of the sons of the Rev. Canon Farrar (185). By this process of printing a variety of tints may be obtained, and the example in question is produced in the red chalk or Bartolozzi style.

The portrait studies (220) of Mr. Abel Lewis, Douglas, Isle of Man, are good specimens of the art, and have gained a medal. A great advance has been made of late years in figure-subject pictures, and this year this class of work forms one of the most satisfactory features of the exhibition. "Cherry Ripe" (231), by Messrs. J. Chaflin and Son, Taunton, and "Homeward" (239), by Mr. Robert Slingsby, Lincoln, both have received the Society's medal, and no one will venture to deny that they thoroughly deserve the honour. The "Sisterly Intercession" (240), by Messrs. Chaffin, has dramatic power of no mean order, the attitudes and expressions of the three *dramatis personæ* being natural and unstrained. Mr. Joseph Gale, Long Lane, Bermondsey, an amateur, has been awarded a medal for studies of Cornish fisher folk (307), the great merit of which is their spontaneity, the grouping being happy, and the subjects selected with tact and judgment. There are some clever studies of flowers (323), by Mr. Henry Stevens, Addleston, Surrey, which have gained honours. A charming little figure subject called "Gloaming" (391), by Mr. Adam Diston, Leven, Fife, is deserving of high commendation. It represents an old lady about to light a paraffin lamp, and the sense of approaching night is by judicious toning cleverly conveyed. Mr. Diston has also been awarded a medal.

Amongst the amateur contributors Mr. J. W. Boord, M.P., holds a conspicuous place, his frame of "Marine Views" (462) being highly creditable productions. There is some good landscape work by the Photographic School of Military Engineering, Chatham, by Mr. Ernest H. Goold, Mr. T. M. Brownrigg, Mr. E. Fox, Mr. H. Mansfield, Mr. F. Hollyer, and others. Photographic apparatus and chemicals are displayed on the table and in the room by the different makers, and professionals and amateurs will doubtless find this not the least interesting part of the Exhibition. It may be mentioned, in conclusion, that the Council have resolved to keep the Exhibition open till November 16th; and that as a new feature, and one likely to prove of great advantage to those interested in photography, the Gallery will be open every Monday, Wednesday, and Saturday evening, at a reduced charge, the object being to enable persons whose stock in trade consists in no small degree of sunlight to visit the Exhibition without sacrificing that to them indispensable natural commodity.

[*From the* Morning Post.]

Though photography has already advanced far on the road to perfection, it does not seem to have made any marked progress towards that desirable goal during the last few years. The quality of the collection opened for private view on Saturdap is, taken in general estimate, good, but it is certainly no better than that of its immediate predecessors. The art seems stationary. A remarkable feature of this Exhibition is the vast preponderance of dry-plate photographs. Wet collodion has all but disappeared. Whether a more vigorous negative and greater delicacy of detail have been obtained under the "dry" system is perhaps a mootable point, which, however decided, must still leave to that process the signal advantage that it is less dependent than any other upon variations of temperature. It has been found that in the dry plates the films retain their smoothness and evenness of texture in all climates. The best works in the Gallery are the landscapes, sea-views, and flower pieces. Of portraits there is a fair, though not abundant, display; but the fancy figure subjects grouped to the semblance of *genre* pictures too often want strength of character and grace of composition. From the censure must be excepted "Cherry Ripe," by Messrs. J. Chaffin and Son, a charming little picture, fine in tone and full of expression. Among the most attractive things in the collection are Mr. H. Stevens' flower subjects; Mr. M'Leigh's "Misty Morning on the Wear;" Mr. W. J. A. Grant's photographs taken on board Mr. Leigh Smith's yacht *Eira*, during the cruise to Franz Josef Land; Messrs. Byrne's panel portraits of children; Mr. H. P. Robinson's "Wayside Gossip;" Mr. Frank Sutcliffe's seaside scenes; Colonel H. Stuart Wortley's views in Tahiti, for the book on Tahiti, by Lady Brassey, now in the press; Mr. J. A. Kay's portraits of ladies; and the various views of picturesque scenery by Messrs. Trenemen, W. K. Burton, Matthew Whiting, J. G. Horsey, E. Hyde, A. Pringle, E. Loelig, and the Photographic School of Military Engineering.

Correspondence.

OBERNETTER'S NEW EMULSION.

Sir,—I am not in the habit of publishing my failures, but the notice of Obernetter's new method recalls the fact that some two years ago I conceived an idea very similar to that of Mr. Obernetter, *i.e.*, to form the bromide in solid gelatine.

My experience ran thus. My bromide salt was dissolved in the gelatine in daylight, and when this was set, the silver solution was poured on the top. I left this for about three weeks; no combination took place beyond a very thin layer of bromide about the thickness of tissue paper, formed on the top of the set gelatine. From that experiment I came to the conclusion that a combination would not take place, although in this case I thoughtfully put the denser liquid (the silver solution) on the top, thinking it would dialyse through the gelatine. I fail to see, without having tried any further experiment, how that by a reversal of the operation a successful issue would result. I have published the fact that bromide of silver formed in an excess of silver is far more sensitive than when made in excess of bromide: its extreme sensitiveness, I have no doubt, caused many to fail. If bromide of silver is formed cold, and without ammonia, and when set is immersed in a solution of—

Ammonia carbonate ... ... 1 ounce
Water ... ... 20 ounces

for twelve hours, it will increase in sensitiveness very much; of course it requires washing in the usual way.

Granularity in bromide is not a necessity to sensitiveness; a sensitive fine bromide gives density; on the contrary, a granular bromide gives thinness. It may not be generally known that ammonia will not ripen gelatino-bromide emulsion nearly so much when the nitrates are removed.—Faithfully yours, A. L. Henderson.

PHOTOGRAPHIC NUISANCES.

Sir,—For some time past I have been thinking of writing to you respecting certain photographic nuisances, and now that "Exact Measure" has commenced, I will continue a little complaining of the nuisances connected with the use of commercial dry plates. I have been a user, and often a maker of gelatine plates ever since Mr. Swan advertised his first plates in the News, and must say that nothing has ever proved such a nuisance to me as commercial plates have done. It is only occasionally that I am bothered with plates that are too large, although now and then a pair of plyers are required to take off an extra width at one corner; but the greatest nuisance has been a too thin and uneven coating. I have not confined myself to one maker, but have had plates from at least ten different makers. Some have had only a few faulty coated ones, others have had a general thinness, and one maker's plates have proved very bad, not more than one dozen out of the last half-gross being at all fit to put into the dark-slide. All the others are so thin either at one end or all over, that they can be easily seen through, and as these plates are very rapid you may guess what sort of negatives they yield.

The next serious nuisance is that makers will label plates ten or twenty times, when they prove only about three or four times as rapid as a good collodion plate; also plates of different batches, but labelled the same, prove very different, not only in rapidity, but in other qualities. A short time since I was out working three sizes of plates, all labelled alike, but while two sizes worked with quite clear shadows and full density, the other size was about twice as rapid, tending to fog and thinness, and gave a halo around any extra light. As a rule, the emulsions used on the plates have proved excellent, but occasionally a batch is inclined to fog, or does not give a sufficient range of tones, so that if they are exposed for the shadows the high lights have no modelling; but if these plates are about half-timed for shadows, the lights will be round, or in the case of landscapes or architecture, outlines of skies will run into the subject like a fog. I have often written to the makers of these plates in as kind a way as I can, as I should much rather get good plates than grumble about indifferent ones; but, with one honourable exception, I have always been told that no one else out of their many customers ever find fault, but are continually praising the plates and sending fresh orders. The exception above-named was a case where six dozen half-plates proved a great trouble from too thin and uneven coating. The maker sent me four dozen quarter-plates as some recompense, although stating at the same time that my complaint was quite alone. But, unfortunately, my negative box contains the proof of their thinness, especially at one end of the plate; sometimes, when the first two or three dozen of a gross has not pleased me, I have returned the remainder, and some fresh ones have been sent, but always with the information, soon or late, that those returned turned out "simply perfect," or "splendid."

But just now I am come to a standstill with one house. Several weeks back I sent them an order for plates, which, after a considerable delay, was attended to; but the plates proved very badly coated, so that four or five of each dozen were useless. When I had had enough of them, I sent the remainder back, stating my reason, but no notice was taken; so in about six weeks I wrote to enquire if the plates and letter had reached them, when in about ten days a letter arrived stating that a parcel of plates were sent to replace those returned, and that they were from a splendid, well-tested batch which had given great satisfaction to all who had used them; but alas! they were worse than the first; for, as I said at the beginning, out of six dozen there were not more than one dozen usable. After seeing the first dozen, I wrote to the maker stating the case, and he wrote back quite sharply, calling my complaints "totally unaccountable," and stating that he used those returned before, and "found them most splendid," and asking to be obliged by the return of the other five dozen unopened, when cash to their value would be remitted. Now, as I thought it very strange that I should always manage to open the only faulty packets (according to the makers), I determined to see what the other five dozen were like. So one night after work I opened the lot, and did not find six worth exposing. They were all very thinly and unevenly coated, most of them can be easily seen through if held between the eye and window of dark room, and are now in one lump in my cupboard as witnesses to the carelessness of their maker; and if I hear of any technical meeting in London this year, I shall most likely submit them to the judgment of the meeting, if such proceeding is in order.

Now that I have had a good grumble, I hope someone else will take the trouble to do likewise, for it is not likely that I am the only one to suffer, even if I am "the only one to complain," as the makers tell me. If any one should require proof of what I have written, I can furnish it, and should be happy to send a specimen of the half-gross named above to any one interested.—Yours truly,

E. Williams.

A PROPOSED PIRACY SYNDICATE.

Dear Sir,—In the later development of photographic publications, there is perhaps no greater source of annoyance or loss to the successful producer of art studies, &c., than to find the result of his labour copied and sold about the streets by hawkers, and, in many instances, by well-to-do tradesmen, for a merely nominal charge. As in many cases the photographer does not know how to stop these piracies, and may be unable to afford either the time required to enquire into the matter, or the necessary expenditure attending the prosecution, could not some sort of photographic defence association be formed, to be managed by an honorary committee, and employing a secretary and solicitors well versed in matters pertaining to copyright, which should contain within its registered members all photographers who would care to join by the payment of, say, £1 1s. per annum into the general fund? Such a society could take in hand the case of any member whose registered work had been pirated, and by some division of damages, when obtained, render itself self-supporting. In this manner the society, I think, would succeed in doing away with piracies, and would doubtless in most instances compensate those on whose behalf action was taken.—I am, your obedient servant, W. E. Downey.

Proceedings of Societies.

South London Photographic Society.

The opening meeting of the present session was held on Thursday evening, the 5th inst., the Rev. F. F. Statham, M.A., President, in the chair.

The minutes of the previous meeting were read and confirmed.

The Chairman expressed regret at seeing so small a gathering at the opening meeting of the session, which he attributed to the fact of several members being absent from town, but hoped it would not prove to be a precedent with regard to the rest of the session. He announced that at the next meeting nomination must be given in for election of officials of the Society in December.

Mr. Emery then read a paper on the "Decoration of Pottery by Photography" (see page 612).

The Chairman thought the members were very much indebted to Mr. Emery for giving them the benefit of his valuable experience, which he thought contained the germs of what might prove to be a very useful process.

Mr. A. L. Henderson thought the difficulties in the process were such as photographers might overcome; the depth of colour in the examples shown seemed to be quite sufficient, and he could not see any more insurmountable obstacle in the process than that which might proceed from the opposition shown to the process by painters on porcelain.

Mr. Emery, in answer to a question as to the kind of ink used, said the oil used, in its cool state, was of the consistency of bird-lime. All the colours used must have a mineral basis, but they were not expensive, none of them costing more than 8/- per lb.

Mr. Brooks asked if it would be possible to use a gelatine film inked with colour, take an impression off it on to the piece of pottery, and then continue inking the film for successive pieces.

Mr. Emery replied that a flexible typograph, something like the relievo impression Mr. Brooks alluded to, could be made use of, as, for instance, the india-rubber stamps now so much in vogue. He said that they could and did use that kind of thing for putting stamps on the back of earthenware; but that their best specimens were produced from engraved copper plates, and the colour left upon the base of bisquit earthenware when washed away would be sufficient for the base of an electrotype mould.

Mr. Henderson thought they might employ the platinic salts in lieu of other pigments. In producing some thousands of enamels during the year, he used platinic salts.

Mr. Emery said that the difference between Mr. Henderson's artistic work, and what they required to produce in pottery, was a wide one. They sold twelve plates for 2s. 6d. By producing intaglio plates in any way, provided only the impressions were sufficiently deep to contain the ink, they obtained what they needed.

In reply to Mr. Brooks' question whether a gelatine intaglio would be sufficient, Mr. Emery said that it would not, as they must have something that would bear rough usage.

A vote of thanks was passed to Mr. Emery, who was invited by the Chairman to be present at the technical meeting in November.

Mr. E. Dunmore next read a paper entitled "A Resumé of the Past Season" (see page 613).

The Chairman, referring to Mr. Dunmore's remarks with regard to gelatine and collodion respectively, said he quite agreed that quality was often sacrificed to rapidity, and that this would probably to a certain extent continue until the mania for very rapid plates, which was the outcome of the gelatine process, had somewhat subsided.

Mr. Brooks was of opinion that the inferior results obtained from gelatine plates were, in many instances, due to development.

Mr. Dunmore said some of the emulsions used would not give sufficient gradations of tone, which was the fault of the particular sample used.

Mr. W. Brooks next read a paper entitled "A Visit to West Cornwall" (see p. 614).

The Chairman remarked that the Royal Cornwall Polytechnic Society seemed to stand foremost among such societies in Great Britain in encouraging photographers to send in their works, both for disposal and for competition for the prizes offered, in the same manner as the paintings sent to the Royal Academy.

Votes of thanks having been passed to Messrs. Dunmore and Brooks for their papers, the meeting closed.

London Provincial Photographic Association.

At the meeting held on Thursday, the 5th inst., Mr. B. B. Prestwich in the chair,

Mr. Henderson showed a print of a group of ladies and gentlemen from a negative taken in Paris by the light of a number of Chinese lanterns, the exposure being about fifty seconds.

Mr. Debenham passed round some negatives that had been marked by rain, but on flooding them with rainwater the spots almost entirely disappeared.

Mr. Haddon said he found that either rain, distilled, or tap water would give these markings, but if the negative was soaked in tap water they were then only visible by reflected light.

Mr. Debenham also showed a negative with a small semi-transparent spot enclosed in an opaque spot in the film. In the course of a lengthy discussion which ensued,

Mr. Brown attributed the spot to a small piece of glass which had lodged on the plate, and stated that he had noticed deep holes or pits gradually formed in solidified gelatinous solutions if kept for any time, and attributed it to particles of matter which had fallen on the surface.

Mr. Haddon had noticed the same, but attributed it to a fungoid growth.

Mr. Henderson showed the draining-board alluded to by him at the last meeting, and it was suggested that brass nails should be substituted for the iron ones.

It was announced that arrangements had been made for the meetings of the Association to be held at the Mason's Tavern, Mason's Avenue, Basinghall Street, E.C.

Edinburgh Photographic Society.

The ninth ordinary meeting of the Society was held at 5, St. Andrew Square, on the evening of Wednesday, the 4th inst., John Lessels, Esq., President, in the chair. There was a very large attendance, the room being inconveniently crowded.

The minutes of the last meeting were passed unanimously, and the following gentlemen admitted ordinary members:—Messrs. Robert Wright, John V. Gregory, and James Dick.

Mr. William Crooke read a paper (see page 615), specially intended for the benefit of beginners in the practice of photography, and illustrated by practical demonstrations of the development of gelatine negatives, and showing his mode of securing uniformly good results when the negatives were known to be correctly exposed, over-exposed, and under-exposed. Proceeding to develop, he said:—The solutions required, and which for convenience sake we shall designate A, B, C, D, E, are as follows:—

A.—Pyrogallic acid	30	grs.
Water	10	oz.
B.—Liquor ammonia (s. g. ·880)	1	oz.
Bromide of potassium	1½	dr.
Water	2	oz.
C.—Liquor ammonia (s. g. ·880)		
D.—Bromide of potassium (sat. sol.) ...	2	dr.
Water	2	oz.
E.—Liquor ammonia	1	dr.
Water	2	oz.

Plate No. 1, having received the proper exposure, should be developed by first soaking it for about a minute in two ounces of solution A; then, by adding half a dr. of B, the image will soon make its appearance. When the details are almost out, add another half dr. of B; in about thirty seconds the image will have received its full density; then wash for a few minutes previous to fixing. Plate No. 2 has received three times the correct exposure, and must first be immersed in two ounces of D for a few seconds; then pour off, and apply two ounces of A, half a dr. of B, and half a dr. of D. When the image has appeared evenly over the plate, as much pyrogallic as can be heaped on a florin should be added, and after a few seconds have elapsed, add 1 dr. of B, keeping the plate in motion until the full density is attained; wash and fix as before. Plate No. 3 got only half the exposure necessary, and consequently will need immersion in two ounces of E for about a minute; this is poured away, and two ounces of A, with 1 dr. of B, added; when sufficiently dense, wash off. Plate No. 4 is similar to 3 in point of exposure, but shall be treated in a slightly different manner. Immerse first in two ounces of A for a few seconds, add half a dr. of B, then 1 oz. of water, and last of all, 1 dr. of C in 1 oz. of water. The plate must be lifted while the latter solution is added, for if poured on any one part of the plate it may cause fog.

Fixing Solution.

Sodium hyposulphate (sat. sol.)	1	part
Water	4	parts

Mr. N. Macbeth, R.S.A., said that amateurs or others who were now commencing to study photography had a great advantage over those who commenced in the old wet-plate days. Then the greatest difficulties were encountered in the preliminary processes of preparing a good sensitive plate, involving many details, any one of which being faulty necessarily interfered with the results; now all these troubles were non-existent, and the difficulty only began at the development. He advised some mechanical appliance to correctly indicate time of exposure, as the agitation of the moment often caused a mental incapacity to appreciate correctly the length of time given, and thus an element of uncertainty was introduced.

Mr. Turnbull said he was not too old to learn, and he had noticed a few hints in Mr. Crooke's communication that he should adopt in practice. He, however, advised Mr. Crooke to employ rapid rectilinear lenses for interiors instead of doublets, as recommended, as, under all conditions, the correctly constructed rectilinear lens gave straight lines if the camera were not tilted.

Mr. W. Nelson said that he had found a whistle sharply blown induced a most acceptable pose in horses, and when it was necessary to take portraits in the open air, one of the best things to aid in securing desirable relief by shadows was an ordinary umbrella.

Mr. W. Hulme considered a simple drop or spring shutter the best for every-day use.

Mr. Lessels always used ferrous-oxalate developer—he found it much more manageable in his practice than the alkaline. He chiefly employed his camera to secure architectural details, and occasionally he was reluctantly compelled to tilt his camera. In such a case he found the double swing-back of the very greatest value in lessening the distortion of the image. In the focussing he always compared, when possible, some perpendicular line in the subject with perpendicular lines drawn on the focussing screen. For architectural interiors he advised a long exposure and small stop, with selection of time of day to secure the most appropriate light for the special subject.

Mr. Pringle found difficulty in securing harmony when much foliage occurred with architectural subjects. He greatly appreciated Mr. Crooke's advice in regard to the taking of portraits in ordinary rooms.

Mr. Crooke said that his experience led him to prefer exposure by hand in all cases, except when the extremest rapidity was absolutely necessary. A hearty vote of thanks was accorded to Mr. Crooke.

Mr. Alexander Mathieson directed attention to the splendid display of photographs which adorned the walls of the room, the work of members of the Society during the past season. He said that while a general invitation had been sent out to all the members, the exhibited pictures were produced by those members who had constituted themselves into the Edinburgh Photographic Club. Very great good had resulted from these meetings, as on each night demonstrations and discussions of an eminently practical character occupied the meeting. This made the evening meetings extremely interesting and profitable, hence it very rarely happened that any member of the Club was absent; in fact, the members felt they could not afford to lose the advantages of attendance. In consequence of the limited capacity of the room, the number of members was of necessity limited, but when vacancies occurred he advised the members of the Society to show themselves worthy of election by bringing forward practical matter at the ordinary meetings of the Society, and by entering heartily into the discussions. Each member of the Club was expected to supply at least one specimen of his work each season. These specimens were exhibited on the walls that night, and at the next meeting of the Club they were to be exchanged among the various contributors by ballot.

A hearty vote of thanks was accorded Messrs. Jameson and Matheson for the great trouble they had taken in carrying through the necessary arrangements for the display.

Mr. Bashford intimated that the committee for opening the packages sent in for the International Competition would meet on Monday the 9th inst., in the large room belonging to Mr. Andrew Elliot, Princes Street, who had most generously lent it for the purpose, and where the pictures would be on exhibition first to the members and then to the public. He said the council in instituting this competition, bearing in mind the extreme difficulty they have experienced in obtaining pictures suitable for presentation, and after the most laborious endeavours finding that the selected prints have not on all occasions given the general satisfaction that is desirable, have determined to leave the selection of the presentation prints for the next five years in the hands of the members themselves, so that the pictures deemed the most acceptable shall unmistakably be selected.

It is believed that this competition is the first of its kind, and the council is specially anxious that the awards shall be strictly in accordance with the popular acceptability of the pictures; hence they could not leave the awards in the hands of one or two experts or judges.

Every member will be entitled to indicate the five pictures in the Exhibition which he shall feel the greatest desire to possess, and it is particularly requested that each member will place the numbers of the pictures he selects in the spaces on the voting paper in what he considers their order of desirability. The committee of scrutineers will be governed by the number of votes awarded to each picture, and their positions on the voting paper. Voting by proxy will not be allowed.

Full details will be found on the voting papers, which members will receive by post, together with other necessary information.

Mr. Wane exhibited a camera that had been lent for the purpose. It was devised to carry eight sensitive plates, so arranged that any plate could be exposed and mechanically adjusted to the plane of the focussing glass by means of a dial. It appeared very compact, simple, and not likely to get out of order. A tripod stand was also shown; each leg was composed of a three-draw telescopic brass tube, with screws to adjust the legs at any length within the maximum.

After a vote of thanks to the chair, the meeting adjourned, the exhibition of pictures keeping members till a late hour.

Sheffield Photographic Society.

The above Society held their annual meeting in the Masonic Hall, Surrey Street, on Tuesday, October 3rd, when a goodly number sat down to an excellent tea, provided by the steward, to which full justice was done.

After tea the chair (in the absence of Dr. Morton, who has gone to India for a brief period) was taken by Mr. Dakin, Vice-President.

Mr. Chadburn was proposed and unanimously elected a member of the Society.

The Secretary reported that in consequence of illness, and consequent absence from home, of the Treasurer, the accounts for the past year had not been audited as usual. They were, therefore, left for consideration to the next meeting.

The election of officers for the ensuing year then took place, with the following results:—

President—Dr. T. H. Morton.

Vice-Presidents—Mr. J. D. Leador, Mr. J. H. Rawson.

Treasurer—Mr. W. B. Hatfield.

Hon. Secretary—Mr. J. Taylor, Holland Place, London Road, Sheffield.

Council—Messrs. Dickenson, Ainley, together with the officers.

Mr. Dakin then vacated the chair, which was taken by Mr. Rawson, one of the newly-elected Vice-Presidents, who briefly expressed his thanks for the honour done him.

Some modifications of the rules were then taken into consideration, and ultimately agreed upon, after which the meeting was adjourned.

Talk in the Studio.

Electricity and Speculation.—Some experiments which have been recently made on electrical locomotion serve to indicate the utter impracticability of storing a useful amount of motive force, by means of the Planté secondary battery, which has recently been brought before the public under other names; and it is to be regretted that published accounts of these experiments are calculated to mislead the unwary investor. In one case an amount of force equal to that exerted by a large locomotive during less than half a minute was stored by 45 ponderous secondary batteries, the operation of charging and removal costing sufficient to pay for something like sixty-five times the force as generated by means of a steam engine. When such results as these are put forward as a practical and industrial success, one cannot help looking back more than forty years, when the illustrious Jacobi actually realised a somewhat more economical propulsion by electricity on the waters of the Neva. The following quotation from a leader which appeared in the Photographic News over a year ago, may be re-read with advantage. "Some of the daily papers have been predicting extravagantly great results from the use of secondary batteries, because four cells constructed on the above-described principles, and weighing, with their packing-case, about 75 pounds, stored up an available force of a million foot pounds, and this potential force was transmitted from Paris to Glasgow. The newspaper writers appear to have been influenced by the large look of the word million, and they probably lost sight of the circumstance that in conveying the box several million foot pounds of force were expended, and this circumstance somewhat damps the half prediction that the force of the Niagara Falls will some day be stored in secondary batteries and conveyed all over the North American continent, if not all over the world. A million foot pounds represents the actual work of a strong horse during a period of rather over half an hour; the force developed by a powerful locomotive in about ten seconds, or the energy produced in actual practice by the combustion of three farthings' worth of coal in a gas motor engine." The electrical *transmission* of force will prove of undoubted value in numerous cases, a pair of dynamos being used, one as a generator, and the other as a motor; but the so-called storage of electricity is quite another matter.

FERRANTI'S DYNAMO-MACHINE.—In reference to a "Note" in another column, we take from the *Times* the following:—"It has been evident from the first introduction of the electric light by the arc and incandescent systems that inventors would busy themselves to discover some means of producing the current at less expense. When the electric light companies were being so rapidly formed and supported by public subscriptions some time back, we warned especially the buyers of the shares at high prices of the risk they ran of having the ground cut from under them by a new discovery. Electrical scientists have been diligently at work trying to improve upon the bulky and expensive dynamo machines now in use, and we understand that Sir William Thompson patented a new invention for a simpler and more efficient dynamo machine only a short time before an electrician in Messrs. Siemens' establishment hit upon much the same thing. The great feature in the new machine is the absence of iron in the revolving armature, very greatly decreasing its weight, and, by enabling the field magnets to be brought very close together, greatly increasing its efficiency. In fact, it is stated that a Ferranti machine to produce 10,000 incandescent lights, or an equivalent number of arc lights, can be manufactured for less than one-fifth of the cost of the cheapest dynamos at present before the public. The increased efficiency of the new machine is aided by the abolition of the commutator. The announcement of this new machine has been, we are informed, greeted with incredulity, and naturally some perturbation has been caused among those interested in existing dynamo machines leading to letters having been addressed to us raising points in reference to engagements entered into with subsidiary companies. Before publishing the numerous letters referred to, we thought it better to make enquiries, and the result in the case of the Hammond Company is the following letter which, as regards the engagements of that Company to the subsidiary companies will, it is hoped, be satisfactory:—'The Hammond Electric Light and Power Supply Company (Limited), 110, Cannon Street, E.C., Sept. 21.—Sir, In order to correct certain misapprehensions which seem to exist in reference to our Company, I beg to advise you that we were not constituted to work the Brush system solely, though we acquired the Brush rights over certain counties. In order to extend our field over the whole of Great Britain, we have now acquired the sole agency of the Ferranti machine for the districts not covered by our Brush concessions, which we still hold. In reference to those subcompanies which we have founded, our directors desire to give them the full benefit of the new invention, and will offer them the use of the new dynamo without demanding any further payments for a new licence beyond that which they have already paid to our Company, the desire of the Board of this Company being that all their offshoots should participate fully from time to time in the successes of the parent Company.—Yours faithfully, ROBERT HAMMOND, Managing Director.'"

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—We have been asked to state that this Association has changed its place of meeting, and that for the next three months, at least, it will meet every Thursday evening at eight o'clock at the Mason's Hall Tavern, Coleman Street, E.C. The London and Provincial Association will be glad to welcome to its meetings any visitors to the exhibition of the Photographic Society of Great Britain. For the information of such of these as incline to join the new Association, we may state that the annual subscription is 5s.

THE PHOTOGRAPHIC MONEY DISPUTE.—This case was resumed at the Clerkenwell Police Court, on Wednesday, when, after further evidence, Mr. Hosack, who said there was a great deal too much animus shown on both sides, again adjourned the hearing.

ACCIDENT TO A PHOTOGRAPHER AT BIRMINGHAM.—A remarkable accident occurred near to Stourbridge on Sunday. Mr. Charles Moody, a local photographer, was walking along the old Stamber Mill viaduct, on the Great Western Railway, when he was suddenly seen to disappear. It turned out that he had fallen through the old bridge into the river Stour below, a depth of about a hundred feet. He was speedily rescued, though in an insensible condition, and it having been ascertained by medical examination that no bones were broken, he was conveyed home. Mr. Moody has recently been photographing the old viaduct from different points, and it is supposed that he was studying a position for a new picture when he fell through.—*Birmingham Daily Post.*

SUPPOSED INCENDIARISM.—A PHOTOGRAPHIC STUDIO BURNT DOWN.—On the 4th inst., the photographic studio of Mr. D. S. Jones, of Matlock, Bath, was destroyed by fire. The building was only partially insured in the Lancashire and Yorkshire Insurance Company. Much sympathy is felt for Mr. Jones, who is regarded as an accomplished man in his profession. The origin of the fire is supposed to be incendiarism, and the damage is estimated at about £200.

A PHOTOGRAPHIC ACTION.—At the Metropolitan Court, Bloomsbury, on Friday last the case Easterbrooke *v.* Mathews was heard before Mr. Judge Bacon, in which the plaintiff, a photographer, trading as S. I. Mair and Co., 272, Regent Circus, sued the defendant, John Mathews, 135, Oxford Street, to recover the sum of £1 16s. for work done. The plaintiff's manager said the work mentioned in the particulars before the Court was supplied at the defendant's request, who ordered the goods personally; he had done work with the firm of Mathews and Son up to 1880, which had always been paid for. The work now sued for was executed upon the order of the present defendant, Mr. John Mathews. The defendant stated that he was merely manager at the time of the firm alluded to, and was not a partner at the time the action was brought; but in cross-examination admitted that he became a partner in March, 1822, and that his sister, Catherine Mathews, was the original firm. After considerable legal discussion, the learned Judge said he was of opinion that at the time the goods were ordered the defendant was merely a paid servant of the firm, in which capacity he was not liable to pay any trade debt. Judgment must therefore be entered for the defendant with costs.

To Correspondents.

*** Several answers are unavoidably postponed until next week.

*** We are reluctantly compelled to leave over till next week our article on "Swan Lamps for the Show-Case" and "At Home."

J. BULLOCK.—1. There is no doubt that constant exposure to the vapour of ammonia is likely to tend to be injurious to the eyes, and even to affect the health; but it must be remembered that many have sufficiently strong constitutions to resist such influences for a long time. 2. Common washing soda answers fairly well, but is perhaps not quite so convenient as ammonia. Borax and phosphate of soda may also be used.

FRANK JOLLY.—A cautious treatment with a weak solution of cyanide of potassium, or a mixture of cyanide of potassium and alum, is sometimes effectual, but there is a considerable probability of utterly ruining the negative. If you value the picture, it would be well to make as good a transparency as possible before commencing to work on the negative.

G. WEST & SON.—Notices appear in the PHOTOGRAPHIC NEWS from time to time, and we can suggest no method of obtaining earlier information than writing to the secretary of each Society.

J. SIMMONDS.—1. A weak solution of Rosaniline dye in warm water, a small quantity of acetic acid being added to prevent the deposition of the colouring matter. 2. Rub down with a stick of charcoal cut at an angle of about 30° to the direction of the axis. 3. You had better use ordinary sweet oil, unless the arrangement is of such a nature that the parts are likely to become much heated. 4. One part of shellac in five or six of alcohol. 5. Light has either no action on it, or so little as to be of no importance; but if you procure some of the natural bitumen there will be no difficulty. We have obtained it from Hopkin and Williams.

RETFORD.—Very little is gained as regards colour by bleaching it, as the film is so thin as to make the tint almost imperceptible. On the other hand, the mechanical qualities almost invariably suffer to a great extent by the bleaching.

IN TROUBLE.—The glaze is very bad, containing a large proportion of lead, and being very imperfectly fixed, while the whole body of the ware is thoroughly saturated with partially decomposed emulsion. No wonder you are troubled with red fog; use either glass or thoroughly vitrified porcelain.

SILVER.—It is the effect of damp, and if you take care to thoroughly dry your paper, no fresh cases will arise.

N. T. NEWSON.—1. The mineral constituents are phosphate of lime and carbonate of lime.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1259.—October 20, 1882.

CONTENTS.

DIRECT POSITIVES IN THE CAMERA.

Scarcely have we had time to appreciate the due importance of Herr Obernetter's simplified emulsion process, than another hardly less important communication comes to us from that gentleman's laboratory. This last relates to the production of direct positives in the camera, and, according to our contemporary, the *Mittheilungen*, the method is both a practical and simple one.

Here are the details. A gelatine plate is exposed in the camera about double the ordinary period, and then developed in the usual way with ferrous oxalate. The development is continued, indeed, until the back of the plate is completely black. About ten to twelve minutes are generally required to bring about this result.

The plate is now perfectly black on both sides. A two per cent. solution of chromic acid, or a solution of one gramme of bichromate of potash and five grammes of nitric acid in one hundred grammes of water, is then poured over the un-fixed plate until the black colour has disappeared, and a bright image composed of pure chromate of silver is produced.

The plate is then further treated in day-light. To remove all the chromate of silver, it is washed with very dilute ammonia, say one part of the latter mixed with one hundred parts of water.

Finally, the plate is again laid in an oxalate developer, and this is permitted to act until the desired vigour is obtained. If the plate gets too vigorous, the action of the developer is at once suspended, and the image is washed and fixed.

Herr Obernetter prefers to employ for the process an emulsion poor in gelatine, such as he produces by his new *modus operandi*; if there is much gelatine in the film, the manifold operations to which the plate is subjected naturally enough lead to difficulties, such as frilling, creasing, &c., of the film. In fact, the great thing is to work with a film containing as little gelatine as possible.

At the last meeting of the Berlin Society for the Advancement of Photography, a number of plates produced by this process were submitted to the meeting, and invoked universal admiration. It was then remarked that the method was an improvement of Jaehn's plan of producing direct positives, which, our readers may remember, we published in these columns about two years ago.

Herr Obernetter now prefers to make all his reproductions by his new plan, in preference to employing the clever graphite method that he has used for years past; indeed, he has had it in operation, it appears, for the past twelvemonth. It is very frequently of importance to secure a negative direct in the camera, from another negative, especially in the case of enlargements, and this new method affords an easy plan of doing so.

The last number of the *Mittheilungen* has an illustration, which has been printed from reproductions obtained by the new method.

THE SWAN LAMP FOR THE SHOW CASE OR WINDOW.

Mr. Mayland has thoroughly demonstrated the practical value of our suggestion to use the small Swan lamp for the illumination of photographic pictures, and we now propose to give full details as to the fitting up and management of the lamps.

Our readers know that when the course of a voltaic current is partially obstructed by an indifferently good conductor, heat is generated; while the imperfect conductor may become white hot, and serve as a source of light. A thin thread of carbon is the bad conductor usually chosen, and in order to prevent its combustion it becomes necessary to enclose it in a glass bulb, carefully emptied of all traces of atmospheric air. Here, then, we have the Swan lamp.

The battery most suitable for supplying the electric current is that devised by Bunsen, and a single cell or element of this form of electric generator is represented below. C represents a carbon rod or block, and this

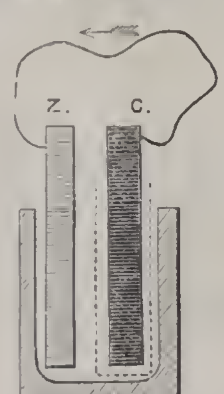

Fig. 1.

stands in a cell or tube of porous earthenware, as represented by the dotted lines. The interspace between the carbon block and the porous cell is filled, to within about an inch and a half of the top, with strong nitric acid. The porous cell stands in an outer jar of salt-glazed stoneware, and this outer jar contains dilute sulphuric acid; one volume of the strong acid diluted with nine volumes of water. A plate of amalgamated zinc is immersed in the dilute sulphuric acid; but this zinc element is ordinarily made cylindrical, so as to encircle the porous pot, instead of being shaped as represented in the diagram. When the battery is charged, as described above, and the projecting portions of the polar elements are joined by a conducting wire, a current passes; and the wire becomes more or less heated according to its diameter and length. Although there is every reason to believe that the electric transmission is not strictly of the nature of a current, we shall use the ordinary language, and assume that the current passes in the direction of the arrows. When a current of high potential or tension is needed, several cells of the battery are connected in series, as shown below (fig. 2), so that the currents become (to use a figure of

Fig. 2.

speech not altogether orthodox) reinforced or exalted as regards tension; and to satisfactorily work two of the five-candle Swan lamps, it is necessary to use seven cells of the battery; cells holding about a pint and a-half being suitable in ordinary cases.

Before considering the mode of charging the battery, and setting the lamps in action, we will give a list of the articles required for setting up and working a pair of lamps, together with the cost, assuming the articles to be bought at semi-wholesale houses in London.

Apparatus:—

Seven $1\frac{1}{2}$ pint or quart cells of Bunsen battery, with brass terminal clamps for the connecting wires	£1	18	6
Two five-candle Swan lamps	0	12	0
Two stands for ditto	0	3	0
Three pounds No. 18 cotton-covered copper wire	0	6	0
Files, emery cloth, &c.	0	1	0
	3	0	6

Stock of Materials for Commencement.

One Winchester quart of commercial nitric acid, s.g. 1·42, at ... ... 6d. per lb.	0	4	2
One Winchester quart of commercial sulphuric acid at ... ... 2d. per lb.	0	2	4
One pound of mercury...	0	3	0
	0	9	6

Just £3 10s. serves, then, to instal the necessary plant; and now as to the working details. First arrange the batteries in a row on an outside window sill, and fix up a board so as to shoot off any rain which may fall. Next undo each brass clamp, and replace them, after having carefully filed or cleaned those parts which come in contact with the battery plates, and also brighten the inside of each hole through which a connecting wire may pass, using a small rat's-tail file for the purpose. Starting from one end, connect the carbon of the cell with the zinc of the next; and the carbon of this next with the zinc of the following, and so on, just as represented in the diagram; while the greatest care should be taken that those ends of the connecting wires which are held by the terminal clamp are carefully cleaned or filed, as metallic oxides are very indifferent conductors of electricity. The arrangement just described will leave a free carbon plate at one end of the series, and a free zinc plate at the other end, and to it are connected the main conducting wires. These conducting wires may pass through walls or under floors until they terminate in the case or the window to be illuminated, where they must be bifurcated or branched, as shown in the diagram, so that equal currents pass through the lamps A and B. The branches are best soldered on, but a firm twisting together will answer. The actual placing of the lamps in relation to the picture or pictures to be illuminated must depend altogether on individual taste; but it should be remembered that the Swan lamp may be placed in a position which would be altogether impossible in the case of a gas flame. Either the small stands sold in the shops may be used, or the lamp may rest against the pictureframe; while in some cases it may prove convenient to make use of a wide-mouthed bottle as represented below.

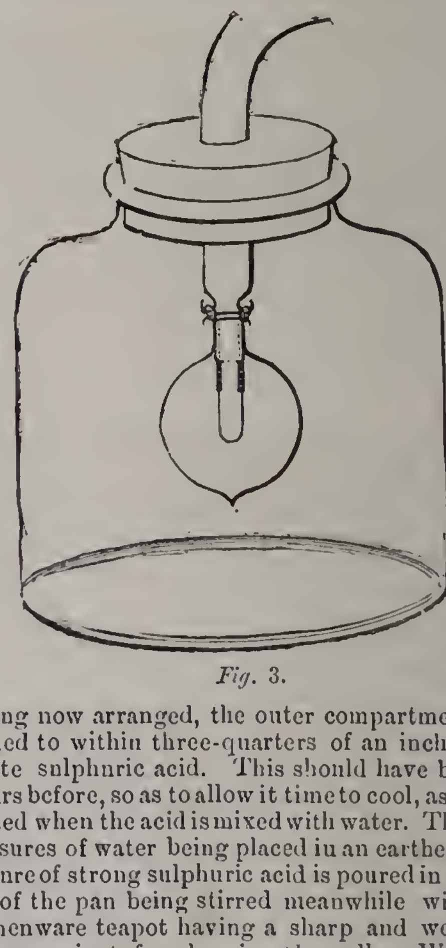

Fig. 3.

All being now arranged, the outer compartment of each cell is filled to within three-quarters of an inch of the top with dilute sulphuric acid. This should have been mixed some hours before, so as to allow it time to cool, as much heat is generated when the acid is mixed with water. The required nine measures of water being placed in an eartherware pan, one measure of strong sulphuric acid is poured in slowly, the contents of the pan being stirred meanwhile with a stick. An earthenware teapot having a sharp and well-pouring spout is convenient for charging the cells. When all the outside compartments are thus nearly filled with the dilute surplus acid, the next step is to fill the interspace between such carbon plate and its porous cell with the strong nitric acid, using an earthenware teapot as before, and taking care that the level of the nitric acid shall not be higher than that of the dilute sulphuric acid in the outside compartment. As soon as the last cell is charged with nitric acid, the lamps will start into action, and continue until either the circuit is broken by disconnecting one of the wires, or the acids are exhausted; this latter event ordinarily taking place about twelve hours after charging. As soon as the battery commences to act, it is well to listen carefully with the view of detecting any evolutions of gas bubbles from the zinc plates; and if any effervescence is detected, it is a sign that the coating of mercury which has been applied to the zinc is discontinuous or defective. To remedy this, the plate is removed, and a little mercury is applied to the defective spot, and spread by means of a piece of rag attached to a stick. The mercury is best projected on the plate by means of a spurting bottle, such as is represented by fig. 4. This simple

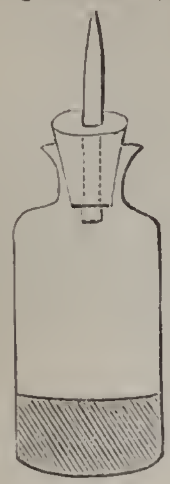

Fig. 4.

arrangement, which was first shown to us by Mr. G. F. Williams, consists merely of a small vial, fitted with a drawn out jet of glass tube, adapted to it by means of a cork; and a slight jerk serves to project the mercury in small and easily regulated doses.

When the light is no longer required, the acids should be emptied out—if exhausted they are best poured into a small hole dug in the ground—and all parts of the battery should be well rinsed. The metal portions of the carbon plates and the outer glazed cells may be laid out to dry after the rinsing, but the porous cells ought to be left in water until again required, supposing that they are to be used next day. If it is intended to dry them and store them away, they should be soaked for a few days, the water being occasionally changed.

It is generally advisable to start with fresh acids on each evening, but two short evenings' work may be got out of the batteries, as evidenced by the following quotation from a letter which Mr. Mayland addressed to us.

"The light has been a great success. I have reduced the expense by disconnecting it each night, and pouring the nitric acid back. It burns splendidly for two nights, but not so brilliantly on the third. I think of putting on another cell, freshly charged, for the third, and seeing the effect. I came to grief over it one night in lifting out the porous pot with nitric. Probably it was held a little too tightly, for it broke up, smothered me, and burnt a whole suit of clothes. Carefully filing the screws, &c., pays well. To-night it is burning splendidly."

Two lights cost from 9d. to 1s. per evening for materials consumed.

RETOUCHING.

The subject of retouching is one which is seldom discussed in the photographic periodicals. It is difficult to say why this should be. There is no doubt that when it is employed within limits, there is no process which may be more useful to the photographer than that of retouching. It serves to reduce, or even to annihilate entirely, many of the faults peculiar to photography. At the same time we venture to say that nothing has had a greater tendency to degrade photography as an art than the abuse of the power which the retoucher possesses.

We have from time to time taken the opportunity of pointing out where might be seen at photographic exhibitions, and other places, examples of how not to do it, in the way of retouching; in other words, we have shown cases in which the utmost manipulative skill has been expended to degrade a photograph from a picture to a nonentity. Let us not be misunderstood. We are not speaking against legitimate retouching, but against the abuse of retouching.

We ought possibly, before going further, to say a few words as to what we consider to be legitimately within the bounds of the retoucher's art, and what without. We are speaking purely of portraiture. Let us suppose a certain number of negatives—untouched—to be placed before us. We will take two as typical. The one is that of an aged man—a face furrowed with the lines which tell a history, and indicate a character; the other that of a young and lovely girl—a face which painters love to draw, because, in doing so, they give the reflection of a pure and happy soul.

Now let us descend to the practical details of the matter. In each case it is possible—that is to say, the skilful retoucher is able, by the use of his pencil—to obliterate any effect which, in the print, will show as a dark spot against a light background. Such effects show on the negative as transparent portions against more opaque ones. In the case of the patriarch, these portions will be the representation of the lines and furrows which, as we said, told the history and the character of the man—in fact, make him a patriarch; whereas, without them, he would appear imbecile.

What is the inclination of the retoucher? Without doubt, to work with his pencil on these more transparent parts of the negative till he has made them equally—or almost equally—dense with the rest of the face, with the effect that we have represented a mixture of age and youth. We have the features of an old man, with the smooth skin of a young one. This we take as an example of the abuse of the retoucher's art, the practice which serves only to degrade photography in the eyes of all men of good taste.

We pass now to the other case—that of the lovely maiden. Here, at first sight, it would appear to the observer that such perfection reigned in the subject that no improvement could possibly be made in the representation which the camera would give thereof. Yet look a little more closely. Here, on the cheeks and forehead, are one or two marks. What are they? Tell it not in Gath! There is no doubt that on the face of our beauty there are several freckles. Yet the reader will say—but so incipient and undecided that it takes an almost microscopic examination to detect them. Perhaps so; but let us refer to the negative. Here, doubtless to the surprise of the non-photographer, the marks which an occasional observer would fail to detect in our model are distinctly—nay, strongly—indicated, the fact being that they are of a yellowish or non-actinic colour. With a single circular ouch of the pencil each disappears. Here we have a ttypical example of the true use of retouching.

We have taken two extreme cases. What would a portrait of the picturesque, patriarchal, bareheaded *Echo*-seller of the Strand and neighbourhood, whom we all know, or rather knew, be with the lines all touched out of the face? What would a portrait of one of our "little beauties" be, were the freckles which show themselves to the camera, but not to the eye, not removed?

These are extreme cases, and between them lies a vast range of others in which the greatest discretion ought to be exercised as to whether or not the pencil is to be used, and if it is to be, then to what extent. The mistake, in nine cases out of ten, certainly lies in retouching, when a better, more artistic effect would have been produced without.

There is no doubt that photography tends to exaggerate certain defects, to make them more pronounced than they are to the eye. We have given as an example of this the case of the strong manner in which incipient freckles are rendered. We shall sum up a thousand other details when we say that, as a rule, the print from an untouched negative gives the impression of a person older than the sitter in reality is. To counteract this tendency is evidently nothing more than a leaning towards truth, and is therefore not only justifiable, but commendable. Nay, we shall go even farther. We will admit that in the cases of "persons of an uncertain age" it is allowable to give the benefit of a doubt, and to carry the retouching process a shade farther than a strict adherence to truth will allow. What we protest against—and that most earnestly, because we believe that by the practice much harm is done to our art—is the custom of obliterating entirely those marks and lines which give beauty to many an old and withered face.

We remember, on the occasion of last year's exhibition, looking through the portraits shown. Here we found excellently rendered the faces of those who were young and fresh; but nowhere could we find what may be so well rendered by photography, a face giving the idea of decided and vigorous character. We say nowhere, but at last we came on one. It was hung so high that we could not closely examine it. We were surprised at this, as the picture was evidently an excellent rendering of a splendid head, and the more so as there was, not far away, but on the line, a photograph of a well-known man whose head might have made an excellent picture, but for the over-zealous use of the retoucher's pencil. Our surprise vanished when we looked at our catalogue. Alas! the high-hung picture was a copying from a painting. What an opportunity here for those who say that photography is not a fine art to hold up the finger of scorn! Such an example is almost enough truly to make us side with those who cry down retouching altogether, and say it is a vicious practice. Yet our better reason tells us that these are not correct. It is not the use, but the abuse, that is to be decried. Our most earnest hope is by no means to see the art of retouching discarded, but to see it kept within its proper limits; then it will be truly useful.

We are well aware that in blaming photographers in the matter of over-retouching, we are in reality laying the onus on the wrong party. It is the sitter who is most to blame. It is his indiscriminating vanity which demands that, when he is an old man, he shall be shown as a youth, and it is this same vanity which leads to his being represented as a characterless imbecile—which, perhaps, after all, he is; still, surely the photographer is not blameless in pandering to this vanity for the sake of filthy lucre, instead of holding out for his art. A painter would not so give in.

THE PHOTOGRAPHIC EXHIBITION.

Second Notice.

Turning our attention to the screens, and beginning at the last picture, we come to an enlargement of an artistic group (466), in crayon style—three graceful girls—by Mr. W. E. Debenham, who in another frame (392) shows the original, together with some other excellent portrait work. Major Gubbins, R.A., exhibits some interesting album views (465) of Indian scenery, and also a collection of tiny sketches from the New Forest (102) printed in platinotype. Mr. H. Manfield contributes a goodly number of good pictures, some of them also printed in platinotype. "Lynmouth Harbour" (463), and "A Devonshire Cottage" (98), are capital studies, the latter, with its leafy trees and bowery foliage, charmingly composed; while another delightful picture is that of "Studland in Dorset," a green paradise on the South Coast, which we congratulate Mr. Manfield on having discovered. Some pictures of Cape scenery and Madeira scenery are also in Mr. Manfield's collection—an Ostrich Farm, that we have before noticed, is very curious—all of which denote a landscape photographer of high skill and excellent taste.

Mr. J. W. Boord, M.P., makes his first appearance as an exhibitor in Pall Mall, contributing a series of Marine Views (462); of these, we like best the yacht *Swift*, taken from on board another craft. The yacht is in full sail, making its way through a rough bit of water, the waves brisk and forcible to a degree. Messrs. W. A. and T. J. Skill send some fine pictures of Lincoln Cathedral (461, 119, 142), all of which do justice to the grand proportions of the ancient pile. Mr. George F. Dew, of Coventry, is represented by half a dozen frames which contain for the most part excellent work. Of them, we admire most "St. Michael's, Coventry" (136), in which the elegant taper spire is rendered with exceeding skill and good taste; it is a subject that only a courageous man would attempt, and that only a patient one could succeed in. Two views in Warwickshire (160, 161) also call for praise, exhibiting, as they do, considerable artistic training. Mr. George Bruce, of Dunse, whose pretty collodio-chloride prints are still fresh in the memory of most of us, has forwarded several portrait studies: "The Flower Girl" (459) is an excellent picture; and so, too, is "Dominica" (254), a smiling Italian girl, playing the accordion, who is looking at us with her pleasant olive face as if soliciting patronage. Mr. Frederick Hollyer, who has always shown himself an adept in platinotype printing, forwards several productions this year. "Richmond" (457) is a pleasing sketch, and so is "Hastings" (70); but perhaps the most effective is "A Winter Morning," a drear view of one of the London bridges, which might fittingly illustrate Tom Hood's "Bridge of Sighs."

Mr. C. Stephens exhibits studies of sea and cattle (456); and Mr. Emil Seelig, "Views at Cassel (455) and England (367), of which the winter scenes are the best; some of the pictures are rather too dull to please. Of Mr. E. A. Maxwell's exhibits we like best "Deerman's Lane" (306), and of those of Mr. Peter Burges, the studies of ferns and silver birch (413). Mr. Burges' "Storm Brewing" (453) is also an effective picture. Mr. Cecil V. Shadbolt exhibits his clever balloon photograph (171), certainly the best taken in this country, and a frame of leafy landscapes (452), of which the Old Mill, Ambleside, will probably find most admirers. Mr. E. H. Goold is another exhibitor of platinotype prints, of which there are many this year; he shows "Pareham Park" (450) and other pictures. Mr. J. R. Ritchie, working with his so-called Arabin emulsion, has sent half-a-dozen frames: Killicrankie (117), in which the still waters and overhanging foliage are effectively shown, is one of the best in the collection. Mr. Archer Clarke forwards two frames, of which the one representing shipping in the Thames and Atlantic (448) contains the most praiseworthy work. Two series of views taken around Lowestoft by Mr. W. J. Hollebone (446, 447) contain some bright little sea pictures; the interiors are, however, too dark for our taste. A capital picture of Chingford Mill (445), with its timber, and mirror-like mill-pond, is contributed by Mr. J. Herbert.

Of Mr. Alfred Hendrey's pictures we prefer "The Fisher's Haunt" (432), a sequestered nook where the waving rushes and yellow waterlilies grow; but "The First Primrose" (82) is scarcely less taking. Mr. F. Bills sends some clever studies of fruit and fish, of which "In the Store Room" (433) and "A Neglected Corner" (434) are good representatives. Mr. J. T. G. Glossop's nice little sketches about "Virginia Water" (431), and his coast scenes, "Torbay" (371), indicate considerable taste, while his management of foliage is in some cases masterly; Mr. Glossop also exhibits six Daguerreotypes taken in 1843 at Rome by Borghesa (472). Mr. W. K. Burton shows some good pictures taken with emulsion of his own preparation; "Whitley" (412) is his best contribution, we think. Mr. G. A. Ferneley contributes three frames, of which we like "Riverside Sketches" (385) the best. Mr. A. Youngman shows an instantaneous yacht picture (428), and Mr. S. G. Hooker has several marine views that denote unmistakable talent; a quaint group of Boulogne fisherwomen (427) is one of these, and a study of a beggar is not less successful. Some bijou sketches of North Wales (408), also by Mr. Hooker—to wit, those of Carnarvon and Conway Castle—are also pleasing, full of detail, and very well lighted.

The work of Mr. Edmund Hyde is all of it so good that it is difficult to point out the most worthy. Mr. Hyde has devoted himself more especially to village scenes, and

"Lustleigh Village" and "Rushford Mill" (426) are trite examples of our rural homes. In another part of the room enlargements of these same pictures are to be found; but for ourselves, we prefer the miniature impressions of the sweet English homesteads that Mr. Hyde depicts so well.

Mr. T. M. Brownrigg's careful work is known to every visitor at Pall Mall, and the pictures he exhibits this year will sustain his well-earned reputation. "Beachy Head" (424) and Lake at Blackwater (31) are both fine pictures, the latter being exceedingly good; two views near Goring (34, 35) are also well worth looking at. Messrs. G. West and Sons, of Gosport, exhibit some regatta sketches (423), and also a fine representation of a torpedo explosion (74). Mr. J. A. G. Branfill, also a skilful marine photographer, shows a series of yacht pictures (421, 422), together with a pleasant view in Cheshire (285). Mr. W. Davies' leafy pictures, "The Comb Factory" (420), and "Millers' Dale" (406), are delightful productions; and scarcely less satisfactory is "Near Ashford Hall" (19); indeed, Mr. Davies unites a keen eye for the picturesque with a thorough knowledge of technical photography. Mr. Charles Reid exhibits two frames of studies of animals, &c. (270, 411).

Mr. George Renwick shows some capital work, among which the "Lighthouse, Douglas Head" (72), the white beacon deftly poised upon the black strata of rock, cannot fail to strike the spectator by its wonderful force and vigour. "Off Ramsay" (139), and "Douglas Harbour" (394), clear and bright photographs, also by Mr. Renwick, are pictures that likewise repay study. "Richmond on Bank Holiday" (407) is sent by Mr. Hilditch, who also exhibits a transparency of St. Paul's Cathedral (168). Mr. F. Downer shows some studies of children (105), and three excellent examples of crayon work on opal (284, 382, 404). Messrs. E. Day and Son, of Bournemouth, send two of the sketchy portraits for which they have of late years acquired a high reputation, the best being "Surprise" (400); they also forward two very creditable studies "In the Hayfield," and "Working Homewards" (401, 402). Mr. Arnold Spiller has four pictures: "Leverton" (399), a village scene, in which the shadows are subdued, while yet there is plenty of warm sunlight, is a painstaking bit of work: and the same may be said of the river winding among the tall rushes "On the Kennett" (398). Mr. J. S. Catford, of Ilfracombe, sends two frames of soft sketchy portraits (253, 397), exhibiting much taste and artistic feeling; they are mounted on glass, a measure that adds to their brilliancy.

Mr. G. Sydney Whitfield is represented by three pictures of Welsh scenery (197, 395, 396). Mr. J. A. Kay, in "Waiting for my Lady," shows a clever sketch of "Horse and Trap," and in another part of the room exhibits some good portrait work (153, 172); a study of Mr. Perrini (208), likewise by Mr. Kay, is also excellent. Mr. D. Ireland, Junior, of Broughty Ferry, sends a collection of magnificent views from Norway, which are called in the catalogue "Views in Germany" (373). Of these productions of an amateur of the Dundee Photographic Society we have already had occasion to speak, and we are very glad that visitors to the Pall Mall Exhibition have an opportunity of seeing them. "Molde Fjord" is a delightful sketch, and so is "Lillehammer." The clearness and brightness of Mr. Ireland's pictures are wonderful, and we may say, in a word, that we have never seen Scandinavia so well pourtrayed before. Mr. Ireland has most happily seized the characteristics of the country—the still meres with their pine-fringed banks, and the rocky headlands so sharp and clear in the pure north light. Here we must leave our notice for this week; we take the opportunity, however, to mention the names of the following exhibitors who were omitted from our list of last week, viz., Mr. G. M. Jones, Mr. H. Schüren (of Hamburg), Mr. G. Hadley, and Mr. Lydell Sawyer.

At Home.

MR. FREDERICK YORK AT BRIDGWATER.

When Rear-Admiral the Duke of Edinburgh was plain Prince Alfred, and but a simple midshipman on board the *Euryalus*, he made a voyage to the Cape of Good Hope and Natal. The voyage was undertaken, of course, in the ordinary pursuit of duty; but still it was the Queen's intention that the young Prince should learn something more than navigation during the long sea journeys his profession compelled him to undertake. In those days the Prince had no thought of becoming a musician, and fiddling took up none of the time that generally hangs so heavily on the sailor's hands; but he had another hobby, and that was photography. So that he might be at no loss for assistance and instruction in the art, Her Majesty commissioned a gentleman well skilled in the art to accompany His Royal Highness, and this gentleman was Mr. Frederick York.

Mr. York still speaks with pleasure of the days when he formed one of the Ward Room mess on board H.M.S. *Euryalus*. Prince Alfred and he worked together indefatigably to secure pictures of the places visited, and many were the pleasant excursions made in company. Together, they passed from Natal into the Boer country, of which we have heard so much lately, the little detachment from the ship making a right Royal progress. "The people everywhere were overjoyed to see the Prince," says Mr. York, recounting his travels, "and whenever they could, they gave us a Royal salute. At Blomfontain there happened to be but one gun, and this a very old and crazy one; however, they fired this one gun, and burst it, too, killing a couple of men." Of course there was hunting and shooting in plenty; "but I never was much of a shot," adds Mr. York, "and they used to laugh at me a good deal in consequence. What caused them most merriment, I think, was my mistaking, one evening, a gnu, with his bushy mane, for a lion. I took a shot at him from my tent, and missed, and was fearful he might be coming after me."

There are no gnus at Bridgwater, but game that Mr. York pursues with much better success. For here, at this busy little town on the river Parret, where it is said every bath brick in the world is made, Mr. York produces all those charming lantern slides, or transparencies, that have made many a Christmas party jolly, and changed, for an hour at least, those sorry little urchins of workhouse and infirmary into bright and happy beings. Here, in this big brick building, is the fountain of delight and amusement to thousands; here is concentrated at this moment the essence of pleasure soon to be diffused throughout our Kingdom and Colonies. If giving pleasure to others is indeed the highest form of happiness, then must Mr. York be a happy mortal, for during the past ten years an average of 50,000 slides has been annually produced here in Bridgwater.

Mr. York's establishment is not a very big one, but it gives employment to fourteen assistants—male and female—and takes up every nook and corner of a large house. His slides, or transparencies, are all made in the camera, and with wet collodion, being toned with bichloride of platinum. The original negatives are of various sizes, and herein lies the first difficulty Mr. York encounters in his work. It may be said: "But why should this be the case; why not have all negatives taken the same size?" For the simple reason that Mr. York has to get what he can; he wants the best pictures possible of a certain object, and with this intention buys perhaps half-a-dozen negatives. He soon finds out which yields the finest transparency, and when the negatives are put away, this one bears a distinguishing mark. The negative may measure twelve inches or only six, but the mark upon it specifies the kind of camera to be used—for all slides are made of the same dimensions—when more transparencies are desired.

We say "the kind of camera to be used," because Mr. York has, so to speak, no movable cameras on the premises. His cameras are solid, roughly-made apparatus, constructed by a carpenter on the premises, and every sized plate has its own camera. In these circumstances there is obviously no time lost in experimenting and focussing. You give an assistant a negative, and tell him to make a hundred transparencies; he looks at the mark on the negative, reaches down the proper camera, and the work proceeds forthwith.

The glass plates used are large enough for four transparencies. After cleaning, they are albumenized in the ordinary way, and then coated with collodion and sensitized. There is a repeating back to the camera, so that there is no difficulty about taking the four images one after another.

Let us take a glance at the work itself. At the back of the building are two yards—the lantern yard and the printing yard. We proceed to the former. Here are a collection of out-buildings, and under one of them we find two assistants busy at work making transparencies. The cameras slope upwards at an angle of 45°, and the roof is uncovered where the light enters them. The cameras at this moment are facing west, for it is afternoon, but similar arrangements exist on the other side for morning work. Before each assistant is an American clock, so that all four exposures of the one plate may be precisely the same, this exposure varying from ten to sixty seconds according to circumstances. The exposures are simply brought about by capping the lens, and after four exposures have been made by means of the repeating back, the dark-slide is withdrawn, and taken into the laboratory; here it is at once developed, and, after washing and draining, handed over to another assistant to tone.

Mr. King, who is Mr. York's manager at Bridgwater, is good enough to give us his toning formula. He makes up his stock solution of:—

Bichloride of platinum	4 ounces
Water	40 ounces

and of this he puts two ounces to a Winchester quart of water, the result being one grain of platinum salt to one ounce of water. Mr. King employs no less than eight toning baths for his transparencies, these being ranged of a row. No. 1, however, into which the plate is first dipped, is a well-nigh exhausted solution, and No. 2, into which the transparencies go next, is little better. The baths, in fact, increase in strength until No. 8 is reached. As the baths get exhausted, they are thrown away, or, at any rate, No. 1 gets thrown away every time a new No. 8 is made. The transparency is brought step by step from one bath to another, until in No. 8 it assumes a black tone; it is then taken back again to No. 3 or No. 4, and immersed until the blackness begins to turn once more to brownness, when the tone is deemed a desirable one. The toning usually takes about ten minutes; prolonged toning gives a red tint, which must be avoided.

Mr. York tests his transparencies by laying them on a sheet of white paper. In the transparent portion there should not be a trace of covering; if the least film be visible, the image is rejected.

Outside the laboratory, in the sun, is a row of Winchester bottles standing upon a shelf. These contain the silver baths in course of doctoring. The silver solution, when not actually in the dipping bath, is here set to sun, and if it has become surcharged with alcohol and ether, it is also boiled before further use. "I like to boil down my baths until the liquid pretty nigh crystallizes," says Mr. King, "and then I am quite sure of getting rid of all volatile matter."

Here, in the varnish room, are the transparencies drying. They are a heterogenous lot. This picture of the Tower of London, and this one of Jumbo at the Zoo, illustrate "A day in London," an interesting lecture by Dr. Croft, in which the spectator is taken by the aid of photography to all the wonderful sights in town. Here is another set of slides illustrating the war in Egypt; here pictures of the Arctic regions; and here, again, science slides, designed to help youngsters to understand something of light, astronomy, physics, the spectrum, heat, &c. Mr. York takes up one of the quadruple pictures—it has now been varnished—places it on a cutting-board, provided with a suitable guard, and with two cuts of a diamond divides the plate into four. Thus divided, the plates go into the mounting-room, where by means of black paper masks and strips of the same material, and a little paste, the lantern slide is speedily completed. But it is only by exceeding care, and rejecting probably twenty-five per cent. of his pictures, that Mr. York is enabled to maintain a high level of excellence. No branch of photographic industry, in fact, presents from first to last more difficulties and troubles than this delicate one of producing lantern slides of a uniform character.

We pass through room after room devoted to the various manipulations. A large kitchen with water-supply, sinks, &c., is made to serve three purposes, by simply fitting the window with a blind of yellow tammy. Glass plates are cleaned here, paper after sensitizing is here dried, and the toning of prints is also conducted here, the yellow blind being simply pulled down when these last two operations are in progress. The negative store-rooms are likewise of interest; the negatives are all put away in boxes, these latter being in huge pigeon-holes, and all labelled according to the nature of the subject they contain. Here is the carpenter's department, where cameras, packing-boxes, printing-frames, and all sorts of photographic apparatus, is made on the premises. Here is a sort of retouching room, or, rather, room where lantern slides representing statuary and the like are blocked out with black varnish, applied with a camel's hair brush. Here is the print-drying room—for Mr. York produces a vast number of paper prints, besides his lantern work—and in this room we pick up a hint of value. In the centre of the room, exposed to the full air of the apartment, is a sort of dinner-wagon—or rather central structure supporting shelf upon shelf of canvas, or, as it is called, coarse "shirting." The prints are laid upon these canvas shelves to dry; but before this, they are put, a score or two at a time, upon a thick glass plate, and rolled with a wooden rolling-pin. In this way the water is readily expressed in a most perfect manner, and subsequently the drying upon the canvas is very quickly completed.

A final word on the subject of residues. Mr. York does not proceed in any unusual manner; he employs old paraffin casks, to be purchased for half-a-crown a piece, to collect the liquors, putting in a tap about a third of the way from the bottom. As the precious metal is thrown down, either in the form of chloride or sulphide, he draws off the waste liquid from above. By having several casks always in use, he can treat them one after another, and thus manages to recover the last trace of silver from his waste. The value of Mr. York's residues last year was seventy pounds.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

The Ramsgate Sands Photographer—The Electric Lighting Act—Amateur Photographers and Gelatine Plates.

The Ramsgate Sands Photographer.—The photographic tout, or "doorsman," as he used to be called in the glass positive times, is rarely seen now-a-days, but he is not extinct. He, or his descendants, to speak correctly, have passed into the stage of full-blown photographers, and are to be met with in London in small numbers on Blackheath or Clapham Common, at Margate and Ramsgate in shoals. The sands at these watering places, beloved of by the Cockney, are the happy hunting grounds of the touting photographer, and here he does in the season a thriving business. Of course, he has competitors in the niggers the donkey boys, and the thousand and one persons who have some excuse for extracting money out of the visitors' pockets, and he has to hold his own in the race. We do not know, in respect to pushing his wares, that he is worse than the others; but the police of Ramsgate seem to think so, and they have determined, to use the words of their superintendent, to "make an example." Some days ago, one of these wandering photographers was hauled before the magistrates for pestering people to have their portraits taken, and we learn, from the policeman who gave evidence, that the defendant "pursued a gentleman, took hold of his arm, and wanted him to go to the place where the machine was. Defendant asked almost every person that passed him to have their photos. taken, and if they refused, insulted them." We should like to know precisely the policeman's notion of an "insult," since the superintendent afterwards stated that there were forty or fifty young fellows who were taking likenesses, but that "he did not think the defendant was worse than the others." If, therefore, the whole fifty observed the practice of offering the alternative of either being photographed or being insulted, the sands must be unbearable; so that, on the whole, it is probable the constable exaggerated a little, so far as the "insult" is concerned. But there is no doubt the fifty are very pertinacious, because "one lady who came to him (the superintendent) said that the man pestered her so much to have her photo. taken, that she hired three chairs for herself and children to get out of their way. They then came and asked her again, and when she refused, they said she had better have her child's likeness taken, as he was very sickly, and would not live through the winter." We are not sufficiently acquainted with the manners and customs of people and photographers on Ramsgate Sands to quite understand how the hiring of three chairs could protect one from solicitations to have one's "photo." taken, unless chairs are used as weapons of assault and battery, which is scarcely likely in the present instance; but we do not hesitate to condemn the species of intimidation adopted. The photographer who resorted to this mode of getting custom was certainly no student of human nature, and he would have had a far better chance of success had he gone into ecstacies over the beauty and grace of the child. It is interesting to learn from the superintendent that it is "high time the Improvements Commissioners obtained a provisional order from the Local Government Board to enable them to frame bye-laws to regulate these fellows." This is bewildering, to say the least, as it is news to learn that the powers of the Local Government Board, which we, in our ignorance, have always thought had to do with paupers, will have to be invoked before the photographers on Ramsgate Sands can be "regulated." It is certain, however, that the authorities at Ramsgate mean war to peripatetic photographers, as the magistrates fined the defendant half-a-crown and ten shillings cost, and threatened that if any other case came before them it would be dealt with more severely. Perhaps before the Improvements Commissioners commence the regulations which might end in improving photography off the sands altogether, it would be as well if the photographers tried to regulate themselves.

The Electric Lighting Act.—The photographer should be interested in the provisions of the Electric Lighting Act, as when the time comes for electricity to be laid at one's door, it will be strange if he cannot avail himself of the electric light on dark and foggy days. It must be confessed that the companies which have been formed in so great a hurry will have a good deal of up-hill work to do. A company can acquire powers in two ways—either of a licence for seven years, to be obtained from the Board of Trade; or of a provisional order—or, in other words, a special Act. The initial step of obtaining a licence is one of some difficulty, because the consent of every local authority having jurisdiction within the area proposed must be first obtained. The consent involves competition among the companies themselves, and as every metropolitan vestry and the majority of provincial local boards have already been applied to by all the companies now in existence, the contest is likely to be a remarkably lively one. To this may be added the not unlikely prospect of the local authority itself undertaking to supply electricity, and, in this case, of course, all competition for outsiders will be shut out. One of those debateable points which appear inherent in every Act of Parliament crops up in this Act. Although a licencee must obtain the consent of a local authority, nothing is said about the latter having power to refuse unconditionally all applicants. The inference, indeed, to be drawn, is that the Act compels a local authority to adopt some system of electricity, but leaves open the question of which one. Anyway, the point is one which will delight the heart of lawyers, and contains quite enough in it to fight over. In the case of a provisional order, the consent of the local authority is not necessary; but the said authority can, if it chooses, petition against the order while it is pending before Parliament, and the Bill will be referred to a select committee in the usual way. These, briefly speaking, are the initial conditions for the supply of electricity; but, of course, the Act specially provides for details in relation to the breaking up of streets, &c.; but these details are of more concern to local authorities than to the photographer. What is, however, of special concern to him is that the "undertakers," as the licencees are termed, are not to require consumers to use any particular form of lamp or burner. This is highly important, because it is clear that all lamps are not suitable for photographic purposes, and if any restriction were enforced, the photographer might not be able to avail himself of electricity for his work in the studio. It will, in all probability, be some time yet before electricity takes the place of gas; but that this period is fast approaching is almost certain.

Amateur Photographers and Gelatine Plates.—The critic of the *Times* in his (on the whole) favourable notice of the Photographic Exhibition, makes a statement about which it would be interesting to have some little information. In noticing that, while the general standard of excellence in artistic results has been raised, it is difficult to find an improvement as regards pictures of the highest class, he accounts for the average excellence by the increased facilities offered by gelatine plates. Amateurs "work away, spoiling a good many plates, getting a good many average pictures, and every now and again turning out a perfectly successful one. The successes are shown, the failures are forgotten." Probably there is truth in this, but we fancy it may be said with equal truth of the man who does not work in the hap-hazard way in which the *Times* critic seems to infer. As every one who has ever dabbled in photography well knows, there are any number of contingencies operating against a perfectly successful result, and though the photographer may be the most careful, painstaking, and artistic of men, if he be not favoured by luck, his best result will have some flaw. This, however, by the way. The point to which we desire to direct attention is this. The writer of the notice says: "The amateur may, if he chooses, send the exposed plates back to the maker to develop and print from, his share in the production of the finished picture being confined to the choice of a suitable subject and a good point of view." No doubt this is possible; but, we would ask, is it a fact? It is very certain that all our most skilful amateurs, though they may purchase their gelatine plates, would scorn the idea of having them developed by hands other than their own. If it really be that this plan forms one of the elements in the "general average" of excellence as shown by the Photographic Exhibition, it will become necessary for the council to institute some rule that the exhibitor of a picture shall state whether he or the maker of the plate has developed it. At present, however, we fancy there is not much need; at all events, the manufacturer of the gelatine plates should be able to settle the doubt.

Notes.

The inauguration dinner of the Institute of Chemistry takes place this evening at Birmingham under the presidency of Professor Abel, C.B., F.R.S.

"The Studios of Europe" is out of print, the first edition being completely exhausted. No other edition will be printed till next year.

The twelve elementary lessons in dry-plate photography, which appeared in these columns, and are now published as the "A B C of Modern Photography," are translated into French and German, and will be issued by M. Gauthier-Villars of Paris, and Dr. Liesegang of Düsseldorf.

Mr. Plener is at present in Vienna, prosecuting his experiments connected with the preparation of pure bromide of silver, which he separates, it will be remembered, from the lighter gelatinous mass by the simple expedient of centrifugal force. Dr. Eder has kindly proffered Mr. Plener his aid, and this, indeed, is the reason why Mr. Plener is continuing his experiments in the Austrian capital. So we may well expect to hear something of importance before long.

The sensation of the week—at any rate, among the learned societies—has been the discovery of a Gallo-Roman town near Poictiers. A temple has been unearthed more than three hundred feet long, a theatre and a hostelry. There are fine steps and massive columns, sculpture of rare execution, bronze and earthen articles—in short, it is a little Pompeii in the middle of France. But we have had no confirmation of the story so far by photography; the camera is a capital antidote for exaggeration, and in a few weeks no doubt we shall be able to judge how far the discovery is romance, and how far reality.

Without wishing to discredit in any way this particular "find," we may point out that travellers' stories have been far less wonderful since the days of photography. Especially is this remarkable in the case of "natural wonders." When the illustrations in our books of travel could not be compared with photographs, it is surprising how tall mountains used to be, how mighty were the waterfalls, and how curious the trees and foliage of foreign lands. The camera not only tells the truth, but is the cause of truth in others.

Judging from the number of photographers who attended the Convention in the United States this year at Indianopolis, the meeting was a great success. No less than 328 votes were taken on the subject of the next meeting-place, which has been fixed at Milwaukee. The President-elect is Mr. J. E. Beebe, of Chicago.

A capital portrait, by the Ives' process, of the late Mr. J. H. Fitzgibbon, Editor of the *Practical Photographer*, is given this month in the *Philadelphia Photographer*. This photo-engraving process is one of the most satisfactory yet brought out, since it is the only one that has been presented to the public printed in an ordinary journal alongside ordinary type.

The *Daily Chronicle* is indignant because a ganger or foreman, superintending some railway works, was so unmindful of police orders as to clear away a quantity of earth which had fallen on a man and killed him. If the police, instead of giving childish orders which they have no power to enforce, had secured photographs of the scene, the jury would have been able to form an excellent idea of the nature of the accident.

No less than twenty-two millions of money have been subscribed to Electric Companies in Great Britain, France, and America; the last has invested about ten millions, and the balance represents the money paid for shares by English and French. People will soon be asking when dividends are likely to be paid on this enormous sum, and then, perhaps, we shall hear of a rapid fall in electric shares.

As we chronicled the departure of the Arctic yacht *Kara* on her dangerous journey due north, we must not omit to tell of its safe arrival home again on Monday last. The brave little craft, which our readers will remember only measures forty tons, met with some terrible vicissitudes; and on one occasion, Mr. Grant writes us, they were hard and fast in the ice for three weeks. After touching Novaia Zemlia, and falling in with Mr. Leigh Smith and the crew of the *Eira*, the *Kara* coasted northwards some two hundred miles. But here, again, the yacht got into difficulties—jammed by icebergs against a small island until its bulwarks were stove in—and it was deemed expedient to land the ship's stores and begin building a store-house. On the 3rd of last month, however, the crew managed to get out of the trap, and by great good fortune found the ice-masses loose enough to steer southward.

"I have done very little photography," says Mr. Grant, "for we have had enough to do to look after the ship and ourselves. The scenery in many parts was wretched; nothing to see but bleak rounded hills and ugly rocks, all of which soon got covered with snow." Mr. Grant tells us it was not the relieving ships that found Mr. Leigh Smith, as has been narrated; as a matter of fact, Mr. Smith found them. Moreover, there was a Russian ship lying in the bay when the crew of the *Eira* rowed into it, so if our expedition had not been there, the poor fellows would have found their way safely to Norway or Russia. Bye-the-way, Mr. Grant must have been very pleased on his return home to find his pictures at Pall Mall had secured a medal.

It is more than two years ago since we suggested in these columns the recording by means of photography of the sunshine signals transmitted by the heliographic mirror. Signals can be reflected for upwards of a hundred miles by simply employing a mirror to turn a ray of sunshine into a particular direction, and it is but the other day that we recorded the feat of sending a message by this means from one of the pyramids near Cairo all the way to Alexandria. The signals of the heliograph, we said, appear to the receiver like pin-points of brightness, or stars seen in the daylight, and whether these signals are of long or short duration, so they are termed long or short signals, and the signalling alphabet, like the Morse code in telegraphy, is built up of these long and short signals. Our suggestion was to photograph the pin-points of brightness upon a movable sensitive film, when of course the long-shining signals would appear as long lines, and the signals of short duration as short lines; the signals thus recorded might be read by any telegraphic operator.

Our suggestion is about to be adopted in Mauritius. There is no telegraphic communication between the islands of Mauritius and Réunion in the Indian Ocean, so the authorities are about to resort to the simple expedient of communicating by sunshine signals. The distance is 134 miles, and if the ray reflected cannot always be seen by the naked eye, there will be no difficulty about doing so with a telescope. Mr. L. P. Adam is organizing the signalling service, and he hopes, it is said, to record his messages by causing the light-spot to impress a moving band of gelatino-bromide of silver paper. Not only sunshine signals, but the light from a bright petroleum lamp, it is thought, will travel the distance, for the atmosphere is very clear; in fact, it has been found that a sunshine beam reflected from a mirror 150 miles distant is to be seen in the telescope after passing through six thicknesses of smoked glass. If a cheap apparatus for moving the photographic film could be devised—and there is no reason why it should be more costly than the Morse telegraph instrument—we see a likelihood of light signals being substituted for the electric telegraph in other countries besides Mauritius; for if sunshine is not indispensable, and messages can be written down, this cheap method of telegraphing will obviously have much to recommend it.

M. Chabot, the well-known expert at handwriting, died this week. He was generally called as a witness in cases of disputed handwriting, and made comparison a good deal by the aid of a magnifier. His experience of the vagaries of penmanship was very great, and if he had only given more attention to photo-enlargements of handwriting his evidence would have been still more valuable. They manage these things better in France, Lawrence Sterne would have told us; photographic enlargements, in which the upstrokes and downstrokes are represented twenty inches high, are produced of the handwriting in dispute and of the authentic handwriting, and these are then handed to the judge or jury for comparison. It is much more satisfactory to let the latter form their own opinion on the characteristics made apparent by the camera—tiny splutterings, saw-edges, unsteady hair-lines, &c.—than have them sworn to by a witness with a spy-glass, who may be called by one side or the other.

Unfortunately, our English Law Courts, unlike those of Paris, have no Government photographic establishment at their service, on which to rely for the discharge of such duty impartially. It is true our judges admit photographic evidence to a certain extent, but they would scarcely be warranted in accepting it in all circumstances. The most readily obtained authentic handwriting appears to be that upon receipt stamps; we have seen photographs of these, at Paris, enlarged to monster dimensions, so that every stroke of the pen can be analysed with accuracy.

The question of forming an Association for the Defence of Photographic Copyright is attracting considerable attention, and we think that if an energetic secretary took the matter now in hand, the Society would be as good as established. We doubt, however, if the calling of a public meeting of photographers would be the best way to initiate proceedings. Our advice would be, first of all to get a list of photographers who publish, and to apply to these for their goodwill, inviting a small donation of 5s. or 10s. towards preliminary expenses. Then a general meeting might be held; and if the Association could be established on a firm and impartial basis, there is no reason why it should not thrive by payment of a small annual subscription. In many cases, to show a bold front would suffice to stop piracy, and expensive legal proceedings are unnecessary.

The perforating pen of Edison is like a black-lead pencil, in which the lead is replaced by a fine needle kept in rapid motion by a minute electro-magnetic engine. Pfaundler makes a retouching pencil on the same principle, the black-lead being made to rapidly move up and down like the needle of the Edison pen, thus producing a fine stipple on the negative.

Thanks to the exertions of Mr. H. Trueman Wood, the energetic secretary of the Society of Arts, a Siemens' dynamo machine has been secured for the rooms of the Society. As an eight-horse Otto engine already exists on the premises, it will be possible at an early period to institute some interesting photo-electric experiments before an audence.

The last theatrical event of importance is the production of Rip Van Winkle at the Royal Comedy. Despite the charm of the music and brilliancy of scenery and appointments which have secured the general approval of the press, we protest once more against the lack of intelligence displayed by the scene-painter. It may be difficult to fix upon the exact whereabouts of Sleepy Hollow, or to localise the village of Falling Waters; but the home of Washington Irving's sweet romance is nevertheless well known to us all. It passed at foot of the silvery Kaatskills, beside the green-shored Hudson river, a mountain paradise that the American story-teller has ofttimes depicted with his loving pen.

Now photographs of the Kaatskill Mountains show us the craggy peaks with a foreground of rich foliage, while the banks of the Hudson, we know from the author's own description, are the reverse of sterile and barren. Yet, at the Comedy Theatre, we see in the landscape nothing but scrub and stone, stunted trees and grey boulders, the broad river, in fact, flowing through a wilderness. This is all the more unreasonable since romance does not call for such a change of scenery, for dear, delightful, drunken Rip lived in a happy thriving village, and it was because the wild mountains were so far away that he sometimes remained out of a night. There is not the least objection in the world to enhancing the charm of a poem by altering its setting; but in this case, both romance and reality suffer without rhyme or reason.

Patent Intelligence.

Grants of Provisional Protection.

4527. Butler Julius Carter, of Edith Road, West Kensington, in the county of Middlesex, for an invention of "Improvements in electro-magnetic engraving machines."—A communication to him from abroad by George McKendree Guerraut, of New York, United States of America. —Dated 22nd September, 1882.

Notices to Proceed.

2780. William Thomas Morgan and Robert Leamon Kidd, both of Greenwich, in the county of Kent, for an invention of "Improvements in the manufacture of sensitive paper, and blocks or tablets thereof for photographic purposes, which invention comprises an improved method of reproducing pictures from such paper."—Dated 13th June, 1882.

2790. Albert Aron, of Rose Street, Newgate Street, in the city of London, Importer, for an invention of "Improvements in albums for holding photographs and such like articles."—A communication to him from abroad by Adolphe Aron, of Rue Turenne, Paris, France.—Dated 14th June, 1882.

Patent Void through Non-payment of Duties.

3968. George Smith, of Great Portland Street, in the county of Middlesex, for an invention of "Improvements in the construction of lamps for magic lanterns and other purposes."—Dated 3rd October, 1879.

This invention relates more especially to lamps used for the purpose of obtaining light for magic lanterns, but it is also applicable to lamps used for other purposes, such as signalling on railways or on board ships. It has for its objects improved methods of constructing and arranging and fixing the several parts of the flame chambers of the lamp, that is to say, the chamber in which the flame burns from which the light is derived, and also improved methods of increasing the amount of light utilized from such flame. My improvements are especially applicable to lamps burning mineral oil, but they may also be applied to lamps burning other oils, or inflammable liquids, or gas. In such lamps as heretofore ordinarily made, the flame chamber is provided with suitable apertures for regulating the supply of air to the flame, and carrying off the products of combustion; and it is made of sheet iron or other metal, having its two ends quite open, but closed when the lamp is in use by plates of glass somewhat larger than the openings, and kept in their places against the ends of the chamber by clips or springs. It has been found, however, that in lamps so constructed, these glass plates are liable to break from becoming unequally heated, their outer edges remaining comparatively cool, and being exposed to currents of cold air rushing between them and the ends of the chamber; also that such currents of air affect the steadiness of the flame. The first part of my present invention consists in novel methods of constructing the flame-chamber so that the glass plates which form its ends fit closely, and are less liable to be broken by the heat. I make the flame-chamber cylindrical in end view, and I close its ends by circular plates or glass, talc, or other sufficiently transparent material fitted into cells formed or fitted upon the ends of the cylindrical chamber, and of nearly the same diameter as the latter. The glass plates being somewhat less in diameter, therefore, than the cylinder, become equally heated, and are little liable to break, whilst the ends of the cylinder being sufficiently accurately closed, currents of cold air cannot pass between them and the edges of the glass plates. I prefer to make the cylindrical cells in which the circular glass plates are fitted in such a manner that they enter the cylinder for a short distance, and are then provided with narrow flanges against which the glass plates rest, and are held in position by wires or rings sprung into their places outside the plates, or by screws or other equivalent means. By this method of construction the plates are not only less liable to break, but if one of them becomes cracked in consequence of the heat, the pieces are prevented from falling out, and the light is not so materially affected as in the case of ordinary lamps, where the pieces are liable to fall entirely away. Flat plates of glass may be used for the purpose described, but I prefer to make them concave, more especially the one used for the purpose of closing the back end of the flame chamber. I place such plates in their cells with their convex side outward, and upon the plate at the back end I deposit upon such outer side a thin coating of silver by any of the ordinary well known methods, the silver acting as a reflecting surface, whilst if thin enough it is sufficiently transparent to allow the flame to be examined through it for the purpose of adjustment and regulation. In order to increase the whiteness of the flame in such lamps I sometimes adjust and fix in the flame one or more wires or thin plates of platinum or other metal not easily fused. Having now described my invention, and the manner in which it is to be performed, I claim the method of fitting and fixing circular, flat, or concave transparent plates in cells in the ends of the flame-chamber of lanterns substantially as described and shown in the drawing. Also the concave glass reflectors, so fitted into a cell at the end of such flame-chamber, and coated with a film of silver sufficiently thin to be transparent, substantially as and for the purpose described. Also, the introduction of metal wires or plates not easily fusible into the flame, for the purpose of increasing the light from such lanterns.

Patent Granted in France.

58,807. Ricard and Co., of Paris, for "Coloured photographs on stuff and tissues of silk, wool, &c., and means and processes of obtaining them."—Dated 19th August, 1882.

Patent Granted in America.

265,226. Thomas A. Willson, of Reading, Pa., for "Lens and manufacture thereof."—Application filed 20th March, 1882. No model.

Specifications Published during the week.

Disclaimer and memoranda of alteration. Nos. 2101 (1870) and 3101 (1872). The Celluloid Manufacturing Co. Pyroxyline and solid collodion. The alterations refer to the details of the celluloid manufacture.

1166. J. J. Sachs, for "Improvements in the production of surfaces for printing, &c." Price 4d.

In carrying out my said invention I proceed as follows. I first prepare the surface to be engraved or etched, which surface may consist of a plate or roller or other form of surface. Taking, for example, a roller, I first coat it with a varnish or layer of some substance or material which will resist the action of the chemicals in an etching bath or metallic or galvanic bath; when this resist is dry, I paint over the surface with some sticky substance, as, for instance, solution of gums, gelatine, starch, paste, or the like in water or other solvent, and while this sticky substance is wet I lay round the rollers, or on the surface, the design, which may consist of any open or closed fabric or material or substance—for instance, gelatine, rubber cloth, paper, and the like. Suppose, for instance, I take a piece of lace, I wrap it round the roller, and it adheres to the roller, the substance super-imposed on the resist causing it to do so. The lace is thus attached to the roller, and I can now adjust the edges of the lace so that the pattern repeats itself perfectly round the roller; or the lace edges may be sewn together previously, thus forming, as it were, a tube, which I can then slip over the roller; or I can place the lace or pattern on the roller, and cause it to adhere afterwards by means of the sticky substance mentioned, without first covering the surface with the sticky substance, and in that case I cover it afterwards with the sticky substance, which soaks through and causes the pattern to adhere to the roller or surface. While this sticky solution is still wet I can adjust the pattern in any way, and arrange it so that it shall repeat itself round the roller; or if the ends be sewn together as before mentioned, the repeat is provided for in the sewing. In the latter case, when lace or any woven or worked fabric is used, and the two ends joined or sewn together so as to form a repeating pattern, this is then slipped over the roller. The moisture in the gum or sticky substance causes the pattern to contract and clasp the roller tightly, so that when the pattern fits the roller moderately well when dry, the addition of water only, or of acid, or alkaline or other liquor, is sometimes sufficient to hold it in its place, during the subsequent operation, especially if the pattern be kept damp or moist; or in some cases the pattern can be fixed on the roller or surface in a dry state, and kept dry throughout the process; but I prefer to use the wet process, as it produces better results. When gum or sticky substance has been used as mentioned, the roller or surface, with the lace or pattern adhering, is dry, and when dried is ready for cleaning out. This can be done by hand, using an instrument pointed by preference like a chisel, with which the gum or equivalent, and the resist beneath, showing through the interstices of the pattern, are removed and are scraped away, leaving the bare copper, metal, or other surface which is subsequently acted on so as to be etched by an etching liquid, or metal can be deposited thereon by galvanic or other means. This cleaning can also be effected by means of the sandblast, or similar contrivance where metallic or other hard particles are substituted for sand, and this is the most expeditious manner of doing it; or the exposed parts may be cleaned of the resist by a brush the bristles of which are stiff or composed of wire, which brush scrapes off or detaches the resist through the interstices of the pattern, but leaves the covered parts untouched. After cleaning, the roller is ready for etching, but to prevent error I prefer to take off the pattern first, by soaking it in water or acid or other solvent for the sticky substance used, and then (cutting the lace or pattern if it has been joined before putting it on the roller) the pattern can be easily removed and the surface inspected, and any faults rectified before etching. The etching is or may be carried out as stated in the specification of my previous patent No. 266, dated the 21st day of January A.D. 1881, with or without the aid of an electric current. To produce the reverse effect, instead of etching the roller or surface prepared in the above manner, I deposit copper or other metal on the exposed bare parts by electro deposition, the metal depositing on the bare parts, whilst the parts covered with resist remain unaltered. To produce, for example, say pin engraving, I take a mill covered with pin engraving, and run it over the roller or surface before commencing the process, and thus the whole surface is covered with this engraving. I then proceed as before, and when finished, I have as result a roller or surface, the outstanding parts of which print the pin or other engraving while the sunken parts print a solid pattern, thus giving beautiful effects. This is especially useful for printing oil colours, as for instance, for printing on oil cloth.

1252. W. D. Saull and W. R. Brooks, for "Spring Clips for holding programmes, notices, &c." Price 2d.

This invention relates to improvements in the construction of spring clips which are specially applicable to holding programmes in theatres and other places of amusement or entertainment, and which are also suitable to be employed for suspending notices, and for other analogous purposes. The said improved clips are constructed in the following manner. A plate is arranged between two projections or enlargements on a suitable bed plate or base, and is retained in that position by means of a pin or pins, or other similar contrivances so arranged that the plate is capable of rocking thereon when actuated, as will be well understood. The front end of the said plate is bevilled or slightly cut away towards the bed plate, and is caused to bear against the latter by a spring, of any suitable form, placed between the bed plate and the under surface of the opposite end of the said rocking plate.

A GLANCE AT THE FRENCH PHOTOGRAPHIC EXHIBITION.

On our return to Paris after a couple of months' sojourn in central France we hasten to the *Palais de l'Industrie*, in order to run through the photographic exhibition, which we had left in full course of preparation. That which first strikes us as characteristic of this exhibition is, that quality certainly outweighs quantity—the exhibits only take up two rooms. It is the number of instantaneous pictures which deserves admiration. This interesting style of reproduction, which constitutes one of the most beautiful and useful applications of photography, tends to generalize itself more and more, since it can be employed with very rapid dry plates; it is, therefore, not surprising that such splendid specimens have been sent, notably those by M. Grassin, of Boulogne-sur-Mer, and Maison Neurdien, of Paris. The studio of Carlos and Marguerite Relvas is represented by a magnificent collection of photographs of all kinds, printed for the most part by the phototype process—that is to say, in a permanent manner.

The houses of Guinsac of Toulouse, Berthaud frères of Paris, Aubry of Brussels, Lemercier and Co. of Paris, Roches of St. Cloud, Unchelut and Walkmau of Paris, and Gutekunst of Philadelphia, exhibit very fine phototype prints. Under this head we have much pleasure in observing the marked progress made in the application of this remarkable process, which has unfortunately been too long without its full importance and practical utility being appreciated. The various photographic journals published in Germany, Austria, and Belgium continually show fine specimens of phototype printed in new establishments for that purpose. The *Bulletin* of the Photographic Society of France publishes in a recent number a phototype from the machine presses of the house of Brunner and Winterthur (Switzerland). This reproduction is due to M. Lugardon, a painter of Geneva, and a very clever amateur photographer. It represents children in the baths of the Rhone at Geneva; as an instantaneous picture, it leaves nothing to be desired. These young swimmers give themselves up to their sport, and even the splashes resulting from their frolics in the chopping waves have been immobilised and fixed on the negative. Mr. Muybridge has had a very complicated apparatus constructed for his study of animated nature, but really that is not necessary: with a simple tourist camera, gelatine plates, and a good shutter, one can realize every minute what he has with a cumbersome apparatus of considerable size. There is nothing else striking to note in this exhibition, which shines, it is true, in the artistic character of the greater number of works shown, most of the fine scientific applications, and even experiments towards technical progress, having been excluded. It must be remembered that in this exhibition of the decorative arts photography only comes in as a graphic process for decorating paper. Special processes have nothing to do in this artistic exhibition, or else they occupy insignificant places. This accounts for the small number of works shown, and the imposed omission of most of those applications so worthy of admiration which honour the actual photographic science. Leon Vidal.

SWING BACKS AND RISING FRONTS.

BY W. E. DEBENHAM.

The use of wide-angle lenses in photography is commonly spoken of and written about, with reference only to their employment for producing pictures of large size in proportion to the focal length, when their characteristic, the wide-angle, is brought into full play. It is of course obvious that with a lens of the same length of focus, a picture identical in every respect may be produced on a plate of given size with a wide-angle lens, as with one of ordinary angle stopped down to the extent for out-door work. The one circumstance in which the wide-angle lens will not do work that the smaller angle one will accomplish, is that which arises when, from deficiency of light, or from the desire to work instantaneously, a larger aperture or diaphragm is employed with the latter instrument than the former will define properly with.

Wide-angle lenses, then, will do everything except work so quickly as the narrower angle instruments; and they have a special use in some cases, where the plate to be covered is not larger than an ordinary angle lens will suffice for. The particular use referred to is that which occurs when a high building is to be photographed, the distance from which (where the camera can be retracted to) is limited.

Take the case of a building of such a height, and the distance available for the camera to be such that the whole subject, building, sky, and foreground, would be properly contained on a plate, the length of which equals the equivalent focus of the lens, and the foreground and lower part of building up to the level of the camera occupy one-quarter of the height of the plate. Now, with a small angle lens, the only method of getting in the whole of the subject is to tilt the camera upwards, and the inclination of the vertical lines must then be overcome by the use of the swing-back.

This use of the swing-back, in exactly the reverse direction to that in which it is generally turned, when it is desired to bring foreground and distant objects simultaneously into focus, puts all the image except across one line, out of the plane of definition. The plan which I consider far better, under the circumstances, is to use a wide-angle lens, to have the camera level, and to raise the front carrying the lens to the height requisite. The accompanying diagrams will illustrate the two methods, the size of plate, and amount of included picture being the same in each.

In all lenses, particularly those intended for out-door work, the field is made as flat as the optician can make it; that is, the focus of the marginal pencils is so lengthened that a good image is obtained upon a flat plate, instead of requiring a curved or cupped surface as would otherwise be the case. The illustrations, therefore, are those of a flat field lens. With the amount of curvature generally present, there would arise a somewhat different result; but not at all different enough to invalidate the argument.

In fig. 1 the camera is level, and the lens front is raised to the height necessary to bring the centre of the subject on the centre of the plate. The plane of definition, *d d*,

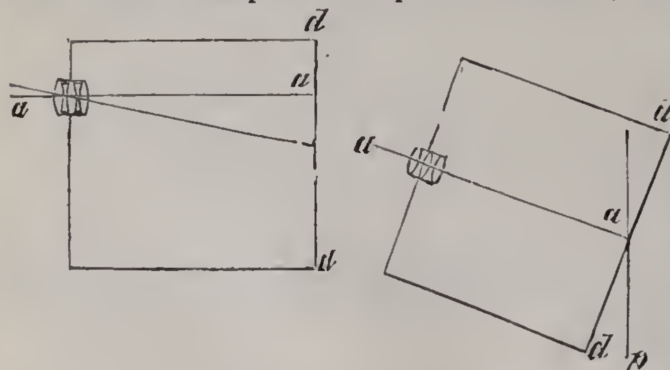

Fig. 1. *Fig.* 2.

is at right angles with the axis, *a a*, of the lens, and the plane of the plate is coincident with that of definition.

In fig. 2 the camera is tilted, and the back, *p p*, swing, to keep the perpendicular lines parallel, and the plane of definition only cuts the plane of the plate, *p p*, in one line. It must be noticed that not only is the focus displaced to the extent indicated, but that this is aggravated by the fact that the top of the building, being farther from the lens than the lower part and foreground, has its focus nearer the lens than the latter, whilst the swinging of the back has removed the plate further.

There is one other advantage in the use of the rising front rather than the swing-back; it is that the foreground receives more illumination through the lens than the top of the building and the sky. With the tilted camera the rays from the centre of building pass through the circular opening of the diaphragm, and those from the top and bottom are diminished, owing to the elliptical form which the diaphragm assumes to rays passing it diagonally. With the raised front and level camera the lower part receives the greatest illumination, and the ellipticity, and consequent diminution, of the bundle of rays progresses regularly upwards, so that the sky and brightly-lighted top of the building get considerably less exposure than the foreground.

The late Mr. Thos. Sutton contrived an arrangement of the diaphragm with a single lens to produce this effect. The stop, instead of being at right angles to the axis of the lens, was tilted forwards, so as to give the foreground more exposure than the middle and upper part of the picture. To tilt the camera upwards produces, to a certain extent, exactly the contrary result.

In many cases it is not necessary to have remarkably wide-angled lenses in order to obtain the required image with a high-rising front instead of a tilted camera; but cases do arise in which the widest angle that can be obtained in a lens is none too great. It is to be regretted that there is a disposition among opticians to cut down the margins of the lens, so that the angle is limited to that at which good definition is given. From this cause it sometimes happens that a picture, otherwise good, is marred by the sharp circular line cutting off the sky from the top or corners. Fine definition is not wanted on these blank spaces; but if the glass had been a little larger, light would have passed through, and a good sky effect rendered.

THE CITY AND GUILDS TECHNICAL INSTITUTE.

We extract from the prospectus just issued all that relates to the examination in photography. Although the word "gelatine" is not mentioned throughout, we presume that it is included under the emulsion processes. Still, we should have thought that the gelatino-bromide process was important enough to be printed at full-length with the other minor methods cited.

I. The Examination will include questions founded on such subjects as the following, but will not necessarily be confined to these subjects:—

1. The characteristic properties of pyroxiline for the manufacture of collodion, and the various substances employed for the purpose, as well as the solvents, such as ether, alcohol, wood, naphtha, &c. Different qualities of collodion.
2. The Daguerreotype process, the calotype process, the wet process, dry plate processes with the silver bath, emulsion processes, and the principles involved in each.
3. The theory of development by the acid and alkaline methods. The theory of intensification.
4. Printing in silver and other metals, toning, and fixing; printing in carbon, Woodburytype, vitrified enamels.
5. Special applications of photography to engraving, typography, lithography. The principles of the Woodbury and calotype processes.
6. Special applications of photography to astronomical and microscopical purposes, as well as for recording meteorological and other observations.
7. General principles of portrait and landscape lenses. The principles of construction of cameras.
8. The various apparatus in ordinary use by photographers.

II. Full Technological Certificate. The Candidate, who is not otherwise qualified (see regulations, rule 33), will be required to have passed the Science and Art Department's Examination, for the full Certificate in the Ordinary Grade, in the Elementary Stage at least; and for the full Certificate in the Honours Grade, in the Advanced Stage at least, in *two* of the following Science subjects:—I. Practical, Plane, and Solid Geometry. VIII. Light and Heat. X. Inorganic Chemistry. XI. Organic Chemistry.

III. Works of Reference:—"Researches on Light," by R. Hunt, "La Lumière," by E. Becquard; "Philosophical Transactions; Royal Society," 1840 to 1843; "Scientific Memoirs," J. Draper; Miller's "Chemistry;" "Treatise on Photography," by W. de W. Abney.

Correspondence.

OBERNETTER'S NEW EMULSION.

Dear Sir,—Feeling deeply interested in Obernetter's method of making emulsion, of which you gave a sketch in your issue of the 6th inst., I lost no time in trying to ascertain how far such a method was practicable, but I must confess I went to work with grave apprehensions of hopeless fog.

I dissolved 1 gramme of gelatine and 1·5 grammes nitrate of silver in 20 c.c. of water, and allowed to set. I then broke up the jelly with a silver folk, and poured over it 2 grammes bromide of potassium dissolved in sufficient water to cover the mass. I left this standing for three hours, poured away the liquid, and washed the set emulsion for another three hours. I then dissolved the emulsion, made up to 30 c.c., and coated plates.

I will now refer to two of these plates upon which I printed transparencies, and which I send for your inspection.

No. 1.—I was amazed to find this plate develop absolutely free from fog. After development I placed it in my fixing bath, one in which plates had been previously fixed, and upon removing it I was disgusted to find that it was thickly veiled with yellow fog.

No. 2.—This plate developed similarly to No. 1, but I took care to fix it in perfectly fresh hyposulphite, with the result that I obtained the most perfect immunity from fog of any kind.

I may say that the plates, as far as I can judge, are not very rapid, but I mean to try how far speed can be obtained by boiling. At any rate, I can speak for the simplicity and rapidity of the method, and believe it has a future before it.—Yours truly, Vero C. Driffield.

[The plate marked No. 2, which Mr. Driffield sends us, is quite free from fog.—Ed. P.N.]

Dear Sir,—In your account of the Obernetter emulsion you mention that German photographers can purchase details of the process for £5, an amount, I believe, equal to one hundred marks (German). Can you tell me (1) whether photographers in this country are expected to pay the same; (2) whether amateurs will be required to pay the same as professionals, who will obtain profit from the process? Thanking you, in advance, for an answer to these two questions—Believe me, yours very truly,

An Amateur.

[We believe no arrangements have yet been made by Herr Obernetter for the sale of his process in this country; all we know of the matter is contained in the announcement which will be seen in our advertisement columns.—Ed. P. N.]

Dear Sir,—My attention has been drawn to your notice of a new process or mode of compounding an emulsion by Herr Obernetter.

At a meeting of the Halifax Photographic Club, November 11th, 1881, Mr. Councillor Smith gave a practical demonstration of the making of gelatine emulsion. I took part in the discussion that followed, stating that for some time previously I had been experimenting with a view to obviate the necessity for prolonged cooking and its attendant evils, and my aim had been to discover some method by which silver bromide could be formed in the finest possible state of division, my theory being that the mode of effecting the combination of the silver and bromine, as then practised, attained this end "too rapidly" for the silver bromide resulting to be of the most suitable character for high sensitiveness, unless subjected to after treatment by the application of heat. I therefore sought out some method by which a retarding influence might be brought to bear at the time of combination, causing this operation to proceed more gradually and under control.

I also came to the conclusion that the plan of using a very small quantity of solvent for the silver caused the latter to be brought into contact with the bromide in too concentrated a form to favour fineness of division in the resulting silver bromide. I therefore decided to mix the silver in a larger quantity of water, and then add the greater proportion of the gelatine proposed to be used, and, after dissolving, allow to set hard. This I carried out. I then mixed the bromide with the remaining quantity of water and gelatine, and slightly heated until the latter was dissolved. With a clean shaving-brush I applied the bromide liquid to the argentic gelatine pellicle, passing the brush rapidly to and fro, painting, as it were, the one into the other. After the compound had been treated in this manner, gentle heat was applied, the liquid filtered, and allowed to set; afterwards it was washed and drained, again dissolved and filtered, *but not cooked.* I tested this sample of emulsion in a week's time, when I found the results to be about medium rapidity, the quality being excellent.

In the meantime, still thinking over the matter, it occurred to me that the brushing might be dispensed with, and the argentic gelatine pellicle simply cut up into very small pieces and allowed to soak in the bromide solution until combination was effected by absorption, finishing this process by gentle heat, and agitating, then filtering and washing and finishing as before without cooking—results about the same as before, but, for some reason, a very slight trace of fog, though not sufficient to do any harm.

I next proceeded as above, but reserved a portion of the silver in solution unmixed with the gelatine; the remainder was carried through all processes up to the point of washing. The emulsion, after being thoroughly set, was again cut up into fine pieces, and the remaining silver solution added, and allowed to be absorbed as far as it would, and the whole slowly dissolved and agitated; then it was set, washed, and finished in the usual way, the cooking again being omitted. When tested, this gave clean and rapid results, but not extremely so.

Mr. Illingworth, an able emulsion worker, and a Polytechnic medallist for the present year, volunteered to try my plan and report results at the next monthly meeting of the Society. This he did, stating that a finer emulsion he never saw, and it was very sensitive. I believe he used a formula by Mr. Forrest for his proportions, but of this I am not certain.

As my method appears to me to be extremely similar to that of Herr Obernetter, claiming, as I do, priority of adoption for "little England," I have asked our Secretary to verify the above details; not that I would for a moment begrudge "big Germany" an equal share in any merit there may be in the new principle propounded, should my surmise prove correct.—Yours most respectfully,

W. Clement Williams.

I beg to state that the foregoing is a correct report of what Mr. Williams laid before the Halifax Photographic Club on November 11th, 1881.

Edward Gledhill,
Hon. Sec. to Halifax Photographic Club.

THE DEFENCE ASSOCIATION.

Dear Sir,—I should be quite ready to support the suggestion for an Association; but how are we to begin? How are we to get photographers to feel confidence in it? I see Mr. Downey suggests a subscription of £1 1s. per annum. I should think half or quarter of this amount would suffice, and then we should have plenty of members. The subscription to the French Syndicate of Photographers is but seven francs, I believe. We could do it quite as cheaply—could we not?—Yours faithfully,

October 17. One who has been Pirated.

Dear Sir,—With reference to Messrs. Downey's letter in the News of the 13th *in re* the "Piracy of Photographs of Celebrities," I would suggest that they, or some other photographer, call a meeting of photographers interested in the matter, and make an attempt to form a society to deal with photographic piracy. If this is done, I am quite ready to undertake the secretarial duties *pro tem.*

Unless some such society be formed the evil will become intolerable, but with energetic measures it may be stamped out; and, as so many are interested, it is scarcely fair to wait for one man or firm to undertake the prosecution.—Yours faithfully, W. T. Wilkinson.

PRACTICAL INSTRUCTION IN PHOTOGRAPHY.

Dear Sir,—Seeing a note on "Photographic Instruction" in your paper for the 6th inst., I am sure it would meet with great support if some enterprising photographer were to start a class in London, as there are many amateurs who would be glad of learning the different processes, myself amongst the number. By printing the above note, no doubt some one will start a class; if this were done, I am sure it would be well supported.—I remain, yours, &c.,

F. R. G.

THE FERROUS OXALATE DEVELOPER.

Dear Sir,—In my recent article upon the "Development of Gelatine Dry Plates with Ferrous Oxalate," I was taxed with animus by the author of the article in "Autotype Notes." Now, to disprove that accusation, I shall be glad if you will insert this letter in the News.

In the article above referred to, I made the assertion that when using certain plates, under no circumstances was it possible with a ferrous oxalate developer to get as good results as when pyrogallic was used. To this assertion, "The Author, &c.," gave it as his experience that ferrous oxalate, on the contrary, gave much better results than pyrogallic.

Since writing the article, I have had an opportunity of trying some plates that are sent out by the Autotype Co. specially prepared for ferrous oxalate development, with the result that my previous experience is entirely reversed. With Autotype plates, the ferrous oxalate developer not only gives a negative in *about half the time*, but of a much superior quality than when pyrogallic is used; in fact, these plates are evidently prepared for ferrous oxalate development, and only yield the best results when that developer is used. This statement is, I hope, sufficient to acquit me of animus.—I remain, yours faithfully,

W. T. Wilkinson.

PHOTOGRAPHIC NUISANCES.

Sir,—Your correspondent, E. Williams, seems somewhat relieved after he has, as he says, had a good grumble, and hopes someone else will do likewise. Now, for my part, I am not inclined to do likewise, but otherwise. E. W. is quite mistaken in thinking there are no good commercial plates in the market. While being willing to admit some makers' plates are very inferior, those, at any rate, of one firm whose films I have used for several years daily, are everything to be desired. I have got them from different dealers, and thus have had the chance of getting different batches. I could always mix them without the least fear of getting different results, but always found them the same both in quality and uniformity in sensitiveness, and never do I remember having a bad batch of this maker's plates. I could also say the same of other makers; but when I am satisfied with one, my motto is to stick to it, and I would advise E. W. to do the same if he wishes to succeed; he would then, I think, have less complaints to make. As to makers labelling their plates ten or twenty times when they prove less rapid, I will admit it is a fault they would do well to remedy; but that is not so bad as E. W. would have us believe. Trusting he will take courage from the fact that there are many good makers of commercial plates yet,—I am, yours truly, Geo. Pendry.

Dear Sir,—Kindly grant me space to pour out my pæan of praise and gratitude to those two worthy souls, Messrs. "Exact Measure" and E. Williams, for their letters entitled "Photographic Nuisances." May every earthly blessing fall upon them! May their hands be strong to labour! &c., &c.

I, too, have suffered. Listen to my plaintive cry. Boxes labelled, "These plates are from ten to twenty times as rapid as wet plates," have brought sorrow and anguish. In boxes said to contain one dozen, I have found from six to eight fit to use; the others all duffers—spotted with powdered glass, dead flies, thumb-marks, scratches, dents, and fancy portraits of Jumbo in different poses; the coating of the plates in some parts too thick, in others too thin; some glasses too large, some too small, some cut askew. All these, when complained about, the indignant manufacturer calls "microscopic" defects.

Mr. Editor, can you call it a microscopic defect that blots out, perhaps, one of the dearest, prettiest little noses that ever a dainty little miss of sweet seventeen brings you to photograph for her? And then the temptation to bad language! Oh! my dear friends and dry plate makers, think of this, and of the little boy in the dark room, whose mother has sent him to you to benefit by your artistic taste and Christian example. Do try and be more careful in future, because your plates are all very good if only prepared with ordinary care and judgment.—Faithfully yours, Augustus W. Wilson.

Proceedings of Societies.

Newcastle-upon-Tyne and Northern Counties Photographic Association.

The ordinary monthly meeting was held on October 10th, in the College of Physical Science, Newcastle, Mr. Sawyer in the chair.

In the absence of the Secretary, Mr. J. P. Gibson read the minutes of the last meeting, which were confirmed.

Messrs. Pae, Galloway, Martin, Cambell, Swinton, and Templeton, were nominated as candidates for election at next meeting.

It was resolved that three judges be appointed for the November exhibition of photographs—one to be an artist, one an amateur, and one a professional photographer; and Mr. Way, Professor Herschel, and Mr. Laws were elected unanimously.

It was decided that pictures for competition be sent in without the sender's name attached, which, with some identifying mark, were to be enclosed in an envelope to the Secretary. It was also decided that only pictures taken since Jan. 1st, 1882, be eligible for competition. A suggestion that the council be requested to ask members to furnish photographs of their own production for decorative purposes as well as for competition was adopted.

Mr. Laws reported that the sub-committee appointed to procure an enlarged photograph of the late Professor Marreco had not as yet been able to find a negative suitable for reproduction.

The meeting concluded with a vote of thanks to the Chairman.

London and Provincial Photographic Association.

At the meeting of this Association held at the Mason's Hall Tavern, Basinghall Street, E.C., on Thursday, the 12th inst., Mr. P. F. Richards in the chair,

A Member showed an unexposed gelatine plate prepared from commercial pellicle on which were a number of spots, which the maker of the pellicle attributed to over-heating. In the opinion of the meeting they were identical with what are known as "Coignet's spots."

Mr. Cowan said that he had caused these spots with a gelatine that did not otherwise give them, by keeping the emulsion in a sieve for about fifty hours previous to coating. He thought they were caused by fermentation; this, in a measure, bore out Mr. Henderson's theory that they are caused by carbonic acid gas, which can be removed by continuous exhaustion under a receiver.

Mr. Burton showed a negative with several splinters of glass in the film; there were no insensitive spots round these, and no repulsion of the emulsion seemed to have taken place.

It was suggested that it would be interesting to know the form of the glass crystals, and also at what stage they fell on the film.

Mr. Burton said that if a plate had flaws or marks in it, it could be easily ascertained if they would show in the prints by placing a piece of white paper at the back, and if then visible on looking through the glass, they would print in a diffused light.

Mr. Reiman showed a transparency developed by the addition of three grains of oxalic acid to the pyrogallic developer; it was a good rich colour, but he found it slow in developing.

Mr. Prestwich had tried the formula, and found it slowed the development about ten times, and also slowed the plate.

It was said that the colour of the plate in daylight was a green yellow.

Mr. Henderson said that some two years ago he had experimented with a view of forming the bromide in solid gelatine by a somewhat similar process to that of Mr. Obernetter. In his case the bromide salt was dissolved in the gelatine by daylight; this was then allowed to set, when the solution of silver was poured on the top, and the whole allowed to stand for three weeks, without any combination taking place, except that a very thin layer of bromide was formed on the top of the gelatine.

An interesting but desultory conversation followed, in which Messrs. F. W. Hart, Debenham, Cowan, Burton, Coles, and others took part.

It was resolved that a register should be kept at the Association of situations vacant, and of assistants requiring employment.

Photographic Society of Ireland.

The opening meeting of the session was held on Friday last, the 13th inst., in the Royal College of Science, E., and was largely attended, Mr. George Mansfield being in the chair.

Mr. Hutchinson Smith explained the results of his summer's work on rapidly moving subjects, and explained Messrs. Watson's patent Addenbrook exposer, which had been kindly lent by them for exhibition, and which was much admired. He considered that personally he had obtained his best results with an ordinary shutter of simple form; many of the others, though of more complex construction, failed to expose the plate as equally as might be desired.

Professor Barrett exhibited a curious sample of crystallization on a gelatine plate, which was generally considered to be that of alum which had not been sufficiently removed by the washing.

The names of ten new proposed members were handed in to be balloted for at the next meeting, which will be held on the 10th November, and which will be the annual general meeting of the Society.

Photographers' Benevolent Association.

The Board of Management held its monthly meeting on October 4th.

After minutes of the previous meeting were read and confirmed, Mr. E. G. Ballard, of Rochester, was elected as an ordinary member of the Association.

The Photographic Society of Great Britain having placed their Exhibition at the disposal of the Association on Thursday, November 16th, from 7 till 10 p.m., it is hoped that members will make a point of attending the Gallery at 5a, Pall Mall East, on that date.

Talk in the Studio.

Photographic Society of Great Britain.—The next technical meeting of this Society will be held on Tuesday, October 24th, in the Exhibition Room at the Gallery, 5a, Pall Mall East; when, amongst other matters, the apparatus exhibited will be explained. The chair will be taken at 8 p.m.

Electro-deposition of Copper on a Large Scale.—The steel telegraph wire used for overhead lines in the United States is now copper plated, the present works being in a position to deposit two tons of copper a day. When all arrangements are complete, it is estimated that by an expenditure of 980 horse-power no less than 15,000 lbs. of the metal will be deposited in twenty-four hours, or about 16 lbs. per day for each horse power.

Isolation.—Men's pursuits have an isolating tendency. Sporting, literature, art, science—whatever may absorb attention—helps to cut off those absorbed from the rest of the world. It is curious to look on at a railway bookstall at a busy hour, and to notice the varying tastes that have to be gratified, and also to see how one man's predilection is a puzzle to his neighbour, and *vice versa*. Half-a-dozen of us rush into a compartment and begin to be absorbed in our papers. One has, let us say, the *Athenæum*, and soon he is gloating over the prospects of the book-season. His thirst for literary novelties is gratified by the announcement of the volumes which this or that firm have in preparation for the winter, and he is gratified at the prospect of the splendid harvest. The absorbing interest thus excited is a puzzle to the purchaser of the *Sportsman*, whose interest is centred in horses and their doings, or in the "records" of athletes and others whose names are ever on his lips. What an absurd fellow the man of books is to him; and, in return, how that individual wonders that the other should waste his time over columns of racing stuff, or the doings of people he never heard of. The man with the *Era* finds its pages a mine of interest, and even the advertisements have a charm that is irresistible. Frivolous and foolish, indeed, does this seem to the sedate reader of the *Guardian*, the church news in which alone seems worthy of a reasonable being. Yet the possessor of the Photographic News smiles compassionately on him as a harmless enthusiast with a hobby, while he absorbs into his brain technical details relating to his beloved art; while he, in his turn, excites the commiseration of the severe student of the *Economist* seated by his side. In all these cases special objects of interest invest the lives of those devoted to them with a peculiar zest, for the man is to be pitied who has no hobby; but none the less is the effect isolating. Were the readers to throw down their papers and begin a conversation each on his own topic, it would be singularly wanting in vitality. And the impression created in each and every breast would be that the rest were ignoramuses worthy of commiseration. The fact that Tennyson had in the press a new poem would not impress the backer of "Own Brother to Potiphar." Both would seem to be devoid of natural curiosity if they were indifferent to the claims of the new actress at the Foldcrolity, all these would appear heathens from caring nothing about the rumours of Churchmen having claims to the vacant mitre, while an indifference to the latest discoveries in photography or the newest problem in finance would certainly stamp the company in the eyes of two of them as devoid of reasonable enthusiasm in respect of subjects closely associated with social progress.—*South London Press.*

The Heliograph in Mauritius.—Some time ago we drew attention to the importance of establishing telegraphic communication between the Islands of Mauritius and Réunion in the Indian Ocean, in order that the approach of cyclones could be signalled from one place to the other, and thus the great damage to ships and property which they cause be avoided by taking proper precautions. The idea of employing the heliograph for this purpose, in default of a submarine cable, has occurred to Mr. L. P. Adam, who has procured in France two great telescopic heliographs of Colonel Mangin's design for the purpose of establishing communication between the plateau of Pouce in Maritius, and the crater of the wood of Nèfles in Réunion. The distance between these two elevated stations is 134 miles, and the crater bears south-west of Pouce. When we remember the recent heliographic successes of General Ibanez and Colonel Perrier over a distance of 180 miles between the frontiers of Morocco and the coast of Spain, it will be seen that Mr. Adam has a good chance of success. Moreover, by aid of a small automatic eclipser devised by M. Viger, a clockmaker in Maritius, he is enabled to transmit despatches automatically on the Morse system. He also hopes to register the messages by the use of selenium in a process similar to that employed in some observatories for recording with the middle wire of a meridian telescope, or by causing the light spot to impress a photographic gelatino-bromide of silver band of paper passing under the spot. Experiments with Colonel Mangin's apparatus shows that at a distance of 150 miles the luminous beam is visible in the telescope even after it passes through six thicknesses of smoked glass which have considerably reduced its intensity. The conclusion, therefore, is that signals produced by a petroleum lamp with flat wick seen edgewise placed in the focus of one of M. Mangin's apparatus will be visible from one island to the other, and will allow of a cyclone being announced from Maritius twenty-four or thirty-six hours before it reaches Réunion.—*Engineering.*

Scientific Investigation by Photography.—The nature of vibratory motions which accompany the propagation of flame in combustible gaseous mixtures have been investigated, says *Nature*, by MM. Mallard and Le Chatelier. They have studied, with the help of photography, the period of accelerated and very irregular velocity, accompanied by sound, which follows a (first) period of slower, silent, and regular propagation, in a tube closed at one end, and having its combustible gaseous contents (bioxide of nitrogen and sulphide of carbon) lit at the other. A vibratory movement is indicated, the amplitude increasing as the last third of the tube's length is neared (where is one of the ventral segments of vibration). A mean pressure of at least 5 atm. is produced for a few ten-thousandths of a second. The mean velocity of propagation is accelerated as the amplitude and rapidity of the vibrations increase.

THE ABSORPTION SPECTRUM OF OZONE.—Chappuis has recently made a careful study of the absorption spectrum of ozone, and finds no less than eleven bands, the positions of which he has carefully determined. Mere traces of ozone may be detected if a column of sufficient length is examined spectroscopically. When traces of nitrogen are present in oxygen used for partial conversion into ozone, a compound of oxygen and nitrogen is formed, which gives a peculiar spectrum of fine dark lines.

THE COLOUR OF WATER.—Experiments made by J. Aitken confirm the usual notion that pure water has a blue tint; but he finds that the theory of selective reflection is insufficient to account for all the variations as to tint met with in the case of natural accumulations of water. Whitish particles are suspended in the water of the Mediterranean, and the tint varies from deep blue to chalky blue-green, according to the proportion in which these particles may be present.

THE PRINCE OF WALES' VISIT TO BRADFORD.—Shortly after the Prince and Princess of Wales visited Bradford, Mr. J. M. D. Worsnop, of 154, Leeds Road, forwarded through the Right Hon. W. E. Forster a cabinet sized instantaneous photograph of the Prince in the act of receiving the key from Sir Henry W. Ripley to open the Technical School. On the 16th of August Mr. Worsnop received through Mr. Forster a letter from Sir F. Knollys, dated from Marlborough House, stating that the Prince will be happy to accept an enlarged copy of the photograph. Shortly afterwards Mr. Worsnop forwarded to Marlborough House an enlarged copy, beautifully framed. On the 30th of September he received a letter from Sir F. Knollys, dated from Abergeldie Castle, Ballater, Aberdeenshire, acknowledging the receipt of the picture, which has been handed to his Royal Highness and accepted by him.—*Bradford Daily Telegraph.*

AERIAL PHOTOGRAPHY AND TELEPHONY.—The Municipal Council of Paris having voted a grant of 1,000 francs to the Academy of Meteorological Ascension for the purpose of making experiments in aerial photography, an ascent was made on Sunday by members of the Academy from the Carrefour de l'Observatoire. They carried with them an apparatus for taking instantaneous photographs. This had six lenses pointing to different directions, so as to embrace the whole of the horizon and to produce a panoramic photograph. The balloon rose 200 metres. A telephone was afterwards fitted up in the car to enable the occupants to communicate with their friends below.—*Daily News.*

PHOTOGRAPHIC EXHIBITION IN EDINBURGH.—Yesterday afternoon there was a private view of an exhibition of some 150 photographs in No. 16, Princes Street, under the auspices of the Edinburgh Photographic Society. The photographs are all of more than ordinary excellence, and in one or two instances a high level of art has been attained. One of the best pictures in the exhibition is a landscape with figures (No. 104), which has scarcely a fault—either from an artist's or a photographer's point of view. The landscape No. 82 is a well-balanced composition, the details being brought out with a pleasing softness. No. 58, a Continental village view, is praiseworthy in many respects, as is also No. 59; but here the sky is suspiciously like a "made-up." Taken as a whole, the landscapes are superior to the figures. Two ambitious *Genre* pictures, one of them called "Well-earned Repose," have the artificial setting much too prominent. "Brambling" is, however, a good composition, the figures of a number of children being happily poised over a bramble bush. In "Chequered Sunshine and Shade" the woodland scene is marred by the figure of the lady who leans against the tree being in too studied an attitude. "Gloaming," an old woman trimming a lamp, is skilfully managed, the figure being thrown in fine relief against the darkened background of a cottage interior. There are a number of studies (principally of expression) by that gelatinous process which gives the appearance of a red chalk drawing. They are all of them very successful, and are presumably by a well-known photographer, who has made this description of photograph a speciality. One of these studies, "Speak, for thy Servant Heareth," is perhaps as fine a treatment of fleeting sentiment as any in the room. No. 48, "The Knight's Daughter," a lady seated reading a letter at a small table, is remarkable for the easy poise, careful arrangement of drapery, and softness of tone. Among a number of other pictures, all of them possessing merit, may be mentioned a series of photographs of palatial rooms, views from the Cape of Good Hope, and groups of young ladies in Egyptian dresses and with Egyptian surroundings, the latter a memorial of the ball of the Black Watch in the Music Hall last season. A very interesting specimen of work by a new process is shown. Instead of the subject being printed from the negative on to silver paper, a sheet of prepared gelatine is used, an electro-type is taken of this gelatine, and the result is a plate from which very fine copies have been taken in ordinary ink.—*Edinburgh Courant.*

A SHAM PHOTOGRAPHER.—A not altogether novel species of fraud was disclosed during the hearing of a case at the Derby Sessions on Wednesday. A man named Frederick Ward was charged with obtaining sums of money from various persons by false pretences. It appears that the prisoner went about with something which resembled a photographic apparatus, and, under pretence of taking likenesses, obtained the money he was charged with fraudulently procuring, as the sitters never received their photographs. The apparatus was examined by a professional photographer, who pronounced it a "dummy." The Recorder sentenced the prisoner to twelve months' imprisonment.

To Correspondents.

H. HOWARD.—1. By reading the specification, you will be able to see if your arrangement is practically identical with that patented. Supposing it to be practically identical, and that you make it for sale or for use in your profession or trade, you will be liable. 2. We cannot undertake to advise as to the validity of any patent. A principle cannot be patented, only an arrangement. 3. See description of Mr. Spinks' shutter on page 321 of our present volume. 4. You had better reject the defective emulsion and make fresh.

SOUTH DEVON.—You may be quite sure that when a lens is included, the circumstance is certain to be stated in the advertisement.

CONCAVE GLASSES.—Several correspondents are informed that concave glasses suitable for coloured photographs on glass are to be had from J. Barnard and Co., artists' colourmen, 339, Oxford Street. Mr. Ashman's paper appeared on page 465 of the present volume.

WATER.—1. It will do no harm, as there is no trace of silver left. 2. Add three grains of chrome alum to each ounce, and if this is not enough, try a larger quantity.

CHARLES KNIGHT.—No. 1249. See notice under *Concave Glasses.*

ENQUIRER.—Boxwood dippers are occasionally used, but there is some risk of contaminating the bath. Silver wire is far preferable.

W. W.—See notice under *Concave Glasses.*

J. HAVERSON.—A leader on the subject will appear shortly.

H. J.—You will be likely to find what you require by looking through our advertising columns.

C. E. G.—We do not know of any satisfactory remedy applicable to such a case.

C. BARRINGTON.—It is pretty evident that you have purchased a useless instrument in which one lens has been replaced by a glass having no qualification for the position except that of fitting into the cell. Its value is that of the metal forming the mount.

SAMUEL BONTHORNE.—1. Make it of dry pine, and thoroughly saturate with melted paraffin wax. 2. Certainly not, as such a proceeding would lead to the destruction of the whole arrangement sooner or later. 3. About one-tenth of an inch thick. 4. Yes. 5. It can be bleached quickly by means of a solution of chloride of lime, the action being especially rapid if sufficient hydrochloric acid is added to partially decompose the compound.

H. G. H. CONYBEARE.—1. The markings probably arise from the presence of a trace of greasy matter; perhaps condensed petroleum vapour, as you suppose. 2. It is certainly very annoying to receive plates so carelessly cut as regards size, and there can be no doubt that the makers are in strict law responsible for any loss which may have arisen from the faulty condition of the goods.

G. KEDGWIN TURVEY.—You will find full information on the matter in Mr. Debenham's paper, which appears in our present issue.

PHOTOGRAPHS REGISTERED.

Mr. H. G. PIKE (Chester)—Photo. of Statue of Daniel Rowland.
Mr ANCKORN (Arbroath)—Photo. of Group of Officers of Salvation Army.
Mr. J. WHITE (Littlehampton)—Three Photos. of Ulsters and Dresses.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1260.—*October* 27, 1882.

CONTENTS.

PLATINOTYPE PRINTING.

As the days draw in at this time of year the number of prints which can be got from a negative in a day becomes fewer, and this more especially in London. This is particularly trying to the landscape photographer, because the time has just passed when he may, with profit, use his camera, and, could he turn his spare hours to the production of prints from the negatives he has taken, he would save time which must otherwise be taken from the brighter months of the spring, when he will grudge it, because once more he will wish to take to the field. This of course applies particularly to the amateur, who is his own printer. To the professional, who keeps a printer working whilst he is taking negatives, the loss of time is not so much felt.

Taking these facts into consideration, the amateur ought to hail with delight any process which curtails the exposure which it is necessary to give the print under the negative. In the platinum process we have such a saving of time made as is represented by something like three to one. This does not sound very great, but few who have not tried it can conceive what a difference it makes in a day's work to get from two to three prints in place of one. It makes it possible to get as many impressions in a dull winter day, as with the slower process may be had in a bright summer day, working the same number of hours.

We have mentioned the waning strength of the light as a special inducement to the use of platinum for printing at the present season, but the greater sensitiveness of the medium under consideration over albumenized paper is only one of its minor advantages. We believe that if all the advantages of the platinum process over the silver printing processes were fully appreciated by photographers, the use of the former would become much more general than it is.

We believe that several misconceptions as to the capabilities and adaptabilities of the platinum process are common. One of these is that it is only possible to get a good platinum print from such a negative as would, with albumenised paper, give a hard result. This is a mistake, and arises from prejudice acquired by the long practice of silver printing. Let us suppose the case of a negative somewhat too thin for silver printing. What is the reason why we cannot get a good print from such a negative? We know that if we take a very light impression from it, and look at it as it comes from the frame, we may find that the result is charmingly soft and beautiful; but we know that we cannot retain this appearance. The picture will not tone. It will be impossible to get any richness of colour. The consequence is that the negative is considered too thin; but this is not because the picture from it will necessarily have too little contrast to give an artistic result, but because it will not have sufficient depth of colour to satisfy the conditions necessary for the obtaining of a satisfactory tone.

It is quite different, however, with platinums. Here there is no such thing as toning. The colour is the same in all cases, and is always artistic. The consequence that a picture having less contrast in it than is necessary for a silver print will be pleasing to the eye if it be light enough. This is enough to counterbalance the fact that, from the same negative, a platinum print will always show a somewhat weaker contrast of light and shade than with a silver one, and it may be said that if a negative be dense enough to give a good silver print, it will be dense enough to give a satisfactory one in platinum.

The greatest advantage of all in the platinotype process is of course the permanency of the results. It is unfortunate that photographers do not give the attention which they might to this point. They look more to the praise of the moment than to the production of lasting results.

Probably (next to the permanency of results) the greatest advantage of the platinum process is to be found in the extreme simplicity of the manipulations. These are inconceivably less troublesome than those involved in silver printing, if the best results are to be had by the latter process.

The terrible toning bath is replaced by a solution in which it is merely necessary to dip the prints for a second, when a never-varying result is gained. The fixing and prolonged washing of the silver print are replaced by the dipping in an acid solution, and the subsequent rinsing in a few changes of water; whilst an advantage greater than might appear at first sight is to be found in the fact that platinum prints do not cockle in drying.

The only stage at which difficulty can possibly be found is in judging the time necessary to leave the prints in the frames. The faint yellow or greyish image looks strange at first, but very soon the photographer gets used to it, and will probably lose fewer prints by misjudgment of exposure than he would if he were using albumenized paper. Few photographers seem to remember how long it took them to acquire the judgment necessary to allow, in printing, for the reduction in depth which will take place in the toning and fixing baths.

The only point where any real difficulty is to be found in the use of platinum paper as compared with silver, is in that of combination printing. For example, in printing-in skies, it is almost necessary to use an actinometer, or to judge the time by guess, because, if a sky be printed till it is visible before development, it will be far too dark afterwards.

The ultimate appearance of a platinum print calls for little remark here. We would only say that it always appears at a disadvantage when hung alongside of silver prints. So, for the matter of that, does a soft and mellow painting alongside of harsh and garish pictures. This does not prevent the less brilliant picture from being the most artistic, and, when viewed alone, the most pleasing.

Probably the reason why the platinum process has not done more to oust our old but fickle friend, albumenized paper is, that it affects the photographer's pocket. It is more expensive Probably, however, if the greater waste in the silver process were duly considered, the difference in price would be less than is generally supposed.

The one great and absolutely necessary precaution to take in platinum printing if success be desired, is to keep the paper dry. The other conditions may, it is our experience, be varied considerably without much damaging the final results.

THE COLLOTYPE PROCESS IN PRACTICE.

That theory and practice are two very different things holds good in photography especially, and perhaps in no other branch of our art have so many theoretical formulæ been promulgated than in the Collotype or Lichtdruck process. As our readers are aware, we have had an opportunity of seeing collotype printing in operation in several European establishments of note, and have, from time to time, published in these columns our experiences. But requests still come to us so frequently for information on the process, that we have deemed it well to make a practical summary for the benefit of those who are working—or desire to work—the method.

The formulæ and manipulations here set down are those of Löwy, Albert, Allgeyer, and Obernetter, four of the best authorities on the subject, and we can assure our readers there is nothing described but what is actually practised.

Glass Plate for the Printing Block.—Herr Albert, of Munich, uses patent plate of nearly half-an-inch in thickness, as most of his work is printed upon the Schnell-press (machine press). Herr Obernetter, of Vienna, since he only employs the slower and more careful hand-press, prefers plate glass of ordinary thickness, as being handier in manipulation, and better adapted to the common printing-frame.

Herr Löwy, of Vienna, again, uses plate glass a quarter of an inch thick, as his productions range from the finest to the roughest.

Preliminary Coating of the Glass Plate.—Herr Albert's original plan was to apply a preliminary coating of bichromated gelatine to the thick glass plate, the film being exposed to light through the back of the glass, and thus rendered insoluble and tightly cemented to the surface; this film serving as a basis for the second sensitive coating, that was afterwards impressed by the negative. This double treatment is now definitely abandoned in most Lichtdruck establishments, and, instead, a preliminary coating of soluble silicate and albumen dissolved in water is used.

Herr Löwy's method and formula are as follows:—

The glass plate is cleaned, and coated with—

Soluble glass	3 parts
White of egg	7 ,,
Water	9 to 10 ,,

The soluble glass must be free from caustic potash. The mixture, which must be used fresh, is carefully filtered, and spread evenly over the previously cleaned glass plate. The superfluous liquid is flowed off, and the film dried either spontaneously or by slightly warming. The film is generally dry in a few minutes, when it is rinsed with water, and again dried; at this stage the plate bears an open, porous film, slightly opalescent—so slight, however, as only to be observed by an experienced eye.

Application of the Sensitive Film.—We now come to the second stage of the process, the application of a film of bichromated gelatine to the plate.

Herr Löwy's formula is as follows:—

Bichromate of potash	16 grammes
Gelatine	$2\frac{1}{2}$ ounces
Water	20 to 22 ,,

According to the weather, the amount of water must be varied; but in any case the solution is a very fluid one. An ounce is about 35 grammes, as most of our readers know. A practical collotypist sees at a glance the quality of the prepared plate without any preliminary testing. A good preliminary film is a glass that is transparent, yet slightly dull; the film is so thin you can scarcely believe it is there. The plate is slightly warmed upon a slate slab, underneath which is a water bath; it is then flooded with the above mixture of bichromated gelatine, leaving only sufficient to make a very thin film. When coated, the plate is placed in the drying chamber.

Drying the Sensitive Film.—Much depends upon the drying. A water bath with gas-burner underneath is used for heating, and a slate slab, perfectly level, receives the glass plate. The drying chamber is kept at an even temperature of 50° C.

The object to be attained is a fine grain throughout the surface of the gelatine, and unless this grain is satisfactory, the finished printing block never will be. If the gelatine film be too thick, then the grain will be coarse; or, again, if the temperature in drying be too high, there will be no grain at all. The drying is complete in two or three hours, and should not take longer.

The Negative to be Printed from.—The sensitive film being upon the surface of a thick glass plate, it is necesssary that the cliché or negative employed should be upon patent plate, or not upon glass at all, so as to ensure perfect contact. Best of all, is to employ a stripped negative, in which case absolute contact is ensured in printing. It is only in these circumstances that the most perfect impression can be secured. If the negative is otherwise satisfactory, and only requires stripping, it is put upon a levelling stand, and fluid gelatine of a tolerable consistence is poured over it. When dry, a pen-knife is run around the margin, and the film leaves the glass without any trouble.

Herr Obernetter says that many of the negatives he receives have to be reproduced before they can be transformed into Lichtdruck plates, and he employs either the wet collodion process or the graphite method, according to circumstances. If the copy is desired to be softer than the original, collodion is employed; if vigour be desired, graphite is used, and here is his formula:—

Dextrine	62 grains
Ordinary white sugar	77 ,,
Bichromate of ammonia ...	30 8 ,,
Water	3·21 ounces
Glycerine	2 to 8 drops

The film is dried at a temperature of 130° to 140° F., in about ten minutes, and whilst still warm is printed under a negative in diffused light for a period of five to fifteen minutes. In a well-timed print the image is slightly visible; the plate is again warmed a little above atmospheric temperature in a darkened room, and then fine levigated graphite is applied with a fine dusting brush, a sheet of white paper being held underneath to judge of the effect. Breathing upon the film renders it more capable of attracting the powder. When the desired vigour has been attained, the superfluous powder is dusted off, and the plate coated with normal collodion. Afterwards the film is cut through at the margins of the plate by means of a sharp knife, and put into water. In a little while—from two to five minutes—the collodion with the image will be detached from the glass; the film is at once turned over in the water, and brought out upon the glass plate. Under a soft jet of water any air-bubbles that may exist between the collodion and the glass are removed, and then a solution of gum-arabic (two grammes of gum dissolved in one hundred grammes of water) is poured over, and the film is allowed to dry spontaneously.

Exposure of the Printing Block under the Negative.—The exposure is very rapid. Anyone conversant with photolithographic work will understand this. At any rate, every photographer knows that bichromated gelatine is much more rapid than the chloride of silver he generally has to do with.

There is no other way of measuring the exposure than by the photometer or personal experience, and the latter is by far the best.

After leaving the printing-frame, the plate is immersed in cold water. Here it remains at discretion for half-an-hour, or an hour; the purpose, of course, being to wash out the soluble bichromate. It is when the print comes out of this bath that judgment is passed upon it. An experienced eye tells at once what it is fit for. If it is yellow, the yellowness must be of the slightest; indeed, Herr Furkl (the manager of Herr Löwy's Lichtdruck department) will not admit that a good plate is yellow at all. A yellow tint means that it will take up too much ink when the roller is passed over it. The plates of Herr Obernetter, however, are rather more yellow than Herr Löwy's —certainly only a tinge, but still yellow; and Herr Obernetter's work proves, at any rate, that the yellowish tinge is by no means inseparable from good results.

The washed and dried plate should appear like a design of ground and polished glass. The ground-glass appearance is given by the grain. If there are pure high-lights (almost transparent) and opalescent shadows, the plate is a good one.

Printing from the Block.—We have now a printing-block ready for the press. If it is to be printed by machinery—that is to say, upon a Schnell-press—the surface is etched; if it has to be more carefully handled in a hand-press, etching is rarely resorted to—it is moistened only with glycerine and water. To etch a plate for a Schnell-press, it is placed upon a levelling stand, and the following solution is poured upon it :—

Glycerine	150 parts
Ammonia	50 ,,
Nitrate of potash (saltpetre) ...	5 ,,
Water	25 ,,

Another equally good formula, recommended by Allegeyer, who managed Herr Albert's Lichdruck printing for some years, is :—

Glycerine...	500 parts
Water	500 ,,
Chloride of sodium (com. salt)...	15 ,,

In lieu of common salt, 15 parts of hyposulphite of soda, or other hygroscopic salt, such as chloride of calcium, may be employed.

The etching fluid is permitted to remain upon the image for half-an-hour. During this time, by gently moving the finger to and fro over the surface, the swelling or relief of the image can be distinctly felt. The plate is not washed, but the etching fluid simply poured off, so that the film remains impregnated with the glycerine and water; at the most, a piece of bibulous paper is used to absorb any superfluous quantity of the etching fluid. After etching, the plate is taken straight to the printing-press. The inking up and printing are done very much as in lithography. If it requires a practised hand to produce a good lithographic print, it stands to reason that in dealing with a gelatine printing-block, instead of a stone, skill and practice are more necessary still. Therefore, at this point the photographer should hand over the work to the lithographer, or rather the Lichtdruck printer. It is only by coaxing judiciously, with roller and sponge, that a good printing-block can be obtained, and no amount of teaching theoretically can beget a good printer. To appreciate how skilful a printer must be, it is only necessary to see the imperfect proofs that first result, and to watch how these are gradually improved by dint of rolling, rubbing, etching, cleaning, &c. In all Lichtdruck establishments, two kinds of rollers are used—viz., of leather and of glue. In some establishments, too, they employ two kinds of ink; but Herr Löwy manages to secure delicacy and vigour at the same time by using one ink, but rolling up with two kinds of roller.

Collotype printing is not merely done by hand-presses, but is also done by machinery. At Herr Albert's a gas-engine of six-horse power is employed to drive the machines, and each machine requires the attention of a skilled mechanic and a girl. The press is very like the lithographic quick press. Upon a big steel bed lies the little collotype block. The glass printing block, with its brownish film of gelatine, moves horizontally to and fro, and, as it does so, passes under half-a-dozen rollers, which not only supply ink, but disperse it. Some of the rollers are of leather, and others of glue, and whenever the printing-block retires from underneath them, an inked slab takes the place of the block, and imparts more ink to the rollers; sometimes as many as eight rollers are used, for the difficulty of machine printing is to apply the ink as delicately and equally as possible. It is necessary at intervals to damp the block, and when the printer in charge finds this to be the case, he stops the press, and applies a little glycerine and water with a cloth or sponge; then a leather roller is passed over to remove superfluous moisture, and the press is again started.

Herr Obernetter relies upon the Star or *Stern-press*—a small lithographic press—one man sufficing to manage it, who turns a wheel with large spokes, reminding one of the steering-wheel of a ship. The Lichtdruck plate, gelatine film upwards, is laid upon a sheet of plate-glass by way of a bed, the plate having first been treated with a solution of glycerine and water; it is then inked up as previously described, except that Herr Obernetter uses two kinds of ink—a thick one and a thin—applied by two rollers of glue. In the first place, a moist sponge is rubbed over the surface; then a soft roller, covered with wash-leather, and of the appearance of crêpe, is passed over two or three times to remove surplus moisture; then a roller charged with thick ink is put on, and then another with thin is applied. It takes fully five minutes to sponge and roll up a plate, the rolling being done gently and firmly. A sheet of paper is now laid upon the plate, the tympan is lowered, and the scraper adjusted with due pressure; a revolution of the wheel completes the printing, the well-known scraping action of the lithographic press being used in the operation.

Some Lichtdruck prints are printed upon thick plate-paper, and are ready for binding without further ado, these being for book illustrations. Other pictures that are to pass muster amongst silver photographs are, on the other hand, printed upon fine thin paper, and then sized by dipping in a thin solution of gelatine; after drying, they are further dipped in a solution of shellac in spirit.

THE PHOTOGRAPHIC EXHIBITION.

Third Notice.

The pictures of Herr Julius Braatz, of Stettin, attract attention, if only by reason of their subject matter. "Boy Assuming Manhood" (379), being rather too high for close inspection, is, to our thinking, the best; a little fellow busy with his father's pipe, which might well illustrate the amusing story Mark Twain tells, with a Dutch accent, about "my first shmoke," the scene shown in the picture being none other than "De Leetle Room Where I Shleeps." But the most conspicuous of Herr Braatz's contributions are two scenes from Little Snow-white and the Seven Dwarfs (317 338), in which the photography is excellent, but the grouping and draping a little too stagey and stiff. Mr. W. Adcock, whose interiors are always good, has essayed this year to impart life into his pictures, and in two cases, at least, with considerable success. There is a ludicrous humour very telling about "Yesterday—a threat of discharge" (376), where two maid-servants appearing at their master's breakfast-table are bidden to behave themselves better in future under pain of dismissal; and in the companion picture "To-day—they give notice to leave," where the same prim serving-maids tell the lord of creation. to his amazement, to suit himself this day month. Mr. Adcock's "Game is Won" (354) is scarcely so successful.

Mr. F. Beasley, Junior, a landscape photographer of high reputation, exhibits several prints of merit. Two little pictures of a Scotch Smithy (375, 353) represent excellent work, full of detail, vigorous, and yet with that evenness of tone characteristic of the man who has his work perfectly under control. The Mediterranean scenes and studies of Tropical Foliage (191, 192) are no less praiseworthy. Of Mr. Joseph Paget's pictures (374 358), we like best the Russian Church at Jerusalem, the Church of the Nativity at Bethlehem, and the Parthenon; the hard contrast of light and shade to be found in the East, which mars so many photographs, is here avoided entirely, and while there is the bleaching action of the sun and weather upon the stone monuments plainly marked in Mr. Paget's pictures, none of them offend with glaring light and pitchy darkness. Indeed, Mr. Paget's Eastern scenes are among the most successful we have ever seen. Mr. John Duncuft shows two pictures, of which "The Salmon Ladder" (372), with a fine bit of massive rock in the foreground, is the most striking. Mr. G. M. Jones has a frame of meadowland pictures (370), several of which are very pleasing. The right-hand print at the top is our favourite, where some pollard willows overhang the sedgy stream, and the lazy river scarce moves beside the rushes. Mr. G. Hadley's frame (366) also includes several praiseworthy pictures; he is more successful, however, in his interiors —Hostel Library, Lincoln, is a capital bit of work—than in his landscapes, some of which are a little too dark to please us.

Messrs. Morgan and Kidd forward several portrait enlargements (362-365) made upon their gelatino-bromide paper, which are more than satisfactory; the portraits of Sir G. Airy and Miss Marten are, indeed, exceedingly fine, combining a high degree of softness and vigour with excellent effect. Mr. L. Berry's best exhibit is "The Ploughman's Baggin" (360), in which a pair of dappled Flemish horses are shown standing in the deep furrows; this fine picture Mr. Berry has wisely enlarged, and is to be seen amplified in another part of the room (25). Mr. Berry's "Gleanings from Nature" (347) is also well worth looking at. Mr. T. J. Dixon's sole exhibit is a frame showing the interior of some artists' studios (355). These peeps into palatial abodes—painters of late have become very luxurious in their surroundings—are rendered with exceeding skill and taste, the rich tapestry and carpets, the screens and knick-knacks that abound, affording a contrast that the photographer must have found rather trying. Herr H. Schüren, of Hamburg, sends a study of "Faust" (352), which has much to recommend it, being forcible, well draped, and admirably lighted; the only fault we find is, that the aged philosopher does not look old enough. Herr Schüren has also several fine examples of portraiture.

The Woodbury Company, as usual, exhibit some magnificent enlargements. One of the finest is an exquisite portrait of Madame Modjeska (300), by Messrs. W. and D. Downey; and two others from negatives by Mr. J. E. Mayall, of New Bond Street (44, 56), are scarcely less beautiful. There is a smoothness and brightness about the work rarely to be seen in photographic enlargements. Some fine landscapes are also shown by the Woodbury Company, one of them being Mr. Boord's yacht *Swift*, a picture already noticed (341). Mr. B. J. Edwards forwards a series of sea sketches (345, 346), of which "Leaving Lowestoft," a remarkably fine bit of work, is one of the most successful. Mr. Edwards has also several New Zealand views (312, 313), of which "The Pink Terrace" and "The White Terrace" have a special charm; a study of "Stalactites," in the same collection, is also a beautiful picture. Of Mr. Milman Brown's contributions we prefer the "English Cottage Home" (45), a rustic homestead amongst the trees, led to by a pathway through the meadow, which serves as foreground. "The Landslip" (344), by Mr. Brown, will also please. "Holiday Memories" (340), which is entered in the catalogue as the work of Mr. Garrett, is in reality a contribution by Mr. G. Christopher Davies, and contains some delightful sketches of bracken and foliage. "On the Banks of the Orwell" and "Pin Mill" are sweet little rustic studies. Another frame by Mr. Davies is made to tell the story of decoying wild duck (318), and is most interesting. Mr. G. P. Garrett shows "English Views" (339), and "Views in Switzerland" (319), the latter including some very careful and successful work. The most attractive is a view of Mont Blanc, a difficult subject, as many photographers know to their cost. Mr. Garrett shows the hoary giant in his full proportions, the shining white glaciers being made to contrast well with the matt snow slopes around; a study of rugged firs in the Alps also merits notice. Mr. F. S. Schwabe has some good views of the Pyramids and the Sphinx, but they are unfortunately hung too high for close inspection. Mr. Edward Fox's best picture is a tree study "Elm" (75), a monarch of the park laid low by the storm; Mr. Fox's prints are also for the most part hung too high to see with comfort. Mr. T. C. Hepworth exhibits six interiors (329); in some of them the shadows are too deep.

The Autotype Company show specimens of various branches of photography. One of the most interesting of their exhibits is some Collotypes which are *facsimiles* of the Codex Alexandrinus (511). There are, as our readers may know, but three authentic manuscripts of the Bible in existence, one in Berlin, a second in St. Petersburgh, and the Codex Alexandrinus, which the Autotype Company have copied. Twenty years ago a copy of the Bible M.S. was therefore priceless; now the whole can be purchased for twenty-five pounds. A frame of vitrified portraits (328) is noticeable not less because it is the only exhibit of the sort, as because it includes some very large and very fine specimens of ceramic-photography. A study of a female head—a ten-inch plaque—in red pigment is exquisite; and another specimen scarcely less perfect is the portrait of Mrs. Admiral Maxse. The Autotype Company also send many brilliant enlargements; a view on the Dargle by Mr. Payne Jennings, the big grey boulders in the foreground, between which the mountain stream forces its way, the steep banks and overhanging trees hung with deep foliage and interlaced with creepers, is a wonderful example of the enlarging camera. Nor are the portraits, several of them life-size, less successful. Notwithstanding their size, there is a refinement and a finished "engraving-like look" about them which will do much to dispel the dislike still entertained in many quarters for photographic enlargements. If work of this standard can be produced, we shall not find portrait painting so widespread in years to come.

Mr. Charles Andreae, who, like a thorough-going amateur, makes his own plates, sends several specimens of careful work; "Oak Struck by Lightning" (314), the rugged giant knee-deep in bracken fern, is one of his best, though Mr. Andreae's pictures of Portsmouth (115) are some of them exceedingly good. Mr. W. J. Belton's "Cottage" (311) is very English in its aspect, and is a delightful print; in another part of the room, among some instantaneous studies of steamers (69), also by Mr. Belton, there is other noticeable work, in the water left behind by a steamer, the changing surface of the waves being caught in all its beauty, and appearing almost iridescent to the eye. Mr. McLeish's well-known study of a "Fiddler" (292), which we have noticed at other exhibitions, is here, and therefore needs no additional praise on this occasion; but we must not forget to call attention to two other fine pictures of Mr. McLeish: "Views on the Tees" (22), close to "A Misty Morning," of which we have already spoken, and cannot speak too highly.

Mr. Seymour Conway's pictures (288, 81) this year will add further to his high reputation. Their soft brilliancy is such that at first sight they appear to have been printed upon collodio-chloride paper. They recall the admirable work of Russell Manners Gordon, by their clearness and purity; there is plenty of vigour, but no hardness. Look at "Llamberis Pass and Lakes," or "Dwygyfylchi," as ugly a name as ever was given to a pretty picture. Mr. W. R. Marsh contributes some wave effects at Bognor (287), which were decidedly well worth photographing, and should command the attention of some of our learned physicists. Mr. F. Lupson shows a picture of a Newfoundland dog (286). Mr. R. N. Harman exhibits some leafy studies (275, 194, 193), which would have been better for a little lighter printing.

Captain Abney sends half-a-dozen little Alpine pictures. The huge crystalline masses of the Görner Glacier (278) are exceptionally fine, and in Lyskammon and Riffelhorn (279) there is a charming effect obtained by a soft shadow falling on the delicate white slope of the Lyskammon. A brilliant sunset contrasting with the black hulls of some beached fisher-boats at "Broadstairs" (280) is another effective study by Captain Abney. Mr. Andrew Pringle's "Views of the Scotch Lakes" (271) include some enchanting scenes, as witness his delightful peeps at Loch Katrine and the graceful falls at Inversnaid; a richness of tone pervades Mr. Pringle's work, that must be the envy of every landscape photographer. Mr. Arthur Debenham only sends one picture, a bold sketch of the massive columns at the entrance of the Forum Civili at Pompeii (269). Mr. Glen Payne sends a series of studies (257), and some farmyard scenes (264, &c., 246, &c.), several of the latter exhibiting considerable merit; while of Mrs. Glen Payne's we like best, "Rustic Music" (228), a lad piping to his little sweetheart, whose black eyes and pensive expression, framed in a quaintly frilled bonnet, are simply delightful. In other juvenile studies, Mrs. Payne shows also much taste and artistic ability. Mr. W. Wainwright, Junior, exhibits both land and sea studies (258, 79), and in both is equally successful. His foliage pictures are clear and full of detail, and yet with plenty of shadow, and the same knowledge of light and shade is admirably put forth in the dashing yacht studies he also shows. Mr. H. Waterhouse Pope shows a picture of a dog (256). The Reverend Mr. Barlee exhibits a haymaking group (252), together with some tasteful views of Yarmouth (178, 151). Mr. G. E. Alder's "Game of Cards" (251) is good photography, although we do not care for the subject. Mr. W. D. Sanderson has several fine studies of "Woodland Monarchs" (249, 238), the latter picture exhibiting the fine proportions of a fallen tree in a singularly effective manner; several interiors are also the work of Mr. Sanderson, but we miss the grand landscape pictures he was wont to exhibit years ago.

APPARATUS AT THE PHOTOGRAPHIC EXHIBITION.

Although pictures form the staple of the Pall Mall Exhibition, the various photographic appliances placed on and around the table are not altogether without interest. Apparatus for wet-plate work is only notable for its absence, excepting so far as Mr. Shew exhibits one of his expanding or accordion-like changing-boxes, fitted up with a water-tank, and the old-fashioned paraphernalia for out-door operations; still it appears to us that Mr. Shew's compact and neatly-made changing-tent or box, excellent as it is, would hardly admit sufficient light to enable development to be carried on with certainty. Shew's light-tight plate-box (No. 474) is one of the best and lightest which we have seen, as its efficiency does not depend on the excellence of one joint—it being built up out of several layers of textile material. A stepped plate store or case, arranged something after the fashion of the usual letter paper-case, and connected with an electric bell, is shown by Mr. Langton, the bell being screwed on the back of the box, and the battery being placed under the table; when the box is opened the electric circuit is completed, and the bell begins to ring, continuing to sound until the case is once more closed. It would of course be quite easy to arrange this kind of thing so that a distant bell—say in the principal's office—should ring during the time the case is open; but it would be better to place the contact piece so that the bell should sound as soon as the catch or fastening of the box is drawn back, as we noticed that the box exhibited could be opened to the extent of one-eighth of an inch without sounding an alarm, and that the ringing ceased as soon as the box was nearly shut. Folding ruby lanterns are exhibited by the Sciopticon Company, Mr. Werge, and Mr. Shew, that first mentioned being the lightest, and no doubt the cheapest, while that contributed by Mr. Shew is a trifle heavier, as the cardboard of which it is composed is neatly covered with, and strengthened by, book-binder's cloth. Mr. Werge's lamp is a pyramidal arrangement with red silk sides, the whole folding down into a wooden box.

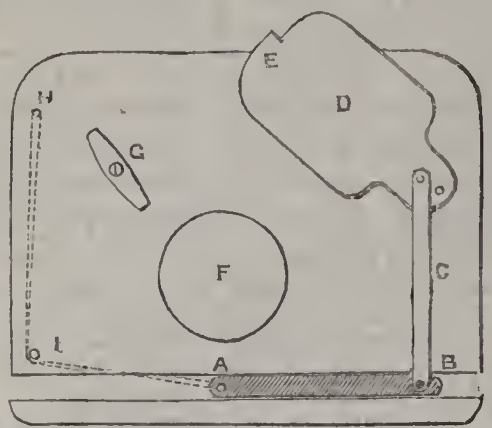
The dark slide appears to find increasing favour as a means of carrying the sensitive plate afield, as complex mechanical changing-boxes, such as were shown last year are not to be found in the present Exhibition. Photographers evidently appreciate the advantages of being able to take a small or large number of plates with a corresponding amount of luggage, and it is certainly unpleasant to know that one slip of the hand, or careless movement, may be fatal to the whole day's work. The light double slides of the Sciopticon Company have already been described in the News. Mr. George Smith, the manager of the Company, makes a point of lightness, and his portable camera, with his brattice stand, are evidently the out-come of careful study, and do him much credit.

The "eclipse" light apparatus of Mr. McLellan appears to be a very useful invention, and consists of an arrangement for burning magnesium wire in oxygen. A metal gas holder, capable of containing about twelve gallons, is fitted with a glass globe, so arranged that by filling it with water, and opening two stop-cocks, it becomes charged with oxygen from the holder; a stopper is then removed, and a piece of lighted magnesium wire, coiled in the form of a helix, and mounted on the usual laboratory deflagrating plate, is introduced into the globe of oxygen. The actinic intensity of the magnesium light is so enormously increased by the presence of the oxygen that a cabinet picture may be taken with an exposure of one second, and even drop shutter pictures may be obtained. It is said that about one hundred exposures may be made with one gas-holder full of oxygen, this costing about 6d. The apparatus is simple in form, and, consequently, inexpensive—probably something less than £5 would cover the whole expense of apparatus and materials.

As regards cameras, there is little to be said, good cabinet work being contributed by various makers and dealers. The Brooks Academy camera and the Enjalbert, each of which is intended to contain a number of plates, have already been described by us. On a camera exhibited by Messrs. Watson and Son, we find a simple arrangement for obviating the convenience of turning the focussing screen back over the camera when the dark slide is placed in position; instead of being simply hinged to the back of the camera, the focussing screen is attached by a double hinge or toggle-joint, this arrangement allowing the screen to be fixed parallel with the back, and about an inch behind it, when the dark slide is to be placed in position.

At the social gathering, held on Tuesday evening last, some of the apparatus shown was brought under discussion; but the main interest of the meeting centred on the exhibition, and trial of several forms of quick shutter ; after which Mr. McLellan demonstrated the method of working with his " Eclipse " light apparatus.

Messrs. Watson and Son called attention to a simple form of " go-and-return shutter," embodying the principle carried out by Mr. Harrison some two years ago. The shutter in question is made of ebonite, and is intended to be fitted in front of the lens.



A sliding piece, AB, is joined to the flap ED by a connecting rod, C, and it is obvious that a motion of the slide, either to the right or to the left, will serve to close the flap over the opening F. Let us suppose that the slide is pushed to the right, the flap covers A, and that the detent, E, is made to engage in the notch E. Under these circumstances the shutter is closed and the india-rubber band, HIA, is stretched to the utmost, on releasing the flap by withdrawing the detent, the shutter rapidly opens and shuts as the sliding piece AB travels to the end I of the groove. The shutter is very neatly made in ebonite, and works with a degree of smoothness and steadiness which one would hardly expect in a return-motion shutter.

Mr. E. Hyde next exhibited a simple flap shutter, mounted inside a camera, the flap being so recessed into its seating, and fringed with a bordering of velvet, as to thoroughly ensure the obstruction of all rays of light. Mr. Hyde's shutter is actuated by a small crank which projects from the side of the camera, and a very ingeniously-constructed metal shield serves to cover the slot which allows the apparatus to be raised with the front of the camera. Mr. Hyde's shutter has satisfactorily stood the test of rough usage in various parts of the world.

A double flap shutter of the " go-and-return " type was exhibited by Mr. Shew, this apparatus being provided with a brake, intended to reduce the speed. Such a shutter is comparable to Watson's shutter made with two flaps, and it of course opens from the centre. Mr. Collins introduced a shutter of this character about eighteen months ago ; but we believe that the difficulty of adjusting the brake so as to give the required speed proved an obstacle to its general use. The Addenbrooke shutter was exhibited, and this somewhat complex instrument is doubtless calculated to do good service when time and attention can be devoted to the management of such a delicate and complex apparatus. Among the cameras shown at the meeting, that of Rouch may be classified with the cheaper instrument made by the Sciopticon Company, a separate base-board, or mainstay, being used in each case. This system, so general on the Continent, is certainly conducive to lightness, although such cameras take rather longer to set up than the model ordinarily used in this country.

An interesting feature of the meeting was the ardent enthusiasm with which various amateur photographers set forth the special advantages of those cameras which they had used during the past season, but it must not be lost sight of that intelligent and thoughtful manipulation are far more important than the possession of a highly-organized and extremely well-made camera. We have seen admirable work executed under very trying circumstances by a very cheap and roughly-made camera of the scenograph type.

Mr. Cowan demonstrated the rapidity and exactness with which glass may be cut—even in a nearly dark place—by means of his patent cutting-board and guides.

A NEW AMERICAN STUDIO.

There are some extensive studios in the United States, if the new establishment, opened last month by Mr. Frank L. Morrill, has many equals. According to the *Lowell Daily Citizen*, the rooms of the new establishment are twelve in number, and occupy about 6,000 square feet. The main room, which is to be used as a reception room, is, we are told, 32 feet square, and 15 feet high.

It is lighted by a large skylight, and is shaded by a screen suspended from the roof. The walls are tinted in India red, with olive trimmings, and an open fireplace with heavily carved mantel occupies one end of the apartment.

At night the room is illuminated by rows of gas jets suspended above the screen, and so arranged that the light falls on the walls. The atelier is the finest in the country, being supplied with a skylight 18 feet square, the glass being one quarter of an inch in thickness, and set in an iron frame. The room is 25 by 40, and is finished in natural colours. Leading from it are two ladies' retiring rooms ; two dressing rooms, supplied with marble set bowls and plate glass mirrors ; two laboratories and a printing room 18 feet square. There are also a finishing room, a printing room, a negative room, and an artist's room. All the rooms, with the exception of the reception room, are finished in pine, with hard wood floors. Electric bells and speaking-tubes connect the rooms, and steam is supplied through radiators. The conveniences are unexcelled for completeness, and it is very questionable if there is such another photographic gallery in the country. The view of the city from the windows is very fine, and will alone repay a visit to the rooms.

By-the-Bye.

A NEW SCIENTIFIC INVESTIGATION BY PHOTOGRAPHY.

We have already pointed out how much photography has aided scientific research of recent years—how the astronomer, the chemist, the surgeon, the botanist, the meteorologist, the physicist have availed themselves of the camera in their work. We have shown, too, that photography does not merely in this connection act in a servile capacity, simply recording fluctuations and changes—as in our observatories, for instance—but that it is also employed for observing the most subtle phenomena and in detecting delicate symptoms which are to be observed in no other manner. In fact, the camera, like the microscope, has of late earned for itself a place among select philosophical apparatus, and has become one of the most trusted of investigating instruments.

Within the last few months one other department of science has been added to the many that have recognized photography as a valuable means of investigation. Mathematicians have now found an important use for the camera, and before long we may expect to see the apparatus in the study of the theoretical man of science, as it is now an indispensable adjunct to the scientific experimentalist. The laws of motion, the theories of Newton, the governing rules of dynamics and statics, over which theory has long held supreme sway, are about to enter the realm of practice, and photography is to demonstrate to us what previously only the mathematician could determine by abstruse calculation. The important function that photography here performs will at once be understood when we mention that many problems and recognized data are based upon calculation alone, and although the mathematical accuracy of these can scarcely be doubted, it will be with the utmost satisfaction to all men of science to have these experimentally demonstrated, and by such an unerring witness as the camera. Again, it is always possible in a mathematical calculation that, while there is no error in the final result, there may be error in detail—the errors in question neutralizing one another; these, if they exist, photography will at once discover, so that here is one benefit the more that is likely to result from the adoption of the camera by mathematicians.

Most of our readers have heard of the catenary curve—the curve, that is to say, taken by a suspending chain. Knowing the weight of a chain and its length, any mathematician can calculate the curve it would assume, and he could, in this instance, after setting it out, verify his calculation by actual experiment. But there are many cases where the mathematician must rely upon his calculations alone, and is unable to verify his result—at any rate, experimentally. It is so in the case of the trajectory curve, or curve made by a stone flying through the air, or a cannon ball as it is sent on its speedy journey. Two things determine the nature of this curve—namely, velocity and gravity. The resistance of the atmosphere interferes with the speed of a projectile, and this, of course, the mathematician takes into consideration when he estimates the velocity; but it is extremely unlikely, although he may sketch the beginning and end of the trajectory curve correctly, that the intermediate points he sets down are without error. Photography, however, is now capable of depicting this curve, and of showing the mathematician if he is right or wrong in his theoretical result. Thanks to M. Marey's ingenious photographic apparatus, which has already been described in these pages, we are now able to follow the mathematician in his work; we shall be able to confirm many of the beautiful Newtonian laws of gravity and velocity, and no doubt, in many cases, detect errors—they may be but minor ones, but still errors—which, but for the existence of photography, might never have been discovered.

It would be foolish to deny that Mr. Muybridge's instantaneous photographs of animals in motion constitute the germ of this new departure in scientific investigation. M. Marey was one of the first to appreciate the teachings of these pictures, which demonstrate the motion of limbs and muscles in a way that had never before been imagined. The study of animal mechanics became a new science in the presence of these photographs; and not only in science, but in art, are the Muybridge pictures instructive. For, in the same way as a knowledge of anatomy is, if not imperative, highly conducive to good painting and sculpture, so we may take it for granted that the numerous positions assumed by animals in motion—regarding them, if you will, as a mere bundle of dry facts—cannot but fail to teach the art-student something of the functions of limbs and muscles. M. Marey, who had for some time past occupied himself in study inganimal mechanics in birds, at once set about applying photography to his investigation, and, proceeding with his interesting research, passed from the observation of animate to inanimate things. Systematically progressing step by step, he soon forged ahead of his teacher, and now M. Marey is on the threshold of an investigation which is drawing upon him the eyes of the scientific world.

We may here, in a few words, briefly refer once more to M. Marey's instrument, and to the results he has achieved. Muybridge, it will be remembered, employed for his experiments a series of cameras set up in a row, alongside a sort of race-course, and as the animal came by, it was successively photographed in these cameras. Across the race-course were stretched very light threads, every one in connection with a camera, and the horse, or whatever the animal was, as he touched these threads, one after another, made the exposure. The consequence was, that in the end, Muybridge secured pictures of the animal in the various positions he assumed while moving. Marey only employs one camera instead of many. Again, instead of using a perfectly white background, as Muybridge did, he uses a black one, illuminating the moving object as brightly as possible. As it would be very difficult to produce a dead-black screen, Marey uses a darkened recess for background, and his object moves across this. If he kept the lens of his camera open during the whole time the moving object is in the field of his camera, the result would naturally be no well-defined image, but a blurred one right across the plate. To obviate this, the camera is made to expose a hundred times during a second, and thus he gets not one, but many successive images. In front of the camera is a rotating wheel with spokes, which alternately caps and uncaps the lens, and the velocity of this wheel being accurately timed, it permits you to make some very important observations. The motion, during one-hundredth part of a second, is recorded, and to further make the result complete, at certain intervals the spokes of the wheel are double size, so that another check and means of registration is at hand. To indicate the rapidity and completeness with which M. Marey's camera works, we may mention that he has been able to photograph letters and words traced by means of a black stick having a white nob at the end. Spelling his name with this rod against the dark background, while the camera was set in action, he was able to obtain the word "Marey" upon his gelatine plate when this came to be developed.

We published a wood-cut of one of M. Marey's photographs some weeks ago, it will be remembered, the picture representing a man in the act of running. He has now proceeded further, and is engaged, as we have said, in depicting various curves, an indication of which previously could only be divined by the aid of the mathematician. Thus the path taken by a stone thrown across the field of the camera is shown on the gelatine plate. The stone is enveloped in a bit of white paper to be as visible as possible, and M. Marey secures on his sensitive film the parabolic curve taken by the stone as it rises and falls in its flight. The photograph secured is not a blurred image, but a clear dotted line, each dot and space representing the one-hundredth of a second. As the intervals of exposure are accurately measured by the spoked wheel, it is possible, therefore, not only to secure in the form of a dotted line the path of the projectile, but to have, as well, a tell-tale of its velocity through every instant of its flight. Thus, in the case of a stone being thrown into the air, the dotted lines appear short and close together at the top of the curve where the velocity is least, while the lines are longer in the photograph at the lower part, that is, where the stone is rapidly falling. A stone at the end of a string whirled round by a person alternately standing still and walking forward, has also given some instructive photographic records, which are likely to explain something more than we know at present of the laws of motion.

M. Marey has so far, of course, only entered upon the threshhold of this interesting investigation, and what he has done is only preliminary to a more exhaustive research. Still, the novelty and interest of the results already obtained are very great, and we may look forward with confidence for some remarkable disclosures from M. Marey's ingenious photographic apparatus.

The next "By-the-Bye" will be "About Photographic Journals."

Notes.

The Emperor of Brazil, one of the few princes who has a practical acquaintance with chemistry and photography, is personally organising four expeditions to observe the Transit of Venus in December next.

We print in another column information on the subject of producing incombustible designs upon an incombustible surface. One of these days, by the aid of the platinotype process, we may be able to print incombustible photographs upon asbestos fabric.

The Austrian *Jahrbuch*, which annually makes its appearance in Vienna under the able editorship of Dr. Hornig, the president of the local photographic society, will contain this year, as frontispiece, a heliogravure portrait of Captain Abney. Another German annual—the *Kalender*—makes its second appearance this year under the direction of Herr Karl Schwier.

Mr. J. H. Jennings, whose interesting paper on micro-photography we published last month, is good enough to sends a charming example of the *Navicula Lyra*. He says:—"I have taken many photographs with a $\frac{1}{16}$ inch objective, yet I never cease to wonder at the results gained from using such a tiny atom of glass. From six to nine flashes of burning magnesium—pieces of wire half-an-inch long—give sufficient illumination for a well-exposed negative, sharp to the edge; the biggest portrait lens would scarcely be as rapid."

Photographers in London and Paris who desire to prosecute their labours in a balloon are more fortunate than their brethren in Vienna. By a recent municipal law in the capital of Austria, those who desire to enter the car of a balloon to take photographs or for any other purpose must first of all comply with a series of strict regulations. In fact, in Vienna, no one is permitted in a balloon until he has shown that he has been through a thorough course of instruction with a competent aeronaut, a dictum that savours of the well-known warning never to enter the water until you can swim. Moreover, before being permitted passage in a balloon, aspirants are to be compelled to procure a permission, in the first case, from wife and family, should they happen to be married men.

With a paternal government to take care of them, however, the Austrians do not seem to be free from balloon accidents. Only on Sunday last a misfortune happened that dangerously injured the occupants of a car, who foolishly made an ascent during stormy weather. In descending, the wind dragged the balloon a distance of four kilometres into a churchyard, where, rushing along with terrific speed, it knocked down a dozen marble monuments and a high brick wall. The two occupants of the car were thrown out, and found among the graves very grievously hurt.

The custom of adorning the *menu* at a dinner with a photographic portrait of the hero or founder of the feast is one that should become popular. Last week at Paris, on the occasion of a banquet to Mr. Stanley the African Explorer, this was done, and our contemporary the *Standard* speaks in high terms of the elegant card placed upon the plate of every guest. "The *menu* was adorned with Stanley's photograph," we are told "and was in itself an artistic *bijou*." The specimens in a studio reception room, are generally in the same groove, and photographers would do well to bestow a little thought in designing some tasteful applications of photography, to catch the eye of visitors. Here is a hint to be noted.

Several attempts, more or less successful, have been made to produce photographs upon an ivory-like surface. The difficulty, for the most part, lies in the production of an artificial ivory. This can be done in a most simple way, we are told, by dissolving shellac in ammonia, and then adding finely-divided oxide of zinc. A white pasty material is in this way furnished, from which the ammonia is driven off by heat. It may be pressed into any desired shape in this condition; but a better result is obtained, it is said, by powdering the material first of all.

Our friendly correspondent, Dr. Hermann Fol, of the Geneva University, has devised a repeating camera to take snap shots rapidly one after another. It can be held in the hand, so as to take aim, and as many as eleven plates may be exposed in rapid sequence. The size of the plates is obviously somewhat small, measuring four-fifths of an inch; but as the lens is sharply focussed, the photographs may very well be enlarged. Dr. Fol tells us the mechanism is rather elaborate; still, with the aid of diagrams he hopes shortly to describe it in an intelligible manner.

"Friends on the jury" has always been a ready explanation by the green-eyed monster, why other people have medals and he has none, and to avoid unfair play of the sort, it has been suggested again and again to forbid all labelling of the pictures exhibited. Some such plan is now being tried in the North, but with what success we do not know. For ourselves, we have little faith in it, for if the jurors are familiar with photographic work—and none other should serve—they will probably be able to name correctly without any prompting the authors of much of the work before them. On the occasion of the Newcastle Exhibition last year, it was at first intended to deny the jurors a list of the exhibitors; but since more than half of the pictures shown were as familiar to these gentlemen "as household words" the uselessness of such denial was at once obvious.

A new style of portrait has been introduced into Germany, in which it is sought to blend the visiting card with the carte-de-visite. The origin of the latter was due years ago to the same intention, it may be remembered, and hence the name. The new idea, therefore, is only an old one resuscitated; but the proposed way of carrying it out is novel. The modern "visiting card" is a thin black mount with gold edge measuring 7 by 4 centimetres, say $2\frac{3}{4}$ by $1\frac{1}{2}$, inches. The front of the card carries a miniature portrait with a gold line running round it, and with the name of the firm in small type at the bottom; while, on the back of the card, is the name of the owner, also written in gold. The combination of black and gold is said to be very effective on the little card, and the idea is to produce them cheaply so that purchasers may be tempted to put them into their card-cases. The only objection that strikes us, for the moment, is that the result may be mistaken for a mourning card.

The gentleman who travelled all the way from Blackburn to Pall Mall on Tuesday last, and then found the newly-organised Social Gathering of the Parent Society not to be the "Technical Meeting" of the South London Society, thinks that any title which has become the property of a Society through ancient use should be respected by other associations.

A Paris contemporary presents its readers with a picture of a group of crocodiles reproduced from a photograph taken at Kurrachee. Although many of our readers have doubtless seen the picture, they may not be familiar with the story of its taking, as told by *La Nature.* So we translate it for their benefit.

An English traveller exploring the neighbourhood of Bombay, and carrying a camera, in which to secure the beauties of nature, passed by Muygapier in the vicinity of Kurrachee. Among other things, our tourist-photographer desired to secure a negative of a magnificent group of trees on the margin of a still stream, and with this view set down his tripod, drew the cloth over his head, and begun to focus. Suddenly he perceived a huge crocodile put its head above water and make for the shore; a second monster followed, then a third, until a whole band lay open-mouthed before him. Other people would have beat a hasty retreat; our Englishman remained. He coolly proceeded with his focussing, and when he done, with all the phlegm that characterises his race, slipped in his collodion plate, and took the creatures portraits as they basked in the sun. When he had finished, he put on his hat, and retired.

"Enamelled by Oeffelein" we see appended to some charming young ladies at the Exhibition in Pall Mall; but whether the smiling faces have been enamelled before being photographed or afterwards, we are not told. As all visitors to the Exhibition are not versed in photographic manipulation, in fairness to the fair ones, they should be more explicitly labelled.

In collecting residues it is a matter of importance that the silver should be thrown down as quickly and completely as possible. Most photographers have two or more receptacles for waste liquids, so that in one of them the liquid may remain in a state of subsidence, after suitable treatment, for at least twenty-four hours, when the exhausted portion at the top of the receptacle is drawn off to make room for more. This is a very good plan, and it is better still to stand the receptacles in full daylight. The precipitation of the chloride or sulphide takes place more quickly in the light than in the dark, and in summer more rapidly than in winter.

Let any one try this experiment. Obtain two tall glasses, twenty inches high, if possible, and fill them with a dilute solution of nitrate of silver. Add enough hydrochloric acid, and to spare, to precipitate all the metal, and then cover one of the vessels up from the light. At the end of a dozen hours uncover again, and examine the two vessels side by side. The solution that has been screened from the light will still be turbid, containing, therefore, silver in suspension; while in the other the silver is all of it at the bottom, and the liquid is clear and transparent. It stands to reason, therefore, that if the liquor in the first instance had been drawn off and thrown away, some silver would have gone with it; while in the second case the liquid might have been run off without loss. *Ergo*: stand your residue tubs not under cover, but exposed to daylight.

An interesting experiment in light signalling has been made in Paris by M. Mangin. A small balloon filled with pure hydrogen was sent up, being held captive by a rope containing two copper wires. A Swan lamp, placed in the gas inside the balloon, was made incandescent by a current from below, and the whole aërial machine thus rendered brilliantly translucent. As the balloon could be illuminated and darkened according to the will of the person holding the rope, signals could be made to a distance without difficulty. According to our contemporary—*Nature*—the Morse system of long and short signals was adopted, and read with success. Here, then, is a valuable means of telegraphing with light that is likely to be useful, especially for military purposes. Of course the balloon envelope must be transparent to render the experiment successful, and the hydrogen pure, if its full effect is desired.

Patent Intelligence.

Application for Letters Patent.

4954. James Templer, of 8, Park Place, London S.W., in the county of Middlesex, for an invention of "An improved means or method for utilizing balloons for photography, photographic surveying, or other purposes."—A communication to him from abroad by Henry Elsdale, of Halifax, Nova Scotia.—Dated 18th October, 1882.

Grants of Provisional Protection.

4324. Lorentz Albert Groth, K.G.V., Civil Engineer and Managing Director of the Universal Inventors' and Patentees' Financial Company, Limited, 30, Finsbury Pavement, London, E.C., for an invention of "A new or improved apparatus for enlarging or reducing maps, drawings, and other such like delineations."—A communication to him from abroad by Josef Eymannsberger and Marcus Menn, Engineers, of 73, Rue SeJaine, Paris.—Dated 12th September, 1882.

4651. John Young McLellan, of Glasgow, in the county of Lanark, North Britain, Analytical Chemist, for an invention of "Improvements in artificial-light apparatus for photographing, and applicable otherwise."—Dated 30th September, 1882.

4671. Charles Picton Evans, of Birmingham, in the county of Warwick, Gentleman, for an invention of "Improvements in the art of photography."—Dated 2nd October, 1882.

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. IX.—Estimation of Silver Nitrate, Chloride Bromide, and Iodide of Potassium.

In an article in the Photographic News on "A Plea for the Burette," we described a process for estimating the amount of silver nitrate in a silver bath; but in the present lesson we are about to explain a method which will enable the student to analyse silver solutions with greater exactness, and indirectly estimate soluble chlorides, bromides, and iodides.

In silver estimations, a standard solution of sodium chloride and a dilute solution of *neutral* potassium chromate is required.

For preparing the standard solution, absolutely pure sodium chloride must be prepared, unless colourless rock salt can be obtained. Dissolve about three ounces of common salt in the smallest quantity of water, filter the solution, and add to it about three times its volume of pure, strong hydrochloric acid, when a white precipitate of pure sodium chloride will be formed. Filter the acid liquor, and wash the precipitate on the filter with a little dilute hydrochloric acid (1 : 4), and transfer the salt from the filter to a large porcelain crucible. Heat gently at first, and when all the moisture and acid are driven off, increase the temperature for a few minutes, so as to make certain any trace of adhering moisture is expelled. When cool, powder the salt, and preserve it in a *dry* well-stoppered bottle.

Weigh very carefully 58·5 grammes of powdered colourless rock salt, or salt prepared as above, place a small funnel in the neck of a *litre flask*, put the weighed amount of salt in the funnel, wash the salt into the flask with water by means of the wash-bottle, and fill the flask up to the graduation with distilled water. When all the salt is dissolved, pour the standard solution into a dry stoppered bottle, and label it

Standard Solution.—Sodium Chloride.

1 c. c.	=	·0,585	grammes	sodium chloride
,,	=	·17	,,	silver nitrate
,,	=	·108	,,	silver.

To perform an analysis of commercial silver nitrate, weigh out exactly 3·4 gramme of the sample, dissolve it in about 30 c. c. of distilled water, and make the solution up to exactly 50 c. c. by the addition of water. The object of dissolving the salt in a small quantity of water, and afterwards diluting it, instead of dissolving it at once in the 50 c. c., is that a solution of silver nitrate occupies a greater volume than the water in which it is dissolved. Pour the solution into a burette, take 10 c. c. of the standard sodium chloride by means of a pipette, and place it in a small evaporating-basin with two drops of a three-grain solution of neutral potassium chromate. Let the silver solution drip slowly from the burette into the basin, stirring its contents with a glass rod till a permanent blood red precipitate is formed, when at once turn off the tap of the burette, and note how many c. c. of the silver solution has run out.

In order to calculate the result, multiply the amount of silver nitrate which one c. c. of the standard solution of sodium chloride is equal to, by the amount of the latter solution taken. Divide the product by the number of c. c. of silver solution run out of the burette, and multiply the quotient by the amount of water used to dissolve the sample of silver nitrate.

The calculation may seem a little difficult at first sight, but an example will make the rule more intelligible. First turn to the label on the bottle of sodium chloride solution, we see that 1 c. c. = ·17 of silver nitrate; now ·17 multiplied by 10 (the amount of standard solution placed in the dish) gives 1·7. We will suppose that 26 c. c. of silver solution was run out, therefore 1·7 divided by 26 equals ·0,654; but 50 c. c. was used to dissolve the silver nitrate, therefore ·0,654 multiplied by 50 equals 3·27, the amount of pure silver nitrate contained in 3·4 grammes of the sample analysed; or, calculated in percentage, it equals 96·2 per cent.

To determine the amount of silver nitrate in a negative bath, fill the burette with the bath solution, instead of the solution made by dissolving the sample of silver nitrate in 50 c. c. of water, and proceed exactly as in the analysis of silver nitrate. To calculate the result, multiply the number of c. c. of standard sodium chloride solution used by the amount of silver nitrate, which is equal to 1 c. c. of the standard solution, and divide the product by the number of c. c. of the bath solution run out at the burette, the quotient being the amount of silver nitrate contained in 1 c. c. of the silver bath.

For example, the burette was filled up to the top graduation with an old silver bath, 10 c. c. of standard sodium chloride solution (1 c. c. of which equals ·17 gramme of silver nitrate) was poured in the dish, and 12 c. c. of the silver bath was required to produce a permanent red precipitate; therefore. 10 multiplied by ·17 equals 1·7, and 1·7 divided by 12 equals ·14 grammes, the amount of silver nitrate contained in 1 c. c. of the bath solution, or about 57 grains to the ounce.

In estimating soluble chlorides, bromides, or iodides, a standard solution of silver nitrate is required. Weigh out exactly 17 grammes of silver nitrate (the triple crystallized, if dry and colourless, will answer the purpose), and transfer it to a small funnel placed in the neck of the litre flask, washing the adherent crystals into it by means of a wash-bottle, and, when the salt is dissolved, fill the flask up to the graduation with distilled water, pour the solution into a large stoppered bottle, and label it

Standard Solution.—Silver Nitrate.

1 c. c.	=	·017	gramme	silver nitrate
,,	=	·00,585	,,	sodium chloride
,,	=	·0,119	,,	potassium bromide
,,	=	·0,098	,,	ammonium bromide
,,	=	·0,166	,,	potassium iodide

To analyse a sample of potassium bromide, weigh out exactly ·238 grammes of the salt, dissolve it in about 20 c. c. of distilled water, and pour the solution into a small evaporating dish with two or three drops of the dilute solution of potassium chromate. Fill a burette with the standard solution of silver nitrate, and allow the solution to slowly drop out through the stop-cock into the solution of potassium bromide, and proceed with the process exactly as described above in the analysis of silver nitrate.

To calculate the result, multiply the amount of potassium bromide, which 1 c. c. of silver nitrate solution represents (see label), by the number of c. c. of standard silver solution run out of the burette, and the product is the amount of the pure salt contained in ·238 grammes of the sample.

For example: ·238 grm. of potassium bromide was taken, and 19·5 c. c. of silver solution required to produce a permanent precipitate; therefore, as 1 c. c. of the standard solution represents ·0,119 grammes of potassium bromide, ·0,119 multiplied by 19·5 equals ·232 grammes of pure salt contained in ·238 grammes of the sample under examination, or 97·5 per cent.

For analysing ammonium bromide by this method, ·196 gramme should be taken; while for potassium iodide as much as ·332 grammes are required. The amount of soluble bromide contained in a washed or unwashed gelatine emulsion can easily be estimated by this process.

For example: 50 c.c. of unwashed emulsion was poured into an evaporating basin, with about an equal volume of distilled water, and two or three drops of a dilute solution of potassium chromate. Standard silver solution was run in till a permanent red precipitate was formed, 5 c. c. being required; therefore, as 1 c. c. of silver solution represents ·0,098 gramme of ammonium bromide (the soluble bromide used in the preparation of the emulsion), ·0,098 multiplied by 5 equals ·049 gramme, the amount of excess of soluble bromide contained in 50 c. c. of the emulsion.

FRENCH CORRESPONDENCE.

INSTANTANOGRAPHS—DR. VAN MONCKHOVEN'S WORK—THE POITEVIN SUBSCRIPTIONS.

Instantanographs.—We must just say a few more words on this interesting subject of instantaneous pictures, so much the order of the day. It is very evident that the aim of all photographers, and especially amateurs, is to reproduce animate nature in such a manner as to immobilise movements in any situation, however rapid the movement may be. We have already, by this means, arrived at very fine results, and have seen M. Neurdins' pictures, for instance, of yachts and steamers taken while in motion on 10 by 12 plates, occupying almost the half of the surface of the negative, and the ropes are rendered as sharply as if the vessel has been still; and, as ships travel irregularly, extreme rapidity of exposure is required. M. Lugardon, whose name we have already mentioned, has frequently taken horses prancing, and has seized the moment when all their four legs were off the ground, but one must work with lightning speed to obtain such results. The shutter employed, in this case, is that by MM. Thury and Amey, of Geneva. We have by us a remarkable collection of instantanographs by a Swiss photographer, M. Schaufelberger. There are swans swimming on the waters with wings spread, and taken in every possible position, whether in motion or repose. These photographs are perfectly sharp. Instantaneous photography is, to our mind, the greatest triumph of the art. By this marvellous result everything may be produced, rendering great service both to the art of drawing and science. Inanimate objects and living creatures in repose may be accurately copied without the help of photography—with less exactness it is true—but by dint of patience and talent it may be done; while with instantaneous photography the rapidity of sight of the human eye is too feeble to allow the numerous varieties of motion which operate at once in a bird on the wing, or an animal running at full speed to be seized. That which the eye is incapable of seeing, of course the imagination cannot retain for the purpose of drawing. The photographic lens sees, and the sensitive plate retains it. We assist daily at similar wonders, and the idea has come to us that these instantaneous studies ought to be encouraged by special prizes given in the exhibitions where only instantaneous studies of objects in motion would be admitted. We predict that the greatest success would attend the first exhibition of this kind, and we shall suggest it to the Photographic Society of France. The prints would be of minor importance as the negatives would be examined and might be printed by whatever process one liked. If the idea be good, and it responds well to the present state of photography, we hope it will be taken up and carried out to its full and entire extent.

On Dr. Van Monckhoven's Work.—Poor Monckhoven, whom we so highly esteemed, and whose name was continually cited in the PHOTOGRAPHIC NEWS, as in every other photographic publication, is no more. He has been suddenly taken from his family, friends, and the service of photography at the moment when he dreamed of still greater destinies for all the sciences with which he occupied himself with so much ardour. He hoped to have played his part in this new progress. But why speak of dreams never to be realised. Let us be more practical. The great industry of the preparation of gelatine plates at Gand, started by Monckhoven—will it survive him? In this respect, we can answer in the affirmative. Our late friend, as if he had a presentiment of his premature end, had initiated his people in the preparation of his excellent emulsion in such a way that everything would be provided for, not only for the continuation of this manufacture, which is not less than 1,200 dozen half plates per day, but also for its increase which it requires at this moment, for the success of Monckhoven's plates has been such up till now that the demand exceeds the supply. There are certainly other manufacturing houses well supplied with apparatus, the products of which are very good; but there has not been any on the Continent to rival with the Belgian factory. A total of 1,400 plates per day means a surface of 336 square meters coated with gelatino-bromide, constituting the amount of from 7,200 to 1½ million francs per annum. By putting these figures together, an idea may be formed of the immense importance of this single factory, the direction of which is incumbent upon the the widow of our deeply regretted friend.

In the midst of such an industrial success, Monckhoven ever sought to raise himself to the highest summit by his researches in the science of physical astronomy. He applied all that he obtained from photographic science to extend its rights to universal consideration, and to conquer by the help of splendid and purely scientific works still more serious claims to renown. Although he had not been able to accomplish such noble projects, he cannot have left this world without having the sweet satisfaction of having led a most useful life, and of whom it may be said that he left a name destined long to survive him.

Poitevin Subscriptions.—The Poitevin subscriptions have reached the amount of about 5,500 francs; but it is fully expected that new donations will considerably raise the sum of this last result. It is all one can do to consecrate the memory of this *savant*: but this sum will, however, be insufficient if the idea is to be carried out of raising a monument in a public square. In this case, perhaps the State will complete the necessary sum.

Our photographic societies will not commence their work until next month; we hope then to have interesting technical doings to address to the NEWS. LEON VIDAL.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.*

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Intensification.—The redeveloped negative is placed in a saturated solution of bichloride of mercury, to which a little muriate of ammonia may be added, and allowed to remain till it is quite white; or, if there are fine lines, the action should not be carried beyond the dark grey stage, for fear of filling up the lines. It is then well washed, and flooded with a dilute solution of hydrosulphate of ammonia, about one part to four of water. This at once changes the colour of the film to a dense opaque black, and if the foregoing operations have all been properly carried out, the lines will have perfectly retained their clearness and transparency. Should they, however, be slightly yellow, they may be cleared with a weak solution of citric acid in water.

Instead of hydrosulphate of ammonia, many operators use a solution of cyanide of potassium about 5 grains to the ounce, containing sufficient nitrate of silver to form a permanent precipitate. This gives a good black ground with clear lines. A solution of ammonia, about 1 part to 8 parts of water, may also be used to blacken the image.

The use of bichloride of mercury being in many ways undesirable, it may often be usefully replaced by Carey Lea's solution of cold saturated solution of—

Bichromate of potash	3 parts
Hydrochloric acid	1 part
Water	48 parts

After re-development the plate is plunged into a tray containing this solution, and in a short time the film will become of a uniform bright citrine yellow. It is then

* Continued from page 598.

taken out, washed, and treated with the hydrosulphate of ammonia, which changes the colour of the film to a dense purple or chocolate brown. A solution of Schlippe's salt may be used instead of the hydrosulphate, in which case the colour of the ground will be more scarlet.

A mode of intensifying that has been found very satisfactory by Mr. Baden Pritchard and others, is that proposed by Messrs. Eder and Toth (Photographic News, Vol. XX., pp. 100 and 573). The developed and fixed negative having, if necessary, had all trace of deposit on the lines removed by treatment with iodine and cyanide of potassium as before described, is thoroughly washed in ordinary, and finally in distilled water, and immersed in a filtered solution of—

Nitrate of lead	4 parts
Ferridcyanide of potassium ...	6 ,,
Distilled water	100 ,,

and allowed to remain until the deposit has become quite opaque. The plate is then well washed till the film becomes of a clear white, and is then flooded with a solution of hydrosulphate of ammonia 1 part to 5 of water. This at once blackens the deposit, and as soon as the action has penetrated through the film the plate is well washed with ordinary water.

Should a thin negative not become sufficiently dense even after a prolonged application of the lead bath, it is a good plan to treat it with a 10 per cent. solution of sulphate of cadmium. The sulphide of ammonium is then applied as before.

The greatest care is required in washing, when using this intensifier.

Instead of hydrosulphate of ammonia, a solution of Schlippe's salt may be used :—

Schlippe's salt	10 parts
Water	100 ,,
Caustic ammonia	5 ,,

A solution of bichromate of potash may also be used, and will give a dense yellow negative. Eder and Toth recommend a ten per cent. solution of the yellow chromate of potash as giving images of a deeper yellow than the bichromate.

A very satisfactory way of obtaining density after the lead intensifier is to treat the plate first with a solution of iodide of iron made by digesting 10 parts of iron filings and 5 parts of iodine with a little water, and, when the iodine is dissolved, add water to make up 300 parts.

The plate is then well washed, and flooded with a two per cent. solution of permanganate of potash, which turns the colour of the film black. The solution of permanganate may also be used without the previous application of the iodide of iron, but a stronger solution at five per cent. will then be required, and the colour of the film will be browner.

Another mixture commonly used for intensifying black and white line subjects is the double iodide of mercury and potassium used in one or two solutions.

Abney gives the following single solution. To a solution of—

Bichloride of mercury	2 grains
Water	18 ounces

add a solution (10 grains to the ounce of water) of iodide of potassium till the red precipitate formed by its addition is on the point of becoming permanent. This may be used stronger with advantage for map work.

In using the double solution, the plate may first be flooded with a solution of iodide of potassium at two per cent.; this is allowed to act for about a minute, then poured off and replaced by a solution of bichloride of mercury 1 part to 200 of water. This treatment is continued till the required density is obtained. Or, as recommended by Mr. Bolas, the plate may first be immersed in a saturated solution of bichloride of mercury, and left for five or ten minutes till perfectly white. After a rinse in water it is transferred to a solution of iodide of potassium one grain to the ounce of water. The whitened deposit becomes yellow, and when the yellow tint has quite penetrated the film, the plate is well washed, dried, and varnished.

Additional density may be obtained, if desired, after treatment with the iodide of mercury, by the application of the solutions of hydrosulphate of ammonia, silver cyanide, or ammonia as before described.

(*To be continued.*)

THE VALUE OF PHOTOGRAPHY IN THE TRANSIT OF VENUS.

Professor Harkness, in his recent address before the American Association for the Advancement of Science, on the Transit of Venus, expressed himself, says *Anthony's Bulletin*, in the following terms on the importance of photography in connection therewith :—

The question of instrumental outfits having been disposed of, stations were selected and parties despatched to almost every available point. The United States, England, France, Germany, Russia, Holland—in short, nearly all the nations of the civilized world—took part in the operations. The weather was not altogether propitious on the transit ; but nevertheless a mass of data was accumulated which will require years for its thorough discussion. When the parties returned home, the contact observations were first attacked ; but it was soon found that they were little better than those of the eighteenth century. The black drop, and the atmospheres of Venus and the earth, had again produced a series of complicated phenomena, extending over many seconds of time, from among which it was extremely difficult to pick out the true contact. It was uncertain whether or not different observers had really recorded the same phase, and in every case that question had to be decided before the observations could be used. Thus it came about that, within certain rather wide limits, the resulting parallax was unavoidably dependent upon the judgment of the computer, and to that extent was mere guess-work. Attention was next directed to the photographs, and soon it began to be whispered about that those taken by European astronomers were a failure. Even yet I am not aware that the Germans have published anything official on the subject; but the English official report has appeared, and it frankly declares that, "after laborious measures and calculations, it was thought best to abstain from publishing the results of the photographic measures as comparable with those deduced from telescopic view." From the way in which these photographs were taken, Sir George Airy saw that they could not yield position angles of any value, and therefore differences of right ascension and declination could not be determined from them ; but they did seem capable of giving the distance between the centres of Venus and the sun with considerable accuracy. Upon trial this proved not to be the case. No two persons could measure them alike, because "however well the sun's limb on the photograph appeared to the naked eye to be defined, yet, on applying to it a microscope, it became indistinct and untraceable, and when the sharp wire of the micrometer was placed on it, it entirely dissappeared." In short, the British photographs are useless for the present ; but Sir George Airy hopes that in the future some astronomer may be found who will be capable of dealing with them.

We turn now to the American photographs. They present a well-defined image of the sun, about 4·4 inches in diameter, and are intended to give both the position, angle, and distance of Venus from the sun's centre. A special engine was at hand for measuring them ; but when they were placed under the microscope, only an indistinct blur could be seen. Here, again, was the same difficulty which had baffled the English ; but fortunately its cause was soon discovered. The magnifying power of the microscope was only 37½ diameters, which seemed moderate enough. But was it really so ? The photographic image of the sun was about 4·4 inches in diameter, and this was magnified 3·31 times by the objective of the microscope, thus giving an image 14·56 inches in diameter. To yield an image of the same size, a telescopic objective would require a focus of about 1·563 inches ; and if the eye-piece of the microscope, which had an equivalent focus of 0·886 of an inch were applied to it, a power of 1·764 diameters would be produced.

This, then, was the utterly preposterous power under which the image of the sun was seen when the photograph was viewed through the microscope, and no useful result could be expected from it. Means were immediately provided for reducing the power of the microscope to 5·41 diameters, and then the photographs seen through it appeared as the sun does when viewed through a telescope magnifying 255 diameters. After this change all difficulty vanished, and the photographs yielded excellent results. The measurements made upon them seem free from both constant and systematic errors, and the probable error of a position of Venus depending upon two sets of readings made upon a single photograph is only 0·553 of a second of arc. To prevent misunderstanding, it should be remarked that this statement applies only to pictures taken between second and third contact, and showing the entire sun. The small photographs taken between first and second contact, and, again, between third and fourth contact, proved of no value.

Correspondence.

THE DEFENCE ASSOCIATION.

Sir,—Passing the other day through Farringdon Street I saw for sale, price one penny, a copy of one of my royal portraits; it was in company with half-naked French women. You may therefore well believe that I should hail with delight the formation of an association, such as Mr. Downey suggests. I think, however, with "One who has been Pirated," that a subscription of five shillings would be quite sufficient.—Yours, &c.,

Arthur James Melhuish.

Dear Sir,—In reference to Mr. Downey's letter of the 13th inst., I beg to say I shall be most willing to become a member and pay a guinea a year. As all photographers are not equally concerned in this matter, would it not be feasible to accept members at different subscriptions?—Very faithfully yours, Harry Pointer.

Dear Sir,—Having read the correspondence in the Photographic News, relative to the formation of a syndicate to protect photographic copyrights, I beg to suggest that the present is the most opportune of times for such formation, as the proceedings before the Lord Mayor's Court will, of necessity, attract considerable attention, and will aid some in coming to a conclusion whether the action of such a syndicate is likely to be attended with success or not. May I suggest, in reply to "One who has been Pirated," that so far from Mr. W. E. Downey's estimate of a guinea subscription being excessive, that in addition there would, of necessity, in starting such an association, have to be a guarantee fund—in the first place, to enable the promoters to secure reliable legal information, and also to establish the confidence referred to by one of your correspondents. If some of the firms more particularly interested would subscribe to such a fund, and one of their number—say Mr. Downey—were to call a meeting under the presidency of some gentleman well known to the profession, the whole matter could be thoroughly considered, and action taken at once.—I am, sir, your obedient servant,

Edwin A. Cade.

FERROUS OXALATE DEVELOPMENT.

Dear Sir,—We see that the illogical, but irrepressible Mr. Wilkinson has rushed into print *re* Dry Plates in general, and Autotype dry plates in particular, and, by an amusing process of reasoning, seeks to show that the purchase and trial of Autotype plates in October acquits him of a charge of "animus" brought against him in August. Here are the facts: The Autotype Company publish now and then, for private circulation amongst clients, a certain modest sheet, which they dub Autotype Notes. In the "Notes" for July appeared an article recommending ferrous oxalate developer for dry plates; the Editor of the Photographic News reproduced this article in his journal of July 28. A week after, Mr. Wilkinson is in print with a short article entitled "Ferrous Oxalate Redivicus" and commences it in these words: "There is a disposition in some quarters to advocate a return to ferrous oxalate developer, especially by *manufacturers of plates* who. for some reason or other, *cannot make emulsion free from chemical fog.*" Considering that the article, extracted from the *Autotype Notes*, appeared the previous week, that it strongly advocated the use of the ferrous oxalate developer—that the *Autotype Notes* is very well-known as the occasional *brochure* of the Autotype Company—we think there will be little difference of opinion as to to the animus shown, and, moreover, against whom it was shown.

But your correspondent was not allowed to have the matter quite his own way; he has been considerably sat upon for this article of his, to say nothing of the author of the article in *Autotype Notes* who brought up heavy guns and pounded away. A week or two later, Mr. Campbell Swinton, Mr. O. C. Smith, and Mr. John Doe oppose Mr. Wilkinson's estimate of the ferrous oxalate developer, set at naught his experiments, and send work of their own to the Editor of the News as a practical testimony of the error of Mr. Wilkinson's notions.

Mr. Wilkinson states that, "with Autotype plates, the ferrous oxalate developer not only gives a negative in *about half the time*, but of a much superior quality than when pyrogallic is used." Now will Mr. Wilkinson be "surprised to hear" that this is absolutely and entirely a mistake on his part—that no such peculiarity of development exists, and if it did, from the mode of testing plates employed by the Company, must have been instantly discovered.

The mode of testing is this: A 9½ by 6½ plate is cut in two, the halves are exposed one after the other to a test scale and transparency with a constant source of light; one-half is developed with ferrous oxalate, the other with the saccharine pyrogallic, as given in the Autotype Company's instruction. Very frequently two portraits are taken on a double half-plate in a camera with a repeating back, the plate cut in two, and one-half developed with pyrogallic, the other with iron.

Mr. Wilkinson may, perhaps, not be inclined to believe us when we say that, in most cases, these two developers show nearly identical results; that sometimes the pyrogallic shows a number more on the scale, sometimes the iron. Very frequently there is nothing to choose between them, and if anyone should doubt these facts, abundant demonstration can readily be afforded. The Autotype Company.

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of the above held at the Mason's Hall Tavern, Thursday, Oct 19, 1882, Mr. A. Reimann in the chair,

M. Julio Valleto, of Mexico, was introduced to the meeting, and showed some excellent specimens of Mexican photography (promenades and cabinets) they were on wet collodion plates, and having much the appearance of gelatine pictures. He stated that the light in Mexico was very good, and even the exposure for the prints exhibited being about 25 seconds with Dallmeyers 4 B lens stop about 2¼ inches. One great feature in these photographs was, that in many instances the backgrounds were wholly or in part put in by hand in the back of the negative by working in a film of varnish with a needle or crayon.

Mr. W. S. Orsman gave the results of some experiments he had made in the action of a solution of alkaline bromide on a cake of gelatine containing bromide of silver; the experiments had been made in two test tubes, the silver in one case being placed in the gelatine and in the other the bromide. A piece of parchment paper was stretched over the bottom ends of the tubes which were open, and they were then stood in water a quarter of an inch deep, the result, in each case, was that the solution on top was stronger than that contained in the gelatine, and he found that the action had only extended part of the way into the gelatine, the action going on longer when the bromide was contained in the gelatine. He had not tested the water for any salts that might have dialysed into it from the gelatine. He had also placed some of the gelatine solution in a concave glass dish, and allowed it to set, and partially dry round the edges, afterwards pouring the bromide solution over it, and found that the drier the gelatine the quicker the silver was absorbed; the time taken to go through the centre portion where it was wet and thick was one and a-half hours.

Mr. Henderson, in reply to a question, said he thought the gelatine used in his experiments was a neutral one.

Messrs. A. J. Brown and W. Coles thought the reason that Mr. Henderson failed in converting the whole of the silver into bromide, was due to the thickness of the gelatine, the bromide first formed forming a barrier between the two solutions and preventing further action taking place.

Mr. A. Haddon showed a combination pipette and stirring rod blown from a piece of stout glass tubing, which he thought would be useful in mixing silver solution with the bromide in preparing emulsions; it differed from an ordinary pipette in being made of tubing with a wide bore, so allowing the solution to be poured in at the top, and the bottom being drawn out to a very fine point, it would trickle out very slowly, while the hand was at liberty to stir at the same time.

Mr. Henderson showed a cutting-board of Mr. Cowan's, across which he had stretched a piece of string, so that, as the diamond passed along, the pressure of the glass on the string would cause the glass to divide. He had made some experiments upon the so-called "reversed" action of light upon gelatine plates, using a ferrous oxalate developer, $4\frac{1}{4}$ plates were exposed behind a sensitometer, for four, ten, thirty, sixty seconds, the first three being developed with 3 ounces fresh developer to each used all at once; the last had 5 ounces developer used in successive portions, throwing each lot away as the action grew weak. In those exposed for thirty and sixty seconds he noticed the appearance of reversal; but by continuing the development, the parts which at first were clear instead of dark, gradually darkened; he considered the appearance of a reversed image was due to liberation of bromine which retarded develepment in the much over-exposed parts of the plate, and that by using fresh solution and continuing the developing action, all appearance of reversal would disappear.

Mr. W. E. Debenham remarked, that by the term reversed action of light was not meant that the exposed portion was brought into its original condition or anything more that the over-exposed portion was no longer amenable to development.

Mr F. W. Hart had successfully intensified some thin gelatine plates by treating, first, with an alcoholic solution of bichloride of mercury, then, after washing, placing first in water containing $1\frac{1}{2}$ drops strong ammonia to each ounce, then into a solution of 1 1 drop of a solution of sulphide hydrogen gas in glycerine to 4 ounces of water.

Mr. Debenham enquired if this method possessed any advantage over the use of Schlipp's salt, which did not smell so strong as sulphide of hydrogen solutions.

Mr. Hart said the advantage was in not introducing salts into the film, and thereby the time much required for washing lessening.

Mr. Henderson asked Mr. Hart if he thought mercury followed by lime water would give a stale result.

Mr. Hart thought it would, but objected to it on the ground of the introduction of solid mater into the film.

Mr. G. Thorpe, Nelson House, Stoke Newington Road, was elected a member of the Association.

Manchester Photographic Society.

The annual meeting of this Society took place on Thursday, Oct. 12th 1882, at the Manchester Mechanics Institution, Mr. E. Leader Williams, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The Hon. Secretary (W. J. Chadwick) then read the Annual Report:—

"On this, the 27th annual meeting of this Society, your council have to congratulate you upon the very successful year we have just passed through. It is satisfactory to be in a position to state that, notwithstanding the heavy calls that have been made upon our exchequer, we have been able to meet them promptly, and to still preserve a balance in hand. Although we have had 29 new members added to our list, we have to record several resignations; our numerical strength is now 104 against 89 last year. The attendance has been on the increase, the average being $46\frac{1}{2}$ this year against 44 last year.

"On referring to the proceedings of the Society we find that the following papers have been read:—'Ammonia Bromide,' by James Young; 'Light,' by Harding Warner; 'Gelatino Bromide Films (with practical demonstrations),' by A. Pumphrey; 'Opals and Paper Printing by Gas Light,' by Percy Collis; 'Stray Thoughts Touching Our Recent Exhibition,' by J. Pollitt; 'Hyposulphite or Thiosulphate,' by A. Brothers; 'Legal Points Relative to Instantaneous Shutters,' by E. Dutton. In addition to these we have had negatives, prints, and apparatus exhibited by many members of the Society, including Messrs. E. Leader Williams, A. Brothers, J. Leigh, J. Pollitt, Sefton, Greatorex, Schofield, Brier, Coote, Openshaw, Young, Kershaw, Bainbridge, Dale, McLellan, A. Knott, Chilton, W. Blakely, Taylor, Percy Collis, A. Booth, Edmund Eccles, C. Pearson, Woodward, and the Hon Secretary, whilst many of the leading commercial firms have largely contributed to the interest of the meetings by forwarding novelties and interesting subjects in the shape of pictures and apparatus.

"But the great event of the year was the Photographic Exhibition—consisting of nearly 3,000 photographs—visited by over 5,000 persons; and although the cost of this Exhibition approached nearly £200, we have the satisfaction to record that it surpassed any previous photographic exhibition ever held in the North of England.

"The use of the magic lantern has not been omitted from our proceedings, and some very beautiful slides have been shown on the screen by many members.

"The out-door meetings have again been very successful, and considering the very unfavourable weather, they were well attended.

"Our Rooms for meetings have been changed, and our rules have been revised.

"We have now to conclude by stating that we have elected more new members than in any previous year; we have more members on the rolls of the Society than ever. More subscriptions have been paid, though, we regret to say, many are in arrear. More calls have been made upon the finance of the Society, and more friends have been ready to meet the demands. More members have attended the meetings, a sign that more interest has been displayed; and more members have come forward with papers or exhibits.

"Our worthy Treasurer will now lay his balance sheet before you, after which we beg to resign our respective offices, wishing you the same success and prosperity in the coming year."

The Hon. Treasurer (W. G. Coote), submitted the accounts, and presented each member present with a printed copy of the balance sheet.

The report and balance sheet were well received by the members, and it was resolved that they be accepted.

It was resolved that the accounts relative to our late Photographic Exhibition be published for the guidance of other societies:—

The election of officers next took place, resulting as follows:—

President.—Mr. A. Brothers.

Vice-Presidents—Mr. J. Leigh, Rev. Canon Beechey, Messrs. R. Atherton, J. Dale, J. Warburton.

Council—Messrs. W. Blakeley, John Brier, Thomas Chilton, F. Flowers, Joseph Greatorex, S. D. McLellan, John Pollitt, John Schofield, Thomas Sefton, and N. Wright.

Treasurer—W. G. Coote.

Hon. Secretary—W. J. Chadwick.

Messrs. J. G. Jones, R. H. Raynor, and Geo. H. Sidebotham, M.D., were elected members.

Mr. S. D. McLellan exhibited an instantaneous shutter attached to a quarter-plate camera, explained the working, and showed how he dispenses with the use of a tripod stand by fixing it under his arm at the time of exposure.

Mr. W. G. Coote showed a drop shutter in which a strip of writing paper served for a very effectual trigger. He also exhibited some splendid prints from negatives taken during his holiday rambles.

The late President (Mr. E. Leader Williams), in vacating the chair, made an appropriate little speech, and the new officers took up the reins, when the meeting was dissolved.

The next meeting will be on November 9th, which evening is to be devoted to an exhibition of members' work during the present year, and a demonstration of "Platinotype Printing," by Mr. Openshaw.

Talk in the Studio.

South London Photographic Society.—The annual Technical Exhibition Meeting of the South London Photographic Society will be held in the large room of the Society of Arts, John Street, Adelphi, on Thursday evening, November 2nd, 1882, at 8 p.m., and admission will be free. The Sub-committee beg to call attention to the rules framed to facilitate business, in order that all subjects brought before the meeting may receive adequate attention :—1. That papers be allowed to be read (which must be as short as possible, and as much to the purpose as can be written), such papers to be sent to the Secretary on or before Nov. 2nd. 2. That opportunity be granted for practically working a process, or making an experiment, consistently with the time at the disposal of the Committee. 3. That secret processes or patented articles, with the names of the inventors, and their objects, be only briefly stated by the Secretary or by a member of the Committee. 4. That explanations be allowed, but only absolutely in reference to the practical uses of the articles shown. 5. That questions may be asked of exhibitors, referring only to a clearer understanding of the subject; but that no discussion be allowed respecting objections or differences of opinion on any matter. 6. That packages be delivered, free of charge, by six o'clock on the evening of the meeting, the exhibitor to arrange for clearing away the same. The meeting for members will commence at 7·30 p.m. for the nomination of officers for the ensuing year. All communications to be made to the Secretary, Mr. F. A. Bridge, Hon. Sec. (*pro. tem.*), 9, Norfolk Road, Dalston Lane, London, E.

The Balloon Society.—At a meeting held on Friday Dr. Jabez Hogg read an interesting paper on Protoplasmic Evolution, and it was stated that light is not only very unfavourable to the development of bacteria, but that exposure to bright sunshine rapidly destroys these organisms, and to the circumstance that it is of the greatest importance for patients suffering from zymotic diseases to occupy well-lighted rooms was commented on. Discourses of notable interest are often delivered at the Friday meetings of the Balloon Society, but there appear to be radical defects in the business arrangements of the Association. Although the annual subscription is no more than five shillings per annum, any member who arrives over fifteen minutes after the opening of the meeting is subject to a demand of one shilling for admission to the Aquarium before he can gain access to the lecture room. As a set off against this, we may mention that, after the lectures of the Balloon Society, it is usual to distribute tickets for the following meeting indiscriminately to those asking for them, these being available for admission to the Aquarium between 6 and 8.15 on the following Friday, and a large proportion of the tickets thus issued are used by persons merely seeking free admission to the Aquarium.

Robbery at Messrs. Wratten and Wainwright.—We regret to hear that a serious robbery was committed on Thursday in last week at the premises of Messrs. Wratten and Wainwright, in Great Queen Street, Long Acre. As will be seen by an announcement in our advertising columns, a large number of valuable papers were secured by the housebreakers; but, strange to say, the thieves left behind them many articles of considerable value. Thus, while securing a certain amount of cash that happened to be on the premises, they left untouched a large quantity of nitrate of silver and a collection of costly lenses, the intrinsic value of which was considerable. For this reason it may be presumed that the theives had little acquaintance with matters photographic, and that they were, indeed, of the ordinary burglar type.

Piracy in Photographs.—At the Mansion House Police Court on Wednesday, William Smith attended before the Lord Mayor in answer to summonses issued at the instance of Messrs. Elliott and Fry, and Mr. Downey, photographers, charging him with pirating photographs of Miss Kate Vaughan and Lady Lonsdale, belonging to them. Mr. Montagu Williams appeared for the complainants; Mr. Selberberg, solicitor, represented defendant. Mr. Williams said there there were a number of summonses to be heard by the Court for the piracy of certain photographs, the property of Mr. Downey, photographer, of Pimlico, and Messrs. Elliott and Fry. He had communicated with the other side, and was content that the following terms should be come to—namely, that the defendant should plead guilty upon two of the summonses—one of Miss Kate Vaughan's portrait, belonging to Mr. Downey, and the other of Lady Lonsdale, the property of Messrs. Elliott and Fry, and that the full penalty of £10 should be inflicted in each of the two summonses, with such costs as the Court might think proper to allow; and further, that the other summonses should be adjourned *sine die*, in order to see whether the practice would be discontinued by the defendant. There had been in the City of London and elsewhere a very large piracy of valuable works, the property of Mr. Downey, Messrs. Elliott and Fry, the London Stereoscopic Company, Mr. Bassano, and other photographers, and it was at last felt that a stop must be put to it. The defendant was not liable in respect to what he was he was going to say; but he might inform the Court that even opposite the Mansion House there were barrows full of these photographs which were being sold to the public. He (Mr. Williams), however, thought he was doing right in taking a plea of guilty on the two summonses, and he should ask the Court to adjourn the others *sine die*, the defendant agreeing to give up all the copies in his possession, and not to sell any more. The Lord Mayor said he thought the prosecutors had met the case in a very proper spirit. Mr. Solberberg, on the part of the defendant, said he had agreed to the course mentioned, on the ground of propriety. There could be no doubt that these photographs were the property of the prosecutors, and in all the circumstances, so as not to raise any useless objection, the defendant would plead guilty. However, it must not be taken that the defendant had had anything to do with the sale of the photographs in the streets. The Lord Mayor then fined the defendant £10 on each of the two summonses relating to the photographs of Miss Vaughan and Lady Lonsdale, with £6 6s. costs. The money was immediately paid.

The Photographic Money Dispute.—At Clerkenwell, Captain Herbert Kerr, of 22, Busbey Place, Clarendon Road, appeared on an adjourned summons to answer a charge of having unlawfully, by false and fraudulent pretences, obtained from Lieutenant Arthur Henry Loringe, divers sums of money of the value of £2,070, with intent to defraud. The allegation was that the defendant had, by false pretences, induced Lieutenant Loringe to invest the sums mentioned in the Photographic Artists' Supply Association, the affairs of which Company are in liquidation. Mr. Besley appeared for the prosecution, and Mr. Grain for the defence. The case has on previous occasions been before the Court. After some further evidence Mr. Hosack said he must again adjourn the case. He asked Mr. Besley whether there was any probability of the case being brought to an end before Christmas. He could not at present see that the slightest evidence of fraud had been brought forward. Mr. Besley promised to finish his case at the next hearing, and the case was adjourned for a fortnight.—*Daily News.*

The Velocity of Light.—Preparations are nearly completed at the Case School of Applied Sciences, Cleveland, Ohio, for a re-investigation of the velocity of light, by Professor A. A. Michelson, late of the Naval Academy at Annapolis. The velocity found (186·380 miles a second) differed slightly from that obtained by M. Cornu at the Observatory at Paris, in 1874, and also, it is said, from that obtained more recently by Professor Newcomb, at Washington. The results of the last-named observations have not been published. Mr. Michelson has accordingly been requested to repeat his experiments; money for the purpose, about 1,200 dols., having been promised from the Bache Scientific Fund. The Cleveland *Leader* says that two small buildings have been erected for the experiments on the grounds of the Case School. The larger of the two, 16 by 45 feet, contains the chief apparatus. Two thousand feet west of it is a smaller building containing a stationary mirror. In the experiments the light traverses the space between the buildings and back again to the apparatus, by whose movement data are obtained upon which the velocity of the light is measured.

Incombustible Writing and Printing Paper.—Asbestos fibres of the best quality are washed in a solution of potassium permanganate, and bleached with sulphurous acid. Ninety-five parts of the prepared fibre and five parts of wood fibre are mixed in water, saturated with lime and borax, which renders the paper, after rolling, capable of being written upon. To obtain an ink which resists fire, a mixture of platinum chloride and lavender oil is added.—*Journal of the Society of Chemical Industry.*

To Correspondents.

*** We cannot undertake to return rejected communications.

W. H. G.—Such an apparatus is not very well adapted for treating an unmounted print, and we would advise you rather to enamel them with collodion. Warm a glass plate, and rub it over with a piece of crude and unadulterated bees' wax; after which polish off all excess by means of a flannel rubber. Now coat the plate with collodion and, when the film is set, soak in water till no appearance of greasiness is visible. Next immerse the coated plate in a warm solution of gelatine—one part in twenty of water—and bring the face of your print in contact with the collodion face. When the plate and print have been removed from the gelatine bath establish contact between them by the application of a squeegee to the back of the print. Clip the edges of the print to the glass by means of strips of reglet and American clips, and leave in a warm room to dry. The dry print is easily removed from the glass by applying a pen-knife to the edges; all this is very easy, and a considerable number of prints can be enamelled with great rapidity. Let us know how you succeed.

A. Read.—1. See the formulary. 2. We know of no method except making a reproduction by the camera. 3. It is better to use it moderately fresh, as it oxidizes to some extent by exposure to the air.

Emulsion.—1. Use a larger proportion of gelatine. 2. Add a trace of chrome alum to the emulsion.

An Assistant.—1. Our impression is that it is sold by Messrs. Houghton and Co., of Holborn. 2. We have sent it by post.

E. W.—1. Ordinary re-crystallized nitrate. 2. The "A. B. C. of Photography," published by Piper and Carter, 5, Castle Street, Holborn.

R. O.—We quite agree with you; send it back.

Darwen.—Not so good a chance as in this country.

X. X. X.—1. If not worth a sovereign or more, you may regard it as absolutely valueless. 2. All you can do is to communicate with the principal photographic publishers.

3988.—See Mr. Ashman's article on page 466 of the present volume. We expect to receive the results of his recent experiments before long.

J. Berrynan.—1. You can obtain the apparatus from Griffin and Co., Long Acre. 2. A light of ten candles would efficiently light up one picture or a show-case, but not a window. Try this first, as the manipulation of a very large number of batteries is troublesome.

F. D.—1. The price would no doubt be the same as that of bromide plates, supposing a demand for them to arise; but we have not heard of anyone making them commercially. 2. Hardly sensitive enough.

L. B.—We will write to you.

J. J. M.—See Mr. Jenning's article in our issue of Sept. 15th.

David Banstead.—1. Because the paper has not been sufficiently dried. 2. A substratum of albumen is to be preferred, unless you intend to modify the second preparation as proposed. 3. A simple solution of shellac in alcohol, say four ounces of shellac to each pint. 4. As far as our own experience goes, it is entirely a matter of indifference which is used.

S. Fleischer.—A reversed negative is required for the single transfer process, and there are several methods. If the negative is to be taken especially for the work, you had better set a reversing prism or a mirror in front of the lens; but in the case of an existing negative, the safest way is to make a reproduction. The best method, as regards results, is to strip the film; but this involves some risk.

S. B. C.—Go to a photographic material store and select one for yourself. The chief qualities to be considered are—lightness, rigidity, cheapness, portability, adaptability to sloping or uneven ground, and the absence of a multiplicity of separate parts. No stand can possess all these qualities in a high degree.

Phosphor.—Yes, as a waste product in the alkali manufacture; but this form is not phosphorescent.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water $1\frac{1}{2}$ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water $\frac{1}{2}$ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add $\frac{3}{4}$ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia $1\frac{3}{4}$ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge $\frac{1}{4}$-oz., liquid ammonia $\frac{1}{2}$-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol $\frac{1}{2}$ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron $\frac{1}{2}$ oz., glacial acetic acid $\frac{1}{2}$ oz., alcohol $\frac{3}{4}$ oz. The amount of proto-sulphate iron may be diminished to $\frac{1}{4}$ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to $\frac{1}{4}$ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. $\frac{1}{2}$ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash $1\frac{1}{4}$ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash $\frac{1}{2}$ oz., gelatine $2\frac{1}{2}$ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts. camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz.; dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1261.—November 3, 1882.

CONTENTS.

SOME NOTES ON ALKALINE DEVELOPMENT.

"Was the development forced?" is a question which we very often hear asked iu connection with effects produced with dry plates. The replies that are made to such questions, and the general remarks of photographers on the subject, show that there is considerable misconceptiou as to what really constitutes forcing. There would appear to be a general impression that the use of a developer which contains a certain percentage of ammonia means forcing without regard to the nature of the plates with which it is used.

We remember to have witnessed a competition between two rival plate makers. The two makes of plates were both excellent, but of totally different natures. The plates of one came up dense and brilliant with two minims of ammonia, and would fog with four; those of the other stood easily anything up to twenty miuims, although doubtless, with sufficient exposure, they would have come up dense enough with two. Now, as the competition was intended to discover which plate was the most rapid, each competitor naturally used as strong a developer as he thought safe, and each got excellent results, and that with about equal exposures; but there was a complaint from one of the rivals that the other was *forcing* development, inasmuch as he was using a greater percentage of ammonia. This complaint we consider to have been totally uncalled for, aud about as unreasonable as if a wet-plate man were to complain that a dry-plate worker was taking an unfair advantage iu that he was not using the acid iron developer for his plates.

We hold that forcing is not reached until there is danger of fog, however strong a developer may be used. We have had experiences of plates which differed far beyond the limits of ordinary developers in the quautity of ammonia which they would stand, or even which they required. At a recent photographic meeting, Mr. A. Cowan showed us a plate which had been developed by a solution containing but one minim of ammonia to the ounce, and that after but very short exposure had been given. Mr. Cowan did not mention what quantity of bromide was in the developer, nor did he say whether the plate would have stood more ammonia. The negative had the appearance of being fully exposed, and was certainly dense enough to give a most brilliant print. Now, it is quite conceivable that the plate in question would not stand two minims of ammonia; yet, inasmuch as it was capable of giving an excellent negative with a short exposure, it could uot be called other than a good plate.

During some recent experiments in emulsion, we made some plates which, with an ordinary developer, required a very long exposure, yet which were of so hardy a nature that a developer containing fifty minims of ammonia to each ounce would not cause fog when there was but one grain of bromide of ammonia to the ounce of developer.

Besides pointing out that whether a plate is forced or not depends ou the uature of the plate rather than on the strength of the developer, we wish to indicate the folly of using a "test-developer" to discover whether a plate is good or not, and also the mistake of using a "standard developer" wheu it is desired to ascertain the rapidity of plates.

A good plate is not oue that will stand a certain developer without fog; but it is one which will give a good negative with a short exposure, whatever developer suits it best being used. For example, the plate which we have supposed would fog with two minims of ammonia is a better one than that which would uot fog with fifty, inasmuch as it would give as good a negative with one minim as the latter would with twenty-five, and that with a shorter exposure; yet, had a "test-developer" been applied to the two, certainly the first would have been rejected. Agaiu, in the very first case which we described, where plates were tried against each other, one set of which would fog with four minims of ammonia, whilst the others would stand twenty, how unfair it would have been to test the two for sensitiveness with the same standard developer

The correct developer for any plate is the strongest which it will stand without any danger of producing fog in such parts as have had no exposure to light. It is worth while making a trial of any batch of plates from which it is proposed to use a large number, so as to ascertaiu what the proportions for the developer really should be. This is very easily done in the following manner. Let a developer be made up containing (say) one graiu of pyrogallic aud one grain of bromide of ammonia to each ounce; let a plate be exposed under a negative, under a sensitometer plate, or in the camera, care being taken in any case to have a certain proportion of the film totally protected from light; now let the solution described above be poured over the plate, and let ammonia be added very slowly till perceptible fog is produced, the quantity of ammonia being observed. We shall suppose that two ouuces of developer were taken, and half-an-ounce of a ten per cent. solutiou of ammonia added to this before fog made its appearance. It will be seen that, to produce fog, a developer containiug twenty-four minims of ammonia to two and a-half ounces of solution, or about ten minims per ounce, was required. Now, to give a margin for safety, aud for the forcing of a somewhat under-exposed negative, it is necessary to limit ourselves to the use, in uormal cases, of only about a third of the quantity of ammonia which will produce fog; that is to say, the quantity of ammonia to form a normal developer for the plates in question will be about three—or, at the most, three and a-half—miuims to the ounce.

We have now to determine the quantity of pyrogallic necessary to give a sufficient density. Let a plate be exposed in the camera, and a trial be made with one grain of pyrogallic, one of bromide, and three or three and a-half minims of ammonia to each ounce of the developing solution; it will be easy to discover from the appearance of the resulting negative whether the quantity of pyrogallic is too great or too small. If the negative be too dense, the pyrogallic must be reduced; if it be not dense enough, it must be increased. When we have found out the quantity which gives the correct density, we may congratulate ourselves that we have discovered the very best developer for the particular plates which we are working, and we should only depart from it when an abnormity, either in the exposure or in the nature of the subject, calls for an abnormal developer.

SILVER IODIDE IN EMULSION.

The iodide question is by no means properly understood at the present time in all its bearings; but the recent experiments of Schumann not only serve to throw some new light on the matter, but will doubtless lead to a further and closer experimental study of the subject. Fresh exposures made on some of Herr Schumann's plates, about nine months old, proved that with bromo-iodide films the action extends notably beyond that visible in the case of bromide plates, and that this difference becomes increasingly great as the light is richer in the rays corresponding to low rates of vibration. A difference was clearly noticeable in the case of pictures taken at various hours of the day, in some of these instances the bromo-iodide and pure bromide plates being simultaneously exposed with twin lenses; a rough estimate being that the iodide plates are double as sensitive as corresponding pure bromide films. This relative sensitiveness, however, appears to be very widely departed from in the case of exposures made by petroleum light; as when twenty to thirty minutes was required to impress a mere trace of an image on a bromide film, a similar exposure of a bromo-iodide plate gave a negative which, if not fully exposed, was at least capable of serving as a makeshift. A study of these results leads to the conclusion that when the light is specially rich in yellow and red rays, the bromo-iodide plate is not merely twice as sensitive as the bromide plate, but rather six or eight times as sensitive.

Schumann's spectrographic experiments are equally surprising; as not only did an attempt with the light reflected from a greyish evening sky serve to impress a tolerably extended spectrum on a bromo-iodide plate, while a similar exposure would scarcely affect the bromide film; but with the highly actinic light of burning magnesium a striking difference was noticeable. About two grains and a-half of magnesium wire, burned an inch from the slit of the spectroscope, served to impress a vigorous spetrum on the iodide plate, the characteristic band in the green being notably well defined; while a similar experiment made with a bromide plate resulted in the production of a weak image in which above-mentioned band was altogether absent.

It is curious to note that the remarkable difference between bromo-iodide emulsion and pure bromide emulsion appears to be greater in proportion to the extent to which the former has been treated with ammonia; at least, one would gather from Herr Schumann's experiments that this holds good up to a certain point, and the circumstance is of special interest when it is remembered that silver iodide is practically insoluble in ammonia.

Unless there is some notable and unobserved source of error in connection with Schumann's experiments, we may expect them to lead to an important advance in the struggle for extreme sensitiveness; a quality of special importance when feebly actinic lights are alone available.

THE PHOTOGRAPHIC EXHIBITION.

Fourth Notice.

Professor W. F. Donkin, M.A., of St. George's Hospital, a well-known member of the Alpine Club, contributes this year a magnificent series of pictures from the Higher Alps. Look at the "Bietschhorn" (236); from the massive mountain towers aloft a sharp snowy spire reaching to the heavens; while, to add further to the romance of the situation, one cannot see to the bottom of the dark valley—it is so deep—out of which the mighty giant rises. The "Dent de Géant" (1) is a scarcely less marvellous picture; and in the "Jungfrau" (235) the snow slopes in the sunlight have that glossy satin-like sheen, to view which is alone worth a fatiguing day's climb over moraine and glacier. Professor Donkin very skilfully avoids the chalky glare that detracts from most Alpine pictures, and herein lies the chief point of success; never have the soft snow-fields of the Higher Alps been more successfully painted. A fine head of a dog (232), well pourtrayed, is sent by Mr. Henry Dixon, who also forwards some of his familiar "Relics of London" (501). Mr. G. Selwyn Edwards forwards three frames, the sedgy banks of "Oulton Broad" (225), with its growing reeds and trim craft, being most successful work. Messrs. Heath and Bullingham are represented by a frame of good cabinet portraits (204), and by three studies (223), the centre one a charming work; it is that of a lady gracefully draped in a soft woollen shawl—one of the most successful of photographic draperies—the face and features being very delicately modelled. The pose and lighting are also exceptionally good, and altogether it is one of the most delightful portraits in the Exhibition. Mr. Silvester Parry, who has acquired a reputation for cathedral interiors, sends the stall work of Chester Cathedral (219), a very successful work; the absence of unequal lighting is here most marked, and those who would know to what perfection interior-photography may be brought, have here a useful lesson before them. The best contribution of Mr. J. W. Robinson, Jun., is an old street in Newcastle (73), an exceedingly quaint architectural study.

Mr Edward Brightman sends some sunny sketches from the south of England, all of them bright and pleasing. "On the East Lynn" (209), a mountain pathway leading among flowerets and ferns, is a rare study; there is plenty of shadow among the fern tufts, and yet it is so clear that every detail of the delicate stems is seen. "Cottages at Lynmouth" (210), again, is one of those sweet homely scenes in Old England that lose nothing of their charm at the hands of a master in the art like Mr. Brightman, of whose good taste and high skill there is evidence in every contribution. Mr. Charles F. Wing contributes a frame of good portraits (206); and Messrs. Adams and Stilliard are also represented by portraiture (205), their frame, among other excellent pictures, containing a capital likeness of Dr. Siemens, and another of Captain Abney. Mr. George Tuohy shows two frames of portraits taken by artificial light, which are certainly highly successful, together with a group of Chertsey grandees welcoming the Duke and Duchess of Albany (140), a picture remarkable for the singular fact that not one of the group is looking at the camera. Messrs. Lombardi and Co. contribute three frames of portraits (198, 197, 189), which include much high-class work. Mr. Clive F. Pritchard shows a picture of "Lausanne Cathedral" (195), in which the quaint flying buttresses of this ancient pile are shown to particular advantage, the point of view as well as the lighting indicating both tact and judgment. Mr. Lyddell Sawyer contributes two pictures of considerable merit—"Shadows" (186), and "Sunbeams" (187); if the same lady-model has served for both—and we fancy this is the case—the pictures, besides indicating much artistic culture and exceeding good taste, are also wonderful examples of "expression."

Mr. Robert Faulkner's exhibits are marked with the same refinement and delicacy that have hitherto characterised his studies of infant life. The most delightful of his pictures is "Lady Sybil" (185), a tiny maid, rarely limned in red pigment; the pose and draping of this little creature are perfect, reminding one of Miss Kate Greenaway at her best. "Katherine and Mary Hart Davis," a quaint little pair of coquettes, also in red pigment, are no less successful. Mr. Faulkner also sends a large frame of baby faces, conveying every phase of humour in the changeable Kingdom of Lilliput. A frame of Mr. F. Downer (190) escaped our attention when we before mentioned that gentleman's name, and, therefore, we here refer to his work once more; this series embraces several examples of grouping that denote study and earnestness of purpose to instil fine art into photography.

The Luxograph Company exhibits some good portraits taken by artificial light (171). Mr. H. Stanley's contribution of portraits (170) deserved better mounting and framing, for it contains some work decidedly above average merit. Of Mr. Thurston's "At-Home Pictures" (167) we like best the little family group on the steps, which has been arranged with much care. Mr. John M. Thomson forwards a frame that will interest many, containing, as it does, studies of clouds for meteorological purposes (166). It was only the shape and nature of the cloud masses that Mr. Thomson desired to secure, and necessarily the landscape, where shown, is under-exposed; but for all that he has succeeded in securing some beautiful pictures, as well as some beautiful effects. Mr. H. E. White's "Golden Eagle" (165) is a fine fellow; but he is perched on too high a pinnacle to study closely.

Mr. H. Trueman Wood sends four pictures, of which the "Avenue in Tewin Water Park" (93)—the quaint fantastic forms of the gnarled trunks laid bare in wintry weather—and "Tintern Abbey" (94) are the best; the ivy-grown ruins of Tintern, with its broken columns, being, indeed, a most complete little sketch. Mr. J. Maclanachan shows three fine twenty-inch portraits, that deserve high praise, both by reason of the facile posing, as also for their deep rich tones. Mr. Maclanachan has mastered that obstinate difficulty of securing full details and rich shadow at the margin of his portraits while duly preserving the balance of light and shade in the features of his model. The graceful folds of the drapery, the delicate work on lace and embroidery, are perfectly rendered, and yet not at the expense of the face and bust. Colonel Stuart Wortley's name is not in the list of exhibitors; but a frame of five collotype pictures of Tahiti, printed by the Autotype Company (147), shows us that the Colonel still handles the camera with taste and skill. "Hiliaa Lake," beside which rises a clump of tall palms, their elegant stems bending towards the water, the foreground a mass of big tropical leaves, and in the distance a wealth of soft foliage, make up together a delightful picture; to mention another photograph, of merit of a different stamp, "Our Family of Servants" may be cited.

Mr. J. A. Langton exhibits two frames, both of which are hung too high for critical inspection; the portraits on porcelain (113), however, seem to denote good work. Mr. H. N. King has several examples of his "royal" interiors, enlargements from the series he has before exhibited; one of the most successful is the "Green Drawing Room at Windsor" (120), and another, scarcely less fine, is the "Grand Reception Room" (144). Mr. Mure's untouched portrait, taken in a sitting-room (126), is too far off to examine; and the same may be said of Mr. John Nesbit's platinotype print (123), representing an original drawing by W. R. Woods. Mr. P. H. Emerson forwards several pictures printed in platinotype, most of them a little too dark, we think; "On the Granta" (106), and "Near Inverarnan" (43), are the most successful. Of Dr. Plaister's studies, the best by far is the "Bridge at Wastdale Head" (20), which is quite a little gem, the hill-side scenery clear and soft, as many a tourist has seen it in the cold grey light of morning; we compliment Dr. Plaister no less upon his capital emulsion with which he has secured his pictures. Mr. Simeons Norman's "Burgess Hill Wood" (87), with its wood-cutters, is a delightful picture, very soft in its detail and distance, and altogether an artistic composition. "Hassock's Gate," a wintry picture, with leafless trees and steely brook, is no less praiseworthy; his frame of sketches is indeed a very creditable one.

Mr. William Muller has three fine series of pictures. In the middle frame (86), "The Herdsman, Staffa," is admirably rendered; the step-like mountain is shown at its full height, and its peculiar formation capitally pourtrayed; in "Shiel Village," the rendering of the distance is perfect, and altogether it is one of the best landscapes in the Exhibition. We like also "Glen Shiel," in the same frame, very much; Mr. Muller does not permit his camera to depress the horizon as many photographers do, and the grandeur of his pictures is in a great measure due to the fact that he figures the mountains by the roadside at their full height. Mr. A. Johnson sends some studies of "Fishing Boats at Wick" (80), which have a good deal of character about them. The livid green colour of the mounts of Mr. W. Trenemen's pictures detracts somewhat from their excellence. Mr. Trenemen sends two frames containing many delightful views; "Magpie Island," with its old willow and cattle, and "Wargrave Church," muffled in ivy (65), are most pleasing little sketches; and so, too, are "Cromford Bridge," and "At Lynmouth" (26). Let Mr. Trenemen try the effect of a black mount with gilt bevels for his little pictures, and he will find them vastly improved. Mr. C. J. Palmer sends but one picture, taken in mid-ocean (64); the swelling sea in the foreground is wonderful, and would please many of our marine painters. Mr. Peter Mawdsley shows a fine collection of views, some of them taken with drop-shutter exposure; No. 6, in which we see a limpid pool, the surface patched with duck-weed, and above, the trailing branches of a lofty ash, is the most pleasing.

Mr. Matthew Whiting sends a large contribution. Mr. Whiting is one of the distinguished few who make good emulsion and good pictures. A view of "Midhurst," a stately elm on the highway beside the stone bridge, and beyond, a cottage nestling among the trees (59), is one of the prettiest of Mr. Whiting's collection. "Portsmouth," in which we see a towering three-decker, in grey and white, riding proudly at anchor among the tiny black fishing craft, is also a capital picture, and one, too, that will be valued in years to come when line-of-battle ships are as dead as the Dodo. In a second frame (47) we have another delightful marine sketch, in which the waves are flecked with silver sunlight. Mr. David Green sends "Thunder Clouds" (41), an effective sky picture. Mr. Edward Dunmore's pictures look like summer pictures, and that is a pleasant quality that photographs do not frequently show. In "Which Way," and "Country Lane" (27), there are the warmth and luxuriance of summer-time; the pathway is dappled with sunshine, and among the leaves and the branches there is a glow that cannot be mistaken. Mr. A. Bisset Thom sends a picture of the Memorial Fountain in Hyde Park (15); and Mr. Robert Harris forwards a frame of pictures taken on board s.s. "Arab," while going at full speed (14); the latter are full of life and character. From the School of Military Engineering, at Chatham, come half-a-dozen brilliant landscape pictures, the work of the clever Sappers attached to that establishment. Whether the peculiar brilliancy of the prints is due to collodion or not, certain it is that they afford a contrast to many pictures in the room. "On the Lynn" (10, 12, 13) are the best; considerable artistic ability is manifest in the way in which the dark tree trunks are made to contrast with the feathery foliage in these leafy pictures. Monotony is, in this way, most happily avoided, and justice done to the Devonian Paradise. Finally, we have to mention a bold and characteristic portrait of the President of the Society on the table, from the studio of Mr. J. A. Melhuish.

By-the-Bye.

PHOTOGRAPHIC NEWSPAPERS AND JOURNALS.

One matter for surprise among photographers abroad is, the abundance of photographic literature in this country. Not only are they astonished at the vitality and energy of photographic authors in Great Britain, but the readable matter placed before those who peruse the English papers week after week appears to them overwhelming. Our friends abroad—used for the most part to the appearance of a thin monthly journal, or, perhaps, a fortnightly one—marvel at the fecundity of English photographers; and although there are examples at this moment on the Continent of weekly newspapers devoted to photography, these are but of recent origin and scant proportions.

England has not only taken the lead in photographic literature, but its follower in the race is but a bad second. Dr. Hornig, the worthy editor of the Viennese journal—the *Photographische Correspondenz*—has recently written on this subject, and, we think, suggests the true cause of British supremacy. It is because in this country there are so many skilful and intelligent amateurs in photography, as there are with us in other callings and occupations. It is in British blood, seemingly, to take readily as an amateur to science, art, technics, athletics, and a hundred other things besides; and it is no less in the blood to undertake thoroughly what is undertaken at all. What holds good in rowing, cricketing, volunteering, and the rest, holds good also in scientific occupation, and it is no rarity in this country to find an amateur riding his hobby so well, that he distances those who are professional racers; so that in the end he takes his place with the best of them. Of the poet, it is said that he is born, and not made; but of Grace, the cricketer, who is a doctor; of Whymper, the mountaineer, who is an engraver; of Spottiswoode, the President of the Royal Society, who is a printer, and others who have distinguished themselves out of their original calling, the same may be said with equal truth.

It is because of the thoroughness of British amateurs that the cultivation of our sports and pastimes, and of science and art, is undertaken with such genuine success. There is no such hard-worker in a particular sphere than he who works out of sheer love and liking. We probably work harder—that is to say, do more work in a given time—than our brethren elsewhere, and in like manner our recreations are conducted in the same vigorous spirit. The amateur photographer is no exception, and he takes, if anything, more interest than the professional photographer in the occupation. He contributes his full share towards photographic research and to the progress of photography both as an art and as a science; he is no less energetic in his support of photographic literature. The leisure he devotes to experiment or to research is never lost; he jots down what he thinks may be useful to brethren of the craft, and freely places it at their disposal through the public press. Uncertainties to be cleared up, and obstacles to be overcome, have a peculiar attraction to him, and he is never happier than when a problem presents itself to be solved. The professional, every-day photographer cannot give up his time, for the reason that his bread, and that of his family, depends upon his securing so many certain results within a given time; and even when his experiences are valuable, he may neither have the time nor the inclination to make them public. It is, then, mainly, as Dr. Hornig has pointed out, because we have in this country a legion of amateur photographers—ladies and gentleman who work intelligently and steadfastly with the camera—that our literature happens to be so well represented.

We have said that there are weekly photographic journals besides those in this country. At this moment two such papers exist, both of them published in Germany. One is the *Photographen Zeitung*, published in Thuringia, at Weimar. Weimar is classic ground for literature, since Schiller and Goethe are buried within its walls; Kotzebue, the author of the "Stranger," was born there; and our own Thackeray lived in the town for some years; indeed Thackeray has painted Weimar pretty truly in *Vanity Fair* under the name of Pumpernickel. Being in mid-Germany, the little town is well-suited for the publication of a central organ, and though the *Zeitung* is still small, its energetic editor, Herr K. Schwier, has shown himself equal to the task of conducting a periodical journal of the kind. The other weekly paper is the *Wochenblatt*, which is printed in Berlin under the able editorship of Dr. Stolze; this paper gives subscribers a good deal to read comparatively, for the weekly issue consists of sixteen columns; but, taken altogether, its contents are but a quarter that of the Photographic News.

Of fortnightly journals there are two on the Continent. The *Moniteur de la Photographie*, of which our esteemed Paris correspondent, M. Léon Vidal, is chief editor, is well known to most of our readers. The *Moniteur* is better off than its German contemporaries, because it has fewer opponents; in Paris, and the larger French cities, it is the principal organ of photographers, and since its able editorship by M. Vidal, the dimensions of the paper have considerably increased. Another fortnightly in the highest rank is Dr. Vogel's *Mittheilungen*, which is often quoted in these columns, and which, if its pages are limited, rarely contains any matter of unimportance. Dr. Vogel's paper is the official organ of the Berlin Society for Advancement of Photography, one of the busiest of the Continental societies.

The *Photographisches Archiv* can scarcely be called a fortnightly journal, and yet it appears more frequently than once a month. Twenty numbers in the year is, we believe, its allotted appearance, and in Dr. Liesegang's experienced hands it enjoys great popularity throughout the Fatherland. The *Archiv* is published in Berlin and in Düsseldorf.

Coming next to monthly periodicals, we find the number much increased. America here steps in, and adds her quota, one of the most spirited periodicals of our cousins being Mr. Fitzgibbon's *Practical Photographer*, a becoming volume, neatly bound, with elegant letter-press, printed on good paper. The *Practical Photographer* issues from St. Louis,* while from Philadelphia comes Mr. Wilson's *Philadelphia Photographer*, another comely pamphlet, printed in a style and upon paper that put our own journals to shame. *Anthony's Bulletin* is a third well-known photographic newspaper, hailing from New York, a compact and well-printed little volume; and the *Photographic Times*, a fourth, also published in New York, is remarkable for an improvement during the past twelvemonth, both in substance and form, which will assuredly be lasting, so long as our esteemed colleague, Mr. J. T. Taylor, fills the editorial chair. We do not mean to flatter our American contemporaries when we say that their columns are filled with sound and readable matter, for the simple reason that much of the literature they publish comes from this country in the first instance. Like the much-advertised "Waverley Pen," indeed, our own photographic literature comes "as a boon and a blessing" to brother-editors in America and on the Continent.

Of the Continental monthlies, the palm must be given to the *Correspondenz*, the able journal of the Vienna Society, edited by Dr. Hornig, and the *Bulletin de la Société Française*, which emanates from Paris. Two Belgian societies issue journals which are occasionally very good; these are the *Bulletin Belge* and the *Bulletin de l'Association Belge*. Unfortunately, whether it is that their contributors are not constant, or the societies they represent do not bestir themselves, the contents are at times disappointing, for the simple reason that some of the numbers are of high excellence. A second paper is also published at Vienna, the

* News comes to us this week that the *Practical Photographer* has ceased with the death of its talented editor.—Ed. P.N.

Notizen, which is remarkable if only for the readable little papers that Dr. Vogel is wont to contribute to its pages.

Besides the *Bulletin*, Paris publishes the *Revue Photographique*, dealing with historical and monumental subjects in connection with photography; as also another monthly newspaper issued under the auspices of the Chambre Syndicale. The monthly journals of Frankfort and Munich, which appeared some months ago, are, we believe, temporarily suspended; but Holland boasts two papers, the *Tidschrift* and the *Navorscher*, devoted to photography. Signor Borlinetto edits the *Rivista*, from Brindisi, the only Italian town represented by a photographic journal. Russia has enjoyed the benefit of a journal for a twelvemonth and more; and Denmark has a monthly termed the *Meddelser*, which is printed in Copenhagen. Spain is without a photographic journal, albeit there has recently been published one in the Spanish language, printed at Havannah, called the *Boletin Fotografico*. Altogether the number of journals devoted exclusively to photography, published on the Continent and in America, may be summarised as follows:—Weekly, 2; fortnightly, 3; monthly, 16.

The "By-the-Bye" next week will be "The Photographic Copyright Defence Association."

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.*

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

At the Imperial Geographical Institute at Vienna the following solution is used to darken the film after treatment with saturated solution of bichloride of mercury—

Chloride of gold aud sodium	... 4·37	parts
Water	350	,,

added drop by drop with constant stirring to a solution of—

Hyposulphite of soda	13	parts
Water	350	,,

The mixture is allowed to stand for an hour or so, till it is free from colour, and may be used over and over again if kept in the dark. This seemed to give good intense images at the Institute, but I have not been very successful with it myself.

Another intensifier, containing uranium, is also used at the Institute:—

A.—Nitrate of uranium	17·5	parts
White sugar	17·5	,,
Distilled water	700	,,
B.—Red prussiate of potash... ...	17·5	,,
White sugar	17·5	,,
Water	700	,,

This is used after fixing, first applying A, and then B, and washing thoroughly afterwards.

At the same Institute, negatives from unsuitable originals, in which the lines are liable to choke up, are dried after the first intensification with iron, or pyrogallic and silver, and treated in a peculiar manner so as to prevent the lines being fogged in the after strengthening with mercury, &c. A solution of—

Gum-arabic	175	parts
White sugar	175	,,
Bichromate of potash	58	,,
Glycerine	18	,,
Water	350	,,

with a little ammonia added, is poured over the negative, and when it is dry the plate is exposed to light on the glass side to about 13° or 14° of Vogel's photometer, then soaked for about a quarter of an hour in cold, and then in tepid water, until the relief appears. The plate is then dried, and may be strengthened with mercury and gold until the ground is perfectly opaque, the transparent gummy relief in the lines preventing their clogging up.

From the method of intensification above given, the operator will be able to select that which may seem to suit him best; but for regular work on large plates, the treatment with bichloride of mercury and hydrosulphate of ammonia or cyanide of silver seems to be the most certain and effective.

Varnishing and Finishing.—After intensifying, the negative is dried, and varnished with a good strong varnish; or, if not required to produce many copies or to be kept, it will be sufficient to flow the plate over while wet with a solution of gelatine, about one part to thirty of water, to which a little chrome alum may be added.

After the negative is dry, transparent spots and other defects should be touched out with indian ink or black varnish. In touching out on the film side, care must be taken to keep the varnish on thin and free from any grit or lumps, which would prevent the close contact of paper and negative in printing, and spoil the sharpness of the result. This is especially important with reversed negatives for printing direct on stone or zinc. A good deal may be done to clear up broken and fine lines, by cutting them in on the varnished negative with a sharp steel point or cutting edge.

The negative is now ready for printing. Difficulties of climate being against the employment of gelatine dry plates in India, I have not sufficient experience of their use for copying purposes to lay down any rules for guidance. There is no doubt that they will come largely into use for this class of work. They have the advantage over the wet collodion process of greater sensitiveness, and, with suitable emulsion, the required intensity can be secured by the imple application of the ferrous oxalate developer restrained with bromide to preserve the clearness of the lines.

(To be continued.)

* Continued from page 652.

MR. J. COMYNS CARR ON PHOTO-ENGRAVING.*

Having traced the progress of wood engraving in its latest and most extreme development, it becomes our task to consider those various mechanical processes that now place themselves in competition with the engraver's art. That these processes should already occupy an important place as a means of book illustration is scarcely remarkable, seeing that they can be employed at a cost very much lower than is required even for the commonest and coarsest wood-blocks. That they do not yet display an equal refinement and perfection in the rendering of an artist's work must indeed be allowed, and there is still a certain superiority possessed by the wood block which has not been attained by any of the mechanical processes; but that this superiority will be preserved, it would, I think, be rash to assert. Within the last few years nearly all these different processes have been developed with remarkable rapidity and success, and I believe it probable that, before long, results will be obtained such as even the most delicate wood-block cannot rival. All these processes, as you are doubtless aware, have been the outcome of the invention of photography. For some time there was a disposition to use direct photography for book illustration, never, I think, with very fortunate effect. The appearance of a photograph has absolutely nothing in common with that of printed text, and it is impossible to combine the two so as to produce a satisfactory or harmonious result. Direct photography, then, as a means of book illustration, scarcely deserves consideration; but although a volume adorned with photographs can never be a very lovely object, the attempt to make use of photography for this purpose has led to valuable discoveries, which have been fruitful in other directions. Perhaps the most important of all the discoveries was that by which the photographer was enabled to obtain from the negative a print which should be permanent and indestructible.

The carbon print never exhibits all the refinement and delicacy which belong to the silver print; but the fact that it is indestructible, and that it may be produced in any tint or

* Being an extract from his recent Cantor Lectures.

colour that is desired, gives it a special value of its own. You are no doubt familiar with the marvellous reproductions of drawings by the old masters which have been made by Mr. Braun, of Dornach, and which are printed by the carbon processes. When you have no original at hand, it is difficult sometimes to believe that the photograph itself is not the drawing, and it would certainly be impossible to find any means more suitable for the reproduction of this particular class of work. This carbon process is constantly employed in the illustration of books under less advantageous conditions. A way has been discovered of multiplying the carbon prints mechanically, and, in certain instances, the results obtained are sufficiently good; but, as a rule, this process gives but a poor and lifeless copy of any work of real art. If the original drawing be in line, the lines as they re-appear in the print lose much of their force and vigour, and in all cases the surface of the print has a dull and lifeless appearance, and much of the refinement of tone which may be secured in the original negative is altogether lost.

I shall not, however, attempt to compare or to discuss the different modes of producing these photographic prints. I have referred to the carbon process because it really forms the basis of one of the most interesting and admirable of the many modes of photographic engraving. Hitherto, in speaking of book illustration, I have limited myself to the art of the wood engraver, but as these mechanical processes are equally applicable either to printing in relief or intaglio, I shall bring to your notice specimens in both kinds, and briefly explain the means by which they are produced. Perhaps the very finest examples of mechanical engraving are those which bear the name of Mons. Amand-Durand, of Paris. The reproductions which he has published of the works of Dürer and Mantegna, and of other of the earlier masters of engraving, are of unapproachable beauty and excellence. I have heard Mr. Reid, the accomplished and learned keeper of prints and drawings at the British Museum, declare that it is almost impossible, in some instances, to distinguish between the copy and the original, and certainly to those who cannot possess the originals these plates of Mons. Amand-Durand offer a delightful substitute. Of the manner in which they are produced I cannot speak with any authority. That it is based upon photography is of course certain, and it is mainly, though not wholly, mechanical in its operation. Mons. Amand-Durand is a skilful engraver on metal, as well as the inventor of this wonderful process, and there is no doubt that he supplies, with his own hand, any deficiency that may exist in the plate as first produced. But although these plates are certainly the most perfect of their kind, they deal for the most part with only a special class of work. As a general rule, Mons. Amand-Durand limits himself to the imitation of engravings in line, and he has not, save in a few instances, tried to reproduce the effect of a chalk drawing or of a drawing in wash. In this sense, therefore, the process employed by M. Goupil has a wider scope, and this has its English counterpart in the invention of a similar kind made by Henry Dawson. One of the very first set of plates produced by Mr. Dawson, after his invention had been perfected, consisted of a series of copies from drawings by the old masters, which are published in the catalogue of the Grosvenor Gallery. I have brought them with me to-night, and although I do not doubt that Mr. Dawson can now do much better than this, I think you will admit that they are, in certain respects, astonishing examples of imitative skill. Mr. Dawson makes no great secret of the principle on which his process is founded, and I may therefore briefly explain to you the ingenious mode in which this admirable result is obtained. You will observe, in the first place, that these are impressions from metal plates, printed in the same manner, and by the same press, as a copper or steel engraving, but instead of the picture being engraved upon the plate, as one might expect, the plates are themselves, so to speak, produced upon the picture. It is the picture in Mr. Dawson's process which really creates the plate; and the way in which this is accomplished is so remarkable, that perhaps you will allow me to give a few words of explanation. The first thing that Mr. Dawson does, after having photographed his subject, is to take from his negative a carbon print; this print is taken, not on paper, but on glass; and as the principle of a carbon print consists in the deposit of solid pigment, the picture so taken upon the glass represents a very delicate work in relief; that is to say, the surface of the picture is very slightly raised upon the smooth surface of the glass. This impression is then covered with a thin coating of gold, which acts as a powerful conductor of copper, and the glass is now placed in a galvanic bath, where the copper is gradually deposited over the whole of the plate. When the deposited copper has attained a sufficient thickness, it is taken from the bath, and the glass is removed. We then have a copper plate with the picture cut upon its surface, exactly corresponding to the carbon print; that is to say, those portions which in the print were in relief, are now in intaglio, and every delicate gradation is exactly reproduced as in the original negative. The copper-plate now resembles, in every respect, the work produced by the engraver. According to the character of the original, it partakes of the nature either of an engraving in line, or of a mezzotint engraving, and it is this quality of mezzotint surface which Mr. Dawson rightly regards as constituting the special claim of his invention. The difficulty here with which he had to contend was to give such a surface as would hold the ink, and this he has now accomplished in a very remarkable degree. A certain amount of hand-work must occasionally be added, in order to correct the defects of the photograph, which sometimes gives undue force to the delicate portions of the original drawing; but, broadly speaking, the process is purely and wholly mechanical, and the copper-plate, as we have seen, is absolutely grown upon the raised print.

There is scarcely any kind of original work to which this process may not be applied with success. In the reproduction of a drawing in pen and ink, the result resembles a strongly bitten etching. It is equally successful in imitating the effect of a drawing washed with a brush, or of a drawing in chalk; but as deposited copper is always more or less soft in substance, the plate, before it is used by the printer, is covered with a thin film of steel, and we have then a surface which is practically indestructible, and from which any number of impressions can be taken, for so soon as this thin film of steel shows signs of wear, the printer stops his labour, and the steeling is renewed. This process of steeling a plate is now very generally applied to engraved work on copper, and its effect is practically to abolish the distinction which once existed between proofs and prints. The value of a proof in former times consisted in the fact that it gave an impression of the plate in its full strength, before it had become worn by successive printings; but now there is in reality no limit to the number of impressions which can be taken from the steel plate, nor is there, as is sometimes supposed, any loss of the most delicate workmanship by the process of steeling. Indeed, Mr. Rajon, the well-known etcher, told me once that, for his own part, he almost preferred an impression taken after the plate had been steeled. Mr. Dawson's invention, which I have been describing, cannot, of course, rank among the more economical modes of book illustration. Copper-plate printing must always be costly, and by its nature it is unfitted for incorporation in printed text, but for the more expensive and luxurious sorts of book illustration it offers remarkable advantages, and it is especially valuable as a mode of reproducing, with absolute fidelity, the earlier forms of art. A process similar in kind, and evidently based upon the same principles, has been perfected in Paris by Mons. Dujardin; and in the *Gazette des Beaux Arts*, for the present month, may be seen some very remarkable specimens of the work he produces. In certain cases, the process enables us to do away altogether with the intermediate services of the draughtsman. Furniture, armour, or objects of vertu, may be reproduced directly, and with absolute fidelity and refinement; indeed, the result is, in some respects, more subtle than can be shown even by the most minute and careful engraving. No handiwork could preserve, with equal success, the appearance and surface of an embossed shield, or of a carved cabinet.

But the processes hitherto described, although they serve to illustrate the successful advance of mechanical invention, have only an indirect bearing upon our subject. They suggest comparison, not with the wood-block, but with the various modes of engraving on copper and steel; and although the initial outlay needed to produce one of these plates is infinitely below what would be demanded by a skilled artist, who had to etch or grave the design upon the plate, the means of multiplying impressions still effectually hinders the general application of such processes to the purposes of book illustration. All pictures taken from a copper-plate press must rank as what the French style *planches à part*. They can be inserted in the pages of a printed volume, and may powerfully add to the attractiveness, but they cannot be printed with the same facility or by the same means as are employed for producing impressions from movable type. If, therefore, the genius of modern scientific discovery had gone no further, its influence upon the practice of book illustrations would not have been considerable. These processes, indeed, are highly valuable in the enlarged opportunities they offer for the reproduction of works of art. M. Goupil's invention, as you are aware has in a measure superseded engraving as a mode of multiplying copies of a picture in oil or water colour. The photograph is taken direct from the original painting, and transferred to the copper without the intermediate aid of any skilled handicraft; and however much opinions may differ as to the beauty of the results so obtained, it is impossible to deny that they carry an astonishing effect of illusion and resemblance. For it is to be observed that the impressions from Messrs. Goupil's plates do not merely compete with the older processes of engraving, but, in some respects, may be said to supersede them. Engraving on copper or steel, even in the hands of the most skilful exponents, does not aim at any minute imitation of the painter's handling. It has always been regarded rather as a translation than a reproduction, and its exercise has been determined by special laws and traditions, which may be said to constitute a recognized convention of style. In the first place, it is to be noted that, save in the case of mezzotint, all engraving is executed by means of line, and this fact serves, in itself, to distinguish the reproduction from the original, and to make the spectator sensible that the artist's invention has been translated into another language. And even in the finest examples of mezzotint, which so successfully preserved for us the masterpieces of Reynolds and Gainsborough, there is no attempt to suggest the actual appearances of the picture. The necessities of translation are still frankly and clearly acknowledged, and although the subtle modulation of tone comes nearer to the effect of painting than anything that can be produced in line, the result nevertheless ranks as the product of a separate art, which leaves room for the assertion of the engraver's individual style. But with these mechanical processes, based upon photography, this is no longer the case. It is the picture itself that is transferred to the plate, shorn only of the grace and attraction of colour. Something is necessarily lost by the way, for colour still offers certain hindrances to the photographer which modern science has not yet entirely removed. But, on the other hand, the mechanical process is able to afford a degree of realism in regard to the details of execution such as no engraver would have thought of attempting. In the most successful of these plates the actual impasto of the paint is successfully reproduced. The varying relief upon the canvas, which results from a vigorous handling, tells as a relief upon the carbon print, and is transferred again to the metal from which the printed impression is finally taken. Every touch of the brush is faithfully preserved, even where it is not exaggerated, and where colour is added, the effect of illusion is sometimes positively startling. This use of colour is, of course, only applicable to reproduction of water-colour drawings, and is, in fact, only a revival of a mode of copper-plate printing that was practised in England a century ago. It is impossible to get from a metal plate either the solidity or the gradation of a finished painting in oil, but, on the other hand, transparent tones of colour may be so distributed over the surface of the metal as to give the effect of a washed drawing in water-colour. You have, no doubt, seen in the printseller's shops some marvellous imitations, by Messrs. Goupil, of water-colour drawings by artists of the Continental schools. The more elaborate methods employed by our own water-colour artists would not so readily lend themselves to the process; but where the technical means are simple, and where the tints are laid on in a broad style, the resemblance is striking and remarkable. As we are treating of colour printing, I may be allowed to point out that the means here employed are essentially different from those which are used for wood blocks. The preparation of a copper-plate, from which a coloured impression is required, is in itself an artistic process. The printer paints upon the metal as though he were painting upon paper. Each separate space must be supplied with its appropriate tint, which again must be cleaned in such a way as to yield varying strength of tone; and when this has been done, the impression is taken at once, and by a single printing.

(To be continued.)

QUALITY OF PHOTOGRAPHIC LIGHT NECESSARY TO BEST RESULTS.

BY J. F. COONLEY.*

As to the quality of light best adapted to produce perfect photographic results there are various opinions. For a long time efforts have been made in the direction of accelerators to shorten the time of exposure, with the view of taking pictures in any, or almost any, kind of light, on cloudy or rainy days, early in the morning and late in the afternoon; and at this late day it is no unusual thing to see displayed in conspicuous places in front of various photographic establishments a legend like the following:—"Equally as good pictures taken in cloudy as in clear weather." And many people, both in and out of the photographic profession, are to-day labouring under the impression, and honestly believe, as good pictures can be taken on cloudy, rainy, overcast days, when the atmosphere is devoid of actinic rays to a very great extent, as when the opposite conditions prevail, providing they can be successful in keeping the sitter quiet long enough to overcome the difference in the strength of the light.

This is thought by them to be the only requisite—that if the subject is properly timed, or sufficient to bring out the shadows under development, it is all that is necessary or possible to do in that direction; and, working with this idea, the fraternity have been imposed on and swindled periodically by a few sharpers with some secret or patent process for making pictures in any kind of light, or no light at all, in an infinitesimal period of time, or "quick as a wink," thereby sacrificing everything that is artistic or beautiful in nature to the ridiculous notion or idea that any kind of light is good enough to make pictures, providing you use Professor Humbug's Extra Rapid Double Distilled Lightning Catcher to produce them. With this idea of rapidity of exposure constantly in their minds, they have entirely ignored the quality of their work, or left that to take care of itself.

I have always thought, and still think, that great rapidity or rapid action below a certain point is not possible in conjunction with fine results, and in portraiture is not desirable. We all know that light is of various qualities, from the very brilliant to extreme weakness, and that neither extreme is best for producing pictures; but a happy medium between the two will always give the best productions, other conditions being equal

The quality of light is greatly changed by the size, height and position of the sky and side lights, by the kind of glass used in the lights, and again, by the age or time it has been in use, and the condition in which it is kept as to cleanliness, &c.

All those things must be taken into consideration in estimating the quality of a light. Plate glass is, without doubt, much the best for a light. We got a purer and better light through plate glass than we possibly can through the ordinary glass in use for most sky and side lights. But if it were possible to make pictures at all times of the year without glass of any kind between the sitter and the sky, I am positive that much more rapidity could be attained. From some results I have produced in making portraits without the aid of a glass light, I believe that one-half the strength of light is absorbed or wasted by passing through the glass sky-light. Of course, I mean the ordinary light used in most galleries for portrait work. I believe it possible to build a light very low down, with a fine quality of plate glass, that can be worked very rapidly, but with the loss of certain effects necessary to maintain that balance of light and shadow, and harmony between them, so essential to have in a picture, and without which they are open to criticism.

The theory of the quality of light is a subject worthy of our best thoughts; and the more thoroughly we investigate this subject, the better we will be prepared to take advantage of all the ideas that practice or accident may develop, and create that harmony and beauty in our work so much sought after by every true lover of the photographic art.

The foregoing remarks and conclusions apply to portrait work exclusively; but the same principle, in a modified form, must govern the production of the landscape artist. A bright clear atmosphere, free from fog, mist, and smoke, with the sun in the right direction to light the subject to the greatest advantage and impart the best effects, are the conditions most favourable. With these conditions, a fine subject and all the brilliant effects that a bright sunlight alone can impart, we secure the lights and shades, the half-tints, the brilliant, glistening lights on the foliage, the beautiful reflections mirrored in the water, the gradual fading away in atmosphere and perspective of the distance and middle distance—in fact, we have before us the motive for a most effective and brilliant picture; but wait until the sun is obscured—the light has changed, and the day is cloudy and devoid of those principles of light and effects described in the preceding description. Then what do we see? We have the same subject before us, but how changed! The wand of the magician has passed over it, and its beauty has departed, to be restored only when the proper

* *Photographic Times.*

light is brought to bear upon it again. Reverse these opposite conditions. Take the two pictures, and, when finished, put them side by side, and observe what the quality of the light does for us. It will require no other argument to convince the most sceptical that it is not only light, but the quality of that light, which determines whether we have a picture or a map of the subject before us. There is no method in photography that will reproduce what the light does not first produce for us. If this is deficient or of an indifferent quality, the resulting pictures will show it, no matter how or by whom produced, or by what process; and the sooner this principle is recognized and acted upon, the sooner we will have more pictures that are entitled to be called art productions.

This principle *is* recognized by a few, and their pictures show that they are aware of what is essential as to quality in light to produce the work they are doing. It requires close study and correct observation to master this problem; but once have it firmly placed, and we will avoid untold annoyance if we are ambitious to produce fine pictures by the photographic process in combination with what artistic knowledge we, or some one else working with us, may possess.

Notes.

The Exhibition in Pall Mall remains open but a fortnight longer; its closing is definitely fixed for Thursday, the 16th inst.

The Year-Book of Photography—now in its twenty-fourth year—will be published on the 20th prox.

Those of our friends who would honour us with a communication—and we trust that any having practical experiences or new ideas likely to be of value to their fellow-workers will send them—will increase the favour many fold if they forward their contribution early this month, and set forth as *briefly* as possible. The space available grows year by year more limited, notwithstanding the circumstance that the number of pages in the Year-Book have been much increased.

For the last time, the Arctic yacht, *Kara*, finds a place in our "Notes." A fortnight since we announced its safe arrival home from its perilous voyage in the Polar seas; but, making its way from Hartlepool to Wivenhoe, the little craft foundered, and was completely lost. All hands, however, were saved, so that there is happily no cause to regret the loss of any of the brave crew who went to the rescue of the missing *Eira*.

"A photograph of yourself, endorsed on the back by the minister of some registered place of worship, will be the most satisfactory proof of identity you can bring." So said the Patent Office authorities, when a patentee, who had omitted to retain a copy of his provisional specification, applied for leave to refer to that document.

Photography plays an important part in the every-day routine of the Patent Office, as all drawings which accompany specifications are reproduced by photo-lithography, and the original sketches must consist of clean black lines on white paper (no colouring being allowed), so that reproduction may be easy. The Patent Department has had under consideration a scheme for reproducing the original manuscript of each specification in a similar way, as notable mistakes often occur in the printed specifications as at present issued. A manuscript reduced to one-sixth of the original linear measurement, or one thirty-sixth of the area, is generally quite legible.

The Penny Science Lectures at the Royal Victoria Music Hall are reported a success; but the lectures, it appears, must have sustained interest, otherwise the thirst for knowledge of a Waterloo Road audience gets quickly quenched. In the words of one of the committee: "Any breakdown of the apparatus, however temporary, places the success of the lecture in serious danger; there are stamps and whistles of impatience at any pause," when an experiment fails, or a pre-arranged explosion does not go off. For this reason lantern lectures, our committee-man thinks, are best adapted to the frequenters of the well-beloved "Vic." We would suggest the exhibition of photographic transparencies, which, from the size of the hall, might be projected most successfully by a powerful lantern; they would afford an advantageous means of instructing and interesting an audience of this kind.

The stereoscope is again under discussion. It is a long time since the memorable controversy between Sir Charles Wheatstone and Sir David Brewster anent its invention took place, a combat that resulted in a draw. Mr. W. le C. Stevens, who publishes his remarks on the subject in the Journal of the Franklin Institute, has now been engaged in investigating the theory of the stereoscope and binocular vision in general, and has set out the results of his research in a very interesting form.

The *Comptes Rendus*, the official organ of the French Academy, contained last month two photographic illustrations by Marey, reproduced by means of the similigravure process of M. Charles Petit. The pictures illustrate the recent research into animal mechanics undertaken by M. Marey with the aid of the camera.

The photographer, like the engineer, should always have a rule in his pocket; and if he carries the Chesterman coiled steel tape measure, he will be able to measure curves as easily as straight lines. He may also, like our friend Mr. W. K. Burton, use it as a seconds pendulum; it being merely necessary to draw the tape out to one metre, or a trifle over 39 inches, and hold the ring while the case is allowed to swing.

"The best pictures I ever produced were taken with a home-made camera, unsteady at every joint, and requiring three focussing cloths to keep light out." So writes one of the Pall Mall medallists in reference to our recent statement that care and judgment are more important than the possession of a first-class camera.

The *Practical Photographer*, published at St. Louis, has ceased to appear with the death of its editor, the late Mr.

Fitzgibbon. The number of photographic journals published in the United States is thus reduced to three—viz., *Anthony's Bulletin* and the *Photographic Times*, published in New York, and the well-known *Philadelphia Photographer*

The Edinburgh Photographic Society is trying an interesting experiment. The Society has decided on spending its money upon a presentation print to its members, and, as our readers are aware, photographers from all parts have been invited to send contributions to an exhibition in the Scotch capital which is now open. Certain awards will be made to the photographers whose pictures are chosen; but the choice will not rest with a judge or a jury. All members of the Society are to vote; they are asked to examine the pictures carefully and critically, and set down their verdict on a voting paper. The ultimate choice will then be determined by these papers. The experiment is a bold and novel one, and we shall be interested to hear how it succeeds.

Rumour tells us—with what truth we know not—that one of the prints selected by the Edinburgh Society is "Brambling," by Mr. Slingsby, of Lincoln, a picture now hanging on the walls at Pall Mall.

Mr. Muybridge has printed his clever "animals in motion" on paper strips for the Zoetrope, so that it is now within the power of any one interested in the subject to test the truthfulness of the quaint attitudes by looking at them as a whole. A Zoetrope is a most simple instrument to construct—indeed, Mr. Muybridge gives explicit directions on the strips in question—and if his pictures in motion appear therein as interesting and amusing as in the lantern, there is little doubt about them becoming popular.

"How to Photograph Groups on the Stoop," is the title of a recent paper by Mr. J. T. Taylor. He does not instruct the photographer, however, how he may "stoop to conquer," nor does he advocate the photographing of models grouped in a bowed posture; the "stoop" Mr. Taylor refers to is the front door-step of New York houses, where it is the fashion to congregate on summer evenings, something after the manner of a "five o'clock tea" in the old country. Mr. Taylor aptly suggests the making of "stoop" pictures.

Alphonse Karr, in his charming book entitled *Promenades hors de mon Jardin*, makes the suggestion that coins of the country should bear upon their face other likenesses than that of the Sovereign. It is very well, no doubt, that the date of reign of king or queen should be perpetuated by this means, but it would be possible, argues Alphonse Karr, to employ our money to perpetuate the memory of other great people as well. For example, he says, if during the present century coins had been produced with images upon them of Daguerre, Balzac, and Victor Hugo, there would be evidence in time to come of the date when these great men lived.

The suggestion is well worth repeating, and if at any subsequent period the advice of Alphonse Karr is taken, it is within the bounds of possibility that the image on the coins in question will be a photographic likeness. By making use of the Woodbury or gelatino-relief process, a portrait in bas-relief is obtainable without much difficulty, especially if the portrait happens to be a profile. Coins of this stamp, bearing photographic portraits in relief, would indeed be valuable.

Ruskin was referred to, not long ago, to decide upon the talent of a photographer. Our friend had heard it stated that the great art critic expressed himself in high terms of approbation over certain photographs emanating from the former's studio, declaring, indeed, that our friend was the best photographer in the world. Accordingly, Mr. Ruskin was written to, to ask if he really had said so, and whether he would object to repeating the opinion upon paper; whereon came a reply to the effect that Mr. Ruskin had no recollection of having said such a thing, but if he did, he would have no objection to repeating his opinion as soon as he had seen the work of the remaining photographers in the universe.

There is a reaction setting in in favour of slow plates and slow development. It is so rare that a very rapid exposure is necessary in every-day photography, that there is no call for "lightning" plates, in nine cases out of ten; the latter are, indeed, a positive disadvantage, several capable landscape photographers avow, and without arguing the question, point to their results, which are more successful with slow plates than with quick ones. There is no doubt about the advantages of slow development in landscape work—Russell Manners Gordon, Berkeley, Conway, Ireland, and other skilful landscapists, all uphold this teaching.

A Continental contemporary suggests the employment of whiting and water for rubbing over machinery that is to be photographed. Some treatment is necessary, of course, to obviate the glare of polished bearings, and to deaden the bright reflections, which become "solarised" long before the shadowed portions of a machine have been properly exposed. In Leeds and Manchester the photographing of machinery is now performed with excellent effect, and manufacturing engineers have their new machines depicted with the camera, in preference to sending round wood-cuts or engravings.

Under any circumstances, it is a difficult business to photograph a machine smoothly and effectively, and little success is likely to ensue unless the whole is first covered with a grey paint or wash. One of the best in use by photographers is the following :—

Dry white lead	5 pounds
Lamp black	2 to 5 ounces
Gold size	1 pint
Turpentine	$1\frac{1}{2}$,,

The amount of lamp black is varied according as a light grey or dark grey is best suited to the machine, or the lighting. The paint is quite harmless, and is easily removed with turpentine rubbed on with a handful of cotton waste.

Patent Intelligence.

Application for Letters Patent.

5086. Richard Brown and Robert William Barnes and Joseph Bell, all of the city of Liverpool, in the county of Lancaster, Photographers, for an invention of "Improvements in and relating to the production of printing surfaces from gelatine reliefs."—Dated 25th October, 1882.

Grants of Provisional Protection.

4747. Francis Joseph Emery, of Burslem, Staffordshire, Earthenware Manufacturer, for an invention of "Improvements in photographic engraving."—Dated 5th October, 1882.

Patents Granted in France.

148,215. Roosevelt, for "A direct process of obtaining photographs on zinc, copper, &c."—Dated 1st April, 1882. Class 17.

148,298. Lapre, of Paris, for "A pocket photographic match-case."—Dated 6th April, 1882. Class 17.

148,309. Hutinet, for an "Insulator for separating negatives obtained by the gelatinous bromo-silver process."—Dated 7th April, 1882. Class 17.

148,364. Magne, for "An autographic process and producing impressions with fat ink, whereby the original is converted into a matrix."—Dated 11th April, 1882. Class 17.

Patent Grantod in Belgium.

59,109. L. H. Phillippi, of Hamburg, for "Reproduction of drawings, wood-cuts, &c., on metal by photography."—Dated 25th September, 1882. Original Patent, 10th January, 1882.

Patents Granted in Germany.

23,160. H. Mikowetz and Co., of Vienna, for "A process for copying printed matter."—Dated 12th February, 1882. Class 15.

20,182. G. S. Street, of Moncton (Canada), for "A copying frame for photographs, prints, calking, and other processes."—Dated 21st May, 1882. Class 57.

20,183. O. Siepmann and O. Pustet, of Iserlohn, for "A photographic process for obtaining pictures of metal objects with their metallic lustre."—Dated 11th June, 1882. Class 57.

Patent Granted in America.

265,669. Hannibal Goodwin, of Newark, N.J., for "Phototypography."—Application filed 30th November, 1881. No specimens.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

A New Sensitizing Agent—Photography and the Suppression of Vice—Photographs in Natural Colours—Exhibition of the Manchester Society.

A New Sensitizing Agent.—The list of edible substances used in photography has recently been augmented. Beer, coffee, tea, hops, sugar, have all in their turn been pressed into service, while gelatine threatens to attain to a huge monopoly. The latest addition is somewhat of a novelty: it is nothing less than white pepper, of which use is made as a sensitizer. The advocate of the new pepper developer is Mr. R. T. Wall, of Longfleet, Poole, who has taken out a patent for his invention. According to the specification, we learn that the way to make the sensitizer is to take one pound weight of freshly-ground white pepper, and macerate it in one to two pints of ether or alcohol for some days, then press the tincture through one or more filtering media. In using, a little mastic varnish or oil of turpentine is added to the resultant solution if ether is employed, while spirit varnish is used when alcohol is the vehicle; and the resultant solution is spread over the surface to be sensitized and exposed in the usual way. This pepper sensitizer is also recommended for powdered pigments, which, cold or warm, may be brushed or dusted over the surface for the purpose of developing the image. Mr. Wall also makes an elastic medium for printing on uneven surfaces for gelatine, sugar, glycerine, chrome-alum, spirit, thymol, or boracic acid, or any preservative agent. A glass plate is prepared by gluing a strip of paper round the edge of the plate so as to form it into a dish; the mixture is poured into this dish, and left to set; a negative tissue is put over it, and it is placed on a dried pepper-sensitized surface, the developing being effected with the following solution:—

Water	4 ounces
Sugar	1 ounce
Gelatine	1 ,,
Glycerine	6 ounces
Thymol	some drops
Alcohol	½ ounce
Saturated chrome alum	some drops

We must confess that this pepper sensitizer stimulates our curiosity. It is, of course, impossible to say what substances are and are not sensitive to light; but no one would have suspected that so powerful an agent existed in the domestic cruet.

Photography and the Suppression of Vice.—It is not pleasant to find the following in the annual report just issued of the Society for the Suppression of Vice:—"There is, however, one phase of the traffic still existing, over which your Committee, unhappily, have ceased to have any control—namely, the exhibition in shop windows of nude photographic figures, and what purport to be reproductions of persons in theatrical costumes. Cases have been brought before the magistrates, but they have refused to interfere. The result has been construed into a license, so that it is now difficult to discriminate to what the alleged license extends. To risk a seizure and a prosecution is dangerous; a failure is fatal, as success on the part of the dealer would be quoted as a precedent, and advantage taken to exaggerate that license by still more indecent exhibitions." While there are many photographs exhibited in certain shops (happily few) which are coarse and vulgar, it is to be feared that the Society for the Suppression of Vice, in its extreme anxiety to protect public morals, cannot always be considered the best judge of what is really indecent. The report says: "Cases have been brought before the magistrates, but they have refused to interfere." Why? The report does not tell us, and we are therefore led to only one conclusion—that the magistrates did not agree with the Society in its estimate of the photographs seized. The whole matter can be reduced into a very small compass. Either the photographs were indecent and obscene, or they were not. If the magistrates considered they could be so characterised, then most certainly Lord Campbell's Act would apply; and why the Society should raise a false issue by remarking that the magistrates "refused to interfere," we fail to understand. Unfortunately, prudish people are the quickest to discover indecency where it does not exist; and they cannot recognise the fact that a nude figure artistic in conception may be absolutely pure, and a draped figure in its suggestiveness absolutely indecent. There are, it is sad to confess, some photographs so hideous that one shudders at the depth of depravity which can initiate such foulness; but these are quite outside the argument, and the more of such monstrosities the Society can destroy the better. But in respect to simply nude figures, we would prefer that they should be judged by an artist rather than by the well-meaning Society for the Suppression of Vice.

Photographs in Natural Colours.—The problem is solved—or, at least, nearly so. Mr. E. Berliner, of Boston, U.S., is the happy individual who has volunteered to put everybody on the right track. Mr. Berliner has found out that, after exposing a sensitive gelatine plate to several glass plates of different colours, each colour-strip, after washing, is distinguished by a certain thickness of remaining gelatine, We have no doubt that Mr. Woodbury has occasionally noticed this phenomenon, and possibly two, if not three, other photographers; but it has been left for Mr. Berliner to turn this important fact to account in the search for photographs in natural colours. Mr. Berliner says:— "Under the above facts the problem would be to compound or produce a substance which combines the power of a strongly-refracting crystal with the sensitiveness of a chrome gelatine plate. By exposing such a plate to coloured light, and afterwards washing it, the remainder, when viewed through a Nicol's prism or other polariser, should show certain colours which stand in certain relations to the original colours which acted on the plate." There it is—the whole secret in a nutshell! Here is a chance for anybody who wants to make a sensation during the ensuing season! Mr. Warnerke is generally ready to investigate any idea and improve upon it: will he kindly tackle the combination of a strongly-refracting crystallised sensitive chrome gelatine plate?

Exhibition of the Manchester Society.—It is gratifying to see the success which has attended the Exhibition of the Manchester Photographic Society. Though without the prestige of the annual Exhibition in Pall Mall, its receipts were two-thirds of the receipts of the latter last year. In proportion to the relative population of London and Manchester, this result must be considered exceedingly good, and indeed would go to show that more interest in photography is taken by the general public in the country than in London. It was certainly a bold step to incur expenses to the amount of £200 on the exhibition alone; but it cannot be said that the Society were deceived in the support which they received from the outside public. It is true there is a balance on the wrong side; but this, we presume, will be covered by the subscriptions. For many years the Exhibition of the Photographic Society of Great Britain was a terrible drag on the general funds; but lately its prospects have improved. Manchester, therefore, may well take courage, and hope that its next exhibition will more than pay its expenses

FRENCH CORRESPONDENCE.

LIEBERT VERSUS PIERRE PETIT—POCKET CAMERA—PROGRESS MADE IN ELECTRICITY.

Liebert versus *Petit.*—The action entered against Pierre Petit by M. Liebert has just been heard at the district court. It was a case of infringement of patent, which had been under discussion in the PHOTOGRAPHIC NEWS about two years ago. Pierre Petit had set up an electric light apparatus copied from Mr. Vander Weyde's, which is based on an effect of double reflection. The court decided that Liebert's demand was well founded, and fined Pierre Petit three thousand francs damages, forbidding him the use of this apparatus patented by Mr. Vander Weyde, and of which M. Liebert is proprietor for France. It was not, as was well put in the verdict, a question of monopolising the use of electric light, but employing, during the existence of the patent, an instrument constructed on the principle invented by Mr. Vander Weyde. We do not know whether an appeal will be made from this sentence.

New Pocket Camera.—We have had the opportunity of seeing at M. Marion's, in Paris, a small apparatus ingeniously constructed, known by the name of the Academy camera. Although it has several slight imperfections, the maker might easily remedy them to render it most conveniently portable. The plates are only four centimetres square, rather small to be of the highest value. Why are apparatus of this kind not always fitted with automatic action? It seems to us that it would answer the purpose better, and it has been adopted by M. Enjalbert in the construction of his photo-revolver, still unfinished.

Progress made in Electricity.—News has reached us from Munich that M. Marcel Déprez has made new progress in the transmission of motive power through iron wire. It is said that he has transmitted a force of forty-horse power through telegraph wires. If such is the case, we shall not be long before our streets will be traversed underground by an electric channel bringing us motive power and light. We hope that the photographic art will gain much by this great progress. LEON VIDAL.

SIMPLE METHOD OF MIXING SOLUTIONS FOR ALKALINE PYROGALLIC DEVELOPMENT.

BY J. KAY.

I TAKE a bottle of pyrogallic containing one ounce of the acid, and add 14 drams of methylated spirit, which gives a concentrated solution, and may be labelled "Stock Solution," and one, I find, that keeps much better than a solution I used for many months, which was made the proper strength in the first instance. For ordinary use I take 2 drams of stock solution and dilute with 6 drams of methylated spirit, and keep in a wide-mouth 3-ounce stoppered bottle. I find 1 ounce of this quite sufficient to have mixed at a time. I now have a solution which contains:—

Pyrogallic acid	1 ounce
Methylated spirit	7 ounces

or rather it would read thus if the whole bulk were so mixed.

If about to develop a half-plate, I take $\frac{1}{4}$ dram of this dilute solution and put into an ounce measure; or, rather, I have a $\frac{1}{4}$ dram marked on my ounce measure, and pour the pyrogallic direct in, as pouring a $\frac{1}{4}$ dram from one measure to another would not be a very profitable proceeding; I then add common water to make up 6 drams. The reason I use so small a quantity as $\frac{1}{4}$ dram of pyrogallic solution is, that it is advisable, in saving time and water, to employ as small a quantity of spirit as possible. The strength of this pyrogallic solution when diluted with water as above mentioned is $2\frac{2}{3}$ grains to the ounce, which I find to be very suitable for studio work. For the ammonia solution I take:—

Common water	80 ounces
Liquid ammonia ·880 s. g. ...	1 ounce
Bromide ammonium	6 drams

6 drams of this solution added to 6 drams of the pyrogallic solution is ample for developing a half-plate. I would strongly insist upon using a good proportion of bromide in the developer. It is a good preventive of green fog, beside giving clearness to the shadows of the picture, and brilliancy to the negative. In cases where plates have a decided tendency to fog, I use double the amount already stated. I am aware that rapidity is to some extent sacrificed by a free use of bromide, but with me rapidity is only a means to an end. The great end in view is a good negative; everything else must be subordinate to that.

Just a word, in conclusion, relative to the complaints which have lately appeared in the NEWS. Some of the writers have appeared annoyed by the misleading doctrines which are printed on the lables sent out with dry plates, by which photographers are led to expect dry plates ten, twenty, and even thirty times quicker than wet collodion. For my part I think their complaints are just. All that I can say about the doctrines themselves is, that they are misleading. The plates may be as described, but I take it the collodion must be about the colour of the ruby glass we are so familiar with now. To say that a dry plate is twenty times quicker than a good wet collodion plate is—well, I do not suppose anybody has found one yet in the market fifteen times quicker; as I told a dealer the other day, who was speaking about the twenties and the thirties of a well-known firm as innocently as you please, I had been seeking for the last eighteen months or more to find a plate that I could dub a tenner. I believe the most rapid plate in the market might be safely labelled six times quicker than a good wet collodion plate, and that, too, when developed with the smallest proportion of bromide possible; at any rate, if any of the numerous readers of the News have found anything more rapid, the Editor, as a personal friend, I am sure would oblige me with any particulars forwarded to him likely to put me on the right track to become possessed of such a boon. I am now using a batch of plates marked twenty times quicker than wet collodion, and I find that the maker would have been much nearer the mark had he omitted the cypher.

LABORATORY NOTES FOR THE PHOTOGRAPHER.

M. Campo publishes, in the *Bulletin* of the Belgian Association, a condensation of simple and practical methods furnished by chemistry for the examination of bodies, a work that may be of use to some of our readers.

All unknown substances whose nature is to be ascertained should be dissolved in water, or else brought to that soluble condition, generally by the help of some acid. A small portion of the solution, which is divided into three or four parts, is taken, diluted with water, and treated with a few drops of one or other reagent. These last ought also to be in the form of aqueous solutions. The acid or alkaline character of the solution, the odour, flavour, and density of the body to be examined, are important indications, the observation of which must not be neglected. The substances in use in photography are rarely of complex composition, and therefore the mode of operation is much simplified.

Sulphuric acid (and the sulphates in general) give, in solutions of chloride of calcium, a white precipitate soluble in hydrochloric acid; with acetate of lead, a white precipitate soluble in caustic potash; with all the barium salts, and notably the chloride, a white precipitate (work with a solution slightly acidulated with one drop of hydrochloric acid).

Hydrochloric acid (and the chlorides) give, with nitrate of silver, a white precipitate of chloride of silver insoluble in nitric acid.

Nitric acid stains the skin, wool, and silk, yellow. It colours (as do the nitrates) reddish-brown a mixture of sulphuric acid and sulphate of iron.

Hydrobromic acid (and the bromides) form a pale yellow precipitate in solutions of nitrate of silver; by adding a little chlorine water, and shaking it up with ether, this precipitate becomes reddish brown.

Hydriodic acid (and the iodides) form, with solutions of nitrate of silver, a rich yellow precipitate.

Acetic acid is easily recognisable from its characteristic odour.

Oxalic acid gives, in solutions of chloride of calcium, a white precipitate insoluble in acetic acid.

Tannin (tannic acid) gives, with the ferric salts, a black precipitate (common ink).

Pyrogallic acid may be known by its characteristic odour.

Salicylic acid gives, in solutions of oxides of iron, a deep violet precipitate.

Citric acid, boiled with an excess of lime water, gives a white precipitate. Upon the addition of nitrate of silver and ammonia it furnishes a white precipitate, which becomes re-dissolved in an excess of ammonia.

Tartaric acid gives, with chloride of calcium, a white precipitate in chloride of ammonium; with acetate of lead, a crystalline precipitate soluble in ammonia and nitric acid.

Potassium Salts.—Carbonate of potash, with an acid, causes a violent disengagement of carbonic acid, and in a solution of nitrate of silver a pale yellow precipitate of carbonate of silver, without giving off carbonic acid.

Bicarbonate of potash gives the same reactions as the preceding, only it disengages carbonic acid in nitrate of silver solutions.

Neutral oxalate of potash (neutral reaction) gives, in solutions of chloride of calcium, a white precipitate of oxalate of lime soluble in nitric acid.

Chlorate of potash gives, in solutions of nitrate of silver, a white precipitate, soluble in ammonia. Chlorates detonate when mixed with concentrated sulphuric acid.

Bromide of potassium. See hydrobromic acid.

Iodide of potassium. See hydriodic acid.

Cyanide of potassium may be recognized by its odour; it is very soluble in water, but slightly in alcohol, which precipitates it.

All potassium salts dissolved in water form a yellow precipitate in bichloride of platinum, and white in tartaric acid. They colour an alcohol flame lavender.

Sodium Salts give an intense yellow colour to an alcohol flame. They are very soluble, and precipitate white in potassium antimoniate.

Borax shows a feeble alkaline reaction; a bead of it heated in the presence of metallic oxides partakes of their respective colours.

Chloride of sodium (see hydrochloric acid). It decrepitates on the fire. Insoluble in pure alcohol.

Phosphate of soda is soluble in four times its bulk of water; forms with nitrate of silver a yellow precipitate, soluble in nitric acid.

Acetate of soda, when heated, gives off a strong odour of vinegar.

Ammoniacal Salts.—Fixed alkalies—such as potash, soda, and lime—evolve, even when cold, a gas which turns red litmus paper blue.

Barium salts colour a lamp flame green, and form yellow precipitates with chromate of potash.

Calcium salts (lime) form, with oxalic acid, insoluble white precipitates.

Magnesium salts give, with phosphate of soda, ammonia, carbonate of potash, or soda, white precipitates.

Iron Salts.—A. Ferrous salts—Chloride, oxide, sulphide, sulphate, and carbonate.

B. Ferric salts—Perchloride of iron, oxide, and sulphate.

A. The ferrous salts in solution are of a bluish green colour. Their taste is sweet, afterwards astringent, resembling that of ink. They form a blue precipitate by the ferricyanide of potassium (red prussiate).

B. The ferric salts are reddish yellow in solution, rough, and astringent. They form a deep blue precipitate with ferrocyanide of potassium (yellow prussiate), and red with sulphocyanide.

Silver Salts.—The chloride becomes violet in the light, and may be dissolved in ammonia and cyanide of potassium.

The bromide turns greenish yellow in the light, and is less soluble in ammonia.

The iodide is of a pale yellow colour; ammonia and cyanide render it quite white.

These three insoluble salts may be reduced to metallic silver in the presence of hydrochloric or sulphuric acid, and zinc or iron.

Nitrate of silver. See nitric acid.

Salts of Mercury.—Bichloride of mercury gives, with iodide of potassium, a red precipitate, highly soluble in an excess of iodide.

Salts of Gold.—Chloride of gold forms a purple precipitate in solutions of chloride of tin; also with sulphate of iron.

Salts of Copper.—Sulphate of copper shows a deep blue colour with ammonia, and gives a chestnut brown precipitate with ferrocyanide of potassium (yellow prussiate).

THE FOCUSSING OF COPYING LENSES.

When a lens is to be employed for copying purposes, a common custom prevails to secure the sharpest possible focus in the centre of the picture with the full aperture of the lens, and then to insert a small diaphragm with which to do the work required

With lenses of short focus it is immaterial in what way sharpness is obtained; but when the solar focus of the objective is of fifteen, twenty, or twenty-five inches, it is of consequence that special precautions be taken to obtain from the lens the best class of work it is capable of giving, and this cannot be done by the means indicated in the previous sentence.

Let a lens of large aperture and long focus be mounted on a camera having a ground glass so fine as to permit of a magnifying glass of a considerable degree of power being employed to aid in securing the utmost sharpness. It will, in many cases, be found that, after focussing very sharply, if a small diaphragm is then inserted, the image on the ground glass will not be so crisp as it is possible under the altered circumstances to make it; that, in order to give the image at its best, it will have to be racked out a little way—from an eighth to a quarter, or even a half inch—according to circumstances. It will also be found that when the sharpest focus when using the small diaphragm has been secured, if the diaphragm be then withdrawn, the image shown upon the ground glass will be out of focus in a very serious degree.

The foregoing represents the case as observed when focussing a view in nature. But this difference between sharpness with a diaphragm and sharpness without one is doubled when the lens is used for its legitimate purpose, that of copying; because a lens having a solar focus of twenty inches has that focus increased to forty inches when used in making a copy the same size as the original, and the distance between the two planes of greatest sharpness must be multiplied by two to show what it amounts to.

We could have given a diagram showing the optical reason for this discrepancy, and indicating the path traversed by a ray upon entering and passing through a lens, but we do not judge it to be necessary at present, preferring to confine our remarks to a simple answering of the question, "How should the focus be obtained?"

Let all the arrangements and general adjustments be made with the full aperture of the lens, on account of the facility afforded by the greater amount of light for doing so. Then insert the diaphragm by which the work is to be done, and complete the focussing by the aid of a magnifying glass. Should the amount of light transmitted by the small or working diaphragm prove to be too little to enable the focussing to be easily effected, then make use of a diaphragm one size larger for this purpose, because the difference effected in locating the precise position of the focussing plane by the substitution of a small diaphragm for one that is but one size larger is practically nothing.—*Photographic Times*.

Correspondence.

FOG IN GELATINE PLATES.

Sir,—Having read the discussion in your columns about fog, I venture, although quite a beginner, to trouble you with a few remarks on the subject. I have noticed in emulsion prepared by myself that, besides appearing when there is excess of nitrate, or when the nitrate of silver is brought too suddenly in contact with the solution of gelatine or bromide, plates freshly made gave fog in those places which were not thoroughly dry before exposure.

I have lately made an emulsion, carefully following the formula recently published by Mr. Henderson, which gives very good results quite free from fog. All my experiments have been made with the same gelatine, so I have reason to think that the cause of fog is more likely to be found in the mode of preparation and in want of care in developing and fixing than in the gelatine itself. Prevention is better than cure, and I believe that, in using care in the preparation of the emulsion or developing, and fixing with the least light possible, fog may, in nine cases out of ten, be avoided.

A propos of Mr. Henderson's formula, how would it answer if, instead of stirring the alcohol into the emulsion, the emulsion were gently filtered into the alcohol? It seems to me that by the latter system the precipitated emulsion would be much more finely divided, and washing thus rendered more perfect and easy.

As regards Pyrogallic *v.* Iron development, are your readers acquainted with M. Chardon's formula?—

Water	... 100 c. c.
Oxalate of potass. ...	... 20 grammes
Lactate of iron	... 10 ,,
Bromide potass. ...	... 0.10 ,,

which I find excellent.—I remain, sir, yours respectfully,
C. H. Goodall.

DEFENCE ASSOCIATION.

Dear Sir,—Allow me, through the medium of your columns, to thank the several gentlemen who have communicated with me upon the above subject. It certainly appears that such an institution is both required and desired. I hope to be able to arrange a meeting at an early date after the issue of next week's News, at which I shall be glad to see any gentleman interested in the subject. It would, perhaps, be better to defer any proposal as to future action till such meeting assemble. Meanwhile I have written to a gentleman well known in photographic circles asking him to preside.—Faithfully yours,
W. E. Downey.

PHOTOGRAPHIC NUISANCES.

Sir,—I have read with interest the letters on "Photographic Nuisances" in your journal. As I am residing abroad I have not received your paper for some days, or I should have sent some remarks on this subject earlier. Since I came to Italy I have had plates from several well-known English makers. Some have been good, others quite useless from thin or spotty films. With two of these makers I have remonstrated. Their cry is that the fault must be in my wrong development of their plates; and this after I have been using many of their plates successfully for several years past, and they have been advertising my name in your paper as testifying to the value of their plates. A year ago I was speaking on this subject to a former member of Council of the Parent Society, and he said, "Oh! the dry-plate makers will be sure to say you do not know how to develop their plates." It is a good idea to use the name of an experienced dry-plate worker as a testimony to the value of commercial plates, and then, when he says some of the plates sent him are bad, to turn round and say he knows nothing about their development. I have a letter now by me from a well-known member of the present Council, and he writes as follows:—"I have many samples of plates constantly sent me to try, but (for obvious reasons) I never have any bad ones sent me." He also says that he is aware that bad plates are at times sent out, even by makers with the best reputation; that when they have made a name they often get careless. A professional photographer from Wales lately wrote me his belief that the amateurs and smaller professionals get the bad and doubtful plates, and the larger professionals get the good ones. This is probably true to a great extent. I have been, however, able this year to get very good plates for iron development made in Italy; I have found all I have used (several dozen) excellent.—
Yours, &c., A Dry-Plate Photographer.

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of the above Association, held at the Masons' Hall Tavern on Thursday, October 26th, Mr. C. H. Searle in the chair,

Mr. C. G. Collins presented a very handsome ballot-box to the Association, for which a hearty vote of thanks was passed to him, and it was resolved that a tablet should be engraved and fastened in the box, recording the gift and the date thereof.

Mr. Henderson passed round two tubes containing portions of a 20-grain solution of gelatine, containing in the one case silver, and in the other the bromide, to which their respective equivalents of silver and bromide had been added on the top; after 24 hours, in the tube containing the silver in solution above the gelatine, scarcely any bromide was formed, while in the other tube a layer of bromide ¼-inch thick had formed; but after two days the action in the first tube increased in rapidity till it passed the other, and at the end of three days about half the bromide was converted. The gelatine containing the silver remained perfectly colourless till it began to set, when it became opaque, and almost like an emulsion. This he attributed to impurities in the gelatine, possibly a carbonate, and suggested that it would be interesting to know if the bottom portion would again become clear on heating; this was tried, and it was found it did not clear.

Mr. Prestwich enquired what advantage was expected from this method.

Mr. Henderson said that much more silver could be got into a given quantity of gelatine than by the usual methods.

Mr. Prestwich had tried a somewhat similar method, but had not been quite successful; he had made his experiments in a flat dish, and after 1½ days the silver was not all converted; the following was the formula used:—

No. 1.—Ammonia nitrate of silver	...	100 grains
Alcohol	...	2 ounces
Water	...	1 ounce
No. 2.—Gelatine	...	120 grains
Water	...	3 ounces
No. 3.—Bromide ammonium	...	66 grains
Iodide "	...	1 grain
Chloride of ammonia	...	2 grains
Water	...	2 ounces

This would have succeeded better with a softer gelatine.

Mr. Prestwich said it had been suggested to him by Mr. Drosser that it would be advantageous to treat pyro. developed negatives with a solution of 1 ounce sulphuric acid to 1 quart of water; he had tested and found it removed all pyro stains, leaving the negative with all the qualities of a ferrous oxalate developed plate, and much like a collodion negative.

Mr. Coles showed two negatives, both supposed to have received the same exposure; one was developed with caustic potash, the other with ammonia, the first appearing much more exposed than the other. He also showed a series of transparencies from one negative, each receiving the same exposure, and intensified according to various formulas, viz., Wilkinson's platinum and mercury; Dr. Eder's carried to stage, where it commenced to reduce; Edwards' with hypo.; Edwards' followed by Schlippe's salt; and the formula given by Mr. Hart at the last meeting. The result was in favour of the Schlippe's salt, or Mr. Hart's method.

Mr. Henderson said a large plate manufacturer had attributed green fog to impurities in the bromide, and he had experimented with a sample of bromide known to give green fog, samples of which he now passed to several members, and asked them to report thereon.

Liverpool Amateur Photographic Association.

The usual monthly meeting of this Association was held on Thursday evening, the 27th ult., the President, Mr. E. Roberts, in the chair. The minutes of the September meeting having been read and confirmed, Mr. H. Williams was elected a member of the Society.

The Hon. Secretary laid upon the table a copy of the report of the Geological Society's Proceedings for the past year, which had been obligingly sent by the Hon. Secretary of that society.

A letter from Mr. E. Cocking was then read, enclosing a number of tickets for the Photographic Exhibition in London. When these had been distributed among the members, the Chairman proposed a cordial vote of thanks to the President and officers of the Photographic Society of Great Britain for their kindness and courtesy.

Mr. J. Y. McLellan then exhibited the new "eclipse" light. The apparatus is very compact and ingenious, and enables a small coil of magnesium wire to be burnt in oxygen. The result is an intense light, which permits of a portrait or group being taken in a single second. Mr. McLellan first showed the effect of burning the wire in a mixture of half air and half oxygen, and then in oxygen alone. The brilliancy of the latter light was exceedingly great, and it was noticed that there were no unpleasantly strong contrasts of light and shade upon the faces in the room, but that the half-tones were present to a satisfactory extent. Mr. McLellan answered fully all questions put to him, and gave an account of the simple apparatus for producing his supplies of oxygen.

The Chairman cordially thanked Mr. McLellan for his very interesting demonstration, and made an amusing reference to the last display of a similar kind in that room, when the Hon. Secretary burnt a pyrotechnic compound in a lantern of his invention, and endeavoured to get rid of the smoke evolved by means of a huge chamber constructed of piled-up band-boxes.

Mr. W. Atkins passed round a number of very beautiful calotype negatives by the late Mr. J. Cooke, taken by him some twenty-five years ago. The negatives were exceedingly fine specimens of the process, and were greatly admired.

Mr. J. T. Corkhill said that recently he had found a number of valuable negatives, which were unvarnished, much stained by silver markings caused in the printing, and asked for information as to the best way of remedying the evil.

The Rev. H. J. Palmer recommended a strong solution of hyposulphite as the only means of removing such stains.

Mr. H. N. Atkins gave a demonstration of the platinotype process, explaining fully the very simple operations of developing and fixing the prints. Mr. Atkins' prints were beautiful specimens of photographic art, and his demonstration was as successful as it was instructive.

The Chairman expressed, on behalf of the members present, the great pleasure with which he had watched Mr. Atkins develop these beautiful little pictures by the platinotype process, and the hearty thanks of the Society for his very useful and interesting demonstration.

Mr. H. N. Atkins exhibited a new instantaneous exposure of his own invention and manufacture.

Mr. Schenkenhofer exhibited and explained his clever and useful apparatus for toning and fixing silver prints.

The Chairman, in proposing a vote of thanks to Mr. Schenkenhofer, said that he was quite sure every member present had been greatly interested and instructed at the sight of this apparatus.

The Chairman announced that Mr. Ellerbeck's "at homes," at No. 7, The Elms, Peel Street, The Dingle, would be held on the second and fourth Tuesdays in each month until further notice.

The Hon. Secretary suggested that an annual report of the proceedings of the Society should be published, to contain the rules, full report of proceedings, papers, and demonstrations of the past year, together with the list of the names and addresses of the members of the Association.

Mr. Twigge advised that an estimate of the expense should first be obtained.

Mr. Macindoe thought that the experiment should be made for one year, at all events, and embodied the Hon. Secretary's suggestion in a formal resolution, which was seconded by Mr. R. Crowe.

Mr. W. H. Kirkby proposed, as an amendment, that a report be published annually, but that it should simply contain the annual report, the rules, and the list of members.

Mr. Ellerbeck seconded the amendment.

After some discussion, it was agreed to postpone the discussion till the next meeting, and both resolution and amendment were withdrawn.

Mr. Ellerbeck thought it would be very desirable that all exhibits at the coming Associated Soirée should be notified to the Secretary in time to be inserted in the catalogue of the contents of St. George's Hall.

Dr. Kenyon exhibited a micro-photograph of a section of rock, taken by polarised light. He had used a common paraffine lamp, and the exposure had been only twenty minutes. He thought this method of obtaining micro-photographs preferable to that by sunlight, since the latter involved danger to the lenses employed. He added that he had used a condenser and also a mirror to produce the picture in question. The rock was a specimen of felspathic porphyry, and the plate used was one of Rouch's.

Mr. Kirkby exhibited some fine prints in platinotype; Mr. Ellerbeck, some equally good specimens of his work at Wells and Glastonbury, in silver; Mr. Corkhill some good instantaneous river scenes; and Mr. Boan a new portable lamp for the dark room.

The meeting was then adjourned.

Talk in the Studio.

A Course of Thirty Lectures in London on Photography.—We are pleased to be able to inform our readers that Mr. E. H. Farmer, of the Chemical Department in Dulwich College, will shortly commence a comprehensive course of lectures on photography at the Polytechnic, it being arranged for the first to be delivered on the evening of Nov. 11th. As assistants, and those connected professionally with photography, will be admitted to the course of lectures for the nominal fee of 6s., it is expected that there will be a large attendance. We gather the following particulars from a preliminary notice which has just been issued:—A course of thirty evening lectures on photography (in connection with the City and Guilds Institute) will be delivered by Mr. E. Howard Farmer (Demonstrator of Chemistry, Dulwich College, and Demonstrator of Natural Philosophy, St. Mark's College) at the Polytechnic Institute, 309, Regent Street, W. The lectures will be of a thoroughly practical character, and such as to enable students to obtain technological certificates of efficiency from the Guilds Institute. The City Guilds also offer the following prizes:—Honours Grade—1st prize, £5 and a silver medal; 2nd prize, £5 and a bronze medal. Pass Grade—1st prize, £3 and a silver medal; 2nd prize, £3 and a bronze medal; 3rd prize, £2 and a bronze medal; 4th prize, £1 and a bronze medal; 5th prize, a bronze medal. Fee to persons connected with the profession, 6s. per session of seven months; fee to amateurs and others, one guinea per half session. The following is a rough syllabus of Mr. Farmer's course:—"Preparation and Properties of Pyroxyline and Collodion"; "The Principles and Practice of Daguerreotype, Calotype, and Wet Collodion Work"; "The Gelatine and Collodion Emulsion Processes"; "The Theory and Practice of Development by Various Methods"; "Printing in Silver, and other Metals"; "Printing in Carbon, Woodburytype, and Photo-Engraving"; "Applications of Photography to Typography, Lithography, &c."; "Application of Photography to Scientific Purposes"; "Principles Involved in the Construction of Portrait and Landscape Lenses, Cameras, and other Apparatus in ordinary use by photographers." Application for tickets should be made at once to Mr. Robert Mitchell, at the Polytechnic Institute, and of whom all particulars can be obtained.

Liverpool Science and Art Classes.—On the occasion of the distribution of prizes on the 19th ult. by Professor Abel, C.B., F.R.S., a report was made of the students who had studied photography, among other subjects. Eighteen students, it appeared, had received instruction in photography, of whom seven went up for examination. Of these, one passed first-class (Mr. Harry Hinchcliffe), who took the President's prize, and four passed in the second-class, viz., Mr. Arthur John Banks (who took a full technological certificate), Francis Caldwell, William Seldon Ramsou, and Augustus Rainger. The class for photography meets on Tuesdays, at 8 p.m., at 9, Hackin's Hey, Liverpool, and is conducted by Mr. Edwin Banks. It is intended for those engaged in photographic establishments, and for amateurs. The instruction comprises a description of the chemicals employed, their manipulation, impurities, modes of preparing them for use, and manner of employing them in photography. The construction and use of cameras and other apparatus are explained, as well as the theory and practice of photographic work generally, not forgetting the application of photography to astronomical and microscopic purposes. The students are afforded opportunity for practical work.

Lost Property.—A correspondent asks us to find a corner for the under-mentioned information, which may lead to the owner getting his own again. On October 1st, there was found in Ashtead Churchyard a set of Waterhouse diaphragms for a large Ross' lens, either 10 by 12, or whole-plate, with Ross' name on inside of case; some of the stops had been re-varnished. May be obtained of Mr. Lisney, blacksmith, Leatherhead.

Royalty at Leicester.—On the occasion of the visit of the Prince and Princess of Wales to Leicester, on the 29th of May last, Mr. F. W. Broadhead, photographic artist, Welford Road, forwarded for their Royal Highnesses' acceptance a very handsome album, containing eight panoramic views of Leicester (forming a complete set) taken from the tower of the municipal buildings, and twenty-four other photographic views of the town. The views were mounted on blue silk, and bound in blue morocco, forming a very handsome volume. By some mischance the acknowledgment of the present was delayed until last week, when Mr. Broadhead received a letter from General Knollys, apologising for the delay, and stating that their Royal Highnesses had been very happy to accept the album.

Salicylic Acid for Preserving Eggs.—Referring to a recent article on the preservation of eggs, our correspondent Mr. M. P. Baumann, of Pittsburg, Pa., gives the following method which in his hands works to perfection. Having filled a clean keg or barrel with fresh eggs, he covers the eggs with cold salicylic water. The eggs must be kept down by a few small boards floating on the water, and the whole covered with cloth to keep out dust. If set in a cool place, the eggs so packed will keep fresh for months, but they must be used as soon as they are taken out of the brine. To make the salicylic solution, dissolve salicylic acid (which costs about 3.00 dols. a pound) in boiling water, one tablespoonful of acid to the gallon. It is not necessary to boil all the water, as the acid will dissolve in a less quantity, and the rest may be added to the solution cold. The solution or brine should at no time come in contact with any metal. In a clean, airy cellar, one brine is sufficient for three months or more, otherwise it should be renewed oftener. For that purpose the kegs, &c., should be provided with a wooden spigot to draw off the liquid and replenish the vessel. Butter kneaded in the same solution, and packed tight in clean stone jars, will keep fresh the whole winter, but must be covered with muslin saturated in the water, renewing it sometimes. Cover the jars with blotting-paper saturated with glycerine. Salicylic acid is harmless, and yet one of the best and certainly most pleasant disinfectants in existence, with no colour, smell, or taste. The water is an excellent toothwash, and the best gargle to prevent diphtheritic contagion.—*Scientific American.*

A New Photo-Electric Battery.—A new battery, which gives a current on exposure to the action of light, has been devised by M. Saur. It consists of a square glass vessel, containing a solution of 15 parts common salt and 7 parts sulphate of copper in 106 of water. A porous vessel of mercury is placed in the solution. An electrode of platinum is in the mercury, and another of sulphuret of silver in the saline solution. The electrodes are connected by means of a galvanometer, and the battery is fixed in a box sheltered from light. The closing of the circuit displaces the needle of the galvanometer, and it is seen that the sulphuret of silver is the negative pole. When the needle has come to rest, if the battery is exposed to the light of the sun the deviation increases. If the light is suppressed, the needle returns to its original position; if a cloud passes before the sun while the battery is exposed to the light, the variations of the needle indicate the fluctuations of the electric current. The effect of the battery is due to the action on the mercury of the bichloride of copper formed by the mixture of common salt and sulphate of copper. The protochloride of copper which is formed reduces the sulphuret of silver; but this reduction requires the intervention of the solar light, which determines the production of the photo-electric current.—*Les Mondes.*

To Correspondents.

⁂ We cannot undertake to return rejected communications.

Henry Spink.—1. Between five and six ounces. 2. The full heat obtainable when the water boils; perhaps it might be between 94° and 96° centigrade. 3. Sometimes from minute projections on the glass plates.

J. H.—Certainly; but only after a second treatment with nitric acid.

C. J. Hyne.—Perhaps twopence may be taken as a minimum, but in the case of a highly-salted paper, as much as threepence worth of silver may be taken up by each sheet. Only by stretching every sheet; but this would probably be out of the question.

W. E. E.—You can obtain provisional protection for six months at a cost of £5 for the stamp, and about 10s. for stationery, &c. Notice to proceed must be given within four months from time of lodging the Provisional Specification. If you employ a London agent to arrange the business for you, the expense will be a little greater.

J. L. Sanford.—We cannot tell you the cost, but you will no doubt obtain full particulars by writing to Messrs. Marion and Co., of 22, Soho Square.

Carte.—1. A trace of the encaustic paste referred to in the Formulary. 2. We do not know which number you refer to. 3. All depends on the hardness of the film and its thickness; but, in ordinary cases, half-an-hour with (say) six changes. Set the plate on its edge in the water.

E. A. Maxwell.—1.—You should obtain a good light provided that the battery is satisfactorily put together, and in good working trim. One principal difficulty with the bichromate battery is maintaining the connections with the carbon plates in good order, as chrome alum tends to crystallise between the carbon and the metal. Why not convert your bichromate cells into Bunsen's? 2. From what we have seen, we are inclined to think that it will prove of real practical value; but we have not made an actual trial ourselves. You could probably obtain one on trial, and should you do so, we would be obliged by your letting us know the result.

Enquirer.—1. The paper or film being damp, nitrate of silver diffuses into the collodion, and causes the dark stain. Always varnish your negatives, and print on dry paper. 2. No alteration is required; but cameras specially constructed for out-door work as ordinarily made as light as possible, and are usually provided with several dark slides. In order to economise space, these slides are made double, or like two usual dark slides joined back to back. 3. In the present state of affairs, it is difficult to say; but we think the latter will require less after-treatment. 4. Only by carefully watching the operation, and removing them at the right time—experience and observation alone help here. 5. It is, as you suppose, merely trade puff, and you will be able to do the same with ordinary gelatine plates. Obtain a couple of dozen from any recognized maker, and work with your present apparatus, letting us know if any difficulty arises. 6. You will probably meet with one for about £15 by advertising in the News; but to erect one yourself would cost about double. You will find several sketches in Pritchard's "Studies of Europe," should you possess a copy. The first edition is, however, exhausted, and the work will not be reprinted till next year.

Hypo.—Hard places or knots in the paper.

J. H. F.—We wish you every success, and shall be glad to hear how you get on.

Hobgoblin.—Notwithstanding your conviction to the contrary, we have but little doubt that the particles arise from the presence of hyposulphite. Review all your operations carefully; keeping a good look-out for any manipulation capable of carrying traces of hyposulphate to the prints during the earlier stages of the work.

M. Hughes.—1. Considering that parts are given throughout, there should neither be doubt nor confusion. You may work with grains, drachams, ounces, or any other weight as the unit. 2. Probably about 8 or 9 degrees higher. 3. A spirit lamp should answer very well.

Enquirer (Sunderland).—1. The former contains oxygen, while the latter does not. Chloride of lime is what you require. 2. Boil it with water in a glass flask.

W. M. P.—You evidently require a comprehensive treatise on the reduction of gold and silver residues; but all of the information you require is to be found in the Year-Books and volumes of the News.

J. H.—1. From any dealer in scientific apparatus. 2. Rather for the show-case, or for lighting up special pictures, than for lighting up windows and reception room. If you wish to go in for it on a larger scale, you had better use a small gas engine, and a dynamo machine. To provide for twelve fifteen-candle lamps would involve an outlay of about £120.

Enquirer (Henley-on-Thames).—1. Its principal use is to remove sulphates. 2. You had better make a fresh bath, as the existing one has failed.

T. Biddle.—They appear to us like silver stains, such as result from the use of damp sensitive paper.

W. W. R. and Co.—We have carefully re-read our notice, and we cannot agree with you. Which statement is incorrect? Only one feature was alluded to; if this is not common to both instruments, we will willingly afford opportunity for explanation.

E. Williams.—A letter awaits you at this office, if you will forward your address.

Captain Turton.—See above. We have not a copy of "rules" nor list of members; Mr. Cocking (the Assistant Secretary), 57, Queen's Road, Peckham, would send them on application. Our Publishers have noted your address.

Lydia.—1. By all means begin with the gelatino-bromide process, and we would recommend you to make your first experiments with the ferrous oxalate developer. 2. A cheap quarter-plate camera and French-view lens will answer very well to begin with, but you are likely to shortly outgrow this apparatus, or to give up photography altogether.

*** Authors may have Reprints of their Articles at 3s. per page per hundred copies; but the order must be given when the proof is returned.

PHOTOGRAPHS REGISTERED.

Mr. Biggs (Enfield)—Photo. of St. Magdalen Church, Enfield.
Messrs. Adams and Stilliard (Southampton)—Group of Members of British Association.
Mr. W. Wardell (Bradford)—Photo. of Lister Park Arch.
Mr. W. G. Honey (Devizes)—Two Photos. of Donkeys. One of Boy and a Turkey. One of Girl and a Turkey.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ¾ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 2 parts, citric acid 1 part, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ¼-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ¾ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1½ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz.; dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

Vol. XXVI. No. 1262.—*November* 10, 1882.

CONTENTS.

EDINBURGH PHOTOGRAPHIC COMPETITION.

The Edinburgh Photographic Society is to be heartily congratulated on the success which has attended their recent competition. Our readers are aware that some months ago the Society decided upon instituting an exhibition which should serve the two-fold purpose of bringing together in Edinburgh the works of the best photographers from various parts of the world, and of placing the Society in a position to choose for themselves a presentation print from among the collection. Accordingly invitations were sent not only to all parts of Great Britain, but to France and Germany, and, to induce co-operation on the part of photographers, a series of medals and money prizes were offered.

There was no novelty in the matter so far, but for the purpose of judging the pictures as fairly as may be, the Edinburgh Society proceeded on a plan which, for its originality, no less than for its impartiality, is much to be commended. As the principal reason for the exhibition was to provide a presentation print for the members of the Society, it was left entirely to the members to choose for themselves. The names of the exhibitors were maintained a secret, as much as possible, by a select company of hangers, who merely designated the frames with numbers; each member of the Society was then provided with a ballot-paper, and invited to inspect and examine the pictures for himself, the instruction being to set down which picture or pictures he preferred. The ballot paper had five spaces, specified as 1, 2, 3, 4, 5, and as five awards were to be made, every member put down five pictures in his ballot-paper in the order of merit. The exhibit, or rather its number, he liked best was filled into space No. 1, the second best into space No. 2, and so on; and the papers being collected, the votes were counted, and the awards duly given in accordance with them.

The members of the Society appear to have taken great interest in the matter, for no less than 461 voted. And now comes a very interesting fact. As many as 332 of these gentlemen voted for the pictures mentioned in the first space, or, in other words, only 129 votes in all went to pictures other than those selected as of first rank. There was consequently a singular amount of unanimity, and ample proof that the members went about the voting with much care and discrimination. Again, the picture that secured the highest award, viz., the gold medal, did not win by a narrow majority, but by an almost universal vote. One of our Edinburgh friends is kind enough to send us an analysis of the voting, of which the fortunate gold medallist ought indeed to be proud.

The winning picture is No. 104, and the statement of the scrutineers shows

Highest number of votes in space 1 given to No. 104
Ditto, ditto, in spaces 1 and 2 ,, ,,
Ditto, ditto, in spaces 1, 2, and 3 ,, ,,
Ditto, ditto, in spaces 1, 2, 3, and 4 ,, ,,
Ditto, ditto, in spaces 1, 2, 3, 4, and 5 ,, ,,

"Could anything be more emphatic?" writes our Edinburgh correspondent, radiantly.

The picture No. 104, we have much pleasure in announcing, is by Mr. H. P. Robinson, of Tunbridge Wells, with the title "Will They Never Come?" who thus adds one more to the many gold medals he has already gained. Says our correspondent: "Now although a few of us were pretty sure as to the author of the picture, yet, in a Society composed as ours is, *only* a few would be able to distinguish it, and even those few were most amusingly deceived by crediting Mr. Robinson with three others." Thus Mr. Robinson wins the gold medal with the only picture he sent.

The second name on the roll is one who is indeed deserving of honour—Mr. Robert Faulkner. Mr. Faulkner secures the silver medal with, says our correspondent, "'Phyllis Frere,' a charming full-length study of a child." Mr. Robert Slingsby's 'Brambling' comes in also for an award, as we hinted last week. Mr. Pellat is another fortunate competitor; and last, but not least, Mr. Adam Diston secures a prize with his picture of 'Gloamin.'"

We hope the example set by the Edinburgh Photographic Society will be followed, if not in its entirety, at any rate in principle. The mode of adjudging the awards seems to have given exceeding satisfaction to our friends north of the Tweed, and it is certainly, from the members' point of view, one of the most satisfactory and impartial modes of proceeding. No doubt, after their experience, the committee of the Edinburgh Society will be able to suggest further improvements of the plan; and we hope that, in any case, they will give the photographic public the benefit of any teachings which the recent competition may have afforded.

CHEMIGRAPHIC ENGRAVING.

It has often been remarked that when the photographer attempts to work photo-mechanical methods, he generally fails, and his failures arise more on the side of those special operations which rather belong to the printer than to the photographer. Let us take, for example, the case of photography; satisfactory success being generally attained as far as the production of the negative, and the fatty transfer are concerned, but when the transfer is laid on the stone, the troubles commence. As a matter of fact, printers have hitherto been more successful in adding photography to their resources than photographers in adding printing, and the reason of this is perhaps to be found in the circumstance that photographers generally under-estimate the amount of care, thought, and judgment which are absolutely necessary for success in such certain printing operations, as, for example, the inking of a lithographic image or a similar fatty device when transferred to a zinc plate.

As having a special bearing on this question, as bearing on certain processes of chemical engraving, we have much pleasure in welcoming the advent of a small manual on the subject of chemigraphy, or chemical engraving, this work being from the pen of Herr W. J. Toifel, a recognised authority in Germany.*

The primary idea of the chemigraphic process is the production of relief printing-blocks by dissolving away the bare metal round about a fatty impression on a zinc or metal plate, the fatty impression being produced by photographic or other means; but the term chemigraphy, or chemical engraving, may be, and is, used in a more comprehensive sense, as indicating chemico-mechanical methods of printing in general.

The various chemigraphic processes have often been referred to in the Photographic News, and certain details have been given from time to time, when we have had occasion to describe the various phototypic processes (most of which include chemigraphic engraving); but we now propose to gather from Herr Toifel's work such details as should enable any photographer who may give careful attention to the subject, to succeed in those branches of the work which differ most widely from his every-day practice.

Let us suppose that the photographer has obtained a photo-lithographic transfer by any one of the processes which have been fully described in the Photographic News from time to time, and that he desires to transfer the fatty image to a zinc plate, and etch this so as to leave the lines in sufficient relief to produce a printing block suitable for the ordinary typographic press. We may safely assume that unless the photographer is also a printer, careful study will be required to enable him to successfully deal with materials widely different in their nature from those used in his ordinary photographic practice, and to take cognisance of the varying circumstances which necessitate divergence from the usual proceeding. Still a photographic training is an admirable preliminary to the study of chemigraphic engraving; and there is sufficient general analogy between the two classes of work to warrant one in coming to the conclusion that a person who has successfully overcome the difficulties of one may be sure to succeed with the other if the attempt be fairly made.

The first matter is to provide suitable zinc plates, and as these may be purchased already planished from the lithographic material dealers, the beginner need not of necessity go through the somewhat tedious routine of surfacing and preparing his own; but as it is very desirable that he should at least qualify himself to deal with the process from the commencement, we will give brief directions regarding the point in question.

Zinc plates about an eighth of an inch thick are adapted for the general run of work, and those that are entirely free from hollow places, scales, or vein-like markings or flaws of any kind should be selected. The plates can easily be cut to the required size by laying a steel straight-edge in the direction of the required cut, and ruling repeatedly in the same place with a pointed steel tool, so as to plough out a series of fine shaving. When the metal is cut nearly half-way through, the plate is turned over, and the operation is repeated on the other side until it becomes easy to break the plate by a slight bending to and fro. The edges and corners having now been smoothed down a little by means of a file, a small hole is drilled at each corner, and the plate is fastened down to the bench by four small wire nails, the best face being upwards. The next step is to scrape or planish the surface with a broad steel scraper, the cutting edge of which is ground to a right angle, care being taken that all the cuts are in the same direction, or parallel with each other. The best way is to planish by drawing the scraper towards onesself, and it should be inclined forwards at an angle of about 20° with the perpendicular. When a uniform surface of bright and clear metal has been laid bare, the plate is unfastened, turned round a quarter of a circle, and re-pinned to the bench, after which the planishing is repeated in a direction at right angles to the first operation. This having been done, the plate is polished with emery cloth; a rather coarse grade, say No. 1½ or No. 1 being suitable for use in the first instance, after which, No. 0 or 00 should be employed. The emery cloth should be wrapped over a cork rubber about three inches square, and fresh cloth should be taken as soon as the grain becomes clogged by fine particles of zinc. The final cleansing of the plate is effected by rubbing it with a mixture of whiting and spirit, and polishing off all traces of this by means of clean blotting-paper. All is now ready for impressing the photographic image on the prepared zinc plate, and for this purpose a lithographic press is required; those generally used in this country being scraper presses. A sufficiently large lithographic stone is laid on the bed of the press, and the scraper is so adjusted as to give a moderate pressure when the zinc plate, three or four thicknesses of blotting-paper, and a glaze-board are laid on the stone. The transfer, or fatty image on gelatinised paper, which is supposed to be already made, is now laid for a few minutes between sheets of damp blotting-paper, in order to so far moisten it as to make it just capable of adhering to the zinc plate when pressure is applied. The polished zinc plate is now laid face upwards on the lithographic stone, after which the transfer is laid face downwards on the polished metal, the blotting-paper and glaze-board are laid over, the tympan of the press is lowered, and a gentle pressure is applied. One corner of the covering is then cautiously turned up in order to ascertain if the transfer adheres well to the zinc plate, and if this is not the case, the pressure is renewed until a satisfactory adhesion is established; the utmost care being of course taken that the transfer does not shift its position on the zinc in the least. When the transfer fairly adheres, the over-lying glaze-board and the blotting-paper may be removed and turned round to a fresh position, after which pressure must again be applied several times. The amount of pressure should be increased each time the plate is passed through the press, and the relative positions of plate and packing should be changed at each pressure, in order to compensate for unequal thickness of the plate or want of accuracy in the construction of the press. It is well now to slightly moisten the back of the transfer with a sponge, and repeat the pressure a few times more, in order to thoroughly impress the fatty device on the zinc; and, at the same time, to loosen its hold on the paper basis of the original transfer. The back of the transfer is now thoroughly wetted, and, after the water has been allowed to soak into it for a few minutes, one corner is lifted, in order to ascertain if it will easily leave the metal plate, and should this not be the case, more time must be allowed. When the paper basis of the transfer has been stripped off, the fatty impression will be seen remaining on the metal plate, scarcely a trace of the printing ink being carried away with the wet paper. The zinc plate is next flooded with water, and its face is very gently rubbed with a soft sponge, in order to remove any trace of gelatinous matter from the spaces between the lines of the device, the plate being next rinsed, and placed in a warm place to dry.

The image having now been transferred to zinc, subsequent operations may be postponed for a few days without mischief ensuing; and we shall describe the following steps of the work in our next article.

* "Handbuch der Chemigraphie." W. F. Toifel. Published by A. Hartleben, Vienna.

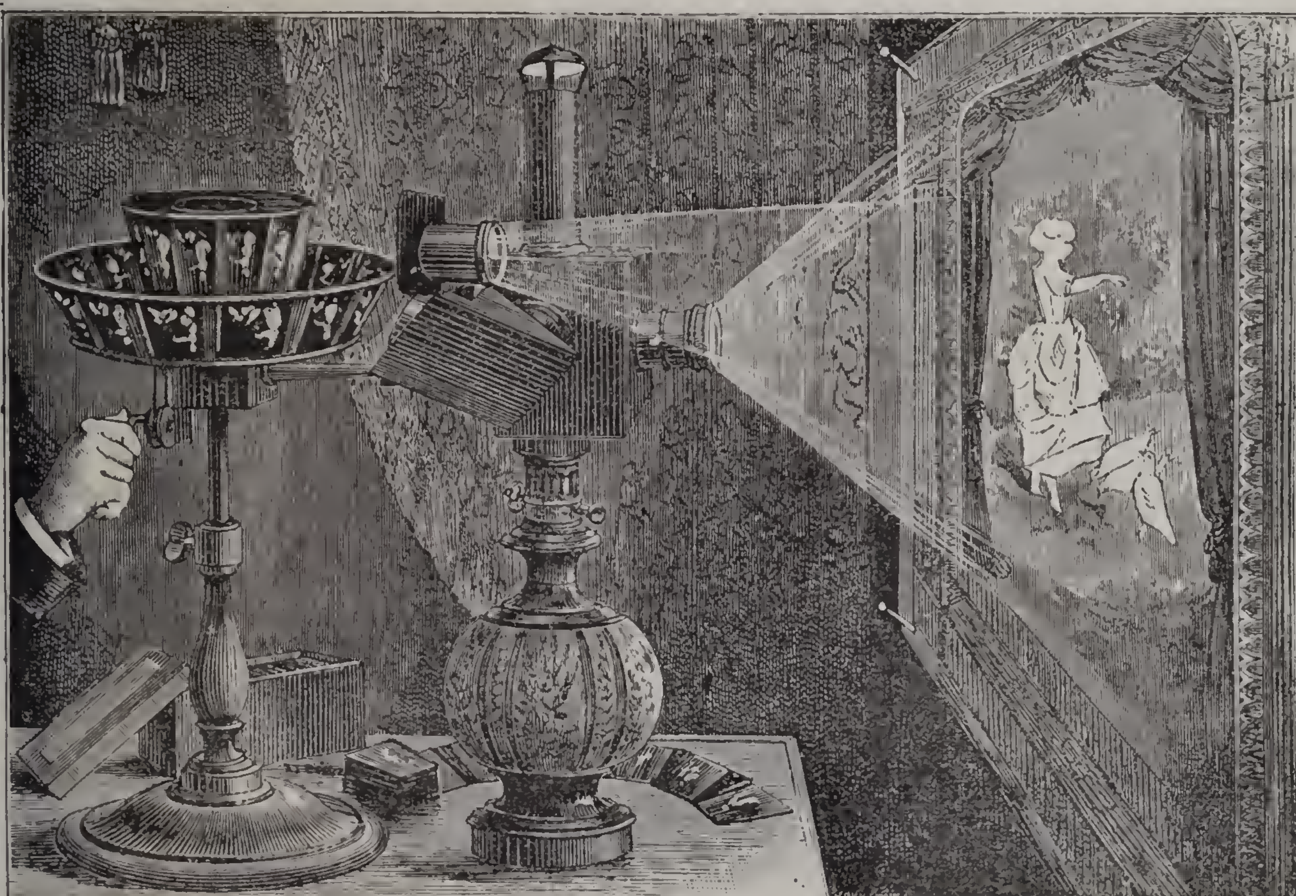
REYNAUD'S PRAXINOSCOPE FOR THE LANTERN.

The photographing of animals in motion has led to some ingenious improvements of the lantern. Many of our readers saw Mr. Muybridge's lantern when in this country, how he brought his pictures, by a sort of Zoetrope action, rapidly before an audience one after the other. The Reynaud praxinoscope does the same thing, and does something else besides: it projects a scene upon the wall, and then animates this scene with living characters.

M. Reynaud's apparatus is said to be capable of being worked by the aid of an ordinary lamp. In the picture here shown, which we take from our contemporary *La Nature*, the whole mechanism is displayed so that our readers will be able to understand the arrangement. There are two projections, although only one lamp is used; one lens projects a scene, the other—the upper lens shown—projects the moving figures.

With the scenic picture or photograph we have nothing to do; that is very simple. As regards the photographs "of motion" which are to follow one another, these are cemented together by joints of fabric, so as to make a band, such as is shown lying on the table. The slides may be coloured if desired, and made to harmonise in this way with the tinted scene on which they are to appear. The bands, which should be made flexible with rubber binding, are placed around the praxinoscope or zoetrope, whichever it may be termed, the instrument, as will be seen, having its sides or circumference distended; the praxinoscope is, moreover, pierced with openings, one corresponding to each picture, as in an ordinary zoetrope. The way in which the praxinoscope is revolved is also shown.

To understand how the luminous rays that form the images are made to fall properly, the reader must imagine a condensing lens which is placed close to the flame of the lamp, but which is not shown in our picture. There is, moreover, a mirror inclined at an angle of 45°, which reflects the luminous rays, and sends them through the pierced openings we have just spoken of. In this way



luminous figures of the moving praxinoscope are formed upon the facets of glass in the upper portions of the instrument, and are thence projected through the upper lens upon the screen.

By converging upon the screen the two lenses of the instrument, we get at once an animated scene.

GLASS.

First Article.

Notwithstanding the numerous attempts that have from time to time been made to supersede in its various forms, it is a matter of remark that probably at no period in the history of photography has there been so much glass employed as at the present. Glass and nitrate of silver appear to hold their own, despite all the efforts of enthusiastic inventors, and probably the more we know of the properties of these articles the less will photographers desire to abandon such tried and trusted friends. We will for the present confine our remarks to glass—glass as applied to the wants and requirements of the photographer in the form in which it daily passes through his hands in the shape of negative plates, whether for wet or dry work—and glance at opal and coloured glass of the sorts usually employed in photography. The aim of these remarks will be, not to write a technical treatise upon the theory and practice of glass making, but rather to familiarize the reader with some articles of common usage in their every-day relation to the art.

Glass itself is an article of great antiquity. We need not search up old books or records to ascertain the precise year when glass was invented—or we might, perhaps, say discovered—for there are stories extant that the first production of glass was by an accident, which happened when some shipwrecked mariners made a fire on the seashore from the materials at hand, and when the fire died out, the stones surrounding it were found to be partially melted, and adhering by a vitreous substance which, in its more refined condition, we now call glass. Whether there is any truth in this story of the origin of glass is not of much present importance; but the narrative serves to introduce us to the elementary form of glass in the shape of vitreous matter; and although various explanations have been forthcoming as to this discovery of glass, such as that the stones employed were natron, or rock salt, it is just as likely that they were limestone, and that the fuel was dried sea-weed, in which case we have in the presence of silica and fire the elements of a vitreous compound.

The art of glass-making is of great antiquity, as proved beyond all doubt by the specimens of really well-made glass dug up in Italy, Greece, and Egypt; but it must be borne in mind that the art then extended only to glassware—flattened glass, and glass for windows for domestic purposes, being, so to speak, a modern inventiou. Taking Italy, and Venice especially, as the birthplace of arts, we find that glass making extended thence throughout the Continent, being fostered in Frauce, and making its way across the Channel until it took up a strong abode in our country. At the end of the eighteenth ceutury window-glass was extensively made in England, principally in the form of *crown* glass—which more anon—and some attempts were made at the beginning of the present century to manufacture what is now called *sheet* glass; an invention the credit of which is entirely due to our esteemed neighbours the French. Up to a comparatively recent period, glass-making in England was under a severe ban by reason of the Excise duty levied upon every foot or pound produced. Until the abolition of this tax, the Exciseman visited the glass house just as he now does the brewery or distillery. It is clear that no trade could thrive under such conditions. By the removal of the duty the industry made a tremendous bound, and glass works in England increased and multiplied. Many of us will remember the window-tax and the enormous price of a pane of window-glass, aud how it became cheapened when the duty was repealed.

Borrowing from the system prevalent in France in the *Departement-du-Nord*, the English and the Belgians had for some time been carrying on the manufacture of what is now called *sheet* glass, and when the duty was removed the opportunity presented itself for the Belgians to pour their cheaply-produced goods into our market, to the unspeakable horror and disgust of our English manufacturers. Before the removal of the duty the Belgians had little or no chance to compete with our own home products; but just about the period of the abolition of the duty they had brought their methods and process of manufacture to such a pitch of excellence, combined with a cheap mode of production, that the tide set in in earnest, and has continued to flow without signs of ebbing, until now it is no exaggerato say that for every hundred feet of glass used in Great Britain, *ninety* feet are of Belgian make! This is a tremendous blow at a great national industry; but our own manufacturers are themselves largely to blame for the present state of affairs; they resolutely set their faces against every innovation; they tabooed the ingenuity of the foreigner; they ignored his inexpensive system of furnaces and appliances, and they refused to copy or imitate him in any way; they thought he would die out; but he knew how to satisfy the public, and he lives.

The *raison d'etre* of the Belgian glass industry is not at first sight very clear. With inferior coals, costlier chemicals, and worse means of transport for the raw material than we enjoy in this country, it is perfectly marvellous that the Belgians can produce goods in no whit inferior in quality to English manufacture, and at about two-thirds of our price. The only satisfactory explanations are found in the fact that the Belgians adopt a less expensive construction in their works, entailing less outlay of capital: the proprietors themselves are nearly all workers; they economise in the production at every point; they employ juvenile and female labour; they have cheap outward transit; and, above all, their workmen are really hard-working; in other words, their labour costs much less than ours. The Belgians are a very hard-working nation, in this respect a great contrast to Englishmen. If Great Britain ever goes to the bad, she will have to thank the British workmen for it.

The chief component of glass is sand. Sand surely is cheap enough, it may be said, and so it is; but it is not all sorts of saud that are suitable for glass-making. Sea sand has been used for many years, and is cheap enough, costing only the labour to carry it from the seashore or sand-banks to the glass works. But sea sand contains a minute quantity of iron, which carries a dull or greenish tint to the glass made from it. For bottles or coarse articles this is of no consequence, but the refined notions of the present age demand goods free from this disagreeable murky tone; especially does this apply to window or plate glass. It was observed that the Belgians made whiter glass than the English, and this, of course, gave rise to the enquiry as to how this happenen, and it was soon traced to the quality of the sand employed. The sand used in Belgium is found underlying the surface soil, is very white and fine, and there are enormous tracts or sand-fields, principally in the district intersected by the Canal de Herenthals, where it is dug out and loaded iuto boats or barges, and brought down to Antwerp, where it is then transhipped into colliers as ballast to return to England, and thus we derive our supplies of sand all the way from Belgium. It goes by the name of Antwerp sand; but this is a misnomer, and causes misapprehension, owing to the idea that, because we know Calais sand and Reigate sand as being actually obtained there, it is imagined that sand is also abundant at Antwerp. There is no sand at Antwerp—there is plenty of mud; but the misnomer is uo less a misnomer than Ostend rabbits, Epping sausages, or Wallsend coals.

There is a variety of inland sand dug in Belgium of a distiuct yellow colour; yet, strange to say, this yields a moderately pure-coloured glass. In England it was the custom to wash the sand before using it, but that was a very costly process; and it will at once be seen that as Belgian sand can be laid down ou the quay at any large seaport in England for about four or five shillings per ton, and needs no washing, an enormous saving is effected by the employment of a sand which not only gives a purer glass, but avoids the expense of washing and drying—items of vital consequence in an industry where cheapness of production is its very life.

DANGERS OF INSTANTANEOUS PHOTOGRAPHY.

The progress which has recently been made in technical knowledge is gradually proving fatal to anything like romance. The electric light banishes the cosy twilight once so precious to lovers, and now that horror called Instantaneous Photography is actually transferring the images of the harmless passers-by to the sensitive plate without the consent or even the knowledge of the victim. Copies of these pictures, which usually are views of the principal promenades, are in due course exhibited in the shop windows, when those who have happened to be thus gratuitously photographed can be only too easily recognised. Only a day or two ago a lady who happened to see one of these views exposed for sale recognized, to her intense amazement, the figure of her own daughter walking arm in arm and evidently talking very familiarly to a gentleman. The mother shakes her head, enters the shop, buys the picture, and half-an-hour afterwards the daughter has to undergo a painful questioning. Unaware of the damning evidence of the photograph, she stoutly denies the charge. The mother, with dire threatenings, says: "But I know it for certain!" Still the young lady denies, till the mother triumphantly produces the fatal photograph!

The young gentleman who was teaching the daughter the piauo does not do so any longer.—*Cologne Gazette.*

By-the-Bye.

A PHOTOGRAPHIC COPYRIGHT DEFENCE ASSOCIATION.

That it is high time photographers stirred in the matter of protecting their copyright is evident to all who have been watching the subject. Piracies have never been more frequent than at the present moment; and from day to day they grow more impudent. There are, roughly speaking, two classes of people who imagine that photographers are sent by providence to benefit them; an unthinking portion of humanity who can appreciate a bold or pretty photograph, but fail at the same time to understand that any skill or taste has been expended in producing it; and secondly, that class who know perfectly well the value of a good picture, and for this reason set about copying it with the least delay possible.

Our illustrated journals and newspapers furnish plenty of examples of the former class; while of the latter, we have simply to go into the poorer and busier districts of cities, or to watering places in the season, and market towns at fair time, in order to see them in countless number. Mr. Josiah Smith is said to have made £12,000 out of the little babies who made their first appearance in Europe at the Paris Exhibition in 1878, labelled "We come all the way from Chicago;" and if so, there is little doubt that had no piracies of the pictures existed, his profit would have amounted to twice the sum. "You Dirty Boy" brought in to the photographer who purchased the right to copy it probably not less than £20,000, but this sum, large as it was, would have been much more if none but authorised photographs had been sold. These are extraordinary examples, we admit, of the value of copyright, but still they show how well worth protecting photographic copyright is; while as a further illustration of how worthless unprotected rights are, we may quote a recent instance in the experience of Messrs. W. and D. Downey, where of the portrait of a popular actor only two dozen copies were ordered by the largest publisher in the trade, and yet on the barrow of a hawker at Hastings, three months afterwards, no less than one hundred and fifty spurious copies of the same photograph were counted.

Still, in presence of these strong facts, there will doubtless be some difficulty in forming a society to protect photographic copyright. It is so hard to get people with varying interests all of the same mind. In France there is a Chambre Syndicale, which occupies itself with the protection of copyright, and does more besides. The Chambre Syndicale considers all matters of a commercial character; and it might be worth while to consider whether, in this country, a similar institution could not be established which would take into consideration matters connected with trading, discounts, commercial integrity, &c., so that photographers who did not take an interest in one branch of the society's doings might take an interest in the other. But it is in the matter of protecting photographic copyright that interest is felt more particularly just now, and to this subject we therefore confine our remarks.

The cost of initiating an institution of this kind, and also of keeping it up, must naturally be somewhat great; but if those firms which are most closely interested in the matter were to set the ball rolling by putting down a substantial sum, there is no reason why the society should not be formed at once; and to such a mode of proceeding we believe several of our London firms are not averse. In this case it would be possible, probably, to put the general subscription at a guinea per annum for the majority of photographers, though the fee can hardly be less. Legal expenses are costly, and although many evil-doers would doubtless fall on their knees before a threat of law proceedings by a society of recognized standing, still, when it did come to an action, the litigation would draw deeply on the funds. In fact, to give our readers some idea of what may be swallowed up in legal expenses, we may cite the case of a fortnight ago at the Mansion House, when Messrs. Elliot and Fry and Messrs. W. and D. Downey prosecuted, the total cost of which prosecution was between £70 and £80. In a civil action, recently fought by one of the above firms, the costs were no less than £240, and this sum might have been double if the evidence had not been so clear.

It is, indeed, not want of evidence, but the disinclination to spend money in pursuing a pirate, that generally stands in the way of prosecution. These barrows full of pirated portraits and consignments of illegal photographs are not put before the public unknown to the leading firms. On the contrary, everything about them is perfectly well known to the detectives who have been employed in tracing the illicit traffic. Where the pictures are made in Germany, the vessel by which they are shipped, the Manchester house to which they are consigned, the dealers about the country to whom they are sold—every detail is on record. "We are advised of every consignment before it comes over," said a gentleman who was behind the scenes, to us last week. "We can watch its arrival in this country, and the distribution of the various parcels; it is only a question whether we think it is worth while to prosecute—whether the game is worth the candle."

But now comes the question to the photographer who is not a big producer, and who only publishes half-a-dozen portraits a year, whether it is worth his while to belong to the association. "It is all very well," he may say, "for your big London firms to start a society of this kind, and ask us to subscribe, but I do not see the force of helping them to get back their own. If they lose a lot of money sometimes, they earn more than I do, and it is no interest to me to put more into their pockets." This is a very good argument, of course; but naturally, at the very outset, some fair and equitable arrangements must be made to guide prosecutions. It is not likely that a man of small means will subscribe to help a neighbour who is better off. The only question that concerns him, and concerns everybody, is whether, by paying a guinea a year, he will be able to make more than that guinea by suppressing piracy.

Now let us turn to the other side of the question—the side of the big producer. We will assume that these are willing to put their hands in their pockets in order to give the association a start, and they hear the plaint of the small producer. What is their reply? It is a very cogent one, and deserves a good deal of attention. They say:—"The smaller producer will decidedly reap the most benefit; for, in the first place, we bring with us all our experience of pirates and piracies, which has cost us so many guineas already, and is such as very few photographers have dreamt of in their philosophy; and secondly, we are willing to share with the association any damages or indemnity that may be paid for pirating our pictures." And as these damages of late years have been very large, we may be sure that the big firms will be the first to acquiesce in that fair and equitable arrangement about prosecuting in which we have just said the small producer would be interested. One firm we wot of received only recently the sum of £700 from a Northern publication which had printed certain portraits without authority; another firm has received £150 and £75 on two occasions; while yet another looks to piracies as an established source of income. Again, in the law case we mentioned above, in which the legal expenses incurred amounted to £240, the damages found by the jury were £500; leaving, therefore, a handsome balance. But to claim and secure these damages a wide sweep of observation is obviously necessary, such as only a big firm or a society can exercise.

Hence, we see, that the small producer has not all to lose and nothing to gain, as at first sight may appear the case. Many a one believes he has not been pirated, for the simple reason that in his little circle of observation no such piracy has met his eye. For ourselves, we should think that any photographer who has secured half-a-dozen popular portraits in the year, and has taken the trouble to publish them, whether the pictures are of royalty, statesmen, celebrities, &c., could scarcely do better than spend a guinea in having these publications watched by a capable society. In any case, it would, we feel sure, be worth while paying a first guinea by way of experiment, and thus give the society a fair start. That it must be under the auspices of no particular clique or set is only a matter of course; but we cannot help thinking that, beyond its mere sphere of protecting copyright, it will do something also to make photographers and photographic publications more respected.

The "By-the-Bye" next week will be "Landscapes and Portraits."

FURTHER NOTES ABOUT COLOURED PHOTOGRAPHS ON GLASS.

BY W. M. ASHMAN.

No. I.

Since writing the last article on the above subject, several enquiries have been made for the working details of the process; therefore, with the Editor's permission, I will give a *resumé* of the method of working, together with some remarks on experiments made.

At the outset, I may say that rendering photographs transparent and colouring them from the back is by no means new, for at various times fees have found their way to the Patent Office and elsewhere. And, under different titles, we are able to discover our old friend again. As many will not care to follow me into the details of recent experiments, I will give the *modus operandi* that works well, leaving the experiments until the last.

Trim a deeply-printed silver print a little smaller than the size of the glass to be used; rub the albumen side gently with a piece of linen rag dipped in benzoline as supplied at the oilman's, plunge it into warm water, and after two changes blot it on a clean towel; place the albumen side upwards on a flat hard surface (a piece of plate-glass), and apply the mounting solution or paste all over it.

Mounting solution is composed of:—

French gelatine	20 grains
Water	1 ounce

to which is added an alcoholic solution of salicylic acid five drops; this requires warming up a little before using.

Mounting Paste.—French gelatine twenty grains, dissolved in water one ounce; to this add an equal volume of ordinary starch paste, and a similar quantity of Kingsford's oswego blancmange, and twenty drops of an alcoholic solution of salicylic acid as an antiseptic; heat the above ingredients over a water-bath for a few minutes, stirring the whole time; when cold it is ready for use. To a previously cleaned convex glass apply some of the same mountant as used on the print all over the inside surface, then lower the print, albumenized side down, gradually on to the inside of convex glass. It does not require any great amount of skill to do this without blisters or creases; but, if such should occur, it may be easily withdrawn and mounted afresh. Well squeegeeing, to remove excess of paste, is the next operation, after which it may be placed on end to dry spontaneously, which will take from six to twelve hours according to the temperature. To make a squeegee, procure a strip of rubber composition about one-eighth of an inch in thickness, cut one edge to fit the bevel of large plates, place a strip of wood on either side, and screw all together, leaving about one inch out on the bevelled side. No squeegee will be found necessary when small plates are used, any excess being more easily removed by the fingers.

When the photograph is quite dry, place it on a cushion, and rub the paper away with fine glass-paper, working gently in a circular direction, the object being to get the photograph as thin as possible, and thereby more easily permeated in the next operation; but care must be taken not to grind off all the paper.

There are several substances suitable for rendering the prints transparent, but I have found as good as any a mixture of

Canada balsam	5 ounces
Solid paraffin	2 ,,
White wax...	2 ,,

Melt at as low a temperature as possible, then place the picture therein, keeping the composition in a molten condition either in a slow oven or on a water bath. If a high temperature be maintained, the print will lose its whiteness, and, when painted, will appear somewhat bilious. At the end of an hour the picture should be examined, when, if it is quite trasparent, it may be removed, and when cool enough the excess wiped off. If, on the contrary, opaque patches are still visible, it should be allowed to get cold, then rubbed down a little more with glass paper, and again put it into the wax composition, allowing it to remain until the marks disappear. When cold, rub off all excess, and proceed with the painting.

A few days ago I was shown some pictures treated as above, but the painting was performed with a shilling box of water colours, and though so little had been done, it was really surprising what a pretty effect it had. To overcome the difficulty of putting water colour on such a repellent surface, my friend said he had used shellac dissolved in borax as a medium to mix the colours; he then found no difficulty in working in any way he pleased on the print, whilst, for the back glass, water answers equally as well as oil colours; but this class of picture seems to lend itself particularly to oil colours.

As I propose dividing this subject into two parts, viz., the preparation and the finishing operations, I see no better time to make a halt than the present. Weeks may elapse between the preparation and the painting without being detrimental to the final result, although it is not my intention to delay the second portion longer than next week if our good Editor can only squeeze enough room for it. In the meantime I would advise all who think seriously of trying a few studies—for such they really are, with ordinary care—to procure a stock of convex glasses from Messrs. J. Barnard and Son, 333, Oxford Street, W.; the sizes and prices are here annexed:—

C.D.V.	$3\frac{3}{4}$ by $2\frac{1}{2}$	per pair	6d.
Cabinet	$5\frac{1}{2}$,, $4\frac{1}{4}$	,,	1s.
Extra do.	$6\frac{1}{4}$,, $4\frac{1}{4}$	,,	2s.
Promenade	7 ,, $3\frac{1}{2}$	,,	2s. 6d.

Messrs. J. Barnard and Son supply mounting paste and other necessary articles if required, but, if I know anything about photographers as a body, they much prefer mixing their own.

MR. J. COMYNS CARR ON PHOTO-ENGRAVING.*

I have described the process of lithography, because it will enable you the better to understand the means by which a photo-engraving in relief is usually obtained. These relief blocks have now been in use for some years, but it is only recently that they have shown signs of sufficient excellence to render them worthy rivals of wood engraving. Their great merit, where they are successful, is that they give us the absolute autograph of the artist. The photographer here takes the place of the wood engraver, and allows the original draughtsman to speak for himself. Or, at least, it should rather be said that this is so in principle; in practice it must be acknowledged that photography cannot always claim the absolute veracity which is sometimes attributed to it. It

* Continued from page 663.

inevitably coarsens, to some extent, even the simple lines of a pen-and-ink drawing, and it takes no account of varying depth or strength of colour. The photographic engraver can distinguish between a broad line and a thin line, though he is apt to exaggerate both; but he is wholly powerless to effect any distinction between a dark line and a light line. In this respect it must be admitted that all these processes are still inferior in effect to the wood-block, in the treatment of which the engraver has at his command numerous devices for giving varieties and refinements of tone. But it must be allowed, nevertheless, that in dispensing with the services of the engraver there is an important gain of another kind. It is something to have the actual touch of the original artist, even though the interpretation is somewhat rough and clumsy; and when the artist has learned to adapt his work to the conditions of the process, results wil be obtained such as could not be secured even by the most painstaking and conscientious engraver. For it is to be observed that the process itself is capable of a vast amount of improvement, and the results now obtained already compare very favourably with the earlier and cruder experiments. Apart from the lack of variety in tone, which was a patent defect of those earlier essays, there was another and more serious disadvantage arising from a certain rottenness and insecurity in the lines themselves. This arose partly from the employment of paper unfitted for the purpose, and partly from an uneven biting of the metal. Photography not only exaggerates the actual work of the draughtsman, but it caricatures the surface of the paper, and if this surface be rough and uneven, the lines, when they are transferred to the metal, lose sharpness and consistency. Mr. Dawson, whose ingenious method of photo-mezzotint engraving I have already described, sought to overcome those defects by a process which he has described as typographic etching. Here the drawing, was actually made upon a prepared plate in a manner partly corresponding to real etching, and the black in relief was afterwards obtained by a cast. But this process had not, after all, the advantage of rendering in *facsimile* an original drawing, and I now, therefore, pass to the consideration of the various modes now adopted for obtaining relief blocks through the intervention of photography.

As the conductor of two artistic magazines, one of which is produced in France, I have had the opportunity of scrutinizing very closely the results produced by the different professors of this kind of engraving both in England and abroad. The principal firms in France at the present time are the Messrs. Gillot, Messrs. Yves and Barret, and M. Petit, and very favourable examples of their skill are to be seen in the pages of *L'Art* and the *Gazette des Beaux Arts*. The point in which they seem to me to surpass most of their rivals in this country, lies in the ability to interpret drawings in charcoal and chalk, as well as drawings in pen and ink. It certainly appears, at first sight, a very remarkable gain to the resources of illustration, to be able to print from a relief-block in such a way as to imitate the crumbling touch of a chalk drawing, and this has, in some instances, been very successfully accomplished. Very much, of course, depends upon the skill of the printer in handling these photographic blocks, as they undoubtedly demand more adroit handling than is bestowed upon the ordinary wood-block. The art of printing illustrated works is unquestionably more widely understood in France than with ourselves, and to this cause we must attribute some part of the superiority which the French processes would seem to possess. In London there are, by comparison, only a limited number of printing firms which devote special attention to this class of work, and although the results obtained in these isolated cases are highly satisfactory, the production is, as a general rule, far more costly. But even the best of these French processes, aided and supported as they are by the greater skill and resource of the French printer, are scarcely superior to a process to which I shall specially draw your attention to-night. This process is the invention of a German gentleman, Mr. Henschell, who is a resident in this country, and who has kindly afforded me every facility for explaining to you the peculiar methods of his work. There are many others of the same kind, and based mainly upon the same principles; but as there are considerable differences in detail, I have thought it best to-night to confine myself to the description of a single example. The faults common to nearly all the processes to which I have referred are, as I have said, of two kinds. In the first place, the line which was firm and steady in the original drawing is apt to exhibit a certain rottenness when it re-appears upon the block, and further, the block commonly fails to distinguish successfully between lines of varying strength. It may even be said that where the original drawing has passages of delicate execution, even though expressed in line, these delicate parts disappear altogether, and the printed impression from the block is, by comparison, crude and coarse in effect. In order to understand why this should be so, it will be necessary to explain the different stages in the production of one of these blocks. The first requisite, common to every process, consists in a good clear negative from the drawing which has to be reproduced; but the real difficulty begins when it is sought to transfer this negative on to the metal. Now, this has usually been accomplished by means of tranfer paper, such as has long been used by lithographers. This transfer paper is so treated as to be sensitive to the action of light, and an ordinary photographic print is then taken upon it, which is afterwards treated with lithographic printing ink and transferred to the smooth surface of the zinc plate. But the conditions which make it necessary to employ this transfer paper are unfavourable to the photographer. In order to secure detail, the light must act through the transfer substance, and fix the image to the paper itself, but unfortunately the exposure required to effect this result intensifies the darker parts of the picture to an exaggerated degree. The engraver has, therefore, to choose between two evils. Either the black parts of the picture will be too strong, or the lighter and more delicate portions will be lost altogether; for unless the light has penetrated the transfer substance and fixed the image to the paper, these delicate features will inevitably be washed away with the transfer material and never reach the metal at all. And this, in fact, is what unusually happens. If an ordinary process block is compared with an ordinary drawing of any subtlety or refinement, it will be found not merely that the lines are rotten, but that many finer lines which gave beauty to the drawing have no existence in the block at all. And there is yet a further disadvantage incidental to the usual mode of procedure. The transfer to the metal can only be effected by pressure, and the pressure has the inevitable result of destroying the delicate work, and rendering the lines indistinguishable. When the image, with whatever loss it has suffered by the way, has been transferred to the metal plate, it is treated very much in the manner already described in connection with lithography. The surface is covered with gum, so as to resist and repel the printer's ink, which is now applied by the lithographic roller, and which only adheres to those parts where the transfer ink has been impressed. The plate so inked and prepared is now ready for the acid bath. It might, if we chose, be treated as a lithograph, and impressions might be taken from it just as they are taken from the surface of the stone. But our object now is to produce a block in relief which shall be adapted for printing in an ordinary press with moveable type, and with this purpose in view, the next thing to be done is to bite away all those portions of the plate which are not occupied by the lines of the drawing. The zinc plate is therefore placed in the acid bath in the same manner as an etching, only that here the process is reversed, and instead of eating into the lines of the drawing, the acid eats away all those portions which surrounds these lines, which are themselves protected from chemical action by the ink which covers them. As the biting gets deeper, care is needed in order to protect the sides as well as the upper surface of these lines, otherwise they would be undermined, and would then fall away; and for this purpose the ink has to be applied again and again during successive stages of the biting.

The method I have been describing is the ordinary method of producing a process block. It may differ in detail, or according to the varying systems of different inventors, but the principle is the same in all, and it is subject in all to the peculiar disadvantages I have pointed out.

In the presence of modern improvements it would be rash to declare that photographic processes have even yet reached the point of full development. Every day brings some new element of refinement, and if the progress in the future is to be measured by that which has been acheived in the past, it is more than probable that the craft of the engraver will be almost entirely superseded. Nor even if this should be the ultimate result of the alliance between science and art, would there be any great cause for regret? As to wood engraving, it has been made sufficiently clear, by our brief examination of its history, that it has never ranked higher than an art of reproduction.

Notes.

The Photographic Exhibition closes definitely next Thursday.

Our friend, Dr. J. M. Eder, has been advanced from lecturer to the dignity of professor at the Technical Academy of Vienna.

Mr. Norman Macbeth, the well-known painter and academician of the Royal Scottish Academy, delivered a lecture on Wednesday in last week to the members of the Edinburgh Photographic Society.

An announcement in another column calls attention to a preliminary meeting of the Copyright Defence Association. Said a member of a firm of photographers to us the other day, "If photographers do not speedily protect their publishing trade, there will soon be no trade to protect. You can buy a copy of any two shilling photograph now in the streets for twopence, and the public will, therefore, soon be asking the question, 'Why give more?' I saw a lady only last week making quite a collection off a barrow in the King's Road, Chelsea."

We mentioned Mr. Ruskin's name last week as a photographic critic, and now bring it forward once more in the same connection. The great art writer tells us, what will be news to many, namely, that he thinks art in photographic portraiture will make no further progress. Perhaps he thinks we have attained to perfection already. However this may be, he says, referring to some portraits recently taken of him by Mr. Barraud, of Oxford Street, "They are the first photographs ever done of me that expressed what good or character there is in me for my own work; and, as pure photography, they seem to me to go as far as the art can at this day; and I do not believe it can ever do much better."

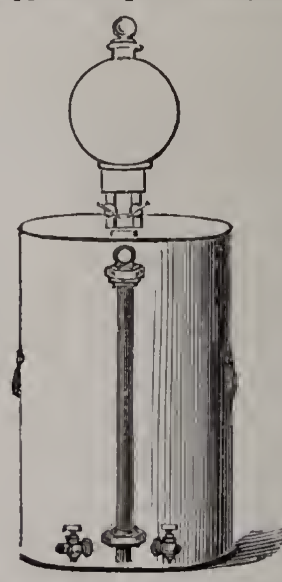
The members of the Berlin Society for the Advancement of Photography have been discussing Obernetter's new method of emulsion making. Herr Roloff and Herr Reichard, as well as two better-known authorities—Herrn Schaarwächter and Prümm—all speak with approval of the new films, the last-named having travelled to Munich to see the process for himself in the Obernetter laboratory. The general opinion goes to confirm that, Mr. Vero Driffield expressed in these pages, that the emulsion is not very rapid; but all agree as to the simplicity and excellence of the method.

Herr Obernetter stores all his negatives in the form of films, and there seems little doubt that years hence this will be the approved way of keeping photographic clichés. The system has many advantages. There is no chance of breakage, the store takes up little room, and no money is sunk in a stock of glass. In the event of fire, films are less likely to suffer, for these can be packed so tightly in packages as practically to be fire-proof.

"Placard him!" This is a method of revenge sometimes adopted by our French friends when they wish to punish a slanderer or other wrong-doer. The name of the victim is displayed in large letters upon the public hoardings, sometimes in badly-written characters, and badly spelt, with the word "cheat," or other obnoxious epithet, beside it. Now there is an idea of improving upon this method of pillory; some Parisians have recently suggested by way of punishment—"Photograph him!"

A certain Paris critic, named Mirbeau, has written in *Le Figaro* an article reflecting on actors in general and comedians in particular. The theatrical world of Paris are in consequence burning to revenge themselves. Some suggest a duel, others that the erring critic be sent to Coventry. But the most novel idea is to have several thousand copies of the photograph of M. Mirbeau struck off and distributed throughout the profession, with a request that any person meeting the original of the portrait should pull his nose. A singular application of photography, certainly!

The "Eclipse Light" apparatus of Mr. McLellan, for taking portraits by artificial light, is represented by the accompanying cut, and our readers will doubtless bear in mind our recent description. The globe is filled with water at the stoppered top, the stop-cocks which sepa-



rate the globe from the gas-holder being closed at the time. When these stop-cocks are opened the water flows out of the globe, while the oxygen enters. All is now ready for burning magnesium ribbon in the gas.

The elaborate work of Pflücker's highly-finished telescopic camera-stand contrasted strikingly with Mr. Harrison's holder. A brass telescopic stand made of tubes fitting closely in each other is all very well until one leg receives its first bruise; but from this time forward such stand becomes practically valueless.

Mr. Harrison generally comes forward with some simple and ingenious contrivance at the Technical Meetings of the South London Society, and the plate-holder he showed on Thursday is so obviously useful and inexpensive that we can only wonder it was not thought of before. A slip of tin-plate two inches wide is bent as shown in the figure,

and will take a single plate from a pile of glasses, or serve to hold one during the process of coating; while for lifting a negative from the developing dish it is just the thing. Thin ebonite would be a better material than tin-plate, having more elasticity, and being less likely to be acted on by chemicals. The strip should be immersed in boiling water, bent to the required shape, and chilled by a dip in cold water.

The Photographic Exhibition might, perhaps, be managed better. Since the present system of issuing tickets available for one only has existed, we have heard frequent complaints from members of the difficulty of obtaining a sufficient number for their friends; and it is decidedly annoying for a member to have to pay sixpence for a catalogue if he should happen to drop in for a few minutes, and wish to look up a picture. If reference catalogues were strung up on the walls at intervals of a few yards, it is possible that the sales might be reduced a trifle, but the true ends of the exhibition would be much more satisfactorily fulfilled.

Dr. Hermann Vogel's "Recent Progress in Photography," of which a favourable notice appeared in these columns two months ago, is to be translated into English by Mr. E. L. Wilson, of Philadelphia, who will also publish the work.

The death of Mr. William Sawyer, the genial Editor of *Funny Folks*, must not be passed over without a line of comment in these columns. Mr. Sawyer, a poet and *litterateur* of considerable mark, took considerable interest in photographic art, and has on several occasions contributed to the News and to the Year-Book. He was a member of the Solar Club, and has repeatedly penned criticisms on the yearly exhibition at Pall Mall. A word of his on the subject of backgrounds may be here repeated.

Mr. Sawyer used to protest against photographic portraits which showed people stuck against a flat background. "You couldn't walk round them if you tried your hardest," he said; "people in real life seldom sit with their backs flat against walls, any more than they sit on the mantelpiece, even when a broad mantelpiece affords facilities for so doing. Of course the photographer will tell me that he knows this as well as I can tell him, and that he is as painfully conscious of the retiring quality of his portraits as any one can be; but there must be a flat clear surface behind the sitter." Mr. Sawyer suggested whether, in order to get more "atmosphere" in rear of the sitter, it might not be possible to employ a hinged background, or other method of breaking up the surface at the back.

Money taken at the Pall Mall Exhibition on the evening of Thursday, the 16th inst., will benefit the Photographers' Benevolent Association; we sincerely hope to see a goodly assemblage on this occasion.

A fatal accident with collodion cotton is reported from Ardeer. For some time past, as our readers may remember, a new and very powerful explosive has been in course of manufacture by the Nobel Explosive Company, in which the terrible detonating qualities of nitro-glycerine and gun-cotton are combined. The gun-cotton is dissolved in nitro-glycerine—for nitro-glycerine is a solvent like a mixture of alcohol and ether—and a pasty mass is the result, which has received the name of blasting gelatine, albeit there is not a particle of gelatine in its composition. The soluble gun-cotton—or collodion cotton, as it is usually termed, in contradistinction to military gun-cotton, which is insoluble—is prepared in the state of fine fluff at Ardeer, and it was during the process of drying this finely-divided material that the accident happened. A Government enquiry is to be held, and we shall probably learn something of the process of manufacture adopted at Ardeer.

We have to call attention—rather tardily, it is true—to a little sixpenny volume which Messrs. Piper and Carter have published on "Recent Advances in Photography." The book contains the series of Cantor lectures delivered this summer by Captain Abney, which contained so much of interest, and were published in these columns.

The other day all the world was talking of an electric launch, a small craft which took on board some tons of secondary batteries in order to move half-a-dozen miles. Now we hear of a wonderful tricycle, which is also propelled by electricity, the driver simply having to direct the machine with a couple of handles. The motive power in this zephyr-like machine is also supplied by secondary batteries, and the weight of these is, we are told, "only one hundred-weight and a-half!" What would the ordinary tricyclist say if you asked permission to put a parcel on his fragile machine weighing "only one hundred-weight and a-half?"

Dr. W. Reissig, a name well known in photographic science, has, it is said, solved that most difficult of problems, the manufacture of a really indelible ink. It is compounded of boiled linseed oil sixteen parts; fine lamp-black six parts; and perchloride of iron from two to five parts. Diluted with a little boiled oil varnish, it can be used for stamping, only the stamp must be of rubber and not metal, since the composition would attack it. As the ink unites both with the gelatine and the paper material itself, traces of the ink can always be detected, even when the latter has been removed.

Patent Intelligence.

Patents Sealed.

2156. Frank Wirth, of the firm of Wirth and Company, Patent Solicitors, at Frankfort-on-the-Main, in the empire of Germany, for an invention of "Improvements in the preparation of photographic plates for subsequent typographic or other multiple reproduction of living or dead objects."—A communication from George Meisenbach, a person resident at Munich, in the empire of Germany.—Dated 8th May, 1882.

This invention consists of a novel method by which any object, dead or living, can be delineated direct by photographic means with stippled or hatched shading, without having to first make a drawing; and such delineation can he multiplied by printing, or engraved as a plate for the reproduction of copies. In order to produce a typographic block, the method to be employed is as follows:—A transparent plate is hatched or stippled in parallel lines. A transparent positive is made of the object. The two plates are joined, preferably face to face. From the combined plates a definite negative is photographed in the ordinary manner. In order to cross-hatch and break the lines of the shading for obtaining a more plastic appearance of the printing made from the typographic or other block, the hatched or stippled plate is shifted or moved once or twice during the production of the said definite negative. This negative is transferred in the usual manner on to a plate of suitable material, which is graved or etched in the usual manner to form a typographic block. For the engraving plates the negative is transformed into a positive, and the latter is transferred on to the etching plate in the usual manner. The negative produced from the combined plate may be used for the production of photographs on photo-lithographic plates. The only definite claim appears to be "the one or more times exerted in moving or shifting of the hatched plate on the photographic negative or positive plate during the production of the definite negative or positive from which afterwards the typographic or other printing block is made.

Grants of Provisional Protection.

4608. Joseph Mayer, of the firm of Mayer and Meltzer, of 71, Great Portland Street, in the county of Middlesex, Surgical Instrument Makers, for an invention of "Improvements in means or apparatus employed in obtaining artificial light."—Dated 28th September, 1882.

Notice to Proceed.

3491. Edward Gardner Colton, of Southampton Buildings, in the county of Middlesex, for an invention of "Improvements in the method of producing photographic images and in apparatus applicable therefor."—A communication to him from abroad by William Kurtz, of the city, county, and state of New York, United States of America.—Dated 22nd July, 1882.

Patents Granted in Canada.

14,883. Anthony C. Dunlevy and Frank M. Campbell, of St. Louis, Mo., U.S., for "Improvements on skylights."—5 years.—Dated 1st June, 1882.

14,934. The Newark Filtering Company, of Newark (Assignee of Patrick Clark, of Rahway), N.J. U.S., for "Improvements on methods of and apparatus for filtering water and cleaning filter beds."—5 years.—Dated 10th June, 1882.

14,935. The Newark Filtering Company (Assignee of John W. Hyatt), of Newark, N.J., U.S., for "Improvements on process and apparatus for the filtration of water."—5 years.—Dated 10th June, 1882.

Patents Granted in America.

265,980. G. Frank E. Pearsall, of Brooklyn, N Y., for "A screen for photographic cameras."—Application filed 31st July, 1882. No model.

266,035. Egerton R. Higgins, of San Francisco, Cal., for "A camera attachment."—Application filed 3rd July, 1882. No model.

Specification Published during the week.

1621. G. L. Addenbrooke, for "Adjustable photographic exposer."—*Provisional protection only*. Price 2d.

My invention is for the purpose of enabling photographers to obtain readily the exact exposure which they may deem proper to give photographic plates in the camera. Several forms of photographic shutters are now in use to which my invention may be rendered applicable. But I prefer a form of shutter made as follows:—A closed box, say 8 inches long, 4 inches broad, and 1½ inch thick (these measures being proportionate) through the lower part of which a hole is made (say three inches in diameter). This box should have inside it two grooves, in which work freely two slides of such size as to cover the aperture. These slides are attached by elastic or springs, one to the top and the other to the bottom of the box. When required to be set, one slide is drawn down to cover the aperture, and the other is drawn into the space above, both being retained by catches. I now proceed to describe my method of withdrawing the catches as in the shutter above described, so as to regulate exposures. I fix on the shutter in any convenient place a simple clockwork train almost exactly similar to the striking train of a clock, and consisting of a long spring, preferably with stopwork to prevent its being wound more than one turn. To the barrel of this spring is on one side geared a revolving fan, the gearing being such as to cause the fan to make, say, from 300 to 600 revolutions for one revolution of the spring barrel. The barrel of the spring is also geared into a cog wheel of rather smaller diameter than the barrel. The arbour of this cog wheel projects through the case of the clockwork, and to it is fixed a metal disc. This disc has on the underside a projection, and a lever working on a central pivot is placed so as to come in momentary contact with this projection as the disc revolves. This lever is connected by a simple metal rod or slip to the lower catch of the shutter, which is made with an arm projecting at right angles so as to receive it, so that whenever the projection on the disc moves the lever, the catch is withdrawn, and the slide it holds liberated. Again, the disc has a movable radial arm having another projection rather further from the centre than the first, and by any convenient means, such as a series of holes at graduated distances round the edge of the disc, this second projection may be set at any required interval from the first. This second projection acts on another lever similar to the first described, and connected in like manner with the upper catch of the shutter. It is thus clear that the disc being set to revolve in a certain number of seconds (say three), the two levers will be moved by the two projections at an interval which bears the same relation to the time taken for a whole revolution of the disc as the arc distance between the points does to the whole circle; the result being, that the operator having wound up the spring, set the radial arm to give a required exposure, and the slides of the shutter, on liberating the clockwork the slides rise and fall respectively at the interval fixed upon, so making the required exposure. Claims. I do not claim, as part of my invention, the use of the shutter above described, but I do claim as my invention,—(1) The use of a simple clockwork train governed by a fan to regulate photographic exposures, such clockwork train to release both shutters, or their equivalents in other forms of shutter, when the apparatus is wound up, the shutter set, and the fly released. (2) The use of a rotating disc with two projections or their equivalent for the purpose of regulating photographic exposures, as above described.

PASTORAL PHOTOGRAPHY.

BY ALEXANDER BULEY.

May! beautiful May! floral May! It is very delightful to dream of sunshine and flowers this cold and foggy weather, especially if you can dream of holiday-making into the bargain. And of all the months in the year in which the hardworked photographer should take his day out, and take it, too, (if he can) without a care, is the month of May.

Everything in nature seems so contented, so lazy and happy. The lilac, crowded with blossoms, like clusters of grapes on a vine, fills the air with its delicious scent, while its contemporary the laburnum more than makes up for its want of perfume in the beauty of its golden chain of blossom. Take as many days as you can in May, my friend; I regret that I can only write of one; but the lilac and the laburnum were very sweet.

A few years ago an extraordinary discovery was made, viz., that all the churches in the country were about to fall in or fall down, and the cry of "Restoration" went forth. In some cases it was no doubt necessary, in others it was carried too far, destroying or plastering over grand bits of ancient stonework, and doing that which some now alive will live to regret.

The cry reached Wedmore, and, funds being found, the parish church was forthwith restored. I did not know the church sufficiently well before its restoration to be able to say anything about the effect in its particular case, but I do know that a year or so ago, upon a beautiful day in May—one of those days when the lilac and the laburnum kept nodding to each other in the softest of soft winds—I packed up, with the assistance of Dan, my eldest son, the wherewithal to photograph Wedmore Church.

The re-opening ceremony was to take place some week or so hence, and I must confess that I conceived an idea of making business and pleasure meet. What else could warrant the pony and trap hired for the day, the lavish order for dinner that was given at the "Swan," together with the reckless tip to the ostler to give me the whole and sole use of his coach-house, in which to plant my tent? Of course the sale of the photographs would give me this grand day out, pay everything, and something over. That was what I thought; I don't think Dan thought much about it. Dan thought a lot of the tart covered with thick cream that the aforesaid lavish order brought about, and very little of the church.

Wedmore Church can be photographed very easily from that point of view from which nobody wants to photograph it. The front and best view, taking in the main entrance, is not so easy. In the churchyard you are much too close, and the churchyard is bounded by a wall over which you can drop (if you like) some ten feet to the road beneath, so that the only way to get a picture at all was to get it from the window of one of the houses opposite.

Dan being nearly ten years old, I of course took counsel with him, but was unable to get to the window he suggested—and which, by the way, was the best—owing to the owner being ill in bed. At the next house, however, we had permission to occupy the "first-floor-front," and, much to the astonishment and alarm of the youngsters in the passage, we made our way with camera and stand to the bedroom, the conditions being a mounted photograph of the church to the good lady of the house. But it was not yet taken; the window was of the old-fashioned lattice sort, very narrow, only half of which would open, and that half protected by a rod of iron running straight across, and, as I found, very much in the way of one of my negatives. After a lot of trouble, placing one end of the tripod upon the chest of drawers, and propping the other with a huge book ("Fox's Book of Martyrs," by the way), and by sundry other devices, the camera was got into position, and the grand old church looked just like a photographer likes a church, or anything else, to look, upon the ground glass—superb. At last! Look, Dan!—capital, isn't it? Now hand over the dark slide. By Jove! here was a go. There was the old-fashioned window, with one of Mr. Rouch's new-fashioned cameras built into it, and the fact that the dark slide goes in sideways, forgotten.

What was to be done? Why, to leave the camera where it was, and insert that dark slide, I must have demolished half the room! Dan laughed—laughed like a boy without a care can laugh. I did not; honestly, I did not laugh. All my trouble for no good! Everything had to come down; "Fox's Book of Martyrs," the tripod, and all the other dodges had to be put aside. Still the thing had to be done. The "first-floor-front" had been taken, a mounted photograph promised, and, above and beyond it all, my own determination to photograph Wedmore Church remained. It was done, after all, in a simple way, only simple ways do not always show to the front. After trying this way and that way, the simple *modus operandi* suggested itself to me to turn the whole thing upside down; that allowed me to draw out the shutter, and, as I was using dry plates, that did not much matter. One moment here, while I point out an advantage attached to dry plates (I think, never before noted) as compared with wet—*you can turn them upside down.* Of course you can, everybody knows that; but supposing I had been forced to photograph that church, as I was forced to photograph the last church I honoured, with a wet collodion plate—how would it have been then? Thanks to the dry plate—not forgetting the well-known "Book of Martyrs"—I overcame the difficulty, and Wedmore Church was mine. The counterfeit presentment of it was mine—not the church, that is worth £600 a-year, is in the gift of the bishop of the diocese, and pastorated by his (the bishop's) son—and photographed by me! The tent put up in the coach-house was originally meant to work wet plates—in a standing position. All I brought of it was the cover, which I put over the tripod, seating myself to develop. An empty hock bottle, with the bottom knocked out, makes a good shade for a candle; the negative or any other box to sit on, and a bucket turned up for the developing, are all you need to see for yourself what you have.

We gave our negatives a good washing in the yard of the "Swan." I held the negative, while Dan pumped, and the ostler looked on—he was a real Somersetshire youth, about nineteen or twenty, I should think. He watched the washing with great interest, and when I had finished, and held my negative up to the light that I might look through it, he delivered himself in the best of Zummerzet:—"If I could larn to do the like o' thic ther, I'd never not have to do with no hosses—not no more." I held a negative in my hand, but that was nothing to the *negatives* that fell upon my ear; he was quite *positive* in his manner, though.

The church being done, there was yet one to do of the "Swan," getting the landlord and landlady to give life to the hostelry by appearing in the front grouped about the round pillars in the porch. Barkis was willing, but nothing would induce the young hostess to pose anywhere in sight, the effect being that mine host appears in the picture where a host should, upon his front steps, while mine hostess can be faintly discerned peeping round one of the pillars.

I used 9 by 7 plates, and developed them in an ebonite dish, which dish was so economically made that after the plate was in, it was difficult to get it out: it was a regular tight fit. That annoyance vanished when I laid a piece of tea twine across the upper end of the dish before putting in the plate. I could raise it at will, look at it, lay it down again, and not once touch the solution with my fingers. A simple dodge—still worth knowing.

The re-opening ceremony took place, and copies were produced in good time, but the sale did not come up to much—nothing to warrant the luxuries of that day out. If the truth were told, the public-house paid far better than the church, and certainly the next church I have a shot at must needs be easier to do, or, sad as it may sound, I shall turn to the public-house.

"All's well that ends well." I had my day out, the landlady of the "first-floor front" had her picture, Dan drove the pony home, and the lilac and the laburnum were ver sweet.

PHOTOGRAPHIC COPYRIGHT DEFENCE ASSOCIATION.

We are requested to announce that a meeting will be held on Wednesday next, the 15th inst., at 7 p.m., in the Chapter Room, Anderton's Hotel, Fleet Street, with a view to forming an Association or Society, to protect the copyright of photographic publications. Mr. George Bishop has kindly consented to take the chair on that occasion, and photographers in the country who cannot conveniently attend are invited to forward any suggestion they may desire to make on the subject of forming the Society, to the Chairman. The attendance of photographers is earnestly requested.

CONSTRUCTION OF STUDIOS.

At the last meeting of the Society for the Advancement of Photography in Berlin, some interesting remarks were made on the construction of recent German studios. Dr. H. Vogel, who was in the chair, exhibited to the meeting a sketch of Hanfstängl's studio, Unter den Linden. It is of extraordinary construction. The roof is not even, but sinks in the middle, so that the side elevation of the studio is like the diagram Fig. 1.

Fig. 1.

The top light is partly changed into two front lights v v, acting powerfully on persons stationed at P P′. This circumstance perhaps accounts for the shortness of exposure necessary, but the lighting seems somewhat diffused. The studio is unusually lofty. The middle depressed part is ten feet high, and the ends are twenty feet.

Herr Bergmann described a studio of the firm of Beyrich, patented in Austria, which he praised highly. It was in many ways to be recommended, and constructed on somewhat the same principle as the preceding.

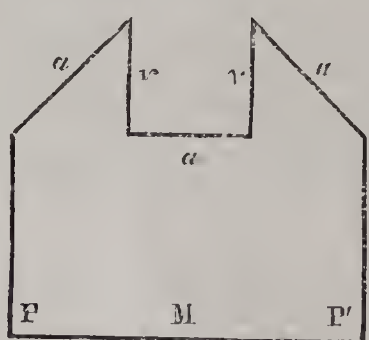


Fig. 2.

Referring to Fig. 2, side view of the studio, sides a a a of the roof are opaque, while v v are glazed. The camera is placed at M, and the sitter at P or P′.

Herr Reichard remarked that in both studios (at least by day-light) the sitter must be posed in the morning on the East, and in the afternoon on the West side, so that to a certain extent one is forced in the morning to work with light from the left, and later in the day from the right; it is self-evident that this cannot be practicable for every-one. He did not doubt that by a suitable arrangement of curtains this difficulty might be obviated, but then the light would be so weakened that there would not be more than in any other studio. The construction of Hanfstängl's studio seems to indicate that a change of lighting was aimed at during exposure, as in Kurtz's new researches. It was stated by Herr Haberland that he had once worked in a similarly constructed studio, and found it only tolerable on cloudy days, but succeeded very badly in sunshiny weather.

WORK IN THE INFRA-RED OF THE SPECTRUM.

BY CAPT. W. DE. W. ABNEY R.E. F.R.S.

It is with a certain amount of dread of boring the readers of *Nature*, that I have taken up my pen to write on the method of photographing with rays of very low refrangibility, since it ought to have passed the limits of novelty. And yet I suppose it has not altogether done so, since almost weekly I have inquiries made as to where the method is described, and am questioned as to how to succeed with it when my correspondents know where to find its description. The Editor also has asked me to write on the subject, so I propose to put as concisely as I can what plan to adopt. It is almost too well worn a scientific adage to repeat that unless you can obtain a sensitive salt which will absorb the rays to be used photographically, you cannot hope for success; and the method which I shall describe presently fully secures this desideratum. To photograph the red and dark rays, then, a sensitive salt must be procured which shall absorb the red and ultra-red rays. The colour of the salt to aim at, then, is a bluish green, which gives a continuous absorption at the least refrangible end of the spectrum. The salt employed is bromide of silver in a modified molecular state, a state, I may say, which is very easy to obtain when the formula below is strictly carried out, but very easily missed if the experimenter is self-inspired to make improvements in the method of procedure. I don't know whether it is something peculiar to photographic minds that there is in them such a large amount of self-assurance, but my frequent experience is that those who try a formula for a photographic preparation invariably try to improve on it before giving the original one a chance of success; and then when failure occurs they blame everything and everybody except their own conceptions. May I ask those who read this and endeavour to prepare the sensitive compound alluded to, to follow out strictly the directions as I described them in the Bakerian Lecture for 1880?

The following is the mode of preparation. A normal collodion is first made according to the formula below:—

Pyroxyline (any ordinary kind)... ...	16 grains
Ether (·725 sp.)	4 ounces
Alcohol (·820)	2 ounces

This is mixed some days before it is required for use, and any undissolved particles are allowed to settle, and the top portion is decanted off. 320 grains of pure zinc bromide are dissolved in ½ oz. to 1 oz. of alcohol (·820), together with 1 drachm of nitric acid. This is added to 3 ozs. of the above normal collodion, which is subsequently filtered. 500 grains of silver nitrate are next dissolved in the smallest quantity of hot distilled water, and one ounce of boiling alcohol ·820 added. This solution is gradually poured into the bromized collodion, stirring briskly while the addition is being made. Silver bromide is now partially suspended in a fine state of division in the collodion, and if a drop of the fluid be examined by transmitted light it will be found to be of an orange colour.

Besides the suspended silver bromide, the collodion contains zinc nitrate, a little silver nitrate, and nitric acid, and these have to be eliminated. The collodion emulsion is turned out into a glass flask, and the solvents carefully distilled over with the aid of a water bath, stopping the operation when the whole solids deposit at the bottom of the flask. Any liquid remaining is carefully drained off, and the flask filled with distilled water. After remaining a quarter-of-an-hour the contents of the flask are poured into a well-washed linen bag, and the solids squeezed as dry as possible. The bag with the solids is again immersed in water, all lumps being crushed previously, and after half-an-hour the squeezing is repeated. This operation is continued till the wash water contains no trace of acid when tested by litmus paper. The squeezed solids are then immersed in alcohol ·820 for half-an-hour to eliminate almost every trace of water, when after wringing out as as much of the alcohol as possible the contents of the bag are transferred to a bottle, and 2 ounces of ether (·720) and 2 ounces of alcohol (·805) are added. This dissolves the pyroxyline, and leaves an emulsion of silver bromide, which when viewed in a film is essentially green-blue by transmitted light.

All these operations must be conducted in a very weak red light—such a light, for instance, as is thrown by a candle shaded by ruby glass, at a distance of twenty feet. If a green light of the refrangibility of about half way between E and D could be obtained it would be better than the faint red light transmitted by ruby glass, since the bromide is less sensitive to it than to the latter. The light coming through green glass after being filtered through stained red glass is almost the best light to use. It is most important that the final washing should be conducted almost in darkness. It is also essential to eliminate all traces of nitric acid, as it retards the action of light on the bromide, and may destroy it if present in any appreciable quantities. To prepare the plate with this silver bromide emulsion all that is necessary is to pour it over a clean glass plate, as in ordinary photographic processes, and to allow it to dry in a dark cupboard.

It has been found advantageous to coat the plate in red light. and then to wash the plate and immerse it in a dilute solution of HCl, and again wash, and finally dry. These last operations can be done in dishes in absolute darkness; the hydrochloric acid renders innocuous any silver sub-bromide which may have been formed by the action of the red light, and which would otherwise cause a heated image.

Let me here give warning that the emulsion formed will be very grainy in appearance, and requires vigorous shaking to cause it to emulsify proper. If it requires a little plain pyroxyline, say about two grains to the fluid ounce should be added to give greater consistency. One thing is certain, if it be not coarse grained under the microscope it will not be sensitive to the required region, and moreover it will be found that on an average it should be about twice as coarse as the average form of bromide which is generally obtained in collodion emulsion. Here let me interpolate a remark. It has been assumed that because an emulsion in gelatine has a bluish colour after it has been boiled, that in this case we have the same form of bromide as that described above. It is a very different form: let me show how. Suppose we throw a spectrum on a gelatine plate, it will be found that G requires about ⅕ of a second with a very narrow slit, whereas to obtain B it will require the best part of a minute, and to obtain rays of lower refrangibility very much more; and that any amount of exposure will not make an impression much below A. With the blue-green bromide in collodion to obtain an impression about G will take some eight or ten seconds, and it will be found that at the same time we have an impression of B. A minute's exposure to the prismatic spectrum will under similar circumstances give an impression as much below A as D is above it, measured not in wave-lengths, but along the photograph. I point out this because a leading Continental photographic experimentalist has expressed himself satisfied as to the identity of the two forms of sensitive salt. They are totally distinct, as if he tried to work with a gelatine plate in the infra-red region he will soon own. Now in reference to the coarseness of grain it is right to call attention to its disadvantages. Its advantage we know. In spectrum work we often come across close pairs of lines. Now suppose each pair happened not to be separated by a larger interval than the grain of the sensitive salt, we shall be unable to resolve such a pair, for the action of either component of the pair, and much more both, if they fell on it, would be to cause, on development, a reduction to metallic silver of the whole grain. Thus evidently such a close pair would be unresolved.

(*To be continued.*)

Correspondence.

FOL'S REPEATING CAMERA.

Dear Sir,—I see you allude in your issue of a fortnight back to the repeating camera I have recently constructed. The way of using is correctly described, but there is an error in the size of the plates. My repeating gun camera carries eleven plates 4 inches by 5 inches, or, more exactly, 9 centimetres by 12 centimetres. Will you kindly note this in the next News?—Faithfully yours, Dr. H. Fol.

PHOTOGRAPHIC NUISANCES.

Sir,—As one among the number of photographers who have been greatly inconvenienced by the uncertainty of commercial dry plates, scarcely ever finding two dozen of the same quality, I would venture to suggest that manufacturers should put up one gross packets of plates of the same batch, so that the professional or amateur should at once know upon using the first dozen from the gross how to regulate development, &c. As the matter now stands, on sending an order to a dealer, one gets plates from many batches, scarcely any two boxes bearing the same number of batch. Some makers label the plates on the outside as to instructions for development; but on opening, one finds a notice "only for pyrogallic development." Your humble correspondent found this out to his delight when twenty miles from home, with only oxalate, &c., with him.—Yours, &c., Midland Counties.

Dear Sir,—I venture to think that the complaints which have lately appeared in the News as to the unreliability of commercial dry plates scarcely represent a tithe of the injustice done to photographers (especially amateurs and the smaller professionals) by the carelessness of certain makers of plates.

I could state some facts which would scarcely redound to the credit of at least one maker, but I forbear, as my present object is to give a suggestion for checking the abuses to which the users of commercial plates are now subjected.

The remedies I would suggest are as follows:—

First, that a committee be formed in connection with each of the photographic societies, to examine and report upon any plates which may be sent to them by the members of the societies; such reports to be published in the photographic journals, giving name of maker of plates, the defects found in such plates, &c.

Second, that such committees should occasionally purchase, or cause to be purchased, *in the open market*, plates by the various makers, and report upon them from time to time.

This course, while doing good to all reliable makers, would place a check upon the unreliable ones, and thus compel them to improve their goods, or drive them out of the market altogether.

This question is of greater importance than photographers in London and other large centres are aware of, and they can form but a faint idea of the inconvenience and loss experienced by those who reside in the small towns and country places at a distance.—I am, &c.,

Thos. Forrest.

PHOTOGRAPHIC JOURNALS.

Dear Sir,—You will oblige me by correcting the statement in your last number of the Photographic News concerning the *Photographisches Archiv;* this journal now appears fortnightly, on the 1st and 15th of each month regularly, and is no longer published in Berlin, but only in Düsseldorf by my firm.—Believe me, dear sir, yours faithfully, Ed. Liesegang.

Proceedings of Societies.

South London Photographic Society.

The Annual Technical Meeting of the above Society was held at he House of the Society of Arts, John Street, Adelphi, W.C., on Thursday evening, 2nd of November, the Rev. F. F. Statham, M.A., President of the Society, in the chair.

There was a good attendance of members, and many visitors also were present, the room being well filled.

The minutes of the previous meeting having been read and confirmed,

The Chairman reminded the members that this was the occasion upon which nominations must be given in for the election of officers for the present session, the ballot for which would take place at their next meeting on December 7th. The following gentlemen were then nominated:—

President—The Rev. F. F. Statham, M.A.

Vice-Presidents—Messrs. Jabez Hughes, Frank Howard, W. Brooks, Peter Mawdsley, and E. Cocking

Committee—Messrs. T. Bolas, W. B. Bolton, A. Cowan, W. Cobb, E. Dunmore, E. W. Foxlee, and G. F. Williams. of the retiring members, were nominated. Mr. E. W. Yorke having tendered his resignation, and Mr. Leon Warnerke being absent from England, Messrs. H. Wilmer and John Nesbit were nominated in their stead.

The Chairman said that with regard to the office of hon.

treasurer, he was sure the members would all agree with him that they would like to have the services of Mr. F. A. Bridge again, who was present this evening, though out of health, and had signified his willingness to undertake the duties of that office for another year. With respect to the hon. secretaryship, he said that Mr. H. G. Cocking having resigned that post, there had been some discussion about the matter at the committee meeting, and as Mr. Bridge had expressed himself willing to combine the duties of this office with those of treasurer, it had been proposed Mr. Bridge should fill the double office of hon. secretary and treasurer, and should have the option of appointing an asssistant secretary to help him with the clerical work, &c., as he could not devote the necessary time himself to these duties. The matter would be brought up again at their next committee meeting, and something definite arranged. He also announced that the annual dinner would take place on Friday, 15th December, provided arrangements could be made for that date. It was proposed to hold it at the Holborn Restaurant as usual: should any change be made in the arrangements, however, the members would be advised of it. He also intimated that the secretary of the Parent Society had kindly sent them a bundle of tickets of admission to the Exhibition in Pall Mall, and any members who desired to take any could obtain them upon application after the close of the meeting. Before commencing the technical meeting, it being necessary to have some one as demonstrator, he proposed that Mr. Brooks, who had acted in that capacity before, should be asked to assist the meeting; and that gentleman having signified his willingness,

Mr. A. G. Langton, of Euston Road, exhibited an improved glass developing dish, which he found to be better than ebonite, as, being transparent, it enabled the operator to watch the progress of the development. It had an india-rubber shield attached to the handle to protect the hands from being stained by the solution. He also exhibited an improved plate-box for the studio.

Mr. George Smith, of the Sciopticon Company, showed a portable tourist camera—half-plate, and very light. The body of the camera had a range of three to eleven inches; but by means of a bellows extension front, which packed inside the camera, the range could be increased to seventeen inches. The peculiar features of this camera are, however, the arrangements by which the motion of the swing-back and movable front are obtained. In the former case the back portion of the camera is attached to the base-board by a universal ball-and-socket joint, which allows it to be clamped firmly in any desired position, the horizontal and vertical swing being gained by the one motion. In the front the sliding portions are kept in position by hidden springs, which, while allowing the lens to slide, do away with the necessity for screws to retain it in position. He also exhibited his "brattice" stand, made of pine, and weighing only 1 lb. 5 ozs. When fixed up, the legs were always kept in a state of tension, and very steady, by means of an alternate pull-and-thrust arrangement of brass bolts. He also showed a lantern for changing plates when travelling, to be used with a night-light, and a dropping bottle for holding solutions.

Mr. E. White, of Forest Hill, showed a changing-box on the principle of a tent fitted on to the top of the plate-box, with sleeves at the sides to work through, and sufficiently large for 12 by 10 plates.

Mr. Shew, of Wardour Street, exhibited a developing-box fixed on a tripod, the inside of which was perfectly water-proof; also a fixing trough, to fix with a very small quantity of hyposulphite, and having a carrier to the plate which could be moved up and down to accelerate the fixing; the trough being made of glass, the operator could watch the progress of the fixing. This gentleman also showed some improvements in his instantaneous shutter.

Mr. Emery, of Burslem, who read a paper at the last meeting on the "Application of Photography to the Decoration of Pottery," sent some specimens in illustration of the process, printed respectively from Woodburytype blocks, ordinary copper plate engravings, and from copper plates reproduced by photography.

Mr. Brooks, by permission of Mr. Barnes, of Mile End Road, showed some early specimens by Scott Archer himself, including an albumen negative, two negatives taken in collodion of a statue in the 1851 Exhibition, a negative taken before the dipper came into use, and taken from the bath with the fingers, and a negative printed from with the iodide left in the film. Mr. Brooks also showed two of Dr. Huggins' small negatives of star spectra.

Messrs. Marion and Co., Soho Square, exhibited a half-plate "Enjalbert" camera and changing-box combined, carrying eight plates, and very compact, which could be used either horizontally or vertically, and with either long or short focus lenses; also a small camera and changing-box invented by Mr. Warwick Brooks, of Manchester, called the "Academy Camera"; also a telescopic tripod for small cameras, formed of brass tubes, the invention of M. Pflücker, an officer in the Belgian army.

Mr. Cowan (on behalf of Mr. George Hare) showed a camera which was claimed to be the lightest, for its size, ever made, with reversible back, focussing up to 17 inches, and swinging to any angle, and the front having swinging action to get side motion.

Mr. A Cowan showed a boiling-jar with wire jacket to protect the fingers; also a developing dish, designed so as to protect the fingers while developing. He also exhibited an improved cutting-board, and a packing-box for carrying small articles, which, when turned upside down, could, by an ingenious arrangement attached to a false bottom, be quickly converted into a dark-tent.

Mr. Harrison exhibited an extempore plate-holder made of tin, which could be constructed in a few minutes; also a method of packing dry plates, consisting of a box or frame made to same size as the rebate in plate box, in which the plates were placed, parted by strings laid alternately backwards and forwards in the frame across them, and finally secured by tying the ends over the last plate.

At the conclusion of the various exhibits, the Chairman thought all present would agree with him that the evening had not been wasted, if only for the sake of the evidence it had afforded them of the great amount of thought and energy which were continually being displayed by photographers, and he thought these technical meetings might be made even more useful than they had yet been. They were first suggested by Mr. W. Brooks in connection with the South London Society, with the object of affording to photographers in all parts of the country an opportunity of seeing what was being done in the photographic world, and of encouraging them to attempt improvements themselves. This was the tenth annual technical meeting since they were instituted, other societies having since taken up the idea; and he hoped the public at large would not forget that all photographers were invited to send in articles for exhibition at this meeting held annually in November. There was one thing he would like to remark, and that was, that photographers seemed to devote all their energies to improving the mechanical branches of photography; he must say he would like to see amongst the exhibits something tending towards improvement in the preparations and chemicals used. He thanked the visitors present for their attendance at the meeting, and more especially those gentlemen who had exhibited, and concluded by proposing a vote of thanks to them, which was heartily accorded.

London and Provincial Photographic Association.

At the meeting of the Association held on the 2nd inst. at the Mason's Hall Tavern, Mason's Avenue, Basinghall Street, Mr. R. Tanner in the chair,

Mr. Debenham said he had prepared a batch of emulsions from the sample of bromide handed him by Mr. Henderson at the last meeting, and also one from a sample of Howard's bromide, and could find no perceptible difference between the two emulsions.

Mr. Prestwich had coated some plates from the emulsion prepared as on Obernetter's plan described by him at the last meeting, but found them very slow.

Mr. W. Cobb showed a print from a negative by Mr. Bevan, of Lowestoft, showing a secondary image caused by a minute hole in the front of the camera; the picture was a river scene, and the effect produced was exceedingly curious and interesting.

Mr. W. M. Ashman mentioned that an amateur friend had placed some plates in a drying box and left them to dry in a fairly lighted room, and when exposed and developed, a picture of the room was found on them; this was traced to a minute hole in the drying-box.

Mr. Debenham said that he had a negative much green fogged, which was inadvertently splashed with some of the solution from a battery, and where the solution had splashed the fog was cleared.

Mr. R. Faulkner was elected a member of the Association.

Halifax Photographic Club.

At the usual monthly meeting of the Club at the *Courier* office, after the reading of the minutes of last meeting, and the same being confirmed, the President (Mr. J. B. Holroyde) called on Mr. Illingworth, a practical photographer in Halifax of many years' standing, and a successful emulsion maker and dry-plate worker, to open a discussion on testing and exposing dry plates, in which all the members took part.

It was afterwards suggested to spend an evening in intensifying weak negatives by different methods with a view to some practical results.

Mr. W. C. Williams is expected to give a practical demonstration on "Enlargements."

Bristol and West of England Amateur Photographic Association.

The ordinary monthly meeting was held as usual at the Association Studio, Portland Street, Kingsdown, on Wednesday, October 25th, Mr. E. Brightman (in the absence of both vice-presidents) in the chair.

Colonel Playfair and Mr. R. E. Strachan were elected ordinary members of the Association; after which,

The Hon. Secretary (Mr. H. A. Hood Daniel) read some notes communicated by the Rev. J. J. Strutt Bird on "The Effect of Light upon Certain Kinds of Ordinary Paper":—"Having observed that the paper upon which cheap newspapers are printed turns very yellow on exposure to light, as a matter of curiosity I procured a piece of plain paper of a similar character, and exposed it under a negative to ordinary daylight for three weeks. The result I produce for your inspection. You will observe a very distinct but faint image of the negative of a buff colour. Speculation on the material which promotes this image may be a pleasant subject for discussion. *Primâ facie*, it seems as if it would be easy to find some means of developing a perfect image, and an interesting series of experiments may result; at all events, the question of cause and effect is worthy of consideration. The paper is of a very common quality, costing 3s. or 4s. per ream." Some sheets of the paper in question were then laid upon the table for any members who cared to experiment with.

Mr. H. A. Hood Daniel said that the chief point of the very interesting experiment Mr. Bird had conducted seemed to be that of turning attention to the possibility of the *paper* of a print decolourising separately, and apart from any change in the chemical picture itself; although, of course, in the latter case, the paper would undergo a considerably different bleaching operation to that which might be performed upon a piece of ordinary paper.

The Chairman remarked that he considered the atmosphere had a great effect upon paper in changing its colour; although, in the present case, of course, the experiment carried out by Mr. Bird was conclusive as to its being solely the effect of light in the case in question.

Mr. Daniel then exhibited one of Messrs. Newton's 4-wick lamps for the optical lantern, which was tested against one of the same firm's 3-wick lanterns. The same oil was used, and exactly similar condensers, lenses, and lanterns; a slide was carefully focussed in each lantern, the disc in each case being of identical size. The comparison as to evenness of illumination, quality and quantity of light, was made in various ways, most clearly proving that Messrs. Newton's new 4-wick lamp was in every way superior to their 3-wick and last previous lamp.

Mr. Phillips remarked upon the great increase in light, and drew attention to the fact of the additional length of iron chimney.

Mr. Goss inquired the reason for making the front glass of the lamp curved instead of straight as in the 3-wick lamp.

Mr. Daniel was unable to reply to the question, but presumed it was in accordance with some idea as to optics which Messrs. Newton had.

Mr. Brightman said that if it were on that score, he should have expected to see the glass curved exactly the reverse way.

The Hon. Secretary much regretted to have to announce that not a single picture had been sent in (except one by himself) in competition for the four medals offered.

A vote of thanks to the Rev. J. J. Strutt Bird and Mr. H. A. Hood Daniel closed the proceedings.

Talk in the Studio.

Photographic Society of Great Britain.—The first meeting of this Society for the ensuing session will take place at the Gallery, 5a, Pall Mall East, on Tuesday next, November 14th, at 8 p.m., when the medals awarded will be presented, and a paper will be read by Mr. W. K. Burton on "A Modified Gelatine Emulsion Process."

Presentation to Mr. F. A. Bridge.—Mr. F. A. Bridge, who has just relinquished his appointment as choir-master of St. Martin-in-the-Fields, was, at a meeting recently held at the Vestry Hall of the parish, presented with a framed testimonial, expressing the regret felt by all at his resignation. The testimonial was handed to Mr. Bridge from the clergy, churchwardens, overseers, and parishioners by Mr. Churchwarden James (in the absence of the Vicar), accompanied by a handsome drawing-room clock, and pair of ornaments *en suite*. This was then followed by an electro-silver reading-lamp from the gentlemen of the choir, and a pair of antique two-handled Dresden cups, covers, and stands from the choir-boys.

A Photographic Reunion.—The annual dinner given by the employées engaged in the London studio of Messrs. W. and D. Downey was held on Friday evening, in the Duke's Saloon, Holborn Restaurant, London. Mr. and Mrs. W. Downey and Mr. and Mrs. W. E. Downey, and a few other friends, were present as guests. For the first time in the history of this annual social gathering the ladies of the establishment, as well as the wives of the artists, were present, the occasion being taken advantage of to bid farewell and God-speed to Mr. Herzog, one of Messrs. Downey's chief assistants, who is returning shortly to his native land—Switzerland—to commence business on his own responsibility. In addition to several valuable presents given to him by the ladies and gentlemen of the firm respectively, as tokens of their good-will, he was, during the course of the evening's proceedings, the recipient from Mr. W. Downey of a very handsome silver-mounted salad dish and biscuit-box. The company numbered forty, the chair being occupied by Mr. W. E. Downey, and the vice-chair by Mr. E. A. Cade. Among the toasts *apropos* to the occasion were: "Success to Photography," by the chairman, which was followed by the appropriate song "In Shadow Land," by Miss Litton. Messrs. Johnson and Bennetto replied. "Prosperity to the Firm" was proposed by Mr. Cade, who dwelt on the world-wide fame of the firm, and to the spirit of family-like affection and regard which pervaded all the departments, and linked them all together—masters and workers—in the strong tie of friendship and mutual esteem. Mr. W. Downey responded, and then proposed the health of Mr. Herzog, wishing, on behalf of himself and the company, success in his future professional career in his native land. Mr. Herzog replied, and concluded by heartily wishing continued and increased prosperity to the firm. Other toasts followed. The vocal and instrumental music supplied by the company was of a very high order of merit, and greatly enhanced the evening's enjoyment.—*Newcastle Daily Chronicle.*

"A Misty Morning."—Mr. W. McLiesh writes:—"I have heard that it is generally considered in professional circles that my picture now in the Exhibition is a combination print. I shall be obliged if you will kindly allow me to assure my professional brethren that it is a direct picture, taken at one exposure, and printed from only one negative."

The Photographic Money Dispute.—At Clerkenwell Captain Herbert Kerr appeared to answer an adjourned summons taken out by Lieutenant Arthur Henry Loring, for that he did unlawfully, by certain false and fraudulent pretences and representations, obtain of and from the said Arthur Henry Loring divers sums of money, of the value of £2,070, with intent to defraud. The allegation was that the defendant had induced Lieutenant Loring to invest money in the Photographic Artists' Supply Association, the affairs of which Company are in liquidation. Mr. Besley prosecuted, as before, and Mr. Grain was for the defence. Mr. Hosack, after some further evidence had been taken, said that this case appeared to have been taken before a civil court. Up to the present there had been no evidence of fraud before him. Mr. Besley said that when his Worship had heard more evidence his mind would no doubt be altered. Mr. Hosack then again adjourned the case for a week.

Reversed Negatives by Exposure through the Glass.—Mr. R. V. Harman writes:—"I have contributed three pictures to the Pall Mall Exhibition, and I think their principal feature has been overlooked. They are 15 by 12 landscapes taken on the reverse side of dry plates in the camera, and printed in single transfer carbon; and not having heard of such a method before, I thought the idea a new one, and that it was worth the attention of those who could turn it to account in the profession, as I always find it a difficulty to get anything done by double transfer even by leading firms. I have little experience in carbon printing, so sent the first impressions on ready sensitized Autotype tissue; but they make beautiful impressions on silver paper, though of course the picture is incorrect." Mr. Harman's idea of exposing gelatino-bromide plates through the glass is not altogether new, but many of our readers will be glad to have an opportunity of actually seeing what good results can be obtained by this simple and convenient method.

A Moonlight View of an Inundation.—Mr. H. Evans, of Chippenham, sends us a picture of the recent overflow of the Avon. He writes :—" The plate had an exposure of three hours and ten minutes, viz., from 9·10 p.m. until 12·20, and the lens used was a single view lens. It was desirable that a photograph should be secured if possible when the flood was at its highest, hence the necessity of a night exposure. The nearest buttress of the bridge you will observe is almost submerged, and I should have forwarded you a copy earlier, but the demand has been very great." Not only are the main features of the view clearly defined and well modelled, but the reflections in the broad expanse of water almost duplicate the principal features of the picture.

The late W. K. Sawyer.—The remains of a ripe scholar and able journalist—one of those read by hundreds of thousands in the daily Press who, may-be, never heard his name—were yesterday conveyed to their last resting-place at Brighton. William Kingston Sawyer, graceful poet and lover of Nature by choice—leader-writer, essayist, and editor by profession—literally died in harness last Thursday morning, being struck down by illness while busily preparing the material to fill the pages of a well-known comic annual. It was a strange irony of Fate that the last efforts of his pen should be to produce "copy" for the readers of a humorous sheet, and suggest ideas to his artists for its comic cuts; but in the strange jumble of work-a-day life merit does not always secure its place. A man of refined tastes, an antiquarian of deep research, a firm friend, and a thoughtful, genial companion, his absent place will be seen with sorrow by many who had the pleasure to call him friend. Mr. Sawyer was for many years a leader-writer on the *Morning Advertiser* and the *South London Press*, and was editor of *Funny Folks* from its commencement to the day of his death. His sketches, poems, and essays might be numbered by the thousand.—*Echo.*

Colour Blindness.—A series of researches having been undertaken by several Russian physicians as to colour blindness, Dr. Kolbe has just published in the newspaper *Vrach* (*The Physician*) the results. Out of 10,828 railway servants examined, no less than 251 were colour-blind, and 32 proved to have an imperfect capacity for distinguishing colours. Three other doctors have made experiments on sailors and pupils in naval schools, and have found 6·08 per cent. of colour-blind, and 8·5 with imperfect vision. Women are subject to a far smaller extent to colour-blindness. Thus, Dr. Kolbe, who has experimented both on men and women, discovered among the men 2·5 per cent. of colour-blind and 7·5 with imperfect vision, whilst among women he has discovered only 0·16 per cent. of colour-blind and 3 per cent. with imperfect colour vision.

Society of Arts.—The following arrangements have been made for the ensuing session :—November 22nd, J. Hopkinson, D.Sc., F.R.S., "Refrigeration by Evaporation of Water in Vacuo." November 29th, P. L. Simmonds, "The Utilisation of Waste : A Retrospect of Recent Progress." December 6th, W. A. Gibbs, "The Artificial Drying of Crops." December 13th, W. H. Preece, F.R.S., "Electrical Exhibitions." December 20th, W. K. Burton, "The Sanitary Inspection of Houses." For Meetings after Christmas :—J. H. Evans, "The Modern Lathe." Captain J. H. Colomb, R.N., "Collisions at Sea." A. J. Hipkins, "The History of the Pianoforte." J. Donaldson, "The Construction of Torpedo Boats." C. F. Cross, F.C.S., "Technical Aspects of Liguification." W. N. Hartley, F.R.S.E., "Self-purification of River Waters." James J. Dobbie, D.Sc., and John Hutchinson, "On the Application of Electrolysis to Bleaching and Printing." There will be three courses of Cantor Lectures; the first will be on "Dynamo-Electric Machinery," by Professor Silvanus P. Thompson, D.Sc. Lecture I.—"The Dynamo in Theory." Lecture II.—"The Dynamo in Practice." Lecture III.—"The Dynamo as a Motor." The Second will be on "Solid and Liquid Illuminating Agents," by Leopold Field. The Third will be on "The Decorative Treatment of Metal in Architecture," by George H. Birch. The Fourth will be on "The Transmission of Energy," by Osborne Reynolds, M.A., F.R.S., Professor of Engineering at Owens College, Manchester. The Fifth will be on "Secondary Batteries," by Prof. Oliver J. Lodge, M.A., D.Sc. The two Juvenile Lectures will be by Prof. Henry Nottidge Moseley, M.A., F.R.S., on "The Inhabitants of the Ocean." The dates for these are Wednesday evenings, the 3rd and 10th January.

To Correspondents.

*** We cannot undertake to return rejected communications.

*** The Year-Book of Photography and Photographic News Almanac for 1883.—Those of our readers who kindly intend favouring us with contributions are earnestly requested to forward their communications forthwith.

W. H. G.—1. You will find the best way is to dry your prints in a folio built up of blotting-paper. As regards rolling the thin unmounted prints, the commercial rolling machines are frequently not made exactly enough to do justice to such a thin material, as one part may escape with but little pressure, while another is thoroughly crushed. This state of things can be remedied to some extent by passing a piece of thinnish card-board through the rollers along with each print. The so-called encaustic paste is much the same thing as the old-fashioned turpentine and bees-wax furniture polish. See the Formulary in last week's News. Rolling-presses can be obtained from any of the dealers in photographic materials, and most stock houses keep encaustic paste ready made.

J. S.—We are sorry that you have failed, but imagine there must have been some mistake. Enquire again.

John Bitford.—The nitrate is best, because it dissolves so readily in alcohol.

Novelty.—Quite the contrary, as the Hoeschotype process was fully described in the News many weeks ago.

Perplexed.—1. You will probably find McLellan's apparatus, as figured in the News this week, to be as convenient as anything. 2. Not unless a very prolonged exposure is given. 3. You had better work by daylight if it is possible.

C. H. Stephenson.—We have no recollection of the matter. When was it?

Novice.—1. Yes; but we prefer to use the alum bath afterwards. 2. Write to Dr. Edward Liesegang, Dusseldorf.

A. L. Dresser.—Thanks.

F. Warner.—Directions cannot be given in a few words. See what Major Waterhouse says in his articles on photo-lithography.

H. Cushing.—1. Thanks for the suggestion, which seems to be valuable. 2. An article on the subject will appear before long.

M. S. (Clapton).—1. They may be all you say; indeed, we hope they are. 2. It would surprise us considerably to hear of such a registration being effected.

Studio.—You do well to determine on following the design of Mr. Wane, and we would advise you to reduce the scale of the dark room and enlarging apparatus as little as practicable. Abundance of room is far more important now than it was in the old wet-plate days. A length of 25 feet for the studio will be abundance.

E. Williams.—We have found it excellent, but at the same time do not find sufficient inducement to abandon the use of ammonia.

W. Barry.—A note awaits you at our office.

J. H.—Probably between £150 and £200.

J. Northam.—Write to Mr. J. J. Atkinson, Photographic Material Dealer, Liverpool.

J. Jolly.—We will devote a leader to the subject before long.

J. Downes.—We have found your ideas to be excellent, and you will find that these applications of the lamp have been fully described in the News during the present and past year.

W. J. Ankorn.—As it is an obvious infringement of copyright, we imagine you will have but little trouble. If the Publisher refuses to give you substantial compensation, instruct your solicitor to take proceedings at once. The law provides for a penalty for each copy of the pirated production, so that your claim will be considerable.

A Subscriber.—One drachm or a drachm and a half. Do not add any water.

A. T. Newington.—See answer to J. Northam.

Silver.—As regards the action of silver, it is much the same as if it were a film of gelatine, but the difficulty of keeping the image fairly on the surface will perhaps prove insurmountable.

Chemicus.—Just as you suppose, a curious case of the large proportion in which a reagent is present serving to reverse the usual order of affinity.

*** Authors may have Reprints of their Articles at 3s. per page per hundred copies; but the order must be given when the proof is returned.

PHOTOGRAPHS REGISTERED.

Mr. F. Downer (Watford)—5 Photos. of Lord and Lady Clarend.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1263.—November 17, 1882.

CONTENTS.

BURTON'S METHOD OF MAKING EMULSION.

At the meeting of the Photographic Society of Great Britain on Tuesday last, Mr. W. K. Burton described a modification iu gelatine emulsion work which seems likely to be of some importance. By his process he brings about without special apparatus or appliance the same result as Mr. Plener does by centrifugal force in the method which we described some time ago; that is to say, he eliminates from an emulsion which has been rendered sensitive by boiling the gelatine and soluble salts, and washes the bromide of silver. This is then ready, either for storing, or for mixing at once with more gelatine to make an emulsion. The method by which this is brought about is briefly as follows:—An emulsion is mixed by any of the formulas suitable for the boiling process—we should think that given in our Formulary would do. The only peculiarity at this part of the operation is that an unusually large quantity of water is used. This is not objectionable, as the water is afterwards to be poured away; and Mr. Burton claims that by the use of it there is greater facility in getting a fine state of division iu the bromide of silver. He emulsified by droping the nitrate of silver in crystals into the bromide solution, and shaking. After boiling in the usual manner for an hour, more or less, the emulsion is allowed to cool gradually to about 120° Fah., when three or four per cent. of strong ammonia and five per cent. of alcohol are added. Again the emulsion is left to cool, and at the end of forty-eight hours the bromide of silver will, we are told, be formed in the form of a precipitate at the bottom of the vessel. It may then be washed by decantation in the manner of a precipitate. The writer of the paper considers it sufficient to pour off the first water which contains the decomposed gelatine, to mix the silver bromide up with one more quantity water, and once more to allow it to settle.

After the operations described have been gone through, nothing remains but to mix the bromide of silver with a sufficiency of gelatine. Mr. Burton states that he has tried the use of various different proportions of gelatine to the silver bromide, and has found very little difference in the results. He has mixed one part of bromide of silver with two of gelatine, aud two of bromide of silver with one of gelatine, without finding any material difference between plates coated with these very different emulsions, so long only as the plates were coated with enough of the preparations to ensure a sufficiently opaque film. In this particular process which we are describing, he lays considerable stress on the method of mixing the bromide of silver with the gelatine.

The former is apt, it seems, to stick somewhat tenaciously to the bottom of the vessel. He places the correct amount of hard gelatine, previously well soaked in water over the silver bromide, in the jar or beaker in which all the processes have up till now been performed. He collects the gelatine in a sort of mop on the end of a glass rod, and, whilst water warm enough to slowly melt the gelatine is being poured into the vessel, mops up the bromide of silver.

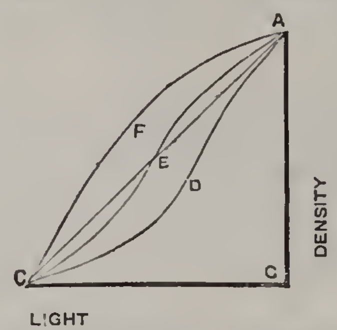
The emulsion which we saw made in this manner at the meeting above referred to was of excellent colour, and showed the bromide of silver to be in a very fine state of division. Of course we have not as yet had an opportunity of trying plates made by the method described, but we understand that, although the emulsion, if used immediately after it is finished, is liable to give somewhat thin images and slow plates, it increases in sensitiveness to an unusual degree by keeping, and eventually gives plates of the extremest sensitiveness, and of very good quality.

From the fact that this emulsion increases in sensitiveness to an extent so much greater thau is usual, the author of the paper argues that there may be some combinatiou between the bromide of silver and the gelatine which requires time, aud which accounts for the superior sensitiveness of bromide of silver when gelatine is the vehicle in which it is suspended. In the ordinary processes the bromide of silver is never freed from the gelatine, and the process of combinatiou, if such there be, may be going on from the beginning.

Mr. Burton judges entirely by colour as to how long the boiling process is to be continued. He boils till there is only a trace of red left in the emulsion. We know from practical experience that it is most difficult under ordinary circumstances to tell when the whole of the silver haloid in an emulsion is reduced to the blue variety, and would remind our readers of a very simple and useful "dodge," which we published some time ago, to facilitate judgment in this matter. This consists simply in placing a drop of emulsion on a piece of glass, spreading it very thinly, and gently warming it over the gas or otherwise. When it is dry, the bromide will be found divided into distinctly defined rings or patches of the two varieties, one intensely blue, the other intensely red. On commencing boiling, the red predominates, and there is very little blue. Boiling may be continued either till the blue predominates, or until there is no red at all. This method is only suitable for emulsions with a few grains of gelatine to the ounce, such as are usually prepared for the boiling method.

The effect which ammonia has on the bromide of silver, besides its effect in rendering the gelatine soluble in cold water, and allowing the haloid to subside, was gone into in considerable detail. It was shown that although ammonia, when added to a boiled emulsion, does not make the emulsion give a higher sensitometer figure, yet it certainly causes it to require a much shorter camera exposure. This is due to a fact which may be stated in a rough manner as follows. If plates be coated with a boiled emulsion before and after this emulsion is treated with ammonia, and these plates be exposed side by side in the camera, those that are coated with emulsion before treatment with ammonia will have the same *amount* of detail as the other, but the finer detail will be of less printing density. To get "well exposed" negatives with each may require periods of time varying as four to one.

The above-mentioned state of things is admirably illustrated by the diagram which Mr. Burton showed on Tues-



day evening. The horizontal line represents light, and the vertical line represents density, each starting from an imaginary zero at the right angle G. The progressive density arising from varying degrees of exposure to light would correspond to the straight line A C, in the case of any emulsion capable of truly representing all variations of light and shade; but such an emulsion has never yet been prepared.

An ordinary ammonia-nitrate emulsion gives a curve corresponding to C F A, and the result is a disproportionately great density of the weaker shades.

The curve C D A represents the result obtained with the usual boiled emulsion; and in this case the weaker shades, such as the deeper tints of foliage, are not represented with their true force. An emulsion made according to Mr. Burton's present directions gives a result nearly corresponding to the serpentine curve C E A, and is calculated to yield results very near the actual truth.

We cannot, of course, speak positively as to the merits of the process till we have had time to make trial of it, but, to judge from the specimens which were shown, there can at least be no doubt that plates of high quality can be made from emulsion prepared with it.

As regards convenience, it is not, as its author points out, adapted to experimental work when it is desired to finish an emulsion in the shortest possible space of time. It will prove, however, we think, useful for those who work in a systematic manner from day to day, and who can have one batch of emulsions going through each of the different processes; one being prepared each day, and put aside, whilst one which has been prepared some time ago will be ready for coating plates..

The process is by no means so expeditious as Plener's, which we described some time ago, nor is it possible by Burton's, as by Plener's process, to get rid of the coarser grains of silver bromide in an emulsion which is fogged, and thereby cure it. On the other hand, Burton's process has the advantage of requiring no special apparatus.

We need scarcely point out that in either of the processes under consideration, the great advantage which is gained lies in the fact that the gelatine which has gone through whatever process is used to gain sensitiveness, and which is sure to have suffered thereby, is eliminated. This is especially desirable when ammonia has been used, as this, by its action on the gelatine in the presence of silver bromide, is liable to produce green, red, and other fogs.

CHEMIGRAPHIC ENGRAVING.

Second Article.

If the zinc plate to which the fatty image has been transferred were immediately placed in the etching bath, there would be a considerable probability of the image becoming cleared off at once, owing to the fact of the lines being so far discontinuous or broken as to allow the acid to permeate through them. In order to render the fatty image capable of resisting the action of the etching fluid, it is necessary to reinforce the lines to such an extent as to convert them into ridges of printer's ink, so far piled up as to preclude the possibility of any trace of acid acting except fairly beyond the area covered by the lines. Before this can be done, however, the general ground of the plate must be so far charged with gum as to enable it to repel the ink. For this purpose, a soft sponge is thoroughly saturated with a strong mucilage of gum-arabic, and after the greater part of the gum has been expelled by gentle pressure, the plate is repeatedly dabbed with the sponge until the gum fairly takes on all parts of the zinc plate which are bare as regards printer's ink. The plate is now allowed to dry without the application of artificial heat. An ordinary lithographic inking roller must be well charged with rather thin printing colour—that is to say, a usual lithographic printing colour slightly thinned with middle lithographic varnish—but before rolling the zinc plate with this mixture it is necessary to once more work it over with the sponge, so as to thoroughly re-dissolve the desiccated film of gum, after which the gum is wiped off with a second sponge moistened with clean water, the zinc plate being thus left uniformly moist, except where the lines of the device exist. The inking roller is now brought into requisition, the still moist plate being thoroughly rolled in all directions, when it will be found that the ink will adhere to the existing ink lines, and will be repelled by the moist metal groundwork. Should any tendency for the ink to soil the ground be noticed, the damp sponge must be immediately passed over the plate a few times with moderate pressure, when it will be found that the previous clearness of the ground will be at once restored. A second gumming should follow, after which the excess of gum must be once more removed by the damp sponge, and the inking operation is repeated until the lines are seen to stand up in distinct relief. In inking the plate it must be remembered that a slow motion and a heavy pressure tend towards the deposition of a large quantity of ink, while a quick motion and a light pressure tend towards the deposition of a thin layer; or these conditions of rolling may even remove ink—that is to say, may reduce a heavy deposit. The same kind of thing holds good as regards the inking slab, quick rolling and light pressure tending to increase the amount taken by the roller, while the quantity on the slab is reduced; and slow rolling combined with heavy pressure serve to reduce the charge on the roller, and increase the amount left on the inking slab. The operations of gumming and inking may often be repeated with advantage five or six times, and care should be taken to pile up as much ink as the lines will hold without any risk being run of any spreading or widening taking place.

A little difficulty may arise from the absorbtion of water by the leather roller, and this hydrated condition may be recognised by a tendency of the roller rather to slide over the zinc plate, than fairly to bite or hold on it. In such a case, the only way is to take a fresh roller, and allow the first to remain exposed to the air until the moisture evaporates.

The inking or reinforcement of the lines having been sufficiently performed, the plate is well rinsed under a rose, wiped with a sponge, and fanned dry. The plate is next dusted over with finely-powdered asphalt powder, an ordinary broad camel's hair pencil being used for its application, and all excess being then removed by means of a soft powder-puff. Instead of asphalt merely powdered, it is advantageous to use a preparation obtained by melting 15 parts of bitumen of Judea with 1 part of ordinary resin and 1 part of beeswax; the mixture being next powdered into cold water, and, after having been dried, it is very finely powdered.

The lines on the dusted plate now appear reddish brown, from the presence of the loosely adherent powder; and in order to cause this powder to thoroughly unite with the printing ink, a very gentle heat must be applied by means of a spirit lamp or gas flame—never more heat than can be borne easily by the back of the hand, and not more than will just suffice to so far cause the asphalt powder and the ink to unite as to make the surface of the lines shining and glassy, rather than dull brown. When the plate has once more become cold, the edges and back are varnished with an alcoholic solution of shellac, and the varnish applied to the borders should not come nearer to the device than one-third of an inch. The varnish being quite dry, a scratch is made through it near one corner of the plate, the action of the acid on the metal thus laid bare serving as a guide to the progress of the general etching; and all is now ready for the immersion of the zinc plate in the first etching bath, which consists of a mixture of one part of strong nitric acid and 40 parts of water. The dish used for containing the acid should be so mounted on rollers as to render it easy to keep up a constant rocking motion while the acid is acting on the metal, this being necessary in order to prevent unequal action of the acid arising from the accumulation of the black impurites which always remain when commercial zinc is dissolved in an acid. As a rule, the first etching bath ought to be allowed to act for about forty seconds in the case of very fine work, or about eighty seconds in the case of coarse work; but perhaps one minute may be taken as an average. But time certainly ought not to be taken as a guide in the case of important work, it being much better to regulate the duration of the etching by an examination of the test line or stroke made through the shellac varnish used to protect the edges of the plate. For this purpose the shellac is scraped away from the sides of a portion of the line, and the depth of the etching is judged of by feeling with a needle point. A good rule is never to carry the first etching farther than to give a depth corresponding to the thickness of a sheet of thin note-paper, and in the case of fine work one-half or one-third of this thickness should not be exceeded. The first etching having been finished, the plate is then well rinsed with water, and is either allowed to dry spontaneously, or is fanned until all traces of moisture are removed.

The lines now stand in relief on the zinc plate, and the subsequent operations are intended to deepen the interspaces so as to fit the block for the printing press.

Review.

Instruction in Photography. By Captain Abney, R.E., F.R.S. Fifth Edition. (*Piper and Carter*).

Captain Abney's "Instruction in Photography" has been so often spoken of in favourable terms in these columns, that it is difficult to add anything now that a fifth edition of the work has appeared. The general introduction of gelatino-bromide into the photographic studio has naturally led the author to devote especial notice to the process in this his new edition, and we find not only details as to the best and most practical methods of preparing emulsion, but also the most approved plans of applying it to glass and paper.

Captain Abney wisely pays a good deal of attention to the mechanical printing processes, which are every day growing in importance, devoting a chapter to the new Stannotype method of Mr. Woodbury. The photo-zincographic, photo-lithographic, and collotypic processes generally, are explained, and, in many cases, working details are given. In a word, the new edition of Captain Abney's work is quite on a par with any of its predecessors.

"TEN TIMES AS RAPID."

BY S. BOTTONE.

I have just noticed a letter in last week's issue, in which the writer feels himself much aggrieved that makers of gelatino-bromide plates should so mislead their customers as to label their productions as being ten times and thirty times as sensitive as collodion; and then goes on to state that, according to *his* experience, a plate six times as rapid as collodion would appear to be the limit of sensibility reached by those self-vaunting deceivers known as "gelatine plate makers." Now, my experience of collodion and its capabilities extends over nearly thirty years, and I still desire to speak well of the bridge which has carried me happily over so many adventures. I confess to a very great admiration of an instantaneous collodion positive on glass, and I know that such a picture may often be obtained within a very small fraction of the time required to secure a good printing negative. But to attempt to compare collodion with gelatine in point of sensibility is like comparing an *arc* light with an *incandescent* in point of brilliancy.

I was working, towards the middle of last month, at getting up a series of slides for a lantern entertainment. Some of the subjects required, from their nature, very rapid exposures, so I had gelatine as well as collodion plates in requisition. I had some of the cheapest gelatine plates in the market, none costing more than 1s. 6d. per dozen. Some of these were marked "ten times rapid," others "thirty times rapid." On Wednesday, the 18th October, the light failed me rather rapidly in the afternoon, and my friend Mr. Gann, who was working with me, proposed that since our last negative had required a hundred seconds' exposure (and this with a neutral bath and fresh pale Mawson's collodion), we should try a "ten times rapid" gelatine plate on the same subject, with an exposure of only ten seconds. The resulting negative, developed with ferrous oxalate, was almost indistinguishable from the hundred seconds' collodion.

I have repeatedly tested the commercial plates of almost all makers, and I have come to the conclusion that it is easier to find plates that are *more* than ten times as sensitive as collodion, than less. So that no misconception should arise, I may mentiont hat the work in hand consisted in copying and enlarging microscopic objects, a work that necessitates the cleanest working, and perfect freedom from fog, and is, therefore, the severest test for any plate laying claim to sensitiveness conjoined to cleanness of working.

WORK IN THE INFRA-RED OF THE SPECTRUM.

BY CAPT. W. DE. W. ABNEY R.E. F.R.S.*

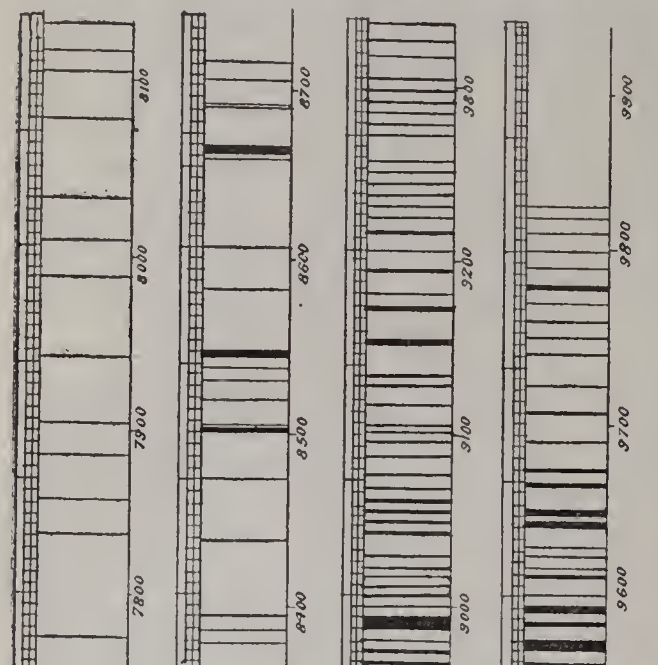
When a photograph of the spectrum on the finest grained plate is examined under the microscope it will be found that the metallic image is composed of grains of silver and nothing else; and that instead of the lines having sharp edges as seen by the eye that they shade. Part of this shading is due to the grain, though the greater part is due to proper absorption, which the eye is incapable of distinguishing. The fineness of grain given by the different processes we may class as follows, in the order of coarseness, the coarsest grain being first:—

1. Wet plate developed by iron.
2. Special bromide emulsion, as before described.
3. { Ordinary collodion emulsion. Wet plate developed by pyrogallic acid.
4. Gelatino-bromide plates.

It will thus be seen that for delicate work the dispersion with the wet plate process and the special bromide emulsion must be larger than when using a gelatine plate if equal resolving power be wished for. The above plate is an instance of this. In it we have the solar spectrum in approximate wave-lengths from Aλ (7,6000) to about λ 10,500. The general impression to the eye is the extraordinary width of the lines compared with those in the visible spectrum. No doubt they are as a rule broader, but their breadth is also to be accounted for in other ways. First, the slit used was not quite as fine as might have been when the

* Continued from page 685.

photographs were taken. Secondly, the dispersion used was the first order of a Rutherford grating 17,200 lines (about) to the inch, and a camera lens of a focus of about fifteen inches. In later photographs nearly all the broad lines have been resolved into pairs or triplets, as have also some of the lines of medium breadth. There are lines, however, like the three broad lines between 8,500 and 8,700 which remain unchanged whatever dispersion was used. This resolution was effected by using a finer



slit and dispersion of the second order; the fine slit alone will not give it. If we take an example in the visible spectrum, and examine the B line with the eye, it will be found to be made up of a series of doublet flutings, each component being apparently of equal intensity. These pairs it is impossible to secure on the photographic plate, unless the second order of the grating spectrum is used; but when secured it will be found that the more refrangible component is more intense, as is the case in certain hydro-carbon flutings. The sole reason why the first order is useless to cause resolution is that the pairs are so close they can both fall on the diameter of the grain of the sensitive compound. On the other hand, with a gelatine plate I have been able to see on one inch and a half every line and more than given in Angström's map from G to F. In this case the grain is almost invisible.

The development of the plate is greatly more difficult than the preparation of the emulsion. A strong developer it will not stand, and I may say also that a very new one is also inadmissible when using the ferrous oxalate development. To make the developer, a saturated solution of neutral oxalate of potash is saturated in the cold, with ferrous oxalate; and then the deep red solution decanted off. When freshly prepared it is useless to attempt to develop a plate with it unless the precaution be taken of adding to it an equal part of a saturated solution of ferric oxalate in the oxalate of potash. Such a mixture may be employed by adding to it immediately before all an equal volume of a solution of potassium bromide (twenty grains of the salt to thirteen of water). The plate may then develop without fog, or it may not; if it does fog, the developer must have more bromide solution added to it, and another trial made. On some days a clean picture seems an impossibility, whilst on others, every one will be perfect. It is not the emulsion that is in fault, since, on a "clear day" and on a "foggy day" the identical emulsion may be used, showing that the developer is at fault. This year this trouble seems to have increased, and I can only lay it down to the different preparations of the oxalates. Of one thing care should be taken, viz., that the developer never shows alkalinity; a drop of dilute sulphuric acid or nitric acid may be added to the developing cup just before development with advantage.

With prisms the photography with the rays of low refrangibility is simple, with one great drawback, and that is the difficulty of obtaining a true focus for the plate. This must all be done by guess-work, and plates exposed till the focus is obtained. When once obtained it is a good plan to mark the camera to show the focus, and at the same time accurately to mark the table on which it stands, so that the *same portion of the lens receives the same rays*. This is more particularly necessary to attend to when using an achromatic lens. I believe it to be easier to use the uncorrected lens than a corrected one, provided always that the camera has a proper horizontal swing-back, which can be shifted through a very large angle at least 30° when using three prisms. If a spherical mirror be used in the collimator and in the camera instead of the lenses, the same difficulties of focussing do not present themselves. The disadvantage of this method is that the edges of the spectrum based are diffused and not straight, and this is awkward when making comparison of different spectra. With a grating nearly the same difficulty arises when using lenses, but not quite to such a degree. If "a" and A be got in focus at the end of the plate, the swing-back being used till this results, and if the lens be placed close to the grating, the whole of the infra-red region will be fairly in focus. This of course only applies to my own grating, which may have a slight curvature. In using the grating we must not forget that the second order overlaps the first order, and the third order the second order, and so on; and if a plate were exposed without any artifice being adopted to get rid of this over-lap, the plate would show two or three spectra. There are several methods of accomplishing this separation, the simplest being to use the absorbing medium in front of the slit. At first I used stained red glass, which cuts off all radiation above the green, leaving thus the tails of the different spectra intact. At present, when wishing to go no further down the scale than λ 10,000, I have found that a deep coloured solution of iodine of potassium in water, about one-tenth of an inch in thickness, is very excellent. The objection to the red glass is that it exercises a certain amount of general absorption in the infra-red region, but with the white glass of the cell holding the solution, and the solution itself, this general absorption is minimized. To get down still further, very thin stratum of a blue dye in tetrachloride of carbon is efficacious in conjunction with the iodine solution. With the above solutions λ 13,000 can be reached. Beyond this limit it is necessary to use other means of eliminating the higher orders of the spectrum. The simplest plan is to place behind the collimator a couple of prisms, and some two feet from the prisms, the grating, so that it only receives those rays which it may be desired to impress. Thus one side of the grating may catch the limit of the red, whilst the rest will be filled with the dark rays The most difficult plan is to place a prism according (as Frauenhöfer did) in front of the grating, in such a way that the axis of the prism is at right angles to the ruling, and parallel to the plane of the grating; this causes a complete separation of all the different orders of spectra. But the resulting photographs are inconvenient to measure, since they are curved, and the position of the camera is also awkward. Another plan is to use a prism in front of the slit; but this, too, I have found inconvenient, for the same reasons as given above. For ordinary work the absorption method is decidedly the most elegant; but then it limits the operations with the spectrum. It was from photographs obtained in this manner that the above map of the solar spectrum was obtained, and as it is before us, it may be well to make a few remarks on it. As to what the lines are due to we are at present absolutely uninformed, except as to some very few. A notable exception to this is the line lettered about 8,600, which is one of the strongest lines in this part of the spectrum. Colonel Festing and myself found that this line coincided absolutely in position with what we call the radical absorption band of benzene, that is to say that by diminishing a thin layer of benzene placed between the slit of the spectroscope and a source of light giving a continuous spectrum, this absorption-band, amongst many others, was the last to disappear, and that it also was the key-note as it were of the absorptions of all benzene derivatives.

A coincidence of this kind would not be fortuitous any more than that the vapour of sodium gives lines coincident with the D lines; and hence we were forced to ascribe this line to benzene or some of its derivations. When first we made this announcement it was facetiously remarked that we had been photographing London smoke; and no doubt, had not other localities for photographing the spectrum been chosen, the reproach (for such it was) might have been just. My visit last June to the Riffel, 8,500 feet high, showed that not only was this said line present, but that it was more intense even than at the level of the sea. There was more unfolding of the spectrum at that high altitude, and lines faint indeed, which had almost escaped registration below, were well marked on the photographs obtained there. The brilliancy of this infra-red spectrum can scarcely be surpassed. When examined at an elevation of 10,000 feet, the general absorption due to water almost vanishes, and with the exception of two congeries of lines which lie beyond those given in the diagram, the whole of the lines shown are stronger than I have ever had them before.

Colonel Festing and myself have also shown the presence of some alcohol derivative, somewhere between ourselves and the sun, and the presence of the absorption lines at a high altitude place it outside our atmosphere. This I was not wholly prepared for, since lately we have been told that alcohol exists in rain water, and rain water can only derive it from the air. The fact, however, remains that it probably exists beyond the limits of our atmosphere. The region disclosed by photography has by no means been exhausted; beyond the region given in the diagram lies one in which we can have a breadth of continuous spectrum, and beyond that, again, beautiful groups of lines, all of which require and deserve careful study. Of one thing we may be fairly certain, that none of them are due to metallic vapours, but are probably due to vapours of non-metallic compounds in some form or another, and these at a comparatively low temperature. It is not unlikely that amongst these will be found oxygen compounds, and, if so, it would be interesting in more ways than one.

AN EARLY TASTE FOR ART—ITS TRAINING.

The Importance of this to the Beginner in Photography, also to those more Advanced, and to the Interests of Art in General.

BY NORMAN MACBETH, S.R.A.*

Art is the representation to the eye or ear of the beautiful in form, light and shade, and colour, and that manifesting more or less the individuality of the mind which originated and wrought it out. The primary condition of art must therefore be the inward perception of the beautiful, and he who has both the faculty to perceive, and the skill to represent the beautiful as he has individually felt it, is the only one entitled to the name of artist. To look back on the first dawnings of our admiration of the beautiful in nature which arrested us, we could not tell why, is one of the most delightful day-dreams of our life. One of the earliest recollections I have of being attracted in this way, is when, as a child in the nurse's arms, I carried home a bunch of rowans (mountain ash) which had greatly charmed me. There was a period, very early in life of all who have made art their profession, when certain aspects of things unconsciously drew them by their peculiar attractiveness; for instance, when spring came round, what endless variety of tint was discoverable in the young leaves; and throughout all the seasons, each month in its course manifesting such wealth of beauty and perfect consistency.

Again, who has not been delighted with the fascinating appearances of metals, such as are seen in steel armour, copper, gold, and silver vessels; or of birds, fish, and shells; or of manufactured fabrics, such as velvets, satin, silk, &c.; all these and other innumerable appearances have been, as it were, the nursery books of artists, through which a craving after art was awakened.

Now what is that subtle quality which is apprehended in nature, or in a work of art, which rivets and charms us, which draws us close to the object from which the pleasure came, then disappears, but which, on our retiring, reappears, and, according to the distance which we stand from the object, assumes various aspects, though never losing its individuality? This is the æsthetic aspect of the object: to catch such appearances, and apply them for the conveyance of thought and pleasurable emotion, is the purpose of art.* Now does the æsthetic aspect of the object lie in itself or in its being viewed at a certain distance; or is there over and above the object so much that is suggested or lent to it by the artist's mind? These three aspects of the question have given rise to different kinds of professed art, which have been more or less presented in past times, are even now from different sources pretty well defined, and it is well for us that they be now clearly understood.

The first—that is, the copying slavishly the object close at hand, and regarding fulness of detail, aye, even to deception, as the perfection of art—this, after all, is but the exercise of the imitative faculty. The second—viewing the object at a distance, rendering it absolutely as it appears—is merely realistic resemblance. But the third—that is, viewing the object also at a certain distance, lending to it what is suggested for good, or taking from it what is not beautiful, treating it by the impulses of the mind; in a word, giving it the impress of the artist's individuality—this is the best and the only art which can properly be said to be worthy of the name.

The first, the merely imitative, attempts, as I have said, to deceive if possible. True art never pretends to be anything but what it is—a representation.

The second, the merely realistic production of appearances, without any special design, resembles very much what the camera produces without any special direction. A lens and good chemistry realise in black and white the details of natural appearances, even atmospheric (or what is properly speaking called aerial perspective), better than any human hand or eye can do; yet there is no art in their productions; they are merely photographic transcripts. And unless there be some design in a drawing, painting, or photograph, in which the artist's individuality is unquestionably manifest, and in which it is worthily presented, it has no claim to be a work of genuine contrivance.

The third aspect of the question which I have described is truly art, because it is that which invests the subject with qualities which express the artist's own feeling and thought upon it.

What I have already said necessarily implies that this fine perception which leads one to choose or reject certain aspects of things must be a faculty. While, to a certain extent, one may be taught to apprehend and make use of æsthetic effects, yet to have such a fine sense or taste for them as will lead the possessor to be unconsciously enjoying them—making them the main part of his thinking and craving after their manifestation or reproduction, is a sure sign of a thorough artistic nature, and deserves to be fostered and encouraged.

It is wonderful to see how, under the most adverse circumstances, such a mind succeeds; and if there be any passion, more than another, difficult to repress, it is the passion for art, if it be of the character I have now described.

We can scarcely conceive of any one being entirely insensible to some æsthetic pleasure, more especially regarding some aspects and representations of nature. For instance, an expansive scene, on a bright sunny day, on land or sea, or a picture which appeals to the affections, and represents every-day life; but in the case of subjects of high art, treated in an ideal manner, it is not to be expected that any but those so constituted or far advanced in art by culture should be able fully to appreciate them.

In the very lowest stages of sensibility to certain æsthetic pleasure, it is simply the nervous fibres that are excited. We see this in the lower animals. On the one hand, musical sounds charm the serpent; and on the other, we hear of dogs howling at music, even at the very best of it; but the faculty of a very fine taste in art, enabling us to feel æsthetic pleasure in the highest degree, can only be the result of a finely-constituted organization, enabling us to apprehend very subtle qualities, and all the more when the mind has been well trained. In like manner no one can be a connoisseur or critic in art, unless he be gifted with this æsthetic faculty, and has a sympathetic admiration for all such genius and talent.

It is not uncommon to hear of some beginners ignoring all literature connected with art, and treating with contempt the

* Read before the Edinburgh Photographic Society.

* Here Mr. Macbeth showed an illustration.

old recognised principles and rules which havo hitherto been adopted. Some have such a strong belief in the mere natural impulses of the æsthetic faculty that they wilfully set at defiance the opinions of others. Certainly if there be an exercise of tho human mind, having a wido domain for freedom of opinion aud independence of law, it is art. Still I would despise nothing; for however keen this æsthotic faculty may be, no great or well-ordered results can bo expected without some system, and that under tho direction of a well cultivated mind and careful study.

Every department of art, poetry, the drama, music, painting, sculpture, and architecture, has its theories and conditions by which it is regulated, and no work can be regarded as successful which has not a sound basis, and most thoroughly fulfils its dssign or purposo.

Wo have need to be ever on our guard against all extravagances, and the production of any art which is either not true to nature, or not in accordance with the conditions of the department to which it belongs. It is long beforo we master the difficulties of ordinary manipulation, and the different ways and manners of going about the treatment of a work of art. Till then we must be patient, and watch the progress of others; but when we have attained by experience a thorough knowledge and acquaintauce with all sorts of theories in art, then we may invent and advance a treatment of art peculiar to ourselves, which becomes very apparent to every one as our individual style.

There is a capital illustration given of this in the life of Haydn. The story is as follows:—A connoisseur once asked Haydn, according to what rule a certain bold progression, which was contrary to the canons of music as then known, was introduced in ono of his works. "Oh, sir," said the composer, with a smile, "the rules are all my very obedient humblo servants." So you see great masters make their own laws, and nobody knew better than Haydn when to break the traditions of the schools.

Unfortunately, however, such is the dosire to acquire a style in art, that those who begin early to feel after this are unconsciously drawn to look more at art in itself than at nature, or the objects by which thought and idea are suggested; hence tho elementary department becomes neglected, and tho work done, though it may have more or less the look of genius in it, being devoid of culture, it is not understood.

It is to the cultivation and training necessary in the elementary department that I would now shortly draw your attention. For a boy at school, education proper (that is to say for every-day life) must not on any account be neglected; and if classics be impossible, French and German should be acquired, especially the former. As to art, no youth should be forced to draw against his inclination; it is only when the desire comes spontaneously that he should be gratified with this pleasure. He should, on the first manifestation of this taste, have his attention at home called not so much to the dry elementary examples of drawing specimen books common to schools, but to good illustrations from books, the work of good designers, clever draftsmen whose style is well matured. Having everything that is bad in art kept out of his sight, he should be left very much to his own taste in subjects and copying them as far as he can to please himself. As soon as there is decided evidence of being able to catch the principal points of a picture, he should be indulged with humorous books, which are very instructive in setting forth the salient points of expression, such as the etchings of Cruickshank, and the illustrations of Punch by Leech, Tenniel, and others, or in some of the more recent simply coloured productions designed by that very clever draughtswoman, Kate Greenaway, or the illustrations of the story of John Gilpin, by Caldecot.

We are living in a time of wonderful richness of design, and no one can tell how much we are educated in art by simply looking at the *Weekly Graphic* or *Illustrated London News*. All such works are worthy of being copied. They afford much pleasure in themselves, and that pleasure is greatly increased when one is able, to some extent, to reproduce the fun or humour that is in them. After the pupil can do these tolerable well, he should be asked next to look at and copy well drawn outlines and details of human character, such as heads, hands, and feet, by the old masters; heads in profile gathered by Lavator in his excellent work on physiognomy; drawings in outline by Sir Noel Paton, such as his illustrations to Coleridge's "Ancient Mariner;" to good photographs, having pointed out to him some of the more subtle qualities of a landscape, such as aerial perspective, the relationship between foreground, middle distance, and extreme distance, the varieties of surface or texture common to every individual object. He should be warned against all exaggerations of perspective, created by attempting to bring into view objects beyond the radius of the eye, or too near in the foreground. He should be taught the importance of viewing an object rightly—the boundary lines of a picture, how much to take in and how much to cut off, all being involved in the distance from the point of sight and the base line of object. An intimate acquaintance with the good and bad treatments of photography becomes most useful in teaching one how to look at, and a direct use of nature itself.

After such an acquaintance with pictorial illustration as I have now indicated, which may be got at home, the pupil may be said to be ready for entering some school of design. Here he will be trained to most careful habits of work. The use of lines and the endeavour to obtain facility in their execution, although uninteresting and irksome at first, amply reward afterwards the pains and labour bestowed upon them.

So much am I impressed with the importance of this, that I would have every pupil very frequently reproduce his outlines at home, large, on a black board with white chalk; this enables the hand to pass freely, and errors and defects of drawing become much more apparent. No education of the eye is better, and no practice for the size of life can excel it.

As soon as facility in this is acquired, ho should enter on the study of the antique, and in place of acquiring great neatness of execution in shading—spending months in mere hatching, as it is called—I would have him at once enter upon painting in monochrome, that is, in one uniform colour from the cast, beginning at first only with a head, and labouring hard to copy all its first appearances most minutely. He should have pointed out to him from the cast the different compartments of light and shade, and their causes, also the colours aud how to use them in monochrome. When this is thoroughly understood, he should be asked to apply this knowledge at home to different coloured objects, such as fruit and flowers. This practice should be kept up for a considerable time, his object being chiefly to acquire a thoroughly trained eyo and the power of reproducing realistic appearances of every kind of object. Such practice trains to great carefulness, and a complete command of materials employed.

Such is the preparation which I humbly consider every beginner in art should make, previous to entering an academy for the study of the living model; and I would have him, as often as he can secure time, keep up his practice in drawing and painting from the antique. I need not point out the importance of this, especially for acquiring a complete knowledge of details, and being familiar with the normal forms of the more exposed parts of the body, particularly the head and hands. Such knowledge purifies, refines, and preserves one against all vulgarity and excess in character.

Having thus studied from the antique, the student should now prepare for entering an academy. In the Royal Scottish Academy it is required of everyone making application for admission that he send in a drawing in full relief from the round, in chalk, also other two drawings of the same, put in the form of skeleton and muscles. If passed, he has all the privileges of a student for four years, during which time he draws by gas-light in the evening, and paints by natural light in the morning. He is daily visited by appointed visitors—members of the Academy—and also superintended by a curator, who has a special care and charge both of models and the students. There is a variety of ways exercised in practice, such as memory sketches of the subject; but the principal occupation is the careful study of the relative proportions of parts of the figure, and correct anatomy. Various prizes aro awarded for the year's work, according to certain conditions.

During his studentship he is expected to exhibit annually at the Academy's Exhibition. His work there is specially looked after by the council of each year; and one of the prizes, the Keith Prize, awarded to the student of greatest general merit in any department of art for that year.

After the term as a student is over, and a year or two gone in actual practice, he is open to put down his name as a candidate for associateship with the Academy. On being balloted for, and accepted, he receives a bronze medal and diploma, and becomes a candidate for academicianship, and is again balloted for (but no election takes place till a vacancy occurs by death, making the admission rare and much valued). On admission he receives a diploma and silver medal, in acknowledgment of which he contributes a diploma picture to the gallery of the Academy. No higher honour awaits him, unless it be that he is eligible to the presidentship of the Academy, and, according to use and wont with his predecessors, in due time receives the honour of knighthood.

Having thus glanced over the different steps in an artist's career, from the first dawnings of taste, through his training, up till its full consummation, I have been led so to treat my subject by way of interesting any who may be seriously thinking of following, in some form or other, an artistic life. What I have alluded to relates chiefly to the painter; it only remains for me now to point out the importance of a good deal of this to the beginner in photography, to those more advanced in it, and to the interest of art in general.

Much of what I have stated in the outset of this paper, regarding a taste for art implying the necessity of an artistic nature and its culture, must have been during my reading applied by the photographer to himself. It does not follow, that, although good at the chemical department, able to produce most perfect impressions of the object photographed, he is also equally good at the arrangement of the subject. The chemical department, seeing it is purely allied to science, knowledge arranged under general truths and principles, that which refers to abstract principles as distinguished from art, may, by strict attention in the course of time, be completely mastered.

Æsthetics, again, called by some the science of beauty in perception, but, properly speaking, the science which manifests the genius of art, is so much the result of personal forthputting, the emanation of an individual mind, that at times it ceases to be a science—like Haydn it lets go the reins, and makes laws for itself. In these circumstances, without the æsthetic faculty and culture, the photographer will never apprehend images, far less produce them. The facts of science, when produced, are very apparent, but not so ideas conveyed by art; there is such a subtlety about them that they only exist by reason of a certain fine organization, which enables those gifted with this perception, either mentally or externally, at once to apprehend forms, and take the greatest pleasure in still formulating, or converting them into an object or subject of some meaning, conveying some sentiment. An artistic nature, when it does exist, very rapidly apprehends in the most trifling material—such as is often seen in an old broken plaster wall, or the half-consumed embers of a fire—that which becomes very suggestive.

Now, this is what I wish particularly to be impressed upon all connected with this Society, who are seeking after art—an essential qualification for their success is, that they must be conscious of an artistic nature going out in the spirit, which I have described. It is not essential that the photographer be a draughtsman, but he should be a thorough artist in feeling, well read in all books relating to art, and especially familiar with such a work from the library of contemporary science as that by Engène Véron on "Æsthetics," which gives, perhaps, the most advanced notions concerning art of the present day. As to the beginner, I would recommend him to study the writings of Burnet (the celebrated engraver of Sir David Wilkie's works), especially three of his volumes—viz., those on the "Education of the Eye," "Composition," and "Light and Shade." They are only to be had in libraries now. Then there is Rowbotham, on the "Art of Sketching"; and also Howard's "Sketcher's Manual." The latter contains very excellent examples, which would be very beneficial in the way of arrangement and general treatment of a subject.

(*To be continued.*)

COLD EMULSIFICATION WITH UNIFORMITY.

BY ALFRED J. BROWN.*

Mr. Henderson has read before you two short papers upon cold emulsification, claiming for what he called his method great sensitiveness and uniformity. I shall endeavour to show you to-night that there is nothing whatever in this method as it stands, more than in any other, to warrant this assertion.

In the first place, I think there is little that he can claim as his own in this method. It is well known that Mr. Cowan has for some time used ammonia in making his emulsions, and allows them to ripen cold—cold in this case being a rather elastic term. The alcohol also was recommended by a gentleman—whose name I forget—long ago, but with this difference, that he gave the true reason for its employment.

I have lately made a few experiments upon these lines, and now give you the conclusions at which I have arrived. After expressing as my opinion that no method is at present really good wherein ammonia is used,† I proceed to my remarks.

It has been known, since its introduction by Dr. Monckhoven, that ammonia so hastens the formation of the silver bromide into the most sensitive state, that, unless it be used at a low temperature, you cannot have it under control. The silver bromide will pass the critical point, and so deteriorate. It is from the inability to stop this continual ripening, this want of control, even if the gelatine be set, that ammonia has probably been condemned by many—unfairly condemned, I think, for were it not for the abominable green fog, it would be the best of all methods, as it is the easiest, because the whole of the silver bromide is acted upon equally, and if the particles are formed in the first place of equal size, will continue so throughout. Of course this does not apply to the ammonio-nitrate process, wherein the silver bromide is formed in a continually-increasing quantity of ammonia, the resulting particles of bromide being of various sizes.*

This—the ammonia—is, as in all such cases, the accelerator; not, as "one of the largest professional plate makers in this country" has "expressed his opinion," "the alcohol." I here protest against capital being made in this way out of what another may say without giving his name, and putting us in a position to judge of the value of his opinion, for I have yet to learn that professional plate makers as a body are infallible. Such remarks may do a deal of harm to a beginner, who might suspect himself, when the method, not he, is at fault, and become discouraged.

The alcohol, however, possibly has a future. It is the greatest restrainer I know. Silver bromide formed in its presence is finer than if it be not used, other conditions being the same. This is even so if no gelatine be used, but not to so marked an extent. It appears to me to possess somewhat different properties, but I may be wrong.

A very fine-particled emulsion may be prepared with less care, and no waste to filter out when it is present; but it also prevents to a remarkable degree the most sensitive state being attained. I have made some emulsions this way without ammonia; the cooking they require is surprising—more, indeed, than I care to submit any gelatine to. This is the reason why some have succeeded with alcohol and ammonia, who have failed with ammonia alone;† with more care they would have done better without it. So great is this restraining power that one almost must use ammonia, and I believe you may even boil in its presence without hurt; but have not tried. I have, however, submitted it to considerable heat. I have not got a rapid plate by this process.

From the foregoing it will probably occur to some that alcohol stopping, or almost stopping, the ripening of an emulsion, the proper time to add it is when a sufficient degree of sensitiveness is attained.

In order to take advantage of the fine and uniform state of the silver bromide when formed in the presence of alcohol, I drew up this scheme:—Place in a bottle 2 ozs. of water and 120 grs. of ammonium bromide, add 240 grs. of Nelson's No. 1 gelatine, and shake well; when it has taken up all the water, and is quite soft, add 2 ozs. of alcohol, and shake again; then put in 180 grs. of silver nitrate (dry), and shake till the whole is converted. The heat given off during this operation is sufficient to quite liquefy the gelatine; keep it in this state for about half-an-hour, then precipitate by pouring into alcohol to get rid of the nitrates, &c., and rinse, to free it from alcohol; dissolve the pellicle in 5 ozs. of water, adding a few grains of ammonium bromide, and cook; pour out to set, and wash in the usual way. The result was a slow plate with cooking, that, with plain gelatine, would have given a rapid one; alcohol was present. I prepared another the same way, divided the pellicle into pieces the size of small peas, washed in running water fourteen hours; result—same as the last, alcohol still present; I could distinctly smell it when melted. Made a third, divided the pellicle as before, placed it upon blotting-board in my drying cupboard till it was quite hard and apparently dry; result—as before, could still smell the alcohol; with a deal of cooking it arrived at the green stage only (transmitted light test).

Further than this I have not as yet had time to go. It would seem that pellicle requires more than ordinary heat to drive off the alcohol, and that a small quantity present in an emulsion prevents the attainment of great sensibility; or, that bromide of silver prepared in this way is physically different. Which is it?

* Read before the London a Provincial Photographic Association.

† It is impossible to make a he thy plate with gelatine that has been in contact with ammonia; it is sure suffer from green fog.

* In most cooking processes also—there being a lack of sufficient agitation—the particles are unequally developed, more especially in this case if the high temperature and short period method be employed.

† I remember well when I was very new that I failed and failed till I was almost weary, making emulsions that were fogged from over-cooking, my first good plate being one that I intended to be very slow. I advise all beginners to make slow plates at first.

Notes.

The Council of the Royal Society have awarded the Rumford medal to Captain Abney, F.R.S., "for his photographic researches, and his discovery of the method of photographing the less refrangible part of the spectrum, especially the infra-red region."

Mr. Malcolm G. Dobbie, the spirited honorary secretary of the Edinburgh Society, is, we are sorry to hear, seriously ill.

Our readers will also regret to learn that the recently-elected honorary secretary of the Photographic Society of Great Britain, Mr. F. Maxwell Lyte, is likewise an invalid.

Mr. Charles Pearce, the official reporter of the Photographic Society, and a well-known contributor to these columns, has been appointed editor of *Funny Folks*.

The medals awarded at the Pall Mall Exhibition this year were presented by the President of the Society on Tuesday evening. We congratulate the president, no less than the recipients, on the occasion, for the former was very happy in the little speeches he made to each medallist, and in his graceful allusion to the pictures which had brought good fortune to their authors.

"By-the-bye, Mr. Burton, I don't see that curious serpentine curve on the plates you have just handed round," said an unmathematical emulsionist on Tuesday evening; "and yet you say that this is the principal advantage and peculiarity of your method." Mr. Burton tried hard to explain all about ordinates and co-ordinates; but he didn't succeed.

Many readers who have found bichromate to be ineffectual in removing the tendency of an emulsion to give fogged images will be interested to know what Mr. Cowan says on the subject: "This characteristic example of dichroic fog well illustrates the original character of the sample, but after it had been squeezed through canvas into a one per cent. solution of bichromate, and allowed to remain one hour, I washed for about twelve hours, and the cure was complete; but the cured emulsion had only half the original sensitiveness. Next time, however, I will try the effect of washing more thoroughly."

An aqueous solution of pyrogallic acid rapidly decomposes, and an alcoholic solution undergoes change more slowly; but a solution of pyrogallol in pure and undiluted glycerine appears to be capable of being kept without change for an unlimited period. Pyrogallic acid dissolved in a mixture of glycerine and water keeps much better than the mixture of alcohol and glycerine as recommended by Mr. Edwards. The presence of glycerine in the developer certainly does no harm, and it is believed by many to be highly advantageous.

One of the surest tests of popularity is undoubtedly the public demand for portraits. Just as at the present moment, in this country Sir Garnet Wolseley's portrait figures by the hundred on the hawker's barrows—it is a piracy of one of Mr. Fradelle's photographs, we believe, that is everywhere—so in America, the sale at this moment of pictures of Mrs. Langtry surpasses all demand ever made for Sarah-Bernhardts, Pattis, Nilssons, &c.

After having repeatedly stated his opinion that the charge against Captain Kerr was altogether based on misapprehension, Mr. Hosack dismissed the case without calling on the Captain to make any defence.

Sir Charles Wheatstone and Sir David Brewster were never very good friends; for one reason, because they were always working upon the same branch of science, and were for ever coming into violent contact. The battle of the stereoscope will still be remembered, in which Wheatstone and Brewster were opposing knights, each claiming its discovery; but there were several other scarcely less notable instances in which the eminent philosophers came to loggerheads. With it all, there was not much ill-will between them, however, as we are in a position to show.

At a *soirée*, on one occasion, when both gentlemen were present, there happened to be a son of Sir David's—a little boy—who very naturally was walked round the room to say how-do-you-do, to the principal visitors. After a while, the boy came to Wheatstone, and was presented to him; but scarcely had the little lad shaken hands, than Sir David called out lustily, "For Goodness' sake, take the child away from Wheatstone—he'll claim him!"

We take this opportunity, by the bye, of informing our readers that a portrait of the late Sir Charles Wheatstone will form the frontispiece of our coming Year-Book, a very fine negative of our native philosopher having been lent us for the purpose by Mr. J. E. Mayall, of New Bond Street.

A photograph of the comet has been secured by Mr. Ferneyhough, of Natal, the picture being spoken of by the *Natal Witness* as reflecting "high credit" upon the photographer. Of course the photograph has been secured at night, but our contemporary, in criticising the result, seems a little surprised at the "surroundings" being so dark. "The comet is seen brilliantly sweeping down in the darkness," it tells us, "while the foreground is composed of jet-black house-tops."

In the *Bazaar* of last week, under the heading "Scientific," a "very powerful pair of field and marine glasses by Jumelle" is advertised. The announcement is similar to the one to which we recently called attention, where a photographic lens by "Breveté" was offered for sale. "Breveté," however, manufactures all sorts of goods in France, pawnbrokers tell us, while "Jumelle" confines himself to *twin* glasses. MM. Breveté et Jumelle are ike the rich man "Kanitverstan," the German journey-man used to talk about. Travelling in Holland the latter asked the name of the owner of a fine dwelling, and the reply was "Kanitverstan," the same anwer being given when he asked for information about a beautiful garden ; and finally when, sad to relate, he met a funeral, the reply given him was as before. It was "Kanitverstan" who owned the fine house and the beautiful garden, and was now dead. The traveller never knew till after his return home that the good Dutch people only meant to say that they did not understand his questions when they uttered "Kanitverstan."

Here is a matter for the Copyright Defence Association to look into, when it is set going. A gentleman enters a studio hesitatingly, with a portrait taken long ago ; he says he fears he has come to the wrong house, as the name of the firm is not the same as that upon the mount ; but he wants some more copies. The attendant in the reception room examines the pictures, and, after referring to a book, tells the customer it is all right, and that the negative was taken there ; how many copies are wanted ? The number is specified, the order booked, and away goes the enquirer. In a few days, however, the latter receives a communication to the effect that the negative cannot be found, but that a supply of copies quite equal to the original will be forwarded without delay. So here we have the case of B copying A's photograph, and with the permission of the unsuspecting model.

We mentioned last week the fact of one firm of photographers having recovered £700 from a periodical for pirating a series of portraits. The photographic studies of Rejlander—from Ginx's Baby downwards—were pirated not by one, but by hundreds of journals, and yet poor O. G. R. never received a penny from any publishing house.

A draughtsman correspondent, writing on the subject of photography on wood, asks when we may expect the wood-engraver to be superseded by the photographer, so that the artist's work may go straight to the printing-press untouched by any intermediary. "That is what we want," our friend adds, a little dictatorially. Our reply may be expressed in quite the same tone, for we answer, in perfect truth, "You have got such a process already." Photography has done its part, but the draughtsman has not done his ; if the artist only made his drawing as he desires to see it in the illustrated journal in which it appears in public, photography would at once save him from that middle man, the wood-engraver.

Unfortunately, the draughtsman will not draw his picture as it is finally to appear in public. In the illustrated journal his picture is composed of black lines more or less thick, and more or less close together, and if the artist would only produce it so, there would be no difficulty about dispensing with the wood-cutter. But draughtsmen, for the most part, do not draw with a black point at all ; their lines are generally grey, and a large number work with a paint brush and washes of different tints. They then leave it to the wood-engraver to translate the tints into lines, and the final result in black and white is therefore the joint work of draughtsman and graver. It is the draughtsman's privilege to grumble at the graver, and if the sketch does not turn out well, it is always the graver's fault. Perhaps it is because there would be no graver to grumble at that the draughtsman is in no hurry to produce his picture straightway in black and white.

But the main reason, no doubt, is that the draughtsman has not been trained to make his picture with black lines. He paints with his pencil rather than draws. Still, it is only a question of time, and the next generation of Tenniels and Proctors will produce their cartoons on Bristol board in black and white, just as we buy them in *Punch* and in *Moonshine*. The sketch will then be photographed, etched upon metal, and printed off in the press with all the delicate bloom of the artist's touch upon it. If zinc etching is not good enough, copper plate may be used ; but in any case, photography now-a-days can reproduce the lines of the artist in their full vigour and delicacy.

Patent Intelligence.

Application for Letters Patent.

5395. Adolph Tuck, of 72 and 73, Coleman Street, in the city of London, Fine Art Publisher, for an invention of "Improvements in ornamenting terra-cotta plaques."—Dated 13th November, 1882.

Grants of Provisional Protection.

5086. Richard Brown and Robert William Barnes and Joseph Bell, all of the city of Liverpool, in the county of Lancaster, Photographers, for an invention of "Improvements in and relating to the production of printing surfaces from gelatine reliefs."—Dated 25th October, 1882.

5131. Henry Harris Lake, of the firm of Haseltine, Lake, and Co., Patent Agents, Southampton Buildings, London, for an invention of "An improved method or process of and apparatus for producing coloured photographs."—A communication to him from abroad by Joseph Chaine, Arthur Durand, and Sallonier de Chaligny, all of Lyons, France, Engineers.—Dated 27th October, 1882.

ON THE PREPARATION OF GELATINE PLATES.

BY E. HOWARD FARMER, F.C.S.*

Since the first announcement of these lectures, our Secretary has asked me to give a free introductory lecture, so that all who are interested in the subject may come and gather a better idea as to them than they can possibly do by simply reading a prospectus. This evening, therefore, I propose to give first a typical lecture of the course, and secondly, at its conclusion, to say a few words as to our principal object. As the subject for this evening's lecture I have chosen "The Preparation of Gelatine Plates," as it is probably one of very general interest to photographers.

Before preparing our emulsion, we must first decide upon the particular materials we are going to use, and of these the first requisite is nitrate of silver. Nitrate of silver is supplied by chemists in three principal conditions:—

1st. The ordinary crystallized salt, prepared by dissolving silver in nitric acid, and evaporating the solution until the salt crystallizes out. This sample usually presents the appearance of imperfect crystals, having a faint yellowish

* Being an abstract of the Introductory Lecture to a course on Photography at the Polytechnic Institute, November 11th.

tinge, and a strong odour of nitrous fumes, and contains, as might be expected, a considerable amount of free acid.

2nd. Fused nitrate or "lunar caustic," prepared by fusing the crystallized salt and casting it into sticks. Lunar caustic is usually alkaline to test paper.

3rd. Re-crystallized silver nitrate, prepared by redissolving the ordinary salt in distilled water, and again evaporating to the crystallizing point. By this means the impurities and free acid are removed.

I have a specimen of this on the table, and it consists, as you observe, of fine crystals which are perfectly colourless and transparent; it is also perfectly neutral to test-paper. No doubt either of these samples can be used with success in preparing emulsions, but to those who are inexperienced, I recommend that the re-crystallized salt be employed. We make, then, a solution of re-crystallized silver nitrate in distilled water, containing in every 12 ounces of solution $1\frac{1}{4}$ ounces of the salt.

The next material we require is a soluble bromide. I have here specimens of various bromides which can be employed, such as ammonium, potassium, barium, and zinc bromides; as a rule, however, either the ammonium or potassium salt is used, and I should like to say a few words respecting the relative efficiency of these two salts.

1st, as to ammonium bromide. This substance is a highly unstable salt. A sample of ammonium bromide which is perfectly neutral when first prepared will, on keeping, be found to become decidedly acid in character. Moreover, during this decomposition, the percentage of bromine does not remain constant; as a rule, it will be found to contain more than the theoretical amount of bromine. Finally, all ammonium salts have a most destructive action on gelatine; if gelatine, which has been boiled for a short time with either ammonium bromide or ammonium nitrate, be added to an emulsion, it will be found to produce pink fog—and probably frilling—on plates prepared with the emulsion. For these reasons, I venture to say that ammonium bromide, which figures so largely in formulæ for gelatine emulsions, is one of the worst bromides that can be employed for that purpose, and is, indeed, a frequent source of pink fog and frilling.

2nd, as to potassium bromide. This is a perfectly stable substance, can be readily obtained pure, and is constant in composition; neither has it (nor the nitrate) any appreciable destructive action on gelatine. We prepare, then, a solution of potassium bromide in water containing in every 12 ounces of solution 1 ounce of the salt. On testing it with litmus paper, the solution may be either slightly alkaline or neutral; in either case, it should be faintly acidified with hydrochloric acid.

The last material we require is the gelatine, one of the most important, and, at the same time, the most difficult substance to obtain of good quality. I have various samples here—notably Nelson's No. 1 and "X opaque"; Coignet's gold medal; Heinrich's; the Autotype Company's; and Russian isinglass.

The only method I know of securing a uniform quality of gelatine is to purchase several small samples, make a trial emulsion with each, and buy a stock of the sample which gives the best results. To those who do not care to go to this trouble, equal quantities of Nelson's No. 1 and X opaque, as recommended by Captain Abney, can be employed. Having selected the gelatine, $1\frac{1}{4}$ ounces should be allowed to soak in water, and then melted, when it will be found to have a bulk of about 6 ounces.

In order to prepare our emulsion, I take equal bulks of the silver nitrate and potassium bromide solutions in beakers, and place them in the water bath to get hot. I also take an equal bulk of hot water in a larger beaker, and add to it $\frac{1}{4}$ an ounce of the gelatine solution to every 12 ounces of water. Having raised all these to about 180° F., I add (as you observe) to the large beaker containing the dilute gelatine a little of the bromide, then, through a funnel having a fine orifice, a little of the silver, swirling the liquid round during the operation; then again some bromide and silver, and so on until all is added.

When this is completed, a little of the emulsion is poured on a glass plate, and examined by transmitted light; if the mixing be efficient the light will appear—as it does here—of an orange or orange-red colour.

It will be observed that we keep the bromide in excess while mixing. I must not forget to mention that to those experienced in mixing, by far the best method is that described by Captain Abney in his Cantor lectures, of keeping the silver in excess.

The emulsion, being properly mixed, has now to be placed in the water bath, and kept at the boiling point for 45 minutes. As, obviously, I cannot keep you waiting while this is done, I propose to divide our emulsion into two portions, allowing one portion to stew, and to proceed with the next operation with the remainder.

Supposing, then, this emulsion has been boiled, it is placed in cold water to cool. While it is cooling, let us consider for a moment what takes place during the boiling. It is found that during this time the emulsion undergoes two remarkable changes:—

1st. The molecules of silver bromide gradually aggregate together, forming larger and larger particles.

2nd. The emulsion increases rapidly in sensitiveness. Now what is the cause, in the first place, of this aggregation of molecules; and, in the second place, of the increase of sensitiveness? We know that the two invariably go together, so that we are right in concluding that the same cause produces both.

It might be thought that heat is the cause, but the same changes take place more slowly in the cold, so we can only say that heat accelerates the action, and hence must conclude that the prime cause is one of the materials in the emulsion itself.

Now, besides the silver bromide, we have in the emulsion water, gelatine, potassium nitrate, and a small excess of potassium bromide; and in order to find which of these is the cause, we must make different emulsions, omitting in succession each of these materials. Suppose we take an emulsion which has just been mixed, and, instead of boiling it, we precipitate the gelatine and silver bromide with alcohol; on re-dissolving the pellicle in the same quantity of water, we have an emulsion the same as previously, with the exception that the nitre and excess of potassium bromide are absent. If such an emulsion be boiled, we shall find the remarkable fact that, however long it be boiled, the silver bromide undergoes no change, neither does the emulsion become any more sensitive. We therefore conclude, that either the nitre, or the small excess of potassium bromide, or both together, produce the change.

Now take portions of a similarly washed emulsion, and add to one portion some nitre, and to another some potassium bromide; on boiling these we find that the one containing nitre does not change, while that containing the potassium bromide rapidly undergoes the changes mentioned.

Here, then, by a direct appeal to experiment, we prove that to all appearance comparatively useless excess of potassium bromide is really one of the most important constituents of the emulsion.

The following table gives some interesting results respecting this action of potassium bromide:—

Excess of Potash Bromide.	Time to Acquire Maximum Sensitiveness.
·2 grains per oz. ...	... no increase after 6 hours
2.0 grains per oz. ...	about $\frac{1}{2}$ hour
20·0 grains per oz. ...	... 7 minutes

I must here leave the rationale of the process for the present, and proceed with the next operation.

Our emulsion being cold, I add to it, for every 6 ounces of mixed emulsion, 1 ounce of a saturated cold solution of potassium bichromate; then, gently swirling the mixture round, a few drops of a dilute (1 to 8) solution of hydrochloric acid, and place it on one side for a minute or two.

When hydrochloric acid is added to bichromate of potash, chromic acid is liberated. Now, chromic acid has the property of precipitating gelatine, so that what I hope to have done is to have precipitated the gelatine in this emulsion, and which will carry down the silver bromide as well. You see here I can pour off the supernatant liquid clear, leaving our silver and gelatine as a clot at the bottom of the vessel.

Another action of chromic acid is, that it destroys the action of light on silver bromide, so that up to this point operations can be carried on in broad daylight.

The precipitated emulsion is now taken into the dark-room and washed until the wash water shows no trace of colour; if there be a large quantity, this is best done on a fine muslin filter; if a small quantity, by decantation.

Having been thoroughly washed, I dissolve the pellicle in water by immersing the beaker containing it in the water bath. I then add the remaining gelatine, and make up the whole with 3 ounces of alcohol and water to 30 ounces for the quantities given. I pass the emulsion through a funnel containing a pellet of cotton-wool in order to filter it, and it is ready for coating the plates.

To coat a plate, I place it on this small block of levelled wood, and pour on, down a glass rod, a small quantity of the emulsion, and by means of the rod held horizontally, spread it over the plate. I then transfer the plate to this levelled slab of plate glass, in order that the emulsion on it may set. As soon as set, it is placed in the drying-box.

This process, as here described, does not give plates of the highest degree of sensitiveness, to attain which, a further operation is necessary; they are, however, of exceedingly good quality, and very suitable for landscape work.

THE PHOTOGRAPHIC COPYRIGHT QUESTION.

On Wednesday evening, a numerously attended meeting of members of the photographic profession was held in Anderton's Hotel, Fleet Street, to consider the question of photographic piracy, and the best means of adopting combined action for the detection and prosecution of those persons who produce and vend, in defiance of the law, piratical copies of photographs duly registered in accordance with the provisions of the Act of Parliament. The chair was occupied by Mr. George Bishop.

The Chairman said the object for which the meeting was convened must be so patent to everybody in the room, that very little explanation would be required from him. If they succeeded in forming a Photographic Copyright Defence Association, it would be beneficial, not only to photographers and publishers, but to everybody directly or indirectly connected with photography. There were other societies that took upon themselves to direct and advise photographers in the scientific and technical parts of the profession; and he felt certain that if it were possible to form a society that would take under its care the material—the monetary and commercial interests—of photography, a great deal of good might come out of it. Of course this meeting must necessarily be of a preliminary nature; but the future action to be taken would nevertheless depend greatly upon what took place in that room. The special object of the meeting was to open a discussion as to the necessity for a society, and hear the opinion of the gentlemen present with a view to future action. He presumed that before the meeting adjourned a committee would be nominated for the purpose of considering what rules it might be advisable to draw up with the view to the formation of an association. One thing very evident was, that no society was ever founded without funds, and no society ever existed without an income. These matters were of primary importance; and another matter, which might well be discussed, was the extent to which those who would be most interested in this movement should contribute towards the formation and sup- of the society. A number of letters had been received expressive of sympathy and support with the movement; among others from the Stereoscopic Company, Messrs. Brown, Barnes, and Bell, Herbert Barrow, Fradelle, Gillard, Robinson, Hughes, Norman May, Mayo, Wilson, Bradley, La Fosse, Weston and Son, Slingsby, and Mawson and Swan. The Chairman proceeded to add that, as a matter of course, it was impossible to form such a society as this in a day. The mere matter of the rules would necessarily take a good deal of time and thought to draw up, because it would not do that any of them should subscribe to rules which might render them liable to a responsibility which they did not intend to undertake. He concluded by calling upon Mr. Downey, Jun., who was, he thought, the originator of the correspondence on the subject, to address the meeting.

Mr. Downey, Jun., observed that, as was well known, the law gave ample power for redress to those photographers who registered their works, and whose rights had been infringed by unscrupulous dealers, after the fashion of the hundreds of thousands of piracies that could be obtained everywhere. A remedy might be obtained in the law courts, but it was so costly a process that few were willing to risk a trial of their grievances. He urged the necessity of their uniting to resist piracies, and remarked that a society, if formed, would be able to act on behalf of its members in defence of their right. The subject was of universal interest to the profession. No photographer, even if he were not at present a publisher, could say how long it might be before he was called upon to take a valuable negative, which might be of untold value to him. In any case its value would be dependant upon the claim he could exercise over it, and he ventured to say, that to the smallest publisher a society would be both a protection and a support. To the agents also—he alluded to the print-sellers—there must be an accruing advantage. When the price they paid for originals was considered, it was possible to estimate their loss, to say nothing of the vexation and annoyance they suffered, when they saw copies sold outside their shop doors at a nominal figure. It ought to be remembered that there were many people who, merely desiring to possess the photograph, regarded the hawked copies as of the same value as those marked in the shops at six times the price. Mr. Downey proposed that the society should consist of what he described as "foundation members" and general members, the subscription to be fixed upon hereafter; and he suggested that a committee of seven or nine gentlemen should be appointed to take the necessary steps for forming the society. He moved, "That this meeting, recognising the necessity of putting an end to the present illegal pirating photographic copyright, thinks it desirable that a society be formed of members of the photographic profession in order to protect such interests."

Mr. S. Walker seconded the motion, which was carried unanimously.

The Chairman then invited suggestions from the meeting as to the best means of promoting the end in view. He added that he had received a letter from Mr. Bird, of the Autotype Company, in which that gentleman stated that copyright gave ample protection in all ordinary cases. "The property of photographs and portraits of celebrities," he went on to say, "is subject to invasion from rascals who are not worth powder and shot, from whom damages cannot be obtained, and who boldly hawk their pirated wares in defiance of the Act of Parliament. By persevering action this nuisance can, no doubt, be put down." Mr. Bird's suggestion was that this end might be obtained if the persons more or less interested combined together. He added that anything less than an annual subscription of one guinea would be useless, and that would require to be supplemented by a guarantee fund, to which the parties interested should subscribe in proportion to the extent of their interest. The Chairman stated that in his opinion anything less than a guinea subscription would be scarcely worthy of consideration. As to the question of a guarantee fund he had to say, on behalf of his own firm, that if nineteen other gentlemen would subscribe ten guineas each, they would be happy to put down ten guineas. There ought to be a sum of 200 guineas to start with, and it would require between £400 and £500 annually to maintain the operations of the society. In his opinion it would be highly desirable to retain the services of a solicitor. It was beyond doubt that the Society would have a good deal of work to do, and it would be also necessary to have the services of a paid secretary. It was not intended that the Society should be, so to speak, the scavenger of the profession, for each gentleman would require to protect his own interests as far as he could, and obtain compensation for piracies if he could. In the event of proceedings being necessary, the Society would doubtless be the best body to conduct them.

The Chairman's conditional promise, on behalf of his firm, of a subscription of ten guineas, was followed by the promise of a similar amount from Mr. Walker and Mr. Luks, and five guineas from Mr. Fradelle.

In reply to Mr. Cobb, the Chairman said he had not the slightest knowledge of the number of photographs registered during the year. It was certainly not half the number that ought to be registered.

The Chairman subsequently put it to the meeting whether the subscription should be one guinea annually or half-a-guinea, with the result that the prevailing opinion was in favour of the larger amount.

After considerable discussion upon matters of detail, it was proposed by Mr. Cobb and seconded by Mr. Luks, that a fund of £200 be raised as a starting fund by voluntary contributions.

This, it was understood, was agreed to.

It was also agreed, on the motion of Mr. Cowan, seconded by Mr. Cobb, that a provisional committee be appointed to go into the question of the constitution of the Society, investigate all the necessary details, and report to a subsequent meeting.

The meeting then adjourned.

Correspondence.

AMATEURS AND THEIR WORK.

Dear Sir,—It has been intimated that amateur photographers are in the habit of exposing their own plates, and then sending them off to the makers or others to have them developed and prints taken from them.

Since no amateur has denied this, it looks very much like truth, and in order that such a statement may not mislead, I beg to raise my voice against it.

I know several amateurs who never get any professional assistance of any kind—men who would scorn to get their work done for them, and then dishonestly call it their own. What should we say to a man who got another to write a book for him, and then prefixed his own name? Yet the cases are parallel.

The question may be asked where the line should be drawn. It seems to me that it is perfectly fair to buy prepared plates and paper. A doctor can buy ready prepared drugs; but it is his knowledge which directs them. So it should be with the amateur photographer. An exposing machine is not an amateur photographer.—I am, &c., An Amateur.

THE GRAPHIC REPRESENTATION OF SENSITIVENESS.

Sir,—On Tuesday evening, at the meeting of the Photographic Society of Great Britain, Mr. Burton used a diagram to illustrate his paper. Various curves were drawn, and were said to represent the gradations of density given by various emulsions. The graphic method so applied is excellent if there be any ready way of investigating the matter so as to get the curves even approximately correct. To my mind, however, there appears to be great difficulty in the way of doing so.—I am, sir, &c., Robert Belton.

PHOTOGRAPHIC NUISANCES.

Dear Sir,—I see by your issue of last week that the complaints of the unreliability of commercial gelatine plates still continue to crop up, and in fact these complaints are becoming pretty frequent, "especially by amateur and small professionals." May I ask, is it not rather the amateur or small professional that is faulty, rather than the poor plate maker?—for, with all due respect for the profession, there is scarcely one operator in fifty who knows how to treat that wonderful agent, a gelatine dry plate.

The great desire for extremely rapid plates has increased the difficulty, especially when extreme cheapness is demanded at the same time. With regard to rapidity, a plate that gives but little latitude in the exposure is unfit to put into the hands of the amateur or ordinary operator, especially the latter, and the want of appreciation of the character of the light, the kind of subject, and future treatment in the dark room, may cause the finest plate to be condemned as worthless, and I have no doubt that in nine cases out of ten the fault lies in the plate-user, rather than in the plate itself.

Cheapness does not tend to secure quality in anything, certainly not in gelatine, and the wonder is that the commercial plates are generally so good when the prices at which the consumer can obtain them is considered, and how miserably small must be the prices obtained by the actual maker. That commercial plates do vary, and that in the same parcel, I am willing to admit, and that this variation is avoidable, I fearlessly assert; but until the plate maker can obtain and afford to pay work-people who can be relied upon to take that extreme care in every detail which alone can secure regularity and perfection in so delicate an article as the gelatine plate, no one, amateur or professionsl, must expect every plate perfect; nor must any plate maker, however excellent and perfect his plates may be, expect to escape the condemnation of his plates from numberless causes over which he has no control, and which are due to the treatment, and not the plate.

During the last three and a-half years I have made and used some thousands of plates, from ¼ to 15 by 12, and have had a very few, indeed remarkably few to discard from any fault in the plates themselves; but this may be due to the fact that I make them entirely myself, unassisted in any part of the work. But this fact proves to me that perfect uniformity can be obtained, for although I make my emulsion in small quantities (about forty ounces), and consequently have to make it frequently, I find my plates perfectly uniform in quality and speed, so far as the general work is concerned (and this is the principal thing), although a slight variation might be detected by a delicate actinometer. I do not aim at great rapidity; I consider a plate that gives a good negative (C.D.V.) in a couple of seconds on an ordinary day, and that will not spoil in more than double that time of exposure, is a generally safe and useful plate for the studio, and may also be used for general and out-door work; and such a plate can be made with certainty, every plate giving practically the same result if properly treated; but though having the most conclusive proof of this, I have little doubt were I to send such plates into the market, they would share the fate of all commercial plates, and some of them be condemned as worthless.

What I wish to establish is, first, that, there is no difficulty in obtaining plates of practically uniform quality in every respect—and, indeed, I am much inclined to think many of the commercial plates are practically uniform—but that the treatment they are subjected to is anything but uniform, or, rather, I might say, is not such that uniform results can be expected.

I write generally, and I trust that none of your correspondents who have had cause to complain of the irregularity of commercial plates (an irregularity which I know exists to an extent) will think for a moment that I accuse them, personally, of inability. I do not doubt the justness of their complaints, but at the same time, until amateurs and operators are better acquainted with the powers of gelatine plates and the treatment they require under varying circumstances, the poor plate maker must content himself to bear undeserved blame. C. J. Dobbs.

Proceedings of Societies.

Photographic Society of Great Btitain.

The first meeting of the above Society for the session 1882-3 was held at the Gallery of the Society of Painters in Water-Colours, 5a, Pall Mall East, on Tuesday evening, 14th November, Mr. James Glaisher, F.R.S, President, in the chair.

The minutes of the last meeting having been read and confirmed, twenty-five new members were elected.

The Chairman said that in the minutes read it was stated that Mr. Maxwell Lyte had been elected hon. secretary in place of Lieut. L. Darwin, R.E. It was his painful duty to inform the meeting that Mr. Lyte had been, and was now, seriously ill, and that the council were not yet free from anxiety on his behalf. Before proceeding to the presentation of the medals awarded at the Exhibition, he said he was quite sure many persons had derived much pleasure from visiting it. The weather had been very bad since the opening, more rain having fallen than in any previous October he remembered; still the Exhibition had been visited by more than 6,000 persons, and they had taken more than £30 in excess of last year's receipts. Proceeding to the presentation of the medals gained, he remarked, with respect to Mr. Grant (who was not present), that, taking into consideration the very great difficulties incident upon the production of photographs in the Arctic regions, that gentleman was to be congratulated upon the success of his efforts. In handing the medal to Mr. Horsey, the Chairman expressed the hope that it might not be the last occasion in which he would have the pleasure of presenting him with one. In the absence of Mr. Sutcliffe, the next gentleman on the list of awards, the Chairman asked Mr. Bird to convey the wishes of the Society for his continued success. To Mr. Robinson, who was received with applause, the Chairman remarked that any exhibition containing his pictures, and not followed by his receiving a medal, would indeed be a novelty. He added that both with portraits and landscapes Mr. Robinson had been most successful, and he only hoped he might long remain with them to gain further honours. Of Mr. Byrne's pictures, Mr. Glaisher said it was a pleasure to look upon them. Mr. Abel Lewis's name had long been familiar to the Society, and he (the Chairman) would never forget the pleasure it gave him to hand him the medal awarded. To Mr. Slingsby the Chairman said: "Though you have not received a medal hitherto, your name has never been absent from the list of those mentioned by the judges as deserving of recognition." Speaking of Mr. Chaffin, who was not present, the Chairman said that he had the pleasure of presenting that gentleman with a medal many years ago, when awards were given for heads, natural size. Mr. Gale and Mr. Henry Stevens were among the absentees, the latter gentleman having written, regretting his inability to be present. The last on the list was Mr. Adam Diston, whose fine examples richly deserved recognition.

The Chairman said there were many other pictures in the Exhibition which had been very near to obtaining medals. He proposed a vote of thanks to the judges and hanging committee.

Mr. W. K. Burton, who was then called upon to read a paper on "A Modified Gelatine Process," remarked that he would not venture to describe it as a new process, as it was only a modification of old methods, though it possessed certain features of novelty. He utilised the property possessed by boiled gelatine emulsion of precipitating its bromide of silver during and after boiling. This was not a new observation, but it had not hitherto been possible to secure complete precipitation with any certainty, but by a subsequent addition of ammonia to the boiled emulsion he not only enchanced its sensitiveness, but also caused the bromide to precipitate with certainty. He then proceeded to describe the details of his method of working, giving practical demonstrations of some portions of the process. A three-grain solution of gelatine was made, to which the bromide was added; to this he next added the requisite quantity of silver nitrate in crystals, agitating until the crystals were dissolved. The thin emulsion was then transferred to a suitable vessel, and boiled in the ordinary manner; after which it was allowed to cool slowly to about 100° Fahr. A mixture of alcohol and ammonia is next stirred in, and the vessel set aside to allow the bromide to subside. The time required for this operation may vary from twelve to forty-eight hours, and when the subsidence is complete, the clear liquid is poured off closely, and replaced by clean water, the precipitated bromide being well stirred, and placed aside to settle a second time. In practice, he found this sufficed to eliminate the whole of the decomposition salts, as well as the gelatine first used. The water having been again poured off, a fresh quantity of gelatine, previously soaked, is placed in the beaker, together with a little warm water. By means of a glass rod, and using the softened gelatine as a "mop," the precipitated bromide can be scraped from the bottom and thoroughly incorporated, forming a fine smooth emulsion, which should then be made up to the proper consistency for use. Even at this stage the emulsion will not have reached its maximum sensitiveness; he therefore advocated its being kept for some days before use, a small trace of salicylic acid, dissolved in alcohol, being added for the purpose of preventing decomposition. Captain Abney had been the first, he believed, to point out the fact that an emulsion improved in sensitiveness by keeping; but in this respect he (Mr. Burton) had found great irregularity when working in the ordinary way, as some emulsions show no improvement whatever, whilst others actually become slower. By his method he had never found an emulsion fail to improve in sensitiveness, if kept for ten days, sometimes to the extent of four or five times, when the maximum appears to be reached. The advantages he claimed for his plan were the following. First, he not only eliminated the whole of the decomposition salts, but also of the gelatine which had been submitted to the combined action of heat and ammonia, which was, in ordinary processes, too often the cause of green fog, yellow fog, brown fog, and numerous other defects so common with gelatine plates. Captain Abney had stated, in connection with Dr. Eder's formula, in which a boiled emulsion was afterwards treated with ammonia, that he found no benefit to accrue from the action of the ammonia. The extra sensitiveness which may be shown by the sensitometer in an emulsion so treated with ammonia would not be exhibited in camera exposures. Mr. Burton then proceeded to explain, by means of a diagram of the curves of sensitiveness and density, how the advantages both of the boiling and ammonia processes were combined in his formula; and concluded by remarking that though, in consequence of the time occupied in completing the emulsion, it might not be much used by amateurs, it would prove extremely useful for day-to-day working, as the actual time occupied was much less than would be the case if the ordinary method of washing were adopted, though it might be necessary to have several emulsions, in different stages, proceeding simultaneously.

A vote of thanks was passed to Mr. Burton for his paper, and as the Chairman remarked that it would be the last evening on which members would have an opportunity of inspecting the pictures, the discussion was postponed till the next ordinary meeting on December 12th.

The next social gathering will be held on Tuesday, November 28th.

Edinburgh Photographic Society.

The twenty-third annual meeting was held in 5, St. Andrew Square, on Wednesday evening, 1st November, Mr. John Lessels, president, in the chair.

Mr. Wm. Dougal (interim secretary during the illness of Mr. Dobbie) read the minutes of the last annual and ordinary meetings, which were approved, and the following gentlemen were unanimously elected ordinary members of the Society:—Messrs. Andrew Gibson, D. Mackenzie, A. Archibald, A. Morrison, C. Fraser, George Dods, William Wyllie, William Morrison, and Mr. James Pursell.

The Secretary submitted the following report for the year ending October, 1882:—

The Council, in presenting the twenty-third annual report, has pleasure in congratulating the members on the continued prosperity of the Society. During the past session the Society has lost four members by death, and twenty-nine by removal and resignation—total thirty-three; whilst forty-eight new members have been enrolled. The total number on the roll at present is three hundred and eighty-seven, and thirteen honorary and corresponding members.

Twenty-five meetings have been held during the past session—nine ordinary, two popular, twelve council and committee, the annual excursion, and the annual dinner. The ordinary meetings have been very well attended, the papers and subjects brought under consideration being practical and instructive. The "popular" meetings still continue to be a very pleasing element of the Society's operations. There were two such meetings, the subjects being:—"A Tour in the Isle of Man," illustrated by pictures lent by Mr. Chadwick, descriptive lecture by Mr. Davies; and "Scenery of the Highlands and Islands of Scotland," pictures lent by Messrs. Valentine, descriptive lecture by Mr. Davies. About seventeen hundred persons were present at these meetings.

The annual excursion was on 6th July. The place selected was Dirleton. The company numbered about seventy. Numerous groups were taken, and a very pleasant day spent. The annual dinner took place on Friday, 18th November.

The following papers were read before the Society during the session:—"Mercury Intensifiers," by Cosmo I. Burton and Arthur P. Laurie; "Manipulation of Argentic Gelatino-Bromide Paper," practically demonstrated, by Messrs. J. M. Turnbull, and William Crooke; "Gelatine Emulsion," by Andrew Pringle; "Symbolism of Nature in Landscapes," by W. Neilson; "Some

Photographic Experiences, including Enamelling, and a recent discovery for the Fixing of Silver Prints," by Alexander Ayton; "Some Experiences in Animal Photography," by Mr. Charles Reid; "A New Theory of the Sun," by Dr. Siemens, F.R.S.; "On Photography as a Handmaid to Medical, Surgical, and other Sciences," by Mr. William Dougall, illustrated with a series of pictures; "The Modern Photographer, his Power and Appliances," by Mr. John M'Kean, with practical illustrations; "A few Practical Hints to Beginners," by Mr. William Crooke, with practical illustrations.

The following were also exhibited and explained:—A simple apparatus for corrugating zinc, an automatic washing apparatus, an adjustable plate box, racks wholly made of zinc, and a hot ventilator and studio roof cooler, by Mr. James Jameson; a folding pocket lantern made of talc stained with chrysoidine, by Mr. Bashford; an album of views taken on coffee plates, by Mr. Robert Murray; an immense number of very large calotype photographs taken in Burmah, by Dr. Hunter; a batch of silver prints, by the Hon. A. U. Erskine; camera and tripod, by Mr. Wane.

A large display of work produced by members during the past year formed an interesting feature of the October meeting.

The question-box has provided matter for discussion of a varied and instructive character. To meet the difficulty of providing the annual presentation print, an international prize competition has been held, one gold, two silver, and two bronze medals, together with £11 in money, being offered. There were thirty-three competitors who sent in one hundred and fifty pictures. The five awards were decided by ballot, in which every member was invited to indicate in their order of desirability the five pictures he considered most acceptable. Each picture was hung anonymously without frame or glass, and no one knew with absolute certainty (excepting the red chalks of Mr. Faulkner) who the pictures were produced by, till after the scrutiny of the voting papers was complete, and the five favourite pictures had thus been indicated. The result of the voting showed that the distinctly greatest favourite was numbered 104, and entitled "Will they never come?" next in order No. 146, "Phyllis Frere;" third, No. 22, "Brambling;" fourth, No. 46, "A Quiet Morning;" and a fifth, No 9, "Gloamin'." On opening the sealed envelopes the fortunate competitors were found to be:—Gold medal, H. P. Robinson, Tunbridge Wells (No. 104); silver medal and £5, Robert Faulkner, Baker Street, London (No. 146); silver medal and £3, R. Slingsby, Lincoln (No. 22); bronze medal and £2, Alfred G. Pettit, Keswick (No. 46); bronze medal and £1, Adam Diston, Leven (No 9). It is gratifying to know that the decision was very pronouncedly in favour of the five selected pictures. As indicating the weight of votes going to the most appreciated pictures, it may be mentioned that more than seventy-two per cent. of the total votes recorded were allotted to the pictures voted on in the first space of the ballot paper. Besides the ordinary members of the Society, a large number of their friends availed themselves of complimentary tickets, and visited the exhibition. The thanks of the Society are due to Mr. Andrew Elliot for his kindness in allowing the use of his room for the exhibition, and to Mr. J. M. Turnbull, who has provided the metal for the silver medals.

Mr. H. H. Pillans read the financial statement, which showed a balance in the treasurer's hands of £5 2s. 8d.

The office-bearers were then elected for the current year.

Mr. Norman Macbeth, R.S.A., after alluding in sympathetic terms to the serious illness of Mr. Dobbie, read a paper entitled "An Early Taste for Art and its Training," &c. (see page 693). The paper was illustrated by diagrams, and pure and hand-modified photographs.

Mr. W. Neilson, in proposing a vote of thanks, remarked that he would begin the training in art as soon as the infant could see, by surrounding the nursery with objects of beauty.

Mr. Lessels spoke of the difficulty he had experienced in getting information, when, as a youth, he came to Edinburgh to purchase books and get the aid of a teacher; but, being unsuccessful in his search, had to return home with his money in his pocket: and pointed out the great advantages possessed by the rising generation, who could get books and teachers not only without difficulty, but cheaply. He specially recommended the use of the black-board as employed in the schools of art on the Continent, where he had seen as many as sixty students in one room, each working before a black-board.

The usual vote of thanks terminated the proceedings.

Dundee and East of Scotland Photographic Association.

The second general meeting of the Association for the winter session was held in Lamb's Hotel on Thursday, November 9th, Mr. David Ireland, vice-president in, the chair.

The minutes having been confirmed, the following gentlemen were elected members of the Association:—Messrs. R. Wilson, James Thomson, Robert B. Thomson, and John K. Thomson. Four other gentlemen were then proposed for election at next meeting.

The Vice-President (Mr. Ireland) then gave the inaugural address in the unavoidable absence of the President. He congratulated the Society, in the first place, upon its strength and rapidly increasing membership. The past year had been a memorable and successful one, and they must look forward to another exhibition at a not distant date. Meantime, let every member strive to higher perfection, and study to keep pace with the rapid progress of the art. The Vice-President then alluded to the dry-plate process and its superiority over former modes for producing transparencies for the lantern, and, in connection with this, said he hoped members would prepare slides for exhibition, and as last year's lantern entertainments had proved of so much interest, the first of the kind for this winter was fixed for an early date. Mr. Ireland concluded by kindly promising to show at one of the meetings a series of slides which he and his son were busy preparing from views, being the results of a summer trip in Norway.

The question-box was then opened, and found to contain two queries—one relative to the most effective mode of keeping pyrogallic in solution, and the other inquiring into the cause of spots on sensitized paper. Both questions gave rise to interesting discussion, and gave ample proof that the question-box will cause some lively sittings. Young members will doubtless resort to its aid to be helped out of their technical difficulties.

Thanks were voted to J. Glaisher, Esq., F.R.S., President of the Photographic Society of London, for his courtesy in forwarding tickets of admission for the Photographic Exhibition in Pall Mall.

A vote of thanks to the Chairman brought the meeting to a close.

London and Provincial Photographic Association.

Mr. W. M. Ashman occupied the chair on the 9th inst., when Mr. Cowan said he had experimented successfully with Captain Abney's formula for clearing green fog negatives by the use of bichromate of potash.

Mr. Cobb having had a batch of emulsion which gave very bad green fog, had added bichromate and allowed it to remain about a hour, then washed for another hour, and coated some plates, and failed to obtain an image even with half an-hour's development; he then washed the emulsion for about eighteen hours, and obtained some of the most rapid plates he ever used; the bichromate seemed to have a hardening effect on the gelatine.

Mr. Henderson said he had some years ago experimented with the addition of bichromate to the emulsion, washing it out with the nitrates, but failed to obtain any good results.

Mr. Cobb enquired if it was considered a necessary consequence that by the use of bichromate the emulsion loses in sensitivenees.

Mr. Henderson found it required a great deal of washing.

Mr. F. W. Hart suggested that the emulsion should be warmed and precipitated in alcohol to eliminate all traces of bichromate.

Some lantern transparencies by Mr. Hepworth, of the *Graphic*, were passed round.

A question was found in the box asking for information as to what was a ten per cent. solution of any chemical.

Mr. Haddon said to make a 10 per cent. solution by weight, 10 parts of the chemical should be taken, and 90 parts of water by weight should be added; then any portion would be a 10 per cent. solution by weight.

Mr. F. W. Hart said a 10 per cent. solution by measure was obtained thus:—Take of the chemical 100 grains, and dissolve in a small quantity of water; place in a beaker, and make up to 100 grains measure with distilled water.

The Chairman showed a developing tray made by fastening strips of glass to a glass plate by means of Prout's glue.

Sheffield Photographic Society.

The usual monthly meeting of the above Society was held in the Masonic Hall, Surrey Street, on Tuesday evening, the 7th inst., Mr. J. H. Rawson, vice-president, in the chair.

The minutes of the last meeting were read and confirmed.

In relation to the question of a presentation print, it was resolved to advertise in the journals, for specimen prints, to be forwarded to the Secretary on approval before the next meeting.

The last year's accounts were then read over, and ordered to be audited and presented for approval at the next meeting.

Mrs. Stringfellow, widow of the late esteemed treasurer, sent an enlarged portrait (by the Autotype process) of her late husband, for the Society's acceptance.

An nanimous vote of thanks was given to Mrs. Stringfellow for her thoughtful gift.

Mr. Rawson brought some very nice stereoscopic views, taken by him during the past season, for the inspection of the members, and advocated the desirability of purchasing a few stereoscopes for the use of the Society at their meetings; and a resolution to that effect was eventually agreed to. He showed a very simple and effective adjustable stereoscope, sent to him from America, which met with general approval.

Mr. Seaman, of Chesterfield, showed a very fine instantaneous view of Chesterfield Market Place, on the market day, when crowded with cattle, farmers, &c. The picture was well defined to the edges, and taken with a Dallmeyer's whole-plate R R lens, on a gelatine whole-plate, and exposed with a shutter of a new construction, devised and made by the Secretary, and giving the foreground three times the exposure of the sky.

After some further discussion the meeting was adjourned.

Photographic Society of Ireland.

The annual meeting of this Society was held in the Royal College of Science, at 8 p.m. on Friday, the 10th inst., the vice-president, Mr. Howard Grubb, in the chair.

The minutes of the previous meeting having been read and confirmed, the hon. sec. (Mr. A. Conan) read the report of the council, from which the following is an extract:—

"In presenting to you the report for the past year, we have much pleasure in being able to announce the continued and increasing success of your Society. During the year, twenty-one new members have been elected, so that there are now, without counting those to be elected to-night, sixty-seven members. Your meetings have on the whole been well attended, and the success of the out-door meeting and of the lantern exhibition would in our opinion justify their repetition in the coming season. The following communications were brought before you:—'On the Gun Camera,' by Mr. John Russell; 'On Professor Stebbing's Gelatine Films,' and 'On the Adaptation of Optical Lantern Fronts to Portrait Lenses,' both by Mr. Thomas Mayne; 'On Mounting Prints on Thin Paper without Cockling,' by Mr. J. V. Robinson; 'On Enlargements on Gelatine Bromide Paper,' and 'On Various Printing Process,' by Mr. Herbert Bewley; 'Notes and Gleanings from a Season's Work,' by Mr. George Mansfield; and 'On Instantaneous Photography,' by Mr. T. H. Smith. Besides the above matter, a number of interesting and instructive exhibits of apparatus and of prints have also been from time to time laid before you, and we have to acknowledge our obligation to those members who have so successfully contributed to the instruction of their fellow-workers, and to express a hope that each member will contribute, as far as he can, his experiences, and the results of his individual researches. During the year a collection of lantern transparencies has been formed, which, as you are aware, are at all times at your disposal for the purposes of private exhibition; and recently we have been able to establish a system of interchange of prints through the medium of a set of albums, which it is intended will shortly represent a permanent exhibition of your work, and considerably enhance the attractions of your future meetings."

The balance-sheet showed the Society to be in a prosperous financial position, the balance in hand being £12 19s. 1d.

The report and balance-sheet having been adopted, the meeting proceeded to the election of officers, with the result that the president, vice-president, hon. secretary, and treasurer were re-elected, and the following gentlemen were chosen as new members of council:—Messrs. G. Mansfield, G. Pim, J. L. Robinson, J. E. Madden, and Thomas Mayne.

The new members of the Society declared elected were Messrs. T. G. Barlow, E. Barton, R. Heron, T. G. Haslam, jun., J. C. Langford, G. Symes, E. Hardman, J. A. Scott, E. Greer, and the Right Hon. Lord Louth.

Among other business transacted was the accord of the best thanks of the Society to the council of the Royal College of Science for the use of the premises, and to Professor Barrett for the use of his laboratory.

Mr. J. V. Robinson then read a paper on "A Reliable Method of Drying Gelatine Films," drawing attention to the avoidance of the danger of cracking or tearing away from the pins usually used, as also of every trace of distortion. He recommended the preparation of a solution of gelatine, such as often used for enamelling prints, and the coating with it of a large sheet of glass. The films, after washing and fixing, were squeegeed into contact with the glass, and left there to dry. They could then easily be removed by cutting round them with a knife, when the negative would come away from the glass without difficulty, and perfect in every respect.

Mr. C. W. Watson exhibited and explained Messrs. Marion's patent "Enjalbert camera," patent Academy camera, and patent "Plucker" stand, also Warnerke's patent actinometer, and patent sensitometer, all of which had been placed at the disposal of the Society for exhibition by Messrs. Marion.

Newcastle-on-Tyne and Northern Counties Photographic Association.

The ordinary monthly meeting was held on Tuesday evening, Nov. 14, at the Literary and Philosophical Institute, Dr. Berwick in the chair.

The minutes of the last meeting were read and passed. Messrs Swinton, Marten, Pae, Galloway, Templeton, and Prof. Bedson were elected members.

The Secretary gave formal notice of a special meeting to be held next month, for the purpose of making alterations in the rules.

The Chairman briefly opened the proceedings, and the Secretary then read the written report of the judges. This document was supplied by Mr. Way, who, on behalf of himself and his colleagues, Professor Herschell and Mr. Laws, reported that they could not speak too highly of many of the works sent for exhibition, all having more or less of merit as good examples of photography. They all remarked (and regretted) the small number of heads sent, there being but two shown, by the same exhibitor, and both being portraits of the same lady. The two selected exhibits were, "A Misty Morning on the Wear," and a view on the Tees, both by Mr. McLeish, of Darlington. The first was a very remarkable production, but as a picture would have been much improved had the black and unattached patches of foliage on the right been left out. The other was much the better picture, nothing being wanted to complete the composition. The report proceeded to speak of other pictures deserving mention.

Professor Herschell remarked that, as a whole, the pictures reached a high standard of excellence, and for some time the judges had difficulty in carrying out the wishes of the Association by selecting the two best. When that task had been performed they found that the two chosen were closely followed by a number of excellent pictures, and they therefore went in advance of their powers, and chose five for honourable mention. He wished they could have done a little more, for his memory recalled pictures which he would like to see again, and which any member of the Society would value. Another year—if Mr. Way's wish that the Exhibition should be a larger one came to pass—he hoped that a proposal might be made for the judges to select a greater number than two.

Votes of thanks were passed to the judges, the chairman, and the secretary.

Talk in the Studio.

Dr. Siemens on the Future of Electric Lighting.—On Wednesday last the introductory address of the session was delivered at the Society of Arts by the Chairman, Dr. C. W. Siemens, and his remarks were principally confined to the relative economy and advantages of electric and gas lighting. The dynamo machine will, when conditions are favourable, transform ninety per cent. of the motive force into electricity, and the apparatus itself is subject to but little depreciation, except that when currents of high potential are used, the copper wire slowly becomes brittle. One-fourth of a square mile appears to be the largest area which can be satisfactorily and economically lighted from one centre. Take, as an example, the proposed lighting of the parish of St. James, which would require no less than a motive force of 33,220 horse power to drive the necessary dynamo machines; and if even these were installed in a central position, the copper conductors would have to be about eight inches in diameter. The maintenance of each 16-candle incandescence light might be expected to cost about 21s. 9½d., against a cost of 29s. for the same light as produced by gas; but this estimate appears to make no allowance for leakage and loss of electricity, and such incidental expenses as collection of rates; while the gas estimate is founded on a clear selling price of the gas. If the cost of the gas were estimated on the same lines as Dr. Siemens adopted for his electrical estimate, the 29s. would be reduced to between 14s. and 16s. Dr. Siemens deprecated the prevalent system of rash electrical speculation, and paid a just tribute to Professor Pacinotti, as the inventor of the so-called Gramme-ring.

PHOTOGRAPHIC COPYRIGHT.—The case of William Smith, an importer of fancy goods in the Minories, who was summoned under the Copyright Act for pirating photographs, the property of Messrs. Elliot and Fry, and Mr. Downey, photographers, again came before Alderman Sir John Whittaker Ellis. Mr. Howard, who appeared for the complainants, said that since the last hearing he had been in communication with the solicitor for the defendant, who had advised him to give up to the prosecutors a much larger number of the pirated photographs than he did on the previous occasion, and the defendant had also paid £20 towards the costs. The prosecutors were perfectly satisfied, and if the arrangement met with the sanction of the court, they desired to withdraw the summons. Sir John Ellis observed that so long as the prosecutors were satisfied that the whole of the copies had been given up, he supposed the object of the prosecution had been attained. He hoped that the matter would not be repeated; but he should certainly advise that any other cases should be prosecuted to the end. The Alderman having given his consent to the arrangement, the summons was withdrawn.

THE PHOTOGRAPHIC MONEY DISPUTE.—At Clerkenwell, on Wednesday, Captain Herbert Kerr, of 22, Bushey Place, Clarendon Road, again appeared on an adjourned summons to answer a charge of having unlawfully obtained from Lieutenant Arthur Henry Loringe divers sums of money to the amount of £2,070, with intent to defraud. The allegation is that the prosecutor was induced, by means of incorrect statements of the assets and liabilities of the Association, to invest the amount mentioned in the Photographic Artists' Co-operative Supply Association. At each of the two previous hearings of the case, Mr. Hosack expressed the opinion that there was no sufficient evidence of fraud, and that the case should have been taken to a civil court. He was satisfied that a case had not been made out of fraudulently obtaining this money. The real point was as to the money that was due to Captain Kerr by the Company. He stated that the Company only owed him £200, whereas they really owed him £1,400. What the prosecution had to do was to show that he had made this statement with a deliberate intention to defraud. They had no evidence of this, but, on the contrary, they had evidence that Captain Kerr intended to waive that sum. Captain Kerr had invested a large sum in the Company, and, so far from the Company being bankrupt, it was still going on. He dismissed the case.

THE PHOTOGRAPHIC CLUB DINNER.—The annual dinner will take place on Wednesday, the 29th inst., at Ashley's Hotel, Henrietta Street, Covent Garden. Tickets, 5s. 6d. each, may be had from the secretary, Mr. Dunmore, 28, Oseney Crescent, Camden Road, and it is arranged for dinner to be on the table at 7 o'clock.

A PHOTOGRAPHIC PROOF.—A Longton farmer and his servant have been fined £5 and £3 respectively for working a horse to death. Photographs of the deceased animal were produced in court, and showed it to be in a fearfully emaciated condition.—*Lloyd's Weekly News*.

REDUCING ACTION OF GLYCEROL ON SILVER SALTS, AND ITS APPLICATION TO SILVERING GLASS.—By G. Palmieri.—After noticing the methods proposed for forming a silver mirror on glass, the author gives the results of his own experiments. If glycerol is added to an ammoniacal solution of silver nitrate, it becomes brown after a time, and gradually deposits a black substance; this action is greatly accelerated by heating the solution, a portion of the silver being deposited as a steel-grey mirror. If a few drops of potash solution are added to the mixture of glycerol and ammoniacal silver, a brilliant mirror is soon formed on the interior of the vessel. The phenomenon is even more striking if the ammoniacal silver solution be first mixed with potash, and glycerol then added: directly the glycerol comes in contact with the silver solution, reduction takes place with formation of a brilliant metallic mirror. If ether is added to the mixture of glycerol, potash, and ammoniacal silver nitrate, as soon as it touches the aqueous liquid a metallic ring is formed at the junction of the two liquids, and in a few seconds reduction is complete through the whole bulk of liquid. If alcohol is added to the glycerol silver mixture, reduction is somewhat accelerated, and the metallic mirror is always brilliant. The results of these experiments show that the reducing action of glycerol on silver salts may be applied technically with advantage to silvering mirrors, both from the facility with which the process may be conducted, and from its economy.—*Journal of the Chemical Society*.

To Correspondents.

*** We cannot undertake to return rejected communications.

THE YEAR-BOOK OF PHOTOGRAPHY AND PHOTOGRAPHIC NEWS ALMANAC for 1883.—Those of our readers who kindly intend favouring us with contributions are earnestly requested to forward their communications forthwith.

Several communications of considerable interest stand over on account of an unusual pressure on our space.

THE EDINBURGH COMPETITION—The name of Mr. A. G. Pettitt, of Keswick, was last week transformed into Pellat by a printer's error. The medal given to Mr. Pettitt was, we are told, the only award for landscape work.

W. SMYTH.—There is none in Melbourne.

LEODIENSIS.—Apply to Mr. J. J. Atkinson, of Liverpool.

HILLS AND SAUNDERS.—Thank you. The souvenir would certainly be considered miraculous by many.

MR. P. P. AVERY.—Will you kindly send your address for a correspondent?

P. L. (Whitehaven).—The method of breaking up the picture into a grain in the kind of way you refer to is difficult, and must be considerably improved before good work can be produced. It is probable that Waterhouse's method of using fine sand will prove better in actual practice, and we shall give full working details of this process before long.

HENRY SPINK.—Each spot is formed around a central nucleus, and the mischief probably arises from some chemically active dust which has alighted on the films while being dried.

VERNON DE VERE.—Both are correct, each being useful upon occasion. No hard and fast rule can be laid down, but you may safely assume that no commercial plates are sufficiently sensitive to yield fully exposed and sharp images of rapidly moving objects during the cloudy weather of the present season.

J. G.—If the spots are the kind which we suppose, they arise from the use of an unsuitable gelatine. Try another sample.

S. B. A.—Either filter the water, or replace the iron pipe by a leaden one.

COXTER.—A lump of chalk placed in the solution will soon render it neutral.

A. J. L.—Mr. Cowell's paper on the subject appeared in the NEWS during April in last year, and his original proportions were—

Citric acid	2 ounces
Alum	1 ounce
Water	10 ounces

The first modification to which you refer is equally useful in some cases; but the last, in which the citric acid is reduced to one-sixteenth of the original quantity, is of but little value.

THEODORE VULLIAMY.—The solution to be added is a saturated solution of oxalic acid; but the system you refer to is not worth resorting to in actual practice, as the extra labour, and the slight element of uncertainty as to the exact strength of the solution at any given time, serve to more than counterbalance any advantage derived from the economy of materials.

H. E. FITZ S.—You seem to have exhausted the list, and we are afraid the case is now hopeless.

ENQUIRER.—Doubtless due to pinholes in the varnish. These may arise if the film is not perfectly dry when the varnish is applied. Clean off by means of spirit, and re-varnish.

S. K.—1. We have not used them ourselves, but believe they are extremely good value for the money, and well adapted for a beginner who is uncertain how far he will go in for photography. 2. Single lenses in most cases.

T. BELSFIELD.—1. If the patent has become void, or expired, the article is no longer protected by patent. It would certainly be an indictable offence to obtain money for it by representing it as patented. 2. Yes, assuming the patent to be a valid one. 3. They are given just as we find them, and, as you say, the most ludicrous ignorance is often displayed.

L. BRENMER.—1. Hydrated sesquioxide of iron, but intermingled with a small proportion of organic matter derived from the vegetable kingdom. 2. When the neutralization is complete, the colour will darken considerably. 3. The decomposition takes place very readily in the presence of a small proportion—say 1 part in 300—of sulphuric acid. 4. A warm solution is best.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1264.—*November* 24, 1882.

CONTENTS.

24/11/82

THE WHIPPLE-CASELLA SUNSHINE RECORDER.

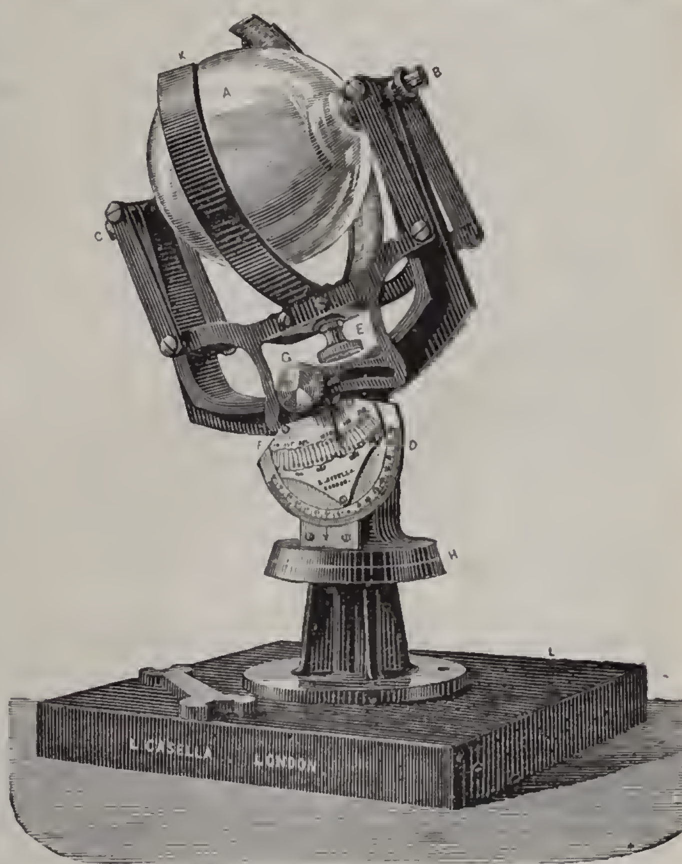
In April last we described in these columns* an apparatus for recording the duration of sunshine. No one is more interested than the photographer in the vigour and duration of the sun's rays that fall upon the earth, and hence we make no apology for bringing before our readers another and improved apparatus constructed upon a design of Mr. Whipple, the director of the Kew Observatory, and Mr. Casella, the well-known optician of Holborn Bars. The instrument, as our readers will see from the drawing, is an adaptation of the glass sphere which Mr. J. F. Campbell was the first to suggest as a ready means of recording the hours and minutes of sunshine. The sphere acts as a convex lens or burning glass, and is thus made to produce a charred line along a printed sheet or diagram that is placed suitably in the focus of the rays. The diagram is divided into spaces representing the hours of the day, and if at sunset it is found that a charred line exists throughout all these spaces, there is proof at hand that the sun has been shining all day. In the same way, if the charred line only appears at certain intervals on the printed sheet, then we know that during certain times of the day only has the sun shone, the actual periods of dull and bright weather being at once shown by the diagram.

About ninety per cent. of sunshine may be in this way recorded, for very feeble sunlight fails to exert any action; but we suggested in our former article that if a more sensitive recording material were necessary, this might probably be produced by treatment of the paper to be charred, with slightly sensitive chloride of silver or other similar medium.

There are, however, some slight defects in the Campbell recorder, which have led to the design of the present improved instrument, one of the shortcomings being the fact that it is necessary to construct the instrument especially for the latitude of the spot where it is to be used. It cannot be transferred from one place to another. The Whipple-Casella instrument, on the other hand, is universal; that is to say, it may be set to work in any part of the world on adjusting the polar axis (B C) of the glass sphere (A) to the height of the pole at the place of observation. When this, the latitude, is known, the adjustment of the instrument may be performed at once by means of a graduated circle (D) provided for the purpose.

Another defect of the Campbell instrument is the necessity of having the diagrams or cards cut to different curvations to fit round the sphere at different seasons of the year, as also the necessity of shifting them from day to day. The Whipple-Casella supporter is provided with several movable card-holders, K, all adapted to receive strips of card cut straight, and of uniform width, so that they are perfectly interchangeable one with another, and the same kind may be used all the year round.

The card-holders are held in their place by a clip, E, so



that when it is necessary to change the paper, one holder is slipped out and another in, an operation occupying but a second or two, leaving the observer at liberty to remove the cards from the holder at any time during the day when convenient, and allowing of his drying them before the fire, if wet, before withdrawing them from the grooves, thereby avoiding the risk of tearing or destroying them in the operation.

In order the assist the observer in placing his card in the proper position for receiving the sun's image, a graduated scale, F, is provided, engraved with divisions indicating the sun's place any day of the year. If, then, the pointer be set to the correct date, and the clamp, G, be screwed fast, the card will be in its correct place.

Owing to the smaller diameter of the circle described by the sun's image round the glass sphere at the solstices than

* Photographic News, 1882, p. 209.

at the equinoxes, it is found necessary to have card-holders to two different diameters, the larger ones to be used during the months of May, June, July, and August, whilst the smaller ones are employed the remainder of the year.

The relative scale value of the trace produced by the passage of the sun's image over the paper also varies to a corresponding extent; but by using a tapering glass scale the cards can be tabulated without any inconvenience.

The most convenient cards are cut from Bristol board, tinted with Prussian blue, and divided into slips 13 inches long, by ¾ inches wide. We cannot help thinking that firms which do much printing would find in the sunshine recorder an excellent check upon work done.

CHEMIGRAPHIC ENGRAVING.

Third Article.

The lines on zinc plate now stand in relief to a very slight extent indeed, but one might imagine at first sight that if the action of the acid had been allowed to continue very much longer, a much more considerable degree of relief would have been obtained: but as a matter of fact, the nearly vertical sides of the lines would have been so far dissolved by the continued action of the solvent, as to finally undermine and cut them off altogether, and this sideward action of the acid is prevented by the next step, which consists in so far warming the plate as to cause the accumulation of ink and asphaltic matter, which is now piled on the lines, to flow down and cover the vertical sides of the relief. The temperature required for this is rather higher than that which was necessary for causing the asphaltic powder to unite with the ink, as previously alluded to; but no precise directions can be given, as samples of asphalt and ink vary much in their physical characteristics. The most convenient method is to place the zinc plate, face upwards, on an iron trellis, and heat it by means of a Bunsen gas burner or a spirit lamp, kept in constant motion, underneath it; an arrangement which renders it easy to watch, with the help of a magnifying glass, the overflowing of the melted material. Over-heating should be guarded against, as certain constituents of the ink are liable to be lost by volatilisation, the remainder becoming brittle and ill-calculated to thoroughly resist the action of the acid. The heating operation having been satisfactorily performed, the plate is allowed to cool.

About equal parts of ordinary lithographic printing ink and middle lithographic varnish are next mixed on the inking slab, and are thoroughly distributed with a moderately soft lithographic roller. By this time the zinc plate will have cooled, and after it has been once more gummed and wiped with a damp sponge, just as previously directed, the moist plate is well rolled with the ink roller, care being taken not to exert too much pressure. The lines thus become charged with a fresh layer of ink; and if any should adhere to the bare zinc, it is probable that the gum has been too thoroughly removed by the damp sponge, that the plate has become too dry, that the ink is too thin, or that overmuch pressure has been exercised in inking. When the plate has been several times turned round and thoroughly inked in all directions, it is well washed, so as to free it from all traces of gum, once more dried, and again dusted with the asphalt powder; once more it is very gently warmed, so as just to cause a partial union to take place between the ink and the powder. When the plate is again cool, it is ready for immersion in the second etching bath; but, before this, a careful examination should be made, and any traces of printer's ink which may adhere between the lines must be scraped away, so as to lay bare a clean surface of metal. Prior to immersion in the second etching bath, a portion of the border must be laid bare, as explained when the first etching was described; and in ordinary cases the same bath as that previously used may be employed; but the action may be allowed to continue for about twice as long a time, as the bath would necessarily be somewhat weaker than before. It is not advisable, however, to etch a much deeper step than that of the first etching, as such a course might endanger the entirety of the finer strokes of the design, and lead to the failure of the whole work. After the second etching, the plate in once more well washed, drained, and fanned dry; after which it is again heated, so as to cause the resist to run down and to cover the vertical edges of the second step, and if the subject consists partly of lines separated by extremely narrow interspaces, it will be found that many of these will be blocked or filled with the resist at this stage, giving the design the appearance of a carelessly printed impression from a stone or block.

The gumming and re-inking of the plates are now repeated in the same fashion as already described, but as the tendency of the interspaces to become soiled with ink is now considerably reduced, an increased pressure may be exercised on the inking roller; but still this pressure must not be excessive. It is, however, of considerable importance not to neglect the precaution of turning the plate round, so as to bring each edge to the front successively, as if this is not done there is a high probability of inequalities occurring as regards the deposition of ink. Once more the plate is thoroughly washed, dried, and dusted with the asphalt powder, a sufficient degree of heat being then applied to cause the thorough fixation of the powder as before, but not heat enough to cause any flowing over of the resist on to the uncovered parts of the plate. A new test line is made, and the etching once more etched, the old bath being used, but as much strong nitric acid as was originally used should be added. A considerably greater depth may now be ventured on, generally rather more than that resulting from both the previous etchings taken together. The whole cycle of operations is again repeated, but instead of dusting with asphalt powder it is better to employ finely-powdered resin, this substance being more fusible and running more readily down the sides of the deeper steps which may now be ventured upon. The number of etchings required may vary from six to twelve, but as the work progresses every care should be taken to at once clean off any trace of ink which may become deposited on the blanks, and during the action of the acid a gentle rocking motion of the tray should be invariably kept up. A more fluid ink and a softer roller are also desirable, as the depth of the etched parts becomes greater, in order that the sides of the relief may become fairly inked; while resin, rather than asphalt, ought to be used for dusting. It is often convenient to continue the etchings until the plate is actually perforated in parts; but this will depend on circumstances, as many will prefer to cut or rout out metal, rather than to dissolve it by chemical means; in fact, the fortunate possessor of such a routing machine as that manufactured by Messrs. Hoe and Co., of New York, would perhaps not etch more than four or five times. The back of the plate should be examined from time to time, in order to see if there is any imperfection in the protecting layer of varnish; as if this is not done the chemigrapher may be gratified by seeing a patch of his work suddenly disappear without warning.

Let us now suppose that the etchings have been carried out to a sufficient extent, and the chemical engraver is anxious to examine the result of his labour. The plate is warmed, and oil of turpentine is poured over it, gentle friction with a brush being employed in order to expedite the removal of the tolerably deep incrustation of resinous and fatty matters; and when the plate has been thoroughly cleaned by successive applications of turpentine, a final scrub with a warm solution of washing soda—one part in twenty of water—is desirable, and, after a good rinse, the plate may be dried.

The success or failure of the work may now be fairly judged of, but some further operations are required before the plate is ready for the press, and these will be detailed in our next article.

THE GRAPHIC REPRESENTATION OF SENSITIVENESS.

BY W. K. BURTON.

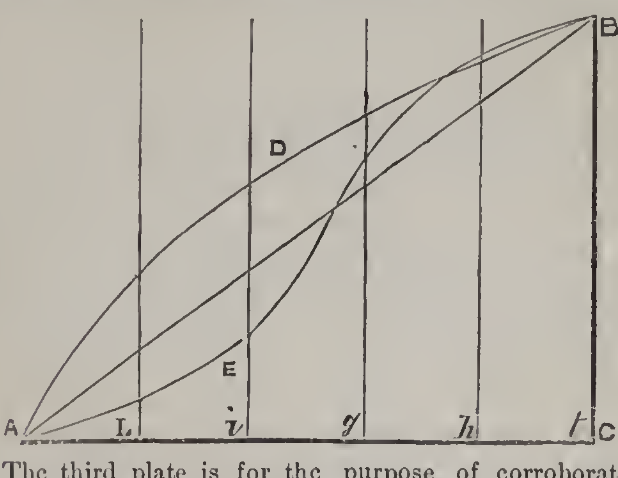
The point which Mr. Robert Belton brings up in a letter in your last issue is one of considerable importance. He asks how the curves which were used at the meeting of the Photographic Society of Great Britain to illustrate the sensitiveness of plates prepared by different processes were arrived at. The question is one which I should have wished to go into at the meeting, but feared that it would take up too much time. Moreover, although the method which I use is simple, it is somewhat difficult to explain in words. In the first place, I may say that, although the method is capable, at least theoretically, of giving results of great accuracy, I have worked it so as to get results which are merely approximate in the widest sense of the word.

The first thing requisite is some method of obtaining an absolutely even gradation of light commencing at zero, and rising to an intensity which will give, when allowed to act on the plates, about the full density which they are capable of. The gradation may either be uniform, or may rise in a succession of steps, each step giving a certain definite amount more light than the one before. The first is, so far as I know, impossible to obtain; the latter may easily be had in the form of a special sensitometer—such a one as will give an arithmetic instead of a geometric ratio of increase of light. It is easy to make one on the principle enunciated by Mr. Cowan, the openings varying in area as 1, 2, 3, 4, &c.

When the sensitometer is constructed, the next step is to expose plates under it. It is necessary to have the plates very thickly coated, so that the density will be independent of the thickness of the film. An exposure is given which will secure almost the greatest density which the plates are capable of giving for the lowest figure or the one receiving most light. I may say here, that I have retained the arrangement of figures usual with sensitometers—that is, calling the portion of the plate which receives most light No. 1; although for the investigation we are considering, it would manifestly be more correct to call the portion which receives the *least* light No. 1. I shall now suppose that three plates of each batch which it is desired to investigate have been exposed, each for the same length of time, and developed.

Even by simple inspection and comparison by eye of the plates, the essential difference may be seen. Let us now suppose that two of the exposed plates of the same batch are taken, and suppose it possible by placing them back to back, or face to face, to superimpose figure 25 of one on figure 1 of another, and figure 24 of the first on figure 2 of the second, and so on. It will be seen that if the gradation of density were correct—that is, that if, throughout the gradations, each one advanced in density the same amount beyond the one before it as another did—all, on superposition, would appear of the same density. Were this the case, it is evident that the line of density would be either straight as A B, or would be a curve of the nature A E B, in one half as much above the straight line as in another below. Suppose, however, that the central figures 10 to 15 appeared less dense than those at either end of the scale, it is evident that this indicates a curve below the straight line. If, on the other hand, the centre figures appear denser, it indicates a curve *above* the straight line, as A D B.

It will be seen that the first example left us the possibility of either a straight line or a double curve. It is quite easy, however, to further investigate the matter, and discover which it is. Let us suppose the figures 1 to 13 superimposed so that 1 covered 13, 2 covered 12, and so on. We will now be able by again seeing whether the centre figures appear more dense, less dense, or of the same density, whether we have a curved line or a straight one; and if the latter, whether it passes above or below the straight line. This method may be carried out to any extent of subdivision, the observations being made to overlap each other. An observation taken between any two figures shows whether the curve comes above or below, a straight line joining these two figures.



The third plate is for the purpose of corroborating results. Thus, let us suppose a curve produced and the conclusion arrived at by measuring vertical lines from it to the horizontal line, that by the density of any two figures added together should equal the density of a third. It is only necessary to superimpose the two figures mentioned, and compare with the third figure on the third plate. Density can be judged with wonderful accuracy by the eye; but it would be possible, of course, to devise some means of investigating it accurately by the action of the light which passes through the portion to be tested on to a sensitive film. I have not done so, and I may say that as the construction of my sensitometer, or rather curve investigator, is such as to allow of nothing else, I have judged entirely by superimposing rows of five figures at a time.

It is evident that the investigation cannot be performed by a sensitometer of the Warnerke type, nor, in fact, by any instrument which is, properly speaking, a sensitometer, as in none is the progression arithmetical. Supposing a hypothetical plate giving equal increase of density, for equal increase of light, exposed under a sensitometer proper, the curve given would be somewhat of the nature of a parabola. Of course it is theoretically possible to compare the curve given by my plate with this, and note the difference; but practically it would not be possible.

I have failed to make my explanation as clear as I should like, but I think that anyone who really understands the nature and use of graphic methods of representation will understand the manner in which I investigate those which I used to illustrate the paper.

FRENCH CORRESPONDENCE.

Prize Winners at the Exhibition of Decorative Arts—Opening Meeting of the Photographic Society of France—Photographers' Copyright Defence Association—French Crystal Palace—New Sensitive Pellicle—Engraving Processes by M. de Lostolot—Rapidity of Shutters.

Prize Winners at the Exhibition of Decorative Arts.—The list of awards given in the photographic section of the exhibition has just been published. We cannot in this space enumerate all the winners, but will give those best known. MM. Berthaud frères take a gold medal for their phototypes, and M. Charles Pettit receives a similar award for his process of similigravure. Among the silver medallists we note MM. Arent of Paris (photo-engraving), Feilner of Bremen (artistic portraits), Gutekunst of Philadelphia (phototypes), Grassin of Boulogne-sur-Mer (for his remarkable instantanographs), Mdlle. Marguerite Relvas, M. Neurdein (instantaneous pictures), MM. Truchelut and Walkman (phototype portraits), and Lecadre, successor of Bingham (reproduction of pictures). This exhibition, as we have previously said, is not important in point of number of works shown, but nevertheless is very interesting.

Photographic Society of France.—The Society had its opening meeting on the 31st ult. It was not a busy one, as is usually the case at the beginning of a session, no communication of veritable interest being made. It will not be the same at the next meeting. It was announced that the amount of the Poitevin subscription is just over 6,000 francs. A small magnesium lamp was exhibited by M. Loiseau. An album for unmounted prints was shown by M. Bonnet; it contains double leaves, bound; where it is double, it is left uncut. The prints are inserted back to back through the spaces cut on each sheet corresponding to each corner of the print. It is simple and ingenious, as with the double leaves the back of the picture is hidden. Two old things have again come to light: a method of engraving on glass by help of a jet of sand, a carbon print having been developed on the glass. The process, which is only for giving outlines, has long since been described by M. Aimé Girard and ourselves. A non-actinic liquid made from a decoction of red cabbage in water acidulated with sulphuric acid, which Mr. Pearsall suggested some months ago, during the course of this year, was also shown.

Photographers' Copyright Defence Association.—We read in the English journals that an Association is about to be created for the purpose of defending the copyright of photographic works. It is certainly an excellent idea, but from this point of view it is not better than that which exists in France. The Chambre Syndicale represents the professional interests of photographers, and takes in hand all matters of the kind. What has been done in France, a special committee might work out in England; and we recommend the promoters of this good scheme to communicate with our Chambre Syndicale, because in both bodies there is a sort of parallel and symmetry, suitable to a perfect understanding as to the case where an action of claiming certain rights should be desirable. The Cercle de la Librarie has, moreover, created a syndic office for the copyright defence of the foreigner. This completes the office of the Chambre Syndicale, and we hope to give sound advice to our colleagues in England, advice based on practical experience, by telling them that they will do well to follow the example of what takes place here.

French Crystal Palace.—The question of a French Crystal Palace has made great progress. The agreement passed between the State and the concessionary company of the park of St. Cloud only awaits the sanction of the Chambre des Députés. The parliamentary commission is unanimously favourable to the approval of this convention. It is to be hoped that these administrative formalities will soon be terminated. It is thought of erecting in the park of St. Cloud a palace similar to that at Sydenham for the purpose of a permanent exhibition. Photography will not be forgotten, and our personal acquaintance with M. Nicole, the promoter of the idea, and who will be the director of the enterprise, will enable us to give many suggestions, whether for photographic exhibitions, or the numerous applications to be made of the art in an establishment of this kind. The cost of the work is estimated at not less than 25,000,000 francs.

Sensitive Pellicle.—M. Bratagne, photographer of Paris, manufactures a pellicular base for gelatino-bromide, of an indefinite length, and, therefore, suitable for taking series of panoramic views. This pellicle resists the action of water, is of great solidity, and as transparent as glass. There is no danger of rapid combustion to fear with it, as with pyroxyline.

Engraving Processes by M. Lostolot.—A work has just been published at Quantin's, entitled *Procédés de la Gravure.* It is written by M. Lostolot, who devotes much attention to photographic processes, and designed more for the public at large, than for the profession. Nevertheless, the book deserves approbation for rendering popular the knowledge of numerous applications generally unknown to the majority of people, even the best informed.

A few Words on the Rapidity of Shutters.—A great deal of time has been devoted of late to the invention of shutters, and this may easily be accounted for. Rapidity tends more and more to form an integral part of photographic work now that gelatine plates work so rapidly as to give good results in a fraction of a second. We only regret that many interesting questions bearing on this matter have not been more studied, together with determination of the necessary exposure regulated according to the conditions under which work is done. We will therefore call attention to a few observations on this subject, which will appear in our *Manuel de Touriste Photographie*, to be published shortly by Gauthier-Villars. Our fundamental position assumes that in the case of an object moving with any determinate speed, and in a direction transversal to the axial line of the lens, the angular variations arising from the movement are greater in proportion as the object is nearer to the lens. This is a fact so evident that it would be a waste of time to attempt its demonstration; but some deductions from it are of such a nature as to enable valuable indications as to the times required for exposure to be gathered; that is to say, the exposure which may be given when two objects are in motion at different distances from the lens. Up to the present time no rules have been available as guides in the matter, and very many manipulators never vary the quickness of the shutter, using one invariable speed on all occasions Indeed, they work without precise knowledge whether the moving object which it is desired to reproduce is at such a distance that it can be photographed with a sufficient sharpness, or not; still, let us hope a careful study of the matter from the points of view taken in our work just referred to will serve to bring about a more systematic and scientific method of timing the exposure.

Leon Vidal.

NOTES ON PHOTOGRAPHY.*

BY E. HOWARD FARMER.

Lecture I.—The Nature of Light.

Photography, in its etymological sense, means writing by means of light, and we must first make ourselves acquainted with the nature of this agent "light," on which we are dependent, in order that we may practically use it with judgment and success.

When we hold an opaque substance between us and an object, we do not see that object. A luminous point throws shadows of opaque substances situated between it and a screen; light, therefore, in a uniform (homogeneous) medium is communicated only in straight lines.

We cannot see on a clear night the light from the sun with which we know the sky above us is filled; neither can we see a beam of light which passes through a room in which the dust has been allowed to settle. Light is therefore invisible.

What, then, is the nature of this light, the nature of this communication, which not only enables us to see, but impresses our pictures, and that, too, after coming from the sun, and yet more distant stars? Is there any physical means of communication known to us by which we can analyse it, and give a rational explanation of the phenomenon it presents?

Yes, there is. A water wave produced in New York harbour may travel across the Atlantic, and break on the

* Being an abstract of a course of lectures delivered at the Polytechnic Institution.

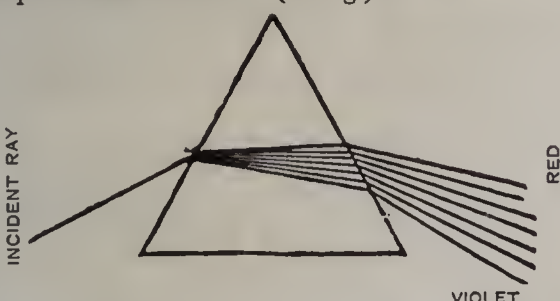
shore of England. A sound wave produced by the firing of a cannon at Calais may break on our ears at Dover. A ray of light produced on the sun travels across the intermediate space, and falls on our eye. We conclude by analogy that this also is wave motion.

In the first case, the medium in which the wave is propagated is water; in the second case, air. In the case of light it is an imponderable elastic fluid, which we suppose fills all space (including that occupied by ordinary matter), and which we call the luminiferous ether.

Both water waves and sound waves take time in travelling; so also does light. The velocity with which light travels is 186,000 miles per second. Therefore, in the falling of an ordinary drop shutter, a wave of light has time to go through the aperture, makes a journey round the earth, and goes again through the aperture before it is closed. The light of the sun (ordinary daylight) is what we call white; when, however, it passes through a blue or red glass, it conveys to the mind the sensation of these colours.

How do we explain this fact by our theory of wave motion? We have waves on water which we call ripples, which only measure a few inches from crest to crest, and waves on the ocean which may measure thirty feet from crest to crest. We may have sound waves in air measuring eight inches or eight feet across, the difference in wave length here constituting sounds of different pitch. Similarly, we suppose that the waves of light have different lengths, the eye interpreting them as different colours.

Let me show you the great Newton's experiment on this subject. He closed the shutters in a room, and made in one of them a small hole through which he reflected a beam of light from the sun into the room. He then placed in the path of the beam a three-cornered piece of glass (a prism). He found that in passing through the prism, the beam of white light was deflected out of its straight course, and split up into various colours (see fig.).



This band of colour obtained by passing a slice of light through a prism is called a spectrum; as you observe, the red light is deflected the least, or is the *least refrangible*, and the violet is deflected the most, or is the *most refrangible*; the other colours occupying intermediate positions. Newton also found that on re-combining the colours of the spectrum, white light was produced.

From these facts we know that white light is not of a simple nature, but is a mixture of waves of different sizes, corresponding with their different degrees of refrangibility.

To light of the same colour ever belongs the same degree of refrangibility, and to light of the same degree of refrangibility ever belongs the same colour (Newton).

The length of these light waves have been measured, a few of them being as follows:—

Extreme red	=	$\frac{1}{33866}$ of an inch.	
Yellow	=	$\frac{1}{43137}$ "	
Extreme violet	=	$\frac{1}{70555}$ "	(Herschel)

If we divide the velocity (in inches) per second by the length of the waves, we shall ascertain the number of waves which pass any point in a second, the result being as under:

Extreme red	399,101,000,000,000
Yellow	509,069,000,000,000
Extreme violet	831,479,000,000,000

So that in an exposure in the camera of one second of time, about eight hundred and thirty-one billions of violet waves break on the sensitive plate.

This fact should make us confident that we have not yet by any means arrived at the limit of sensitiveness with our sensitive plate. Besides differences of wave length, we may have waves of the same length, but of different widths, *i.e.*, the distance between the top of a crest and the bottom of a hollow; this is called the wave's amplitude. In our case, differences of amplitude constitute different intensities of light.

AN EARLY TASTE FOR ART—ITS TRAINING.

The Importance of this to the Beginner in Photography, also to those more Advanced, and to the Interests of Art in General.

BY NORMAN MACBETH, S.R.A.*

On the 18th of November, 1868, I read a paper at the Edinburgh Photographic Society, specially on the principles of art. As that paper was printed in the journals, I have no doubt reference could be made to it if wished. It was accompanied by several illustrations from Howard's "Manual" and others.

Judging from what appears in much of amateur effort, it is evident that there is a lack of knowledge in composition, and a few simple directions may greatly help the beginner.

It is the misfortune of photography, seeing it is more allied to science than to art, that much of what is difficult to acquire by the draughtsman, is never entered upon or thought of by the photographer; hence the eye is never trained, the relative proportions of things to each other are not cared for, and the different aspects in which the subject is made to appear according to the points from which it is viewed are not intelligently gone about, the importance of the principles involved being either not known or not sufficiently considered. Every tilt of the camera backwards or forwards alters the natural perspective. The photographer must bear in mind that, while it is not his hand or eye by which the lines are directed, yet it is only by the intelligence and judgment which he exercises in choosing a proper point of view for the instrument that the pictorial arrangement of lines is produced.

Among the things which I pointed out in the paper to which I have alluded, was that of a special size of picture, having reference to a certain proportion of a field for producing variety of composition. I desire to bring this again for a little before you, and show its import.

After deciding on the breadth of picture—whatever it be—find the square of it. A diagonal line drawn from one corner to the other metes out the size of the length of picture. This proportion of breadth to the length suits almost every subject requiring either a vertical or horizontal form. It so happens that the "half-plate" size used in the camera is as near as possible of the same relative proportions.

Now, as diversity in unity is one of the essential elements of good composition, the method of producing this lies in certain subdivisions of the field being made both vertically and horizontally; every intersection or crossing of the lines constitutes points, which, if anything were constructed on them, would prove expressive.

To divide the field into two equal parts both ways, the intersection would be at the centre; such a point, although some might think it to be conspicuous, is nevertheless not expressive, inasmuch as it is too finely balanced on either side. To subdivide again the two sides would not produce good or expressive intersections, for it would still tend to a too equal balancing of parts.

Now, in order to find expressive parts of a field, in place of dividing it into equal numbers, such as two, four, six, or eight—divide it into unequal or odd numbers—such as three, five, or seven—and you produce points at each intersection which easily compose, and are always expressive.

Bear in mind that the centre of the field is the weakest point in it. To put an object there, especially in a landscape, divides the subject, and raises a conflict of interest on both sides; so much so, that if there be objects of interest on either side, the eye is tortured or distracted. In order to avoid this, and make important parts of a scene or a figure expressive, I view them through a piece of glass—the "half-plate" size—divided into three parts each way, placing the intersections as much as possible over those parts in nature which are important. The

* Continued from page 695.

same lines may be drawn on the focussing glass when it is of the proportions I have described. The "half-plate" size is, as I have said, of the right proportion. This would enable

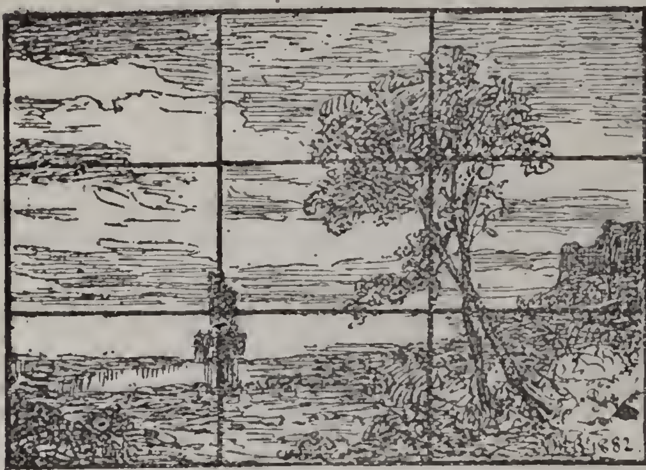


Fig. 1.

Fig. 1.—A land and sea view. A composition only. Is based on the simplest form of subdivisions of three. The centres of each space must be utilized necessarily in the continuity of subject; but they are not *forte* points. The more complicated the subject is with interesting matter, the more you must provide it with divisions in odd numbers to serve.

the photographer to place the intersections on special parts of a scene—such as a ruin, a tree, a river, a boat, groups of cattle, figures, important parts of architecture, and interiors generally.*

Fig. 2.

Fig. 2.—Taken from Mr. Macbeth's portrait of the late Dr. John Bruce, Edinburgh. Is based on the subdivisions of five odd numbers each way of the surface. As in landscape subjects, the more you provide the surface with *forte* point intersections, the more you can introduce matter; every intersection guides in the production of variety.

A larger number of odd-numbered subdivisions, similar to an example by Howard of the same (see fig. 1), may be applied to portraits and groups of figures or objects in a room (see figs. 2 and 3).

As it is only from one point of view that a subject can be treated by photography, it is of the greatest importance that the camera be as far back from the sitter as possible, so as to prevent any undue proportion of parts. The portrait painter in drawing from his subject, often (especially under very limited accommodation) has to look at the sitter from several points of view; first at the head, then towards the body, and lower still—viewing him towards the limbs and feet. This is the only way in which he can avoid the appearances of undue proportion and rapid perspective, common to the results of lenses when the camera has been placed too near the sitter.

Length of studio is of great importance, both for the painter and the photographer. To the painter, giving him ample range for placing his work close to the sitter, and then retiring to feel the comparisons; to the photographer, enabling him to

Fig. 3.

Fig. 3.—Taken from an engraving of Paul Delaroche's picture of Lord Strafford going to execution, receiving a blessing from another prisoner as he passes beneath the window of his cell. This picture has been subdivided into seven spaces each way. It is interesting to notice how much the principle has been realized, although it may not have been acted upon. Delaroche was one of the most accomplished designers which France has brought out.

take very remote views of his subject, so that when enlarged, if need be, the proportions are as perfect as distance and one point of view can render them. Length of range from the camera to the base of picture in a landscape is of equal importance. Generally, if it can be accomplished, the camera should be placed not nearer than twenty paces to the spot where you wish the subject to begin. In order to make sure of this, place there a white handkerchief, and then retire your twenty paces and adjust the camera. The boundaries of the picture are also important; but these determine themselves by the angle of lens, which should not be wide. Vision within the limits of the radius of the human eye—*i.e.*, what is seen by moving the pupils, but not the head—is as much as is desirable for a complete picture. Seldom is more attempted by the painter, unless his intention be for panoramic purposes.

I cannot bring this subject to a close without saying something as a conservator in the interests of right motives and legitimate methods of art. In the art of painting, there are fewer pretenders without training now than formerly, and very little but the best of art is purchased, seeing it is now regarded as a kind of property which, if the artist is rising, the owner is likely to make a profit by. So far the mercenary spirit is at the bottom of many of the purchases that are made, especially at sales. However, at our exhibitions, the sales of works exhibit purer and higher motives. Art is there purchased more for its own sake. Still it is to be feared that landscape work easily gone about, and readily securing a purchaser, from the cheapness of it when compared with figure subjects, which commonly involve more time and money, does not sufficiently promote the highest efforts of art. The desire for gain greatly increases by the ease with which it is secured, and thus, unhappily, retards the right aim of study. There need to be constantly kept before us the highest and purest motives. If this be not done, art soon becomes degraded.

No doubt, unless there be good remuneration for such labour, and the hope of eventually rising to some eminence, there is

* Here Mr. Macbeth showed a diagram illustrative of the method, similar to Howard (see fig. 1).

no calling in life wherein the spirit of a man gets more readily crushed than in the pursuit of the highest and purest art. When we see many making fortunes by photography, and retiring comparatively before the middle of life, what a contrast is presented when we think of several worthy painters only partially successful when age has crept in upon them! Surely it makes one feel the truth of Longfellow's saying, "Art is long, and time is fleeting." Among photographers, however, there have been heroes also, men such as Rejlander, who had his battles to fight, because he was a genuine artist; and even nearer home, in a little quiet town in the county of Fife, there lives one who is able, by his painstaking and plodding efforts, to manifest a thorough poetic spirit, producing such a perfect picture as that of "Gloamin," recently exhibited in the photographic competition collection. It is much to be regretted that so few, even among painters, exhibit the amount of thought in their works that there is in this, and unquestionably it shuts up the opinion that no fine art can be expressed by photography.

It is long since I predicted that the innovation of retouching negatives, especially in portraiture, would yet greatly degrade art. I admit the necessity of touching up spots which are merely incidental to the work; but beyond that, by other appliances on the subject, or further discoveries in development, all that was objectionable in the way of freckles, or undue marking of lines, could have been avoided. I do not see how it is that such an amount of serious labour can be undertaken when, by an application of dry pigment made up of certain density and tone, every brown stain on the face could be obliterated, the lines would be modified, and still the character retained.*

The powder, which is composed of several constituent parts, is put into a mortar and well ground. The parts are as follow, viz.:—1 of vermilion, 1 of French ultramarine, 2 of zinc white, 4 of yellow ochre. A small dabber made of chamois leather stuffed with wool is employed in conveying the powder over the parts requiring modification, and then equalised by the finger; this whole suggestion, however, is at its best but a make-shift. It will be noticed that yellow prevails; this is to assimilate with the freckles in surrounding parts—also to make it less actinic than a powder composed only of vermilion and zinc white alone. It must have been observed that persons of rather a sallow complexion always produce a more definite development; I trust this recommendation may be found practicable.

If photography had had leave to stand on its own merits, it would have been more advanced to-day—both chemically and artistically; and especially more valued for its genuine and authentic production than it is in its present condition—a condition chiefly ministering to the vanity of the more fashionable class of society, and, at its best, but nondescript in character, neither one art nor the other, the absence of homoegeneousness and individuality bringing it into disrespect by all who understand and can readily apprehend what is genuine honest work, be it either in a painting or a photograph.

We are told by those doing a good business in retouched photography that they would have to shut their saloons if they attempted to print an untouched negative. Well, that is very likely now that the innovation has been established and meets the public fancy; but what does it say for a pure photograph—well invented and arranged—being able to rank itself as a work of art, independent of any contrivance to make it pass, in which light it was regarded not so long ago? I am occasionally asked to paint posthumous portraits—indeed, more frequently than I care about, because they are exceedingly irksome, and it is very difficult to please the parties concerned—but, unless the photograph given me be one taken some years ago, I am under the necessity either of declining to enter upon the work, or of getting the photographer to wash off by spirit of wine all the retouched work.†

As I have said, an artist should despise nothing that is taken from life, and be always thankful when he can get a genuine photographic transcript. No artist, unless he cannot draw well, or be able to sustain the likeness, would ever resort to enlargements when he can get life; and it is only in extreme cases of infirmity of the subject that an artist should have recourse to a photograph. Even in posthumous portraiture, I have never in all my necessities used an enlargement by the lantern; I should feel the detail fully before me to be very enslaving. I simply draw it in the usual method, by squaring the surface, not keeping exactly to the rendering of the lens, as most frequently the limbs, hands, and feet are out of proportion.

Certainly there are few professions but what are in some way or other dependent on another. But surely it is to the honour of every profession when it is true to itself, and not appearing in the garb of others. That is the position of photographic portraiture generally, for by the excess of retouching the truth is covered, and the old story of "borrowed feathers" presents itself. It is much to be regretted that a pure, genuine photographic portrait is now so much despised, that it will not pass muster before the public gaze without donning the coat of another.

There is a very good story told of a boy who, having become a member of a certain total abstinence society, had the blue ribbon—a new badge—sewed on his jacket. One day his father came in evidently unwell, and the mother, having no spirits in the house, asked her son to go for some. The boy, true to his pledge, said: "But how, mother, can I be seen going into a public-house with this?" (turning up the lapelle of his jacket). "I say, Johnny, go for the whisky." "O, but, mother, do you not see *that?*" "I say, Johnny, will you not go when I tell you?" "But, mother, just take another look at that!" (the irrefragible blue ribbon). "I say, Johnny," and lifting her hand about to send him to the door, Johnny devises a way of escape, and cries out, "O yes! I'll gang, mother, if you only let me pit on Tammy's Sunday coat that has nae blue ribbon on't!"

Every effort should be made to introduce some other method of overcoming the obstacles which necessitate retouching to the extent to which it is done. The negatives of portraiture are invaluable as transcripts of character, and are more especially felt when the individual subject has ceased to exist. If all the pains bestowed on the negative by retouching were spent on the subject in careful preparation by artistic arrangement and skilful adjustment of camera, or in printing, insuperable difficulties would be overcome, and nobler work achieved. I am confident we are on the eve of great changes for the better in the way of art, as coming from photography. Certainly in the past it has proved, from its transcript character, to have been a great auxiliary to the purposes of art; but it is destined to become more so; by its instantaneous snatches of the movements of animate and inanimate action everything may be arrested and utilized as subjects or parts of a subject for the service of art.

I should have liked, had time permitted, to have descanted a little on a very important feature of photography now in vogue, and which I trust will continue—I mean that of photographs of individuals or groups of a family with the surrounding furniture common to their association, affording ample scope for artistic skill in arrangement. Few opportunities present themselves better for acquiring practice in composition than this. The art properties common to all studios are now very stale, and one is thankful for any demand which produces a change.

Very excellent specimens of this department have been done by the members of the Edinburgh Photographic Club. But the best compositions which I have seen of this kind of work are by Mr. Samuel Walker, of London, who is a photographer of no small artistic skill. These show that the most casual and unconscious expressions of home life may be most successfully secured.

But I must close, and the only thing to which I would allude before doing so is what is to me one of the most important applications of photography—I refer to reproductions of *stage expression during action.* I do not know whether it has ever been tried, but I should like extremely to see the application of instantaneous photography in the interests of the drama. I think, what with instantaneous plates and electric power of some kind, some of the best parts of a piece or parts of a character might be caught. What an interesting thing it would be to some of our leading actors to see their renderings of Shakespeare or other authors' works. How valuable would such impressions (caught in this way) also prove as expositions of arrangement, and as studies of composition to the painter or photographer. No class of artists are better acquainted with the arrangement of their art furniture and with positions of a figure or figures than actors are; and they produce great variety of design. None know also more thoroughly the importance of correct historical costume. All this makes the stage highly educational, and worthy of the closest attention.

These and similar appliances show how helpful one art may be to another, and that every effort in a legitimate and right direction should be encouraged, and so the interests of art in general be greatly promoted.

* Here Mr. Macbeth showed the powder.

† Here Mr. Macbeth showed a specimen of the two aspects of such a portrait.

Notes.

We deeply regret the death of the energetic Honorary Secretary of the Edinburgh Photographic Society, to whom is largely due the great success which has of late attended that body. Mr. Malcolm Gillies Dobbie died on Monday, the 20th inst., aged fifty-three.

The last photographic work of the late Professor Henry Draper was the photographed spectra of the nebula of Orion presented to the French Academy. An exposure of two hours with gelatine plates was necessary to produce some of them; but so marvellous was the delicacy of his apparatus, and the sensitiveness of the gelatino-bromide film, that he succeeded in getting the spectrum of a star of the tenth magnitude. Professor Draper pointed out that his Orion spectra show the hydrogen lines $H\gamma$ and $H\delta$, and traces, moreover, of other essential lines.

M. Flammarion, the well-known astronomer, tells us there is at this moment a quadruple spot on the sun's surface visible to the naked eye, and of far greater size than the earth. We had the pleasure of seeing this spot, or one of a similar character, in the fog on Saturday last, when the orb glared red through a veil of vapour. Assuming the apparent size of the sun to be equal to a cheese-plate, the black irregular-shaped speck appeared in the centre of the disc about as big as a small marble.

Anecdotes about photographic copyright reach us from all quarters. Here is one from the provinces. A buyer enters the premises of a photographer and admires some local views. He takes specimens, and intimates that if the photographer will quickly strike off a few gross, there will be a ready sale for them. The pictures are printed and packed off, and at the end of six months the photographer writes to know how the sale is getting on. "Very sorry, but they did not take at all. Only a couple of dozen sold," is the reply. And no wonder! For it afterwards transpires that the buyer has gone to another studio lower down, with the proofs in his hand, and given an order for 500 pirated copies.

Dr. Eder and Mr. Plener are continuing their interesting experiments in Vienna in the way of separating pure bromide of silver from gelatine emulsion by the simple expedient of centrifugal force. Dr. Eder reports that the bromide of silver thus separated presents several very interesting features. There are distinctly two kinds of silver bromide, he says; that precipitated by alcohol, and that precipitated by water. The former appears to be most sensitive to indigo rays, and the latter to the blue rays.

Dr. Hermann Vogel has been examining some dark brown or chocolate mounts, which a Berlin photographer found turned his pictures yellow. Dr. Vogel found that if he mounted with perfectly fresh paste the prints showed no sign of fading, but with acid paste (containing 5 per cent. of acetic acid), yellowness set in after a few hours. At the same time this acid paste, when employed on other card, did not turn the photographs, neither did the brown pigment when scraped off and mixed with fresh paste act detrimentally. Again, hyposulphite of soda did not bring about the reaction, and therefore Dr. Vogel surmises the fault may be in the presence of ultramarine, sometimes put into paper to counteract yellowness. In any case, as our colleague points out, a starch containing 5 per cent. of acetic acid constitutes a very good test for suspicious mounts.

The little Exhibition at Newcastle seems to have been very successful. Professor Alexander Herschel—an honoured name in photography—was one of the judges, and altogether the collection attracted much attention. "I had no idea Newcastle was the centre of such charming scenery," exclaimed one critic, when informed that most of the views were secured within a fifteen mile radius. "A Misty Morning on the Wear," by Mr. McLiesh; "A Stronghold of the Percies" (Prudhoe Castle), by Mr. J. P. Gibson; "Bywell Castle, on the Tyne," by Mr. Gould; "The Devil's Water," near Carbridge; "The Ivy Grown Mill" of Mr. P. M. Laws; the rustic scenes of Mr. L. Sawyer—to quote a few of the most important exhibits—all went to prove that the coal country is not so black as it is painted.

Mr. McLiesh's beautiful photograph, "A Misty Morning on the Wear," in which we see Durham Cathedral through a veil of silv'ry mist, has been unanimously chosen by the Newcastle Society as a presentation print. Our readers doubtless will feel little surprise at the fact, for the picture certainly excited more admiration at the late exhibition in Pall Mall than any other single work. How it escaped a medal is a marvel.

"Belt *versus* Lawes" has made one fact very plain: photographs are rapidly taking the place of drawings in the sculptor's studio, and nowadays a photographic portrait is well nigh indispensable in modelling a bust. Adam-Salomon was one of the first to learn this, and he learnt something else besides. If photography was useful in the sculptor's art, he found the sculptor's art no less useful in photography; for to his masterly knowledge of lighting and draping, the great French artist owed his magnificent success as a photographer.

The Copyright Defence Association seems in a fair way to be started. Two hundred pounds is the sum fixed as the minimum necessary to form the Association, and there should be no difficulty in getting this amount together from photographers who publish. Still the provisional committee should remember that few people contribute money spontaneously; they like to be asked.

It was very good of Dr. Siemens last week, at the close of his address, to tell the public to be chary about risking their money in electric inventions and electric companies. He had no doubt, he said, that in the end electric lighting would come to be general, but it was a great question whether the present shareholders of companies would see any adequate return for their money. Dr. Siemens' advice is, we suspect, very sound; only, seeing that during the past twelvemonth or so something like twenty millions of money have been subscribed by the public, and there is a lull at present among expectant shareholders, his warning words come a little late.

The boast of our Parisian contemporary, *Le Monde Illustré*, that it has just issued the largest wood-engraving ever known to illustrate journalism, is probably well founded, as its block of the battle of Champigny, by Detaille and Neuville, covers a surface about one-fifth greater than the area of our present number of the News.

We have had balloon photography discussed a great deal of late, some advocating the employment of a large balloon, like Nadar, and others, like Mr. Woodbury, suggesting the use of small balloons, to carry a camera, which is managed by an electric wire from below. But no one seems to have thought of trying a big kite for lifting the camera into the air. A half-pound camera might easily be carried aloft in this way, and, properly fastened to the ærial machine, there would be no risk of gyration, the great difficulty in balloons. With a long tube or cone depending from the lens to keep out extraneous light as much as possible, there should be no great difficulty in securing kite photographs.

Dr. Hermann Vogel sends us a brief but very interesting memoir, which he has just presented to the Royal Prussian Academy of Sciences, combating Norman Lockyer's dissociation theory. Lockyer has recently argued from the fact that certain iron lines in the spectrum of a sun's spot appear broadened, and, moreover, because certain lines appear in the spectrum of the sun's spot, and fail to appear in a spectrum of the protuberances, that there is no iron in the sun, but only its component parts. In a word, as Lockyer before desired to show that the element calcium could be dissociated, so now he wishes to put iron in the same category. Dr. Vogel, in reply to this, tells us that his photo-spectrum researches go to prove that, if the iron lines do show a broadening, this is due not to movement, but to an admixture of a foreign gas having a powerful dispersing action, which acts upon the lines in question. All the lines should be broadened if Lockyer's theory were correct; but they do not so appear in the spectrum.

Look at this picture of an elegant young lady in a well-fitting costume of black, who stands with her arms dropped at full length, holding her umbrella across her horizontally, in a coquettish fashion. See how smart she is, and how neatly gloved! What is her name, we wonder? and wonder still more, when we hear how ten thousand copies of the sprightly damsel are being printed as fast as possible. It is simply a glove advertisement, destined to bring before the public something novel in black kid manufacture.

After this, we may expect to see the large drapery establishments exhibiting photographs of flowing silk robes upon the most dainty figures, milliners showing their distracting headgear framing the comeliest of features, and boot-makers presenting their wares in fascinating style upon short-petticoated damsels, who, permitting, perhaps, a peep at the whitest of stockings, will assume the well-known pose of Serpolette in the *Cloches*, as she sings "Look at this, and look at that."

We said last week that the Year-Book of Photography for 1883 would contain a portrait of the late Sir Charles Wheatstone. Wheatstone, as everybody knows, made a reputation by his researches in light and electricity—with Cooke, he may be said to have invented the electric telegraph—and he was one of the first to estimate the speed of lightning, or, rather, the electric spark. His stereoscope, he invented, strange to say, before the advent of photography, namely in the year 1838, so that stereoscopes preceded photographs, albeit the latter enjoyed early popularity through the former. Sir Charles was for many years on the Council of the Photographic Society, and the earliest stereoscope constructed by him was exhibited at their exhibition is 1873, when the Prince and Princess of Wales honoured the Society with a visit. Sir Charles showed at the same time a series of photographs of a "steam engine in motion" in a stereoscopic zoetrope, a spectacle that excited a good deal of attention at the time.

Luminous and water-proof cardboard is one of the last productions of the paper trade. As photographs suffer more from damp than any other cause, damp-proof card mounts might be useful to photographers; in any case they would like to know how this luminous card is made. According to the *Journal of Chemical Insdustry* the water-proofing is brought about by producing an insoluble compound with bichromated gelatine, so that the material is actually "fixed" by light. Here are the proportions for making the cardboard:—

Water	10 parts
Paper pulp...	40 „
Phosphorescent powder (slaked for 24 hours)	20 parts
Gelatine	1 part
Saturated solution of bichromate of potash	1 „

The proportion of gelatine and bichromate of potash employed is very small, but doubtless quite sufficient to render the card damp-proof. It is possible that a dilute solution of bichromated gelatine such as this might be employed with success for sizing ordinary mounts. The yellowish colour would not be conspicuous if only a weak solution were employed, and the card had a tinted surface.

Said an unwilling maid-servant, the other day, after much persuasion by her mistress to come out on the lawn to be grouped with the family, "Well m'm, I'll come out to be photographed; but I don't like being focussed."

Patent Intelligence.

Notice to Proceed.

3726. Thomas Hargreaves Taylor, of the city of Manchester, in the county of Lancaster, for an invention of "Improvements in apparatus for producing facsimile copies of writings, drawings, figures, and accounts."—Dated 4th August, 1882.

Patent Sealed.

2277. Herbert John Haddan, of Kensington, Middlesex, for an invention of "A new or improved process for producing pictures on glass, stone, metal, and other materials."—A communication to him from abroad by Edouard Godard, of Paris, France.—Dated 15th May, 1882.

Patent Granted in Germany.

20,487. O. Weidemann, of Berlin, for "Reproduction of coloured impressions by means of thin zinc plates."—Dated 22nd April, 1882 Class 15.

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. X.—Estimation of Acids, Ammonia, and Protosulphate of Iron.

For estimating acid and alkaline solutions, a standard solution of both sodium carbonate and sulphuric acid is required.

To prepare the first-named solution, place about two ounces of pure dried sodium carbonate in a porcelain crucible and heat it over a Bunsen burner for about ten minutes, to drive off any trace of adherent moisture. When cold, powder the substance in a dry mortar, and transfer the powdered salt to a dry, well-stoppered bottle. Weigh out exactly 53 grams of the above dried salt, place it in a litre flask with a small quantity of water, and, when dissolved, dilute with distilled water to exactly a litre. The solution must be preserved in a stoppered bottle, and should be labelled—

Standard Solution.—Sodium Carbonate.

1 c.c.	= ·053	grams	sodium carbonate
,,	= ·017	,,	ammonia
,,	= ·049	,,	sulphuric acid
,,	= ·0365	,,	hydrochloric acid
,,	= ·063	,,	nitric acid

To prepare the acid solution, place 28 c.c. of pure strong sulphuric acid in a litre flask containing about 300 c.c. of distilled water, and, when the solution is cool, dilute it to a litre. After preparing the solution it is necessary to ascertain the exact strength of it by means of the standard solution of sodium carbonate, for it is impossible to weigh out the exact amount of acids, as it varies in strength. Fill a burette with the solution of sulphuric acid to be tested, place in a small flask 10 c.c. of standard sodium carbonate solution with about 100 c.c. of distilled water, and a sufficient quantity of solution of litmus to give the liquid a light blue colour. Allow the acid to slowly drip out of the burette into the flask until its contents has acquired a red tint; then boil the solution till the blue colour returns, and again run the acid out of the burette as before. This operation must be repeated till a permanent red tint remains even after boiling for several minutes.

The red tint first formed is produced by the carbonic acid set free in the decomposition of sodium carbonate by the sulphuric acid, but on boiling, the gas is insoluble, and consequently escapes, allowing the remaining undecomposed sodium carbonate to colour the litmus blue. When sufficient acid is added to produce a permanent red tint, the whole of the sodium carbonate is decomposed, and the slight excess of sulphuric acid preserves the red tint, although, on boiling, all the carbonic acid gas is driven off. It will be noticed that the red colour produced by the carbonic acid is of a light claret tint, whilst with sulphuric acid an onion red colour is produced. An experienced analyst can work without boiling the solution by running in the acid till the claret tint first produced gives way to the onion red colour; but as it is rather difficult to determine when the exact point is reached, we should certainly not advise the student to perform the operation without boiling.

In order to calculate the strength of the acid solution, multiply the amount of acid which is equal to 1 c.c. of the standard sodium carbonate by the number of c.c. of standard sodium carbonate used, and divide the product by the number of c.c. of sulphuric acid solution run out of the burette; the quotient is the amount of acid contained in 1 c.c. of the solution.

For example: 10 c.c. of standard sodium carbonate was used (1 c.c. = ·049 sulphuric acid), and 9 c.c. of sulphuric acid was required to produce the permanent red colour; therefore 10 multiplied by ·049 equals ·49, and ·49 divided by 9 equals ·0,544, the amount of sulphuric contained in 1 c.c. of the solution. The amount of ammonia equal to 1 c.c. of the sulphuric acid can be calculated in the same way, substituting ·017 (the amount of ammonia which corresponds to 1 c.c. of the sodium carbonate solution) for ·049 in the above example. The sulphuric acid should be labelled—

Standard Solution.—Sulphuric Acid.

1 c.c. $=$ x sulphuric acid
,, $=$ y ammonia

Of course x and y must be determined for every solution made up, but in the above example it equals ·0,544, and y equals ·019. In order to determine the amount of ammonia in a solution, fill a burette with the standard solution of sulphuric acid, and place 10 c.c. of the solution of ammonia in a flask with a little litmus solution, and run the acid from the burette into the ammonia, shaking the flask gently, till a red colour is produced. In this process the solution is not boiled, because there is no carbonic acid to interfere with the reaction, and also heating the solution would drive off the ammonia.

To calculate the result, multiply the number of c.c. of standard acid solution by the amount of ammonia which is equal to 1 c.c. of the standard acid, and divide the product by the number of c.c. of solution of ammonia used in the analysis; the quotient is the amount of ammonia contained in 1 c.c. of the solution tested.

For example: 10 c.c. of an ammonia solution, used for pyrogallic development, was taken, and 20 c.c. of standard acid (1 c.c.=·019 grm. ammonia) required to produce a red colour; therefore ·019 multiplied by 20 equals ·38, and ·38 divided by 10 equals ·038 grms., the amount of ammonia contained in 1 c.c. of the ammoniacal solution tested, which is equivalent to 3·8 per cent. Strong ammonia, sp. gr. 880, contains 33 per cent. of ammonia, therefore the ammoniacal solution contains rather more than 11 per cent. of strong ammonia.

There are several methods for estimating the amount of ferrous sulphate contained in commercial protosulphate of iron, but the bichromate process is the most accurate.

It is necessary to have a standard solution of potassium bichromate, and a dilute solution of ferricyanide of potassium. To prepare the first-named solution, place about 12 grms. of recrystallized potassium bichromate in a porcelain crucible, and heat gently to fusion. When cold, powder the salt, and preserve it in a stoppered bottle. Weigh out exactly 9·834 grm. of the above dried salt, dissolve it in a small quantity of water in a litre flask, and fill up to the litre graduation with distilled water. Transfer the solution to a stoppered bottle and label thus—

Standard Solution.—Potassium Bichromate.

1 c.c. = ·009834 grm. potassium bichromate
1 c.c. = ·0488 grm. crystal ferrous sulphate.

To determine the amount of ferrous sulphate in a commercial samp'e, weigh out exactly 2·44 grms. of the salt, dissolve it in a beaker in about 300 c.c. of boiled cold distilled water, and add to the solution about 10 c.c. of dilute solution of sulphuric acid (1 : 4). Fill a burette with the standard solution of potassium bichromate, sprinkle over a white plate a one-grain solution of potassium ferricyanide (red prussiate of potash) by means of a glass rod. Run the bichromate solution out of burette into the solution of ferrous sulphate, testing the solution from time to time by taking a drop out with a glass rod, and touching one of the drops of ferricyanide on the plate; at first, a blue precipitate will be produced, but when sufficient bichromate has been run in, instead of a blue precipitate being produced, a brown colour will form on touching the ferricyanide. To calculate the result, all that is necessary is to multiply the number of c.c. run of the burette by ·0188 (the amount of ferrous sulphate which is equivalent to 1 c.c. of bichromate solution); the product represents the amount of pure ferrous sulphate contained in 2·44 grm. of the sample.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Chapter IV.—Reversed Negatives.

In some of the photo-lithographic processes hereafter to be described, in which the photographic image is impressed directly upon the stone or zinc plate by placing the negative in immediate contact with the printing surface, it is necessary that this negative should be a reversed one; that is to say, one in which the image, for example, of a printed paper when looked at on the film side shall read correctly, and not appear reversed as in an ordinary negative. The image produced on the stone from such a negative will appear reversed, just as it would if produced from a transfer, but the printed copy will read correctly.

There are several methods of obtaining these reversed negatives, and they fall within five distinct categories.

1. Methods for taking reversed negative in the camera directly from the object.

2. Methods in which direct negatives are taken, and then stripped from their supporting glass, and either turned over on to the same glass or another, or before stripping the film may be strengthened with collodion or gelatine, so that it may be used independently of any rigid support, for producing either direct or reversed images.

3. Methods for reproducing a reversed negative from a direct one by contact printing.

4. Methods for obtaining reversed negatives in the copying camera from transparencies, and, if desired, on a larger or smaller scale than the originals.

5. Coating glass plates with an opaque varnish, and etching the design thereon with a point.

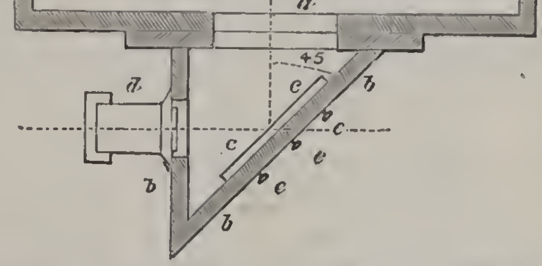
We shall briefly consider each of these methods, referring the reader for fuller details to the text-books and journals.

1. *Reversed Negatives taken in the Camera.*—Of the methods for taking reversed negatives in the camera, the simplest, and in some cases a very efficient way, is to turn the sensitive plate in the camera so that the rays forming the image may act through the glass on the back surface of the film. The method can be used with wet or dry plates, but is perhaps most suitable for the latter. In any case, care is required in the selection of glass of even thickness, free from bubbles, scratching, and other markings and defects which would show on the film. The back of the plate must also be very carefully wiped and cleaned from patches of film, &c. Allowance must be made for the thickness of the glass in focussing, or, if a great deal of this work is done, it will be convenient to alter and adjust the dark slide and focussing glass, so that the back surface of the sensitive plate shall occupy the same position as the ground glass.

In using this method with collodion plates the springs inside the dark slide must be removed, and the plate fixed in its place either with small silver clips at the corners, or with strips of blotting-paper. With gelatine dry plates it will be sufficient to put a thickness or two of paper over the plate to prevent the spring from rubbing the film.

I have not used this method much myself, as I have found a tendency to want of sharpness towards the edges of large wet collodion plates, and very fine lines do not seem to come up so sharply and clearly as when taken direct. The method is, however, largely used for reproduction of maps, with wet plates, at the Military Geographical Institute, Vienna, and with dry plates at the War Depot, Brussels.

The most usual, and perhaps the best, method of taking reversed negatives in the camera, is to use a reversing mirror, which may be placed either before or behind the lens, or between its components, if the lens is of a suitable description. Hitherto the usual position has been in front of the lens, but Herr Romain Talbot, of Berlin, has lately introduced a reversing arrangement in which the mirror is placed behind the lens, as shown in the plan in the figure,



a, camera; *b*, mirror mount; *c*, mirror; *d*, lens; *e e e*, adjusting screws.

and this I have found to work very satisfactorily. A smaller mirror can be used, and it is better protected from injury and from extraneous light. The mounting may be stronger and more solid than when it is fixed on the lens, and it is preferable that the mirror mounting should support the lens, rather than the lens the mirror mounting; though this may, of course, be obviated by putting the mirror in front of the lens on a special mounting attached to the camera independently of the lens. Further, it would appear obviously less likely to cause any interference with the working of the lens to allow it to do its work before the rays are reflected and reversed, rather than afterwards.

The reflecting surface of the mirror used for reversing must be as nearly as possible a true plane, and be coated with a bright highly polished film of silver, in the same manner as the specula of reflecting telescopes. A description of the methods of silvering these mirrors will be found in Captain Abney's "Instruction in Photography;" and Mr. Commin's method as described in the News, Vol. XXVI., page 315, is to be recommended as simple and effective. Other good formulæ will also be found in the Year-Book and journals.

The plane of the mirror must be vertical, and placed so that a line passing through the axis of the lens, and prolonging it, shall pass through the centre of the mirror, and be cut at an angle of 45° (see preceding figure).

The mirror must be kept in a dry place free from fumes which might tarnish it; and with an occasional polishing with a tuft of soft cotton and a little rouge, will keep in good order for a long time. The silver film can be easily renewed at any time.

Instead of a mirror, a right-angled reflecting prism may be used, mounted in a similar manner. With large lenses, such as are generally used for copying maps, the use of a prism becomes almost impracticable, on account of the expense and difficulty of getting blocks of glass of the size required free from defects. There is also a greater loss of light in using a prism than there is with a mirror, and it can only be used with lenses having an angle of view less than 50°.

M. Derogy, the well-known optician of Paris, has proposed a plan of overcoming the difficulties connected with large prisms by placing a small prism between the components of the lens in about the usual position of the stops, the mounting of the lens being altered, so that the axis of the front component is at right angles to that of the back component. Some trials with an apparatus of this kind fitted under my own superintendeuce were promising, and with proper adjustment the arrangement would doubtless answer well. A prism placed behind the lens would probably give very satisfactory results, but on the whole the use of the mirror in preference to a prism is to be recommended.

When using a reversing prism or mirror, arrangements must be made for placing the front of the camera and the sensitive plate accurately at right angles to the original, instead of parallel to it; and for work of moderate size, it is sometimes an advantage to place the original in a horizontal position below the lens.

In other respects the working is exactly the same as with direct negatives, and if the mirror or prism is properly adjusted, and the lens a suitable one for copying, the resulting negative should be perfectly sharp, true to scale, and free from distortion.

2. *Reversed Film Negatives.*—The methods for producing reversed negatives by coating the original unreversed negative with a thick transfer collodion, or with a solution of gelatine, and when dry stripping off the film, and either laying it down again on another sheet of glass in a reversed position, or using it as a film negative, are in many cases most convenient, and even desirable, when strong pressure has to be applied. They have, however, the great defect, especially for map and plan work, where accuracy of scale is indispensable, of more or less altering the dimensions of the image by the contraction of the compound film after leaving its glass support.

There is also a difficulty in keeping film negatives flat, and in India, at least, I have found that collodion films soon become yellow and brittle, while in a damp hot climate gelatine films readily become spotty and mouldy.

If it is desired to retain the rigid support given by the glass, the collodion film may be turned over without much difficulty, if a suitable tough collodion be used. A simple and efficient mode of doing this was shown to me some years ago by Herr Korn, of Berlin. The finished negative, while still wet, is treated for a few minutes with dilute sulphuric acid at 4 per cent.; this has the effect of loosening, and at the same time toughening the film; it is then poured off, and the edges of the film are taken off with the finger nail to a distance of about a quarter of an inch; the plate is then well washed, and the film is brought down so as to extend a little beyond the other side of the glass. A glass plate, previously covered with a solutiou of gelatine at 1 per cent., and dried, is then laid face upwards in a dish of water; the negative is held, film side downwards, above it, and the film being gently drawn away, the upper glass is lifted up while the film is arranged in its place on the gelatinized glass below. The moisture is removed at one end of the plate with a piece of blotting-paper, in order to prevent the film slipping, as it sometimes does. The plate is then carefully drained, dried, and varnished.

Another method, originally proposed by Mr. Woodbury, and which I have found to answer very well, is to coat the dry unvarnished negative with a solution of india-rubber in benzole, about the thickness of collodion. When this is dry the plate is coated with a transfer collodion, made of—

Ether...	20 parts
Alcohol sp. g. ·805	40 ,,
Castor oil	1 part
Pyroxyline	1 ,,

This is allowed to dry thoroughly, and the plate is then laid in cold water for a short time until the film becomes loose; a little sulphuric acid added to the water, about one ounce to the gallon, will facilitate the loosening. The film should be cut with a pen-knife round the edges, and stripped off gently while in the water. It is then turned over, and laid on a clean or slightly gelatinized plate whilst still floating. The film is then gently squeegeed down to its new support, and when dry can be varnished and used as an ordinary negative.

Sometimes a coating of gum, to which a little chrome alum may be added, is recommended, instead of the india-rubber solution; but I prefer the latter.

Negatives thus stripped with collodion may also be used as film negatives, and are thinner than gelatine films; but they have the disadvantage before noticed of becoming brittle, and yellow with age.

For producing film negatives by means of gelatine, a great many formulæ have been given, from which the following, given by Herr Allgeyer in his very practical work on "Lichtdruck," may be taken as a sample.

The fixed and washed negative is flowed over with a filtered solution of gum-arabic at 5 per cent., containing a few drops of a solution of chrome alum at 1 to 60. The plate is then dried, and retouched, if necessary, with black lead, colour not being admissible. Before applying the coating of gelatine, the plate is gently warmed and levelled. If it be of large size, it is desirable to support it on a thick plate of glass.

The solutiou of gelatine is composed as follows:—

White gelatine	100 parts
Water	400 ,,
Alcohol	100 ,,
Glycerine	15 ,,

with a few drops of carbolic acid to prevent decomposition.

Before use, it must be warmed, filtered, and free from bubbles. It is poured on in the middle of the plate, and spread outwards with a piece of paper. The thickness of the coating of solution should be, according to the size of the negative, from 1 to 1½ millimeters (from $\frac{1}{25}$ to $\frac{1}{16}$ of an inch). To prevent the solution from flowing over, the edges of the plate may be rubbed with a little tallow.

When the film has set, the plate is reared up to dry in an airy place free from dust; and, when dry, it is coated with thin plain collodion, or varnished.

(*To be continued.*)

FURTHER NOTES ABOUT COLOURED PHOTOGRAPHS ON GLASS.

BY W. M. ASHMAN.

No. II.

Having prepared the photograph as directed on page 678 of the present volume, the next thing will be to describe the operation of colouring as concisely as possible. The glass supporting the photograph should be laid on the retouching desk, concave side upwards, and the most important points noted. These comprise such things as the eyes, lips, high-lights, hair, flowers, jewellery, and small details, &c., for they must be all coloured on the back of the photograph. I would recommend the beginner to paint in the hair, flowers, and jewellery before attempting the eyes, for they will be found more difficult than any other part of the process. Mix a little each of Naples yellow, Indian yellow, and poppy oil for very light golden hair; burnt sienna and poppy oil for brown hair; and black, Vandyke-brown, and poppy oil for very dark hair. Linseed and boiled oil may be used for the purpose instead of poppy oil; but the latter will be found to answer every purpose.

Having applied the paint to the hair, turn the glass round to see the effect; also whether the whole surface has been covered or not. Should it have been satisfactorily performed, the lips and cheeks may be done next.

They should be painted with a mixture of vermilion and carmine in the following manner. Run a line of colour along the surface with a brush well charged with colour, softening it off with a dry brush. While working with this colour, put a spot in each nostril, to warm up the heavy shadows in the photograph; also in the corner of the eyes, and any other part of the picture requiring that mixture. It will be well to again examine the picture from the front.

All being satisfactory, the eyes may be next attempted. Paint the pupil with pure black, and the light spot in the iris with Chinese white. Mix a little blue with the Chinese white for the white of the eye. When quite dry, paint the iris with a mixture of ultramarine and poppy oil for deep blue eyes; mix black, white, and ultramarine for grey eyes; and for dark brown eyes use Vandyke-brown with black, using poppy oil in each case. If the colours are not strong enough, they may be strengthened; but the first must be allowed to get quite dry before the second application, otherwise a muddy effect will be produced.

Eye-brows, moustachios, and whiskers are coloured by laying on the colour sparingly, and softening off with a dry brush. There should be just enough colour laid on to do this nicely, because too much will look harsh, and not enough tends to flatten the picture.

Paint the jewellery in solid colour, using for gold Indian yellow, Naples yellow, and vermilion; for silver, use Chinese white and black.

Lace should be touched up, the lights with Chinese white laid on thickly, and the shadows with grey composed of black and white. When the colours are dry, attach the second glass by means of gummed paper. Mix Chinese white with all the colours to render them opaque, and apply them roughly over the surface, no part of which should be left uncovered. The flesh colour is composed of Naples yellow, vermilion, carmine, and Chinese white, thickly laid over the flesh parts, deepening the cheeks, if necessary, with vermilion, the shadows with a slight admixture of ultramarine, according to the subject. Dresses will in many cases be left to the taste of the operator; and in painting them it must be borne in mind the sort of background that is intended, for harmony must prevail where large surfaces—such as backgrounds and dresses—are treated. Otherwise, however nicely the flesh and other details may have been executed, if the larger surfaces do not agree, the result must be considered a failure (loud, in fact). Any work put on, if found afterwards to be unsatisfactory, may be easily removed with rectified spirits of turpentine on a piece of linen rag, and the same substance will be found useful for cleaning the brushes, finishing them in a little methylated spirit.

The principal tubes of colour required will be Chinese white, black, Vandyke brown, chrome No. 1, burnt sienna, Naples yellow, ultramarine, Indian yellow, carmine, vermilion, also a bottle of poppy oil; brushes and palette, turpentine and methylated spirit.

As I have detailed the process of colouring at much greater length than I intended, I will say as little as possible about experiments.

The first experiment commenced with the first operation, viz, the print, and I am in favour of using, where practicable, the ready sensitized paper, it being as a rule thin and more easily permeated with the clearing medium than a heavy paper freshly silvered. Then comes the mounting medium; I have used several substances for this purpose, and after repeated trials have decided on a mixture of gelatine, starch, and cornflour pastes in equal quantities; they should be made separately, and afterwards all boiled up together, stirring the whole time. When cold, a beautiful paste results, which is not only useful for mounting photographs on glass, but will be found excellent for ordinary mounting on cardboard. I found that pictures mounted with gelatine alone adhered very firmly to the plate, but the tone became much warmer, and however desirable that may be for plain photographs, it is not advantageous for those which are to be painted. The compound above stated does not produce a change in tone, adheres perfectly, and when dry there is an entire absence of air-bells and surface markings such as seen where starch or cornflour alone had been used.

A preliminary wash in benzoline shows a marked advantage over prints not so treated in preventing the formation of air-bells, and the paper leaving the glass in small patches during the process of drying.

One more point to be considered is the best medium for clearing. Oils may be used—such as linseed, olive, or castor oils—but they require a long time to thoroughly permeate, and if the temperature is raised above 75° or 80° Fah., the print will become very yellow. From twenty-four hours to forty-eight hours may be required, which will be found tedious in practice. Therefore the heating in a mixture of wax and Canada balsam is far preferable; I have used spermaceti, white wax, and solid paraffine, and think the proportions given in the first part of this article as good as any I have tried; but there is a field for experiment in this direction. I may mention that I cleared one print with some Autotype waxing solution, and I intend doing some more in the same manner, but altering the proportions and adding Canada balsam thereto. If, as I anticipate, there should be any gain over the medium previously recommended, I will report the same at an early date.

Correspondence.

COLD METHODS OF EMULSIFICATION.

Sir,—Mr. A. J. Brown's paper read before the London and Provincial Photographic Association, and which appeared in your columns of November 17th, seems to me to be so extraordinary that if it is not intended to give every one their due, it must be to provoke discussion; I heartily congratulate Mr. Brown on his success, especially if the latter was his object, as the debate waxed so warm that an adjournment ensued. In the first place, Mr. Brown represents that I claim the originality of the cold method of emulsification, and then he goes on to give the credit to Mr. Cowan. If my memory serves me well, it tells me that Captain Abney gave a formula for mixing emulsion cold, but I have yet to learn the name of the one who has succeeded in making a good plate by Captain Abney's original formula; Mr. Cowan distinctly disclaims the honor of the discovery.

I think it needless to analyse all Mr. Brown's statements, except that one more particularly where he says, "It is impossible to make a healthy plate with gelatine that has been in contact with ammonia; it is sure to suffer from green fog." Oh, Mr. Brown! this is indeed a good joke.

I presume Mr. Brown will also give the introducer of ammonia and emulsion the credit of having discovered green fog. I may say that I am not aware at what date Monckhoven or Eder advocated ammonia; but at one of the early Brittlebank meetings I not only suggested ammonia, but made some ammonia nitrate for one of the members to try. He failed—got fogged plates. I now believe that the non-success was due to the insufficiently safe light in the dark room.

Concerning green fog, I have discovered (an opinion I have long held) that it is due to more than one cause. I will publish a cure in the next Year-Book—Apologising for thus encroaching on your space, believe me, yours, &c.,

A. L. Henderson.

PS.—I have no authority to give the name of the large maker of gelatine plate referred to in Mr. Brown's paper. Seeing that I am not a professional plate maker, I am at a loss to understand what Mr. Brown can mean by "capital being made in this way." A. L. H.

A GRIEVANCE.

Sir,—I have read with great interest the complaints as to the quality of "dry" plates as sold by the leading makers.

I have two gross half plates which are now almost used up. Every one of these plates, when used for a cabinet picture, requires to be vignetted owing to markings, and almost every plate has a kind of fog running from the edge of the plate to, in some cases, the extent of half an inch. These plates are by one of the best (?) makers.

Another two gross by another leading maker (if not *the* leading maker) have been a great source of anoyance to me. I think I can safely say that nine out of every twelve have been faulty—every plate more or less thin, small holes in the film, corners quite bare, and six out of every twelve have had to be intensified, so thin have the films been.

Some time since I had the pleasure (?) of working some plates from a well-known house; every plate showed green fog and insensitive spots all over the plate, some as large as a threepenny piece. I and my then employer tried every variation of developing and exposure; but the result was always the same (my employer was one of the very first to take up the dry plates, and had had, perhaps, as much experience as any one in dry plates). After entire failure to work the plates, he wrote to the maker. The maker replied that "the plates were perfect, and that the only fault was incompetent developing."

I should like to ask some of the large makers why they do not try to keep up the quality of the plates, and so keep their customers?

Personally I would rather pay more and have them good and reliable. I do not ask for too much, I think, but surely such things as thin plates, uneven coating of plates, holes in films, corners not covered, and broken plates in the middle of a package, can be avoided.

I have had such splendid plates by both makes of whom I speak, that I can fully appreciate faults when they do come.—I am, yours &c., A Sufferer.

Sir,—I should like to make a few remarks on the correspondence that has followed the complaints of "Exact Measure" and myself. I am glad that Mr. George Pendry has secured such a reliable supply of plates, and should be much obliged by the address of the maker; but Mr. Pendry is mistaken in supposing that I think there are no good plates in the market, for I am daily using good, but not quite perfect ones. His advice to stick to a good article is wise, and for about fifteen months I did stick to one maker, his plates being excellent until last May, when they became very uncertain in rapidity, and foggy, and then I looked out for another maker; but those plates, although very good, like those I am now using, were not very rapid, and so I have tried various makers who advertise very rapid plates. There are great differences in the way different makes of plates register light and shade, and the plates that I am now using do not, in my hands, give quite such a round image as those I formerly used, although in uniformity, cleanliness, and even coating, they are firstrate, and moderate in price.

In your last issue Mr. C. J. Dobbs asks if the fault does not lay with the user rather than with the maker? No doubt many a good plate is condemned from want of skill on the part of the user, but the faults most complained of are not chemical, but chiefly uneven and insufficient coating, spots, holes, &c.; and surely it does not require a very skilful person to judge of each defect.—Faithfully yours,

E. Williams.

THE PLÜCKER STAND.

Dear Sir,—Allow me to send you some remarks about my patent telescopic camera stand, spoken of in the last number of your valuable paper.

This stand has been tried now for more than four years, without affording the least trouble. The one I employ myself has been almost daily at work, mostly in Belgium, but I have been with it in Germany, in Switzerland, in Italy, and in Spain. Until now the tripod has not the least bruise; in fact, it is, no more than are any other photographic materials, such as cameras, lenses, &c., &c., liable to get damaged in operation, and then it will stand a very rough handling. When travelling, and the tubes of each leg are fitted in each other, it is as strong as, if not stronger than, other stands weighing, perhaps, ten times as much, and being twenty times as bulky; it could, besides, be protected with a leather or cloth sleeve, which would weaken an extraordinary blow.—I am, dear sir, yours truly, J. F Pluecker,

Antwerp, 14th Nov. Capt. Belgian Artillery.

PS.—I have just made the following experiment: the three tubes of one leg of the stand being slided into one another, I put them flat on a marble floor, and stood upon it about half a minute with one foot, allowing the whole weight of the body to press on the tripod leg; after which I drew the tubes out, and could not discern the least injury to them.

[We are happy to insert Captain Plücker's favourable opinion of his stand; but we must repeat our own, which is to the effect that a sharp blow on any of the tubes would probably prevent their sliding in or out. So long as it is handled with due care, doubtless all would be well.—Ed. P. N.]

AMATEURS AND THEIR WORK.

Sir,—If no one else will take up the cudgels, I will, and strongly protest against the assumption that amateurs are not in the habit of developing their own negatives. I know a number of amateurs, but not one who would not take as much interest in the development as in the exposure of his plates. My wonder is why they do not go further, and make their own emulsion, which is simple enough, and the coating and drying by no means such a bother as seems to be generally supposed. Without fear of contradiction, I say that 90 per cent. of my pictures are from plates of my own make. My time for photography is chiefly limited to a month in the summer, when I manage to take a goodly number of landscapes, from which I print transparencies for the lantern, and make enlargements in the winter. Thus I do not require such a rapid plate as is usually termed "instantaneous," and, in fact, think it a mistake to use such an one for views. Changing the plates at the hotel taxes all one's ingenuity, and a stray ray of light falling on such exquisitely sensitive films may spoil a day's work.

If there are any amateurs who get the professional photographer to develop their plates, I advise them to take him with them on their tour, and let him focus, expose, and develop the plates, and the thing will be complete.—Yours truly, W. H. Plaister.

THE SWAN LIGHT FOR THE WINDOW.

Dear Sir,—I have used the Swan lamps as recommended by you in a recent article, and though the battery is troublesome to manipulate, I can bear testimony to the attractiveness of the light, and of its undoubted use as an effective advertisement. I use it particularly for lighting *opal* pictures, for which it is well suited, and find it gives an impetus to this branch of business.—Yours, &c.,

J. Berryman.

Proceedings of Societies.

Photographers' Benevolent Association.

On the evening of the 16th inst. the Exhibition of the Photographic Society of Great Britain was open from 7 till 10 in aid of the Photographers' Benevolent Association, when the attendance was extremely good, and the Gallery presented a very pleasant aspect, the ladies being well represented, and, judging from appearances, the display of pictures thoroughly interested the visitors.

London and Provincial Photographic Association.

At the meeting held on the 16th inst., Mr. J. Barker in the chair,

Mr. A. J. Brown read a paper on "Cold Emulsification with Uniformity" (see last week's News), and a highly interesting discussion ensued.

Mr. Henderson gave Captain Abney the credit of being the first to introduce a formula for cold emulsification, which "was tried and found wanting." What he (Mr. Henderson) claimed was, that he was the originator of the ammonia nitrate process, he having prepared a quantity and handed it to a gentleman at one of the Brittlebank meetings; he further stated that within the last few weeks he had made great improvements in his process, whereby no green fog was obtained. He said he did not use gelatine in the ordinary manner, but emulsified with a substance called lucine, which he said was a meta-gelatine, and promised that full details of the process should be published in the Year-Book for 1883. He thought that green fog was due to at least two causes, viz., the gelatine and the bromide.

Mr. Cobb had produced some of his best plates by the ammonia nitrate process; but, at the same time, he had also obtained some of his worst failures by that method.

Mr. Haddon found that green fog was obtained by rapid mixing, and not by slow.

Mr. Debenham had seen plates prepared by Mr. Henderson's process clear of green fog, and excessively rapid.

Mr. Cobb said that ammonia nitrate was introduced by Mr. Johnson about July, 1879.

Mr. Orseman thought that green fog was not due to silver; he had tried to remove it by placing the plate in chlorine water. Chlorine having a great affinity for silver in any form, the plate became quite white, all the silver being converted into chloride of silver, but the green fog was still present.

At this stage, owing to the lateness of the hour, the discussion was adjourned till next meeting.

Talk in the Studio.

Mr. Peter Collins' Camera.—A camera recently exhibited at the Dublin Exhibition by Mr. Peter Collins, of Clonmel, and which Mr. Collins has been good enough to forward to us for inspection, deserves the attention of photographers. One of its main points is, that on drawing the slide to expose, a horizontal spring in the upper part of the camera presses into a cavity in the dark box, thus doing the double duty of protecting the plate from light, and also, so to speak, locking the camera. In fact, the dark box cannot again be withdrawn until the slide is put back into its place, and a button at the side of the camera pressed, to move back the spring. Another point is, that the slide of the dark box is solid, so that there is no chance of light entering by a join. The camera is constructed for universal use; it can be employed not only in the studio and out doors, but also for copying, a support and bellows arrangement permitting the camera to be lengthened from the front as well as from the back.

The Indian Troops.—On Saturday afternoon, after the review by her Majesty, the officers and men of the Indian contingent, accompanied by Colonel Pennington, visited the studios of Mr. J. E. Mayall, 164, New Bond Street, who took a number of portraits and groups by the electric light. The visitors (thirty-four in number) were much pleased by the novelty of the process and its satisfactory results.

Photographic Society of Great Britain.—The next social gathering of this Society will be held on Tuesday next, November 28th, at the Gallery, 5a, Pall Mall East, at 8 p.m.

Death of Professor Henry Draper.—The death is announced at New York of Mr. Henry Draper, Professor of Physiology in the University of New York. He was well known through his astronomical researches, which gave him a world-wide reputation, and his photographed spectra placed him in the front rank of photo-physicists. On page 285 of the present volume of the News will be found Professor Draper's last important contribution, and those who take an interest in astronomical photography have no need to be informed that he held the same rank in the United States as Dr. Huggins does in this country. It was only in January of the present year that his father, the late Dr. J. W. Draper, the contemporary of Daguerre and Möser, died—a *savan* whose researches upon light are universally known. Dr. Henry Draper had distinguished himself especially in photo-spectrum work, and had he been spared, we might have looked forward to further important results. One of the last observations of Dr. H. Draper's was in respect to the exquisite sensitiveness of gelatine emulsion in astronomical photography. "It is only a short time since," he writes, "that it was considered a feat to photograph a star of the 9th magnitude; but now I have been able to secure a picture of a star of the 10th magnitude, and this not in the form of a point, but with the light dispersed as a spectrum." Professor Henry Draper's death was announced on the 20th inst.

Treating Gelatine Negatives with Dilute Sulphuric Acid—Platinotype Printing.—Mr. Dresser, of Norwood, writes to us as follows:—"Some time ago I found out a way to make pyrogallic negatives look like wet negatives, and which I described in the News to you many weeks ago. Since then I have tried it frequently, and find it acts very well; beside this, it seems to clear the hyposulphite, and necessitats less washing; this I do not know for certain, but since using it I wash my negatives only for a short time, and have had none go bad or stained. I have told several, who have tried it, and they find it does as I say. You will notice what Mr. Prestwich says at the meeting of the London and Provincial Association, page 670 of the present volume. Try it! Adopt pyrogallic development without sulphite of soda; fix in hyposulphite, then pour on dilute sulphuric acid, one ounce to one quart of water. Do not soak the negative in it for any time, or you will spoil it. After pouring sulphuric acid over, wash well under the tap, and then soak for one or two hours in running water, and you will find your negative look like a wet one without any brown stain. You can clean old negatives the same way—never mind how old—but then you must soak them in sulphuric solution till they are clear. I have also found out that if you put a negative in old iron developer for five or six seconds after using pyrogallic development, it will clear it fairly well, and greatly strengthen it in printing power. As regards platinotype printing, Mr. Dresser says:—"After reading your paper on platinotype printing, I bought a licence, and am very glad I did so, as so far I have found it a great success. I find it much harder to do double printing than in the usual way of silver printing, but manage fairly well. I am doing all I can to get my friends to try it, as I am sure it ought to be better known, and it is so much easier to manage after the picture is printed, and one has none of the horrid hyposulphite, which I think by far the most favourable point of platinotype printing, as I find more trouble with the use of hyposulphite than anything I use in way of photography. How is it we see so little about platinotype in the papers or year-books? As for an amateur who only wants a few prints of subjects he gets while travelling about, it is just the thing, as he can print while away, and have no trouble with washing. I think every photographer ought to know how to do it, as at this time of the year, when the sun is seen so little, you can so easily get a print by the platinotype process, and therefore can develop at once. A friend sent me three negatives one evening, and said he wanted some prints by twelve next day, and did not know how to get them. I said I would do my best, and at twelve next day I gave him three good permanent prints of each negative, and I think that is not bad; it could not have been done with the silver process."

Mr. Thomas Fletcher on Gas and Electricity.—"The Electric Light Companies are exceedingly good customers for gas. I have supplied all, or nearly all, the Electric Light Companies, both in England and America, with gas apparatus, and some of them to a very large extent. Some of them would be considerably puzzled to carry on their business without gas, and many are very large users. Not only in making lamps and apparatus, but directly or indirectly, the use of coal-gas comes in continually. For instance, one maker of cables for carrying the currents, ordered thirty large gas blow-pipes, for brazing up lengths of wire; and the 'Apostle' of the electric light—Edison himself—has sent to Warrington for gas furnaces. Places such as the Savoy Theatre, in London, lighted, according to public statements, exclusively by the electric light, have to use gas for ventilating the place, and I believe I am well within the mark in stating that the gas bill of the Savoy Theatre exceeded seven hundred pounds last winter, in addition to the cost of the electric light."

Guillebaud's Photo-reliefs for Decorative Purposes.—The admirably-finished photo-reliefs produced by Messrs. Guillebaud and Co. have been noticed several times in the Photographic News; but we have several times expressed our opinion that, although the general basis of the work is undoubtedly photographic, the special qualities which distinguish Guillebaud's work are due to a subsequent beating or pressing up of the device at the reverse side. The German specification of Guillebaud, which has just been issued, confirms us in this idea. The patentee insists on the oft-asserted advantage of adopting means to diffuse the light during the exposure of the sensitive gelatine or other body; the use of matt glass and distance pieces of transparent material being especially mentioned. We ourselves strongly deprecate any such attempts to obtain more relief by the diffusion of the light, as the thickness of the necessary gelatine film generally gives too much diffusion. Next the use of damp or even fluid gelatine is recommended; but thoroughly wet bichromated gelatine is but slightly sensitive to light, and attempts to take advantage of the greater sensitiveness of *slightly damp gelatine* were discarded several years ago by the most experienced Woodburytype printers. There is nothing original in the methods claimed of taking moulds and reproducing by electrotype, just the same method being adopted as we have repeatedly recommended in the Photographic News and the Year-Books. The method of stamping up is to cut out a profile in wood of the device, let us suppose a portrait; and to use the ground and figure portions as stamping tools on the wax model. It is desirable that the negative should be so retouched as to reverse the shading of such darks parts as would be hollow in a simple cast from an exposed gelatine relief, as, for example, hair or a dark coat. Guillebaud definitely claims the use of light diffusing mediums, the exposure of undried gelatine, and a particular form of copying frame as far as they apply to the production of photo-reliefs. Our readers will remember that Mr. Emery, of Burslem, recently exhibited a photo-relief of Chiswick Church executed in biscuit porcelain. The mould from which this was cast was made by the method which we elaborated and recently described in the News.

To Correspondents.

*** We cannot undertake to return rejected communications.

J. H.—The appearance is such as to lead to the belief that the mount contains hyposulphite of soda.

G. G. L. B.—1. The term "permanent engagement," as distinguished from a temporary one, signifies that the assistant is taken on rather for current business work than to meet a sudden pressure or the special work of a season; and it need scarcely be said that when an engagement is merely understood to be a permanent one, the usual notice will suffice in the case of dissatisfaction on either side. 2. Unless there is a written agreement to the contrary, the notice required will depend on the periods of payment.

E. Poole.—It would be a difficult task, even for an experienced electro-metallurgist, to gild it by the galvano-plastic method, and there would be a considerable probability of entirely ruining the original. You had better, therefore, be contented to cover it with gold leaf, using the ordinary gold size as a cement. Rub the gold size on, remove the excess, and let it half dry before applying the gold leaf.

H. D.—The dimensions will do very well for a general studio, and you might glaze about fourteen feet run of the roof, and carry the glass to within three feet of the existing wall. As regards the front, you had better glaze to within about two feet of the ground. As a rule, it is better to err on the side of too much glass rather than too little, as it is easy to stop out any redundant light.

F. Gregory.—1. Attend the next meeting, which takes place at the house of the Society of Arts, on Thursday, December 6th, at 8 p.m. 2. The subscription is 10s. or 10s. 6d. per annum, and any communication for the Secretary should be addressed to Mr. F. A. Bridge, at the place of meeting.

G. F. Weber, Jun.—1. Certainly the rounded corner is a little in the way, and will tend to make the lighting unequal on the two sides of the work; we would suggest bringing the whole system of enlarging apparatus more towards the middle of the room. This will give better lighting, and will enable you to get free access to both sides of the apparatus. Remember that notwithstanding the fact that excellent work may be done under unfavourable conditions, it is most important to lose sight of no circumstance which may facilitate operations. The higher up you place your enlarging apparatus, so much the less will the wall interfere. Do not hesitate to write again should you require further information; and we shall be glad to hear how you get on.

Constant Reader.—Moisten the tips of the finger with a trace of oil of turpentine, and rub gently on the varnish until a sufficient tooth or roughness is produced.

G. R. P.—Pickle them in strong soda solution, and scrub off the films, which, if collected, will yield a notable amount of silver. The glass, after a thorough scrubbing, may be rinsed and dried.

C. N. B.—No series is published which would exactly rank as good photographs, all being more or less of the nature of mere outlines. As regards the apparatus, we would expect that Marion and Co., of 22, Soho Square, could obtain it for you through their Paris house.

Ignoramus.—The principal advantages are equality of illumination over a wide angle, and the straightness of marginal lines. For ordinary pure landscape work the single lens is better.

Novice.—To neutralise any acid which may arise from oxidation.

J. Berryman.—1. If you wish to obtain uniform results, make use of a fresh bath every time, as the expense of the bichromate is so small as to be insignificant. 2. Perhaps the glass has been waxed at some previous period in its history; we have experienced no difficulty when a thin substratum of chrome alumed gelatine is employed. 3. Much better to use a fresh solution of gelatine every time.

J. W. Barry (Ajaccio).—There is nothing better than Epsom salts, say half a teaspoonful, and if you ask for sulfate de magnésie you will obtain it without difficulty.

G. W. Hale.—Thanks for your interesting communication, of which we will make use shortly.

Positive on Glass.—Before experimenting with it, you would do well to obtain as good a copy as you can by means of the camera; make attempts not only by reflected light, but also with transmitted light. To whiten it, immerse the plate in a saturated solution of mercuric chloride, and allow it to remain till the blackening which first sets in becomes reversed. Copy the picture at this stage by reflected light, using a black foil behind the picture. If you should still fail, immerse the plate in a 10 per cent. solution of ammonium sulphide, wash, dry, and you will have a negative.

D. T. (Lewes).—Both difficulties may be overcome by developing on collodionized glass, instead of on the flexible support. The glass should be well waxed, and, after collodionizing, should be soaked in cold water until all aspect of greasiness disappears.

CONTENTS.

GELATINE IN THE PRESENCE OF NITRATE OF SILVER.

Three well-known members of the Vienna Photographic Society, Captain Pizzighelli and Lieutenants Hübl and Stadler, have recently investigated the behaviour of a mixture of gelatine and nitrate of silver. Obernetter, as our readers know, in making emulsion, mixes his gelatine with nitrate of silver solution in the first place, and when set, puts it into a closed apparatus to be treated with the bromide solution necessary to form the haloid silver salt. This innovation in emulsion making has no doubt led the above-named gentlemen to undertake a research upou the subject, and the results of their study are, therefore, at the present moment of unusual interest.

We will describe the outcome of their labours as briefly as possible. If a solution of nitrate of silver is mixed with gelatine at a high temperature, an instantaneous browning of the mixture ensues; at a very low temperature, however, there is very little change in colour at first, though a yellow tint becomes apparent after a few hours—even if light is excluded—and in a few days the mixture assumes a brownish-red. In the presence of daylight the colouring, of course, follows at once. Employing darkly-tinted silver gelatine of this type in emulsion making will result in producing the well-known red fog; but, apparently, a serviceable emulsiou may very well be made with a mixture only slightly tinted.

When a large proportion of nitrate of silver solution is added to the gelatine, the latter loses its setting properties in a great measure. Thus, a solution of equal parts of gelatine and silver sets pretty well after a short time; but if the proportion of silver is doubled, then, even after an interval of some hours, the mass is by no means firm. This defect may, however, to a great extent be counteracted by the addition of alum, only the latter has some disadvantages that become apparent in the subsequent operations. Thus the process of bromising is rendered more difficult, and on the employment of ammonia, a precipitate of hydrate of alumina ensues; moreover, the addition of alum is limited by the fact that a most difficultly soluble salt—silver sulphate—is formed.

A trace of free acid, it is found, robs mixtures of silver and gelatine almost completely of their property to gelatinise. But it is different iu the case of a mixture of gelatine and ammonio-nitrate of silver prepared by the treatment of nitrate of silver with ammonia; such a mixture easily sets in the form of a hard cake, and its colour does not alter even after standing for days.

That bromising of the silver-gelatine mixture proceeds very slowly, is the next point laid down by our commission of three. But here the concentration of the mass, as also the nature of bromine salts employed, exercise a material influence. Thus a concentrated mixture takes a long time to be acted upon by the bromine solution, the ammonium salt having, by the way, a quicker action than the sodium, and this again working with more energy than bromide of potassium. As we have said, the addition of alum to the gelatine goes to prevent the penetration of the bromine salt.

By employing concentrated gelatine and bromide of potassium solutions, it is often quite impossible to bring about a uniform formation of bromide of silver. In this case a section of the bromised gelatine mixture reveals three distinct layers; an outer one, containing a large proportion of coarse-grained bromide; a middle layer, containing less silver bromide, but in a finer state of division; and finally a translucent mass, containing but bromide of potassium. This fact can only be explained by the circumstance that not only does the bromide of potassium penetrate the gelatinous mass, but that silver solution exudes from it. To prevent any such inequality or defect, it is necessary, obviously, to employ the proper proportion of silver salt and gelatine, as also to control the strength of the solution of bromine salt.

The next point taken up by the Vienna Commission was as to the nature of the silver bromide formed. An emulsion produced from gelatine and silver nitrate permits red light to pass, and the bromide of silver particles are for the most part in the form of minute well-shaped crystals, apparently hexagonal, and equal iu size to about 0·006 millimetre. On the other hand, an emulsion prepared from gelatine and ammonio-nitrate of silver, or from gelatine and silver nitrate with a mixture of bromine salt and ammonia, yields green silver bromide; this emulsion permits blue rays to pass ouly, and crystals of silver bromide are in the latter case but unfrequently met with, and iu the former, not at all.

As regards the sensitiveness of these emulsions, the Commission reports it to be less than that usually found in gelatine plates. For instance, an emulsion formed by bromizing a mixture of 20 grammes of silver nitrate, 20 grammes of gelatine, and 300 cubic centimetres of water was much less sensitive than au ordinary emulsion after half an hour's boiling; the latter was at least twice or three times as rapid. An emulsion formed with gelatine and ammonio-nitrate gave a much more favourable result, however, but even this was not so sensitive as the ordinary emulsion.

A fact worth noting, says the triumvirate of photographic chemists, in connection with the use of ammonia, is, that the silver gelatine then yields negatives of great density. Altogether, the investigation embraces many points of interest, and it will furnish an admirable starting point for any of our readers who desire to experiment with the Obernetter process. Its simplicity is a great recommendation, while the circumstance that that there is no need for working in ruby light or in darkness is another advantage that will be valued by many. That the emulsion does not possess a high degree of sensitiveness will be regarded as a drawback by some, though not by everybody; in any case, photographers are not likely to rest until the new *modus operandi* has been thoroughly investigated.

BURTON'S EMULSION METHOD.

Since describing a fortnight since the process which formed the subject of a paper read by Mr. W. K. Burton before the Photographic Society of Great Britain, we have taken the opportunity of giving it a practical trial. Our experience leads us to corroborate in the main the results described by the author of the paper. We have also, in the course of our experiments, got some bye-results which we consider worthy of notice. We have made in all four emulsions, in each case, varying the results. Before commencing to describe them, we should state that the numbers which we give as representing sensitiveness are read from plates exposed under the standard sensitometer. As we have widely different figures given by different operators as representing the average sensitiveness of good commercial plates, we recently took samples of the rapidest plates made by eight different plate makers, exposed them, and developed them each with the developer recommended by the maker. The figures we got varied from 15 to 20, which latter is the highest we have ever got from any commercial plate. The average got by adding the numbers, and dividing by the number of plates, was a shade under 17·5. We may therefore take from 17 to 18 to be the average sensitiveness of a good plate, so far as such can be gauged by the sensitometer.

In our first experiment we made up our emulsion precisely as directed by Mr. Burton, but we poured off the first water after about twenty-four hours, the second after about fourteen. Each of these waters was far from clear, but as we know how very little silver haloid in a fine state of division will make a great show, we thought little of this. We kept the two waters—40 ounces in all—and, evaporating a portion of it, found that it held in suspension a total of a shade less than a grain of solid matter per ounce; that is to say, we had, roughly speaking, lost by decantation nearly 40 grains of the silver haloids out of 440—a quite appreciable loss, certainly, but one which we thought would not be likely materially to affect the final result.

We finished this emulsion, and on testing got No. 15 of the sensitometer and a thin image; that is to say, a plate which was somewhat slow, and which lacked the power of giving brilliancy. After keeping the emulsion for six days, plates coated with it gave the figure 18 and a somewhat denser image, but still one not quite as dense as should be.

We now set about to make three separate emulsions. These we shall call Nos. 1, 2, and 3.

No. 1 was made precisely according to instructions. In No. 2 the only variation from instructions was that the alcohol advised by Mr. Burton to be added along with the ammonia was omitted. No. 3 was boiled for two and a half hours with periodic stirring, but no ammonia was added. The first two were allowed to stand for forty-eight hours, when the supernatant fluid was found to be practically clear. It was poured off. In No. 3 the water was by no means clear. After a lapse of another day it was, however, very nearly so, and was poured off. The same length of time was in each case allowed for the second subsidence.

The emulsions were made up, and plates coated, with the following results.

All gave this time dense and vigorous images. No. 1 gave the figure 15; No. 2, the figure 17; No. 3, the figure 19. On exposing in the camera, the rapidities appeared to be about 1, 2, 2; that is to say, the plates Nos. 2 and 3, giving respectively figures 17 and 19, were as nearly as possible of the same rapidity, and almost double that of No. 1, which gave 15 only.

And now for the lessons indicated by these results. In the first place, it would appear that the bromide of silver which is in the finest state of division is that which tends to give density to the image, and that the loss of a quantity of this finely-divided bromide, representing a very small percentage of the whole contained in an emulsion, gives thin images. It is therefore necessary, in such a process as the one under consideration, to allow as little as possible of the haloid to pass over with the washing water. Of course the larger particles of bromide are the first to precipitate, and the finer the last. When we have leisure we shall make a series of emulsions, taking advantage of this fact to enable us to separate a quantity of precipitating bromide into particles of different sizes. We think it quite possible that in every emulsion there is a considerable quantity of silver bromide in such a state of division that it will readily pass through a filter, but yet is so coarse that it does not add to the efficiency of the emulsion, but might, on the contrary, with advantage be separated out and cast into the residue tub.

The next fact which we gather from our experiments is that it is an advantage to leave out the ammonia given in the original formula, as it appears to act only as a restrainer. We do not see that it is at all necessary to guard against putrefaction of the gelatine, especially as even if such does take place, the putrefied gelatine will be afterwards eliminated. We must acknowledge having got the hint to omit the alcohol from the paper by Mr. Alfred Brown recently printed in our columns.

As the emulsions last mentioned have only recently been finished, we are unable at the present time to give the result of keeping them. It is quite possible that No. 1 may in a week's time increase in rapidity, so as to catch up or overtake the other two. At present we would decidedly describe it as a somewhat slow emulsion; but we were given by the author of the paper to understand that this was to be expected in the case of plates coated immediately after the gelatine is mixed with the washed haloid. The others, Nos. 2 and 3, on the other hand, give plates of a sensitiveness quite up to the average, and if any marked increase takes place in their case, they will give plates of very exceptional rapidity.

It will be seen that we have found it at least possible to do without any ammonia at all. The emulsion made from the bromide which had gone through the very long time of heating mentioned, showed no tendency to fog. We have found the process quite a workable one, and have discovered no difficulty in any of the manipulations. The quality of the plates has been excellent.

MENDING THE MINOR DEFECTS OF NEGATIVES.

Although but few ordinarily attend the Social Gatherings of the Photographic Society of Great Britain, it occasionlly happens that matter of considerable interest is discussed in a manner so thoroughly informal as to contrast strikingly with the ordinary meetings of the photographic societies. On Tuesday last the assembly consisted of thirteen gentlemen, who sat around the table in the Council Chamber of the Photographic Society; and while they regaled themselves with the tea and coffee so liberally provided, they discussed the best means of patching up such negatives as are generally good, but may be disfigured by trifling blemishes.

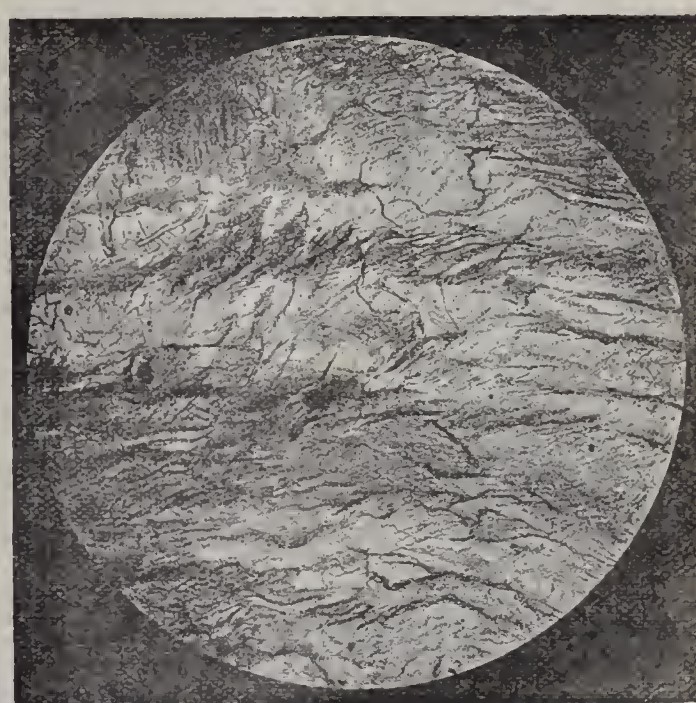
The most usual defect, and perhaps that which on the whole causes most annoyance, is the small transparent spot, generally somewhat larger than the so-called pin-hole, but still of inconsiderable size. Mr. Sebastian Davis referred to the use of carmine mixed with gum, but remarked that there is considerable difficulty in so applying it as to avoid overstepping the bounds of the transparent spot, as in such a case, a lightish ring appears on the print; and this ring is often even more noticeable than the dark spot which would have arisen if the negative had been let alone. It is very desirable to thoroughly incorporate the carmine with the gum, and we would recommend the addition of a trace of ammonia, as this not only tends to dissolve the pigment, and so yield a mixture better calculated for delicate work, but it also serves to somewhat soften the varnish, and give rise to a thorough union between the pigment and the resinous material; the kind of spotting or retouching now referred to being generally carried out on the varnished negative. Ox-gall is also used for a similar purpose, but a trace of Castille soap will serve just as well. Mr. England seemed to look on the blacklead pencil as better calculated to be of service for shading over spots; but when circumstances make it desirable to use anything of the nature of a pigment, sepia is convenient, as its tint harmonises well with that of the negative, and its physical condition is such as to well fit it for the work. Gelatine negatives are frequently seen with ring-like transparent marks, due, apparently, to the de-sensitizing action of solid particles which may either remain in the emulsion despite the straining, or may settle on the films before they are dry. These may be stippled over with a pigment, as mentioned by Mr. Bedford, or may be shaded over by means of the retouching pencil. But it is well to adopt some means of roughing up the film first, Mr. Ashman's usual plan being to abrade the surface with a fine needle; but there are instances in which a retouching medium is convenient. One ounce of common resin dissolved in two ounces of oil of turpentine answers well, a small quantity being rubbed on the varnished negative either with the tip of the finger, or with a small tuft of rag, the friction being kept up until the surface is dry and rough. Powdered resin, or a mixture of powdered resin and dextrine, is sometimes made use of; but powders tend to produce a lumpy and uneven surface.

The printing-in of clouds was referred to as one of the most frequent after-operations required to be performed on the negative, it being very difficult to realise the conditions necessary for securing both sky and negative on the same plate. The use of waxed paper sky negatives was well spoken of, and they seemed to be regarded as being more convenient in practice than glass negatives. They are, however, subject to the disadvantage of readily absorbing silver, and of becoming granular in texture, owing to a physical change of the wax; but Mr. Ashman pointed out that this granulated texture can be remedied by holding the negative before the fire so as to soften the wax. Mr. England strongly advocated the simple plan of working-in clouds on the back of the negative with Indian ink, and remarked that a very moderate amount of artistic culture is necessary for this purpose; while the rapidity and the ease with which the work can be altered also recommend this method. The Indian ink may be applied with a brush, and then stippled or distributed by a rag stump, or even the top of the finger. We have frequently made use of Brunswick black for a similar purpose, and are inclined to think that it offers some advantages over Indian ink, as a most delicate and transparent shading can be produced by rubbing down the dried work with a rag slightly moistened with benzole or turpentine. If, on the other hand, an attempt is made to reduce the dried Indian ink by friction with a moist rag, the whole thickness is removed at once, leaving bold and ragged edges.

PHOTOGRAPHING THE INTERNAL MICROSCOPIC STRUCTURE OF METALS.

BY J. VINCENT ELSDEN, B.Sc. (LOND.), F.C.S.

One of the most characteristic properties which is common to all metallic substances is their extreme opacity. This opacity, however, is not perfect when the metals are reduced to exceedingly fine leaves; pure gold, for example, when hammered out to a thickness of about $\frac{1}{200000}$ inch, or ·0000125 mm., allows green light to pass. Nevertheless, so little light is transmitted, even by the thinnest metallic leaves, that the examination of their molecular structure by the aid of a microscope is impossible, and still less could that structure be photographed. Thinking, however, that something might be learnt from the effects upon the molecules of malleable metals, of the extreme pressure to which they have been subjected, I devised, after some consideration, a method whereby metallic leaves can be made sufficiently thin, and, at the same time, transparent enough to enable a photograph to be taken of their structure enlarged to any required extent by means of a microscope. My experiments were chiefly confined to gold and silver, since these metals, of all others, are to be obtained in leaves of the greatest tenuity; but I also examined the structure of Dutch metal, tin, lead, and other more or less malleable metals. In the case of silver leaf, the method adopted was extremely simple. The silver leaf was first fastened down upon one of the ordinary glass slips used for mounting microscopic objects. This can be done with a very thin solution of gum. Care must be taken to have the leaf spread out as flat as possible, leaving no wrinkles upon the surface; for these would interfere with the appearance of the leaf, by transmitted light, by presenting layers of varying thickness and opacity. The leaf is then covered with a weak solution of iodine, and allowed to dry, or, more convenient still, it may be coated with bromine, which evaporates spontaneously, and is immediately dry.



The effect, in either case, is to convert the silver leaf into a perfectly transparent film of iodide or bromide of silver, which preserves most perfectly the minutest details of structure of the original metal. This film is well adapted to microscopic investigation; but its yellow colour is so non-actinic as to be rather against its employment for obtaining a photograph showing the structure satisfactorily.

For the latter purpose, the following method is by far preferable. The silver leaf, having been fastened as before upon a glass slip, is subjected, for a few moments only, to the action of chlorine gas. This can readily be done by simply passing it over the mouth of a test-tube in which manganese di-oxide and hydrochloric acid are heated together by a spirit lamp. The chlorine rapidly attacks the metal, but it does not act upon it uniformly. Owing to the great pressure to which the silver leaf has been subjected, its particles have become arranged in more or less parallel fibres, which are bound together in interlacing masses, somewhat resembling masses of human hair.

These fibres are less easily attacked by chlorine than the intermediate portions; so that, if the action is stopped in time, the metallic fibres will be left imbedded in a matrix, so to speak, of silver chloride. In order to render this fibrous structure still more apparent, the whole mass is next coated with plain enamelling collodion, and, when thoroughly dry, the glass slip is immersed in a solution of hyposulphite of soda. By this means, the collodion film being permeable by the hyposulphite solution, the silver chloride is dissolved away, and nothing remains but the mass of interlacing metallic fibres, which are kept in position by their adhesion to the collodion film. Frequently, during the operation, the collodion film separates from the glass slip; but this is not of the slightest consequence, as it can be handled with impunity, and again mounted upon the slip when the solution of the chloride is complete. In this way can be obtained a perfectly transparent representation of the structure of the silver leaf in a condition which favours its reproduction by photography. By the ordinary methods of microscopic photography a negative can be obtained, showing the magnified structure to great perfection.

The methods given above, however, are not applicable to all metals. In dealing with gold leaf, it was found advisable to render the film transparent by coating it with collodion, and then reducing it to extreme tenuity by immersing it in a solution of *aqua regia* for a short time. A similar result can be obtained, in a more certain manner, by the action upon the gold leaf of a solution of perchloride of iron or cyanide of potassium. By this means the leaf is much more slowly attacked than by the *aqua regia*, and the action can, therefore, be more easily stopped when the required degree of transparency has been obtained. Gold leaf shows the same tendency to a fibrous structure as silver, but in a slightly less marked degree. Other metals, like tin, show no trace of any fibrous structure, the particles being essentially granular.

The extremely fibrous arrangement of the particles in silver and gold leaves is doubtless the result of the great pressure by which they were beaten out, and is no doubt intimately connected with the tenacity of these leaves, the leaves of the granular metals, like tin, being far less tenacious than those of gold and silver.

Doubtless similar methods to the above might be adopted for photographing the minute structure of many other substances, which, in their natural condition, are too opaque for this purpose.

PHOTOGRAPHIC WRECKS.

BY EDWARD L. WILSON.*

A good many mistakes are made by photographers who begin to feel a little of the vanity which comes from prosperity. One of the most fatal of these is the disposition to discount the future, and to enlarge and improve their quarters more speedily than their business warrants. I would be one of the last ones to say a word against progress in any direction which would improve a photographer or the art which he represents, and yet, with the knowledge that I have of the history of many men in the profession in this country, I am compelled to say that the most fatal mistakes that have been made by those who once seemed to have a fortune almost in sight, and who ultimately failed, have been in the direction of extravagance in improving some other person's property for the sake of having what they choose to call "a palace of art."

One need not go further than the city of New York, and look into the history of photography there, to find the truth of what I say. All of us can remember when certain leading spirits moved from their down-town studios to places further up in the city where rents were much higher, and where, in their anxiety to obtain "desirable locations," they yielded to the proposition of their landlords, and, *at their own expense*, made an extravagant outlay, thus embarrassing themselves to a greater extent than they were ever able to recover from. It is not necessary to mention names, but I could point to no less than six or seven who, fifteen years ago, stood in New York as the grand lights of photography, but who have made an utter failure of it, and who have had to give up all these "palaces," and were glad to inhabit smaller quarters. Some of them lost all they had, some only a part; but all have been disappointed, and doomed to a life of hardship the rest of their days.

But this fatality, so to speak, is not confined to New York Philadelphia has had her share of just such wrecks. Chicago has had similar fortune; and how many smaller places have had photographers who have indulged in extravagance, and lost their all in the same way? I would not feel called upon to mention this matter now, were it not that I learn through the vast correspondence which comes to me continuously, the constant disposition to do this same thing on a greater or smaller scale. I believe thoroughly in photographers being comfortably fixed in pleasant and attractive places of business, and in their having about them every convenience which will enable them to produce the best work in the most expeditious manner, but still at the least possible cost to themselves. And if our younger generation desires to profit by the experience of those whom they have been taught to look up to as "veterans" in the art, they will steer clear of this great rock upon which so many have split.

If capital be meagre, it is best always even to pay a higher rent, and to have some one else invest in the arrangement of the studio, than to undertake too much one's self, and to find out afterward that the anticipations of business have not been realized, and that the whole must be given up to some one who holds a mortgage upon the property.

This temptation is not peculiar to photographers solely, but is a common thing in all lines; but as our interests lie with photographers, it seems wise and best at this time to place on record a word of caution. Sometimes this extravagance is resorted to in order to fulfil the false idea of getting ahead of one's neighbour. This is by no means necessary. It has been my experience that good work attracts more trade than a "palace." I can point to more than one studio where the proprietor indulged in a "palace of art," but his work was so inferior as to prevent him from getting the share of trade that one would think that his palace would attract for him; while in the same city I have seen the humble occupant of a place with more stairs to climb as busy as he could possibly be, with a good force of hands from morning to night, and making and saving money.

There is an old adage that "every dog has his day." Had photography been invented when that adage was written, doubtless its author would have substituted the word *photographer* for that of the other animal. For in scanning the history of photographers for a few years back, it can be truly said that very many of our older ones have had their day in the sense which the coiner of our adage meant, or, in other words, they have had prosperous days, and, neglecting their opportunities, have become neglected and forgotten.

The moral of all this is meant to be that photographers should not be anxious to become possessed of extravagant establishments. It is better to lay by a sufficient sum to enable you to bear any loss that may occur from such an indulgence without hampering your business. No extravagance should be indulged in when it would in one's business or take him from it. Those who attended our convention in Cleveland, in 1870, probably remember, as they stood on the back platform of the car chatting with Dr. Vogel, while they passed through certain portions of Ohio, a long series of oil derricks and over-turned machinery which lined some portions of the road, and how a certain individual compared the disappointment which must have followed the ruin here to that which many photographers at that time were feeling because of the extravagance in the line in which I have indicated.

I trust a word to the wise will be sufficient, and that our rising generation, who are becoming famous, and who even now have their eyes open, will not build up some other person's "palace," but will have a care first to build themselves a lasting reputation, and have a good round sum of money before they go too far.

* *Photographic Times.*

By-the-Bye.

LANDSCAPES AND PORTRAITS.

A photograph must be either a landscape or a portrait. So, at least, most people were wont to think, even if the majority are not of the opinion still. Medals were given for landscapes, and medals were given for portraits, and photographers were usually classed as pre-eminent in the one branch or the other. Some ten or twelve years back, it is true, another term came into general vogue—worse luck to the photographer who aimed at making pictures—and *genre* prints began to be spoken of. *Genre* is an indefinite name at best, but it was thought sufficiently appropriate for work undertaken by photographers who could not make up their minds to produce a portrait pure and simple, or a photograph of land and water. The estimation at which a *genre* picture was held is easily gauged by looking at the prospectuses of bye-gone exhibitions held in London and elsewhere. If a dozen medals were set apart for portraits and landscapes, a single one was deemed sufficient for the new class of picture; or, if gold and silver medals were proclaimed as the awards in the recognised branches of photography, the *genre* pictures were set down to divide a bronze medal between them.

We do not know if those who introduced the word *genre* photograph attached any specific meaning to it, or whether, as is indeed most likely, it was simply borrowed from the painter's vocabulary. It is a little difficult to define what a *genre* painting is, for authorities are divided on the subject. Thus while one author tells us that "genre" is applied to "various branches of painting except history and landscape," another says that *tableaux de genre* are paintings of interiors, and adds gratuitously that they are called so *d'une manière fort impropre*. Again, a third definition is, that a *genre* picture is one that tells a story. Still, all agree in this, that a *genre* picture is a picture, and not a mere representation of a bare fact or phenomenon.

Therefore, if we have adopted the word from painters, a *genre* photograph means a pictorial photograph, and instead of being at the bottom, it should be at the top, of the departments of photography. This is a home-truth that photographers will be bound to recognise sooner or later; and, indeed, in the case of the Photographic Society, the matter is, we are glad to see, half-recognised already. We mean that, instead of separating the pictures in the Exhibition into classes, they leave it to a jury to award medals as they please to the most deserving exhibits. In other words, in an art exhibition, only one standard is employed, namely, that of art. Whether the pictures exhibited year after year on the walls of the Pall Mall Exhibition have much or little to recommend them in the way of artistic treatment, it is only according to the standard of art that they can be judged; and even those critics who deny that any photograph can possess even a modicum of artistic feeling can at any rate say which pictures are least offensive to good taste, and award the palm to these.

In speaking thus, we are, of course, only alluding to the general pictures in an exhibition, and not to those having special qualifications to recommend them, and whose appraisement comes under the notice of another class of judges. We speak of photographs as pictures, and we say that in future exhibitions it were well indeed if the words portrait, landscape, and *genre*, are altogether ignored. Very soon after photographic exhibitions were established a notice was issued that carte-de-visite portraits were not desirable, and that, if forwarded, only a limited number would be admitted. It would be wise if the same rule applied to cabinet portraits as well; for exhibitions, although established for the benefit of photographers generally, must have some limits imposed, else the collection would speedily degenerate into a number of ordinary show-cases. In the ordinary every-day work of the photographer one is less interested than in his endeavours to progress as an art-student or as a pioneer in art photography.

To show sterling work is the object of an exhibition, and whether this is in the form of a simple landscape, or portrait, or study, or interior, so long as it has pictorial merit, it is welcome; and a man who achieves a photograph of merit, and forwards it for exhibition, it should be remembered, not only increases his own reputation, but the repute also of photography in general.

We need not dwell upon the fact that photographs which were neither pure landscapes nor pure portraits have been much neglected in our exhibitions. Everybody is perfectly aware of the fact. They have not been admitted to the same advantages as portraits and landscapes. We do not mean that the latter have been overrated, or that they have not the art-qualities the so-called *genre* photographs possess; on the contrary, there have been, as a rule, more art feeling and good taste displayed in in these branches than in many *genre* prints, for the simple reason that in creating a pictorial photograph, most photographers fail. What we ask is that all shall compete on the same platform. If this is not done, we foresee the approach of much controversy and endless wrangling. Who shall decide that a photograph belongs to this class or that class? The bust of a lady is decidedly a portrait, and a group of trees upon a sloping lawn is decidedly a landscape; but let the lady be reading a letter, or the landscape have a figure gathering sticks in the foreground, and what are the pictures then? Some judges would say that the portrait is still a portrait, notwithstanding the letter, and the landscape has not altered its character. But what if we give the pictures a title, calling the first "Is it True?" after Rejlander's admirable study, and the second "Harvest for the Winter;" do we change them into *genre* pictures in that case? Only the other day we had an illustration of the difficulty. Mr. Pettit's picture, which secured one of the awards at the Edinburgh Exhibition, is stated to be the only landscape that secured a medal. This is nonsense. Mr. H. P. Robinson, of Tunbridge Wells, had the gold medal awarded to him for a picture which was as much a landscape as anything by Turner, Wilson, Linnell, Calcott, or any other distinguished landscape painter.

Some photographers are content with landscapes pure and simple, while others think that life and animation are imparted by one or more suitable figures. But in any circumstances the introduction of figures should not be regarded as a cause for relegating the productions to an inferior class; yet this is what has been done time after time in our past exhibitions. The hanging committee, or the jurors, have taken upon themselves to say which is a *genre* picture, and which is not, and these productions have been arbitrarily put on one side and thrown out of competition, although representing the application of consummate taste and rare skill, and just in that direction, too, in which efforts are most praiseworthy. To take an example, we may put forward, with little fear of contradiction, all Rejlander's studies as belonging to no other class but that of so-called *genre* photographs. There was a story in every one of Rejlander's pictures. "Homeless," a ragged beggar-boy asleep on a London doorstep; "Did She?" where a laughing face listens to a humorous story; "Grief," "Despair," "Resignation," and other female studies, would but be regarded as *genre* photographs according to present regulations, and entitled to compete only in a class where the prizes are fewer and of less value than those accorded for pure landscapes and portraits.

We have already pointed out the folly of giving medals for portraits as portraits, since a judge cannot form a true opinion on the subject unless he has the models themselves before him; whereas, if he regards the photographs as studies, then all competitors are on the same footing. We hope that the day is not far distant when neither "portrait" nor "*genre*" photographs find a place in the prospectus of an exhibition, and that, whatever the nature of the photograph, it be judged by its pictorial value. There would be no harm in dividing pictures into interiors and exteriors; but, as a rule, the less attempts at division, the more likely is a spirit of fairness and good faith to prevail.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

CHAPTER IV.—REVERSED NEGATIVES—*continued.*

BEFORE stripping the film, it should be placed in a damp place for an hour or so, to prevent the breaking up of the film. When the negatives are to be stripped, the plates must not have a substratum, nor should they be varnished. The film negatives should be kept perfectly flat between sheets of paper when not in use. Old varnished negatives may sometimes be stripped successfully by the above methods after removal of the varnish with a suitable solvent; but as there will always be a risk of destroying the negative, it is better to employ one of the multiplying processes to be described further on.

When the image is to be printed directly on to a metal plate or lithographic stone, materials which, even with every care, often have hollows in their surface, which render it difficult to obtain sharp results with glass negatives, it is a good plan to transfer the negative film at once on to the sensitive coating, whether bitumen or bichromated gelatine. By this means the most perfect sharpness is secured; but, as a rule, the negative will only serve once, and, in case of failure, must be taken again.

For zinc or copper plates coated with bitumen, the following method, used at the State Printing Office, Berlin, will be found useful.

The negative is first treated with a bath composed of—

Sulphuric acid	1 part
Glacial acetic acid	1 ,,
Water	320 parts

It is left in this for a short time till loosened, and is then washed with water. The film is then lifted off the glass in a dish of water, and laid down reversed on another glass plate. In order to give intensity, the film is blackened with a solution of bichloride of platinum. The plate is immersed in a bath containing one part of a solution of—

Bichloride of platinum	1 part
Distilled water	128 parts

to thirty-two parts of distilled water. When sufficiently blackened, it is carefully lifted out, rinsed with water, and laid in a large dish containing a mixture of—

Glycerine	1 part
Water	4 parts

The coated zinc or copper plate is also placed in the glycerine solution, and the loose film is carefully drawn on to it, and fastened to one end with a narrow strip of lead. The film is smoothed out till free from wrinkles, and air-bubbles are removed with the aid of a brush. The plate is then lifted out obliquely, so that the solution may drain away. If the film does not lie firmly enough, its edges must be fastened with strips of gummed paper.

Film negatives may be laid down on bichromated gelatine by first waxing the gelatine surface with a solution of wax in benzole, and then transferring the film negative to it in a bath of spirit of wine, and squeegeeing it down in the usual way.

Gelatino-bromide negative films may, according to Chardon, be stripped if the precaution be taken, before coating with emulsion, to rub the glasses with powdered French chalk, and coat them with plain collodion, which is allowed to dry. After the negative is finished and dried, it is coated again with collodion, and when this is dry, the compound film may be easily removed from the glass.

III. *Reversed Negatives by Contact Printing.*—It often happens that a reversed negative is required when only a direct image is available. In such cases one of the best and simplest methods that can be employed for obtaining a reversed negative from the direct one is that known as the "dusting" or "powder" process, in which a glass plate is coated with a hygroscopic mixture of gum, sugar, and bichromate dissolved in water, thoroughly dried with heat, and then exposed to light under the negative to be reversed. After removal from the printing-frame, the gumming film is dusted over with very fine plumbago, which adheres to it in inverse proportion to the action of light; *i.e.*, the parts rendered insoluble and unhygroscopic by the action of light refuse the powder in proportion to the intensity of the action of the light, while the protected and more or less hygroscopic parts, attracting moisture from the air, and so becoming tacky, take the powder readily, and thus an exact transcript of the original negative is produced, but reversed.

A great many formulæ for the gummy mixture have been published, but I have succeeded well with the following, slightly modified from one given by Geymet in his "Photo-lithographie."

Gum-arabic	50 parts
Glucose	100 ,,
Sugar	20 ,,
Saturated solution of bichromate of potash	125 ,,
Saturated solution of bichromate of ammonia	125 ,,
Water	1,000 ,,

carefully filtered.

The glass plate having been cleaned with care, so that no greasiness may remain on, the surface receives a thin and even coating of this solution, poured on like collodion. It is then dried over a spirit lamp or hot plate, if of large size, and exposed at once under the negative to be copied. It is next taken into the dark room and brushed over with fine plumbago till the image appears of the proper strength. The development of the image may be helped, if necessary, by breathing on the plate or laying it in a slightly damp place to absorb moisture from the air.

After development the plate should be left for a few hours, so that the plumbago may become thoroughly attached to the film, and is then exposed to light from the back to harden the whole coating. It is finally soaked with water to remove the bichromate, dried, and varnished.

Reversed negatives may also be obtained by contact printing on a dry collodio-bromide plate. After exposure to light in the printing frame, the plate is developed, as usual, with alkaline pyrogallic, the development being pushed till deposited silver is apparent in the deepest shades at the back of the plate. After development the plate is washed with water, and a mixture of equal parts of nitric acid and water is poured over it. This dissolves the reduced silver in the exposed parts of the film, leaving a negative image formed of silver bromide in the unexposed parts. The plate is then well washed with water, followed by a very dilute solution of ammonia to neutralize any acid remaining. After another thorough washing, the plate is again exposed to light, and developed, as before, with the alkaline developer, which produces a negative image. If too weak, the image may be intensified in the same way as an ordinary wet collodion negative.

Mr. Bolas has published (PHOTOGRAPHIC NEWS, vol. xxiv., p. 304) a method of obtaining reversed negatives by contact printing applicable to gelatino-bromide dry plates, and results I have seen by it are exceedingly good.

A gelatino-bromide plate is soaked for a few minutes in a four per cent. solution of bichromate of potash, and after this it is rinsed for a few seconds in a bath composed of equal volumes of alcohol and water. On removal from this it is laid down on its back, and the moisture blotted off with clean blotting-paper, the paper being pressed gently into contact with the plate by means of a cloth.

The paper is removed, and the plate is dried in a warmish place. When dry, the plate is exposed to light under the negative to be reproduced, giving the same exposure as one would give a carbon print in the same light. After exposure, a delicate positive impression is visible on the exposed surface. The plate is first soaked in several changes of cold water in order to remove the excess of bichromate of potash; and when this is done, the plate is developed with any suitable developer, preferably with pyrogallic acid and ammonia.

Under the action of the developer, the nature of the picture rapidly changes, the light parts becoming dark and opaque, while the parts already tinted by the action of light either become actually clearer, or appear to be so by contrast. The positive, having been converted into a sufficiently dense negative, is rinsed with water, and fixed with hyposulphite in the usual manner.

Captain Biny, of the French Engineers, has published a somewhat similar method (Photographic News, vol. xxvi., page 79).

A gelatino-bromide plate is immersed for ten minutes in a four per cent. solution of bichromate of potash, and allowed to dry. When quite dry, it is exposed in a pressure frame below the negative to be reproduced. The plate is then taken into the dark-room, and immersed in water to remove the bichromate. It is next rinsed in two waters, and then, being placed on the black ground of the bath, it is exposed to diffused light for a few seconds. The plate is then developed with the ordinary ferrous oxalate developer, when the image will become visible either as a negative or a positive, according as the original from which the copy has been taken is one or the other. It is then fixed in the usual way. In order to prevent stripping of the film, it is a good precaution to expose the back of the film to the light, either before exposing it in the printing frame, or afterwards.

4. *Reversed Negatives in the Copying Camera.*—When the reversed negative is required to be either larger or smaller than the original one, the most convenient method of producing it is by first obtaining a transparency, either in the camera or by contact printing on dry plates, or on the special carbon tissue prepared by the Autotype Company for this purpose; and this transparency is copied in the camera to the required scale. The details of various methods of making transparencies are given in Captain Abney's "Instruction in Photography."*

5. *Factitious Negatives.*—When circumstances permit, very fine results may be obtained by the use of what may be called factitious or artificial negatives, in which the drawing is etched or engraved in by hand with a point or graver on an opaque film. The drawing being made direct, the negative will be reversed, and suitable for contact printing; but if the negative is required for transfer printing, the drawing must be reversed as it would be if drawn direct on stone or engraved on copper.

Several methods of obtaining these factitious negatives have been proposed. A very good one, which I used many years ago, is to coat a glass plate of the required size with ordinary iodized collodion, sensitize it as usual, then expose it for a moment to light, and develop till the film is perfectly opaque; wash, dry, and varnish. If suitable collodion and varnish are used, the film will cut very cleanly, and the greyish colour of the developed film is quite clear enough to enable the progress of the drawing to be seen if the plate is laid over a piece of black paper or cloth.

Rodriguez coats a well-cleaned glass plate with an 8 or 10 per cent. solution of gelatine, to which sufficient carbonate of lead has been added to form a sort of paste. The coating is applied with a brush, so as to form an even, thin, and uniform coating, without showing transparent places. The plate is then dried in the open air, or with gentle heat.

* Piper and Carter, 5, Castle Street, Holborn, London, E.C.

To draw on the plate, it is laid on a piece of black paper, and the drawing, having been (if necessary) traced on the coating in the usual way with black or red paper, is cut in with points or gravers. Corrections may be made, if required, with a brush and a little of the preparation.

When the drawing is done, the dust is brushed away, and the plate treated with a watery solution of hydro-sulphuric acid, which turns the white carbonate of lead to an intense black. The plate is then dried, and varnished. Mr. Toovey's method, by which I have seen some very admirable results—more like delicate *aquafortis* work than photo-lithography—is given by Mr. L. Hart as follows. Take—

White wax	80 grains
Litho varnish	3 drachms
Benzole	3½ ounces

Dissolve the wax in the benzole, and add the varnish; clean some glasses of the required size, and spread a very little of the solution on a lithographic printer's inking slab. Now with a lithographic roller lay on the glass a very thin coating of this varnish; while still wet, shake over it powdered orange chrome through a very fine sieve, and, when covered, dust it about on the plate with a dusting brush softly and with a circular motion; let it dry, and then flow over it the following:—

Turpentine	3½ ounces
Litho varnish	1½ drachms

When this is evaporated, dust over in the same manner with the white colour known as *blanc d'argent*, place the plate to dry, and it is then ready to be etched or engraved.

In the Administration of the French *Ponts et Chaussées* at Paris, an ingenious method of transforming a drawing on paper into a photographic negative is used. A tracing or drawing is made in lithographic ink on tracing-paper, taking care to have plenty of ink on the lines, and not to cut the paper. The drawing is then laid on a board over a piece of blotting-paper, and brushed all over with a strong solution of aniline brown in water, and, when dry, is rubbed over with a tuft of cotton soaked in turpentine, which removes the ink, without altering the coloured ground. The lines then appear clear on a dark reddish-brown ground. The negatives thus obtained are good, but more suited for coarse than fine work.

Positive Clichés.—In some processes of photo-lithography and photo-zincography a positive cliché is necessary. This may be obtained by any of the methods used for making transparencies, but the plate will probably require extra intensification to obtain lines sufficiently dense.

M. Rodriguez, of Lisbon, exhibited at the Paris exhibition of 1878 some very good positive clichés obtained by rubbing over a piece of finely-ground glass with powdered sandarac, and then drawing on it with a fine pen and Indian ink mixed with a little sugar and glycerine, in order to prevent the ink drying completely and leaving it tacky. The drawing is then dusted over with very fine plumbago, which darkens the lines, and makes them quite opaque. The plate is then varnished.

In the photographic ateliers of the Topographical Brigade of Engineers, at the Hotel des Invalides, in Paris, drawings on tracing-paper are largely employed as clichés for use with the Commandant de la Noë's process of *topogravure*, in which the sensitive surface is bitumen on a plate of zinc, as will be described hereafter. The drawings are made on fine, thin, white tracing-paper, with very black Indian ink, and the names, stamped in printing ink, are dusted over with bronze powder to make them more opaque. I have seen exceedingly clean nice work produced from these tracings.

A good deal of information on the subject of reversing and mulitiplying negatives and positives will be found in Vidal's *Phototypie*, and Husnik's *Gesammtgebiet des Lichtdrucks*, as well as in the pages of the English photographic journals.

(*To be continued.*)

Notes.

Professor Tyndall's Christmas Course of Lectures at the Royal Institution will be on "Light and the Eye."

Mr. Edwin A. Cade, of 8, Osborne Terrace, Clapham Road, is acting as secretary to the Provisional Committee of the Photographers' Copyright Defence Association.

We are happy to announce that Professor Alexander Herschel, M.A., a name long honoured by photographers, has promised a paper for the YEAR-BOOK, "On the Relations of Radiation to Material Structure." Mr. H. P. Robinson, Dr. Eder, Professor Donkin, M.A., and Mr. Whipple, B.Sc., the Director of Kew Observatory, will also contribute to its pages.

Professor Alexander Herschel sends us a tiny photograph of a tuft of primroses growing on the banks of the Derwent. The pale flowrets coyly nestling among the spear-headed grass, their delicate petals in contrast to the thick, strong leaves around, make up a charming little picture; but the worthy professor of physics at the Newcastle College of Science nevertheless protests vehemently against the favouritism and unfairness of photography in its representation of the dainty spring flowers. "The picture," he says, "is a crying example of the whims of silver salts ordinarily prepared, in picking and selecting their favourite colours for impression only. So, because the eye of a primrose is a little fairer than its canary-coloured lips, photography rejects it, and prints it a black centre in the poor thing's corolla. What would an orange tree with ripe fruit look like in a photograph, I wonder?"

Lieutenant von Reisinger, in the *Correspondenz*, expresses himself well satisfied with emulsion made on the Obernetter principle. His method, in brief, is to take three grammes of gelatine, 80 cub. cents. of water, and three drops of saturated alum solution. To this he adds, in daylight, five grammes of silver nitrate dissolved in 20 cub. cents. of water. After the mixture has set in a shallow vessel, it is put, finely shredded, in a beaker in the dark room, and covered with a pretty strong solution of bromide of potassium. After standing the night, the liquor is poured off, the shreds washed in five changes of water, and finally dissolved for application to the glass, adding a little more alum. There was proof of silver having separated during the period of bromizing, but Herr von Reisinger speaks very highly of the resulting emulsion and the simplicity of the process.

Touching our recent "By-the-Bye" on rapid exposures, Major Waterhouse thinks that an entirely new departure in the construction of apparatus is required in order to make the most of the advantages offered by modern dry plates. The old cameras and dark slides did well enough for dry collodion plates when exposures were counted by the minutes, rather than seconds or fractions of a second; but now gelatine enables us to secure subjects that could never have been touched by dry collodion, some quicker means of replacing the focussing glass by the sensitive plate, and exposing at any moment, is much wanted. The Assistant Surveyor-General of India suggests that this might be done by an arrangement of mirrors as described, for instance, by Mr. Harmer, in the NEWS in 1879, or by using duplicate lenses.

Major Waterhouse continues:—"A repeating arrangement for successive exposures is also a requirement. One knows, of course, that these things have been made, but you want to find them at the dealers and apparatus manufacturers. Your advertising columns show that the attention of the latter is being directed to the special wants of dry-plate photographers; and no doubt, before long, many improved forms of apparatus will be in the market. Something on the principle of Janssen's slide or *revolver*, employed at the transit of Venus in 1874, might possibly answer; in this, the sensitive plate revolves past an opening protected on both sides, when focussing, by ruby glass."

Among the salvage from the *Gulf of Finland*, recently stranded in the Red Sea, we hear of a quantity of dry plates, one maker alone being represented to the extent of £150. Considering the remarkable de-sensitising power even of traces of common salt, and its property of slowly but surely permeating porous substances, we would imagine this salvage to be of but little value. Salt water perforates the ordinary zinc lining of a packing-case in a few hours.

Again we have in the Brussels mystery a very telling illustration of photography assisting justice; in fact, the detection of the assassin was due to the camera alone. After shooting Bernays, the mysterious Mr. Vaughan decamped, leaving behind him a mass of letters and documents signed by this name. Who could Vaughan be? asked the detectives; for the fugitive had scattered about so many scraps of writing with this signature, that they felt sure the name was assumed. So they photographed the handwriting and distributed copies among the tradespeople of the principal towns in Belgium. The plan succeeded. A Verviers shopkeeper fancied that the handwriting was that of one Léon Peltzer, with whom he had business correspondence, and so communicated with the police. This proved the first link in the chain that has since fettered the brothers Peltzer.

A new photo-electric battery has been constructed by M. Saur. It consists of a square earthenware vessel containing a solution of 15 parts sea salt, 7 parts sulphate of copper, and 100 parts water. A porous pot containing mercury is put into this solution. One of the electrodes, of platinum, is plunged into the mercury; the other, consisting of sulphide of silver, is dipped into the solution of salt. The battery is placed in a box screened from the light. By putting a galvanometer in circuit, the effect of light on the battery is at once detected, a cloud passing over the sun immediately influencing the current. The theory of the battery is explained by the action of the mercury upon the bichloride of copper formed by the mixture of the sea salt and sulphate. The proto-chloride of copper reduces the sulphide of silver, but this reduction requires the intervention of sunlight, which determines the photo-electric current.

At the last meeting of the French Academy of Sciences a good deal of interest was shown in some photographs taken by M. Ferrand, a Lyons chemist, of ink spots which had been purposely made to cover up certain writings. M. Ferrand demonstrated how photography could produce a picture of characters thus hidden from the eye, his prints showing the ink spots and the writing beneath as well. The fact is explained by the different photographic properties of the two inks, which are superposed. When, however, the ink blot proves too much for the camera—as is sometimes the case—M. Ferrand recommends the cautious treatment with some reagent which acts unequally on the two inks, thus bringing about the desired contrast, and then photography may be brought into play to some purpose.

Photographers, and amateurs espceially, are warned against lens forgeries, which seem to be very rife just now. Within the space of a week no less than four cases have been detected by a well-known firm under whose attention the instruments came. They were marked with the name of Dallmeyer, but on that gentleman being consulted, he found all were spurious. One was a very impudent case; it was a lens marked "No. 3, W. A. Landscape"; and the focus, which should have been no more than ten inches, was found to be upwards of twenty-six.

The forgeries have, indeed, been so frequent and barefaced, that Mr. Dallmeyer has taken steps to trace their origin, and hopes in this way to bring the matter to a speedy issue. But we may inform our readers that he is always happy to examine any doubtful lenses that may be brought bearing his name, since it is a matter of more importance to him than to the intending purchaser that no spurious lenses be in existence. No doubt Messrs. Ross and Co. and other opticians of standing would, in like manner, afford their valuable advice if called upon.

Next Wednesday, if all goes well, we shall be favoured with a sight of the transit of the planet Venus across the disc of the sun. The phenomenon is only partially visible in this country; but still it will be well worth the while of any photographer having a long-focus lens to get a record of the phenomenon. He will never have the chance again, for when the next transit occurs—four-score years hence—there will be few of us living. The first external contact of the tiny black planet will be at 1 hr. 55 m. 57 sec., p.m.; but as the sun sets at ten minutes to four, our observation of the interesting object will be but brief. As some sort of guide of the size of the sun in the camera, we may mention that a lens of twenty-six inches focus, such as many photographers possess, will produce a disc measuring about five-sixteenths of a inch; but a sharp image of this size could, of course, be enlarged many diameters.

Gatschina has lately become known as the only refuge in which the Emperor of Russia trusts himself. Recently, alterations of an extensive nature have been carried on at the palace, and, according to the *Archiv*, photography is largely employed as a safeguard against treason and treachery. Every workman must, prior to his engagement, be photographed under the auspices of his employers, and even the women engaged in upholstery work are required to submit their portraits before entering the precincts. The photographs are not only carefully recorded in the police office, but copies are distributed among the caretakers, so that they may know if any strange face meets them.

A few weeks ago we gave the particulars and expense of fitting up a pair of 5-candle Swan lamps for the show-case, and, as a consequence, we have been asked for an estimation of the cost of lighting a whole shop-front and shop with incandescent lamps. This is another thing altogether, for a number of powerful lamps of 20 or 25-candle power would be necessary; and to set these in action a dynamo machine and small gas engine are required. Still, the expense would not be very great; thus, for a series of ten such lamps, the cost of gas and dynamo engines. with installation complete, the charge is £170, Messrs. Calder and Co., of the Westminster Bridge Road, who gives the estimate, undertaking to set up the arrangements anywhere within eighty miles of London. Three-halfpence per hour is the estimated cost of working the engine by gas or oil.

Most people know that there is a good deal of profit made upon Christmas cards, and that the selling price bears little relation to the sum paid to the original producer. But there is reason in all things, and we cannot but think that to charge eighteenpence for a picture that the photographer sells for twopence halfpenny, has very little logic in it. We do not say that the soft little landscape on its tinted card, with neat border and gold lettering, is not worth what is asked for it, but it is possible the sale would be quicker if the commercial community were satisfied with less profit.

Patent Intelligence.

Patent Void through Non-payment of Duties.

4607. Joseph Wilson Swan, of Newcastle-upon-Tyne, for an invention of "Improvements in apparatus for coating glass and other surfaces with gelatinous or viscous photographic compounds."—Dated 12th November, 1879.

Patents Granted in France.

148,516. Barrault, of Nemours, for "A screen for photographic operations."—Dated 17th April, 1882. Class 17.

148,652. Plener, for "A photographic emulsion."—Dated 28th April, 1882. Class 17.

148,660. Rouaix, of Paris, for "A photographic apparatus for superseding the camera obscura."—Dated 29th April, 1882. Class 17.

Certificate of Addition.

147,376. Lacroix, for "Photographic paper for obtaining proofs in dark lines on white ground."—Dated 27th April, 1882. Class 17.

Patents Granted in America.

267,095. Charles H. Mann, of Philadelphia, Pa., for "A drop shutter for instantaneons photography."—Application filed 28th July, 1882. No model.

267,227. WILLIAM KURTZ, of New York, for "A method of and apparatus for producing photographic images."—Application filed 6th June, 1882. No model.

TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. XI.—ESTIMATION OF HYPOSULPHITE OF SODA, OXALIC ACID, OXALATE OF POTASH, AND CHLORIDE OF GOLD.

HYPOSULPHITE of soda is frequently contaminated with sulphate of sodium and other salts, which are quite incapable of acting as fixing agents; it is therefore very important that the photographer should know how to estimate the amount of hyposulphite—or thiosulphate, as it now termed—contained in the commercial salt.

A standard solution of iodine and a solution of starch is required. To prepare re-sublimed iodine for the first-named solution, place in a small evaporating-basin about 15 grms. of pure iodine and 3 grms. of potassium iodide, cover the vessel with a rather larger basin full of cold water, and heat the lower basin gently over a sand-bath, when the iodine will vaporise and condense in grey crystals on the outside of the upper basin. The crystals should be occasionally scraped off with a glass rod, and preserved in a stoppered bottle, the water in the upper basin being changed at the same time.

Weigh out exactly 12·7 grms. of the above re-sublimed iodine, about 18 grms. of pure white potassium iodide, and dissolve in exactly a litre of water in the usual way. The solution must be kept in small bottles filled up to the neck, and always in a dark place, otherwise it soon loses its strength. The bottles should be labelled thus:—

Standard Solution.—Iodine.

1 c.c. = ·0127 grm. iodine.
,, = ·0248 ,, hyposulphite of soda.

The starch solution is made by pouring about 50 c.c. of boiling water on to about 5 grms. of pure white starch made into a paste with a little water. If 10 c.c. of alcohol be added to the solution, it will keep for about a month. In order to perform an estimation, weigh out exactly ·496 grm. of the sample of hyposulphite of soda, dissolve it in a small flask in about 200 c.c. of water, and add a few drops of the starch solution. Fill a burette with the standard solution of iodine, and allow the solution to slowly run into the flask containing the hyposulphite and starch, till a permanent blue colour is produced, showing that all the hyposulphite has been decomposed by the iodine, and the slight excess colours the starch blue.

To calculate the result, multiply the amount of hyposulphite (which is equivalent to 1 c.c. of the iodine solution) by the number of c.c. run out of the burette; the product is the amount of pure hyposulphite contained in ·496 grm. of the salt tested. Thus, supposing 19·5 c.c. of iodine solution was run out of the burette, ·0248 multiplied by 19·5 equals ·4836, the amount contained in ·496 grm. of the sample, which is equivalent to 97·6 per cent.

For estimating gold chloride, oxalic acid, and oxalate of potash, a standard solution both of oxalic acid and potassium permanganate is required.

For the first solution, pure re-crystallized oxalic acid must be prepared, and thoroughly dried in several pieces of bibulous paper, taking care to use the acid as soon as possible, otherwise it will slowly effloresce. Weigh out exactly 63 grms. of the pure acid, and dissolve it in the usual way in a litre of water. The solution will keep well and should be labelled thus:—

Standard Solution.—Oxalic Acid.

1 c.c. = ·063 grm. oxalic acid.
,, = ·092 ,, neut. potassium oxalate
,, = ·0316 ,, potassium permanganate.
,, = ·101 ,, gold chloride.

To prepare the second standard solution, weigh out exactly 31·6 grm. of pure potassium permanganate, and dissolve it in the usual way in a litre of distilled water. If the salt be perfectly pure, 10 c.c. of the solution should be exactly equal to 10 c.c. of the standard solution of oxalic acid; but as the solution is very liable to be somewhat weaker from the presence of impurities in the permanganate of potassium, it is necessary to standardise the solution before using it. Fill a burette with the permanganate solution, place exactly 10 c.c. of standard oxalic acid in a flask with 2 or 3 c.c. of dilute sulphuric acid (1 : 4) and about 500 c.c. of distilled water. Warm the contents of the flask to about 140° F. (60° C.), and run the permanganate from the burette into the flask, till a permanent pink colour is produced in the solution, even when heated till nearly boiling. If exactly 10 c.c. is required, the solution should be labelled—

Standard Solution.—Potassium Permanganate.

1 c.c. = ·0316 gram potassium permanganate
,, = ·092 ,, neutral potassium oxalate
,, = ·063 ,, oxalic acid

If more than 10 c.c. of permanganate solution be required, in standardising, the above numbers must be multiplied by 10, and the product divided by the number of c.c. of permanganate required to produce the pink colour. Thus, supposing 10·1 c.c. were used in the above experiment, in order to calculate the amount of potassium permanganate really contained in the solution, we first note that in the above label 1 c.c. = 0316, therefore ·0316 multiplied by 10 equals ·00316, and ·00316 divided by 10·1 equals ·031179, the exact amount of permanganate contained in 1 c.c.

In order to analyse commercial samples of oxalic acid, weigh out 1·26 grm. of the substance, dissolve it in about 300 c.c. of water with 2 c.c. of dilute sulphuric acid, and heat to about 140° F. Run the above permanganate standard solution in the usual way out of a burette into the solution till a permanent pink colour is produced.

To calculate the result, multiply the amount of oxalic acid which is equal to 1 c.c. of permanganate, by the number of c.c. run out of the burette; the quotient is the amount of pure oxalic acid contained in the weight of the substance originally taken. Thus, for example, 1·26 grms. of commercial oxalic acid was used, and 19·5 c.c. of permanganate (same strength as the above label) was run out of the burette; therefore 19·5 multiplied by ·063 equals 1·2285 grms, the amount contained in 1·26, or 97·6 per cent. To analyse oxalate of potassium by this process, dissolve 1·84 grms. in 300 c.c. of water, add 5 c.c. of dilute sulphuric acid, and proceed as in the above method.

For example: 1·84 grms. was used, and 19·8 c.c. of standard solution of permanganate required to produce the pink colour, therefore 19·8 multiplied by ·092 (the amount of oxalate of potassium which is equivalent to 1 c.c. of the standard solution) equals 1·8216 grms., the weight of pure potassium oxalate contained in 1·84 grms. of the substance. If the sample shows an acid reaction, the percentage may, on analysis by the above process, appear to be over a hundred, from the presence of an excess of oxalic acid in the salt.

To analyze chloride of gold, weigh out 1·01 grm. of the sample, dissolve it in about 10 c.c. of water, add 15 c.c. of standard solution of oxalic acid, and add sufficient distilled water to make the volume up to exactly 300 c.c. Keep the solution in a warm place for about twenty-four hours, when the chloride of gold will be reduced to the metallic state, forming a deposit at the bottom of the vessel. When the reduction is completed, transfer 100 c.c. of the solution by a pipette to a flask containing about 300 c.c. of distilled water with 2 or 3 c.c. of dilute sulphuric acid, and run in from a burette standard solution of permanganate, as in the above process for estimating oxalic acid.

To calculate the result, multiply the number of c.c., run out of the burette by 3, and subtract the product from the number of c.c. of standard solution of oxalic acid, provided 1 c.c. of permanganate is exactly equal to 1 c.c. of the oxalic acid (otherwise, of course an allowance must be made for the difference); the remainder, when multiplied by ·101, equals the amount of pure gold chloride contained in 1·01 grm. of the sample.

NOTES ON PHOTOGRAPHY.

BY E. HOWARD FARMER.

LECTURE II.—THE EARLY HISTORY OF PHOTOGRAPHY AND THE DAGUERREOTYPE PROCESS.

A.D., 1556, the alchemists noticed that horn silver (fused silver chloride) blackened when exposed to the sun's rays.

1777, Scheele, the great Swedish chemist, discovered that silver chloride is very readily darkened by blue light, and very little, or not at all, by red light (origin of the employment of red glass in our dark-rooms). He also proved that when this darkening occurs, chlorine is liberated, and that the darkened salt acted upon by ammonia leaves a residue of metallic silver.

1801, Ritter extended Scheele's experiment. He found that silver chloride darkens in the space beyond the violet end of the spectrum, demonstrating the existence of rays which do not excite vision; these are now called the ultra-violet rays. Ritter also observed that the red (least refrangible) rays not only do not darken silver chloride, but that they actually whiten silver chloride that has been darkened in the blue (more refrangible) rays.

1802, Wedgwood, the great potter, and Sir Humphrey Davy, coated paper and leather with silver nitrate and chloride, and obtained profiles by the agency of light; they, however, could not fix the pictures thus produced.

1827, Niepcé came to England, and brought specimens of pictures taken in the camera. He discovered the property of light of rendering various resins insoluble.

1839, The Daguerreotype process was published. The same year Mr. Fox Talbot communicated his paper process to the Royal Society, and first produced negatives. Mungo Ponton also this year discovered that potassium bichromate, when on paper, alters in composition by exposure to light.

1840, the Rev. J. B. Reade accidentally observed the development of the latent image by gallic acid.

1841, Calotype process introduced by Fox Talbot (description postponed).

1843, Sir John Herschel first took pictures on glass, and recommended the use of hyposulphite of soda for fixing.

1851, Scott Archer and Dr. Diamond introduced the collodion process in a practical form.

The Daguerreotype Process.—A silvered copper plate is polished with tripoli and rouge and chamois leather buffs, until the surface is quite free from scratches, when it is exposed to the fumes of iodine for about three minutes, or until the surface presents a bright yellow colour; and then to bromine until it assumes a violet hue, when it is ready for exposure. After exposure no image is visible; but on placing the plate above mercury heated to about 150° F., it rapidly appears, the lights being represented by an amalgam of mercury and silver, and the shadows by silver. It is fixed by immersion in a 10 per cent. solution of hyposulphite. After washing, the image may be intensified by pouring on the plate mixed solutions (very dilute) of gold chloride and hyposulphite, and heating over a spirit lamp. The picture should be protected with a glass plate.

Theory of the Process.—The iodine (and bromine) attack the silver, forming a thin film of silver iodide (Ag I). On exposure to light this is reduced to sub-iodide—

$$2\ AgI = Ag_2I + I$$

The silver underneath the film acts as a sensitizer, combining with the iodine set free to form fresh iodide. On development the silver in the sub-iodide forms an amalgam with the mercury.

FRENCH CORRESPONDENCE.

OPERATORS' EXAMINATIONS—POITEVIN ON PHOTOGRAPHIC IMPRESSIONS—EXHIBITION OF DECORATIVE ARTS—TECHNICAL SCHOOL OF CHEMISTRY AND PHYSICS—M. BRETAGNE'S ENDLESS PELLICLES.

Examinations for Photographic Operators.—The Chambre Syndicale of Photography, at the last meeting on the 9th ult., fixed the date of the first session of examinations for operators for the second fortnight in March next. All applications should be addressed to M. Lévy, President of the Chambre Syndicale, 113, Boulevard de Sébastopol, Paris. Particulars of these examinations may be obtained of the Editor of the PHOTOGRAPHIC NEWS, in London, or M. Lévy, in Paris.

Second Edition of Poiteven's Work.—A second edition of the treatise on photographic impressions by Poitevin has just been issued from the house of Gauthier-Villars. This work is a complete abstract of the principal discoveries of this illustrious inventor. We have inserted appendices and notes rendering it very different to the former edition. Collectors of works relating to our art will not fail to provide themselves with this treatise, the historical and technical importance of which will not escape them. It is indispensable to all photographic libraries.

Closing of the Exhibition of Decorative Arts.—This Exhibition, the limit of which had been fixed for the 15th of November, has been prolonged to the 30th of the same month. The distribution of rewards has not taken place yet; we mentioned the names of the principal winners in our preceding letter.

Formation of a Technical School of Chemistry and Physics.—The Municipal Council of Paris has just founded a Technical School of Chemistry and Physics. The idea is excellent; but it seems to us that, if it is desirable to make it complete, there should be room in such a school for a special course relative to the industrial applications of light to the graphic arts. Photography receives aid from physics by the optical instruments employed; and from chemistry, by the processes and manipulations of which it makes use. The rôle played by photographic applications in the industrial arts is now considerable, since in France alone it amounts to the sum of thirty millions of francs. A course of this kind would naturally belong to the Conservatoire National des Arts et Métiers. It would, therefore, well fill its place in the municipal school in question. Without trespassing the boundaries of any other subjects, it would be, on the contrary, one of the special and immediately practical applications. We should be pleased to see this truly useful, but at present neglected, course of instruction organised at once.

M. Brétagne's Pellicles.—A Parisian photographer has just manufactured endless translucid pellicles—that is to say, of a length not exceeding six metres. These pellicles coated with gelatino-bromide constitute sensitive films perfectly suitable for panoramic reproductions. The panoramic apparatus destined for their use is in course of construction. The pellicle will unrol itself from one reel to roll round another while passing the focus of the lens, itself partaking of an equal circular movement, in such a manner as to reproduce by one continued movement circular panoramic views, and to print them afterwards in one piece, as the negative will be formed of one continuous band. Specimens of these pellicles which we possess show us that they are composed of gelatine allied to a substance capable of hardening it. LEON VIDAL.

CONCAVE GRATINGS FOR PHOTO-SPECTRUM WORK.

THE prism is fast falling into disuse as a means of producing a spectrum to be photographed, and, instead, the employment of gratings is becoming more general. The grating, so-called, consists of a number of finely-ruled parallel lines very close together, so that a beam of light striking them, becomes diffused. It has been the custom to produce these gratings on a plane surface, but photographs of the spectrum can be produced much more sharply and correctly, it seems, if the lines are ruled upon a concave surface. At the last meeting of the Physical Society, Professor Rowland, of Baltimore, exhibited a number of his new concave gratings for giving a diffraction spectrum. He explained the theory of their action. Gratings can be ruled on any surface if the lines are at a proper distance apart, and of the proper form. The best surface, however, is a cylindrical or spherical one. The gratings are solid slabs of polished speculum metal ruled with lines equidistant by a special machine of Professor Rowland's invention. The number of lines per inch varied in the specimens shown from 5,000 to 42,000, but higher numbers can be engraved by the cutting diamond. One great advantage of their use is that the relative wave-lengths can be measured by the micrometer with great accuracy. The author has designed an ingenious mechanical arrangement for keeping his photographic plates in focus, and by it pictures of great distinctness can be obtained. Professor Rowland exhibited some 10 inches long, which showed the E-line doubled, and the large B groups very clearly. Lines are divided by this method which have never been divided before; and the work of photographing takes a mere fraction of the time formerly required. A photographic plate sensitive throughout its length is got by means of a mixture of eocene, iodised collodion, and bromised collodion. Professor Rowland and Captain Abney, R.E., are at present engaged in preparing a new map of the whole spectrum with a focus of 18 feet.

In reply to Mr. Hilgar, F.R.A.S., Professor Rowland stated that if the metal is the true speculum metal used by Lord Rosse, it would stand the effects of climate, he thought; but if too much copper were put in, it might not. In reply to Mr. Warren de la Rue, he said that 42,000 per inch was the largest number of lines he had yet required to engrave on the metal.

Professor Guthrie read a letter from Captain Abney, pointing out that Professor Rowland's plates gave clearer spectra than any others; they were free from "ghosts" caused by periodicity in the ruling; and the speculum metal had no particular absorption.

Professor Dewar, F.R.S., observed that Professor Liveing and he had been engaged for three years past in preparing a map of the ultra-violet spectrum, which would soon be published. He considered the concave gratings to make a new departure in the subject, and they would have greatly facilitated the preparation of his map.

ANIMAL PHYSIOLOGY.

BY M. MAREY.*

An indispensable complement of the applications of photography to physiological researches is the authentic reproduction of images obtained, the easy printing of copies, and the possibility of interspersing them in the text of a book; these conditions have been realized in a very satisfactory manner by M. Petit, by means of a process which he calls *similigravure*. Two specimens of these prints will enable the reader to appreciate all the resources of applied photography to certain scientific demonstrations.

Fig. 1 shows the successive attitudes of a man walking at parade step, as it is called in our schools of military gymnastics.

MILITARY GYMNAST MARCHING AT PARADE STEP.

This figure is obtained by means of successive photographs on the same plate. I hasten to remark that the copy presents almost all the imperfections of the original negative. Thus, at the lower portion, the background is not of an intense black, and the attitudes of the legs and feet do not stand out well. This is due to defects in the screen in front of which the photographs were taken, its lowest part not realizing the condition of absolute black so well as above.

Across the fifth figure may be noticed a vertical white stripe; it is the trace of a post supporting the black screen. This post will disappear in the new arrangement I intend making with regard to the screen. My present apparatus does not yet permit of photographing the nude figure, the movements of gymnasts being difficult to seize under the folds of flowing garments.

However, such as it is, this print gives at the first glance a good deal of information. It shows that at each complete step the walker presents different attitudes; that the step was taken in three-fifths of a second, and that during the time the head made two vertical oscillations, the maxima corresponding to the centre of support of each of the feet, while the arm effects ample oscillations contrary in movement to the corresponding

Fig. 2.

leg. The successive phases of change of foot or leg may easily be followed, and in all these alterations one may estimate the real value of the displacement effected

* Read before the French Academy of Sciences.

between two consecutive images, in the space, say, of one-tenth of a second.

The second figure represents a white horse leaping over an obstacle. It was an old Syrian stallion, as a horseman would recognize from its aged form. The screen in this case has fewer imperfections than the other, but I hope in my future experiments to improve it still more.

LIGHT AND LIGHTING.

BY THOMAS H. KANE.*

The principles governing the illumination of the photographic model are matters of importance to the professional photographer, for without a proper knowledge of them it is impossible to work intelligently, or to solve the problems which are likely to occur in practice. Yet how few of us thoroughly understand these principles. Veterans who have grown grey in the service are equally as deficient in this respect as many of us of more recent date.

The valuable and instructive paper which Mr. Coonley read before the Association of Operative Photographers (see News, Nov. 3, p. 663), dealt principally with the quality of light There are other phases of this subject that will repay attention. In the illumination of the model, and the making of the negative in addition to the quality of light, it will be found necessary to give some attention to the volume or amount of light employed; its distribution on the subject; the direction from which it comes; the interior illumination of the studio; the relation of the sitter to both top and side-lights; the aspect of the sky; the manipulation of the light by curtains, screens, &c.

The aspect of the sky, the condition of the atmosphere, and the daily and yearly altitudes of the sun determine or modify the quality of the light, as was stated by Mr. Coonley. It sometimes occurs that light from a clear, unclouded, blue sky is less actinic than that from white or light-tinted clouds. A hazy, humid, or dingy atmosphere also affects the quality of light.

The angle at which the sun's rays meet the earth—in other words, the daily and yearly altitudes of the sun—must also receive attention in connection with the subject of actinism, for it involves the question of refraction, which, as is well known, implies a loss of actinic power, as is shown by the waning actinism of the solar rays during the autumn and winter. At these seasons the sun's rays enter our atmosphere at an acute angle and are refracted, giving the yellowish light which we have all observed; while during the spring and summer they fall on the earth at a greater angle, are less refracted, and possess greater actinic power, as we know.

The light is sometimes modified by other causes with which we are not acquainted. An illustration of this occurred about a year or so ago, when for a day or two the solar rays were of a pinkish tint. The phenomenon was very peculiar.

The quality and condition of the glass used for glazing the studio have a modifying action on the actinism of the light, as was explained by Mr. Coonley.

The amount of diffused or reflected light in the studio must be observed, as it plays an important though subordinate part. Where the sky and side-lights have been properly constructed, this point will not be of so much importance as it would be under an imperfectly-constructed skylight—as, for instance, a very high light. Unless the interior of such a room be sufficiently illuminated, the lighting of the model will, under certain conditions, be defective, especially in the shadows. An illustration of this is found in the difficulty experienced in photographing dark or dimly-lighted interiors.

The volume of light by which the model is illuminated is another point deserving of consideration. It is advisable to employ as much light as possible consistent with the attainment of the desired effect. In making this statement I do not wish to be understood as advising the use of a great flood of light from one or all directions. When the image on the ground glass appears flat, lacks roundness and softness, or does not show every detail, even to the minutest, it is probable that too great a volume of light is being used, or that some other detrimental agencies are at work. The part that a volume of light plays may be observed in a darkened room by admitting light through a door-way or window, with the door or sash opened to different widths. In a similar manner the same effect may be studied in the operating room by opening the top and side-light curtains to different widths.

* *Photographic Times.*

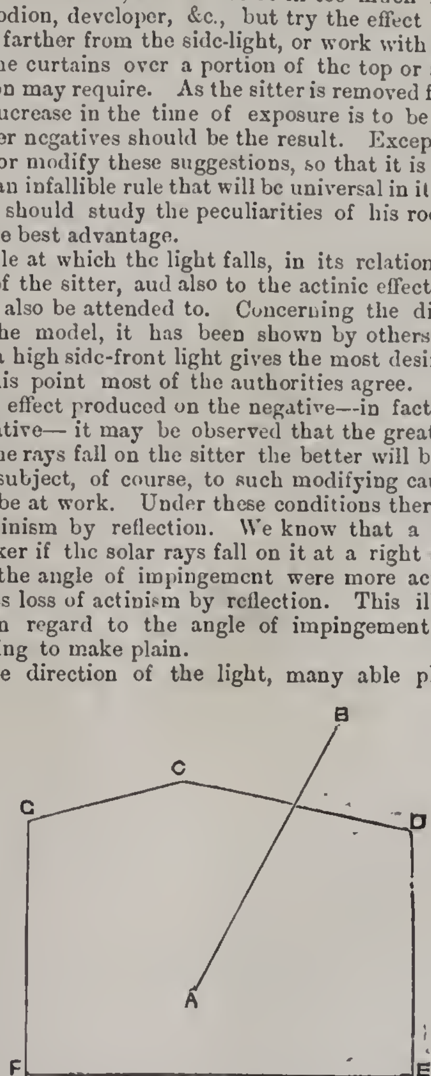
It seems desirable to sit the model in shade, not shadow, and then illuminate with either direct or diffused light as may be wished. The resulting effects of this mode of lighting are fine. A familiar illustration is found in the brilliancy of the stars at night, when the moon is not visible. In the increased light of the moon's beams this brilliancy is considerably diminished; in the blazing light of the sun this brilliancy disappears, and the stars themselves become invisible, while their contrast in twilight is not near so fine as in the deeper "shades of night." Some poet has noticed this, for he exclaims—

"How fair amid the shades of night
Appears the star's pale ray!
Before the sun's more dazzling light
It quickly fades away."

The relation of the model to the top and side-lights should also receive attention. Do not confine your sittings to a single spot unless there are good reasons for doing so. On the contrary, work all around the room as the occasion requires. In some studios a point from six to ten feet from the side-light affords a satisfactory distribution of light on the model, and the attainment of a proper actinic effect in the negative. If a negative has been properly timed, and the development proceeds too rapidly, and the fault be not with the chemicals, look for it in defective illumination, and do not be in too much haste to condemn collodion, developer, &c., but try the effect of removing the sitter farther from the side-light, or work with less light by drawing the curtains over a portion of the top or side-lights as the occasion may require. As the sitter is removed from the side-light an increase in the time of exposure is to be anticipated, while better negatives should be the result. Exceptional causes may alter or modify these suggestions, so that it is impossible to lay down an infallible rule that will be universal in its application. Each one should study the peculiarities of his room, and then work to the best advantage.

The angle at which the light falls, in its relation to the illumination of the sitter, and also to the actinic effect in the negative, must also be attended to. Concerning the distribution of light on the model, it has been shown by others that what is known as a high side-front light gives the most desirable results, and on this point most of the authorities agree. In regard to the actinic effect produced on the negative—in fact, the quality of the negative— it may be observed that the greater the angle at which the rays fall on the sitter the better will be the chemical effect, subject, of course, to such modifying causes, if any, that may be at work. Under these conditions there will be less loss of actinism by reflection. We know that a negative will print quicker if the solar rays fall on it at a right angle than it would if the angle of impingement were more acute, because there is less loss of actinism by reflection. This illustrates the principle in regard to the angle of impingement which I am endeavouring to make plain.

As to the direction of the light, many able photographers



C, D, E, F, G is a vertical section of a skylight room, of which C D is top light, D E side-light, E F floor, F G vertical wall. G C covered roof. A B is a plane besecting the top-light at a right angle, and A is the point referred to.

assert that a light from one general direction gives the best results. Hence it has been suggested in skylight construction to use a single sloping light, which would embody the properties of both top and side-lights. Without endorsing the single sloping light as the best form of skylight, but conceding its valuable features, the writer thinks that the principle enunciated concerning the direction of the light is correct, for it is not advisable to have a great volume of light from all directions falling on the sitter. If it be necessary to illuminate the model with light from more than one direction, the principal light must be stronger than the rest, and the others subordinate and subdued. Equally strong lights from various directions are likely to prove fatal to good work and correct illumination. Some operators curtain the upper half of the top-light, using the lower half and the side-light. Other equally able men, like Reutlinger, of Paris, curtain the upper half of top light and lower half of side-light, using the upper half of side and lower half of top-light for work.

One more point, and I will close. In every studio there are points where a maximum of actinic effect is attainable. Each one should endeavour to ascertain where those points are. In my room I have found them in a plane bisecting the top-light at a right angle. The diagram will, perhaps, make the matter more intelligible.

If these few beads "at random strung" will induce some of the abler members of the profession to still further discuss this subject of lighting, the purpose of this paper will have been accomplished.

Correspondence.

FOCUSSING SCREEN AND CARRIERS.

Sir,—In these days of dry plate photography, new ideas and suggestions follow each other in rapid succession.

My object in writing is to ask whether up to this time cameras have been made without focussing screens, as for indoor work with dry plates I certainly think this article a superfluity, insomuch as if the door of dark slide was made small enough to open inside the framework of the camera, it would be a more simple arrangement to have a plate of ground glass the exact size of sensitized plate, whereon to focus, placed in the carrier, this being removed and replaced by dry plate for exposures.

The above arrangements would, I think, have many advantages: firstly, the distance between lens and ground glass and lens and plate would perforce be identical; secondly, the image could be placed more surely in the exact position desired on plate; thirdly, it would facilitate work; and lastly, I may suggest, lessen cost of production.

If the idea is not in use, and you can find space for these few lines, possibly the suggestion may be of practical value.—Yours, &c., Fletcher Ritson.

COLD EMULSIFICATION WITH UNIFORMITY.

Dear Sir,—I will try and reply to Mr. Henderson's mis-statements in the order in which he makes them.

The first few lines of his letter I must pass by, as I cannot exactly grasp the meaning of them. He is clearer, however, when he says the debate waxed so warm that an adjournment ensued. Allow me to say the debate was, in my estimation, not warm, and that it was adjourned because of the lateness of the hour; moreover, the discussion was only upon side issues (green fog, &c.), which I had referred to in a foot-note, added two or three weeke after the paper was written, principally to make my meaning clearer.

I did not represent that your correspondent claimed the originality of the cold method, &c. My paper was a comment upon two communications to our Association (see Photographic News, August 18th, and October 6th). I was referring only to the particular process under consideration, which had nothing whatever to do with the question of who first emulsified cold. If anyone cares to take the trouble to turn to p. 487 of the News, and then to p. 170, "Photography with Emulsions," he will see that the processes are practically the same, *except* that Mr. Henderson uses alcohol, which I maintain deters, if it does not prevent, exalted sensitiveness. I think the similarity of the processes quite justifies what I said, that "there is little that he can claim as his own in this method."

Then your correspondent says he thinks it needless to analyse all my statements. He shows, probably, more judgment in that sentence than in the whole of the preceding and following ones.

There is no joke, good or bad, in the statement as regarding plates made with gelatine that has been in contact with ammonia suffering from green fog. I hope to find time shortly for a communication upon this subject.

The next sentence is again foggy. I confess I don't know what it means.

Then your correspondent claims to be the first who used ammonia in emulsions (he does not say for what purpose). I know nothing of the Brittlebank meetings, but, if my memory serves me well, it was Dr. Monckhoven who first *published* a working process wherein it was used. If your correspondent can establish prior claims to its publication, he will probably thank me for giving him the opportunity; if he worked it only in secret, the less said about it the better. As to his statement concerning green fog—cause and cure—albeit he trumpeteth as loudly as Jumbo, I must ask your readers, for the present at least, to take it *cum pound-and a-half-o salis*.—I am, yours truly, Alfred J. Brown.

A FORTUNATE PHOTOGRAPHER.

Dear Sir,—In your valuable paper of September 29, which has just come to hand, you state that "a guinea a dozen—or, rather, a guinea for ten cartes-de-visite —is the highest price charged in any photographic establishment in London at this time, or indeed anywhere." I am at the present moment getting £2 per dozen, and sometimes £2 10s., for cartes-de-visite; cabinet portraits, £3 per dozen. Half-a-dozen cartes are charged £1 10s.; and half-a-dozen cabinets, £2.—I remain, faithfully yours, J. Trim.

Kimberly, Diamond Fields, South Africa, November 2.

TIME OF EXPOSURE.

Sir,—I notice in your report of the meeting of the Edinburgh Society of October 4th, that one of the members advised employment of mechanical means to correctly indicate time of exposure, and Mr. W. Crooke, in his paper read at the meeting, gives instructions to the beginners to commence to count "one" as the cap is taken off the lens, and "two, three" for an exposure of two seconds.

A better method, by which exposure can be judged easily to one quarter of a second, is as follows:—Any person who plays in an orchestra (especially the big drum) has occasional "rests," in which several bars have to be counted. This is done by counting the bars 1,2,3,4—2,2,3,4—3,2,3,4, &c., for as many bars of rest as may be indicated by the score.

Most persons will find, on trial, that to ejaculate the words *one, two, three, four, five*, as quickly as possible, will occupy one second of time. Some persons can ejaculate only up to four, some up to six.

By timing ourselves by a watch, and counting up to 1,2,3,4 or 5, or 6, as the case may be, a few times, we can easily ascertain our average, and know to a nicety the pace at which we can form the words audibly or inaudibly.

I can myself count up to twenty seconds, and be pretty sure of arriving at the close within half a second of truth; and as I only count four to the bar, I can expose to exactly one-quarter of a second.

The plan is by no means new, but it is simple and useful. The words can be inaudibly ejaculated, and an emphasis on the leading numeral aids in eliminating chance of error.—Yours faithfully, J. C. Hannyngton.

Proceedings of Societies.

The Postal Photographical Society.

At a committee meeting held Nov 18, at 21, Ladbroke Grove, W., the following resolutions were passed:—

1. That the Committee, having before them the competition

prints, and having regard to the number in each class sent in and the quality of the work shown, authorise the Hon. Secretary to expend out of the funds of the Society 15s. for two prizes of 10s. and 5s. each for the first subject (landscape) ; 5s. for a prize for the second subject (portrait) ; and 7s. 6d. for a prize for the third subject (the set subject), such money to be spent upon something of a photographic character selected by the winners.

2. That the portfolio of competition prints be sent to each member twice, and that it shall be kept by each member for *one* clear day only the first time round.

3. Mr. J. Pocock was unanimously elected president in accordance with rule 6.

That a competition be invited among members for the spring : pictures to be sent lightly mounted before April 10th, 1883. That a prize be offered for the best view, one for the best portrait group or figure subject, and that a prize be offered for the best "set subject," the same to be a "winter subject," figure or view. That the prizes to be awarded should be proportionate to the number and excellence of the exhibits, the other conditions of competition to be the same as those of the current November competition.

5. That all members be requested to express their stops in terms of the focal length of their lenses, and not by numbers.

6. That it is desirable to send a frame of specimens of the Society's work to the Photographic Society's next exhibition. That members be asked to co-operate under the form of a competition, that any subject may be sent, the fitness for exhibition to be determined by the committee, and the names of chosen exhibitors will appear on their own work.

7. That when lists of the members are printed, all prize-takers be distinguished by an asterisk or otherwise.

London and Provincial Photographic Association.

At the meeting of the above held at the Mason's Hall Tavern, Basinghall Street, on the 23rd inst., Mr. Brigenshaw in the chair, the discussion adjourned from last meeting on Mr. Brown's paper on "Cold Emulsification" was continued.

Mr. Henderson said that in his opinion Captain Abney was the originator of cold emulsification, and that plates free from green fog could and had been produced even in the presence of ammonia, and he had letters which proved that many besides himself had been able to do this. As regards alcohol, he had long since published the effect of alcohol on emulsion, and the person whose name Mr. Brown had forgotten might be himself. Dr. Monckhoven, when advocating ammonia in order to hasten the formation of the most sensitive form of bromide of silver, points out that a high temperature produces fog ; therefore a low temperature is preferable to boiling, since by boiling ammonia is produced, a high temperature also tending to produce granularity. Though the credit of adding ammonia to emulsions is usually given to Dr. Monckhoven, Professor Stebbing had at a meeting of the French Photographic Society reclaimed the ammonia method for an Englishman. Mr. Henderson further said he did not find alcohol act as a powerful restrainer ; he had used in some cases as much as 80 per cent. without any evil effects. If mottling appeared from the use of a large proportion of alcohol, he soaked the plate in water before development, and the mottling disappeared.

Mr. Brown, in reply, said that the reason so many had succeeded with cold emulsification in the presence of so much ammonia was in his opinion due to the powerful restraining action of the alcohol present : he did not give the credit of cold emulsification to Mr. Cowan, but simply that he ripened his emulsion by keeping it some time in the presence of ammonia.

Mr. F. W. Hart thought that Mr. Johnson was the first to use ammonio-nitrate in the manufacture of gelatino-bromide plates.

Mr. Brown asked if alcohol in any way increased the sensitiveness of bromide of silver.

Mr. Henderson said that by its use he was able to produce a much finer division of the bromide of silver, and also greater speed.

A question was asked, "Why harder lighting was necessary with gelatine than with the wet process ?"

Messrs. Cowan and Debenham thought the reverse was the case.

Mr. Henderson said that greater contrast is necessary, and if the two processes were tried side by side, it would be found to be so.

The Chairman drew attention to the great resemblance between the picture in the *Art Journal*, 1872, vol. xi, new series, entitled "Cherries Ripe," by Metzmarcher, and "Cherry Ripe," of the late Pall Mall Exhibition, and remarked on the coincidence of similar ideas occurring to two different artists.

Mr. Mark Carey was elected a member of the association.

Glasgow Photographic Association.

A general meeting was held on 16th November, when the following business was transacted.

Messrs. Francis Kerr, George Y. Henderson, Patrick Falconer, and W. H. Queen were admitted members.

The Question-Box having been opened, the questions proposed gave rise to some discussion, after which

Mr. Norman Macbeth, R.S.A., read a paper on the "Art Aspects of Photography," recently communicated by him to the Edinburgh Society. The paper was received with marked attention, and the meeting unanimously awarded Mr. Macbeth a vote of thanks.

The Secretary intimated that at next meeting Mr. Mc Lellan would give a demonstration with his new Eclipse light, and members were invited to bring their own cameras to test its powers.

Talk in the Studio.

The Social Gathering or Intermediate Meeting of the Photographic Society.—On Tuesday last the principal subject brought under discussion was the best means of mending the minor defects of negatives ; and our readers will find in another column a full account of the remarks made on this subject. The now generally recognised advantage of enlargements from small negatives over extremely large direct pictures was considered, and it was remarked that on enlarging a gelatine negative, details often appear which cannot be traced in the original negative ; but a member said that all such can be readily traced by adopting the method of a powerful oblique illumination, so well known to microscopists. Mr. England referred to a trifling difficulty which sometimes presents itself in Alpine photographic work owing to the legs of the tripod becoming warmed by the solar heat, and then sinking steadily in the ice during exposure ; and he said that by resting the tripod on three small stones, all difficulty on this score might be easily overcome. Before the close of the meeting general dissatisfaction was expressed with respect to the use of the term "technical meetings" as a designation for the social gatherings, the term "technical meeting" being so universally understood to signify the annual gathering of the South London Society. Mr. Sebastian Davis, who occupied the chair, said that he naturally took some interest in the matter, as he had assisted Mr. W. Brooks in organising the annual technical meetings of the South London Society—these being now a thoroughly recognised photographic institution ; and in committee he had strongly opposed the adoption of the same title by the Photographic Society of Great Britain. The next social gathering will take place on Tuesday, December 19th, at eight o'clock.

South London Photographic Society.—Thursday next, December 7, being the annual meeting of this Society, the election of officers for the year ensuing will take place, and the general and financial reports be submitted. The decision of the judges with regard to the artistic competition will also be made known.

The Photographic Club.—The Annual Dinner of the Association, which took place on Wednesday evening, was one of the best attended at which we have been present, about fifty gentlemen being assembled. The Rev. F. F. Statham presided in his usual friendly manner, and the proceedings were diversified by music and recitations, a song and violin performance by Herr Behnke being especially approved of. We may mention that this gentleman is working in conjunction with the eminent surgeon, Mr. Lennox Browne, in order to obtain a series of photographic representations of the organs of the throat while being exercised in the production of the various musical notes. Herr Behnke obtained such throat pictures some twelve years ago, when using bath plates and the lime light ; but it is hoped that the old results will be far surpassed when gelatino-bromide plates are used in conjunction with the electric light.

Mr. Andrew Pritchard, F.R.S.E., died at his residence in St. Paul's Road, Highbury, on the 24th inst. Born in 1804, he devoted himself early to the study of the microscope and the minute animal world which it revealed. He published in 1827 a memoir "On the Art of Forming Diamonds into Single

Lenses" (Royal Institution), and subsequently fifteen other works and editions connected with microscopy. "A History of Infusoria," of which the fourth edition was published in 1861, is still a standard work of reference on the subject. He was one of the oldest members of the Royal Institution, with which he had been connected for nearly half a century.—*Times.*

The Newcastle Photographic Association.—At a recent council meeting of the Photographic Association, Mr. J. T. Dunn was appointed a vice-president, to take the place of Professor Marreco, and Mr. J. W. Robinson was elected to take the place of Mr. L. Davidson on the council.

To Correspondents.

*** We cannot undertake to return rejected communications.

"A Misty Morning on the Wear."—We believe the price you name for Mr. McLiesh's picture is that paid only by the members of the Newcastle Society; however, you had better write to him at Northgate, Darlington.

X. Z.—1. It is, as you suppose, owing to the fact of the acids not being of full strength. 2. Thanks for the suggestion.

Carbon.—If you will take the trouble to look back for two or three months you will find full details of the ingenious method by which double-headed and two bodied photographs, the so-called monster pictures, are ordinarily produced.

G. Rossi.—It is generally a result of over-emulsification, but sometimes results from the layer of emulsion on the glass plate being too thin.

E. C. Bath.—1. Benzole will soften it, but not bring it into a state of true solution. 2. A mixture of Canada balsam and turpentine.

S. W. O.—If you add less alcohol, say about a quarter of an ounce, the result will probably be satisfactory. You might also reduce the proportion of ether, and increase the benzole to a corresponding extent.

Constant Reader (York).—An india-rubber roller may be used instead of the usual leather lithographic roller; but it should be well vulcanised, and turned in the lathe to an exact cylinder.

Constant Reader (Islington).—1. Equal parts. 2. Heat in a water bath, by all means. 3 You might easily gather from the context that the work must be carried on in a non-actinic light.

G. R.—By cleaning them off, as suggested last week, and then finding someone to try the glass; we fear, however, that the latter process will prove more difficult than the former.

Studio.—1. Use light bars of T iron with the central web placed upwards (⊥), and so depthed as to come about an eighth of an inch above the floor-level. The most suitable wheels for running on these are cast iron plate pulleys, such as are used in window frames for the sash-line to run on. The actual guage of the tramway must depend on circumstances, but about eighteen inches will suit in ordinary cases. 2. The north side.

Pyro.—1. We hope to give them in abstract. 2. The book is now in the press. 3. Roscoe's "Elementary Chemistry," published by Macmillan and Co., would suit you very well.

Eighty.—Try a weak solution of potassium cyanide.

E. Turner.—From any stationer or dealer in fancy goods.

S. Comber.—1. All will depend on the wording of the agreement; but from what you say we should imagine that there may be some doubt as to the real meaning. 2. About one-tenth should be iodide. 3. It is so usual an impurity that it is rare to find a commercial sample entirely free from all traces. After neutralising the solution with nitric acid, add about one-fourth the quantity which was required for neutralisation. A few drops of chloride of barium solution are now added, and if sulphates are present to a considerable extent, a white precipitate will be formed immediately; but if traces only are present, the precipitate will only be deposited after some hours. The nitric acid should have been previously tested; but it is necessary to dilute with water, as strong nitric acid gives an immediate precipitate with a barium salt.

F. Fowler.—1. The action is almost instantaneous, unless a notable excess of a strong acid be present. 2. In such a case it is much more convenient to work on the film before varnishing. 3. About one-fifth part by volume.

Charles B——.—There is no legal aspect to the question, as it merely depends on gentlemanly feeling and politeness.

Printer.—Burn the cuttings in an ordinary fire-place, and reduce the ashes by the method you mention.

In Trouble.—The bath is almost certain to be alkaline under the circumstances, and it is probable that three drops of nitric acid to each pint will prove a cure. It should slowly redden blue litmus paper.

Dark Room.—You have evidently failed to dry your paper sufficiently, and there is very little chance of the mischief being remedied. Mop the surface with a solution of potassium cyanide, and wipe as dry as possible. Next remove the varnish by means of warm alcohol, and soak the plate in a weak solution of cyanide, say 1 part in 50 parts of water.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ¾ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1¾ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts. water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ¼-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints. *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ¾ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Encaustic Paste.—Best white wax 1 oz., oil of turpentine 5 oz.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1¼ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts. camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz.; dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1266.—*December* 8, 1882.

CONTENTS.

OUR SUPPLEMENT.

We have little to say in introducing Mr. McLiesh's picture to our readers, for its beauty speaks for itself. The fine outline of Durham Cathedral as we see it limned in the mist, across the placid water, is in delighful contrast to the strong branches and vigorous summer foliage through which the old North country pile is seen. Our illustration is the first, we hope, of a long series, which, if all goes well, will accompany these pages at regular intervals, whereby we shall bring vividly before our readers the progress of photography as an art, in the same way as we have striven hitherto to mirror its scientific aspect.

"A Misty Morning on the Wear," Mr. McLiesh assures us, is from a single negative, and that it was secured upon a gelatine film need scarcely be stated. It was a familiar picture to all visitors at Pall Mall this autumn—these can judge how perfect is the printing process by which it has been reproduced—and although it secured no medal, the Newcastle Society have done Mr. McLiesh the honour to choose it as their presentation print.

The "Ink-Photo" process of Messrs. Sprague and Co., of Martin's Lane, Cannon Street, by which the illustration is produced, has much to recommend it. In the first place, it is far cheaper than any other mechanical process which will reproduce a photograph from nature; and secondly, it admits of the most rapid printing. Doubtless a collotype impression could be produced of a more delicate character, but we should inform our readers that the impression before them is taken, not from the original negative, but from an ordinary silver print. Printing by collotype would be at once more costly and less rapid.

The "ink-photo" method is, as our readers will see, a species of lithography. Ordinary photo-lithography has been in use many years; but, as is well known, it is applicable to black and white lines only. In our picture, it will be seen that the entire image is made up of a kind of stipple, more or less dark according to the depth of half-tone and shadow. Once put upon the lithographic stone, the work of printing goes on apace, as many as 1,000 copies an hour being "pulled" if necessary.

The finest prints are obtained from a pale photograph with clean details—a much faded print frequently giving exceedingly good pictures—but the best and truest result is given by a carbon transparency. Messrs. Sprague and Co. have already issued some excellent illustrations in the *Engineer* and *Engineering*, and there is every likelihood of the process being extensively employed ere long in our illustrated periodicals.

GLASS.

Second Article.

In our former article we commented upon the importance of the use of a pure sand and its direct influeuce upon the colour of the resulting glass; but there are other considerations bearing upon the same issue which cannot be overlooked. In the early specimens of window-glass, the colour was almost invariably a dirty green colour, as witness the old glass in our cathedrals; which colour it is now our pleasure to affect—imitation of the antique being considered true art, whether it be to adorn the cathedral or the gin palace. As already stated, this dirty green colour was almost entirely attributable to the iron and other impurities in the sand; but the alkali employed to flux the sand has also much to do with the colour of the glass made therefrom. The earlier glasses were, no doubt, made by the use of kelp salts (burnt sea-weed), or potash (wood ashes), which contain a considerable percentage of iron, to say nothing of the impurities in the flint or quartz employed by our ancestors in their glass-making operations. During the present century the alkali employed by glass makers has been almost exclusively salt cake (sulphate of soda) employed in its crude state, just as it results from the decomposition of common salt by brown vitriol, this being effected in iron pans, and from which, as well as from the vitriol itself, considerable traces of iron are carried into the sulphate of soda, or, as it is termed, salt cake. A few words of digression may be permitted here to explain what probably not one Englishman in a hundred understands, viz., the manufacture of that article of everyday use—soda; whether as salt cake, soda ash (washing powders), carbonate of soda (soda crystals), or the white powder erroneously called carbonate of soda, but which is really the bi-carbonate of soda.

Perhaps sodium in its various forms is one of the most widely diffused substances to be found in nature. Spectroscopists know, to their annoyance, that the sodium band is seldom absent when least wanted; and if we reflect upon the millions of tons there must be in the waters of the ocean, we cannot help thinking that sodium plays an important rôle in the economy of nature, very difficult for us mortals to comprehend. However, the source whence we obtain our common alkali known as soda is ordinary salt—rock salt, simply refined.

If we take a handful of common kitchen salt, put it in any suitable vessel, and pour thereon a few ounces of vitriol (sulphuric acid), sulphate of soda is formed, and hydrochloric acid is given off. In the English chemical manufactories crude or brown vitriol is made by roasting "pyrites" (native sulphide of iron), and allowing the fumes to rise into large leaden chambers, where by the aid of steam, nitrous vapours, and atmospheric oxygen, complex reactions are brought about, after which the products condense and form sulphuric acid or crude vitriol. Into a large iron pan as much as half a ton of common salt is thrown, and then down a leaden spout a sufficient quantity of the brown vitriol is allowed to trickle so as to completely decompose the salt; hydrochloric acid gas is copiously evolved, and this is led off to a special arrangement to be condensed into liquid hydrochloric acid. The result of the action of the sulphuric acid on the chloride of sodium is sulphate of soda. The sulphate of soda is then roasted, and salt-cake, as used by the glass maker, comes out as the climax of this exceedingly simple chemical experiment. Salt cake, or commercial sulphate of soda, is a friable, white, cakey substance, with just the faintest trace of green when seen in a strong light. That trace of green, when seen as the curious stuff rides in truckloads through the sunlight as it is being shunted into the glass-works, signifies the presence of iron.

To follow the salt-cake until it becomes washing soda or bi-carbonate of soda, we must still a little further digress. The salt cake has now to be converted into black ash, and to effect this a certain weight of the salt-cake is wheeled in an iron barrow, and shot out on the floor, and mixed with another certain weight of small coal (termed slack) and of chippings of limestone (carbonate of lime). This agglomeration is then shovelled on to the horizontal floor of a furnace over which passes the flame of a fire which roasts the queer-looking mass. It bubbles and burns whilst the workman torments it with an iron bar until he gets it into a pasty condition. resembling a Brobdignagian plum-pudding, when he rakes out the seething mass into an iron wheel-barrow, in which it sets. It is then known as a black ball, but of a totally different sort to those occasionally employed by the members of the Photographic Club.

The said black balls (which, by the way, are square, and take the form of the interior of the iron wheel-barrow), are taken to the lixiviating vats, which are large iron pans, into which these square black balls are pitched, and hot water run in, which dissolves out the carbonate of soda; for the chemical reader will have gathered that the effect of roasting sulphate of soda in the presence of carbonate of lime has been to induce the carbonic acid to unite with the soda, the sulphur going to the lime to make what is known as alkali waste. The solution is now evaporated into soda ash, this is then dissolved, and the solution allowed to crystallize, when washing soda is the result. By this time the substance is carbonate of soda, and to convert this into the bi-carbonate, the crystals are packed in huge chambers into which carbonic acid gas is forced; the acid gas readily becomes absorbed by the crystals, which turn quite white, and when ground up and packed in barrels or kegs, the snowy white powder becomes the merchantable article properly termed bicarbonate of soda.

After reading this digression it may be said, "What has this got to do with the making of glass?" Well, it has very much indeed to do with the making of glass, for glass cannot be made without an alkali, and, for reasons of economy, either salt-cake or bicarbonate of soda must be used. It is only of late that the bicarbonate has been so used to any extent, for whereas salt-cake has been and still is used in many glass works, the price of bicarbonate of soda having fallen to a lower price than has ever hitherto been known (about £6 per ton), it has come much more into use than formerly, being preferred as giving a glass of purer colour than is obtained by the use of salt-cake.

It will now be comprehended that the alkali is quite as important an item as the sand was shown to be, and bi-carbonate of soda is as much superior to salt-cake as Belgian sand is to common sea sand, from a glass manufacturer's point of view. Indeed the question of cheap and pure alkali appears solved in the introduction of bi-carbonate of soda. The use of pot or pearl ashes, except for the highest qualities of glass, is quite out of the question, by reason of the price, which is many times that of the soda salt. In those countries where natural alkalies abound, and where a manufactured article such as soda would have to be imported, of course advantage is taken of the article nearest at hand; thus saltpetre, potashes, pearlashes, borax, and boracic acid find use in glass making, serving as fluxes of the sand, flint, limestone, or other principal ingredient. Here, however, recurs the previous question of the colour of the glass thus made. If one of the ingredients be impure, it will avail little if all the others are pure—we speak here of purity as the absence of iron—because all glasses are more or less degraded in tone by the presence of minute traces of certain metallic oxides, especially iron. Therefore, it will be pretty clearly conveyed to our readers that, as regards purity of colour—or, more correctly speaking, entire absence of colour—the first essentials are the employment of pure materials, and we have now shown that the sand and the flux should possess this property in the highest degree.

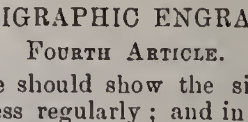
The foregoing remarks are directed mainly to the article of clear glass, such as crown glass, sheet glass, polished plate, or patent plate, all of daily use in a thousand requirements, and all employed in photography. Given, a colourless glass made from pure materials in their correct proportions, we can desire nothing better. Light would be transmitted practically unaltered, at least photographically, and if the glass remained colourless when exposed to light and air, which it does not always, we should then be able to modify it in a variety of ways to suit our further requirements, such as coloured or ornamented glass.

Probably no more glaring examples of impure glass can be found than are met with daily in the shape of common wine or beer bottles. These are often made from the crudest and roughest materials imaginable, so extremely inexpensive as to provoke a smile of incredulity when we are told the cost of a ton. But the fire, and the labour, and the carriage, and the profit, have all to be taken into the account; and however cheap the materials may be, even beer bottles cannot be made for nothing.

CHEMIGRAPHIC ENGRAVING.

Fourth Article.

The cleaned plate should show the sides of every line stepped more or less regularly; and in the case of a line standing fairly by itself—that is to say, at a considerable distance from other lines—a cross section in a vertical plane will show distinctly the step made by each etching, the edges of these steps being ordinarily sharp and well defined. The following arrangement indicates the configuration of a section taken at right angles to a line:—



These sharp angles, if not removed, would tend to take a charge of printers' ink from the roller, and to set it off on the paper during the process of printing; and it is usual to subject the plate to one or more subsequent etchings in order to clear away these objectionable asperities.

A hard lithographic roller is charged with a moderate amount of a special stiff ink; this may consist of ordinary letter-press ink, with about one-fourth of its weight of wax. When the ink has been properly distributed, the plate is very slightly warmed, but not so much as to in any way cause inconvenience if it be held in the hand for some minutes, and the plate is next carefully and steadily rolled in various directions with the inked roller; but care must, however, be taken that little or no pressure is employed, the mere weight of the roller being sufficient in ordinary cases. Under these circumstances the upper faces of the lines become covered with a complete protective layer of ink, and in order to cause this to flow down the sides of the first, second, or, at most, the third step, the plate is once more warmed; but it is as well to ink it once more when it has become nearly or quite cold. After this it is dusted with the asphalt powder, and a gentle heat is applied, so as to cause the ink and asphalt to thoroughly unite, and to flow down a little farther than was the case with the ink, it being generally safe to cover the first four or five steps. A test line is now made on one of the edges of the plate, and a mixture of one part of nitric acid and forty parts of water is used as before for etching. The action may be allowed to continue till the test line shows a depth of about half a millimetre, after which the plate is washed, dried, and thoroughly cleaned, as after the final etching of the first series. The clean and dry plate is now once more inked; but this time it should not have been previously warmed, and the greatest care should be taken not to allow any ink to flow down the sides of the relief. Once more the surface of the plate is dusted with asphalt powder, and very gently heated, but not sufficiently to cause the ink to become completely incorporated with the asphalt, or to run down the sides of the steps. All is now ready for the final etching, which is intended to round off the angles of the first, second, third, and fourth steps. One and a-half parts of nitric acid with forty of water will prove about right as regards strength, and one minute to a minute and a-half is generally sufficient.

Once more the plate is cleaned with turpentine or benzoline, and certain mechanical operations are required to fit it for use. In the first place, those portions bearing no part of the device are cut away with drill, saw, and chisel, so that the shape of the plate roughly corresponds with the outline of the device, after which any other widely-extending whites should be cut out in a similar manner. The next step is to mount the plate on a block of wood, so as to bring it to exactly the usual type height; the most convenient way of fastening it down to the wood being by means of small wire nails. Any considerable portion of the wood block which may extend beyond the plate should be shaved down, so as to slope towards the margin. The block is now ready for the printer; or, if the photographer wishes to print from it himself, he must obtain a small press and inking roller. Care and observation will enable him to obtain good impressions without any special instruction; but if he can spare half-an-hour with a good pressman who is "making ready" for printing from a wood engraving, he will gain some ideas which will, at any rate, serve to help him in his progress as a typographic printer. There are several small and popularly-written hand-books of letter-press printing, either one of which may be useful to the chemigrapher.

Our fifth and final article on chemigraphic engraving will deal with the method of printing directly on the zinc plate by the asphalt process of Niépce.

PHOTOGRAPHY AND THE TRANSIT OF VENUS OF 1874.

As our readers know, the value of photography in observing the transit of the planet Venus across the sun has been a moot question for some time past. The American astronomer still holds vigorously to the worth of photographic results, but in England the opinion is divided. Our contemporary, *Nature*, gives an interesting account of the manner in which photography was employed by various nations in 1874, and the results obtained. A perusal of this at once shows why all do not agree on the importance of the camera as an observing instrument. Speaking of this 1874 transit, our contemporary remarks that while all astronomers decided upon employing photography, there was much difference of opinions as to how it should be applied.

The European astronomers preferred instruments modelled upon the Kew photo-heliograph, whose objective has 3·4 inches aperture and 50 inches focus, giving an image of the sun 0·482 of an inch in diameter, which is enlarged by a secondary magnifier to 3·93 inches. On the other hand, the American astronomers contended that photographs taken with such instruments would be affected by troublesome errors due to the secondary magnifier, that position angles could not be measured from them accurately enough to be of any use, and that it would be exceedingly difficult to determine the exact linear value of a second of arc. They advocated the use of horizontal photo-heliographs, which are free from all these disadvantages; and the instruments which they adopted had apertures of 5 inches, and focal distances of 38½ feet, giving images of the sun slightly more than 4 inches in diameter. Notwithstanding this radical difference of opinion respecting the best form of photo-heliograph, the astronomers of the old and new worlds were in perfect accord as to how the instruments should be employed. Between the first and second contacts, and again between the third and fourth contacts, photographs about five minutes square, showing the indentation cut by the planet into the sun's limb, were to be taken at intervals of a few seconds; and from these it was hoped the true times of contact could be deduced with great accuracy. Between the second and third contacts, pictures of the entire sun were to be taken at short intervals, and the positions of Venus relatively to the sun's centre were to be obtained from them by subsequent measurements. In the latter case, the photo-heliograph took the place of a heliometer, and was superior to that instrument in its power of rapidly accumulating data.

The question of instrumental outfit having been disposed of, stations were selected, and parties dispatched to almost every available point. The United States, England, France, Germany, Russia, Holland—in short, nearly all the nations of the civilised world—took part in the operations. The weather was not altogether propitious on the day of the transit, but nevertheless a mass of data was accumulated which will require years for its thorough discussion. When the parties returned home the contact observations were first attacked, but it was soon found that they were little better than those of the eighteenth century. The black drop, and the atmospheres of Venus and the Earth, had again produced a series of complicated phenomena, extending over many seconds of time, from among which it was extremely difficult to pick out the true contact. It was uncertain whether or not different observers had really recorded the same phase, and in every case that question had to be decided before the observations could be used. Thus it came about that within certain rather wide limits the resulting parallax was unavoidably dependent upon the judgment of the computer, and to that extent was mere guesswork. Attention was next directed to the photographs, and soon it began to be whispered about that those taken by European astronomers were a failure. Even yet I am not aware that the Germans have published anything official on the subject; but the English official report has appeared, and it frankly declares that "after laborious measures and calculations it was thought best to abstain from publishing the results of the photographic measures as comparable with those deduced from telescopic view." From the way in which these photographs were taken, Sir George Airy saw that they could not yield position angles of any value, and therefore differences of right ascension and declination could not be determined from them; but they did seem capable of giving the distance between the centres of Venus and the sun with considerable accuracy. Upon trial this proved not to be the case. No two persons could measure them alike, because "however well the sun's limb on the photograph appeared to the naked eye to be defined, yet on applying to it a microscope, it became indistinct and untraceable, and when the sharp wire of the micrometer was placed on it, it entirely disappeared." In short, the British photographs are useless for the present, but Sir George Airy hopes that in the future some astronomer may be found who will be capable of dealing with them.

We turn now to the American photographs. They present a well defined image of the sun about 4·4 inches in diameter, and are intended to give both the position angle and distance of Venus from the sun's centre. A special engine was at hand for measuring them, but when they were placed under the microscope only an indistinct blur could be seen. Here again was the same difficulty which had baffled the English, but fortunately its cause was soon discovered. The magnifying power of the microscope was only 37½ diameters, which seemed moderate enough, but was it really so? The photographic image of the sun was about 4·4 inches in diameter, and this was magnified 3·31 times by the objective of the microscope, thus giving an image 14·56 inches in diameter. To yield an image of the same size, a telescopic objective would require a focus of about 1,563 inches, and if the eye-piece of the microscope, which had an equivalent focus of 0·886 of an inch, were applied to it, a power of 1,764 diameters would be produced. This then was the utterly preposterous power under which the image of the sun was seen when the photograph was viewed through the microscope, and no useful result could be expected from it. Means were immediately provided for reducing the power of the microscope to 5·41 diameters, and then the photograph seen through it appeared as the sun does when viewed through a telescope magnifying 255 diameters. After this change, all difficulty vanished, and the photographs yielded excellent results. The measurements made upon them seem free from both constant and systematic errors, and the probable accidental error of a position of Venus depending upon two sets of readings made upon a single photograph is only 0·553 of a second of arc. To prevent misunderstanding it should be remarked that this statement applies only to pictures taken between second and third contact, and showing the entire sun. The small photographs taken between first and second contact, and again between third and fourth contact, proved of no value.

These investigations consumed much time, and before the result from the American photographs was generally known, an international convention of astronomers was held in Paris to consider how the transit of 1882 should be observed. The United States was not represented at this conference, and, guided only by their own experience, the European astronomers declared that photography was a failure, and should not be tried again. They knew that the contact methods are attended by difficulties which have hitherto proved insurmountable, but under the merciless pressure of necessity they decided to try them once more. Unfettered by the action of the Paris Conference, the United States Transit of Venus Commission took a very different view of the case. Its members knew that the probable error of a contact observation is 0·15 of a second of arc, that there may always be a doubt as to the phase observed, and that a passing cloud may cause the loss of the transit. They also knew that the photographic method cannot be defeated by passing clouds, is not liable to any uncertainty of interpretation, seems to be free from systematic errors, and is so accurate that the result from a single negative has a probable error of only 0·55 of a second of arc. If the sun is visible for so much as six minutes between the second and third contacts, by using dry plates thirty-six negatives can be taken, and they will give as accurate a result as the observation of both internal contacts. These were the reasons which led the American Commission to regard photography as the most hopeful means of observation, and thus it happens that the astronomers of the old and new worlds differ radically respecting the best means of utilizing one of the most important astronomical events of the century. The Europeans condemn photography, and trust only to contacts and heliometers; the Americans observe contacts because it costs nothing to do so, but look to photography for the most valuable results.

By-the-Bye.

PHOTOGRAPHIC PRINTING BY THE ELECTRIC LIGHT.

SOME experiments we have recently made in printing with the electric light may have interest for our readers, albeit they are not likely, at any rate for some time to come, to resort to electricity as a general printing agent. As many of our readers know, photographic printing is no novelty. A dozen years ago, when the Woodbury Printing Company were installed at Hereford Lodge, Kensington, a powerful magneto-electric machine found a place among the apparatus to be employed for printing the gelatine tissue when lack of daylight might otherwise bring work to a standstill. The power of this light was, if we remember aright, about 1,200 candles; it was frequently made use of, but we believe, in the end, that daylight was found quite sufficient to produce all the gelatino-reliefs needful, and consequently the more expensive method of light-making fell into disuse. Compared to sunlight or daylight, this electric lamp was very weak, for at the short distance of eighteen inches from the carbon prints, chloride of silver paper was blackened but slowly; indeed, the actinic power exerted was reckoned to be but $\frac{1}{24}$ that of sunlight on a summer's day.

Another photographic use has, however, recently been found for the electric light. The importance of photo-etching to the publishing trade has caused those who undertake such work to avail themselves of electricity for taking negatives, and also for printing upon gelatine paper to secure the necessary transfer. Any picture or engraving in an illustrated paper may be copied by the photo-etching method without difficulty, and a publisher eager to reproduce an illustration from a foreign paper may have an engraving block in his possession within twenty-four hours of snipping out the print with a pair of scissors. Nay, in some cases, a firm will undertake to deliver the printing block in three hours. The chosen print is set up flat on a drawing board, the electric light is directed towards it, and a negative—the wet collodion process is still generally used—is taken in a few seconds. The plate is quickly intensified, put into the printing frame, and, if it is night time, printed by electric light. The transfer is then made, it is laid successively upon stone and upon a zinc plate, and the latter finally etched in acid.

In some cases enlargements are made by the photo-etching process to serve as placards, the size of the original print being multiplied to monster dimensions.

Of the employment of the electric light for taking negatives in this way we shall speak at some future time; on this occasion we confine ourselves to discussing its action upon chloride of silver paper, and paper treated with salts of iron, as in the Herschel or Pellet process. To get printing power sufficient for practical purposes it is necessary to have an arc light of considerable energy, and to employ the direct rays. In producing portraits by electricity, Van der Weyde and others who have followed in his footsteps, although they, too, employ powerful arc lights—from 6,000 to 10,000 candles—do not use the direct rays, but shield these from the sitter by a saucer placed immediately under the source of light. The rays are cast upwards against a parabolic reflector, fashioned like a huge umbrella, and then reflected downwards upon the model. In printing, there is nothing to be gained, but, indeed, much to be lost, by getting rid of the direct rays, and hence the plan usually adopted is to employ the naked light, with a sheet of white paper or other simple reflecting surface behind it.

The light with which we made experiment was of 6,000 candle power. It was a lamp of Messrs. Siemens' construction, worked by a dynamo of their make, which required for its driving an engine of four-horse power. It was our object more especially to ascertain whether the electric light could be employed with any degree of success for printing tracings, and diagrams by the Pellet process, which, compared to silver printing, is somewhat slow. In fact, it would not be far wrong to set down the comparative sensitiveness of silver and iron as represented by the figures 4 and 1.

The distance at which we tested the light was five feet from the carbons. Distance, as everybody knows, plays a very important part in photometric experiments, the intensity of the light decreasing as the square of the distance; so that at $2\frac{1}{2}$ feet from the source of light, this would be four times as powerful as we found it at 5 feet. We chose the latter, however, because tracings and drawings are frequently of large dimensions, pressure frames from 4 to 6 feet in length being sometimes employed in this branch of photography. By placing these upon a movable stand, so that the printing frames are not at rest during the printing, the electric light, even when direct rays are used, can be made to print with uniformity.

A light screen graduated in squares from 1 to 25, such as Mr. Warnerke has recently introduced, was used for making the test. Employing chloride of silver paper to print upon, it was found that in fifteen minutes the number 20 was faintly legible. Unfortunately, the fixing bath dissolves away a faint image very completely, so that the result was only equal to a pale 15 in a fixed and washed print. We are not able to say how quickly a summer's sun would produce a similar print, but on a fine day in mid November at noon, with the sun shining, two minutes and a-half was sufficient to give a like impression. With the sun behind the clouds on the same fine day, and also about noon, ten minutes were necessary to secure what the electric light furnished in fifteen minutes. So we may take it that a 6,000 candle arc lamp, at 5 feet, gives from half to two-thirds the light afforded by an Autumn day at noon without sun, while in the sunshine six prints could be got off, for every one by the electric light.

At two and a-half feet distance, we should get very much quicker results; the printing would go on at least twice as quickly as on an autumn day without sun, but in order to get a light as intense as autumn sunlight, the printing frame would have to be placed at a less distance than two feet.

Printing by the electric light is, therefore, decidedly practical, if it is only worth while to employ it. We have said that chloride of silver paper is about four times as sensitive as the iron process; and, practically, we found that half-an-hour was necessary to produce a Pellet print—that is, employing an ordinary draughtsman's tracing in place of negative—at a distance of five feet from the carbons. With a little management, several big frames may be set printing at one time around an electric lamp, and by changing their places during exposure, the printing action proceeds with considerable evenness over the whole surface.

It is, however, only for special work, obviously, that electricity can be used for printing, since the expense of a powerful light is considerable. Still the advantages are many, especially when it comes to printing with iron or bichromate salts, as in the case of making transfers for the photo-etching process. In both cases, it is impossible to judge with the eye alone as to the progress of the printing. Now, as the illumination from an electric light is practically constant, it is only necessary to reckon by time in order to get a print of the right character. One of the greatest difficulties in both the iron and bichromated gelatine process is thus overcome, and it is possible, with a little care and attention, to produce prints one after the other in succession, all of the same nature as regards depth of printing. The same holds good in the making of negatives in the camera with the electric light; given a certain distance from the object to be copied, a certain lens and a certain diaphragm, the exposure may be reckoned with accuracy, provided, of course, the sensitive film is to be trusted.

FRENCH CORRESPONDENCE.

Photography and Postage-Stamps—Studio for Nature-Printing at Lyons.

Photography and Postage-Stamps.—The Bank of France has always made strenuous efforts to issue bank notes rendered incapable of reproduction by photography; and if it has not succeeded absolutely to prevent counterfeiting, it has, at any rate, made it very difficult. It might be well to ask why the Postmaster-General has not endeavoured to hinder the forging of postage-stamps, which are so easy to reproduce with the camera, and afterwards engraved by means of one of the ordinary processes of photo-engraving? Some months ago it was stated in the newspapers that a great deficit was found in the sale of postage-stamps, and it was attributed to the use made of obliterated stamps, all traces of obliteration being made to disappear. We have tried washing used stamps, but we have not succeeded without the aid of some other substance and, without certifying that this washing is impossible, we do not think that by this means any great risk of fraud exists. It would be so easy to reproduce stamps and print new plates, that we cannot conceive so much time being spent over cleaning the old ones. In fact, the operations of reproduction and engraving offer no difficulties whatever; and the typographic negative once obtained, what can be easier than printing and finally perforating? Photography, perhaps, accomplishes the copying and engraving without the help of an artist; and, as to the printing, a simple typographic press suffices. With the State, however, in order to realise several thousand francs in stamps, great quantities must be issued. The deficit of many tens of thousands of francs cannot be attributed to the washing of obliterated stamps, but more likely to an ingenious photographic counterfeit. Many establishments deliver articles, stamps being returned to the required amount as payment; and this is a method by which hundreds of francs are circulated daily. The postage-stamp is, in fact, a recognised, if not a forced form of paper money; and it seems to us worth while taking some precautions against counterfeiting. We have remarked that English stamps are printed on paper bearing a water-mark, a step in advance of France, where the paper is simply tinted, and does not in that respect hinder the exercise of fraud.

Nature Printing at Lyons.—An establishment for photo-painting has just been set up at Lyons by M. A. Durond, who acts as director. He has invented a process of oil painting on the back of prints or albumenized paper. When painted, the prints are heated in an oven at the temperature of 90°, when all the volatile portions of the oil, fatty essences, &c., are eliminated from the prints, upon which the colouring matter alone remains. By this means the freshness of the colour is preserved, and the photographic image, according to M. Durond, will also resist the action of time. No doubt the presence of an oily body in close contact with the print would preserve it from the damp. This process is patented under the name of *Photonature*,* and it is proposed to execute prints in colour at the same price as those in monochrome. We shall see how this affair will proceed. The opening of the studio is fixed for the 10th inst. A similar one will shortly be organised in Paris.

Leon Vidal.

THE POSTAL PHOTOGRAPHICAL SOCIETY.

The honorary secretary of this Society has been good enough to forward for our inspection a most interesting collection of prints contributed by members, and which forms "Competition Portfolio" No. I. We may here recapitulate what it is the Society strives to do. The want having been felt by many ardent amateurs scattered up and down the country of some means of intercommunication and of comparison of the work they were doing with that being done by others, and the then existing societies mainly located in large towns and centres failing to assist this large class, who lived, for the most part, in country places, it was thought a society which could circulate its members' work by post from place to place and from door to door might have a *raison d'etre*; and though the Society only dates from the 1st July, it now numbers some thirty members, with representative members in all three Kingdoms and in the Principality.

The contributions now under consideration have been sent to the secretary in accordance with an announcement made that prizes would be offered in (1) landscape, (2) portraiture, and in a "set subject" which was "A Rustic Group," such as a painter would introduce; "The Mill;" "Family Troubles," or, "In Doubt." The idea of such a competition was founded on similar competitions familiar to members of sketching clubs, and with a view to encourage a pictorial resource and inventiveness among the members.

* See our Patent List this week.

The forty odd prints, some of considerable excellence, and all of credit to the amateur contributors, amply justify the originators of the scheme, and the collection will now circulate by post to all the members, who are, as it were, their own judges. For with the portfolio is a book for amateurs, and an ingenious plan is adopted by which every member has three votes in each class—one vote for the picture he thinks shows the best negative, one for the best print, and one for the best pictorial composition. The prizes will be decided by the votes, and the committee have determined on giving a second prize for the landscape shown, and also on repeating the competition, prints to be sent before April 10. The first two subjects are the same in this next competition, the set subject being "a winter subject" (view or figure).

We are asked further to say that the first album of contributions is still on its rounds, that the second is ready and will start as soon as the portfolio has got clear ahead, and that the third is now in course of preparation from the prints already sent. The note-book accompanying the first album has been copiously used by members, and the criticisms, though sometimes pungent, are extremely instructive. All members were asked to note down in it, experience in the various intensifiers and in the methods of obviating halation or blurring, and some very practical remarks have resulted.

The name and address of the Hon. Sec. is H. H. Cunningham, B.A., 7, Fig Tree Court, Temple, E.C.

NOTES ON PHOTOGRAPHY.

BY E. HOWARD FARMER.

Lecture III.—Principles Involved in Representing Chemical Changes by Means of Formulæ, etc.

Matter may be defined as that which occupies space and possesses weight; it can neither be destroyed, created, nor transmuted.

Matter exists in three principal physical states called respectively solid, liquid, and gaseous. Solid matter may again be divided into three principal kinds, viz., amorphous, crystalline, and cellular.

In investigating the properties of the different kinds of matter which exist on the earth, chemists find that they can be divided into two great classes; first those which cannot by any known means be split up, or from which nothing essentially different can be obtained—these are called elements; and second, those which can be split up, and consist of two or more of these elements in chemical combination—these are called compounds. There are about sixty-four elements at present known; the innumerable other substances with which we are acquainted being composed of two or more of these sixty-four elements.

The elements are divided also into two classes called metals, and non-metals; there are thirteen non-metals, the remainder being metals.

LAWS WHICH REGULATE CHEMICAL COMBINATION BY WEIGHT.

1. *Law of Constant Proportion.*—The same compound consists invariably of the same substances in the same proportion by weight. Thus it has been found that 188 parts by weight of silver bromide contain invariably 108 parts of silver and 80 parts of bromine.

2. *Law of Reciprocal Proportion.*—The proportion in which any two substances combine together is that in which they combine with every other substance. Thus, 80 parts of bromine combine with 108 of silver to form silver bromide, and 127 parts of iodine combine with 108 of silver to form silver iodide; but 80 parts of bromine is the exact quantity which combines with 127 of iodine. Or again, 35½ parts of chlorine combine with 108 of silver to form silver chloride; but 35½ parts of chlorine is the very quantity which combines with 80 of bromine or 127 of iodine.

3. *Law of Multiple Proportion.*—When one substance combines with another in more than one proportion, the higher proportions are always multiples of the first; this law is well illustrated by the five compounds which nitrogen forms with oxygen, viz:—

Nitrogen monoxide	=	Nitrogen 28	+	Oxygen 16		
„ di „	=	„ 28	+	„ 32	=	16 × 2
„ tri „	=	„ 28	+	„ 48	=	16 × 3
„ tetr „	=	„ 28	+	„ 64	=	16 × 4
„ pent „	=	„ 28	+	„ 80	=	16 × 5

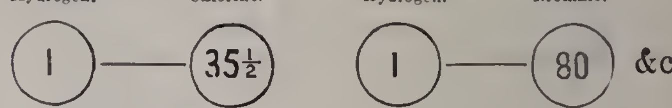
4. *Law of Compound Proportion.*—The combining proportion of a compound is the sum of the combining proportions of its constituents. Thus, 17 parts of ammonia contain 14 of nitrogen and 3 of hydrogen, and 81 parts of hydrobromic acid contain 80 of bromine and 1 of hydrogen; now 17 to 81 are the exact proportions in which ammonia and hydrobromic acid combine to form ammonium bromide.

These laws were explained by Dalton by means of a remarkably ingenious theory, called the atomic theory, and which so facilitates the comprehension of chemical changes generally, that we must consider it for a moment or two.

THE ATOMIC THEORY.

This theory supposes the elements to be aggregations of tiny particles called atoms, which atoms are themselves indivisible by any means. It further assumes that every atom of the same element has the same weight, so that if one atom of hydrogen weighed one-millionth of a grain, every other atom of hydrogen would weigh the same; but that the atoms of different elements have different weights, their respective weights being represented by the proportions in which they combine, or some simple multiple of that number. Thus, if we take the weight of an atom of hydrogen as unity, the weights of the atoms of chlorine, bromine, and iodine would be 35½, 80, and 127 respectively, this being the proportion in which they combine together (see fig.)

Hydrogen. Chlorine. Hydrogen. Bromine.

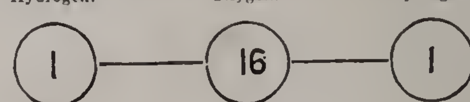


Hydrochloric Acid. Hydrobromic Acid.

Single atoms always combining together, whatever quantity we take of these compounds, there will always be the same number of atoms, and therefore the same relative weight of each element.

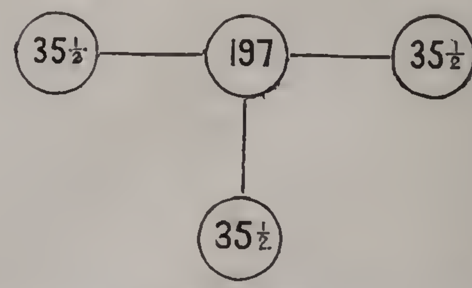
In other cases two, three, four, or more atoms of one element are supposed to combine with one atom of another element, in which case the combining proportion of the latter has to be multiplied two, three, four, or more times in order to represent its atomic weight (see fig.).

Hydrogen. Oxygen. Hydrogen.



Water.

Chlorine. Gold. Chlorine.



&c.

Gold Chloride.

These atoms are supposed to be incapable of existing in the free state, but two or more (either of the same or different kinds) are invariably combined together, and are then said to form a molecule.

It will be seen with a very little thinking that if we adopt this theory, the laws we have been considering follow as a matter of course.

CHEMICAL FORMULÆ.

Chemical formulæ are employed to represent (qualitatively and quantitatively) chemical changes in matter in as simple and abbreviated a manner as possible. In order to understand and use these formulæ, the following points should be engraved on the memory.

The chemical elements are represented by the first and sometimes two letters of their Latin names; thus, Cl, Br, I, Au, and Ag, represent chlorine, bromine, iodine, gold, and silver respectively.

These symbols further represent the supposed weights of their atoms, the weight of an atom of hydrogen being taken as unity, thus :—

Cl represents	$35\frac{1}{2}$	parts	by	weight	of	chlorine
Br	,,	80	,,	,,	,,	bromine
I	,,	127	,,	,,	,,	iodine
Au	,,	197	,,	,,	,,	gold
Ag	,,	108	,,	,,	,,	silver

When two or more elements combine together to form a compound, the compound is represented by placing the symbols of its elements in juxtaposition, the symbol of the metallic element (if present) being placed first; thus, KBr, AgI, represent in the first place potassium bromide and silver iodide, and in the second place their composition by weight.

When more than one atom of an element is required to be expressed, it is done by placing a small number to the right hand, and somewhat beneath the symbol; thus $CdBr_2$, $AuCl_3$ represent one atom 112 parts of cadmium combined with two atoms 160, 80×2 parts of bromine, which is the composition of anhydrous cadmium bromide, and one atom of gold combined with three atoms of chlorine to form gold chloride.

When a number is placed before and on a line with symbols it multiplies all which follow it as far as the first comma, + (plus sign), or full stop; thus $2H_2O$ represents 2 molecules $18 \times 2 = 36$ parts by weight of water, and $FeSO_4, 7H_2O$ represents $FeSO_4 + 18 \times 7 = 126$ parts of water, or common iron sulphate (green vitriol).

When it is required to represent a chemical change, the formulæ of the substances brought together are connected by the algebraic sign +, and the resulting products to these by the sign of equality =; as in algebra, the total quantity on each side of the equation must invariably be the same; thus we represent the formation of silver bromide by the action of silver nitrate on potassium bromide as follows :—

$$\underbrace{\underset{\underbrace{108+14+48}_{170}}{AgNO_3} + \underset{\underbrace{39+80}_{119}}{KBr}}_{\text{Total } 289} = \underbrace{\underset{\underbrace{39+14+48}_{101}}{KNO_3} + \underset{\underbrace{108+80}_{188}}{AgBr}}_{\text{Total } 289}$$

and by which we learn that 170 parts by weight of silver nitrate, mixed with 119 parts of potassium bromide, produce 101 parts of potassium nitrate (nitre) and 188 parts of silver bromide.

All chemical changes belong to one or other of five types, and in order to familiarize ourselves with these formulæ we will take a few examples of each of these types.

1.—*Direct Combination or Synthesis.*

$$H + Cl = HCl$$
$$Ag + I = AgI \quad \text{Daguerreotype plate}$$
$$NH_3 + HBr = NH_4Br$$

2.—*Splitting up or Direct Analysis.*

$$2AgCl + \text{light} = Ag_2Cl + Cl$$
$$HgO + \text{heat} = Hg + O$$
$$AuCl_3 + \text{heat} = Au + Cl_3$$

3.—*Displacement of one Element by another (selective affinity).*

$$KI + Br = KBr + I$$
$$KBr + Cl = KCl + Br$$
$$2AgCl + Zn = ZnCl_2 + 2\,Ag$$

4.—*Double Decomposition.*

$$AgBr + KI = AgI + KBr$$
$$HgCl_2 + 2KI = HgI_2 + 2KCl$$
$$2AgNO_3 + K_2CrO_4 = Ag_2CrO_4 + 2KNO_3$$

5.—*Re-arrangement.*

$$HgI_2 \text{ red} + \text{heat} = HgI_2 \text{ yellow}$$
$$\text{Albumen soluble} + \text{heat} = \text{Albumen insoluble}$$

PROFESSOR HENRY DRAPER, M.D.

The late Professor Henry Draper was born in Virginia, in 1837, but removed to New York when his father, Prof. J. W. Draper, was appointed to the Chair of Chemistry in New York University. At this University Dr. Draper was educated, graduating in Medicine in 1858, after which he travelled abroad. In 1860 he was elected to a professorship in his own University, which he retained till his death the other day. In 1866 he was elected Professor of Physiology in the Medical Department of the University and Managing Officer of the Institution, a position he resigned in 1873.

Dr. Draper's scientific work began with a series of experiments in 1857 on the function of the spleen, carried out by the aid of microscopic photography, an art then in its infancy. On his return from Europe, stimulated by a visit paid to Lord Rosse's 6-foot reflector, he began the construction of a $15\frac{1}{2}$-inch reflecting telescope, and with this, when completed, he took photographs of the moon.

Dr. Henry Draper subsequently constructed an equatorial reflecting telescope of 28 inches aperture, making both the mounting and the silvered glass speculum himself. The object for which this instrument was intended, and which it succeeded in accomplishing in 1872, was photographing the spectra of the stars, a work which has been carried on with such success by Dr. Huggins in this country. Since the invention of the gelatino-bromide dry process the difficulties of this research have much decreased; all the more credit is therefore due to Draper and the other pioneers in this branch of inquiry; he had taken more than a hundred spectra of various stars.

In 1872 Dr. Draper produced a photograph of the diffraction spectrum of great excellence. It comprised the region from below G, wave length 4,350, to O, wave length 3,440, on one plate.

In 1874 Draper was appointed by the United States Transit of Venus Commission, Superintendent of its Photographic Department, and his duties in this connection were so satisfactorily performed, that in the fall of that year the United States Government caused a special gold medal to be struck in his honour at the Mint in Philadelphia, bearing the inscription, "Decori Decus Addit Avito." This was the first time that such a public recognition had ever been accorded to a scientific man in the United States by the Government.

In 1877 Dr Draper printed his paper on the "Discovery of Oxygen in the Sun and a New Theory of the Solar Spectrum." This research has given rise to as much interest as any in recent times; whatever the future verdict may be upon it, it was the result of several years' work and most costly and elaborate apparatus. In 1877 Dr. Draper went to the Rocky Mountains, and made experiments on the transparency and steadiness of the atmosphere at elevations up to 11,000 feet. In the succeeding summer he took a party into the same region to observe the total eclipse of the sun, and was fortunate enough to photograph the diffraction spectrum of the solar corona, which, on this occasion, was shown to be continuous.

During the last autumn and winter he took photographs of the nebula in Orion. These were the first he ever made, and required an exposure in the telescope up to 140 minutes, even when the most sensitive of Eastman's gelatine plates were used.

Dr. Draper's work has been done mainly at his observatory at Hastings-on-Hudson, and at his laboratory in New York. In the former he had three large telescopes.

Dr. Draper's genial nature won him many friends, and many English men of science well knew the hospitable home at Dobb's Ferry. These and many more will sympathise with Mrs. Draper in the loss which not only she but science has sustained in the death of so earnest a seeker after truth.—*Nature.*

Notes.

We welcome a new Americau contemporary, *The Southern Amateur*, a monthly journal published in Baltimore.

Our next pictorial supplement is promised us by the end of December. We are going to try how far the ink-photo process is suitable for portraiture, the title of our picture being, "Waiting to Go On," at a Christmas pantomime.

The first photographic annual has reached us in the form of the German *Kalender*, edited by Herr K. Schwier, of Weimar; our own Year-Book will, as in the past two years, be published punctually on the 20th inst.

Many an amateur photographer, aye and professional too, would practise the beautiful process of Daguerreotype if he only possessed the vapour generators, exciting-boxes, and other strange paraphernalia he has been given to understand are necessary for the production of the image. Mr. William England, one of the few Daguerreotypists still living, has, we are glad to say, promised us to dispel the illusion of all this mystery, and will explain in the Year-Book for 1883 how common utensils may very well be used in the process, and how simple it really is from first to last.

Another article in the Year-Book which will be appreciated by a host of landscape photographers is one written by Mr. J. Gale, upon whom the mantle of Mr. Russell Manners Gordon seems to have fallen. Mr. Gale treats in a practical fashion of the wants of a photographer who may be out for a day or a week, and sums up succinctly the list of apparatus and appliances he should take with him.

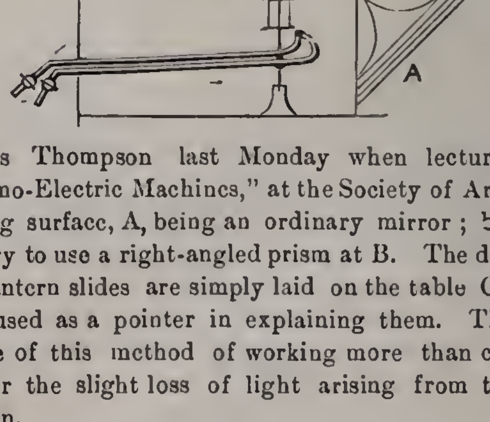
The phenomenon of the Transit of Venus on Wednesday was hidden in the neighbourhood of the metropolis by cloudy weather, much to the disappointment of all photographers with astronomical tastes. Let us hope that Lieutenant Darwin, R.E., the late Hon. Secretary to the Photographic Society, who has gone all the way to Queensland to observe the phenomenon, will be more fortunate.

Plymouth and Penzance seem to have been most favoured for observing the Transit of Venus. At Plymouth there was a fine view of the phenomenon; first a small black indentation appeared, and graduully passed into the body of the sun until a black spot appeared in the solar mass. With a good telescope Venus could be seen inside the sun's limb, yet bound to it by a black ligament, giving the well-described appearance of a pear-drop. In New York, at Yale College, all but the first contact was visible, and several hundred photographs were taken. At Harvard Observatory both the first and second contacts were recorded; while at Washington a dozen good photographs were secured. In Florida, where our friend Mr. J. T. Taylor is living just now, continuous photographs of the phenomenon were obtained. Altogether, therefore, our photographers and astonomers are to be congratulated on their results.

They have had to send all the way to Paris, to our friend M. Gobert, the photographic authority of the Bank of France, in order to get a satisfactory opinion on the handwriting of the prisoners in the Peltzer trial. M. Gobert, our readers will remember, has for a long time past acted as photographic adviser at the Bank of France, and has been so successful in the discovery of forgeries by the aid of the camera, that all doubtful handwriting now passes his inspection. Amounts scratched out and written over, similated signatures—and even forgeries of the blue bank notes, which have lately troubled the leading banking establishment in France—have been detected repeatedly by M. Gobert, whose experience in such matters is perhaps greater than any other living expert.

Three important works come to us this week from the Continent. The first is Poitevin's *Traité des Impressions*, a new edition, entirely revised by our esteemed Paris correspondent, M. Léon Vidal (Gauthier-Villars, Paris). The second is a new edition of our friend Dr. Eder's work on gelatino-bromide, which now appears in a most complete form; and the third book is entitled *Die Platinotypie*, from the pens of Captain Pizzighelli and Lieutenant von Hübl. The two latter works are published at the office of the *Photographische Correspondenz*, in Vienna. We shall have the pleasure of saying a few words about these volumes shortly.

Our diagram will give some idea of the convenient form of demonstrating or optical lantern used by Professor



Sylvanus Thompson last Monday when lecturing on "Dynamo-Electric Machines," at the Society of Arts—the reflecting surface, A, being an ordinary mirror; but it is necessary to use a right-angled prism at B. The diagrammatic lantern slides are simply laid on the table C, and a needle used as a pointer in explaining them. The convenience of this method of working more than compensates for the slight loss of light arising from two-fold reflection.

As the lecture progressed, small magnets were placed on

A MISTY MORNING ON THE WEAR.

the stage, and the lines of force were made obvious by dredging iron filings out of a pepper-box. Afterwards the magnetic properties of conductors were illustrated, and the magnetic condition of Pacinotti's annular electro-magnet (the so-called Gramme ring) was demonstrated.

Now that an inspector of ancient monuments has been appointed in the person of General Pitt-Rivers, we may hope something will be done to protect our interesting relics from Vandals and "trippers." Photography is able to afford a valuable guarantee that no monument is injured or defaced, or rather we should say a trite means of detecting injury or wilful destruction. Certainly some trustworthy record of the monuments as they are at present will be necessary, if the inspector's duties are to be discharged efficiently. Proof of this is afforded by Mr. W. G. Smith, who, writing to a contemporary on the subject of the stone circles at Penmacnmawr, says: "While I was at the smaller circle, I noticed that one of the stones had recently been pulled out of its setting, and was lying beside the hole. I noticed several other stones in the neighbourhood of the circles that had recently been thrown down."

The most efficient plan, therefore, of preserving the monuments as they are—for which duty the inspector has been appointed—would be to have each carefully photographed from two or three points of view, and then make sure from time to time that they are still standing. The photographs, printed of course by a permanent process, would be properly recorded and dated, and any change worked upon the monuments by time could be noted. On the other hand, the detection and punishment of evil-doers would not be difficult if the inspector did his duty. Speaking of some "trippers" visiting the wall of the great camp at Penmacnmawr, Mr. Smith says he saw "several of these terrible persons on the top, taking off the stones from the ancient walls and throwing them down below."

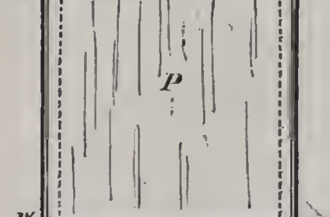
We were not quite right the other day in summarising the points at issue between Norman Lockyer and Dr. H. W. Vogel anent the dissociation of elements. Not merely because several of the iron lines appear broader, but because they are also displaced or curved—in the spectrum of a sun spot—is the basis of Dr. Vogel's objection to the dissociation theory. The phenomenon in question may imply movement, but Dr. Vogel explains it by a fact very often observed in terrestrial absorption spectra, viz., by the mixing of the absorbing body with another one of high dispersion, when some lines of the absorption spectrum are displaced, and others not. In the same way it is possible, Dr. Vogel thinks, that some iron lines in a sun-spot spectrum are also displaced, and others not, if a gas of high dispersive power is mixed with them.

By the way, Dr. Vogel's classification of photographic bromide of silver into two kinds, the blue-sensitive bromide, and indigo-sensitive bromide, appears to be perfectly warranted by the most recent experiments of Plener and Eder in Vienna. These gentlemen can not only produce the two forms at will, but separate the one from the other without difficulty. Step by step we are surely advancing in our knowledge of the wonderful haloid silver salt.

While on the subject of silver bromide, we may mention an interesting result which Tomassi has recently recorded He exposed for three months to the action of sunlight some bromide of silver in water, taking care to shake the same repeatedly, and at the end of this period he found the salt had lost 2·3 per cent. of bromine. Chloride of silver under the same circumstances lost 2·27 per cent. of chlorine. The fact of the bromide parting with bromine in this way points indisputably, our Italian chemist thinks, to the formation of a sub-bromide, of which the photographic image is composed, on the surface of the bromide.

The production of coloured photographs behind glass is occupying a good deal of attention on the Continent. The best results we have seen are those produced by Herr Koller, of Pesth, whose method we described in "At Home" and in our "Studios of Europe." Herr Klose, of Constance, who recently exhibited some of these so-called chromo-photographs at Berlin, gives the following *modus operandi*. Cement your photograph behind a glass plate with wax composition, which renders the picture transparent (Koller employs gum-dammar and Canada balsam, heating the print to obtain the utmost transparency), and paint in on the back all the salient details. A very thin glass plate is then used for backing up, and finally a sheet of drawing paper, upon which pastel colours have been vigorously but smoothly applied, so that they appear through the transparent photograph. The drawing paper is best stretched upon a zinc plate, so as to remain flat and even.

In the *Mittheilungen* appears a sketch of the cardboard box employed by Schwartz for packing dry plates, which seems both simple and effective. We reproduce it here—



k k represents the box as we look down into it, with the cover removed. The plate P is represented by dotted lines. Four wooden uprights, *V V V V*, are at each corner of the box, and serve to wedge the plate in position. The plates are simply laid flat in the box, and separated by strips of cardboard, *a a*, one at each end. The uprights, *v v v v*, keep the strips of cardboard in their places.

Mr. Hannyngton's advice in our last issue to depend upon rapid counting when timing exposures is exceedingly practical, as many experienced photographers can testify. As everybody has his own way of counting, however, he should not adopt the counting of other people. Mr. Haunyngton tells us how, by referring to a watch, the average speed of one's counting can be gauged to a nicety, and we think, for short exposures, the most accurate measurement is arrived at by counting as quickly as one can.

As an example of clever counting, Mr. Hannyngton instances the case of "the big drum" in an orchestra, who has occasional "rests," which he can time to a "beat." We wonder whether our correspondent had in his mind "the big drum" at Exeter Hall, of whom it is said he could count so accurately, that he made no difficulty about leaving his place in the middle of an overture when a number of "rests" came together; he used to slip downstairs, counting, walk across the Strand to his favourite tavern, without ceasing to count, swallow his refreshment, counting meditatively the while, and make his way back into the hall of harmony just in time to bring his sonorous instrument into play again.

Patent Intelligence.

Grants of Provisional Protection.

5395. Adolph Tuck, of 72 and 73, Coleman Street, in the city of London, Fine Art Publisher, for an invention of "Improvements in ornamenting terra-cotta plaques."—Dated 13th November, 1882.

Patent Void through Non-payment of Duties.

4738. Charles Guillaume Petit, Photographic Artist, of the city of Paris, in the republic of France, for an invention of "Improvements in photo-typography."—Dated 21st November, 1879.

The object of this invention is to transform a half-shade plate taken from nature, to a line plate forming a typographic relief. One of the characteristic properties of a layer of bichromated gelatine when exposed for a certain time beneath a photographic plate in the midst of actinic light is, that it resists expansion when immersed in cold water in proportion to the amount of light it receives, and this peculiar property is utilized for producing images from this plate in relievo or intaglio. Another peculiarity of this layer of gelatine is, that it also resists solution in warm water in proportion to the light received, and hence images in relief and hollow can be produced. The only difference between the two is, that in the first case a positive is required for the blacks of the plate forming relief, and, in the second case a negative is used. A white or photogenic substance, such, for example, as wax, susceptible of delicately receiving the impression of the gelatine thus prepared, is employed. This operation done, the surface of the modelling is rendered anti-photogenic by blacking it as superficially as possible with black lead; for example, the modelling thus prepared is placed in an engraving or etching machine in such a position that the point of the tool, which is V-shaped, can make incisions on the surface in a precise and rigorously mathematical manner. The following then occurs:—The maximum of penetration is regulated on the deepest hollows of the modelling by sparing all the large hollows, and cuts the reliefs in proportion to their height. At the second incision, whose proximity to the first is regulated on the highest reliefs, like the first, spares the greatest hollows, and cuts the reliefs in such a manner as to meet the incision made by its preceding course only on the highest, and so to remove all the anti-photogenic matter with which they were covered. Thus, by the successive incisions of the tool well regulated in depth, in proximity to each other and in intersection, an image is formed on the surface of the modelling, which, properly lighted and photographed, reproduces the original plate in a plate formed solely of perfect whites and blacks; that is to say, useful for all kinds of printing reproducing the characteristics of the original subject, especially applicable to typography. The principle of the invention, or the transformation of an ordinary photographic plate into one formed of white and black lines, or points in proportion to the size of the relief obtained by chemical combinations which are rendered insoluble by light, may also be effected as follows:—For the sake of shortening the operations above mentioned, which may be considered as an analysis of the process, by engraving the surface of the wax before modelling, or by the simple use of grained paper, or bearing the dry impression of the several combinations of hollow lines, the modelling is then performed in the following manner:—After having selected a wax or paper on which the depth of the cuttings is equivalent to the highest reliefs of the gelatine, the paper or wax is placed on a hard and perfectly even surface. Above this is placed the gelatine uniformly, and as superficially blacked as possible, and then another smooth hard surface. The whole is then submitted to pressure, and the wax or paper, as the case may be, will each carry in all the lines of their surface as much more black (deposited on the gelatine) in proportion as these lines or grain have been more or less flattened by the reliefs of the gelatine. By this means an image is formed of black and white lines, the depths of colour being proportionate to the reliefs of the gelatine, which image, re-photographed, produces a plate capable of serving as a typographic relief in the manner and by the means specified. I claim the transformation of a half-shade plate taken from nature to a lined plate forming a typographic relief.

Patents Granted in Belgium.

59,223a. A. and G. Bernheim, of Paris, for "Applying photographic portraits on tie-breast-plates."—Dated 9th October, 1882.—French Patent, 30th September, 1882.

59,408. J. Chaine, A. Durand, and Sallonnier de Chaligny, of Lyons, for "Coloured photographs or so-called 'photonature.'"—Dated 28th October, 1882.

Patent Granted in France.

148,834. Meisenbach, for "Preparing stereotype plates by photography."—Dated 8th May, 1882. Class 17.

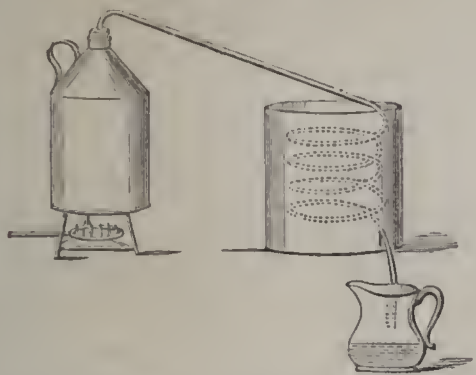
TWELVE ELEMENTARY LESSONS IN PHOTOGRAPHIC CHEMISTRY.

No. XII.—Collecting and Working-up Residues.

As a good deal of interest has been taken in the treatment of residues of late, we make no apology for concluding this series of lessons by describing the processes proved to work best in practice. We shall consider the subject under five headings, viz., alcohol, gold, oxalate, platinum, and silver.

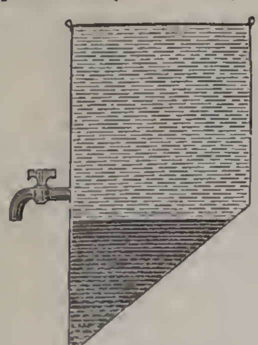
Alcohol.—Now that this liquid is being used so extensively for precipitating gelatine emulsion, hardening and facilitating the drying of gelatine plates, it is very important that photographers should know how to recover the alcohol for future use. The desired result may be obtained either by treating the dilute alcohol with dry potassium carbonate, or by distilling the liquid over quick-lime. In the first process, the potassium carbonate forms with the water a saturated solution which will not mix with the alcohol, thus allowing it to separate, and from its low specific gravity rises to form an upper liquid. The alcohol is drawn off by a syphon, and the solution of potassium carbonate evaporated down ready for future separation. The objection to this process is that it does not free the alcohol from all the water, and is very liable to leave certain impurities still dissolved. Although the alcohol might be used with impunity for precipitating gelatine emulsion, the liquid would not be sufficiently pure for a great many photographic processes; it is therefore preferable to purify all alcoholic residues by distilling over lime.

For alcoholic distillations, an apparatus consisting of a tin oil-can of suitable size, fitted with a perforated cork, is required. A piece of lead pipe half-an-inch in diameter, and about six feet long, one end of which is inserted in the perforated cork, while the other end is bent into a spiral, serves to condense the liquid. The spiral tubing is placed in a small tub or barrel having a hole just large enough to admit the end of the tubing (see figure).



The alcohol residue mixed with an equal weight of fresh quick-lime is placed in the tin can on a sand-bath or a saucepan of water, and heat applied, when the pure alcohol vaporises and condenses in the spiral tubing. The vessel enclosing the spiral must always be kept full of cold water, the warm water being occasionally drawn off from the surface, while cold water is added down a tube at the bottom. Alcohol purified in this way contains about five per cent. of water, and is quite strong enough for all photographic purposes, except for the manufacture of collodion.

Gold.—Most photographers neglect the gold contained in old toning baths, on account of the small amount contained therein, and no doubt in small establishments it is hardly worth troubling about, but in large establishments, where a great deal of silver printing is done, the collection of residues should always be attended to. A large barrel, tub, or wedge-shaped tank (see figure) should be set apart,



Section of Residue Tank.

wherein all used toning baths are collected, and when the vessel is full, a solution should be added, containing about thirty grains of protosulphate of iron for every gallon of the residue contained in the tank. After allowing the liquid to stand for about twelve hours, the supernatant liquor must be drawn off by a stopcock or a syphon, leaving the residue of metallic gold, together with waste liquor to the depth of three or four inches. The remaining liquor and precipitated gold should be thrown on a filter of bibulous paper, washed by pouring hot water over it, and, when dry, the gold is ready for conversion into chloride in the manner previously described.

Potassium Oxalate.—The ferrous oxalate developer, when once used, is generally thrown away; yet how often we hear photographers cry out at its expense; but if attention is given to re-converting the used solution into potassium oxalate, the developer will be far cheaper than any other. Either caustic potash or potassium carbonate will decompose the oxalate solution, but we prefer to use the latter compound.

The solution to be acted upon should be placed in a large beaker, and sufficient quantity of a saturated solution of potassium carbonate added till no further precipitate of carbonate of iron is produced; the solution must then be filtered through bibulous paper, and should appear perfectly colourless. If the solution is still tinted brown, it shows that the whole of the iron has not been precipitated, and that the addition of potassium carbonate and the process of filtering must be repeated.

The solution of potassium oxalate thus prepared contains a certain amount of potassium carbonate, therefore a saturated solution of oxalic acid must be added to decompose the potassium carbonate, the exact point of neutrality being found by testing the solution with litmus paper. The solution should finally be evaporated down till the salt begins to crystallize, and allowed to cool; the mother liquor can be poured off ready for use, and the crystals dissolved in sufficient water to prepare a "saturated solution."

Platinum.—If only workers of the platinotype process knew what a large quantity of platinum salt is wasted when they throw a used developer into the sink, perhaps they would be more careful to collect platinum residues. In the first place, it must be remembered that the prepared paper is coated with a solution containing sixty grains of the platinum salt to the ounce, and that only about one-tenth of the platinum is actually deposited on the print, while about three-fourths of the salt is dissolved, and remains in the developer. It is therefore evident that in order to obtain the greater part of the waste platinum, all that is necessary is to treat the developer with a reducing agent, such as is used for obtaining gold from its solution. The following is the method which has proved most successful in our experience. Place the used developer in a large beaker, and heat the solution over a sand-bath till nearly boiling, then add to the solution one-fourth its volume of a saturated solution of protosulphate of iron; a black precipitate will be immediately produced consisting of pure metallic platinum. The supernatant liquid, consisting of ferrous oxalate, is carefully poured off into the oxalate residues, and the precipitated platinum, after being washed by decantation, should be either converted into chloride, or sold to a refiner.

Silver.—This element is present both in the wash-water of silver prints, and the fixing solutions used for negatives and prints. In order to obtain the silver from the wash-water, the solution must be collected in a vessel similar to that used for gold solutions, and containing two or three handfuls of common salt. When the collecting tub is full, the supernatant liquor should be poured off, leaving at the bottom the precipitated chloride of silver, which must be dried, and either sold to a refiner, or mixed with an equal weight of dried sodium carbonate and fused in a furnace, as described in the lesson on the preparation of silver nitrate.

To obtain the silver from hyposulphite fixing baths, the solution should be collected in the usual way, and precipitated by means of sulphide of ammonium. It is impossible to give any definite quantity to insure the precipitation of the silver, but 3 per cent. of the alkaline sulphide should be added to the ordinary fixing bath used for gelatine plates, while 1 per cent. of the precipitant will suffice for solutions used for fixing silver prints.

To obtain metallic silver, the precipitated silver sulphide obtained as above, must be dried, and mixed with an equal weight of a mixture of potassium nitrate and sodium carbonate, and fused in a blast furnace.

EFFECTS OF TEMPERATURE ON THE LUMINOSITY OF SULPHIDE OF CALCIUM.

BY E. BRIGHTMAN.*

At a previous meeting of the Association I pointed out the fact that the sulphide of calcium is not reliable as a standard light for comparative experiments with the sensitometer, from the fact that an increase in temperature causes an increased luminosity in the previously excited surface. Carrying the experiments I

* Read before the Bristol and West of England Photographic Society.

then made still further, I find the following results. First, that a high temperature not only increases the luminosity of the surface previously excited by light, but that it is also capable of causing luminosity altogether apart from the action of light. Secondly, that a decrease of temperature causes a decrease of luminosity, whether the luminosity has been excited either by light or by heat. Thirdly, that if the temperature be sufficiently reduced, the luminosity altogether ceases.

In order to clearly show the effects of temperature, I have prepared a series of thin glass test-tubes coated with the sulphide of calcium. To No. 1, which is already slightly luminous, I will add some water at a temperature of 212°, you will note an immediate icnrease of luminosity. To No. 2, which has been kept in the dark for some days, so that the luminosity is entirely gone, I will add in the same manner water at 212°; with the result that the luminosity is immediately established. To No. 3, which is brilliantly luminous, I will add water slightly chilled by the addition of a freezing mixture, with the result that the luminosity is considerably lowered; on adding a still further quantity of the freezing mixture the light entirely ceases.

It thus is clearly evident that the sulphide of calcium as a standard light for sensitometrical experiments is utterly unreliable, unless some method is adopted by which a regular temperature could be maintained.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Chapter V.—Theory of Photo-Lithography, and General Considerations.

With the taking of the negative the first and purely photographic stage of the operations comes to an end, and we now enter upon an intermediate stage, in which photography and lithography are to a certain extent combined, in order to produce on the stone or zinc, by the agency of light, an image in fatty ink from which impressions may be printed by the ordinary methods of lithography or zincography.

This result may be brought about in different ways; depending, first, on the nature of the sensitive substance and the chemical reactions by which the image is produced under the influence of light; and secondly, on the mode in which the image is applied to the stone or zinc, whether directly or by transfer.

First, as regards the nature of the sensitive substance, there are two distinct methods of obtaining the photographic image, viz., with asphaltum or bitumen, and with alkaline bichromates mixed with colloid substances, such as gelatine, gum, albumen, &c. In both cases advantage is taken of the fact that if a thin dry film of asphaltum or a chromo-colloid mixture be applied to the surface of paper, stone, or other suitable material, and exposed to light under a photographic cliché, those parts of the film upon which the light can act through the transparent parts of the cliché will become more or less insoluble in the usual solvents, while the parts protected by the dark parts of the negative, and therefore unacted on by light, retain their solubility. The amount of insolubilty thus produced is in direct proportion to the intensity of the light and the duration of its action.

If, after exposure to the light, such a film be washed with a suitable solvent, the soluble parts will wash away, leaving a more or less perfect image in asphaltum or insoluble colloid, both of which substances are capable of receiving and retaining a coating of greasy ink, which will yield impressions suitable for the purposes of the lithographic printer.

Asphaltum or bitumen of Judea is a brownish-black resinous substance or mineral pitch found chiefly in Syria and Trinidad. It is soluble in the volatile and essential oils, such as turpentine, lavender, &c., and also in benzole, mineral and coal-tar, naphtha, and the fixed oils. It consists of three resinous principles; one a yellow resin, soluble in alcohol and ether, forming about 5 per cent. of the whole; if the residuum be digested with ether, a further 70 per cent. of a brownish black resin is obtained which is freely soluble in the volatile oils and in about five parts of mineral naphtha. The remaining 25 per cent. left undissolved by ether is very soluble in the oils of turpentine and petroleum, also in chloroform. According to Kayser this portion is the most sensitive to light, and it may be obtained for photographic purposes by dissolving bitumen in chloroform, and then adding three times the quantity of ether, which precipitates the sensitive principle. A thin coating of a solution of asphaltum in turpentine or benzole is of a light brown colour, which does not perceptibly change in tint under the influence of light, though it loses its power of dissolving in its usual solvents.

From the researches of Niepce de St. Victor and Chevreul it appears that this alteration of asphaltum under the influence of light is due to oxidation, and does not take place in a vacuum or in an atmosphere of nitrogen. Further, the sensitiveness of the bitumen, whether in the solid or dissolved state, may be considerably increased by allowing the air to have free access to it for varying periods, according to the quality of the specimen. It was found by Bayer that if, on the other hand, free access of air was prevented during exposure to light, as when a collodion film is attached to the varnished surface by means of gum, the transformation of soluble to insoluble under the action of light does not take place.

The peculiar property of asphaltum to become insoluble under the influence of light was first utilised by Joseph Nicephore Niépce, of Chalons-sur-Marne, about the year 1813, in the course of the researches he made to find a substitute for lithographic stone by producing images through the action of light on metal plates coated with resinous varnishes; and this was the first known process of permanent photography.

Niépce coated metal plates, usually of tin, with a thin varnish of asphaltum dissolved in oil of lavender. After a sufficient exposure to light under an engraving or in the camera, the plate was washed with a mixture of oil of lavender and oil of white petroleum, which dissolved the asphaltum where the light had not acted, while in the parts acted on by the light it remained insoluble, and formed an image which could be bitten in by acids, and used for printing from, like a copper-plate engraving.

Though asphaltum is now scarcely ever used as a sensitive coating for stone, the earliest practical process of photo-lithography, introduced in 1852 by Messrs. Lemercier, Barreswil, Lerebours, and Davanne, depended on its use. They coated a lithographic stone with a solution of bitumen in ether; the stone was exposed to light under a negative, then developed by washing the varnished surface with ether, which dissolved the coating in the parts protected from the light, while the insoluble parts acted on by light remained, and formed a resinous image, which, after the usual preparation of the stone with acid and gum, could easily be inked up and printed from.

The principal cause of the abandonment of asphaltum for photo-lithography was the very long exposure required to produce the necessary degree of insolubility of the sensitive film, six or seven hours being necessary in a good light, while in dull weather the exposure might extend to days. As noted above, recent discoveries by Dr. Kayser have shown that the most sensitive constituent of asphaltum is insoluble in ether, and by eliminating the less sensitive constituents the sensitiveness of a thin film of this substance is very largely increased. This discovery has again drawn attention to the asphaltum processes, and rescued them from the neglect which seemed at one time almost to have consigned them to oblivion, and they are now very largely used, as we shall see in a subsequent chapter, for obtaining photographic images on zinc, suitable for typographic etching, the superior sharpness of the asphaltum image, and its capability of resisting the acid solutions used for biting, making it peculiarly suitable for this purpose.

(To be continued.)

Correspondence.

CHOCOLATE MOUNTS.

Dear Sir,—In your "Notes" of November 27th, you mention the fading of photographs when mounted on chocolate mounts. I have now entirely discontinued the use of chocolate mounts owing to my own experience. I have found prints (after careful washing and mounting with perfectly fresh paste) fade in a day or two when mounted on the chocolate mount, while prints mounted at the same time on other mounts show no sign of fading.

I enclose for your inspection three cabinet prints on chocolate mounts. In two days from mounting, all the half-tones were gone, and they have faded to what they now are in a month's time.—I am, &c., F. Stanley.

[The pictures sent are very yellow.—Ed. P.N.]

PLAGIARISM.

Sir,—At the last meeting of the London and Provincial Photographic Association, the chairman brought before the members a matter which, as affecting photographic morality, should not be dismissed without some further notice.

Among the pictures to which medals were awarded at the last Exhibition of the Photographic Society, was one called "Cherry Ripe." This, as the chairman pointed out, was copied, as nearly as a photograph from life could be copied from a painting, from an engraving in the *Art Journal* for 1872. The costumes differ, but all else is the same, with the exception of the titles. The engraving is entitled "Cherries Ripe," the photograph "Cherry Ripe," a difference scarcely calling for a great amount of ingenuity in the photographer, but it is a sample of the amount of difference in other respects between the engraving and photograph. I am willing to admit that coincidences are sometimes very surprising, but that this is not a coincidence is satisfactorily proved by the fact that in the same volume of the *Art Journal* is an engraving of a girl with a tambourine, which has also been imitated by the same photographer, the only difference being the substitution of an ugly model for a pretty one, and submitted to the judges in the same exhibition as his own work.

The photographer possibly sinned through ignorance—it is not given to some minds to know that another man's property and ideas are not his own—and this may be a case in which honest photographers should be lenient, and pass some such sentence as "not guilty, but don't do it again." But it now becomes a question if the photographer ought not, in honesty and for his own honour, to return the medal which he has received, I won't say under false pretences, but through a misapprehension on the part of the judges, for they must have relied on the good faith of the exhibitor, and taken for granted that a photographer with a well-known name would not put before them a work which, in all essential respects, was not his own.—Faithfully yours, An Exhibitor.

TIME OF EXPOSURE.

Sir,—The most simple arrangement for timing dry plates is to purchase a "metronome." It struck me three years ago as being just the thing. If you count "anxiety," for fear the sitter moves, or you may give too long or too short an exposure, you make a mistake. I think it extremely difficult to count twice alike. Now the metronome ticks quite loud, and, by shifting the balance weight either up or down, it will go fast or slow just as you wish, according to the known rapidity of your plates. The price is ten to twelve shillings, and will last a very long time, and, when wound up, will go for quite half-an-hour. Almost all music shops keep them, or Marion's, Soho Square.—

James Syrus Tulley.

Proceedings of Societies.

Bristol and West of England Amateur Photographic Association.

The ordinary monthly meeting was held at the usual place, the Association's studio, Kingsdown, on Wednesday evening, 29th November, Mr. J. Davey, one of the vice-presidents, in the chair.

The minutes having been confirmed,

Mr. H. A. H. Daniel, hon. sec., gave notice that at the next meeting he should move to rescind the resolution carried at a previous meeting, altering the date of annual meeting from October to January. He stated that it had been done with the desire to render the meeting of the Association more convenient; but it had been found that it was very awkward not to have all changes likely to be made in the Association accomplished before the end of the current year, and that, on the other hand, the feared difficulty as to the accounts had not been realised.

The Chairman then stated that the next subject for consideration was their "Triennial International Exhibition."

The Hon. Secretary stated that a meeting of the Council had been held at his residence in the preceding week, and he had called it so that the large number of foreign exhibitors should have timely notice and information as to the list of medals, dates of opening and closing the exhibition, &c. He stated what had been decided upon at the meeting of the Council, and remarked that any suggestions from members present would be welcomed.

There was a considerable amount of discussion, and many suggestions offered, the following being the list of medals finally and definitely decided upon.

1. A gold medal for the picture or series of pictures which, in the opinion of the judges, possesses the highest degree of merit, irrespective of size or subject.
2. One silver and one bronze medal for the best and second best landscape or series of landscapes of $8\frac{1}{2}$ by $6\frac{1}{4}$ or under.
3. One silver and one bronze medal for the best and second best landscape or series of landscapes above $8\frac{1}{2}$ by $6\frac{1}{2}$.
4. A silver medal for the best instantaneous picture or series of pictures of land or sea scapes.
5. A silver medal for the best interior or series of interiors.
6. One silver and one bronze medal for the best and second best portrait or series or portraits of $8\frac{1}{2}$ by $6\frac{1}{2}$ or under.
7. One silver and one bronze medal for the best and second best portrait or series of portraits above $8\frac{1}{2}$ by $6\frac{1}{2}$.
8. One silver and one bronze medal for the best and second best *genre* picture.
9. A silver medal for the best enlargement of any subject, and by any process, provided it be the work of the exhibitor.
10. A silver medal for the best enlargement of any subject, and by any process, provided both original negative and enlargement be entirely the work of the exhibitor.
11. A bronze medal for the best transparency or series of transparencies.
12. A bronze medal for the best ceramic photograph or series of photographs entirely the work of the exhibitor.
13. Four bronze medals, to be awarded according to the discretion of the judges, for improved apparatus, materials, processes, or other meritorious productions.

The exhibition will be held, as before, in the Galleries of the Academy of Arts, Queen's Road, opening on Monday, December 17th, 1883, and remaining open four weeks.

The Chairman then called upon Mr. E. Brightman to read his notes on "The Effects of Temperature on the Luminosity of Sulphide of Calcium" (see page).

Mr. Brightman made his remarks most interesting by illustrating them by very conclusive and clear experiments, which, with his remarks, were paid great attention to.

Mr. Daniel ventured to differ from Mr. Brightman as to the sensitometer being so very unreliable from the causes he had mentioned, for he concluded most persons kept their dark-rooms or laboratories generally at about the same temperature when testing plates; and presuming the luminous plate was not unduly fingered, the variation, he should consider, was but trifling. Also it was quite a question if the tablet could be rendered more luminous when in a given temperature than it would be on another occasion when thoroughly acted upon by the magnesium light at a somewhat lower temperature.

Mr. Brightman considered that it was so, and said that he hoped during the session to work out one or two other matters which suggested themselves to him in connection with luminous paint.

The Chairman asked what was a good mode of making a sand-bath.

Colonel Playfair replied that the sand from a fresh-water river was generally the best, being finer than sea sand, and a metal or porcelain dish was as good a holder for it as anything. A bath or other vessel once warmed could be kept so for a long time in a similar manner to that in which the Chinese keep their teapots warm, viz., to place the vessel in a box with a closely-fitting cover, the vessel being well packed with hot wool or flannel.

Some informal conversation and a vote of thanks to Mr. Brightman closed the proceedings.

London and Provincial Photographic Association.

At a meeting of the above, held at the Mason's Hall Tavern, Basinghall Street, E.C., on the 30th ult., Mr. A. J. Brown in the chair,

Mr. Henderson stated the following reasons why in his opinion gelatine plates require harder lighting than collodion, and a lengthy and interesting discussion followed. First, because (as a rule) gelatine plates when developed are thinner and require stronger contrasts; secondly, the liberation of free bromine is greater in the lights, consequently acting as a more powerful restrainer.

Mr. Cowan did not think that as a rule gelatine plates gave a thin image.

Mr. Coles said his experience was that very great rapidity tends to give a thin image.

Mr. Barber had always found in wet plates that when extreme rapidity was attained, the image was thin, and found the same in gelatine plates.

Mr. Debenham thought the discussion had somewhat diverged from the question; it was not admitted by anyone, save the writer of the question and Mr. Henderson, that harder lighting was necessary for gelatine plates. He remembered some time ago reading an article stating it was necessary to have soft lighting for gelatine work in the studio; he thought that the writer of that article was mistaken, and that Mr. Henderson was equally so in asserting that harder lighting was necessary. The best conditions of collodion and gelatine require identical lighting.

Mr. Henderson said that very few had worked the two processes side by side as he had done; if worked together under same conditions of lighting there would be found a marked difference in favour of the collodion, the dry plate negative having no pluck, owing to want of contrasts.

Mr. C. Walters found no necessity to alter the lighting for gelatine plates; he worked the two side by side, and produced with dry plates, with identical lighting, quicker and better results than with wet plates.

Mr. Barker said the quickest wet plate bath he ever made contained nitrate uranium.

Mr. Hart said to prepare a very rapid bath he used a neutral silver, and worked with a collodion not more than two days old; under these conditions he did not get an intense image, but a very brilliant and soft one, which, with very little intensifying, gave a very soft dense and brilliant picture.

Mr. Barker said a good collodion was prepared as follows:—

Alcohol ·815	½ ounce
Ether ·725	½ ,,
Iodide cadmium	2 grains
Iodide ammonia	2 ,,
Iodide sodium	2 ,,
Bromide cadmium	1 grain
Bromide ammonia	1 ,,
Powdered pyroxiline	7 grains

It gave a blue transparent film, was very sensitive, gave good density, kept well, and worked best when about three months old.

Mr. Hart had prepared a similar collodion for abroad, and had obtained splendid results with it when about three years old; when using cadmium in high temperature, pyroxiline was necessary.

Mr. Osman said he would bring forward a theory in connection with the subject for discussion at the next meeting. He however stated that he believed that free bromine was liberated, which acted upon the bromide of silver in contact with it, converted this with a sub-bromide, which was reduced by the developer.

Mr. Haddon pointed out that if the liberated bromine did act upon the neighbouring bromide, it would convert it into per- and not sub-bromide of silver as stated by Mr. Osman.

Mr. Ashman said that the pyrogallic solution alone was thrown on the plate: no image could be obtained without the ammonia solution, therefore he inferred that the bromide of silver was dissolved by the ammonia, and that the solution was necessary for development.

Mr. Debenham said that the ammonia used in developing was so dilute, it could not be supposed to dissolve enough bromide of silver to form the image; besides this, the fact that ferrous oxalate developed the image showed that the solution of bromide of silver was not necessary.

Mr. Orsman, in support of Mr. Ashman's theory, said the question was: Was the ferrous oxalate development a chemical one?

Mr. Debenham replied that even with pyrogallic development, the addition of ammonia was not necessary, as potash or soda would supply its place, and these did not, at all events, act by dissolving the bromide of silver.

Mr. Barker pointed out that one of the functions of the organic matter in the film was to absorb the free bromine that was given off after the impact of light, and the greater the affinity of the organic matter for the bromine, the greater the sensitiveness. He further stated that he had said at a previous meeting that in an emulsion the bromide of silver was formed first, and was then insensitive to development; that organic matter joined the compound next, and rendered it sensitive; and that nitrogen would be found in the more sensitive compounds, much the same as it is found in the more explosive compounds.

Mr. Collins showed a photograph, sent him from the Cape, of the great comet.

Liverpool Amateur Photographic Association.

The annual meeting of this Association was held at the Free Library, on Thursday, the 30th ult., the President, Mr. E. Roberts, in the chair.

The minutes of the October meeting having been read and passed, the following gentlemen were elected members of the Association:—Messrs. W. G. Holland, W. J. Grimshaw, J. W. Whiteman, and H. R. Boult.

The Hon. Secretary read the following report:—

"The Liverpool Amateur Photographic Association enters to-day upon the twentieth year of its existence, and the President and Council are glad once more to congratulate the Association upon its continued prosperity and advancing numbers.

"There have been nineteen new members elected since the last annual meeting; while, on the other hand, there have only been four resignations. The numbers of members on the books at the close of each of the last five years stand as follows:—1878, 59; 1879, 67; 1880, 71; 1881, 78; 1882, 93.

"Our meetings during the past year have been exceedingly well attended, and no effort has been spared in the endeavour to maintain their character for interest and practical usefulness. This is sufficiently evident from the following list of papers read, and demonstrations given during the past year:—'On the Platinotype Process,' Mr. H. N. Atkins; 'Passing Thoughts,' Mr. J. H. T. Ellerbeck; 'On Intensification,' Mr. Houlgrave; 'On Instantaneous Shutters,' 'On Illumination of the Dark-Room,' Mr W. H. Kirkby; 'On Gelatino-Bromide Emulsion,' 'On Landscape Lenses,' Dr. Kenyon; 'On the "Eclipse" Light,' Mr. J. Y. McLellan; 'On Enlarging with Lancaster's Lantern,' 'On Comparative Effectiveness of Intensifiers,' 'On Comparative Values of Remedies for Blistering,' Rev. H. J. Palmer; 'On his Gelatine Films,' Mr. A. Pumphrey; 'On Instantaneous Photography,' Mr. E. Roberts; 'Historical Notice of the Origin and Progress of the Collodio-Bromide Process,' Mr. J. Sayce; 'On a New Toning Apparatus,' Mr. J. Scheukenhofer.

"Exhibits of objects of interest to photographers have been produced at the meetings by Messrs. Atkins, Bean, Blanchard, Bruce, Crowe, Day, Ellerbeck, Forrest, Gorst, Greenwood, Houlgrave, Kenyon, Kirkby, Palmer, Phillips, Phipps, E. Roberts, Sayce, Wood, and others.

"Two summer meetings were held at the houses of the Rev. H. J. Palmer (at Wallasey) and of Mr. E. P. Houghton, at New

Brighton. Judging the attendance of members, they were highly appreciated.

"Mr. J. H. T. Ellerbeck has inaugurated a new and useful feature in the social side of the work of the Association by kindly receiving the members at a bi-monthly 'at home' at his house, for the discussion and practice of the various details of the art of photography.

"The outdoor meetings of the Association have been but few, and these have been scantily attended. The Council hope that, with the largely-augmented numbers of the Association, the excursions of 1883 may be better supported than has been the case of late years.

"An exhibition of the lantern was given in the Free Library Lecture Hall, on December 22nd, 1881, and a large collection of photographs was shown in the adjoining room. The slides exhibited on the occasion were by Messrs. Beer, Ellerbeck, Kirkby, Palmer, and Twigge.

"The Association took a prominent part in contributing to the interest of the proceedings at the *soirée* of the Associated Societies in St. George's Hall, on the 21st of December last. The Chancery Court and barristers' robing-room contained a fine display of prints and apparatus. About 500 pictures were exhibited by Messrs. Watling, Ellerbeck, Boothroyd, Kirkby, Banner, Palmer, and Wharmby.

"A lecture was delivered by the Rev. H. J. Palmer on 'The Popular History of Photography;' and Mr. Forrest showed a large number of transparencies by the lime-light on a sheet of opal glass, giving at the same time an explanatory lecture upon the pictures, which illustrated the ancient ecclesiastical architecture of Europe.

"The first of the annual competitions has taken place since the Council issued their last report, and its success sufficiently justified the addition of this feature to the proceedings of the Association. Rules have been drawn up for the regulation of these competitions, and subjects selected for the years 1882 and 1883.

"The Council have decided that the presentation print for the present year shall consist of an enlargement of a suitable negative, if possible, contributed by a member of the Association.

"The Council consider that the time has now arrived to form the nucleus of a library of books of reference and of text-books, on subjects connected with photography and the arts and sciences allied to it. For this purpose they have decided to inaugurate the twentieth year of the existence of this Association by setting aside a sum not exceeding £5, to be devoted to the purchase of such works, which will be at the service of the members of the Association, subject to certain rules which have been drawn up to regulate their use.

"The thanks of the Association are due to the Library, Museum, and Arts Committee of the Corporation of Liverpool for granting the use of the room in the Free Library, in which these meetings are held; to the Photographic Society of Great Britain for copies of the journal; to the Liverpool Engineering Society; the Microscopical Society; the Field Naturalists' Association; the Philosophical Society, and the Geological Society, for copies of the annual report of their proceedings and transactions."

The Chairman proposed the acceptance of the report of the Council, which was seconded by the Rev. T. B. Banner, and carried.

The Honorary Treasurer then laid his statement before the meeting, showing a balance in favour of the Association of £32 9s. 9d.

The Secretary brought forward the proposal to print in pamphlet form all particulars relating to the Association, and its proceedings during the past year, which was carried unanimously.

The following gentlemen were elected officers of the Society for 1883:—

President—B. Boothroyd.

Vice-Presidents—J. W. H. Watling, M.R.C.S., G. A. Kenyon, M.D.

Treasurer—E. Twigge.

Secretary—Rev. H. J. Palmer, M.A.

Librarian—J. H. Day.

Auditor—W. H. Wharmby.

Council—H. N. Atkins, W. Atkins, Rev. G. B. Banner, A. W. Beer, F. W. Bruce, K. Bean, J. H. Day, W. H. Kirkby, E. Phipps, E. Roberts, B. J. Sayce, and W. H. Wilson.

The rules drawn up for the regulation of the use of the library were passed by the meeting.

The Honorary Secretary hoped that each of the members would make lantern slides from the best of their negatives, and present them to the Association.

The Chairman thought it very desirable that an exhibition of old work should be occasionally held.

Mr. F. W. Bruce proposed that there should be a special prize given for old work.

The Rev. G. B. Banner said that it was not advisable to multiply prizes, and that the Treasurer's balance would not last very long, if so many suggestions for its employment were made and carried out.

Mr. T. Huson, on behalf of himself and Messrs. Pelham and Phipps, who had been requested by the Council to act as judges in this year's competition, then delivered their awards as follows.

Subject.	Number of competing pictures.	Prize winner.
Instantaneous	6	W. H. Kirkby.
Figure Study	6	W. H. Kirkby.
Fruit, Flowers, and Ferns	5	Rev. H. J. Palmer.
Waterfall	6	J. H. Day.
Relics of the Past	6	J. H. Day.
Country Lane	6	A. W. Beer.
Landscape with Distance	7	J. H. T. Ellerbeck.
Winter	1	J. H. T. Ellerbeck.
Own emulsion	2	W. H. Kirkby.
Best picture of the year	49	E. Twigge.
Best series of pictures	11	J. H. Day. J. H. T. Ellerbeck. } equal.

The judges further desired to commend the figure study and instantaneous pictures by Mr. W. J. Little.

The Chairman proposed a hearty vote of thanks to the gentlemen who had so kindly fulfilled the onerous and difficult duty of awarding the prizes on this occasion.

The Rev. H. J. Palmer gave a successful demonstration of the process of enlarging on matt opal.

The Honorary Secretary begged members who propose to exhibit at St. George's Hall, on the 20th inst., to send their prints and apparatus, &c., to Mr. Ellerbeck, 54, Bold Street, on or before Tuesday, the 19th inst. He further announced that the members of the committee for the arrangement of exhibits would meet in St. George's Hall, at 10 a.m., on the morning of the 20th inst.

Mr. A. Tyrer exhibited a number of very fine 12 by 10 prints from his own negatives, and Mr. A. W. Beer a frame of choice specimens of his work among the old halls of Cheshire during the past season.

A cordial vote of thanks having been passed to the Rev. H. J. Palmer for his demonstration, the meeting, which was a crowded one, was adjourned.

Halifax Photographic Club.

At the monthly meeting held at the *Courier* Office, Mr. J. B. Holroyd in the chair,

After the reading of the minutes of previous meeting, Mr. T. H. K. Lees was elected a member of the Club.

Mr. W. C. Williams was then called upon to give his paper on "The Enlargements of Photographs." He especially recommended 5 by 4 and 8½ by 6½ plates as the best adapted and most portable for negatives, and then for enlarging from. He exhibited a sharp and clean negative, 5 by 4, and an enlarged transparency, 15 by 12, from the same. He wished the members especially to well consider both the position and the lighting of a landscape, in order to get the best results. Two of the negatives and enlargements were very choice views in the Hebden Bridge Valley, and comprised a good distance with very well selected foreground of rocks and water, while behind were some fine trees, ferns, and ground foliage; the other was a stranded vessel at Barmouth, North Wales.

A hearty vote of thanks was passed to Mr. Williams for his most instructive paper, of which he will give the second part on January 9th, 1883.

Talk in the Studio.

Photographic Society of Great Britain.—The next ordinary meeting of this Society will take place at the Gallery, 5a, Pall Mall East, at 8 p.m., on Tuesday next, December 12 (the Winter Exhibition of the Royal Society of Painters in Water Colours being on view), when the discussion on Mr. W. K. Burton's paper, read at the last meeting, will be taken; and a paper on "The New Diffraction Grating and Photography," will be read by Captain Abney, R.E., F.R.S.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The annual dinner is fixed for Friday, December 15th, at the Holborn Restaurant. Dinner will be served at 6.30 punctually. Tickets, 5s. each, from Mr. F. A. Bridge, Hon. Treasurer and Secretary, 9, Norfolk Road, Dalston Lane, E.

PHOTOGRAPHIC SOCIAL MEETING.—On Tuesday, the 28th ult., the employées and friends of Messrs. Turnbull and Sons, Jamieson Street, Glasgow, numbering upwards of two hundred, held a brilliant *conversazione* in the Coal Exchange Hall, West Regent Street. Dancing began at eight o'clock to the inspiring music of Adams' talented band. Mr. H. D. Wilbeck emerged from his retirement to do honour to his friend the senior partner of the firm, and acted as M.C. with all his well-known courtesy and energy. Some songs well rendered by a number of amateurs contributed in no small measure to the harmony of the evening.

PURIFICATION OF BEET SPIRIT.—L. Salzer effects this by caustic potash. According to his patent, 80 grams pure potassium hydrate are left in contact with every hectolitre of 90 per cent. alcohol, with frequent stirring during the first twenty-four hours; then 10 per cent. of water is added, and the whole stirred for thirty-six hours. Filtration and neutralisation with tartaric acid follows, after which pure alcohol may be distilled off.

A NEW USE FOR POTATOES.—G. Boeck finds that, if potatoes be peeled and treated with 8 parts sulphuric acid and 100 parts water, then dried and pressed, a mass is obtained resembling celluloid, which can be used instead of meerschaum or ivory.—*Journal of the Chemical Society.*

To Correspondents.

*** We cannot undertake to return rejected communications.

CAPT. TURTON.—We regret we cannot give you the information you ask for.

T. M. AND R. A. J.—Thank you, but your contributions come too late. We are truly sorry, for the loss will be our readers' and our own; still, it is scarcely our fault, if it is our misfortune for we asked for them early last month. The poet most tritely observes, "Thirty days hath November," and we should have been glad of your contribution on any one of them.

J. BARNES.—We do not know of any who make a speciality of such work; but as no unusual qualifications are required, you had better make arrangements with someone in your own neighbourhood.

J. H.—Doubtless the simple carbonate or washing soda is intended; at any rate, good results may be obtained by its use.

VELVET ROLLER.—You should obtain the works of Léon Vidal on the subject. 2. Write to Mr. Woodbury, Java House, The Manor Road, South Norwood, S.E.

F. W. BARBER.—1. Principally a basic ferric oxalate. 2. To workers on a moderate scale, the product is of so little value that it is better not to waste time on it.

CONSTANT READER.—Cheap sets are advertised in our columns; but you had perhaps better get just those things which you actually require.

T. L.—We shall be pleased to have a short account of the methods employed.

W. H. M.—A weak solution of chloride of lime—the so-called bleaching powder—will answer perfectly.

LILAS.—No very detailed account has been published.

S. B. M.—The so-called encaustic paste—see the Formulary last week

HECTOR COLARD.—We believe that Mr. Warnerke has not published full details on this point; but we will endeavour to obtain the information you require.

A. A. CAMPBELL SWINTON.—About one part of Castile soap in twenty of water. If you blow the bubbles with a mixture of gas and air, there is not much difficulty in making them of about the same specific gravity as air. If they are blown in a room free from air currents, it is often practicable to keep them for several minutes before they burst. The addition of glycerine to the soap mixture favours the lastingness of the bubbles, but does not favour the production of the Newtonian thin-plate colours.

D. MCARTHUR.—A little better from a theoretical point of view; but, as a matter of actual practice, we prefer to use the ordinary form.

C. V. H. W.—1. Far too much top-light, hence the dark shading round about the eyes. 2. Just what might be expected, and you had better now extract the silver and make a fresh bath. 3. Try by all means; the difficulties are not nearly so great as you appear to imagine.

COLLOID.—Sulphate of lime in crystals is largely used for the purpose, but clay is more usually employed.

A. LITTLE.—A notable degree of cold is produced when the hyposulphite is dissolved in water; and the solution fixes prints with extreme slowness, unless time is allowed for it to reach something approaching a normal temperature. You may use slightly warm water for dissolving the hyposulphite, but if the solution is used warm, your prints will be considerably reduced.

VAUXHALL.—The expansion will be about one-sixtieth, as regards linear measurement.

W. H. MASON.—Write to Mr. A. L. Henderson, King William Street, London, E.C.

*** Authors may have Reprints of their Articles at 3s. per page per hundred copies; but the order must be given when the proof is returned.

᾿# THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1267.—*December* 15, 1882.

CONTENTS.

ON THE EFFECT OF KEEPING EMULSIONS BEFORE AND AFTER WASHING.

It will be recollected that in describing the emulsions made by Mr. W. K. Burton's method, we gave the results as regards sensitiveness of plates coated immediately after finishing the emulsions. We shall give the result of a week's keeping before entering into the consideration of such observations as we have made on the effect of time in ripening emulsions made by ordinary methods.

We described, in the article alluded to, three emulsions, one made exactly in accordance with Mr. Burton's directions, another showing departure from them only in the omission of the alcohol recommended to be used in conjunction with the ammonia, and the last made without ammonia at all, but boiled for two and a-half hours. These we called Nos. 1, 2, and 3. The sensitometer number given by No. 1 was 15, by No. 2, 17; and by No. 3, 19. After a week's keeping, the numbers were respectively 18, 20, and 21, whilst the sensitiveness to the camera was as near as possible in the ratio of 2, 3, 3; that is to say, the whole of the three emulsions gave plates of unusual sensitiveness. That given by Mr. Burton's exact formula gave plates somewhat slower than those got from the formula slightly modified by the omission of the alcohol or by omitting the ammonia, and substituting for it a long period of boiling. The emulsion which was lowest has increased in rapidity to the greatest extent, and shows a sensitiveness but little short of the others. The greatest increase is represented by 3 or 4, the least by 2. We are now referring to true sensitiveness as exhibited in the camera, and not to sensitiveness as exhibited by the sensitometer.

So much for the particular experiments which we have recently been making. We shall now give the results of such observations as we have made on the effects of keeping emulsions made by the ordinary methods both before and after washing.

An emulsion made by the boiling method may be kept for an apparently indefinite length of time, either immediately after the boiling, or after the bulk of the gelatine has been added. In the former case a considerable subsidence of the bromide is likely to take place, in the latter case not. In both cases a certain increase in sensitiveness will take place, but how much greatly depends on temperature. If this be low—say only about 40° or 45° Fah.—no perceptible change is likely to take place in a week's time. On the other hand, if the temperature range from 60° to 75°, an increase represented by 2 or 3 may occur.

It is in the case of the ammonia nitrate method that the advantage of keeping an emulsion before washing is most evident. It is natural that it should be so, as the whole of the ammonia liberated at the moment of combination is still in the emulsion. The period of keeping which is of an advantage may vary between a week in cold weather, to twenty-four hours in warm. In either case an increase of sensitiveness of from two to three times should take place. The period may be increased without actual destruction to the emulsion, but there would appear to be little advantage as regards sensitiveness, whilst green or red fog is likely to make its appearance. Of course in the case of the acid or neutral method, the ammonia may be added after cooking, when the same result will ensue as if the ammonia nitrate method had been used. We believe Mr. A. Cowan was the first to recognize the advantage of the keeping of an ammonia nitrate emulsion before washing.

Captain Abney was, we believe, the first to notice that, even after washing, an emulsion increases in sensitiveness by keeping. Since he published his discovery, many different opinions have been expressed on the subject. Some have found even greater advantage from ripening than Captain Abney claimed for it; others less, some few none at all, and one investigator has even gone so far as to state that emulsions sometimes become slower by keeping. We believe we can account for an apparent slowing of an emulsion through keeping, even although the sensitiveness in truth did not decrease, but probably, on the contrary, slightly increased. Probably the observations of sensitiveness were made by the aid of a sensitometer. It is quite possible that the emulsion was impressed during preparation with a certain amount of light, not enough to produce fog, but sufficient to give a delusively high sensitometer figure. It is further possible that the free bromide was not perfectly washed from the emulsions, but that a sufficient amount remained to eliminate during a few days of keeping the effect of the light, and restore the sensitometer to the normal figure. It has been stated that soluble bromide even in a dry film may destroy the latent image. We are unable to corroborate this, but we consider it more than probable that in the wet state, as in an emulsion, bromide of potassium or ammonium will destroy a slight effect of light.

There are two factors which greatly modify the extent of the increase of sensitiveness which takes place in an emulsion after keeping. One is the condition of the emulsion as regards acid or alkaline reaction, the other is temperature. A neutral or even acid emulsion will increase in sensitiveness to a small extent. It will nearly double its rapidity, and in this case the increase appears to be almost, if not quite, independent of temperature, so long as a very low degree of heat be avoided. It is only when the reaction is alkaline that the increase is very marked. Here temperature appears to have much to do with the matter. It is not safe to render an emulsion very alkaline after the restraining bromide has been washed out. In fact, anything beyond barely perceptible alkalinity is useful. When the emulsion is slightly alkaline, and the temperature is high, say about 70°. Fah., then the increase of sensitiveness is greatest; but a very great element of uncertainty is introduced.

We had last autumn a remarkable example of this. We made an emulsion which was moderately rapid. It gave the figure 14 of the sensitometer. The plates were quite free from all defects, such as green, red, or other fogs. We rendered it slightly alkaline; more so than we now consider safe. We added nearly a minim of ammonia to each ounce of emulsion. The weather was warm; the temperature of this emulsion, during the time of keeping, probably averaged little, if at all, below 70° Fah. After keeping the emulsion for four days, we coated plates once more. These showed figure 21; that is to say, an enormous increase of sensitiveness had taken place—an apparent increase of seven or eight times, probably an actual one of five or six times. On fixing, however, there were decided indications of green fog—not very great, but still they were there. It was a premonitory symptom of what was to come. We kept our emulsion for a few days longer, and once more coated plates; this time the sensitiveness had actually fallen. The figure given was only 17, and there was dense red fog. This is not the only time in our experience when the advent of red fog appears to have rendered an emulsion less sensitive than it was before. All who have the misfortune to be conversant with red fog must know the appearance—as if the peculiar ruby deposit actually pushed the finer details under.

We may say, in conclusion, that we have at least in cold weather no hesitation in rendering an emulsion slightly alkaline before laying it by to keep, but the reaction should be the faintest possible. Beyond what may be required to render the gelatine neutral, an addition of a minim of ammonia to each six or eight ounces of emulsion is sufficient.

ELECTRICAL CONDUCTIVITY AND MELTING POINT OF CHLORIDE AND IODIDE OF SILVER.

Our readers will remember that we brought to their notice a little while ago an interesting investigation by Mr. G. F. Rodwell on some physical properties of iodide and chloride of silver. We all know in photography how different is the behaviour of these haloid salts, and on this account, if for no other, it is interesting to observe their characteristics elsewhere, if only to trace, if we can, the same peculiarities which mark them in other branches of science. In other words, the behaviour of chloride, bromide, and iodide of silver in the presence of light is often so remarkable that the influence of these same bodies under heat and electricity offers an attractive study, since it may lead us to explain matters we are at present unable to fathom in the formation of the photographic image.

Recently Herr Kohlrausch has published in the *Annalen der Physik und Chemie* the results of a series of experiments which prove that mixtures of chloride and iodide of silver do not behave in the same way, physically, as do these salts separately; moreover, he tells us that the behaviour of iodide of silver in the presence of heat and electricity is totally unlike that of chloride and bromide of silver. In these circumstances, the question naturally arises whether this exceptional behaviour does not bear some reference to the similarly exceptional behaviour observed in photography when iodide of silver is in admixture with other silver salts.

According to Kohlrausch, the melting point of chloride silver is above 485° C. (Rodwell putting it at 451° C.), and the melting point of iodide of silver 450° C. (Rodwell says 527° C). A mixture of equal equivalents of chloride and iodide of silver melts at a much lower point than either of the bodies separately—viz., at 260° C. This, clearly, is a most remarkable fact.

Chloride of silver, bromide of silver, and iodide of silver are good conductors of electricity above the melting point; then, chloride of silver becomes the best conductor, and the worst is iodide of silver, bromide of silver being in the middle.

The electrical resistance of chloride of silver and bromide of silver increases, on setting, very much indeed (passing from the amorphous to the crystalline condition); it rises, on cooling to 20° C., to more than a million times what it originally was. Iodide of silver, on the other hand, does not alter its resistance in the least degree on setting (540° C.), but shows a rapid decrease when it passes from the amorphous to the crystalline condition (145° C).

So that we have here a new proof, quite apart from that in photography, of the existence of different modifications in the three well-known haloid salts of silver.

PLENER'S METHOD OF SEPARATING AND EMULSIFYING BROMIDE OF SILVER.

BY DR. J. M. EDER.

Plener's method consists, as I need scarcely inform the readers of the Photographic News, in completely separating the bromide of silver from a photographic gelatine emulsion by means of a centrifugal machine, the gelatine from which the silver salt is isolated being in most cases partly decomposed, owing to the operation of emulsification to which it has been submitted. The advantages of such proceeding I may here set down:—

1. The bromide of silver is separated from gelatine which has been modified by heating or digestion with ammonia, and which is often a source of fog, flatness, and frilling; this silver salt may then be added to fresh gelatine and emulsified, thus improving the quality of the emulsion.

2. A large stock of very sensitive bromide of silver without gelatine may in this way be kept for some time unchanged, capable of employment at any time in emulsion making, and this bromide has always a uniform sensitiveness.

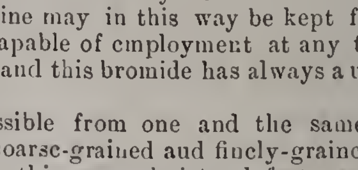
3. It is possible from one and the same emulsion to separate the coarse-grained and finely-grained bromide of silver, and in this way obviate defects and difficulties which their mutual presence leads to.

4. The ripening of the emulsion can also be pushed to the utmost, without fearing any decomposition of the gelatine, which frequently brings about fog, &c.

5. It is practicable in the preparation of the original emulsion to employ not only gelatine, but other substances which are likely to increase sensitiveness, since all these can be completely eliminated subsequently, so that nothing of them remains behind in the finished plates; at the same time, the washing is more complete than in any other method.

Mr. Plener has been staying for some time in Vienna, and, working with him, we have together undertaken certain experiments with his centrifugal machine, in order that I might form an opinion on the value and construction of the instrument.

The reservoir in which the separation takes place consists of a vessel of gun metal.* Some idea of its shape may



be gathered from this sketch, the vessel being first thickly electro-plated inside, and then gilded. The reservoir or

* In experiments undertaken with a rapidly revolving instrument of this kind, much care is necessary; several copper vessels too thinly constructed were destroyed during Mr. Plener's early experiments in London.

separator turns on a vertical axle, which revolves at a speed of from 4,000 to 6,000 revolutions per minute.

On turning at this speed, the centrifugal force is sufficient to throw all the comparatively heavy particles of bromide of silver against the walls of the separator, forming a clotted film over the interior of the instrument, so that, in the end, the liquid gelatine may be poured off and the vessel rinsed with water.

The finely-caked bromide of silver is scraped from the sides of the separator with a spoon, and is now in the form of a paste. This pasty mass emulsifies but badly in water, and soon precipitates, while in alcohol it will not emulsify at all. On the other hand, it becomes immediately incorporated and most uniformly emulsified in a warm gelatine solution, let this be either acid or ammoniacal, the result being a fine-grained emulsion, as fine as the original.

The pasty mass aforesaid dries in the air to a hard gum-like amorphous substance, which is with difficulty pulverised in a mortar. The mass, notwithstanding the washing to which it is subjected, contains gelatine and traces of water; on this subject I will send the readers of the News further particulars as soon as my experiments are ended.

The dry bromide of silver disintegrates quickly in water, and assumes again its pasty character; it may be emulsified just as easily as before drying. It is very different from the flocculent bromide of silver precipitated in water and dried.

Mr. Plener, in my presence, passed several samples through the centrifugal machine, which samples had been prepared in various ways—viz, by means of ammonio-nitrate of silver, the acid cooking method, &c. Even in the case of emulsions very rich in gelatine, the separation was effected in from five to six minutes. The finest precipitated bromide of silver, which I produced for the purpose, Mr. Plener separated in ten minutes.

I found that Mr. Plener's statement was well founded, that every ripe emulsion contains coarse and fine-grained bromide of silver. The former was thrown against the wall of the separator at the commencement of the operation, and the finer silver salt later on. By breaking the centrifugal operation at a certain period, it was possible to collect the two kinds separately. It was found that in a half-ripened emulsion, the coarse-grained bromide was more sensitive than the fine-grained. In an emulsion which approached the maximum of sensitiveness, the course-grained bromide separated, and gave fog, while the fine-grained bromide was perfectly free from this defect, and was very sensitive. The fine-grained bromide of silver gave too dense negatives.

If the separated bromide of silver is put into the developer, it will blacken even in the dark. A film of it applied to an adhesive surface and dried, gives a fogged and very thin image. A dried film of this character, coated with gelatine, gives an exceedingly weak picture, which is fixed with very great difficulty. On the other hand, the silver bromide in form of powder, mixed with gelatine and emulsified, gives brilliant vigorous negatives, which are rapidly developed and fixed.

As regards the chemical quantities of ripened and not ripened bromide of silver recovered by the Plener separator, I must defer my remarks until I have completed the research which I am conducting on the subject. This will take me some time yet, but in due course I will communicate the results to your readers. I may say the same in respect to the mediums I have employed for mixing with the bromide of silver powder under various conditions.

The machine, which Mr. Plener has now employed for upwards of a year, has given exceedingly good practical results, and some emulsion prepared with it repeatedly, showed No. 25 under Warnerke's sensitometer, together with a high degree transparency and density. As the best German commercial houses prepare plates with an average sensitiveness of No. 15 (Warnerke), and the best English instantaneous plates (according to the Photographic News, 1882, page 722) show an average sensitiveness of No. 17½ and a maximum of No. 20, we may take it that the Plener plates are sixteen times as sensitive as the first-named, and four times as sensitive as those of English makers.

Vienna, December 5, 1882.

IMPURE BROMIDE OF AMMONIUM.

The following, which appeared in the last issue of the *Pharmaceutical Journal*, is written by Mr. E. G. Hogg, and may have an important bearing on the work of the emulsionist:—

A somewhat curious case of poisoning having come under my notice a few months since, it has occurred to me that a short account of it might be of interest to your readers, and also be a warning to pharmacists of the necessity of assuring themselves of the purity of the chemicals they purchase. A prescription (written by a physican known to me) consisting of ammon. bromid. and sal volatile in ordinary doses, was dispensed at a Continental pharmacy. The first dose, instead of producing the usual effects, caused violent sickness, the vomit being of a peculiar red colour, accompanied by all the symptoms of irritant poisoning. A portion of the mixture was brought to me by the doctor in question, who went over to investigate the matter. Upon making an examination of the mixture, I found, in addition to ammon. bromid. in solution, there was an insoluble precipitate, amounting to about one grain per fluid ounce of the mixture, which, upon analysis, I proved to be carbonate of cadmium. This result seemed so improbable, that a further portion of the mixture was taken by the physician to a well-known analyst, who confirmed my report. Subsequent inquiry has brought to light the following facts. That the principal fault lay with the manufacturers, who have since acknowledged that they found the whole batch of ammon. bromid., of which that used by the Continental pharmacist was a part, had, through the carelessness of their workmen, become contaminated with a cadmium salt, of which they were large makers. I have since learnt that cases of poisoning by cadmium are rare. In several books that I consulted, I could find nothing about its physiological effects. I am told the colour of the vomit is highly characteristic.

From a medical point of view this, of course, is a very serious affair, much more so than as far as it concerns the photographer; unless, indeed, he happened to be the party dosed.

The bromides have for some time past been largely prescribed in cases of epilepsy, and it might be reasonably supposed that for medicinal purposes none but pure chemicals would ever find their way on to the shelves of the pharmacist; but we fear the demand for cheapness causes a laxity in the manufacture, which the warning in the above letter more than hints at.

Whether such a contamination as cadmium carbonate would influence the photographer in the matter of his emulsions, we are scarcely in a position to state without trial; but this much may safely be said, that in the adoption of any given formula the result may easily be interfered with by the presence of any adulterant which weighs, even although it might be mere sand, because the calculation of equivalents would be completely upset. We have heard of something of the nature of this complaint before, instances of impure bromides having been mentioned in photographic circles; indeed, other chemicals, such as silver nitrate, are sometimes found to be sophisticated.

The subject from a photographic stand-point has sufficient importance to warrant attention, and perhaps some of our chemical readers may have something to say on the matter.

A NEW DEPARTURE IN ALKALINE DEVELOPMENT.

BY JOHN MCKEAN.*

As there is still a conflict going on—if not in the pages of the photographic journals, in the minds of photographers in general—

* Read before the Edinburgh Photographic Society.

as to the best method of developing the gelatino-bromide plate, I need offer no apology in bringing before you this evening my experience in this direction.

That we are now in the possession of dry plates that surpass in many ways our old and well-tried friend the wet collodion, no one will venture now to dispute. It is interesting to look back on the early struggle of gelatine to overcome collodion, and to reflect that, though the former has triumphed, it has not been through any vast improvement in the formula, but in the mode of treating it; and certainly we have yet much to learn before there is anything like harmony of results between plates of different makers.

Looking over the advertisement pages of journals, when the wet collodion held sway, when photographers could do nothing without alcohol, we find that every manufacturer of collodion produced the best article. Photographers knew, however, that each had certain qualifications, and, without disputing the right of priority in either, wisely mixed their different samples, and so secured more favourable results. But now it is otherwise; our picture must be produced according to the individual merit of the plates; and until photographers make their own, they must be content to labour under that feeling of uncertainty which naturally takes hold of one before applying the developer. Doubts arise as to length of exposure, which, in the bustle of a thorough-going studio, is practically impossible to remember; nor is it necessary, for, as we all know, the light must be varied according to the model under treatment. We have as yet nothing practical to guide us in this respect but our own experience, and here it is that beginners naturally fail; though in my own experience there is a wider latitude of exposure in gelatine plates than was at first thought possible—that is, if the developer is cautiously applied—which also requires some experience, imparting knowledge of what really constitutes a good negative. It has always been my aim to simplify the process of development, to call forth the latent image with as little ceremony as possible, with all the bloom and beauty of a perfect negative. How far I have been successful remains to be seen.

There are two developers which have found most favour in the dark-room—namely, alkaline pyrogallic and ferrous-oxalate. The former has always been a favourite with me. Though I have obtained good results with the latter, it requires in my hands more care, and consequently more time and trouble, before proceeding to develop, not to speak of its being more expensive when only a single plate may chance to be operated upon at a time. To these two developers is due, I believe, the success of the modern dry plate. Yet there is still a murmur throughout the profession against that want of something in the gelatine negative which characterised that of the wet collodion. In the former we have certainly more detail in the shadow than in the latter, yet there seems a want of harmony between the high lights and deepest shadows of the picture. The half-tones lack strength; unless in very favourably-lighted subjects their beauty will vanish with the printing.

Having tried several modifications in the pyrogallic developer, using bromide as a restrainer, I began to suspect the latter as the principal agent in the evil just referred to—namely, weak half-tones and exaggerated high-lights in the negative.

I need not mention the many substitutes for bromide that passed over as many plates and down the sink before finding a suitable one to control harmoniously the action of the ammonia. Suffice it to say I found one, a close relation to ammonia, and so beautifully do they work together that they have induced me to dismiss from my formula the services of bromide, and for over six months I have never once returned to seek its aid to help me through the densest fog which I may have encountered during that period. It must not be supposed, however, that I have found in the developer a cure for fog, chemical or otherwise; the plate itself is usually the fountainhead of all our troubles in this direction. We are aiming at greater speed; but, like the good ship in the presence of fog, we must proceed with caution. But to my developer.

A cold saturated solution of bicarbonate of soda	..	1 ounce
Liquor ammonia, ·880 ...	...	1 ,,
Water ...	...	4 ounces

A few drops of the above, according to the size of plate, in a three-grain solution of pyrogallic will develop any good plate with less exposure and with more printable detail in the shadows than has ever yet been secured with the use of bromide. I need hardly say that, should you find the shadows not so clear as may be desired, increase the quantity of bicarbonate; but in this particular I have had no trouble with my own plates.

After development, place the negative for a few minutes in the alum bath; then fix as usual. One or two drops of nitric acid in the hyposulphite solution will dispel any trace of fog that may exist after a forced development in the case of under exposure.

Carbonate of soda and ammonia sounds something like carbonate of ammonia, a chemical, as some of you are aware, used in alkaline development for collodio-bromide plates, restrained in its action by the use of bromide. I have never taken the trouble to enquire into the chemical change, if any, that takes place when making up my developer; yet glancing at the formula it does not seem as if carbonate of ammonia can be formed to any great extent. If otherwise, what is the restraining power by which I am able to abandon the use of bromide?

I shall add no more, further than my recommendation to all at least to give the bicarbonate developer a fair trial; and if you find it as I have—simple, cheap, and reliable—I shall not repent my non-procedure to the patent office.

With your permission I shall now in a practical way show my method of using this "new departure in alkaline development." You have been requested to bring impressed plates for demonstration; but before taking it upon me to do them justice, it is well to remind you that I can only develop that which is impressed by light; but if the plates have a tendency to fog, that shall I also develop. I trust, however, you will be able to see through it, and so proceed.

FLEXIBLE WINDOW FOR DARK TENT.

BY A. B. STEWART.*

Most of the papers read before this Society are the productions of the professional members of the Society, very few being contributed by amateurs. The reason of this is not difficult to discover. Human nature is chary of exposing its own ignorance, and amateurs generally are naturally rather diffident about airing the little knowledge they possess before a meeting of skilled professional workers such as generally fill this room. Of course it is not for me to complain of this fact, as I and other amateurs who are not too old to learn, or too proud to take a hint from the experience of others, benefit by it.

Professional men as a rule—aye, and tradesmen too—are averse to communicating what may be called their trade secrets to outsiders. Photographers, however, form a noble exception to this rule, as in my experience I have always found them one and all ready and willing to give every information required to anyone asking it. And here I would like to express my sense of the obligation which I lie under to this Society as a body for much valuable information conveyed in the papers read before this Society, and published in the Transactions, and the discussions which have taken place on these papers, and to the individual members of this Society, both professional and amateur, for advice and assistance readily and willingly given whenever asked. Gratitude has been defined as a lively sense of benefits to come, and in the future, as in the past, I shall show my sense and gratitude by at once, whenever I find myself in a photographic difficulty, applying to the nearest photographer, sure of obtaining freely whatever advice or information I may need which lies in his power to afford. I come before you, therefore, in the hope that my little contribution may be accepted, not so much on account of any merit it may possess, but rather as an acknowledgment of the benefits I have received from this Society and its members.

My invention—for, although there is not much in it that is actually new, I think I am justified in calling it an invention—is one which may be of very little use to professional photographers or to those amateurs who are possessed of plenty of means, and who can, therefore, easily procure lots of double dark slides or such a camera as that shown by our friend Mr. Wane at a recent meeting; but to those amateurs like myself, of limited means, fond of the art, and pursuing knowledge under difficulties, I think it may prove to be of some service. It is a window for a changing-tent for open-air work, and I make it thus:—On a well-polished plate of glass I pour a film of plain collodion; while this is drying, I dissolve 25 gr. gelatine and 4 gr. bichromate potassium in 1 oz. of water. Then I dissolve 4 gr. nitrate of silver in ½-oz. of water, and mix the two solutions; this forms a dark red emulsion, which I filter, to expel air-bubbles. I then warm the collodionized plate, and pour on sufficient emulsion to form a film of the tint required, and set it

* Read before the Edinburgh Photographic Society.

aside to dry. When dry, I put over it another film of plain gelatine to strengthen and protect it. I show you the result. In its present state it would not stand much rough usage, and I therefore mount the window so made on thin Turkey cotton with gelatine, and give it a coat of copal varnish, after which I fasten it in its place in the dark tent. I show you my completed window. As I have said, there is nothing new in any part of it—all the novelty I claim is the utilization and combination of other men's ideas and applying these to the object in view.

My window has one thing to recommend it—it fulfils all the conditions necessary in an article of the kind. It is non-actinic—as perfectly non-actinic as anything short of total darkness can well be. I have exposed exceedingly sensitive plates under it to the full glare of the sun, of course for as short a time as possible, without a trace of fog. It admits quite sufficient light to enable the operator to change his plates; I show you a few prints from negatives changed in the light transmitted through such a window. It is cheap—the whole thing can be made for less than twopence. It is easily made—every one who dabbles in photography has the whole of the ingredients and apparatus at his hand, and the process is simple. It is perfectly flexible—it may be rolled up or folded with the tent in any way the operator chooses; and practically, with ordinary usage, it is indestructible. Light only improves it by rendering it more and more insoluble. It is waterproof—I had to take shelter under my tent once in a thunderstorm, and had to roll it up wet after the shower was over; it remained so rolled up all night, and was only thoroughly dried when I got home two days afterwards, and it is not a bit the worse. Indeed the window in my dark-tent after one month's constant use—and pretty hard usage too—is as good as on the day I put it in.

ON A MODIFIED GELATINE EMULSION PROCESS.

BY W. K. BURTON.*

I PURPOSELY avoid entitling the modification which I propose to describe to you to-night a new process. Although, so far as I know, it has never before been published in a practical working form, yet I know that the principle on which it depends has often been noticed. This is nothing other than the property which an emulsion made by the so-called boiling process exhibits when, after the heating has been continued for long, the bromide of silver commences to settle to the bottom of the vessel.

I believe I shall best make you understand the process by explaining, as briefly as possible, and without comment, the method which I follow in making an emulsion; after which, I shall go over a few of the more important points in detail, and then describe to you what I conceive to be the advantages of the process over those usually practised.

A.	Potassium bromide	340 grains
	Nelson's No. 1 gelatine	60 ,,
	Water	20 ounces
	Hydrochloric acid, enough to render the solution very slightly acid ... about	2 minims
B.	Iodide of potassium	10 grains
	Water	1 ounce
C.	Nitrate of silver (dry)	400 grains
D.	Ammonia ·88	¾ ounce
	Alcohol	1 ,,
E.	Heindrich's gelatine	360 grains
	Water	20 ounces

I place A in a hock bottle, and warm till the gelatine is melted; I then add the dry nitrate of silver in one quantity, and shake up till I know, by the sound of the crystals striking the bottle ceasing, that they are all dissolved and emulsified. I now add B.

The next operation is precisely similar to that which is usual in the boiling process. The emulsion is poured into any convenient vessel, and boiled for about fifty minutes; it is then allowed slowly to cool to 120° Fahr. D is now added, and the whole allowed to stand for forty-eight hours; at the end of this time the supernatant fluid may be poured off almost quite clear; 20 ounces of water are again added, the bromide being stirred into it. The whole is once more allowed to stand for forty-eight hours, when the water is again poured off. The bromide of silver I now consider to be sufficiently washed. E is added; the two ounces of vessel is warmed, and the emulsion is complete. methylated spirits, with 20 grains of salicilic acid dissolved in it, and 4 or 5 minims of ammonia to counteract the acidity of the gelatine, are added. The emulsion should be kept a few days before coating plates with it.

* Read before the Photographic Society of Great Britain.

Now I propose to go somewhat more into detail in regard to one or two points. First, as regards the formula used I may say that any one suitable for the boiling process will do. The only thing noticeable about the quantities in the formula which I give is the large amount of water used. This I consider very important. There appears to be a general impression that the amount of bromide of silver which a given weight of gelatine is capable of suspending is greater if the quantity of water be reduced so as to make a comparatively concentrated gelatine solution. To take an example, it is, I believe, the general opinion that if the 60 grains of gelatine above mentioned be dissolved in 6 ounces of water, so as to make a 10-grain solution, it will suspend more bromide of silver than if it be dissolved in 30 ounces of water to make a 2-grain solution. The very reverse is the fact. The more a gelatine solution is diluted, the more bromide of silver may be suspended in it, and that in a finer state of division.

In most formulas the addition of a large quantity of water is objectionable, as the emulsion will not afterwards set sufficiently stiffly to allow it to be washed. With the process under consideration the objection does not hold. With the quantity of water given it is *impossible* to get other than a finely divided emulsion of a ruby colour by transmitted light, however carelessly the mixing be performed. I therefore adopt the very simple method of dropping the silver in one mass into the bromide solution, and shaking till the former is dissolved. It will be seen that an emulsion in a very fine state of division, and of a ruby colour, is the result.

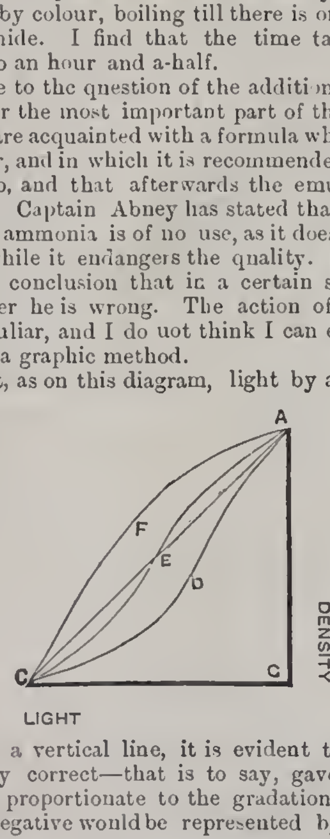
I add the iodide in a separate solution afterwards, for the reason given by Captain Abney—that by so doing the iodide will be in the same state of division as the bromide, the iodine of the iodide replacing so much of the bromine of the already formed bromide of silver.

As regards the time of boiling, I find fifty minutes as an average time. Very insignificant modifications in conditions, however, considerably alter the time necessary: and in practice I always judge by colour, boiling till there is only a trace of red left in the bromide. I find that the time taken varies from forty minutes to an hour and a-half.

We now come to the question of the addition of the ammonia, which I consider the most important part of the process.

Most of you are acquainted with a formula which, I believe, is due to Dr. Eder, and in which it is recommended that boiling be first resorted to, and that afterwards the emulsion be treated with ammonia. Captain Abney has stated that the subsequent treatment with ammonia is of no use, as it does not increase the sensitiveness, while it endangers the quality. My experiments lead me to the conclusion that in a certain sense he is right, whilst in another he is wrong. The action of ammonia on an emulsion is peculiar, and I do not think I can explain it except by resorting to a graphic method.

If I represent, as on this diagram, light by a horizontal line,



and density by a vertical line, it is evident that if a negative were absolutely correct—that is to say, gave a gradation of density exactly proportionate to the gradations of light in the subject—that negative would be represented by a straight line, C A.

I believe no sensitive substance has been investigated which will give such an absolutely correct negative; but that, on the contrary, all sensitive substances will give gradations represented by curves more or less nearly following the course of the straight line C A.

With a boiled emulsion, the curve representing density will follow a course something like C D A. On the other hand, in the case of an ammonio-nitrate emulsion the curve will be like C F A. Now, inasmuch as these curves both commence at the same point, plates which are represented by them will, if exposed under a sensitometer-tablet and afterwards developed, each show the same last figure, aud, if judgment be taken by reading the sensitometer in the usual way, will both pass as of the same sensitiveness. Let them be exposed in the camera, however. It is quite evident that uo exposures can give precisely similar results ; but to get what is somewhat indefinitely described as a well-exposed negative iu each case will require for the plate C D A a much longer exposure than for C F A. I have knowu plates giving the same sensitometer figures, but requiring camera-exposures varying as 4 or 5 to 1. On the other hand, plates requiring the same camera exposure may show differences to the sensitometer of 5 and 6 figures. I am here not taking into account the effects of pre-exposure.

There is an objection, however, to the very high curve C F A, inasmuch as it is a very great departure from a correct rendering of the intensities of light reaching the plate, although it is more like that given by collodiou, which is so often aud so incorrectly held up as a model to dry-plate workers.

It is possible, however, by a combination of the boiling and the ammonia processes, to get any curve between the two extreme ones which I have given. I believe that, with the formula which is above, a curve very like C F A is obtained ; and that is as near an approach to the hypothetical straight line as it is possible to come.

I have always, previous to this, deprecated the use of ammonia in the making of emulsions, because it is liable to give rise to green, red, brown, and other fogs ; but, with the process in question, this drawback is entirely overcome, inasmuch as the bulk of gelatine never comes in contact with the ammonia at all. I have never had a case of green fog in plates coated with emulsions made as detailed.

The alcohol is added with the idea that it will prevent the possibility of decomposition—or, rather, putrefactiou—of the gelatine. I believe it is not very necessary.

With regard to the washing of the precipitated bromide and iodide of silver, of course there is no objection to stirring it with water twice, and allowing it to settle altogether three times ; but I find that, with the amount of washing recommended, the whole of the free bromides, as well as the nitrate and ammonia, are practically got rid of.

In giving forty-eight hours as the time necessary for the bromide of silver to settle, I consider that I am making a very ample allowance. The time taken is naturally very much modified by the form of the vessel used ; it, moreover, varies with conditions which I have not been able to discover. I may say that, on an average, the bromide settles at the rate of about an inch in six hours. Forty-eight hours would thus allow for a vessel eight inches deep. The one I now use has about six inches of fluid in it, and it would take an average of about thirty-six hours for the bromide to settle. Often, however, I have known it to take less than half that time.

It will be evident that the use of a shallow vessel will cause the precipitation to take much less time. There are, however, obvious objections to the use of a shallow vessel. I think it quite likely that means may be discovered of causing the precipitation to take place far more rapidly than I have described. The fact that occasionally the bromide will settle without the addition of the ammonia, whilst at other times it will not, even when the circumstances and treatment are apparently the same, shows that the matter is not thoroughly understood as yet.

I now come to the mixing of the gelatine with the bromide of silver, to form the emulsion. Here, it is just possible that, by carelessness, the operator may fail to so mix the bromide and the gelatine as to get a fine state of division. He cannot, however, fail, if he follow the method which I now show. I have here, in one glass beaker, 360 grains of hard gelatiue soaked in 20 ounces of water; in the other I have the bromide of silver, with the washing-water still over it. I pour the water away, and you will see that it is almost colourless, and that it is necessary to leave only the smallest quantity conceivable, to prevent any of the haloid from coming over with it. I now plump the 20 ounces of water, and the 360 grains of gelatine into the silver haloid. I take a glass rod, and twist the gelatine round the end of it. With the kind of mop thus formed, I scrape the bromide and iodide of silver from the bottom of the vessel whilst I gently apply heat. When the gelatine is melted, the emulsion is complete.

I have tried the result of varying to a very considerable extent the proportion between the bromide of silver and the gelatine iu emulsions made as described, and find that there is remarkably little difference in sensitiveness between an emulsion rich in silver bromide and one poor.

I have divided the precipitated bromide of silver, and to one-half have added double as much gelatine as there was dry bromide, whilst to the other portiou I have added only half as much gelatine as there was bromide. Plates were coated with these emulsions, oue contaiuing four times as much gelatine as the other. In each case the plate was coated until it was thought to be sufficiently opaque. This took, of course, much more emulsion in one case than in the other. Iu fact, the quantity of bromide of silver ou each plate would be approximately the same. On exposure and development the oue plate was scarcely distinguishable from the other. That which had the least gelatine in it showed, after fixing, somewhat of a better colour of image than the other, which, by the way, took an inordinate time to fix.

Only one point still deserves mention, and that is—the effect of keeping the emulsion. Some considerable time ago, Captain Abuey poiuted out that emulsions improved by keeping. I have found this to be so in some cases, but uot in others ; and I have been quite unable to find any rule to account for the action of an emulsion on keeping it for a length of time. I have known an emulsion to increase in sensitiveness several times when kept for a week ; whilst another, prepared by precisely the same formula, did not change or even grow slower. The change is more likely to take place if the emulsion be rendered slightly alkaline. With the formula which I have just given, I have never known an emulsion fail to get very considerably rapider on keeping it a week, whilst the density appears to increase even more than the sensitiveness. I have known an iucrease of sensitiveness, represented by a ratio of quite four or five to one, take place in a week. Those who try the process must not, therefore, be disappointed if plates coated immediately after preparation are thin, and not exceedingly rapid. After keeping for a week or ten days the emulsiou will make plates of the very highest sensitiveness, and giving ample density.

The fact that increase in sensitiveness is so very marked in this process would tend to show that time is necessary to let that combination between pure bromide of silver and gelatine take place, which possibly accounts for the extraordinary sensitiveness of a gelatine plate.

I uow come to consider what I believe to be the special advantages of the process. I have pointed out, as a minor advantage, that as much water as is desired may be used in emulsification. A further advantage is to be found in the fact that, unlike other precipitation processes, the operations gone through to give sensitiveness are exactly the same as those which are used in ordinary cases, and with which all emulsion-workers are familiar. I think that most will find it a decided convenience to do away with the washing of the finished emulsion, and to put in place of it the simple operation of decanting some water, and again filling up the vessel.

The great advantage, to my mind, of this process over most others lies in the fact that the gelatine which has gone through the ordeal of the operation necessary to obtain sensitiveness is eliminated. It is this gelatine which I believe gives rise to many of the evil phenomena which gelatine plates exhibit, especially when ammonia is used.

I am well aware that several processes have been described for bringing about the same result : I need only mention that of Plener, and the acid method. Mine has a certain advantage over Pleuer's, in that no special apparatus is required. The uecessity for a steam-engine, which the process of that geutleman involves, would probably be an objection in the case of most photographers.

The process I have described has, I think, several advantages over that which was described long before Plener's, and which consists in rendering the gelatine which has been used in boiling soluble in cold water by the action of an acid, after which the silver haloids will be precipitated. I have uot been able to get any very great sensitiveness by this process.

Of course I do not recommend the method I have described for use in cases where it is desired to obtain an emulsion in the shortest possible time ; but for regular day-to-day working, as in the case of commercial plate-makers, I can conceive of nothing more convenient, whilst there is, at any rate, no process capable of giving better reults.

In systematic working, the emulsion which was made to-day would be set on one side; that which had been made the day before yesterday would be ready for decantation; whilst that which had been made four days before would be ready for mixing with gelatine and setting on one side to ripen for as long as the photographer thought fit.

I may say that, following advice given by Mr. A. Cowan, I am pouring each emulsion as it is finished into a large stone jar, there to lie till the vessel is full, when I shall commence coating plates with it. The alcohol and salicilic acid added prevents decomposition from taking place.

I imagine that the bromide of silver formed in the process might be dried and kept indefinitely. I have not tried this. I have tried to emulsify it with collodion, but with little success. The very slight nature of my experience with collodion emulsions may, however, account for this.

I pass round one or two plates which were coated with the very first emulsion which I made by this process.

The following will be found to be a suitable alkaline developer for plates made by the method which I have just described :—

Pyro....	1 to 2 grains
Ammonio bromide	1 grain
Ammonia, ·880	3 minims

To each ounce of developer.

WITH A CAMERA IN NORTH ITALY.

BY GREENWOOD PIM.*

It is with some hesitation that I venture to bring the annexed sketch, a very pleasant trip taken this spring to Savoy and Northern Italy, before the members of the Society; but trust that it may prove of at least passing interest—all all events, to any who may purpose turning their steps in that direction.

My kit consisted of a $7\frac{1}{2}$ by 5 camera by Hare, with four double backs, a Ross' portable symmetrical lens No. 4, and also a small single lens without a name, but screwing on to the Ross flange. My stand was a light tripod, folding up, and was constructed for me by a friend, and proved thoroughly satisfactory. I took a supply of Froedman's Dublin plates; also a few of Solomon's Wunderschönen for rapid work and dark places. Although I did not mean to develop to any extent during my tour, I brought a small quantity of Edwards' developer and hyposulphite in solution. For carrying the exposed plates, I had made some zinc boxes, similar to those in which the plates are supplied, the top going quite down over the bottom; inside was a square of Turkey red twill, in which the plates were enveloped when taken from the holders. I found this arrangement answer admirably, and to be much more convenient than folding them up in their own papers and replacing in the card-box, which are usually very flimsy, and easily split at the corners. Moreover, if it was desired to develop while away, a sheet of thin india-rubber replacing the twill turned the zinc box into a developing or fixing tray. I made but little use of them for the purpose, finding the washing in a hotel very troublesome. However, the few I did gave me valuable information respecting exposure.

Now, I would say to anyone contemplating taking his camera abroad—especially to Italy—to take as his main stock very slow plates and a slow lens, as the light is extremely powerful, or otherwise over-exposure is pretty sure to result. For example, in Venice, I found two seconds were sufficient for Froedman's plates, with a Ross' portable symmetrical and No. 4 stop.

Leaving Dublin on the 18th of April last, we made little delay ere we reached our first halting place of any account—namely, Aix-les-Bains, in Savoy, where we remained nearly three weeks, while my companion went through a course of the baths for which Aix is now so celebrated. The village is charmingly situated on the slope of the Revard, on the border of the Lake of Bourget, a sheet of water some twelve miles long by two wide, and overshadowed by the picturesque Dent du Chat.

Although Aix would not be likely to detain a photographer bound for more highly-picturesque regions, such as Chamouni, &c. nevertheless there are several very pretty bits in the neighbourhood in addition to the town itself, with its old Roman-arch church, &c.; such are the mill and stream at Gresy, Haute Combe Abbey, the Castles of Chatellon, and Bordeau on the Lake; while the Gorge and Valley of the Tier and the charming Lake of Annecy are within easy reach by rail. From Aix we proceeded *via* Mont Cenis to Turin, passing through a succession of wooded valleys with snowy mountain peaks, which would doubtless afford abundant occupation for the camera had we had time to stop.

* Read before the Photographic Society of Ireland.

We only remained one night in Turin, there being little to delay either tourist or photographer, so we proceeded to Genoa. There is a very fine Campo Santo or cemetery here, which contains many admirable examples of modern Italian sculpture, whose characteristic is copying details of dress, and with almost microscopic fidelity. Unfortunately, although admitted myself on payment of a small fee, the camera was excluded, the custodian selling photographs of the monuments himself. Genoa is a difficult city to photograph in, as the streets are very hilly, very narrow, and very high (and therefore very dull), defying any amount of swing-back. I essayed a photograph next morning from the Molo or Pier, which is strongly fortified, but it unfortunately proved a failure.

The coast line from Genoa *via* Spezzia to Pisa is extremely picturesque; but so numerous are the tunnels as to almost drive one frantic in one's endeavours to catch a passing glimpse ere one is again engulfed in darkness. An idea may be formed of their number when I say that there are upwards of eighty tunnels in one hundred and four miles of rail.

Early next morning I was in the large open square containing the Cathedral, Leaning Tower, Baptistery, and Campo Santo, where I exposed seven plates, of which five turned out fairly well. Here the custodian of the cemetery, unlike his *confrère* in Genoa, on learning that I was not a resident in Pisa, kindly admitted me and my camera. I might have used many more plates over the quaint old statues, &c., in the Campo, to say nothing of the Cathedral and Baptistery, where there is a very fine pulpit and font. Besides the Cathedral and its satellites, there is but little interest in Pisa.

Our next halt was Florence, where most of my time was occupied in seeing churches and picture galleries. I managed, however, to secure a view or two of the quaint old Ponte Vecchio, with its rows of shops, and the neighbouring houses; also of the Fountain of Neptune, and one or two more. Florentine churches are, as a rule, comparatively uninteresting outside, the chief attractions being within, where the subdued light would render photography a very slow process—much too slow for a passing tourist—to say nothing of difficulties with money, figures, &c.

From Florence a day's run by train brought us to Venice, passing on our way sundry quaint old cities, such as Bologna, Ferrara, Padua, &c., which I would have longed to stop at, and secure these beauties, but time would not admit. However, of all the Italian cities we visited, none interested us so much as Venice, and few present more attractions to a photographer.

Arriving at a railway station is not in general a remarkable incident in one's life; but arriving in Venice for the first time is very striking. The train crosses the Lagune on a bridge two and a-quarter miles long, and consisting of 222 arches. Then, on emerging from the station, which is nothing in itself, you find yourself, not, as usual, under a colonnade, with rows of omnibuses and cabs, but at the top of a broad flight of steps leading to the Grand Canal, which here swarm with gondolas, lying in wait for passengers. The porter of your hotel conducts you to the particular gondola to await your baggage. Presently the gondolier extricates his craft from amid the crowd, and turns into a narrow canal, whence you turn again into the Grand Canal near the Rialto.

Again driving into another narrow canal, after many windings you reach the Grand Canal a third time, near the Piazzitta and St. Marks. Subjects for the camera are simply endless. The Grand Canal is a huge watery avenue of palaces, each one surpassing in beauty the one before it, so that the difficulty is not what to select, but what to pass by.

Then the quaint old houses bordering the smaller canals, and the innumerable stone bridges, so like each other, and yet so different, form any number of attractive bits; to say nothing of the Doge's Palace, the Bridge of Sighs, and the many beautiful churches, such as Santa Maria della Salute, St. Moïsé, San Giorgio Maggiors, &c. The latter looks better in a photograph than in reality, on account of its red campanile. The Venetian churches—or many of them—differ from the Florentine ones, in being more attractive outside than inside. This is especially true of St Mark's, which is a very remarkable edifice in the Byzantine style.

With Venice my trip may be said to have ended as far as photography is concerned; for after packing up my camera in its travelling case, I did not take it out till after my return home, whither we travelled rapidly *via* Milan, Turin, and Paris.

In conclusion, I would say that while the Continent affords a great variety of interesting districts for the photographically-inclined tourist, Switzerland, the Tyrol, Italian Lakes, and the old towns of Northern Italy are well worth visiting, and should be by no means passed over.

Notes.

Mr. W. T. Bashford has accepted the appointment of Honorary Secretary to the Edinburgh Photographic Society. As the Society is larger than any other in this country, the office of Executive is an important one.

We hope shortly to speak of Captain Pizzighelli and Lieutenant Von Hübl's recently-published work on "Platinotype." Meanwhile we have included in our YEAR-BOOK a short account of the mode of working adopted by these gentlemen.

We hear good accounts of Henderson's cold emulsion process from the Continent. Among others, Captain Pizzighelli has been successful in producing good plates. After standing for one hour in the cold, the emulsion indicated 15° on Warnerke's sensitometer, and after six hours, 21° to 21°, the plates being developed with ferrous oxalate. After a lapse of eighteen hours, no increase in sensitiveness was remarked. Pizzighelli does not advise precipitation with alcohol, since the gelatine is thereby transformed into a tough rubber-like mass.

The Obernetter process is also spoken well of both in Vienna and Berlin. All agree that the emulsion does not possess a very high degree of sensitiveness, but in other respects it is highly satisfactory.

The rôle played by "restrainers" in photgraphy—and especially in development—has never been perfectly explained. Many quite neutral or indifferent substances, for instance, are powerful "restrainers," a fact observable in purely chemical operations. Thus, Hood points out, in a recent number of the *Philosophical Magazine*, that the oxidation of ferrous-sulphate ($FeSO_4$) through chlorate of potash ($KClO_3$) is greatly influenced by the addition of indifferent substances. If, for instance, potassium sulphate, sodium sulphate, ammonium sulphate, ammonia alum or potash alum, magnesium sulphate or zinc sulphate, are added, the process of oxidation is at once retarded or restrained; and in most cases the restraining action is in direct proportion to the weight of the inactive salt which has been added.

Mr. Swan would be a little surprised to see the last application of his incandescent lamp. The fairy queen in the new Gilbert-Sullivan Opera of *Iolanthe* wears one of these shining stars in her hair, the supply of electricity coming from a battery which hangs to her dress at the back. Her flowing hair conceals both wires and battery; but the latter need not weigh more than a pound or two if, instead of employing a 25-candle lamp, a smaller one, strained to the utmost, is used in the manner we have already pointed out in these columns. Indeed, we should not wonder if the idea of producing a star-light in this way was not taken from our suggestion.

Another point may be noted in this same production. Mr. George Grossmith—himself a capable amateur photographer—has apparently been studying a photograph of the late Lord Brougham, so correctly has he "made up" face and features after the renowned Chancellor. Most actors make a point of collecting old and rare prints of bye-gone celebrities, upon which to model face and costume—Mr. Lionel Brough is noted for a very fine collection—and if they wish to keep pace with the times, they will now have to form a collection of photographic portraits as well, for a generation and more has slipped by since camera pictures were a novelty.

On Tuesday night, at the Photographic Society, Capt. Abney gave a very good idea of the advantage of a grating over a prism in photographing the spectrum. Hitherto, as we explained a fortnight ago, the general way of securing the spectrum of a ray of light was to send the ray through a glass prism, which disperses it. If you wish to disperse a ray very much, you employ not one prism, but several; but every time that you interpose a prism, you lose a great deal of light by reflection and absorption of the glass; and to gain some idea of the terrible amount of loss from these causes, it may be mentioned that, when a ray is made to pass through ten prisms, all but $\frac{1}{10000}$ of the light is lost. But it is different when you employ a grating—fine lines ruled close together with a diamond upon speculum metal—which also produces a spectrum when light is reflected upon it.

By using a grating, you secure a spectrum with comparatively very little loss; and if your grating be engraved upon a concave surface, as Professor Ronalds has recently suggested, you may get, as well, all the sharp definition of lines prisms give you. In a word, a spectrum equal to that diffused by ten prisms is obtainable with a Ronalds grating, with a loss of but fifty-five per cent. of the light of the original ray. The advantage of a Ronalds grating over glass prisms in photographing the spectrum is therefore very obvious.

To judge fairly of the colour of an emulsion is not very easy at all times; and Mr. Burton's suggestion to mix a few drops with a beaker full of water is particularly useful. On trying it we were struck by the ease with which the colour can be observed; and where several emulsions have to be compared as regards colour, Mr. Burton's method seems to have especial value, as each sample can be adjusted so as to give approximately the same degree of density.

Mr. Burton also says:—"The sensitiveness is reduced by one-fourth when the emulsion contains about half a-grain of free alkaline bromide to each ounce; but a very much smaller proportion has a considerable influence." By-the-bye, Mr. Burton had to emphasise on Tuesday the fact that the chief point of his process was to get rid altogether of the decomposed gelatine with which the emulsion had been made, thus suppressing the tedious labour of washing. Indeed, his resulting silver bromide may be well compared to the sensitive product Mr. Pleuer isolates, and of which Dr. Eder speaks in another column.

"By the way, I observe in the Belt case," says *Truth*, "that there is a conflict of evidence as to whether certain pencil entries have been erased in a diary. This might easily be discovered by holding the pages over steam. If words have been erased, the pressure made upon the paper in writing them would show, and in all probability even indications of lead would be visible." Photography, we would remark, would be a still sharper detective.

The Berlin photographers complained, a little while ago, that commissions were levied upon them by agents who secured for them sitters of celebrity. Paris is now calling out on the same score. Our German friends determined to set their faces against the growing evil, and a request was preferred, through the Society for the Advancement of Photography, that all photographers should refuse to pay such commissions. About the levy of black mail there cannot, of course, be two opinions; at the same time, if the celebrity himself, or herself, is disposed to bargain for a facial copyright, there is no reason why a photographer should not entertain the bargain.

It cannot be denied that the right to photograph is a valuable commodity in many cases. Madame Sarah Bernhardt, for instance, when she went to New York, sold the sole right of taking her portrait for several thousand dollars, and the bargain is said to have been satisfactory on both sides. But it is different when it is not the celebrity, but some unaccredited agent, who gains by the transaction. The demand in this case usually comes after the sitting. An actress or opera-singer is invited, or invites herself, to sit, and, in return, the photographer presents the sitter with a few dozen copies of the portrait. Then it is that the vampire usually appears. He gives the photographer to understand that it was through his influence that the sitting was arranged, and the former, for fear he shall offend or lose subsequent favours, usually pays the fee demanded of him.

One ludicrous point in connection with the whole affair is the fabulous price many third and fourth class celebrities (?) set upon their portraits. A young lady who has been entrusted with a rôle of two lines at some West End theatre, or appears in "the front row" in a ballet, will demand a sum equal to six months' salary, pointing to the portraits of Maud Branscombe and Mrs. Langtry in support of her claim. In Paris it is not unusual for an agent to demand a thousand francs commission, and to get it, too.

Our readers will peruse with interest the first communication that comes to us from Vienna respecting the experiments of Mr. Plener and Dr. Eder. The preparation of isolated silver bromide seems now to be a very simple matter, and our readers may hope for the day when they can purchase a haloid salt of uniform sensitiveness in the shape of powder, which, as Dr. Eder tells us, emulsifies with great readiness in a simple solution of gelatine. Fogging, frilling, and freckling will be unknown in these halycon days to come.

Mr. Mayland has forwarded us from Deal a series of delightful sea sketches. The foreground—if foreground we may call it—is the lapping sea, the smooth translucent waves sweeping one over the other to our feet. In two of the sketches we have the dark form of a shrimper, net in hand, who stands knee deep in the water, sharply limned against the white sea and bright cloud masses. In a third sketch, the middle distance is made up of white crested waves, breaking over into deep-shadowed furrows, while afar off are the tiny forms of vessels riding in the Downs. Another striking effect in one of the studies is a silver line near the horizon, which marks the well-known Godwin sands, the sun shining on the far-off waves as they break over the dreaded bank.

Patent Intelligence.

Notice to Proceed.

5131. Henry Harris Lake, of the firm of Haseltine, Lake, and Co., Patent Agents, Southampton Buildings, London, for an invention of "An improved method or process of and apparatus for producing coloured photographs."—A communication to him from abroad by Joseph Chaine, Arthur Durand, and Sallonier de Chaligny, all of Lyons, France, Engineers.—Dated 27th October, 1882.

Specification Published during the week.

2156. F. Wirth, for "Preparation of photographic plates."—A communication from G. Meisenbach. The subject-matter of this was detailed on page 682 of our present volume.

Patents Granted in America.

267,663. John E. Beebe, of Chicago, Ill., for "A drying-rack for photographers' dry plates."—Application filed 15th September, 1882. No model.

267,821. Erasmus B. Barker, of New York, U.S., assignor to E. and H. T. Anthony and Co., of the same place, for "A photographic shield."—Application filed 31st December, 1881. Model.

PHOTO-ETCHINGS AND PHOTO-ELECTROTYPES FOR POTTERS' USE.

BY F. J. EMERY.

Embracing an opportunity which the kindness of its officers afforded me, I had the pleasure of suggesting to the South London Photographic Society, at their meeting in October last, the extension of photography to the production of intaglio copper-plates suitable to the requirements of pottery printing.

Obviously, the only means of printing on pottery must be by transfer, and the medium must be an easily yielding one.

In the old days this was effected—but only on the glazed surface—by using a supple bat of glue, and the *modus operandi* was as follows.

A thick oil, composed mainly of boiled linseed oil, was rubbed into the engraved lines or dots, and the surface of the copper-plate, first wiped with cotton-wool, was afterwards cleaned with the palm of the hand, itself slightly smeared with whiting.

The glue bat, previously moistened with a damp sponge, was then firmly but gently pressed against the engraving. This brought out the stiff oil, so that the bat carries the design as a low relief typograph. The bat being then pressed steadily against the piece of pottery and carefully pulled back, the transfer design—faintly represented by the oil—was dusted with very finely-ground enamel colour; all loose particles and smear being removed with clean cotton-wool.

This process, although able to reproduce the finest engravings, had the double drawback of limitation in size, and application only to glazed surfaces.

It is said that a scrap of newspaper which, lying in the sun against a piece of biscuit pottery, had imprinted itself on the dry surface, first suggested the employment of tissue paper as the medium of transfer, and at the present time the glue bat—except for small and delicate work—has gone out of use.

Why there is now a good opening for photo-etched or photo-electrotyped copper plates was shown in the paper read on the occasion to which I have referred; and it only remains to be said to those who choose to experiment in this direction, that what is needed is an intaglio copper plate which should have a margin on all sides of three-quarters of an inch, and that I shall be ready to test the work free of charge.

FRENCH CORRESPONDENCE.

The Photographic Society of France—Photography with Magnesium Light—Gelatino-Bromide Pellicles for Negatives—Supplement in Last Number of Photographic News—Transit of Venus.

The Photographic Society of France.—At the last meeting of the Society, many new things in the way of instantaneous pictures were presented, and among them those taken by M. Londe, with his own shutter, and some by M. Demarchy. These prints, more or less perfect, show the continual effort made by amateurs to reproduce animated nature, or objects in motion. It gives supreme satisfaction to an amateur to seize an animal at a gallop, a steed trotting, a crowd, or a flight of birds. Among the studies taken in this direction it is not unlikely that the art of producing instantaneous photographs will soon attain a higher standard of perfection.

Photography with Magnesium Light.—M. Londe showed the Society some *post mortem* prints taken by magnesium light. The photographs are taken in the hospital at all hours of the day or night, and a magnesium lamp is the best means of lighting. The exposure is from five to ten seconds. It is unnecessary to say that gelatine plates are used.

Gelatino-Bromide Pellicles.— The competition organized by the Photographic Society of France for the best process for making sensitive pellicles will be closed on the 31st inst. M. Gaillard has offered a prize of 800 francs, to which the Society has added 200 francs as a reward for whoever fulfils the conditions of the competition the best. On this subject we may be permitted to give a little advice to those who make pellicles. It is useless to superpose a film of gelatine over collodion to be afterwards coated with gelatino-bromide. This is how we would proceed:—On a plate of talc spread a film of 1 per cent. gun-cotton collodion, then pour over this the gelatine in a limpid condition, containing one-half per cent. of alum; as soon as well set, superpose with a fresh coat of collodion, and allow it to dry. When ready, proceed as with glass, by rubbing over the surface with French chalk, and spreading over the sensitive film. By this means the pellicle serving as vehicle or support is rendered almost impenetrable to water, and in the operations of development, fixing, &c., does not admit of greater difficulty than in the employment of glass.

The Supplement to the "Photographic News."—The print published in the last number of the Photographic News has been the object of our attention. The photo-ink process consists, as far as we are able to judge from the interesting specimen in our possession, of a reticulated image obtained by the ordinary phototype process. The phototype or collotype impression is transferred to stone, and printed lithographically. The idea is undoubtedly excellent; but we think a still better result would ensue by transferring the image on to zinc, so as to make a typographic block. We are sure that the iuventor of the photo-ink process will find no difficulty in making phototype blockes from his prints.

The Transit of Venus.—The transit of Venus was hardly able to be observed, the cloudy weather almost entirely preventing a view of the phenomenon. Fortunately, several of our expeditions, especially that under Colonel Perrier, have succeeded in obtaining several photographs during the time of the transit. Leon Vidal.

NOTES ON PHOTOGRAPHY.

$C_6H_5O_7$ or C	189	Citrates

The above table shows at a glance the names, chemical symbols, combining weights, and quantitative composition

* A compound radical consists of a group of elements which enters into or is expelled from combination without itself undergoing decomposition. In the compounds Ag_2 Cl, Ag_2 Br and Ag_2 I Cl, Br & I appear to act as dyads.

of the various elements and compounds in general use in photography.

Thus the symbol of sodium chloride is NaCl, its molecular or combining weight is $23+35\frac{1}{2}=58\frac{1}{2}$ or $58\frac{1}{2}$ grains of NaCl contain 23 of Na and $35\frac{1}{2}$ of Cl; or again, the symbol of iron protoxalate (ferrous oxalate) is Fe (C_2O_4), and its combining weight is $56+88=144$.

The substances marked dyads are equivalent to two of those marked monads; those marked triads equivalent to three monads, and platinum is equivalent to four monads or two dyads.

Thus the symbol of potassium oxalate is $K_2(C_2O_4)$, K being a monad, and C_2O_4 a dyad; or again, iron persulphate is represented by $Fe_2(SO_4)_3$; two triad atoms of iron being equivalent to three dyad molecules of (SO_4).

The element hydrogen forms with the elements and compound radicals on the right-hand list the various acids, *e.g.*, HCl hydrochloric acid, HNO_3 nitric acid, $H_2(C_2O_4)$ oxalic acid, and $H_3(C_6H_5O_7)$ citric acid, &c.

PHOTO-CHEMICAL ARITHMETICAL PROBLEMS.

A.—To find the weight of any substance contained in (or required to form) a given weight of any compound.

1. Obtain the chemical formula of the compound (see Table).
2. Put down its numerical composition (see Table).
3. Make simple rule-of-three statement.

Example: How much silver is there in 50 ounces of silver bromide?

1. The chemical formula is Ag Br
2. Its composition is $108 + 80 = 188$
3. Rule-of-three statement is

188 : 108 : 50
50
188)5400(28
376
1640
1504
.136 *Answer*=28 ounces.

B.—To find the weight of any substance it is required to substitute for another in a chemical change.

1. Put down the chemical equation for the change which occurs in each case.
2. Convert the chemical equations to numerical ones.
3. Make simple rule-of-three statement.

Example.—How much anhydrous cadmium bromide is equivalent to 5 grains of ammonium bromide in a bromized collodion?

1 and 2. The chemical and numerical equations are (see table)

$CdBr_2 + 2Ag(NO_3) = 2AgBr + Cd(NO_3)_2$

| 80   108+62   108+80
112+160   80
160   170   188
2   2
272 + 340 = 376

$(NH_4)Br + Ag(NO_3) = AgBr + (NH_4)NO_3$

18+80   108+62   108+80
80   62   80
98 + 170 = 188

3. Rule of three statement is

98×2 : 272 : : 5
5
196)1360(6·9
1176
1840
1764
··76 *Answer*=6·9 grains.

C. To find the weight of any substance used or produced in a chemical change.

1. Put down the chemical equation for the change which occurs.
2. Convert the chemical to a numerical equation.
3. Make simple rule of three statement.

Example.—How much potassium bromide is required to convert the whole of the silver in 10 grains of silver nitrate to bromide, and how much silver bromide will be produced?

1. Chemical equation is

$KBr + Ag(NO_3) = K(NO_3) + AgBr.$

2. Numerical equation is

$119 + 170 = 101 + 188$

3. Rule of three statement is

170 : 119 : : 10
10
170)1190(7
1190
Answer=7 grains of KBr.

and again

170 : 188 : : 10
10
170)1880(11
170
180
170
10 *Ans.*—11 grains of AgBr.

Silver nitrate, $AgNO_3$

Combining weight 170 of which 108 parts or 63·5 per cent. is silver.

Prepared by dissolving pure silver in nitric acid diluted with an equal bulk of water

$Ag + 2HNO_3 = AgNO_3 + H_20 = NO_2.$

the solution is evaporated until the salt crystallized out, and which then form the ordinary silver nitrate of commerce. In order to purify it, and get rid of the free acid still adhering to the crystals, they are dissolved in water, and the solution again evaporated, when we get re-crystallized silver nitrate.

Silver nitrate thus prepared occurs as fine white crystalline plates which become perfectly colourless and transparent on being moistened with water; it is, both dry and in solution, perfectly neutral to test paper. When heated, it fuses into a clear, transparent liquid: a piece of charcoal dropped into the liquid mass deflagrates and becomes coated with a bright film of metallic silver.

Soluble in its own weight of cold water, but less so if the water be acid; soluble in half its weight of boiling water, also in four times its bulk of hot alcohol. Practically insoluble in ether and wood spirit (naphtha).

In solution it is reduced by Cu, Hg, Fe, &c., metallic silver in a crystalline condition being set free.

$2Ag(NO_3) + Cu = Cu2(NO_3) + 2Ag.$

It is also reduced by protosalts such as $FeSO_4$, $SuCl_2$, &c.

$3Ag(NO_3) + 3FeSO_4 = Fe_2(SO_4)_3 + Fe(NO_3)_3 + 3Ag.$

Organic matter, whether animal or vegetable, more or less quickly reduce it to the metallic state, the rapidity depending on the nature and reducing power of the substance.

These reductions are generally accelerated by alkalies, heat, and exposure to light, and retarded by acids and a low temperature.

Free chlorine, bromine, and iodine, and soluble chlorides, bromides, and iodides, decompose it, forming insoluble silver chloride, bromide, or iodide.

$$AgNO_3 + 3Cl = AgCl + 2HClO + NO_2.$$
$$AgNO_3 + KBr = AgBr + KNO_3.$$

Alkalies and soluble hydrates precipitate it as oxide, which in the case of ammonia is soluble in excess.

$$2AgNO_3 + 2KHO = Ag_2O + 2KNO_3 + H_2O.$$

Tests for Silver Nitrate.—Add a few drops of HCl to a solution in a test-tube; if there be a white precipitate, add ammonia—the precipitate dissolves. *Presence of Silver.*—Fuse a little of the dry salt in a test-tube, and drop in a piece of charcoal—deflagration with evolution of red fumes. *Presence of* (NO_3).—Substance is silver nitrate.

Estimation of Silver Nitrate.—Prepare a solution of KBr containing 112 grains to the pint of water. Put in a narrow-necked two-ounce bottle a drachm of the solution to be estimated, and acidify it with HNO_3; now add (a drachm at a time) the KBr solution (shaking up violently between each addition) until no further precipate is produced. The number of drachms of KBr solution require is the number of grains of $AgNO_3$ in the solution in the bottle, and this multiplied by eight gives the number of grains per ounce.

Impurities in Silver Nitrate.—$AgNO_3$ is sometimes adulterated with other nitrates, such as KNO_3, $Pb(NO_3)_2$, &c. $Pb(NO_3)_2$ can be detected by the bright yellow precipitate given with KI; the best way is to weigh out a few grains of the suspected salt and estimate it

Correspondence.

SMALL LANDSCAPES ON BLACK MOUNTS.

DEAR SIR,—I have recently been mounting my little landscapes upon black gilt-edged mounts, after the manner to which you called attention some time ago. I have no difficulty in getting cabinet-sized black mounts with gold bevels, and the little landscapes mounted on these, showing just an eighth of an inch of black all round, are very effective; but I have difficulty in getting cards for my larger pictures—for whole-plate size, for instance. It seems to me that the manufacturers of these mounts having only portraiture in view, make cards only to suit portraits; and these slender formats are not suitable for landscapes. At any rate, if square mounts are made, suitable for landscapes, I have hitherto failed in procuring them. Possibly if you let this letter appear in your columns, it may be the means of calling the attention of manufacturers to the matter.

Any one who has tried the effect of mounting small landscapes upon these gilt-edged black mounts cannot fail to be pleased with the results, for the mounts frame the pictures as well.—Yours faithfully, A. A. W.

CHOCOLATE MOUNTS.

DEAR SIR,—Your correspondent "F. Stanley" evidently has a very bad quality of mount, to cause his photographs to disappear in a month. For the last two years I have mounted a series of 9 by 7 views on black and chocolate cards, bevel edges, and, as far as can be ascertained, have no cause to regret this effective kind of mounting. Most of these views are sent to stationers, and exposed in shop windows. There are some large photographs of actresses exposed in a theatrical agent's window in the Strand, mounted in the same manner, on chocolate cards; these, I believe, have been exposed to the public gaze for twelve months, and show no signs of fading. There are no doubt some very cheap cards issued "black and chocolate," which give off a very disagreeable smell when damped, showing, I think, decomposition; but in the dearer mounts this is not so.—Yours, &c., P. MITCHELL

GREEN LIGHT FOR THE DARK-ROOM.

SIR,—Since using dry plates I have suffered a good deal with bad eye-sight caused by the trying effects of the ruby light. In consequence, all this summer, I have adopted a green light for my dark-room window, and find it answer better than ruby for seeing the development, &c. It is not in the least trying to the eyes, either in the dark-room or when you come out. I use one sheet of ground glass—one of deep orange, and one of green.

I may add that I use the extra sensitive plates of the best makers, and no foggy results ensue. Possibly these few lines may be of use to other sufferers like yours truly,

W. S. BRADSHAW.

PRIZE PICTURES AT THE LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

DEAR SIR,—In the list of prizes gained in this year's competition of the Amateur Photographic Association, the name of Mr. A. W. Beer appears by mistake as the winner of the prize for "A Country Lane." The beautiful picture which gained the award in this subject was produced by Mr. Kenneth M. Bean, and the hon. secretary greatly regrets the "clerical error" which deprived this gentleman of the honour he has justly gained.—Faithfully yours, H. J. PALMER.

PLAGIARISM.

SIR,—The letter of "Exhibitor" justly exposes one of the grossest cases of plagiarism which has come under my notice; but the mere return of the medal does not, in my opinion, meet the case; an apology in addition is imperatively demanded for being found out in the attempt to foist off as original the conceptions of other brains.

Poor old "Dizzy" was mercilessly taken to task when he "appropriated from the French" the peroration of his speech on the Duke of Wellington's death; but perhaps he was only chaffing the House in his sleeve. At any rate, his punishment was severe, and the present case merits equal retribution.

A word of advice to those "photographic artists" who, while laudably desirous of emulating the works of those more gifted than themselves, are only in the possession of sufficient artistic training and sufficient development of brain to turn to the pages of the art journal for a "crib;" and I would suggest to them, in the absence of a proper lay figure, they can purchase for a few pence a good sized doll, and if they twist and twirl the jointed limbs of this toy, they will doubtless, in course of time, arrive at a "pose" which, whatever characteristic it may possess, will at least bear the charm of originality.—Yours truly,

MAULSTICK.

DEAR SIR,—There cannot be a doubt that it was quite right to call attention to the original of the photograph "Cherry Ripe;" at the same time I cannot help thinking that the flood-gates of indignation have been opened a little too widely. It is more than likely that the author of "Cherry Ripe" was unaware of the extent of the charge to which he laid himself open, and probably was equally ignorant of the circumstance that if he had put the words "After Rubens, &c.," on his picture, he would have been saved from all chance of reproach. It is much to be regretted he did not do this, as he now loses much credit that is probably his due; for when you have turned over the pages of the art journal or magazine, and decided upon an engraving to reproduce with your own models and own lighting in the camera, there still remains the fact that your photograph has still to be done. Let, however, every photographer who takes a picture as his model, understand that he ought always to place upon the frame "After ——," naming the artist whose production has served him for study.—Yours sincerely, Another Exhibitor.

Proceedings of Societies.

Photographic Society of Great Btitain.

The ordinary monthly meeting of the above Society was held at 5a, Pall Mall East, on Tuesday evening the 12th inst., the President, Mr. James Glaisher, in the chair.

The minutes of the previous meeting having been read and confirmed, Miss Rosamond, F. A. Lyell, and Mr. John Jeffcoat were elected members of the Society.

The Chairman stated that the number of visitors to their recent exhibition was 7,439, as compared with 6,221 in 1881, 5,000 in 1880, and 4,803 in 1879; whilst the money taken this year was £41 14s. 6d. in excess of last year's receipts.

Mr. Glaisher then invited a discussion upon the paper read by Mr. W. K Burton at the last meeting, and called upon Mr. Sebastian Davis to offer some remarks.

Mr. Sebastian Davis said he did not anticipate being called upon to open this discussion. He had not had time to read the paper properly, but had noticed that in this and many other processes, an effort had been made to do away with washing the emulsion, and in this particular only could any special interest be taken in Mr. Burton's process. By his method we produce a precipitate of silver bromide in the presence of gelatine, and after a period of forty-eight hours we pour away the clear liquid, leaving the sediment to be mixed with a fresh quantity of water, and again allow to subside for another period of forty-eight hours. After making up the emulsion with the first quantity of gelatine, we are told that the sensitiveness can be further increased by allowing the emulsion to stand for some days; but he failed to see in what respect any advantage was gained over the ordinary method, either in sensibility or convenience. By the ordinary method of emulsification and washing, the same result could be obtained in a few hours Certainly some special claim was made with regard to the action of ammonia, but he failed to see its beneficial effect.

Captain Abney alluded to a series of articles written by himself in 1872, in which he showed, by means of diagrams, the relative gradations produced upon wet and dry plates. He had found that an ammonia-prepared emulsion gave a curve closely resembling that given by the wet plate; while in the case of a boiled emulsion the curve more nearly approached the straight line. The latter form of emulsion was therefore preferable to either the wet plate or the ammonia preparation. With regard to precipitation, he had little to say, except that, being of an impatient turn of mind, he objected to wait forty-eight hours.

Mr. Leon Warnerke said, with regard to Mr. Burton's curve, his own experience led him to think that any boiling process could give a better gradation than the ammonia process, in the latter of which there was always a too sudden falling-off in density. Again, he thought that the boiling process gave greater regularity. Not having had an opportunity of trying it, he was not in a position to say whether Mr. Burton's process was capable of giving the highest sensitiveness; but if it were, he thought it had advantages over the ordinary method of washing. As was well known, emulsion making was an operation of some uncertainty, much of which was traceable to the water employed in washing. This he had found to be specially the case in St. Petersberg, where in summer the water was very impure; and under such circumstances he thought Mr. Burton's method would be decidedly advantageous, inasmuch as it dispensed with the operation of washing

Mr. W. Ackland thought that Mr. Davis had scarcely done justice to Mr. Burton's process, in which the whole of the gelatine which had been submitted to boiling was subsequently got rid of. With regard to the action of ammonia, he thought it was very marked. Using a formula which he had worked for some months, and which ordinarily gave 19 on the sensitometer, the addition of ammonia at once gave him 24, and that without the slightest tendency to green fog. With regard to the time occupied in precipitation, while he was not prepared to say that forty-eight hours were too long, he thought that if the liquid were passed through a filter-paper, at the end of twenty-four hours the quantity of bromide of silver still held in suspension would be found to be extremely minute.

Mr. Herbert B. Berkeley said that in some respects Mr. Burton's process resembled one which he had himself used for some time, though he employed a larger proportion of water, and did not use added acid, his bromide being acid, which amounted to the same thing. In his experience he did not find that continued boiling aided precipitation, though possibly, as Mr. Burton stated, the ammonia acted as a powerful agent in that direction. At the same time processes had been described in which ammonia was said to have the opposite effect. He had never been able to secure perfect precipitation, but the quantity of bromide left in precipitation was so extremely small that it might be disregarded. With regard to Mr. Burton's observation that some emulsions increased in sensitiveness, while others did not, he thought it improbable that an acid emulsion would improve in rapidity by keeping at an ordinary temperature after boiling. Referring to the effect of altering the proportion of gelatine, he did not advocate the use of too small a quantity. He concluded by expressing an opinion that the precipitation process must be looked forward to as the most likely method of producing plates of uniform sensitiveness, and free from green fog.

Mr. J. Cadett thought that the question of gradation depended a great deal on the treatment the emulsion had received. When ammonia was used, a very good gradation would be obtained if a high degree of sensitiveness were not aimed at; but as the sensitiveness was increased, gradation became inferior. With the boiling process the sensitiveness could be pushed to a greater extent without loss of gradation. The beneficial effect of ammonia added to a boiled emulsion was, he considered, only due to the fact that the emulsion had not been properly treated in the first stage. He was of opinion that the highest degree of sensitiveness was obtainable with an acid boiled emulsion.

Mr. Archer Clarke said that he had made five or six batches of emulsion by Mr. Burton's method, and was very much pleased with it; its only fault was that his shelves were getting blocked up with jars. He thought it was a process eminently suited for amateur use, but not commercially. He had been for some time experimenting with a precipitation process, and was now able to make an emulsion and use it within two hours from weighing out the chemicals. He then proceeded at some length to describe his mode of working.

Mr W. K. Burton, in reply, said that Mr. Davis appeared to criticise without having tried the process, and thought that dispensing with the washing was the only advantage to be gained. He had been at some trouble in trying to explain that the chief benefit was found in the elimination of the whole of the gelatine that had been submitted to boiling, which did away with all danger of green fog, as a simple experiment would show. With regard to the effect of ammonia, he thought that Mr. Davis had failed to understand him. He agreed with Captain Abney that the boiled emulsion gave a more satisfactory curve than ammonia, and he had been sorry to have to introduce the latter; but he had recently succeeded in working without ammonia by prolonging the time of boiling to periods of five and six hours. He had just completed an emulsion which was boiled for five hours, and which seemed to be as near perfection as possible, giving 22 on the sensitometer. Speaking of the standard sensitometer, many people imagined that it was of little use; but he found the contrary to be the case. He was glad to hear the result of Mr. Ackland's experience, as it quite coincided with his own. As far as he could see, while he quite appreciated the value of slow plates for certain purposes, this process was incapable of producing any but rapid ones, which might by some be considered a disadvantage. He had been much interested in Mr. Clarke's process; but his own experience was that the slightest trace of free bromide in the emulsion produced slow plates.

The Chairman then proposed a vote of thanks to Mr. Burton and those who had taken part in the discussion.

Captain Abney then gave a brief abstract of his paper on "A New Diffraction Grating," illustrating his remarks by projecting a number of photographic spectra on the screen. This paper will appear in full in a subsequent issue.

After a few remarks from the Chairman, a vote of thanks was passed to Captain Abney.

An announcement was made in connection with the election of officers in February, and the meeting was then adjourned.

The next meeting will be held on Tuesday next, the 19th of December.

At the previous meeting of the Society held November 14th, the following gentlemen were duly elected members of the Society:—

Arthur Ackland, Christchurch, Oxford; W. M. Ashman, 3, Amersham Road, New Cross, S.E.; Luke Berry, Chapel Street, Chorley, Manchester; T. W. Boord, M.P., 14, Berkeley Square, W.; W. J. Byrne, Hill Street, Richmond, Surrey; George F. Dew, Norton Street, Coventry; W. Davies, Greaves Street, Ripley, Derby; Adam Diston, Leven, Fife, N.B.; B. J. Edwards, The Grove, Hackney; P. H. Emerson, M.R.C.S., A.K.C., Clare College, Cambridge; Thomas Fenn, 14, Bedford Square, W.C.; G. A. Garret, 60, Doughty Street, Mecklemburgh Square, W.C.; Major J. E. Gubbins, R.A., Yarmouth, Isle of Wight; W. Harris Heal, 195, Tottenham Court Road; J. A. Kay, 160, St. George's Road, Bolton; W. J. Lancaster, F.R.A.S., F C.S., Colmore Row, Birmingham; E. J. Lucas, 32, Half-Moon Street, Piccadilly, W.; Arthur G. Massey, Belfast; Lieutenant S. Maycock, R.E., Brompton Barracks, Chatham; William Muller, 89, Highbury New Road, N.; Samuel E. Phillips, Holbrook, Shooter's Hill, Kent; Charles Sawyer, 3, Windsor Road, Ealing, W.; G. Graham Toler, 21, Cornwall Gardens, S.W.; W. Trenemen, 7, Great Sutton Street, Goswell Road; and G. Sydney Whitfield, 14, Sandringham Gardens, Ealing, W.

South London Photographic Society.

The ordinary monthly meeting of this Society was held in the house of the Society of Arts, John Street, Adelphi, W.C., on Thursday evening, the 7th inst., the Rev. F. F. Statham, M.A., President, in the chair.

The minutes of the previous meeting having been read and confirmed,

Mr. J. J. Briganshaw, proposed by Mr. W. Brooks and seconded by Mr. E. W. Foxlee, was elected a member of the Society.

The Chairman said the first business of the evening was to announce the award for the prize competition of the past year. He was sorry to say they had not been quite so successful as in preceding years, there being fewer competitiors and fewer prints sent in. The judges had given their award in favour of a print marked with a monogram consisting of a circle with a cross inside it and another cross above it, and on the sealed envelope bearing this monogram being opened by Miss Harding, it was found that Mr. E. Dunmore was once more the successful competitor. A discussion had taken place in committee with regard to these competitions, in order, if possible, to see if any improvement could be made with respect to them. The chairman said it had occurred to him that if they could give something more valuable in the shape of a reward than the Society's medal, they might perhaps induce more of the members to send in pictures for competition. It was the intention of the committee to consider the matter privately, and the result would be reported at a future meeting.

Mr. Foxlee moved and Mr. Brooks seconded a vote of thanks to Messrs. Vicat Cole, R.A., and S. P. Jackson, for kindly giving their services as judges.

Mr. Bridge (the Hon. Sec.) read the report of last year's proceedings of the Society, and also put before the meeting the financial statement for the past year, showing a balance in hand of upwards of £16, after satisfying all claims upon them. Messrs. Wilmer and Collins were appointed auditors. A vote of thanks was passed to the Society of Arts for kindly granting the use of their room, also for permission to use the electric light at one of the meetings during the past year; and, at the suggestion of Mr. E. W. Foxlee, a vote of thanks was also passed to Mr. Woods separately, it having been through his instrumentality that much of the kindness had been received.

The election of officers for the ensuing year then took place, the nominations having been made at the November meeting. The Chairman said that for the office of president, no other name then his own having been put forward, he would be most happy to act again. For Vice-Presidents, Messrs. Jabez Hughes, P. Mawdesly, E. Cocking, W. Brooks, and F. Howard were re-elected unanimously. Committee, of the ten nominations, Messrs. T. Bolas, W. B. Bolton, W. Cobb, A. Cowan, E. Dunmore, E. W. Foxlee, J. Nesbit, and H. Wilmer were elected. For the office of Hon. Secretary and Treasurer, Mr. F. Bridge was elected unanimously.

The Chairman then proposed a vote of thanks to the officers of the past year for their services. He said he did not remember when they had had such a satisfactory balance-sheet, and thought the hearty thanks of the members were due to Mr. Bridge for having pulled them through so successfully, as for performing some very special duties on the abdication of Mr. Garrett Cocking, their late treasurer. The vote of thanks having been passed with acclamation, Mr. Bridge briefly responded.

Mr. Foxlee called for a further vote of thanks to the President, who had, he said, by his regular attendance at the meetings, rendered the office of Vice-President virtually a sinecure.

This having been cordially responded to,

The President said it was a very great source of pleasure to him to act as President. If would be a great grief to him if the Society were on the decline. It had now been in existence something like twenty-three years. There was only one thing required to make the Society more successful in the future, and that was, that they should have some existing rule for providing papers. He thought that they should not be entirely dependent on their own exertions in this respect, and if they were to put themselves in communication with some of the former members, now resident in distant parts of the country, they might suggest useful subjects for discussion, and thus give a helping hand. Meantime, he thought they could not do better than think over in their own minds subjects for papers during the ensuing year, and each member should let Mr. Bridge have a short notice in order to make it known, when he had fixed on something suitable for a paper. With regard to the lantern exhibition, he thought it would be well to try and procure interesting slides, as, for instance, scenes from Egypt, in connection with the late war—in fact, anything which mightt end towards demonstrating the usefulness of photography. He also called attention to the Annual Dinner to be held at the Holborn Restaurant, on Friday, 15th December, at 6·30 punctually. Tickets (5s. each) could be obtained from Mr. Bridge.

The Chairman then put before the meeting, for discussion, a question found in the box, "Would it not be beneficial to the Society if a certain portion of the officers retired annually, not eligible for re-election?" A discussion followed, during which

Mr. Eyres, though of opinion that they could not well dispense with the valuable services of the President or of Mr. Bridge, thought that there should be six vice-presidents and twelve committee, two of the former and four of the latter to retire annually and not be eligible for re-election, by which means the Council would be entirely reconstructed every three years.

The Chairman objected that any proposition of this nature ought to have been brought forward prior to the nomination meeting in November: they had afforded the members every opportunity of giving expression to their wishes if they desired any change in the officers. He thought that if the question in the box had the approval of the members, the result would be to thrust out some of those who had well done their duty in council.

Mr. Bridge thought Mr. Ayres' suggestion might help them in one respect, viz., in getting papers. Perhaps if they infused new blood into the Council every year, they would have more papers from some of the younger members.

Mr. T. Bolas could not help thinking that theoretically, it was the right thing to force new blood into the Committee, but practically it might be awkward. If it were to be done, the Committee ought to be much enlarged.

Mr. Foxlee said that unfortunately large committees did not work.

The Chairman said it seemed to him that if the names of the Committees for a few years back were looked over, it would be found that they were changed very much, which practically fulfilled the object of the question in the box.

The Hon. Secretary called the attention of the meeting to one of the rules of the Society, which stated that "the Committee should be elected from the names proposed at the November meeting," and remarked that, according to this rule, they could do nothing in the matter until the next November meeting.

The Chairman thought that the thanks of the meeting were due to Mr. Eyres for his suggestion, and recommended him to bring the matter forward again a month or two previous to the nomination meeting in November.

The Hon. Secretary informed the meeting that tickets for the lantern exhibition would be sent to all members about a fortnight beforehand, and asked them to bear it in mind when making their Christmas engagements.

The Chairman asked if there was any chance of getting photographs of the transit of Venus, or the comet, for that exhibition?

The meeting then adjourned.

The following is the Secretary's report:—

"In submitting the Annual Report of this Society for 1882, the committee congratulate the members on the continued prosperity of the Society. This is particularly satisfactory, having regard to the existence (in close proximity) of other societies meeting weekly, and therefore, to a certain extent, forestalling many matters of interest that would otherwise, for the first time, probably, be introduced at the meetings of the South London Society.

"The actual number of members for the present year is 78, only four of these being honorary.

"During the year papers have been read as follows, viz:—'Co-operation in Matters Concerning Photography,' Mr. W. Cobb; 'A Few Common Objects of the Studio,' Mr. E. Dunmore; 'A Gelatino-Chloride Process,' Mr. B. J. Edwards; 'Realism and Idealism in Photography,' Rev. F. F. Statham, M.A.; 'Practical Experiences with the Alkaline Developer,' Mr. W. Brooks; 'The Decoration of Pottery,' Mr. F. J. Emery; 'The Past Season,' Mr. E. Dunmore; and 'A Trip to West Cornwall,' Mr. W. Brooks.

"It is scarcely necessary to say that the Popular Lantern Meeting in January was very successful, upwards of 300 slides having been exhibited by various members and friends. The out-door meeting at Hampstead on the 1st of July was also very pleasantly spent.

"The tenth Annual 'Technical' Meeting in November, notwithstanding a series of meetings, have now been inaugurated by the 'Parent' Society, under the same title, was as usual very satisfactory.

"The committee earnestly hope that all the members will exert themselves, so that the ensuing year may be well supplied with papers; and that those who may have communications which they may deem worthy of a 'Paper,' will avail themselves of the 'Question Box,' as very often a simple question on some apparently well-worn subject, will furnish material from which a very interesting and profitable discussion may arise.

"With regard to the 'Artistic Competition,' it must be admitted that this has not met with that amount of success which was anticipated, and the committee intend devoting a special meeting to the re-consideration of the subject.

"In conclusion, the committee tender their hearty thanks to all those members and friends who have contributed in any way to the advancement of the Society during the past year, and trust they may rely on their kind co-operation for 1883."

London and Provincial Photographic Association.

At the meeting of the above Association held on the 7th inst., at the Mason's Hall Tavern, Mr. Mark Carey in the chair,

Mr. Cobb showed a lamp for dark-room use with a bull's eye lens constructed similarly to the lamps used in railway trains.

During a short discussion which took place on the solubility of silver bromide—in which Messrs. Debenham, Brown, Coles, and others took part—

Mr. F. W. Hart quoted the following extract from Pohl:—100 parts ammonia solution s.g. 0·986 dissolve 0·051 parts silver bromide, at 176 F., or about 1 grain in 43 ounces; s.g. 0·986 contains about 3 per cent. ammonia, 0·88 being 33 per cent.

Photographic Society of Ireland.

The usual monthly meeting of this Society was held in the Royal College of Science, Dublin, on Friday, the 8th inst., at 8 p.m., Mr. George Mansfield in the chair.

The minutes of the preceding meeting having been read and confirmed, Messrs. George N. Jacob and C. Frederick Allen were proposed for membership.

Mr. Greenwood Pim read a paper entitled, "With the Camera in North Italy" (see page 759), and Mr. C. W. Watson gave an account of a recent trip in the West of Ireland.

Mr. Edward Roper exhibited a series of views taken in Bournemouth, which were much admired.

Sheffield Photographic Society.

The usual monthly meeting of the above Society was held at the Freemasons' Hall, Surrey Street, on Tuesday, December 5th. Mr. J. H. Ranson, Vice-President, occupied the chair.

The minutes of the last meeting were read and confirmed, after which Messrs. Gilley and Turner were unanimously elected members of the Society.

The Secretary reported that no replies had been received in response to the advertisements which had been inserted in the photographic journals, inviting pictures to be sent for the purpose of selecting a presentation print. The accounts for the past year were presented and passed.

The question of holding another exhibition was then brought before the meeting, and an animated discussion arose upon it; but eventually it was decided to postpone the exhibition until next October, on the ground that the last summer was considered to have been unfavourable for securing many good pictures. It was resolved that the presentation prints for next year be selected from the members' own work of the next season. The meeting was then adjourned.

Dundee and East of Scotland Photographic Association.

The third regular meeting of this Association for the winter session was held in Lamb's Hotel, on Thursday evening, December 7th, Mr. James C. Cox, President, in the chair. There was a large attendance, including members and friends from Glasgow, Arbroath, and other districts.

Mr. C. Johnson, Honorary Secretary, read the minutes of last meeting, which were approved and confirmed. The following gentlemen were unanimously elected members of the Association:—James B. Crighton, James M'Farlane, Mr. Noble, Manager Northern Electric Light Company; William Hendry, Alexander Hutcheson, Alfred Guthrie, Willard B. Wells, Consul, U.S.A.; and Rev. Robert Clapperton.

The Secretary read the report on the lantern exhibition, which was approved, and congratulatory remarks made as to the excellency of the slides shown, and the interesting description given by Mr. M'Call.

Mr. G. D. Macdougald, Public Analyst, read a paper on "Emulsion Making," which he illustrated by a series of very neatly-executed experiments, showing the whole process in a simple and practical manner, and concluded by coating a plate with the finished emulsion.

On the motion of the President, Mr. Macdougald was awarded a hearty vote of thanks.

Mr. John Y. M'Lellan, of Glasgow, exhibited and explained his patent eclipse lamp, constructed for burning magnesium wire in oxygen gas.

Members having been invited to bring their cameras, several plates were exposed to test the light. It was decided that the results should be shown and further experiments made at the next meeting.

The question-box contained three subjects for an interesting and instructive discussion, in which both amateurs and professionals did good service.

It was decided to hold the next lantern exhibition on the 20th inst., when Mr. D. Ireland, jun., will show slides and give "Notes on a Tour in Norway." The usual courtesy to the Chair closed the meeting.

Photographers' Benevolent Association.

The Board of Management of this Association held its usual monthly meeting on the 6th inst. at 181, Aldersgate Street.

Messrs. H. W. Bibbs (Greenock), A. Robinson, and A. Jung (London), were proposed and duly elected members of the Association.

The committee passed a vote of thanks to the Council of the Photographic Society for use of their Exhibition on November 16th, the Secretary stating that the benefit, as far as could be judged at present, would about equal that arising from the *soirée* held in the early part of the year, viz., nearly £10. He also stated that J. Glaisher, Esq., had sent a guinea for the funds of the Association.

The other business having been disposed of, the meeting adjourned until January 3rd at 8 p.m.

City and Guilds of London Institute.

Last evening, at Goldsmiths' Hall, Dr. Siemens, F.R.S., distributed the prizes and certificates competed for last May at the Institute's Technological Examinations. Among the awards the following were given for photography.—

First-class Honours Certificates.—1st. prize, W. A. Watts, £5 and silver medal; 2nd prize, A. J. Spiller, £5 and bronze medal.

Second-class Honours Certificate.—E. Banks.

First-class Ordinary Certificates.—1st prize, G. Embrey, £3 and silver medal; 2nd prize, E. H. Farmer, £3 and bronze medal; 3rd prize, H. G. Templeton, £2 and bronze medal; H. Hinchcliffe.

Second-class Ordinary Certificates.—A. J. Banks, F. Caldwell, A. Raiuger, and W. S. Ramson.

Talk in the Studio.

MR. WARNERKE ON PRACTICAL SENSITOMETRY.—At the Photographic Club on Wednesday evening last, the question as to the difference now generally admitted to exist between camera sensitiveness and sensitometer sensitiveness, was discussed. Mr. Warnerke said that the difference would probably disappear if the highest number reaching a given standard of density were taken as the sensitometer reading; those faint tints which can only be recognised by careful examination with oblique light being disregarded. In order that the full advantage of such a method of reading the sensitometer might be realised, it would probably be desirable to fix the plates and compare them, together with the pattern tint or standard of visibility, by placing them together on a sheet of paper. The sensitometer would then become not only a test of the quality and value, but also of that sensitiveness which can be reckoned on in actual every-day work.

THE BEHAVIOUR OF SELENIUM IN LIGHT.—At the last meeting of the Physical Society (25 Nov.) Mr. Shellford Bidwell gave an account of some experiments he had made to test the theory of Dr. James Moser, that the action of a selenium cell under light was due to the heat rays making a closer microphonic contact between the selenium and the metal electrode, by expanding the material. He submitted selenium cells to dark heat rays, and found their resistance to rise. Under light rays, however, their resistance fell. He therefore concluded that Mr. Moser's theory was erroneous, and that the fall in resistance due to the light rays is the differential result of the rise due to heat, and the fall due to light. He also explained the "fatigue" of a selenium cell by use, as caused by its increase of temperature. When the cell cooled again the fatigue disappeared.

ARTIFICIAL PARCHMENT OR LEATHER. (Chas. Weygang.)—One or more layers of long-fibred paper felted or textile fabrics are treated with glue or gelatine, and then with chromic acid, chromates, alums, or other chemicals well-known to have a tanning or "insoluble-ising" effect on glue or gelatine. It is then rolled between hot or other rolls.—*Jour. Chem. Ind.*

To Correspondents.

*** We cannot undertake to return rejected communications.

JNO. W. BEAUCOCQUE.—There is too much ink on your transfer. The layer should be as thin as is consistent with perfect continuity, there being a considerable risk of blurring if this point is not attended to.

FRED JOHNSON.—1. It is probably no more than a question of careful attention during the process of printing. 2. Not at present, but something of the kind will appear shortly. 3. There are several, and one of them will expire in little more than a month.

R. PIKE.—The process is quite out of date, and it is probable that no work at present in print contains any sufficient description. If you enquire at a second-hand book shop for old works on photography, you are likely to find one with working details.

H. SPINK.—We imagine your bath must have been weak, as we have obtained good results with the formula in question; still you may somewhat increase the proportion of iodizing salts.

W. H. M.—Probably the texture of the paper is unequal.

E. P. H.—Dilute your collodion with about one-third of its bulk of ether and alcohol mixed in equal volumes.

HARRY POINTER.—We shall be happy to insert your letter if you will append your name to it.

AN OLD AMATEUR.—Roscoe's Elementary Chemistry, published by Macmillan at four or five shillings, is a very suitable book for your purpose.

A. B.—We are inclined to think that the essential features are covered by a patent; but we are sure that it would cost you a great deal more to make a single one than the price demanded.

W. H. GOVER.—Gas light, or the light of a number of paraffin lamps, will answer well, provided that a sufficiently long exposure is given. The electric light or the magnesium light is suitable for portraiture. Mr. Solomon, of Red Lion Square, sells the ordinary magnesium lamp, but a far more actinic light is obtained by the arrangement of Mr. McLellan for burning magnesium in oxygen. Look back through our advertisement columns for particulars.

CAMBRIDGE.—Such a lens, though admirable as an optical instrument, and capable of doing first-class work, has scarcely any recognised commercial value as a second-hand article. One was sold at Stevens' Auction Rooms some months ago for 15s. 6d., and a friend of ours recently bought one at a second-hand shop for 25s.

*** Several answers are unadvoidably crowded out this week.

*** Authors may have Reprints of their Articles at 3s. per page per hundred copies; but the order must be given when the proof is returned.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1268.—December 22, 1882.

CONTENTS.

PHOTO-ELECTRIC ACTION IN ROCK-CRYSTAL.

The influence of light on various substances, whatever the result, has always a certain interest to the photographer. With the action of light upon selenium, rendering this a more or less efficient conductor of electricity, according to the power of illumination, we are all of us tolerably familiar; and now an investigation by Hanckel teaches us something of the electrical behaviour of rock-crystal under the action of actinic rays.

Hanckel's experiments have already formed the subject of remark in these columns; he has found, so we read in a German contemporary, in continuing his research, that when the rays of the sun, or of the electric light, or even of a flame or heated body, penetrates rock crystal, there is produced on all six edges an electric pole. These six poles are alternately positive and negative electrically, so that every secondary axis carries at one end a positive pole, and at the other a negative one.

The maximum of these photo-electric or actino-electric spans is reached after some thirty or forty seconds, and remains so long as the rays shining upon the crystal maintain their power. As soon as the light rays cease to impinge upon the crystal, the photo-electric quality ceases in like manner, first quickly, but afterwards more slowly.

An electric arc-light equal to 4,000 candles is capable of producing a photo-electric action upon rock-crystal equal to that provoked by sunlight; a gas-burner (Schmidt's) gives a result about one-seventh of this.

The actino-electric or photo-electric action is, in like manner, produced by heat rays, as many of our readers are aware.

INTENSIFYING GELATINE PLATES.

In the development of wet collodion plates little or no difficulty is experienced in obtaining the requisite density, and in knowing when that requisite density is arrived at, for, by reason of the comparative transparency of a bromo-iodide film of collodion, it is very easy to judge in the pale yellow light of the so-called "dark room" how development progresses, and it is quite convenient to carry that operation on to exactly the required extent, as the cooks would say, to "do it to a turn." Now, in the reign of gelatine, another phase presents itself.

We have extremely dense films; the dimmest of dim lights in the red room; development carried to the very verge of fog, indeed more by time than sight; and so many disturbing and distracting conditions prevalent, that the wonder is our successes are as great as they are, especially when we find such wide differences in the behaviour of the various makes of gelatine plates. There is no doubt that the photographer of the present day must know more of the chemistry of his art than those of the bye-gone age.

The extreme difficulty of judging in the developing room of the density of the plates under development is one of the most serious drawbacks attending the use of gelatine plates. Individuals may know with their own or a given make of plates what are the characteristics under development, and can so time their operations and manage their chemicals that they can very accurately arrive at the result they desire; but it must be admitted that the behaviour of gelatine plates under development is very variable, and it is just this variableness that brings about that uncertainty which may entail either intensification or reduction of the negative. Certain makes of plates will, with their proper exposure, develop so that the resulting negative is almost perfect, requiring neither strengthening nor reducing. Other makes, no matter what the exposure, will invariably require strengthening, but it by no means follows that such a plate should be discarded; on the contrary, some of the very finest results can be obtained with plates of such a character, and for the simple reason that everything is visible on development, intensification being merely required to strengthen the whole image, all over, not in part; this being of course just what does not happen when we intensify wet collodion negatives with pyro. and silver. Then, again, certain other makes of plates will give excessive density, no matter what the exposure, nor what the development. Some plates require a very small amount of ammonia, others a very small amount of pyro.; a sort of apprenticeship being needed to master their peculiarities. Finally, some plates won't yield a vigorous image by any treatment.

We will drop the last-named out of the question, and give our attention to such plates as either develop with lack of density in the high lights, or such as develop an image which requires re-inforcing all over. The subject of intensification of gelatine plates has become a burning one, the more so since it has been found that the readiest method of intensification—*i.e.*, mercurial—is not quite reliable. There are conditions about the behaviour and treatment of gelatine plates which are widely different from collodion, so that the methods of intensification employed in the past will not do in the present. In the acid silver intensification of collodion negatives we have an electro-chemical action set up, whereby the silver is thrown upon those parts most elective, and this deposit, which is partly metallic silver, and partly oxide of silver, becomes sufficiently thick to obstruct the light; thereby the contrast of the whole surface is heightened. But this form of intensification does not usually re-inforce the shadows in collodion plates; hence, if a plate be under-exposed, intensification only makes matters worse. However, acid silver intensification of collodion plates is said to give permanent results, and no doubt, if the operations have been properly conducted, these are permanent; i fading or changes of colour take place, most probably the manipulation, especially the washing, is at fault.

But silver intensification of gelatine plates is by no means an easy matter. It was soon found that ordinarily any attempt to employ acid pyro. silver on a gelatine negative merely resulted in a reddish-brown stain or dye all over the plate. This is usually attributed to the presence of hypo. left in the film, and to a certain extent is true, for the same effect can be produced in collodion plates from which the hypo. has not been effectually removed. It must not be overlooked that the film itself, whether it be collodion or gelatine, is susceptible of being stained by silver, especially in the presence of a reducing agent so powerful as pyro. Various attempts have been made, and with considerable success, to eliminate the hypo., a mixture of citric acid and alum having proved efficacious, not only in removing the yellow tinge, but in eradicating the last traces of hypo. or hyposulphite of silver, after which intensification with acid pyro. and silver can be effected.

Whilst the foregoing succeeds in but few hands, the other method of intensifying by means of mercury is so extremely simple, that if it only had the advantage of stability, really scarcely anything more effective could be desired. Mercury intensification of gelatine plates has the property of intensifying the whole image equally, unlike the action of acid pyro. silver. If we have, say, an instantaneously exposed plate on one of those emulsions which will render everything, but yet give little contrast; on development we may find that forcing beyond a certain limit does not improve matters, and on fixing such a negative we feel disappointed to find that although detail is there even in the deepest shadows, still the whole thing is so flat and thin that it will not give a print by any coaxing. Now if we thoroughly fix it and give it fresh hypo. after it comes out of the fixing bath, then wash and soak for some hours, next immerse in solution of alum and citric acid, wash, dry, and finally immerse in a nearly saturated solution of mercury bichloride, it will bleach, or rather whiten, all over. If the plate be then thoroughly washed, and afterwards treated with weak ammonia, almost any degree of density can be obtained. After this, prolonged washing, with an intermediate bath of alum and citric acid, then more washing, should leave the image so intensified and in about as stable a condition as we can expect. If hypo. had been left in the film even in small traces, the image will actually intensify when placed in the solution of mercury bichloride, and this forms a ready method of gaining just a little intensity, copious washing, of course, following such treatment.

This method of intensification is undoubtedly to be preferred, on the grounds of stability, to that in which hyposulphite of mercury itself is the intensifying agent, for then we have certainly the elements of a changeable colouring matter, and only a short time will be required to alter this so that a beautiful negative becomes a dirty and useless piece of glass.

CHEMIGRAPHIC ENGRAVING.

FIFTH ARTICLE.

THE asphalt process of Niépce is capable of giving by far the finest result of any heliographic method known, when line subjects are to be reproduced; and the application of this method to chemigraphic engraving on zinc has long been practised with success. The asphalt process on zinc gives clearer and more perfect blacks than the transfer method already described, as the protective film of asphalt is continuous, and not a mere net-work like the blacks transferred from the usual photo-lithographic impression. Till recently, the great length of exposure required to sufficiently impress the bitumen film has largely tended to prevent the bitumen method coming into general use; but by the adoption of the mode now given for preparing the bitumen solution, this objection is removed, the exposure required not being very much in excess of that required in the case of the bichromated gelatine process. Reversed negatives are required for the process now under consideration, and these are most conveniently obtained by using a reflecting prism or a mirror when taking the negative.

The asphalt selected for preparing the sensitive solution should be light brown in colour and have a decided odour, and, at the same time, should not be so exceedingly dry and resinous as to be easily crushed into an extremely fine powder. A quantity of the sample selected should be powdered as finely as possible, and put into a bottle so as to about one-third fill it; after which the bottle is nearly filled with ether. The bottle should now be corked, and agitated at intervals during about five hours, when the powder is allowed to settle, and the clear etherial liquid is poured off. This washing with ether is repeated several times—in fact, as long as the ether dissolves anything out of the bitumen—after which the remaining asphalt powder is collected on a filter, and allowed to dry in a warm and dark place. The dry powder thus obtained is dissolved in benzole, so as to form a solution having about the consistency of ordinary black varnish or Brunswick black, and the solution is stored up in a dark place for use.

The zinc plate having been carefully cleaned and prepared as directed in the case already considered, a portion of the bitumen solution is diluted with about its own bulk of anhydrous benzole, the solution being filtered if necessary; after which the plate is coated, just as a glass plate is coated with collodion, and placed in a warm and dark place to dry. Before exposure under the reversed negative it is well to dust the surface of the bitumenized plate over with French chalk, in order to prevent its adhesion to the negative; but, of course, all excess of French chalk should be wiped off before the plate is placed in the printing-frame. In ordinary cases, an exposure of one or two hours is required in good diffused daylight. It is scarcely necessary to say that great care must be taken to ensure the complete contact of the negative with the coated zinc plate.

The exposure being ended and the plate taken into the dark room, its surface is carefully mopped over with a tuft of cotton-wool moistened with oil of turpentine; after which, extremely gentle friction may be applied with the same tuft of wool, the greatest care being necessary to treat all parts of the film with equal force. Under these circumstances, the unexposed portions of the film gradually dissolve away, and the device appears in sharp brown lines on the plate. The development being complete in all parts, a similar tuft of wool charged with olive oil is applied in a like manner, this operation serving not only to arrest the solvent action of the turpentine, but also to remove the bitumen already dissolved by the essential oil. The excess of oil having been wiped off, the plate is gently scrubbed with a tuft of cotton charged with a lather of soap and water, this operation being alternated with washings under a water-rose. When all traces of oil have been removed, the bulk of the water is removed by means of blotting-paper, and the plate is fanned till perfectly dry, and placed in a good light for an hour or so, in order to thoroughly fix the bitumen film. The edges and back of the plate are now covered with a resist of shellac varnish, test lines are made, and all is ready for the immersion of the plate in the first etching bath of one part nitric acid and forty parts of water, as already described. When the first etching is completed, the plate is rinsed, gummed, and inked, just as described in the preceding articles. All subsequent operations are now identical with those already described in connection with the transfer process.

Any of our readers who may experience difficulties in carrying out our directions in actual practice are invited to communicate with us.

By-the-Bye.

EXPRESSION.

Expression in portraiture—"there's the rub." A model may be represented well-posed, well-lighted, admirably draped with brilliant shadows and soft detail, and yet be withal a dread failure, should the expression be wanting. It is the wreath that crowns the work, and distinguishes good portraiture from bad. It is of no avail to be the most skilful of manipulators, to have exquisite taste, to possess a keen eye for effect; if the under-lip falls at the moment of exposure, and a set, wearied look creeps over the face when the critical moment arrives, all your talent and labour are in vain. Indeed, the skill and taste you have bestowed go rather to make matters worse; and the critic's cry of "What a pity!" comes out unhesitatingly when he beholds so much good work cast to the winds.

Every photographer has his own way of treating the sitter; but whatever it may be, if the model is not at ease, there is little chance of securing an agreeable expression. A man's portrait is more easy to get than a woman's, for the simple reason that most men wear hair upon their faces, which in a manner masks the expression. It is around the lips and mouth that the greatest mobility exists, and when these are covered by a moustache, the expression of the lower part of the face does not apparently alter. Indeed, it is said of some men that they take their expression from their beards. A man who has beard and moustache falling downwards in one line, from continually seeing himself grave and stern-visaged, lives up to his beard, and grows solemn, or, at any rate, makes belief to be so. Nobody ever sees him smile, and after a while he ceases also to laugh. In the same way, we are told, the exquisite with whisker and waxed moustache maintains for life the cold and superlative air he first assumed when he began to take so much pains over the cultivation of his hirsute appendages; he becomes so accustomed to the mask he wears, that, after a time, it ceases to be a mask at all. How much truth there is in all this we do not know, but certain it is that the beard governs the outward expression of the mouth, and therefore of the face, in a marked degree. An actor with a beard is never satisfactory; we like to see the full play of his features, and the most important of these are hidden if the working of the muscles around his mouth is not visible.

Anyone who will examine but cursorily the anatomy of the human head at once sees that the muscular system is centred in the mouth, and for this reason it is that the mouth plays such an important rôle in expression. It may be said, in fact, that if the photographer secures an agreeable expression of the mouth, he has done all that is necessary. The "saintly look about the eyes" is but a figurative expression, and has no real existence. There are muscles over the eye-brows, it is true, which concern expression; but the eyes themselves cannot express either joy or sorrow. They seem to laugh or cry according as the mouth muscles act, and it is impossible to say whether a model is sad or joyful if you only see the top half of the face. The late Professor Partridge, of King's College, who was for several years professor of anatomy at the Royal Academy, found it very difficult to get his students to believe that eyes could not flash fire, or languish with sweet melancholy. His painter-pupils were so deeply impressed with "the expression of the eyes," that it needed all the worthy Professor's tact and tuition to convince them to the contrary. To Professor Partridge, indeed, the Royal Academy is much indebted for the sound teaching in anatomy which the establishment enjoys to this day. The plan he adopted to convince the art students of the fact he wished to inculcate—for anatomical drawings did little to advance his dictum—was to exhibit a picture of a face, the lower half of which could be replaced either by a mouth wearing a sad expression or a laughing one. He was then able to show that by simply altering the lower part of the face, the eyes would appear to twinkle with delight, or assume that "saintly look," about which we even now hear a great deal.

Care or pain are at once expressed by relaxing the muscle of the lower lip and allowing this to fall, just as readily as a laugh or grin is produced by drawing in the muscle which is in a line between mouth and ear, and is termed the laughing muscle. It does not require human agency to move these muscles and produce expression; this can be done just as well by electricity, as Duchenne, the French physiologist, has shown. Duchenne published in 1862 a work on the mechanism of human physiognomy, which was illustrated by a series of very telling photographs; in this he showed how, by contracting certain muscles by an electric current, the features of a dead man could be made to assume the various expressions as in life, and, in a word, he produced a very good semblance of the different emotions by merely contracting or relaxing the muscular system of the face. This is a circumstance that retouchers should bear in mind, otherwise they may thoughtlessly remove from a laughing face the outline of that muscle's action which produces the laugh.

It is the lowering of the under lip that, in nine cases out of ten, mars a photographic portrait, when it is marred, and no skill of the retoucher can set matters right again. For this reason one always endeavours to keep the sitter in a humorous mood, for so long as the risible muscle is braced up there is no tendency for the lower lip to fall. Indeed, the falling of the lip only happens when the sitter is left to himself or herself, when perhaps the operations of posing and lighting have lasted too long, and the photographer's stock of lively conversation has come to an end. Fritz Luckardt has a predilection for English sitters, because he says that while they are quiet, they generally smile, the prominence of the front teeth, to be observed more especially in the Anglo-Saxon race, being conducive to a bright expression. But when they leave off smiling, and are no longer animated, then the British model ceases to be a favourite, for, says our excellent Viennese artist, as soon as the lower lip falls, the teeth are disagreeably prominent, and we get the jaded—almost painful—expression that one wants so much to avoid. The corners of the mouth sink, and then good-bye to the cheerful expression.

Some photographers occupy themselves with a sitter for half an-hour, and in this way seek to win the confidence of the model and to set the latter at ease; while others believe that the visitor should not be introduced into the studio till the last moment, and then by doing the work briskly they do not give a chance for any feeling of weariness or fatigue. By both plans, no doubt, success may be obtained, and certainly it is impossible to lay down any law by which all photographers can act. Both the qualities of the artist and of the tactician are requisite in conjuring up a happy expression and catching it upon the sensitive film. But if it is the most difficult of all to obtain, we should remember that it is most valuable.

It is expression that makes the difference between a photograph and a painting, and causes the former to be prized so highly when the original is gone far away—perhaps to that bourne whence no traveller returns. A photograph with a happy expression is not merely a pourtrayal of features, a representation of somebody; it is the man himself, with speaking lips and glowing cheeks, as he lives and moves and has his being.

NITRO-GLYCERINE IN THE DEVELOPER.

BY S. BOTTONE.

Few things have conduced so much to the advance of artistic delicacy in photographic portraiture as the use of a strong iron developer. When we look back at the hard black-and-white negatives which used to result from the employment of a pyrogallol developer alone, we cannot help admitting that although these were *photographs*, they were not *pictures*. But the iron developer may be made to give very different results, according to the mode in which it is compounded; the addition of a mineral acid (especially nitric) rendering the resulting image hard and brilliant. I need not descant on the advantages of employing sugar or gelatine in the developer—that has been sufficiently done by Mr. Carey Lea—but I will call the reader's attention to the extreme delicacy in the rendering of half-tones to be obtained by the employment of an alcoholic solution of nitro-glycerine as an addition to the developer. The large wholesale chemists now keep a one per cent. solution of nitro-glycerine in alcohol, which is used in medicine as a remedy for neuralgia, *angina pectoris*, &c. Though it contains only $\frac{1}{100}$ of its bulk of nitro-glycerine, yet it produces a most marked effect when employed as follows:—

Ferrous sulphate	120 grains
Water	4 ounces
Acetic acid (glacial)	2 drams
Sol. nitro-glycerine (1 per cent.)...	2 ,,

The bath being neutral, the collodion pale straw, and the exposure being full, the result is wonderfully fine, full of detail, and hardly ever requires any intensification.

FRENCH CORRESPONDENCE.

REPRODUCTION OF TORPEDO EXPLOSIONS—TRANSFER PROCESS ON GLASS—M. GRASSIN'S INSTANTANEOUS PICTURES.

Colonel Lébert on the Reproduction of Torpedo Explosions.—While on this subject we do well to attend to a lecture by Colonel Lébert, on the photographic reproduction of torpedo explosions. Experiments of this kind have been made everywhere, notably in France and America; and by the help of six different apparatus, all directed towards the spot where the explosion is to occur, the whole of the phenomenon has been photographed from the commencement to the end of the disturbance. In order that the experiment should possess the desired scientific precision, it only remains for the intervals of time between each successive operation to be chronometrically regulated, and that the shutters employed are exactly equal in the length of exposure. It is only under these conditions that we may hope of attaining to scientific results, permitting an absolutely true appreciation of the entire effect, from the moment it commenced to show itself, until the mass of water thrown up by the explosion has completely spent its force. These very delicate experiments form one of the fine applications of instantaneous photography.

Dr. Hénoque's Transfer Process on Glass.—Dr. Hénoque has shown us his method of transferring outlines obtained by means of a stylus on blackened paper on glass. This mode of describing curves in apparatus for meteorology, physiology, &c., is frequently employed, only the outlines are generally executed on paper rolled on cylinders. To photograph these designs, or project them on a screen, it is usual to transfer them to glass without any alteration, the transparency of which renders it capable of being used in either way. Dr. Hénoque, after removing the blackened sheet from the cylinder round which it has been rolled, spread it on a glass, and coated the smoked surface with castor-oil collodion. As soon as the collodion is set, the plate is plunged into water, and, after a moment, a floating pellicle of collodion rises to the surface, bearing the film of smoke and the traced outline. It is next transferred to glass by means of a sheet of paper, and made to adhere with gum applied all over the plate. Great precaution must be taken to fix the four edges of the pellicle by strips of paper gummed. When dry it forms a perfect negative, or may be used as a transparency to project on a screen. In the same way, as Poitevin has indicated, chalk drawings may be removed from paper and transferred to glass. The paper for smoking, says Dr. Hénoque, should be albumenized and lightly gummed. To smoke glasses on which lines are to be traced with a point, they may be coated with lamp-black paint, and the blackened surface afterwards passed over a petroleum lamp flame. The smoke covers over all the inequalities of the coat of paint, and the design may be immediately traced. It can also be taken off and transferred to another glass in the way already indicated.

M. Grassin's Instantaneous Pictures.—M. Grassin, of Boulogne, an amateur, who exhibited such remarkable work at the last Exhibition, has just sent us some beautiful specimens. Among all the instantaneous pictures of this kind which we have come across, we have not seen any superior to them. Our readers would therefore be interested in knowing what course was pursued by M. Grassin in their production. The lens is of French make (No. 4 aplanatic by Hermages), having focal length of 44 c.m. The aperture varies from 20 to 25 millimetres. The shutter is of M. Grassin's own invention, which is soon to be brought out commercially. As to plates, he uses Monckhoven's, and the most rapid are prepared by himself. M. Grassin obtained a silver medal at the last Exhibition in Paris.

EXHIBITION OF 1882.—FRAMES OF THE FUTURE, TECHNICAL MEDALS, MEDALLISTS, ETC.

BY THOMAS J. PEARSALL, F.C.S., ETC.

The general view of the Exhibition of the Photographic Society of Great Britain is satisfactory. A pleasant feeling is created by the grateful harmony of the pictures. No subjects abruptly intrude, and as the eye selects points for attention it is gratified by the good work and taste shown in the pictures exhibited. The press has given its praise, and the photographic journals are calling critical attention to the displays. Some few general ideas may be hazarded as to the teachings of exhibitions as affecting the public, the development of the laws of taste, and the profession.

This Exhibition is so good that it is exceptional to find a bad picture. It seems a severe trial to bring subjects together for the first time, and it is gratifying to find the photographs and their surroundings to be in harmony. If obvious faults were seen at former exhibitions, they now no longer appear, and it is shown that fair criticism has been well entertained by the art-public. The Greeks and ancients carried mathematics into works of art, and it has been proved that the purity and graces of their ornamental works coincide with the severe and perfect rules of geometry.

It is possible that the moderns of the present day are realising geometrical fitness or forms that surround and display photographic pictures, harmonising, as they often do, with tints and colours; and the time may come when some first-rate critic may prove how elegance and harmony of exhibits are more or less dependent upon geometrical proportions of lines and spaces, subordinating tints and colours. It is possible that satisfactory examples may readily be found of group-forms quite in accordance with pure geometry.

Exhibitions seem happy means whereby the public and individuals can each in their way become the critic of work that may accord or be exceptional to general laws. In exhibitions of pictures there are to be considered the means to show these to the best advantage. Not merely are margins in breadth to be noted—and while white and gold are usually safe for individual examples, yet a particular tone or tint may be desired. Here at an exhibition may be seen the effects of suitable surroundings. The exhibition has a quiet, elegant tone. There is scarcely to be seen any pure colour; all are tones or greys. Here can be studied examples of display, and here can well be decided whether the mounts or surroundings should have any white or light tints lighter than the lightest tints of the pictures, or any tint darker than the deepest shade of the pictures.

Frames.—Undoubtedly gold seems best adapted for frames, and it is satisfactory to find that where gold frames meet together, they seem to meet in a pleasant way, the very spaces between doing much to make harmony, where wood and velvet, &c., seem to show too obviously. "The frame of the future" will probably be of gold, of such complexion and design that it will always show as a frame. Whenever seen, and at whatever angles —distinct from a merely bright line, glancing angle, or partial form—the ornamentation may be enriched in detail and have fine work, or by skilful usage of black designs. Perhaps it will be found the skilful frame-maker will have fair play. Too close following of nature's forms may not be so satisfactory as the ideal forms of art. The wonderful completeness of truth and detail of photography do not require help from the carver, while the subjects will harmonise well with really conventional forms of foliage and ornaments so long shown on objects of ancient art—as the lotus, the pine, the honeysuckle, and acanthus leaves, &c.

In the Exhibition some photographic pictures are seen separately and judiciously framed—some twelve or more —each delicately framed, and the whole enclosed in a massive frame. Thus, while all the detail is to satisfy the observers, the whole forms an art ornament for walls as large as can be expected to be displayed in English homes.

Exhibitions seem to be the happy means for showing the progress of art. Year after year it is very satisfactory for all to see improvement. The good work on the walls is so general that scarcely any picture stands out as of unrivalled attraction; but of the amount of labour and skill the public, perhaps, have no means of judging. So intense is the love of nature and photographic art, that instances can be pointed out where numbers of pictures have been taken before the artist and amateur were satisfied that truthful representations of nature yet embodied the beauties of art which existed in the mind, and some subjects have been photographed ten or twelve times before the operator was sufficiently pleased. While the public see but one picture, many may have been taken to meet the type in the artist's mind as best fitted to give the most pleasant view of nature.

Colour Blindness.—The effects of colour blindness may account for some displays; hence exhibitions may be the cause for calling into action the means for examination of workers in photography. The exceptional examples on the walls seem to suggest the usual percentage of colour blindness, while there are sufficient statistics to show the rate of colour blindness of persons engaged on railways and in signalling, &c. There are few reliable returns of the colour perceptions of persons connected with the fine arts.

Technical Medals.—Of medals it may fairly be said that the public take for granted they are deserved, although they do not always divine the reasons for selections, and they often express sympathy for examples left out in the cold. The public seem grateful for the reasons for an award. Many well-known artists possess the talent that nearly always ensures this reward. They have been loaded with well-earned honours. It is possible there may be power yet to be evoked to advance art. The suggestion is now thrown out that medallists themselves should give a medal, strictly for technical excellence, of subjects they may indicate. They would be the fitting judges of merit, and their award might be deemed by practical men of great honour and service. A medallist's medal might lead to explanations of many difficulties found in photographic practice. If medallists in conjunction with the Society would select subjects, with full illustrations, the public would also be found to esteem technical skill.

NOTES ON PHOTOGRAPHY.

BY E. HOWARD FARMER.

Lecture V.

	Chlorine Cl.	Bromine Br.	Iodine I.
Com. w'ts	35·5	80	127

These three elements form a natural group, having in their chemical relations a remarkable resemblance to each other; they are all obtained from the sea, and hence are called the halogen elements, and their compounds the haloid compounds (from ἅλς, the sea).

Chlorine is a greenish yellow gas, producing violent coughing when inhaled, even in minute quantities. It dissolves in half its bulk of cold water, and is absorbed by slaked lime, forming chloride of lime. In presence of water it forms a powerful bleaching and oxidizing agent. It combines with hydrogen, forming hydrochloric acid, and with metals to form chlorides, such as

$$NaCl, KCl, AgCl, \&c.$$

Bromine is a red opaque liquid, having, if anything, a more irritating smell than chlorine. It is slightly soluble in water, and very soluble in alcohol and ether; its aqueous solution bleaches, but less so than chlorine. It combines with hydrogen to form hydrobromic acid, and with metals forming bromides.

$$NaBr, CdBr_2, AgBr, \&c.$$

Iodine is a crystalline solid, having a bluish black colour, and an odour similar to chlorine and bromine, but much weaker. Water dissolves a very minute quantity of iodine, but it is readily soluble in alcohol, ether, and solutions of soluble iodides. It combines with hydrogen, forming hydriotic acid, and with metals to form iodides.

$$KI, AgI, \&c.$$

Chlorine is the most chemically active of these three elements; it therefore displaces bromine and iodine from their combinations.

$$AgBr + Cl = AgCl + Br.$$

Bromine comes next, and displaces iodine, but not chlorine. Iodine displaces neither of the others.

SILVER COMPOUNDS OF THE HALOGENS.

Silver.

Chloride	$AgCl$	Sub-chloride	Ag_2Cl
Bromide	$AgBr$	Sub-bromide	Ag_2Br
Iodide	AgI	Sub-iodide	Ag_2I

Silver chloride, bromide, or iodide may be prepared by direct combination of the elements; if a plate of silver be exposed to chlorine it becomes coated with a white powder, which is silver chloride.

$$Ag + Cl = AgCl.$$

They are usually prepared, however, by double decomposition between a soluble haloid salt and silver nitrate. When a solution of common salt ($NaCl$) is added to one of silver nitrate, a white curdy precipitate of silver chloride falls, and sodium nitrate remains in solution.

$$NaCl + Ag(NO_3) = AgCl + Na(NO_3)$$

The $AgCl$ rapidly settles to the bottom of the vessel, and the liquid containing the $Na(NO_3)$ can be poured off; the precipitate is then washed several times with water and dried, when we get pure silver chloride.

Silver chloride, bromide, and iodide usually occur as powders insoluble in water and dilute nitric acid; the chloride is white, and the bromide and iodide more or less yellow in appearance; if heated, they fuse into semi-transparent masses resembling horn.

SOLVENTS.

Soluble haloid salts.—They are dissolved to a small extent by solutions of soluble chlorides, bromides, and iodides, with formation of double salts, the amount dissolved depending on the concentration of the solvents.

Ammonia.—Ammonia dissolves silver chloride readily, and also silver bromide, if it be concentrated, but not silver iodide.

Ammonium carbonate.—A solution of ammonium carbonate dissolves silver chloride, but not] bromide (Eder) or iodide.

Soluble hyposulphites (thiosulphates).—They are all three readily dissolved by solutions of these salts with the formation of soluble double salts.

$$2AgCl+3Na_2(S_2O_3)=Ag_2(S_2O_3),\ 2Na_2(S_2O_3)+2NaCl.$$

If, however, the hyposulphite be anything like saturated with the silver compound, an insoluble double salt is formed.

$$2AgCl+2Na_2(S_2O_3)=Ag_2(S_2O_3),\ Na_2(S_2O_3)+2NaCl.$$

Alkaline cyanides.—These very readily dissolve the silver haloid salts, soluble double salts being formed.

$$AgI+2K(CN)=Ag(CN)K(CN)+KI.$$

Alkaline cyauides also dissolve metallic silver when iu a fine state of division.

Silver nitrate.—Strong solutions of silver nitrate dissolve small quantities of these salts, more especially the iodide; most of the dissolved salt separates out on diluting the solution.

Silver sub-chloride, sub-bromide, and sub-iodide are produced when silver chloride, bromide, or iodide are darkened by exposure to light; they can be prepared by placing a plate of silver in solutions of the corresponding per-salt of iron.

$$FeCl_3+2Ag=Ag_2Cl+FeCl_2.$$

They are powdery, dark-coloured substauces, insoluble in water and dilute nitric acid; they are decomposed by fixing agents into silver chloride, bromide, or iodide (which dissolves), and metallic silver.

$$2Ag_2Cl+3Na_2(S_2O_3)=Ag_2(S_2O_3)2Na_2(S_2O_3)+2NaCl+2Ag.$$

Per-salts, free halogens, strong acids, and oxydizing agents generally, convert them into the ordinory salts (Captain Abney).

Thus—

$$2Ag_2Br+CuCl_2=AgBr+AgCl+CuCl;$$

Or,

$$Ag_2Br+Cl=AgCl+AgBr;$$

Or,

$$4Ag_2Br+6H(NO_3)=4AgBr+4Ag(NO_3)+3H_2O+N_2O_3.$$

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Chapter V.—Theory of Photo-Lithography, and General Considerations—*continued.*

In the collo-chromate methods, as we have seen, the sensitive surface is composed of a mixture of an alkaline bichromate, usually the bichromate of potash or ammonia, and an organic colloid substance such as gelatine, gum, starch, and albumen, used singly or in combination.

Under the influence of light, the decomposition of the chromic salt renders these organic substances more or less insoluble in and unabsorbent of water in proportion to the intensity and amouut of the action of the light, and a thin film of such a mixture, after exposure to light, acquires several peculiar properties which have been more or less utilised by the photo-lithographer.

Thus, if paper be coated with such a sensitive mixture, and when dry exposed to light under a negative; and if, after exposure, printing-iuk be applied all over the surface of the print, and it be then washed with water, it will be found that in the parts protected from the light the coating has remained soluble, and is washed away, carrying with it the overlying and superfluous ink. Where the light has acted, however, the lines remain insoluble, and retain the ink, thus forming a clear and distinct image of the subject in printing ink, which may be transferred to zinc or stone. On this principle are founded the *transfer* processes of photo-lithography by the "washing off" method.

If the sensitive coating be applied to the surface of stone or zinc, and when dry exposed to light under a reversed negative, then inked and washed in the same way, an image in greasy ink is obtained which, after due preparation of the stone or zinc, may be printed from in the usual way. This way of working is the base of most of the *direct* processes of photo-lithography.

When the seutitive chromo-colloid film is composed of a substance insoluble in cold water, such as gelatine, it possesses another very valuable property, first discovered by Paul Pretsch, which is, that if, after exposure to light under a uegative, it be wetted, and then inked up with a roller charged with printers' ink in the same way as a damp lithographic stone, it will be found that the ink will be taken up by the parts that have been exposed to light, and thereby rendered unabsorbent of moisture; while the parts which have been protected from the light will absorb so much moisture that the fatty ink will be rejected, and this just in proportion to the amount of protection they have received. If the negative used be an ordinary photo-lithographic negative with clear lines and an opaque ground, the image will appear in black lines on a clean white ground. If, however, the negative be of any ordinary subject, with a full gradation of half-tone, it will be fouud that the parts of the sensitive surface that were under the transparent parts of the negative will take a full covering of iuk. The half-shades will take less and less as they become lighter, and finally the parts that were under the opaque parts of the negative, forming the high-lights or broad whites, will take none at all, and remain perfectly clear.

The similarity of principle between this action of a moistened chromo-colloid surface in taking up greasy ink in the insolated unabsorbent parts, and rejecting it in the uninsolated absorbent parts, and that of a damped lithographic stone in taking up ink in the greasy parts, and rejecting it in the moist gummy parts, was first recognised by Poitevin in the year 1855, and he made it the basis of a photo-lithographic process, which is, I believe, used even now. Poiteviu, however, using albumen for his sensitive coating, never completely recognized the full value of the chromo-colloid film as a printing surface, and always worked on stone, adhering closely to the ordinary methods of lithography.

It was found in practice that the images thus produced on stone, whether in line or half line, though very beautiful at first, would not stand the wear and tear of printing, and as the transfer methods were more convenient, Poitevin's process and others of the same kind have fallen into comparative disuse.

The principle of chromo-colloid printing has, however, been worked out most successfully by Tessié du Mothay and Maréchal, Albeit, Gemoser, Ernest Edwards, and others, who have introduced various methods for printing from a surface of chromated gelatine, supported usually on glass plates, by which photographic prints may be produced in the printing press possessing all the exquisite detail and delicacy of the gradation of an ordinary silver print. The appropriate name of photo-collotype has been given in this country to this group of processes, which, though akin to photo-lithography, are quite independent of it, and, indeed, have almost entirely superseded it for all half-tone work and the finest class of line work. In France, their birthplace, they are known as *phototypie*, and in Germany as *Lichtdr uck*.

The principle of inking up a damp chromo-gelatine surface is beginning to be applied to the production of photo-lithographic transfer prints on paper, in what may be called the *inking-up* methods, which are specially applicable to subjects containing very fine delicate work, which might be removed and lost in the washing-off methods.

There is another property of the chromo-colloid film which deserves mention, though it has not come into regular practical use in photo-lithography. If a chromo-colloid film be prepared containing gum, sugar, and other hygroscopic substances mixed with bichromate, as for the dusting process for obtaining reversed negatives described in the last chapter, and after exposure to light under a positive this film be dusted over with a very fine resinous powder, such as asphalte mixed with a fourth of paraffin or stearic acid, as employed by Window, it will be found that the powder will adhere to the film in the protected parts, which remain tacky just in proportion to the amount of protection they have received, while the exposed and hardened parts will refuse it. In this manner an image may be produced on paper, stone, or metal which may be transferred, printed, or etched as the case may be.

The chemistry of the reactions of the alkaline bichromates on gelatine and other colloids under the influence of light presents a good many difficulties on account of the uncertain and unstable composition of the organic and mineral substances involved, and the exact nature of these reactions does not yet appear to be thoroughly settled.

The early idea was that the chromic acid of the bichromate of potash was reduced to a lower oxide of chromium which remained in combination with the organic body, while the latter itself was altered by the liberated oxygen into an insoluble resinous substance.

This theory was shown to be erroneous by Swan, who was the first to thoroughly investigate the question as regards gelatine. He found that the insolubility of the gelatine was entirely caused by its chemical combination with a chromic compound formed by the neutral decomposition of the gelatine and chromic acid, and thus the gelatine was converted into a leather-like and insoluble substance. That this leather-like substance is not the result of oxidation is shown by the fact that it becomes soluble when treated with oxidising agents, such as chlorine, peroxide of hydrogen, &c.

Incidental to these changes, a portion of gelatine is decomposed, and carbonic acid, and probably also an organic acid, are formed.

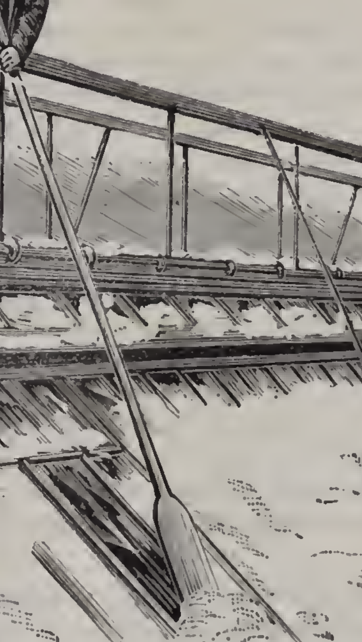
(*To be continued.*)

THE STUDIO—HOW TO VENTILATE AND KEEP CLEAN, OUTSIDE, IN SUMMER, AND FREE IT FROM SNOW IN WINTER.

BY MARSHALL WANE.

In 1879 I built one of two studios with a ridge roof, but in my absence the builder neglected to provide sufficient ventilation; so after enduring the intense heat of two summers, I placed on the top of the ridge a long box-like

cover, two feet wide and two in height (see diagram), this extending on the whole length (thirty feet). On each side, east and west, I had hinged one long glazed sash. These are worked with an Archimedean screw from inside, and can easily be opened one inch or a foot; and the studio is by this means kept cool in summer, and becomes a pleasure to work in. It will be seen by this arrangement that either side can be open, no matter how the wind blows; the frame hinged might be all wood instead of glazed. You will also see that at the extreme top are rails to prevent anyone from falling who is washing the glass with a hose, or clearing off snow in winter; and the approach is made through a window on to a platform joining the studio to the main building. The top is covered with zinc.



End view of studio roof.
A, platform; B, B′, hinged sashes, B′ being shown partly open; C, C′, hand-rails.

Notes.

Our Christmas photograph, "Waiting to go on," will be published next week.

We regret to announce the death of Mrs. Simpson, the widow of the late George Wharton Simpson.

M. Pierre Petit, who was decided by a recent lawsuit to have infringed the Van der Weyde electric light patent for portraiture, has lodged an appeal at the Paris *Palais de Justice.*

Our next elementary course of photography in these columns will have reference to "Printing and Finishing." Like those on Dry Plate Photography and Photographic Chemistry, which have already appeared, the lessons on Silver Printing will be set out in the simplest manner, and pre-suppose on the part of the reader no former knowledge of the subject. Sensitizing, printing, toning, fixing, washing, mounting, burnishing, and enamelling will be treated of, together with simple methods of colouring and mounting on glass. The first lesson will appear early next year.

We see that the popular "lantern lecture" of the South London Photographic Society is announced for the 4th January, at seven p.m., at the Society of Arts, John Street, Adelphi. The honorary secretary, Mr. F. A. Bridge, asks for the loan of any suitable photographic transparencies, which must be three and a-quarter inches high, and be delivered to him at the above address not later than three hours before the lecture.

We have to announce the receipt of the fourth part of Dr. Eder's valuable and comprehensive work on "Photography." The present part of 150 pages deals particularly with the camera and with shutters and dark slides, many interesting woodcuts being included in the volume; and by way of frontispiece there is a Woodburytype print of one of Messrs. Marsh Brothers' wonderful swan pictures. We will give a detailed notice of the work shortly.

The Christmas number of *Truth* is crowded with portraits, several hundred notabilities of the day being cleverly depicted by the wood engraver and the lithographer. Still we owe most of this to photography, an art which serves to familiarise us with the features of almost every great man of the time. Before many years more have passed, we may hope that photography will play the part of the engraver as efficiently and economically as it now delineates.

A very good photograph of the recent transit is sent to us by Mr. J. Joyner, of Cheltenham, the planet showing sharply and distinctly about one and a-half times its diameter from the edge of the sun's disc, and just at the edge of a cloud which partially obscures nearly one-third of the solar disc. Mr. Joyner promises us details of the optical arrangement which he adopted, a matter of some interest considering that the solar image is nearly two inches in diameter, and the picture is not an enlargement.

The Copyright Committee is still actively engaged in formulating and discussing rules and regulations for the new Association, and considerable progress was made with the work on Monday evening last.

Those who employ a drop shutter worked by pneumatic tube will find the cold weather a little troublesome. The rubber inside the brass projection attached to the camera becomes hard and inflexible from cold, and the most vigorous squeeze of the bulb fails in getting the shutter to act. This happens very frequently after the camera has been in the cold studio all night, and the defect may be remedied in a few minutes by holding the warm hand against the brass-work.

The discovery of photography in natural colours, that dim and distant goal towards which many an experimentalist has set out, is made the subject of an interesting story by Mr. G. Manville Fenn in "Cassell's Almanac for 1883." An old gentleman, an amateur photographer who dwells in the West country, pursues the even tenor of his way, taking landscapes and portraits as fancy dictates. There is a charming niece in the background, and a suitor who comes to woo. There is still another who plays an important rôle in the story, a sharp and shifty sort of gentleman, who possesses the secret to photograph in natural colours. He, like most people of the sort, is in want of money to exploit the discovery, and who should be more willing to assist than the old gentleman who practises photography?

The invention makes speedy progress under the fostering care of the amateur, or, at any rate, so the latter is given to understand every time money is asked for. In fact, the old gentleman turns his back upon the suitor of his niece, in his anxiety to give attention to the inventor. Fortunately the lover is a bit of a chemist, and finds out that photography in colours is mere moonshine; he injures his eyesight in the research, but he has no difficulty in exposing the impostor. Having thus rendered signal service to the uncle, we may be quite sure that permission to marry is not long withheld.

The "background" difficulty has been surmounted in most studios. A great many are content to purchase of known makers, who now thoroughly understand the photographer's wants. The main thing is to avoid backgrounds too clearly and vividly painted, pictures elaborate in character and sharp in detail. The less work there is upon a background the better We saw some really good work the other day, produced by a scene-painter with a few touches, and in a few minutes. His modest fee was but five shillings for each sketch.

Not a few photographers sketch their own backgrounds, and we may at once say that if our readers only knew how easy the canvas is to tint, many would be led to try their hands. We do not suggest the production of pictorial backgrounds without experience, but the tinting of canvas with chalks, as practised by Mr. Faulkner, Mr. Robinson, and others. The whole method consists in simply rubbing wet chalks of the desired tint upon a wet canvas surface, and then, when dry, blending and softening the tints by brushing with an ordinary clothes brush. Sharply-limned objects—such as rocks, trees, &c.—become, after brushing, wonderfully soft and sketchy.

In Paris there should be no difficulty about obtaining painted backgrounds at a reasonable price, for the scenic artists attached to the theatres in the French metropolis are paid after a cut-and-dried rate. There is, indeed, but a trifling difference between the prices paid at the Grand Opéra and the minor theatres of the Boulevard du Temple. From six to eight francs per square metre is the extent of the tariff. Elaborate and richly-decorated interiors are charged by the Paris scene-painter at eight francs per square metre, ordinary interiors at seven, and landscapes at six. As a metre is nearly forty inches, a photographic background might be painted for the charge of two or three square metres.

A propos of backgrounds, we see, by the way, that a well-known painter of these in the United States advertises: "Let me paint the backgrounds for a nation, and I care not who makes the photographs."

Marey's instantaneous "photographs of motion" are secured by capping and uncapping the lens at intervals of $\frac{1}{100}$ of a second, while a white object moves across a dark background. The plate developed, then shows the object in various positions on the negative. By employing flashes of electric light—proper means being at hand for making and breaking contact at certain regular intervals—it would be possible to employ any camera of ordinary construction in the work, the object, as before, being white, and the background black. In this way a white stone thrown across the background would be lit up with every electric flash, and a plate exposed during the period of flight would show the path of the stone in the form of a dotted line.

As an electric lamp is now easily obtainable, and the mechanism for obtaining flashes at regular intervals should not be very complicated, we think this system would be more simple than the one M. Marey now employs. Moreover, there would be this advantage; given the flashing machanism, it would be possible to employ any ordinary camera, and any ordinary lens, for securing the photographs.

A total eclipse of the sun of six minutes' duration is promised us in May next—time enough to take photographic observations without number with a well-constructed astronomical camera. Unfortunately, the rare occurrence does not take place in Great Britain, and it is only in Australasia that this wonderful period of darkness in the daytime will happen. Still, expeditions are likely to be sent out by every European nation, since it will be a famous opportunity of improving our knowledge of the strange phenomena outside the solar orb itself, about which we are gradually learning something definite.

Major Volkmer, the principal of the photographic staff of the Ordnance Map Department in Vienna, has devised an ingenious way of indicating forest land in the Government maps. The zincographic printing plate is covered except in such spots where forest is to be shown; it is then sprinkled with finely-powdered resin, and exposed to alcoholic vapour, which fixes the particles of resin upon the zinc surface. The plate is then etched for a short time in acid, and in this way minute cavities are produced, which, when the plate is printed, constitute fine shading of the map in these parts.

Patent Intelligence.

Applications for Letters Patent.

5962. Albert Aron, of Rose Street, Newgate Street, in the city of London, Importer, for an invention of "Improvements in photographic albums."—A communication to him from abroad by Adolphe Aron, of Rue Turenne, Paris, France.—Dated 13th December, 1882.

5970. John Mowat, of Barrhead, in the county of Renfrew, North Britain, for an invention of "Improvements in pentagraph engraving machines."—Dated 14th December, 1882.

6034. Silvanus Phillips Thompson, of University College, Bristol, Professor of Experimental Physics, and Colman Charles Starling, Demonstrator in the said University College, for an invention of "Improvements in photometric apparatus."—Dated 18th December, 1882.

Patent Void through Non-payment of Duties.

4607. Joseph Wilson Swan, of Newcastle-upon-Tyne, for an invention of "Improvements in apparatus for coating glass and other surfaces with gelatinous or viscous photographic compounds."—Dated 12th November, 1879.

This invention has for its object to effect the coating of plates of glass with the photographic gelatinous compound commonly known as "sensitive gelatine emulsion," by automatic machinery, so as not only to obtain more perfect regularity in the coating, but also to effect such coating with greater rapidity and certainty than has hitherto been practicable. And in order that my said invention may be better understood and readily carried into effect, I will now, with the aid of the accompanying drawings, proceed more particularly to describe the same. In order to carry my invention into effect, I construct a machine consisting of a trough containing the emulsion, within which a band, hereafter termed the coating band, revolves, and to which motion is imparted by means of a system of rollers over which it is stretched. Such coating band carries the emulsion over the side and below the level of the trough, and there delivers its charge of emulsion upon the plates as they travel in a continuous train upon a travelling band or table (hereafter termed the plate-conveying band) beneath. I so actuate the coating band and the plate-conveying band, that the coating band and the train of plates upon the plate conveying-band move in opposite directions. In the accompanying drawings, fig. 1 shows a side elevation, fig. 2 an end elevation, and fig. 3 a plan view of my improved apparatus. A indicates the trough; B, the coating band; C, the travelling or plate-conveying band; D, the glass to be coated; E and F are levers for tilting the system of rollers, over which the coating band is stretched in order to bring it into contact, or to remove it from contact, with the plates to be coated; G, G, are the driving rollers, and H indicates the worm which transmits motion to such rollers; I is a sheave for driving the machine from any suitable motor, and J is a weight for keeping the travelling band in the grip of the driving rollers, so as to ensure its travel; K is a pipe communicating with a hot water cistern; L, the immersing roller; M, the coating roller, and N, the guide roller. The trough, A, is made of earthenware, silver, or brass, or any other suitable metal plated with silver, and is jacketted off or fitted with one or more tubes for hot water; while its length is either equal to or exceeds the width of the line of plates to be coated. Its depth and width are determined by the requirements of space for the operation of the immersing roller, L, which is formed of wood, or silver, or of brass, or other suitable metal plated with silver. The coating band, B, is made of india-rubber, while the travelling band, C, is formed either of india-rubber, cloth, linen, cotton, or any other suitable fabric. The

FIG 1

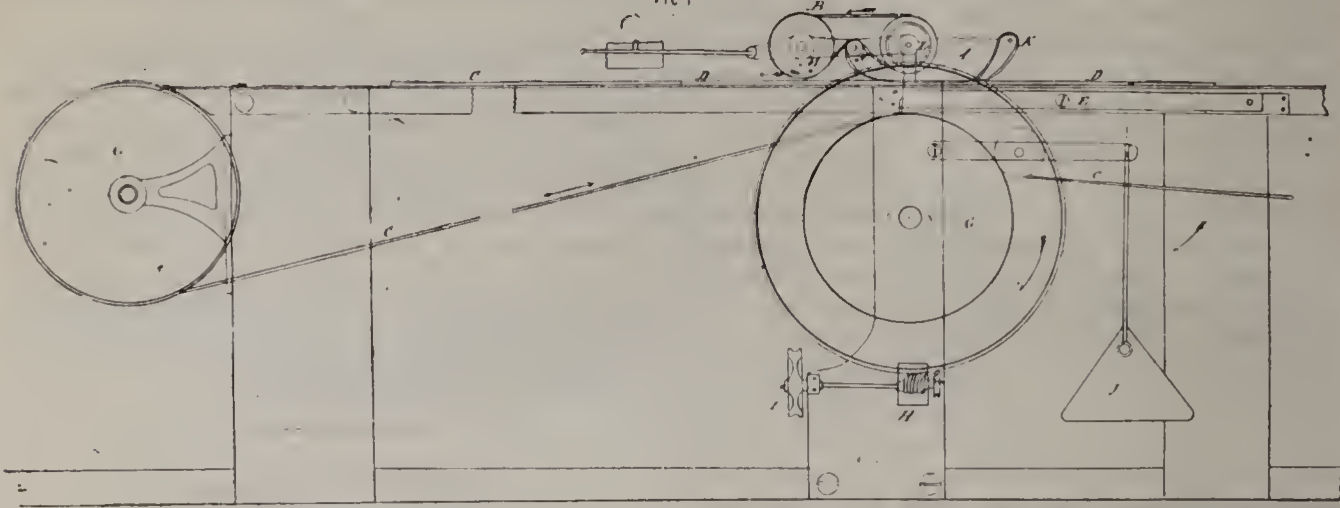


FIG 2

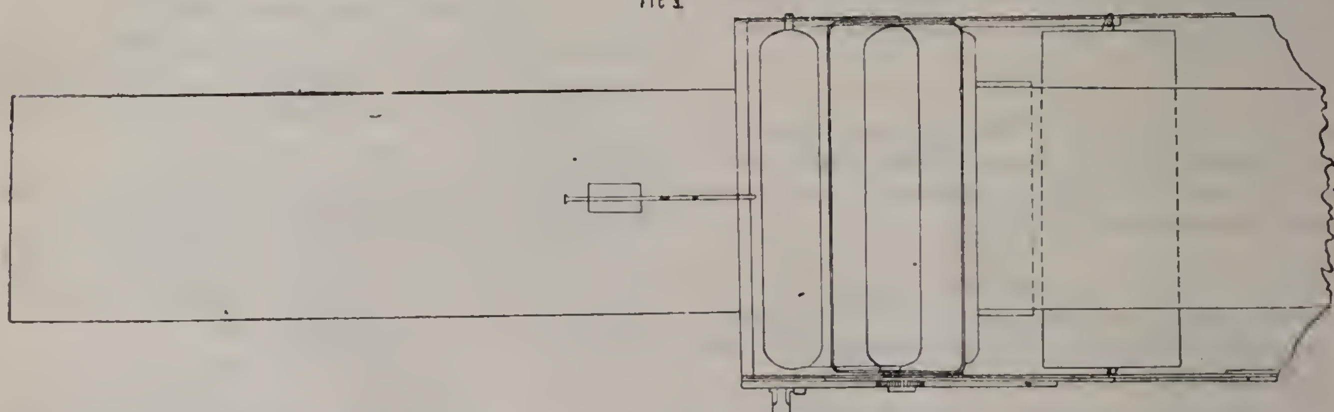
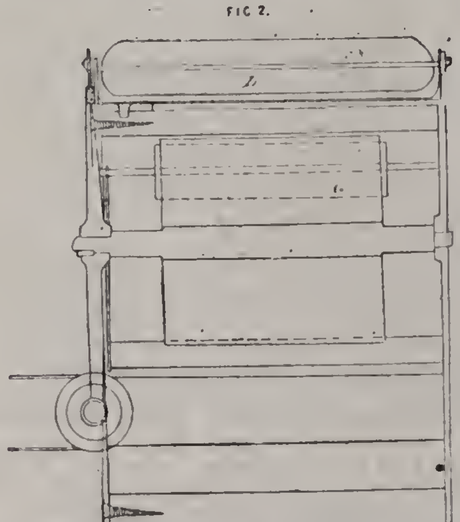


coating roller, M, is made of india-rubber, or any other suitable elastic material, fixed upon a rigid axle, preferably of iron. Having thus particularly described and ascertained the nature of my said invention, and the manner of carrying the same into

FIG 2.



effect, I would have it understood that I do not confine myself to the precise details hereinbefore set forth, as the same may be modified without departing from the principle of my invention, which is to effect the coating of glass and other surfaces with gelatinous or viscous photographic compounds by means of automatic apparatus, so as to obtain a more perfect regularity in the coating, and to perform the operation with greater celerity and certainty. I claim, therefore, as my invention—Firstly, the employing automatic apparatus or machinery for coating glass and other surfaces with gelatinous or viscous photograpihc compounds, for the purposes hereinbefore set forth and described; secondly, the new or improved apparatus, constructed substantially in the manner and for the purposes hereinbefore described and illustrated, wherein a revolving band dipping into a trough containing the emulsion carries a coating of emulsion over the edge and below the level of the trough, and delivers its charge of emulsion upon a train of plates, carried beneath it by a travelling band or its equivalent; thirdly, I claim the use of a revolving band for applying a coating of sensitive photographic emulsion to plates of glass and other surfaces, in order to obtain a more perfect regularity in such coating, and to effect the same with greater rapidity and certainty.

Specifications Published during the week.

2179. A. Foster, for "Squeegees." *Provisional Protection only.*

In my invention I turn a piece of wood of suitable diameter (say about one inch), and then with a revolving cutter or other instrument cut a groove along its whole length, and of abont three-eighths of an inch deep to five-eighths, and of a width just to hold the strip of india-rubber. The rubber is thrust into this groove with glue or any suitable cement, and then nailed or tacked in its place. The ends of the rubber project at least a quarter of an inch beyond each end, and the thickness, depth, or width of the rubber depends upon the size of the apparatus—an eighth of an inch to a quarter or three-eighths will be thick enough, and a projection of half an inch to one inch will bo sufficient for the rubber to project beyond the groove. The rubber and the axis of the handle are not in the same plane, but at an angle of about 40° or other degree wished, according to size.

2211. C. Johnson, for "Producing ornamental or other designs upon tin plates." *Provisional Protection only.*

The object of my present invention is to produce tin plates partly crystallized, but having ornamental patterns, letters, or other devices, which are not so crystallized, some portions of the surface of the plates being crystallized, and the remaining portions showing the tin surface either naturally bright, or illuminated in imitation of gold, or in one or more colours. In order to put my invention in operation I first prepare the tin plates for the crystallization process by heating them in any convenient way until their tin surface is almost fused, and then cooling them with water by a shower or plunge bath, and I then polish their surface. Upon the surface of the tin plates so prepared I print any desired ornamental or other design or device, either by direct printing in a press of any ordinary kind, or by transfer or offset, in one or more coloured or colourless varnishes, using preferably printing inks or varnish containing a sufficient proportion of gold size or other acid-resisting or quick-drying material or materials. When the pattern or other design has thus been printed or produced upon the tinned surface of the prepared plates, I immerse them in a bath of a suitable acid of the requisite strength as ordinarily used, and the surface of the tin will become crystallized upon those parts of the plate not protected by the printed design; whilst the parts so stopped out will retain the ordinary bright tin surface. The printing ink or varnish which forms the design may then be washed away by any suitable solvent or detergent such as turpentine or paraffin, or it may be allowed to remain. Where it is desired to remove the printed or other design after it has dried upon the plates, I place them after crystallization in a bath of cyanide of potassium in a state of ebullition, by which the printing ink is removed, and the design remains as clear bright tin having a silvery appearance. The cyanide of potassium, whilst dissolving the dried printing ink, does not develop the crystals upon the parts of the plate which the ink has previously protected, and these parts consequently remain bright and free from crystallization.

2264. T. R. Johnson, for "Chemically engraving copper or zinc surfaces."

My said invention relates to improvements in chemically engraving copper or zinc surfaces, such as plates for the production of maps, plans, pictures, and in general such work as is now produced with the graver or with the etching needle and etching fluid. It is also applicable for engraving copper printing cylinders, such as are used in calico printing and analogous operations. In carrying out the invention I take from a lithographic stone or from a zinc plate, by means of a lithographic press, an impression in greasy ink on what is called "Scotch retransfer paper," that is to say, paper which is coated with plaster of Paris and paste. This is simply called in "lithography" taking a transfer. This impression I transfer to a chemically clean copper or zinc plate by means of a lithographic or copper-plate press, having first slightly damped either the plate or the transfer. If the transfer is made to a zinc plate, I may slightly grain its surface with pumice powder. The back of the transfer is then damped, and, when the paper has absorbed the moisture, it is removed, and the plaster composition, being carefully rubbed with a wet sponge, comes off, leaving the greasy impression on the plate. The plate is then dried, and a weak solution of gum-arabic slightly alkalised is rubbed gently backwards and forwards over its surface; after which a larger quantity is floated over it to remove any air-bells or blebs which may have been formed thereon. The strength of the gum solution which I have found most desirable is as follows:—For copper, gum-arabic 1 ounce to 19 ounces water; for zinc, gum-arabic 1 ounce to 15 ounces water. The plate is then allowed to dry, and, when dry, the greasy ink is washed out with rectified spirits of turpentine, when the plate is left bare where the greasy impression was, and on all other parts is covered with a thin film of gum. A solution of perchloride of iron in alcohol is then poured on the plate, and this etches it without attacking the ground. The strength of the etching solution which I have found generally most desirable is as follows:—1 ounce dry perchloride of iron in 4 fluid ounces alcohol. But this etching solution can be used with more or less perchloride if the transfer originally on the plate was composed of thick lines or thin ones. Washing in water removes the gum, and leaves an etched plate. Isinglass, albumen, or any substance soluble in water and insoluble in alcohol, and that is repellent of grease, may be used instead of gum. Instead of taking an impression hereinbefore set forth from a lithographic stone or from a zinc plate, drawings in a greasy ink may also be made direct on the plate instead of transferred thereto, and afterwards treated in a similar way; or transfers may be taken from type or any substance capable of yielding a transfer in greasy ink. When using my invention for chemically engraving on cylindrical surfaces, I use the equivalent of a lithographic or copper-plate press for transferring the impression thereto. By my improved process anything already drawn on stone, or transferred to stone, or wood-engravings, or type, can, by simply taking an impression, and without the aid of photography, be converted into an engraved plate; and I would also observe that an essential feature in the working of the process consists in coating a plate with a certain strength of gum that will stand the etching solution, and yet be not so thick as to crack in drying, or prevent the greasy ink from being removed. Having now described and particularly ascertained the nature of my said invention, and the system, mode, or manner in or under which the same is or may be used or practically carried into effect, I would observe, in conclusion, that what I consider to be novel and original, and therefore claim as the invention secured to me by the hereinbefore part recited Letters Patent, is: the combined process of chemically engraving copper or zinc surfaces substantially as hereinbefore described.

Review.

Poitevin's Treatise on Methods of Photographic Printing. New edition, by Leon Vidal.*

We have here rather a detailed history of the patient labours of Poitevin, than a treatise or hand-book on photographic printing methods; but nevertheless, the work not only contains numerous practical directions calculated to materially assist the progress of the student in the somewhat difficult and thorny path of permanent printing in fatty inks, but also many matters of interest relative to early attempts at photography with sensitive emulsion.

When the wondrous discovery of Daguerre was published to the world, Poitevin, then a student at the *Ecole Centrale*, devoted himself almost exclusively to the study of the new art, but rather from a scientific than from an artistic point of view. He perceived at once that the great future of photography depended rather on the production of printing surfaces, than on the making of each individual picture by the special intervention of light, and accordingly he laboured long and patiently in endeavouring to transform the Daguerreotype plate either into a printing mould adapted for use by the copper plate printer, or into a block suitable for typographic printing; but although results of considerable pictorial merit were produced, these methods of photographing did not attain commercial importance.

An exposed and mercurialized, but unfixed, Daguerreotype plate will not receive an electrotypic deposit of copper on those parts which are covered by an unbroken film of bromo-iodide of silver, but the mercurialized parts (the whites of the picture) readily become covered with a film of copper. Such a plate, when cleared or fixed by sodium hyposulphite, presents an image in which the whites are reproduced as somewhat rough metallic copper, while the portions corresponding to the dark shades of the subject present a bright surface of polished silver.

Such a plate, if gummed and printed after the manner of lithography, takes the ink on those parts which have not been covered with electrotypic copper, and consequently positive impressions are obtained. If, on the other hand, the plate is subjected to the action of mercury, the tarnish copper refuses to amalgamate, while the bright silver readily unites with the mercury. Such a partially amalgamated plate takes ink only on those parts free from mercury, and consequently yields negative prints.

It seems that as early as 1849 Poitevin prepared sensitive gelatine plates by coating glass with a mixture of gelatine and silver acetate, and subsequently exposing these to the vapour of iodine, or of bromine and iodine together. The plates required about four times the

* Traité des Impressions Photographiques, par A. Poitevin. Suivi d'appendices par M. Leon Vidal. Paris, Gauthier-Villars.

exposure ordinarily necessary in the case of a Daguerreotype plate, and were developed by means of gallic acid; hyposulphite was used for fixing. Several other gelatine methods were afterwards elaborated by Poitevin, and gelatino-chloride plates were prepared about two years subsequently, and were found to give good results when developed with a solution of ferrous sulphate acidulated with tartaric acid. In 1860 he communicated to the Photographic Society of Paris a method of preparing a bromo-iodide of silver collodion by adding an alcoholic solution of silver nitrate to a normal collodion; but the plates were ordinarily dipped in a weak solution of iodide of potassium in order to de-sensitize the films. Mere washing and treatment with a very dilute silver salt now served to make the plates highly sensitive, and development was effected by gallic acid, pyrogallic acid, or sulphate of iron.

The well-known researches of Poitevin in connection with collotypic printing and other photo-mechanical processes are described in detail; also his printing methods founded on the sensitiveness to light of certain ferric salts; and the work is illustrated with an excellent collotypic portrait of Poitevin executed by *Berthaud Frères.*

A FEW HINTS.

BY J. H. SCOTFORD.

A very fine lubricator.—Sponge over the dry photograph cold water a few moments before burnishing. No other lubrication is needed, and no better or higher polish can be had.

If a gelatine negative refuses in the ferrous oxalate bath to develop sufficient intensity, raise it from the bath, and expose it to the action of the atmosphere for a moment; the improvement is very rapid. This will frequently be found to be very useful.

If too strong mercuric-iodide strengthener has been used, and the silver in the film has been converted to the white iodide of silver, thereby destroying the negative, it can be restored by flowing over the negative a weak solution of sulphide of potassium. This is sometimes useful with other negatives.

The best way to make the mercuric iodide strengthening solution is as follows. Dissolve iodide of potassium (amount indefinite) in water nearly to saturation. Dissolve bichloride of mercury the same. Divide the bichloride of mercury solution into two equal parts. Drop in the potassium iodide into one portion of the bichloride of mercury solution until it has redissolved the precipitate and becomes clear and colourless. Now add the other portion of mercury, which will exactly precipitate all the mercury in the solution. Now add drop by drop of saturated hyposulphite of soda solution, carefully shaking between each drop, till the red precipitate is exactly dissolved, when the solution should be perfectly colourless. This is your stock solution. To use, take seven drachms of water and one drachm of stock solution. This strengthens slowly but wisely, and no negative need ever be spoiled.

For silver developing and toning trays, get your tinman to make a pan of Russian iron, with a heavy iron rod around the edge to strengthen it. The best size for a full sheet of paper is 20 by 26 inches. Caution him to make the bottom as level as possible. Now paint it over inside and out, with two coats of pure asphaltum varnish. Such a dish will be the best and most desirable dish ever used. Small dishes should be made of tin plate.—*Philadelphia Photographer.*

Correspondence.

GREEN LIGHT FOR THE DARK ROOM.

Sir,—I am interested in Mr. Bradshaw's letter of last week. Some time ago, when I had occasion to photograph many hundreds of spectra of various metals by a Siemen's dynamo I noticed that we never obtained a line in the green, and the exposure was in some cases hours long. On the other hand, it was a common thing to photograph the sodium and calcium lines, although the latter were well into the red. This insensitiveness to green light was common to Wratten's, Swan's, Kennett's, and Fox's plates; it would most probably of course be common to all plates, though I cannot speak from experience. Swan made some plates especially for us, but we never got a line in the green even with these.

The inference from these results was of course that green glass can be used by photographers, and I had fully intended making the direct experiment, but other matters intervened.

The subject is of course a detail of considerable importance to photographers, and, if found to hold good, will be welcomed as a useful departure by many. I may add that the combination mentioned by Mr. Bradshaw is precisely that which spectroscopic experience would lead me to select, the region about the E line being undoubtedly extremely non-actinic.

I am not a photographer, and so possibly the use of green glass in the dark room may be an old idea; but I thought Mr. Bradshaw and others might be glad of the special information which I am in a position to give on the subject.—Yours faithfully, Alex. E. Tucker.

CHOCOLATE MOUNTS.

Dear Sir,—I fear Mr. Stanley is not the only one that has been victimized with bad quality chocolate mounts. With me the result of using them proved most disastrous, as, owing to a delay in the carriage, I got quite out, and had nearly a week's printing to mount when they arrived. This occurred in the best part of the season, and customers clamouring for their pictures. The next day I had the vexation of seeing them fading and turning grey, and no other cards in stock. Those that had been sent home and given out I had to get back—no easy matter, as I had nothing better to offer until I got others from London, which took another fortnight. The firm I got them from told me they were sending out thousands daily, and heard no complaint. I do not for a moment condemn all chocolate cards, as I am using the gold-bevelled Malverns, and cannot detect the least change.

I enclose what is left of a picture mounted on one of these cards only three months ago.—I am, yours truly,

Henry Holborn.

LANTERN SLIDES FOR THE SOUTH LONDON POPULAR EVENING.

Dear Sir,—The next meeting of the South London Photographic Society is to be a popular meeting, as it is called, which is an exhibition of lantern slides contributed by members and friends of the Society. It will be held on the ordinary monthly meeting night of the Society, Thursday, January 4th, 1883, at the Society of Arts, John Street, Adelphi, London; and as Mr. F. A. Bridge and myself have undertaken to exhibit any slides that may be sent, I wish to make a few remarks respecting the size of the slides. On a former occasion, when I undertook the task of exhibiting slides submitted, many were much too large to be exhibited in any lantern; some of the transparencies were whole-plate size. The best size for a lantern slide is $3\frac{1}{4}$ by $3\frac{1}{4}$ inches, or they must be $3\frac{1}{4}$ inches high; if they are a little longer it does not matter. I will also thank intending exhibitors, if they possibly can let me have the slides with a numbered list during the day—they can be addressed to me at the Society of Arts—and not leave them, and hand them up to me when the lights are turned out in the room. If the list could be sent to me at my private address before the day of meeting, I should feel obliged, so that I can arrange the different subjects in suitable order.

To those who are not in the habit of making lantern slides, I will just mention what a good slide ought to be. The extreme high lights should be bare glass, and only the deepest shadows opaque. Several slides that were handed to me last year were far too dense to get the light through them; the slightest deposit on the high lights is fatal to a good result on the screen. I trust all those who wish to exhibit will comply with the above conditions, so as to avoid anything like confusion, and that we may have an enjoyable evening. Mr. Bridge will also make arrangements for a little music, and any vocal or instrumental friends will be also welcome. We commence at eight o'clock. Any further information that I can give I shall be pleased to impart.—I am, yours, &c.,

Williams Brooks.

PHOTOGRAPHIC PRINTING BY ELECTRIC LIGHT.

Dear Sir,—I read with considerable interest your paper on "Photographic Printing by Electric Light," as it is but recently that I myself made a few experiments in this direction. I say experiments, but they were something more than that, for I wanted some prints in a hurry, and the sky was so dull that I had to use artificial light as a matter of necessity.

I can fully endorse your statement as to the comparatively feeble power of the electric arc for this purpose. Using commercial ready sensitised paper, my prints took considerably longer to obtain sufficient depth than they would have taken in the direct rays of the sun, although the frames were placed within twelve inches of the light; whilst had they been placed nearer, the negative would have been endangered by the heat. I cannot give exactly the candle power of the light I used, but I believe it was only about half the power of that with which your experiments were conducted. On dull days, printing by the electric arc is decidedly a convenience, but I experienced one very great drawback which you have not mentioned, but may possibly have noticed: the prints were very red in colour, and did not easily take a nice tone. In addition to this, any little defects in the plate showed far more prominently than in prints taken in the ordinary way; in fact, they seemed exaggerated.

I had previously used the electric arc for iron printing when copies of some diagrams were required in a hurry. Half-an-hour was the time required, but the frames were much nearer the light than in your experiments; the exact distance I do not recollect, as it was some time ago, but I believe it to have been about eighteen inches. As the diagrams were on ordinary writing paper, not rendered transparent, my results would in this case also coincide with yours.

C. Ray Woods.

STANDARD LIGHT FOR SENSITOMETER.

Sir,—At the last meeting of the Bristol and West of England Amateur Photographic Association, Mr. Edward Brightman gave an account of the effects of temperature on the luminosity of sulphide of calcium (*vide* Photographic News). He began his communication by a statement totally condemning the use of phosphorescent tablets as standard lights for sensitometers, giving the reason that luminous plates previously excited and subsequently submitted to the high temperature have their luminosity increased.

To consider such conclusion logical, I must admit that the author of it is unacquainted either with papers read by myself on phosphorescence, or with sensitometers, and very simple directions to use them.

Increase of luminosity of the previously excited phosphorescent plate by elevating the temperature is an elementary notion that cannot escape the notice of even a superficial observer. But the proposition for using it as a standard light was based on the observed fact that, provided the excitement and the subsequent use of the luminous plate as source of light is made at the same temperature the result practically is independent of that temperature.

My experiments were made at the temperature of from —15° C. to + 20° C. without showing any difference in the results. In the directions it is indicated that the operator must guard himself not to heat the plate between excitement and exposure, avoiding even to touch the plate with his fingers.

I cannot leave unnoticed a statement made, that high temperature can cause luminosity apart from the action of light.

This error is, however, easily explained by the fact that luminosity in phosporescent plates is very persistant, and, as some observers even say, is noticeable after one month.

Mr. E. Brightman (very likely) experimented on the plate (or powder) not totally extinguished, and submitting it to the high temperature observed only increased luminosity remaining from the last excitement, but not that newly-created by heat; if the phosphorescent plate is totally extinct, no amount of heating can excite it. The same applied to the low temperature. I have a phosphorescent plate on the door of my laboratory in St. Petersburgh; it is naturally frequently exposed to the severest cold, but its luminosity does not suffer by this.

L. Warnerke.

Proceedings of Societies.

South London Photographic Society.

The annual dinner of this Society took place at the Holborn Restaurant on Friday last, the Rev. F. F. Statham in the chair.

Dinner being over, the Chairman alluded to the work of the Honorary Secretary and Treasurer (Mr. F. A. Bridge), whose exertions had inaugurated a new period of prosperty for the Society; the balance now in hand being about equal to the deficit which existed when Mr. Bridge took the management of affairs.

Mr. Bridge said it was hardly fair to rely altogether on the Secretary, as the members should more thoroughly fulfil their duties of attending the meetings and bringing forward matters of interest.

Mr. Jabez Hughes referred to the work done by foreign photographers, and expressed a wish that closer bonds of union should exist between the photographic workers of all nations.

Mr. Warnerke, in responding for the foreign photographers, referred to himself as perhaps an Englishman in a truer sense than the natives, he being English from choice, while they were English from necessity.

Numerous other toasts were honoured, the memory of Monckhoven being drunk in silence, after a few words from Mr. Hughes regarding his manifold labours.

The toast of the evening was, however, in recognition of the amiable and genial qualities of the President of the Society, the Rev. F. F. Statham.

Edinburgh Photographic Society.

The second ordinary meeting of this Society was held in 5, St. Andrew Square, on Wednesday, 6th December, at 8 p.m., Mr. Lessels, president, in the chair.

The minutes of the annual meeting and subsequent meetings of Council were read, approved, and signed. The following gentlemen were unanimously elected ordinary members, viz.:—R. Stuart Dalzell, George Halliday, Alexander A. Inglis, David Grubb, G. Musitano, Arthur Murray Henderson, J. S. Fleming, Arthur Wyllie, and James Smart.

The President then said—In relation to the next part of the programme I shall have a motion to make; but before doing so, must ask your indulgence while I make some preliminary remarks. It will be in the recollection of you all the painful impression made on our minds at last meeting on being informed of the serious illness of our worthy secretary, Mr. Dobbie, by the thought of losing so valuable and esteemed a member of our Society. The members of Council have considered it a becoming duty on our part to place in the records of our Society the great loss we have sustained, and to send a letter of condolence to Mrs. Dobbie. The President then proceeded to give a short sketch of Mr. Dobbie's life, and continued:—His connection with the Photographic Society dates from Feb. 5, 1873, when he was proposed by Mr. J. M. Mackay. His business tact had evidently impressed the Council, as he was made a member of Council in November of same year. After serving his time as Councillor he was re-elected in 1877. He took an active interest in the management of the annual trip It was while exerting himself in the rooms of the Royal Academy, in connection with our great exhibition, that he caught a severe cold, terminating in erysipelas, laying him aside for weeks. Mr.

Dobbie was elected Secretary Nov. 6, 1878, and from this time he impressed his individuality on the billets. At great labour he collected and put in order the literary archives of the Society so far as obtainable, and through his energy new rules were compiled and passed. In November, 1880, he became engrossed with a new idea, which took shape in December of the same year in the publication of No. 1 of the "Transactions," of which he was naturally very proud. The members of the Society who interest themselves in its affairs are all aware of his untiring industry in everything tending to its success and prosperity, and with the enthusiastic sympathy with which he entered into every subject, even although he was not technically acquainted with its details. It is only necessary to say, in a word, that he did every duty thoroughly, and commanded the respect and esteem of the whole Society. At his funeral our Society was represented by about sixty members, including the President, Vice-president, Corresponding and Interim Secretaries, Treasurer, Curator, and Council. The gentlemen were arranged four abreast at Pilrig Church, and walked in front of the hearse to Rosebank Cemetery, thus paying the last tribute of respect for their departed friend. The President moved : "That the Society records in its minutes the great loss sustained by the death of Mr. Malcolm Gillies Dobbie, their Secretary, who for four years conducted their affairs with indefatigable zeal, and by his untiring labours did everything in his power to promote the usefulness and prosperity of the Society. His thorough business habits enabled him to place every matter in a properly organized form ; and he had the credit of originating the publication of the 'Transactions' in December, 1880, an important and useful feature of the Society's work. He was always at the post of duty, and by his kindly and genial manner contributed much to the harmonious working of the meetings, and his efforts to procure suitable papers for the benefit of the members were crowned with success. The Society begs respectfully to tender the heartfelt sympathy of every one of its members to Mrs. Dobbie on her sad bereavement, and to assure her that her husband's services will ever be held in grateful remembrance. The Society begs to express the hope that Mrs. Dobbie will be sustained by God's grace in her sore affliction, and that she will have some comfort in the knowledge that a large circle of friends, who hold his memory in loving regard, condole and sympathize with her in the great loss which is deeply felt by all." The President also moved that this motion be communicated to Mrs. Dobbie by the Interim Secretary.

Mr. W. T. Bashford, in seconding the motion, made the following remarks : It is perhaps appropriate that I should say a few words on this sad occasion, seeing that Mr. Dobbie and I were by a succession of coincidences brought into peculiar intimacy through this Society, being both elected members the same year, both elected office-bearers in the same year, both continuing to hold office till his death, with the exception of one year each. We were each identified with the same principles as to the management of the Society's affairs ; and in all sincerity I may say, no man ever had a more energetic, more honourable, more enthusiastic, more nobly-disinterested colabourer than he was. Mr. Dobbie was a prominent and much esteemed member of other organisations ; and while I am sure his nature would compel him to discharge faithfully all duties connected with them—while each would benefit by his courtesy, his business tact, his energy, his thoroughness—while each in its turn would occupy a prominent place in his active mind, yet of all his connections I believe I am right in saying that he cherished that of the Edinburgh Photographic Society as the one in which he had the most solicitous interest ; for which he underwent an incalculable amount of physical and mental labour continuously for years. Yet to him it was a labour of love. From the year 1876, when our Society passed through such a critical period of its history, till his death, the progress and general welfare of our Society became his hobby, and all matters (other than the business with which he was connected) were quite subservient to its interests. The Society has lost a devoted secretary who faithfully discharged the onerous duties attached to his most important office, often under very trying circumstances, and every member has lost a friend.

The recommendation of the Council was unanimously adopted.

The Interim Secretary read the extract minute of Council of date 1st December, recommending "That Mr. Bashford be appointed Secretary to do the whole work, with an honorarium of fifteen guineas, the arrangement to be for one year."

Mr. Turnbull moved in terms of this recommendation, which was seconded by Mr. Mathison, and carried unanimously.

The motion by Mr. Pringle, seconded by Mr. Horne, brought up from last meeting, "That an honorarium of ten guineas, with the thanks of the Society, be awarded to the corresponding secretary in recognition of the great amount of extra labour devolving upon him during the past year," was discussed, and finally, on the motion of Mr. Mathison, seconded by Mr. Turnbull, remitted to the Council with powers.

Mr. A. B. Stewart exhibited and described "A Flexible Window for the Dark Tent."

Mr. Tamkin considered the unmounted film shown by Mr. Stewart well suited to the purpose proposed, but feared that when mounted on the cloth it would obstruct too much light.

Mr. Mitchell said, when used in open daylight, he believed it would be sufficiently translucent.

Mr. Alexander Mathison, in proposing a vote of thanks to Mr. Stewart, asked if the material was suitable for a non-actinic lantern.

Mr. Stewart Smith seconded the vote of thanks (which was carried unanimously), and hoped that other members would be induced to follow Mr. Stewart's example, and bring forward matters of practical value.

Mr. Stewart said he had used the material for a lantern, and found it answer thoroughly.

Mr. J. M'Kean read a paper on "A New Departure in Alkaline Development," illustrated by the successful development of five negatives on plates by various makers. At Mr. M'Kean's suggestion it was decided that members should defer discussion, try the method proposed during the coming month, and bring up the results at next meeting of the Society. A hearty vote of thanks, on the motion of Mr. Tamkin, was accorded to Mr M'Kean.

Dr. Alexander Hunter, F.R.C.S.E., read an interesting paper entitled, "Canterbury, its Cathedral and Antiquities," illustrated by a fine series of photographs. The paper embraced a history of Canterbury from the earliest known records, and its rise to eminence as an archiepiscopal see, and included a history of the cathedral and its various architectural phases—each part, as far as possible, being illustrated with photographs.

Mr. W. Nielson, in graceful terms, proposed a vote of thanks to Dr. Hunter, which was unanimously accorded.

After thanks to the Chairman, the meeting terminated at a late hour.

London and Provincial Photographic Association.

At the meeting of the above Association held at the Mason's Hall Tavern on Thursday, the 14th inst., Mr. W. Cobb in the chair.

Mr. A. L. Henderson read a reply to some notes which have been published on the history of the ammonia process of emulsification, and it appears that the ammonia process, in a rudimentary form, was practised in 1876 by Mr. Johnstone, who advertised an ammonia nitrate of silver salt for use in emulsion making ; and Mr. Henderson said he did not even lay claim to originality as regards the use of ammonia, but merely gave a good working formula, in which alcohol and ammonia played an important part.

Mr. Hart showed a trough for washing negatives ; it was constructed of metal, and held about one gallon ; the plates rested in an inner tray, touching only at the extreme edges, which tray could be removed and placed in a current of air for the purpose of drying the negatives ; it possessed an ordinary syphon spout, the water playing in jets between each plate from a number of fine holes in a pipe running along the top of one side.

Mr. Prestwich had used a trough in which the water jetted from the bottom.

Mr. Cowan thought it would be improved by constructing the inner tray to hold various sized plates.

Mr. Debenham showed two prints illustrating how the eyes of a squinting sitter might be brought parallel by suspending a black thread in front.

Newcastle-on-Tyne and Northern Counties Photographic Association.

A special meeting was held (previous to the ordinary month'y meeting) in the College of Physical Science, Newcastle, on Tuesday, December 12th, for the purpose of revising and amending the rules.

The ordinary meeting was held afterwards, Mr. Downey in the chair.

Messrs. Fothergill and Hogg were elected members.

The nominations for the election of council were given in.

After a little discussion, it was resolved to hold a dinner in connection with the annual meeting.

The Chairman called upon Mr. A. L. Steaveuson to present to the authorities of the College of Physical Science an enlarged portrait of the late Professor Marreco, from the members of the Association.

Mr. Steavenson said Professor Marreco had been a most valuable member of the Association, and was ever ready to give the members his assistance, and the members of the Association trusted that by the presentation of his portrait to the College in which he had worked, his memory would be kept green.

Professor Aldis accepted the portrait on behalf of the College, and said it would be a great pleasure to all connected with the College to have such an excellent representation of their deceased friend. The portrait would be placed in the very best place the authorities could find in connection with the College.

The representatives of the College present were Professors Aldis, Herschel, Lebour, and Dunn, and Mr. Bunning (Secretary).

A paper on "Transparencies," with lantern illustrations, was then given by Messrs. J. Hedley Robinson and Dr. Williamson. The transparencies illustrating the paper (about sixty in number) were thrown on the screen by the aid of Hughes' lantern, and gave very marked pleasure and interest to the members present.

A hearty vote of thanks was carried by acclamation.

Manchester Photographic Society.

An unusually large meeting of this Society was held at the Manchester Mechanics' Institution, on Thursday, November 9th last, Mr. J. W. Leigh, President, in the chair.

The minutes of the previous meeting were read and confirmed. Mr. George Wood, Senr., and Mr. Alfred Bancroft were elected members of the Society.

The Chairman explained that since the last meeting Mr. Alfred Brothers had resigned office in the Society (for reasons unconnected with the Society), and the Council had conferred the honour of president upon himself. Although, personally, he would have preferred it had been otherwise, he would endeavour to fulfil the functions of the office to the best of his ability.

Mr. Joseph Greatorex said he had come across what to him was a curious chemical phenomenon when making up a ferrous-oxalate developer. He first mixed a solution of iron sulphate and made it decidedly acid (with hydrochloric acid) to litmus paper; next he mixed a solution of oxalate of potash, and made this solution also decidedly acid to litmus paper (with the same acid); upon mixing these two acid solutions together in the usual quantities, to his great surprise he found the mixture did not show any acid reaction to litmus paper.

Mr. John Dale said he had tested for himself, and found it exactly as Mr. Greatorex had stated. He had tried the experiment with various kinds of acids, the result being in all cases alike. He (Mr. Dale) brought two acid solutions with him to demonstrate the matter before the members. After showing their acid properties, the solutions were mixed in the proportion of one to three; but, upon applying litmus paper again, no acid properties were visible. He was unable to account for what had taken place.

Mr. E. Openshaw then gave a demonstration of the working of the platinotype process, developing about a dozen large prints, which were passed round to the members.

Votes of thanks were passed to the members who had taken part in the matters before the meeting, and the remainder of the evening was devoted to inspecting an exhibition of a large collection of photographs, the work of the members.

Mr. W. G. Coote exhibited a collection of views, amongst which were coast scenes and some interiors. Mr. J. W. Leigh (President) exhibited a large collection of both silver and platinotypes; Mr. J. Pollitt some interiors, printed in platinotype; whilst Messrs. Sefton, Brier, Wood, Wade, Chilton, Foldes, McKellen, Smith, Greatorex, Flowers, Openshaw, Dr. Sidebotton, and others also contributed to one of the finest exhibitions of members' work ever seen at any of the Society's meetings. Mr. A. Reston's portrait studies, taken with view lenses, reflected great credit upon the artist; and Mr. Percy Collis's opal pictures were much admired.

A table was set apart for apparatus and novelties. Altogether the meeting, which was attended by about 120 members and riends, was considered a decidedly successful one.

Another meeting of the same Society was held at the Manchester Mechanics' Institution, on Thursday, 14th inst., Mr. John Dale, Vice-President, in the chair.

The minutes of the previous meeting were read and confirmed. The ballot was declared in favour of the following gentlemen:—Messrs. John Harding, Benjamin J. Young, Wm. H. Baird, H. D. Herring, W. Whittaker, Henry E. Lees, John Greaves, and and Rev. H. V. Macdona.

On the motion of Mr. J. Pollitt it was resolved that a printed list of members' names and addresses be published, and issued to the members of the Society.

The Hon. Secretary said that doubtless many members of the Society, like himself, had a collection of photographic and scientific apparatus which they had now no use for, and would be glad to get rid of. He therefore proposed that a sale by auction be arranged for the next meeting (January 18th, 1883).

The idea was at once taken up, the details of the arrangement being left in the hands of the Secretary.

The remainder of the evening was occupied with an exhibition of lantern transparencies on the large screen. The lantern was manipulated by the Honorary Secretary. Over 300 slides were exhibited by Messrs. Percy Collis, W. G. Coote, T. Sefton, H. Smith, J. Pollitt, J. W. Wade, Dr. Sidebottom, and others.

Mr. Johnson exhibited some very beautiful photographs of microscopic objects, and subsequently promised to read a paper on micro-photography at the first convenient meeting.

The exhibition closed with a collection of slides by Messrs. Woodbury, Ferrier, York, Valentine, and Wilson.

The Photographic Section of the American Institute.

A meeting was held at New York, October 3, President Newton in the chair.

The reading of the minutes of the preceding meeting having been dispensed with,

Mr. Gardner related his experience regarding the combining of gelatine and gun-cotton, by dissolving the smallest possible quantity of the former in acetic acid, and then adding sufficient alcohol to cause it to flow nicely over the plate. He had followed the formula strictly, but found that the addition of alcohol precipitated the gelatine. Reversing the operation he dissolved it in acetic acid, and poured the product into alcohol; Precipitation of the gelatine ensued, however, if the solution was allowed to stand.

Mr. Jahr believed that, whenever gelatine was dissolved and alcohol added, the former was precipitated. He had never observed any chemical change. The alcohol only preserved the acetic acid in the solution; but nothing could be accomplished without the acetic acid.

Mr. Hoyt remarked that he had dissolved gelatine in strong acetic acid and alcohol, and had no difficulty. The solution left a clear fine film. He had added four to five times the quantity of acetic acid, and it set rapidly. The alcohol was added when cold. The acid must be very hot in order to hold it. Only two acids dissolve it—nitric and acetic.

Mr. Newton: Gelatine, when dissolved and immersed in a solution of alum and salt, three parts to two, became insoluble. By adding hydrochloric acid, it may be re-dissolved; but then it would dry hard, and to a great extent become insoluble.

The Secretary proceeded to discuss the advantages of a double flat dish, improvised from a few strips of hard wood grooved in the centre from end to end, and then cut into lengths for the size required. These were fastened by screws at the corners, and the sheet of glass introduced; either side could be used, and the ordinary photographic chemicals had no effect on it.

Mr. McGeorge intimated that another ingenious means of making a dish had been devised wherein the wood-work and the paraffin were utterly repudiated; all that was necessary being to take the same piece of glass, heat it, and turn up the edges.

Mr. Newton then spoke in reference to a developer with which different acids had been used—among them, he thought, oxalic acid. He was now satisfied that no bromide was necessary in the development of any of the commercial plates: the gelatine itself is a sufficient restrainer.

Mr. Gardner gave his method of intensifying negatives with mercury, as follows:—First, a solution of bichloride of mercury half-an-ounce; water thirty ounces. Secondly, a solution of bicarbonate of soda one and a-half ounces; liquid ammonia one ounce; water twenty ounces. Thirdly, a solution of citric acid one hundred and twenty grains; pyrogallic acid sixty grains; water twenty ounces. The plate, after removal from the solution of bichloride of mercury, when washed, should be flowed with an admixture of the bicarbonate of soda and ammonia and acid solutions, in equal parts, when the negative will presently turn black and become vigorously intensified. The use of hyposulphite of soda and ammonia ordinarily rendered the plate too weak for his purpose, but it was sometimes found useful where the intensification was too great.

Talk in the Studio.

The South London Photographic Society.—On Thursday week, Jan 4th, 1882, the Annual Lantern Meeting of the South London Society will be held in the large room of the Society of Arts, at seven o'clock p.m. Messrs. Bridge and Brooks have promised to lend their magnificent triplex lantern; and those of our readers who send slides should take care that they do not exceed 3¼ inches in height. The Lantern Meeting (first Thursday in January) and the Technical Meeting (first Thursday in November) are the red letter days of the South London Society, and it is the custom to send free admission tickets to those non-members who may apply to the Secretary. Applications, enclosing a stamped and directed post wrapper, should be made to Mr. F. A. Bridge (honorary secretary), 9, Norfolk Road, Dalston Lane, London, E.

Royal Polytechnic.—Mr. E. H. Farmer's next lecture will be on Saturday, Jan. 6th, when the gelatine process will be treated of.

Novelties in Portraiture.—

"'Beauties' rushed to various studios,
And demanded to be taken,
In a dozen new positions,
On a tricycle or donkey,
Making hay, or making mischief;
Dressed as 'Sisters' of a Convent;
Tending on a wounded Guardsman;
On a yacht, or playing billiards;
Or in a balloon ascending;
In a church, or in a kitchen
Making dainty apple-dumplings;
In a hammock, on a pillion—
Anywhere, so it was novel."

Truth—Christmas Number.

A Bad Example.—There are many curiosities in connection with advertisements of death, but one seldom meets with anything more curious than the announcement made in connection with the recent death of the child of a well-known Maori chief. The sorrowing parent was unkind enough to publish the names of no fewer than *eight* doctors who had attended the poor child in its last illness. Can we wonder at its death? Probably it was only intended as another way of saying "died of the doctors." We, most of us, find one doctor enough when we are out of sorts, but could any of us survive eight? Whether each of them attacked the poor child in turn, or whether they made a united onslaught, we are not informed, but in either case, the result was the same. One is reminded of the old story of the host who, when carving a pheasant, pleasantly remarked, "Doctor So-and-So killed that bird." "Dear me," said a grim guest, "what was he treating it for?" Similarly one's curiosity is somewhat excited as to the manner in which the eight doctors disposed of this unhappy little mortal whose death is so strangely accounted for. While on so grim a subject, I may as well reproduce a document which has been sent me as a unique specimen of advertising. It is said to have been prepared by a well-known firm of photographers, with a view to distribution among the relations of "dear departeds," and purports to be a verbatim copy:—"Dear Madam,—It is with great regret we hear of the demise of the late Mr. W——, your husband. Though not wishing to intrude unduly on your distress at the present time, we cannot help suggesting to you that the more pleasant the memories connected with the departed, the more easily would the condolence be effected (*sic*). We would respectfully suggest that nothing would bring the memory of the dear departed so vividly to your recollection as a life-like copy of the "original" (*sic*). This is easily obtained by sending us a carte-de-visite, which we enlarge to life-size in the highest style of art, for the sum of 25s. This is an opportunity which may not occur again.—In deepest sympathy, we remain, madam, yours respectfully, —— & Co." The idea is undoubtedly a brilliant one, and will no doubt be adopted by others than the original proprietors of it. The "melancholy pleasure" with which an undertaker waits on his customers, and the subdued grief of the "unmitigated woe department" in warehouses of mourning finery, are duly paralleled in this touching circular. That suggestion that the opportunity "might not occur again" is a touch of genius. Perhaps the circular won't be issued. The wide publicity given to it in this passing note may suffice to set inquiring minds searching for its enterprising authors. I am told it is a selection from several competitive designs.—*Otago Daily Times.*

To Correspondents.

*** We cannot undertake to return rejected communications.

F. H.—Either a fine pen or a sable brush charged with indian ink is ordinarily used, and a very little practice will enable you to write backwards. 2. Write on a piece of thin paper with a stylus or blunt point, smoke the face of this paper over a candle, and lay it back upwards on the negative. You can then easily trace over the lines again (the impression made by the stylus being visible at the back of the paper) so as to set off some of the soot on the varnished film. This set-off will then serve as a guide in writing.

S. J. Muir.—See our Year-Book, which was published last Wednesday. 2. We will post you the titles of a few foreign works on the subject.

W. T. Wilkinson.—In such a case we imagine that early registration would become absolutely imperative, and even then the case would be a little doubtful.

J. J.—The process is extremely troublesome, expensive, and uncertain when compared with modern methods.

Photo-Astronomograph.—Write to Mr. J. Joyner, 408, High Street, Cheltenham.

W. G.—Rub the surface over with a trace of the so-called encaustic paste.

A. Donald.—We will hand the note and specimens to the gentleman mentioned; and we shall be glad to have a paper from you, descriptive of your method.

J. C. L.—That which is second on your list will be more rapid than the first, but the exact ratio will depend on a number of circumstances.

W. A.—1. Quite right, a print from one would be a negative. 2. Yes, if you add a little ox-gall or Castile soap. 3 The very best results; only you must take care not to over-expose.

A. Harrison Hill.—Thanks.

Samuel Henburg.—1. It certainly gives a realistic air to the whole affair. 2. Nearly twice as strong as is really necessary, and in this case all over the quantity actually required is liable to do mischief.

Messrs. W. & D. Downey.—The information you give is highly interesting, and we shall not fail to make use of it at the proper time.

J. B. Holroyde.—A letter for you has been sent to our office.

Robert Afford.—You will see that we have done our best to meet your wishes.

H. O. Robson.—1. Like other organic bodies rich in nitrogen, it gives off ammonia when heated in a close vessel. 2. Insoluble in ether, but easily soluble in benzole. 3. The ends of the marginal lines will curve inwards.

M. I. T.—Doubtless you have very much over-exposed all the plates; try about one-twentieth of the exposure, and exercise the greatest care to exclude all trace of injurious light from the dark room.

Beginner.—The gelatine has become thoroughly altered by the long-continued action of heat and moisture. Recommence the whole series of operations.

*** Authors may have Reprints of their Articles at 3s. per page per hundred copies; but the order must be given when the proof is returned.

THE PHOTOGRAPHIC NEWS.

Vol. XXVI. No. 1269.—*December* 29, 1882.

CONTENTS.

THE WARMING OF THE STUDIO.

The photographic studio as usually constructed presents unusual difficulties as regards warming and the exclusion of damp, while the fact of the most exposed situations being perforce selected for the location of glass houses serves to considerably increase the difficulties of the situation.

When the general structure of the studio is brickwork, and an ordinary chimney with the usual open fire-grate are admissible, nothing can be better; but in cold weather a good fire must be kept to counter-balance the cooling influence of the considerable window area, and care must be taken that very large volumes of smoke do not issue from the chimney at such times as to occasion any obstruction of the light. It is quite true that the ordinary fire-grate is defective as regards the utilisation of a considerable proportion of the heat of combustion, but this waste of heat is more than compensated for by the collateral advantages, such as general comfort, non-obstruction of valuable floor space, and a cheerful aspect of affairs.

It very frequently happens, however, that no brickwork enters into the construction of the studio, and the only kind of chimney which can be used is an iron stove-pipe. In such a case the ordinary system of heating by means of hot water circulating in a system of cast iron pipes may be adopted, one of the potable annular boilers being used. Still the hot water pipes are not only unsightly, but, unless considerable expense is incurred in placing them, they prevent that free and unobstructed use of the wall space which is so essential to the photographer in making arrangements for group studies. Still more than this, the cast iron pipes are very liable to burst through the action of frost in winter, as the average studio cools very rapidly; and the interval between Saturday and Monday often serves to nearly equalise the internal and external temperatures. In the summer, hot water pipes are terribly in the way, and we know of more than one case in which this inconvenience became so great as to lead to their removal, a course involving a considerable expenditure.

Considering that artificial heat is only required in the studio for about five months in the year, we think that when the ordinary fire-grate cannot be used it is best to employ small cast iron stoves, fitted with the usual sheet iron flue piping. One or more of these can be placed in its cast iron tray or fender, fairly out of the range of the general work, and sheet iron safety-pieces can easily be set in the framing of the studio where the flue pipes pass into the open air. A material advantage of this system of heating is to be found in the circumstance that the whole affair can be cleared away or replaced in a very few minutes, so that no floor space need be lost when a fire is not required. A frame containing an enlargement can be used to cover the sheet iron shield which covers the exit hole of the stove pipe; but it is best to allow the outside bend and lengths of pipe to always remain in position. There are many advantages in allowing the smoke pipe to pass out horizontally rather than vertically, but as these will be obvious to all, we need not enumerate them.

Much taste and ingenuity have been displayed in the designing of potable stoves, the flat or American model being most generally approved of. These can generally be had with a hot water boiler and small oven, and a cast iron filigree dome, which, when placed over the stove, conceals everything but the glowing front of the fire, and gives to the kitchen stove a decidedly ornamental aspect.

The stove is as much required as a protection against the mischievous effects of damp as against cold, damp being especially prejudicial in many branches of photographic work. The conditions under which moisture is deposited from the atmosphere are so frequently misunderstood, and mistaken views are so often acted on, that some few words in explanation may be useful. Air will always dissolve or absorb a certain amount of water, and the amount of moisture which a given amount of air can dissolve depends on the temperature, the capability of air for dissolving or absorbing moisture increasing enormously as the air becomes hotter. Let us imagine a little water to be poured in a tin box, and the lid to be closed. In a very short time the enclosed air will absorb the maximum quantity which it is capable of taking up, provided, of course, that excess of water is present. Water thus saturated with aqueous vapour is ordinarily called moist or damp, and it is ready to deposit moisture or dew immediately it is cooled by contact with any substance colder than itself. If, on the other hand, the air in the box be heated, it becomes "dry" in the ordinary or popular sense of the term: that is to say, it becomes capable of taking up more moisture; and if the supply of water in the box holds out, the air will soon become again "damp," or saturated with aqueous vapour. The air being thus warm (*i. e.*, above the temperature of immediately surrounding objects) and damp, a film of moisture will be immediately deposited on any body at the surrounding temperature which may be placed in it. If the box be allowed to cool, moisture will be deposited on the sides of the box as the capacity of the air for moisture becomes reduced.

On a cold day in winter the atmosphere contains but little moisture, as the capability of the air for taking up aqueous vapour is reduced very much by the cold. Let us now imagine the case of a studio or room the contents of which have become reduced to or near the level of the external temperature. There is no special tendency to deposit moisture, and the contents of the room remain fairly dry; but when a thaw sets in, the external warm air speedily becomes saturated with moisture, the increased temperature enabling it to take up a considerable amount. This warm and moist air penetrates into the studio, and becoming cooled by contact with bodies much colder than itself, immediately deposits some of its aqueous vapour; this deposit taking the form of a dew on the solid body.

Those compact bodies which take a long time to change their thermic condition become most bedewed when a sudden rise of temperature occurs, and it is no uncommon thing to see such a mass of iron as an anvil covered with moisture for several days after the commencement of a thaw.

Damp thus deposited when a sudden rise of temperature occurs, often causes serious damage to photographic apparatus, but if the photographer take care to anticipate the thaw by thoroughly warming his studio when the external temperature is falling, there is but little danger of moisture being deposited on the objects inside; but it is when the external temperature is rising that there is especial need for artificial heat as a protection against damp.

As many of our readers are now likely to be contemplating the erection of new studios for the work of the coming season, we will before long publish a short series of articles on the principal points to be attended to in the selection of a site, and the construction of the building.

FRENCH CORRESPONDENCE.

Non-Success of Platinotype in France—Phosphorescent Plate for Lighting—Printing with Vitrifiable Ink—Ferrous Oxalate Developer—Phototype Process and Letterpress.

Non-Success of the Platinotype Process in France.—The platinotype process has not yet found favour among us. What is the reason? It is not known enough, and the industrial application of it, adopted and put in practice by the purchasers of Willis's patent, was defective—to my mind, at least. Platinotype prints, on being compared with silver on albumenized paper, show a want of transparency in the shadows, and the cold tone is opposed to the warmth of a silver print. It is said that the platinotype process is permanent, while silver only lasts a certain time. This is not in general an important reason for its adoption, as photographers are more anxious to satisfy their patrons at the moment, than to think of the future. The public ought to be chiefly concerned in the permanent quality of this process. A son, for instance, in ordering a photograph of his parents, wishes for a lasting image of them; the author of a book desires it to be illustrated in a stable manner; collectors of various reproductions can only admit prints as unalterable as engravings and lithographs among their treasures. Unfortunately, it is not brought before the public sufficiently to enable them to realise its durability. It usually happens that photographers impose upon their sitters and patrons the process which is in most frequent use—namely, the silver printing One reason which may have contributed to the rejection of the platinotype process with us, while it is so largely practised in England, Austria, America, Belgium, &c., is the method by which the working is organised. Licenses have been granted, and the sensitive paper is only sold to those who have licenses—surely a bad way of bringing forward a printing process but little known, by limiting the practice of it to certain restrictions. It would have been better to have sold the sensitive paper to whoever wished for it, and to have charged more, than to enforce an annual payment for the right of using the process. Since the fine publication of Pizzighelli and Hübl, it has been determined to set up its manufacture in Austria. It has been undertaken by the firm of Just, of Vienna. The publishing in France by Gauthier-Villars of this admirable treatise on platinotype will bring it more closely to public notice. The only difficulty offered will be the preparation of the paper; but, when that is overcome, there will be numbers who will eagerly avail themselves of its numerous advantages.

Phosphorescent Plates as affording Illumination. — Mr. Brightman does not think it possible to fix a standard of light obtained from the phosphorescence of sulphide of calcium, an opinion contrary to that of our learned friend Mr. Warnerke; and he bases his objection on the great influence temperature has over its luminosity. After reading what Mr. Brightman has written on this subject, I have made some experiments in temperatures varying between 20° and 30° C., and I came to the conclusion that Mr. Brightman had practically formed an erroneous impression. What appears more probable is, that from several samples of the phosphorescent substance they appear more or less luminous. whatever be the temperature, under the influence of the same source of exciting light. In my next letter I will report on the results of my experiments with phosphorescent surfaces purchased at various places. This objection is really serious if it is not confirmed by experience relative of differences to temperature. I have just perused Mr. Warnerke's reply, and as it fully re-echoes what I should say myself, I adhere to what Mr Warnerke says. Omitting the question of temperature, the question of luminosity remains to be solved, greater or less according to the stimulation of the same light on various specimens. In a word, it remains to be seen if the batches of sulphide of calcium are luminous in the same degree; for if not, all observations made upon them with a sensitometer would be useless.

Mode of Printing with Vitrifiable Ink.—As I am occupied in making an addition to the series of photographic publications (I am at work upon a photo-ceramic treatise), I have undertaken numerous experiments on the means of photo-mechanical printing with vitrifiable inks. The difficulty to be overcome is great when a direct collotype has to be printed. Not that it is impossible to use metallic oxides with the addition of the usual fatty varnish, but so little colour remains on the printed surface that the fire destroys a great part of the half-tint. Generally, lithographers who use traced impressions on pieces of porcelain, print their various monochromes with a fatty mordant, afterwards superposing the suitable colouring matter. The sticky mordant retains much more than if the colour were mixed with it. For coloured ceramics I advise a lithographic impression to be made first, as in my photochromic process; then, when fixed and burnt in, I apply a phototype image as highly charged with metallic oxides as possible, very hot, and again fired. It is needless to remark that the lithographic designs are prepared in their respective colours.

The Ferrous Oxalate Developer.—It is well known that the ferrous oxalate developer is excellent, but it also presents many advantages independent of its developing qualities. It does not soil the fingers, and, besides, may be regenerated by the addition of tartaric acid and exposure to light, as indicated by M. Andra. M. Borlinetto has just found another use for it in the Bunsen electric battery, where it acts perfectly. The pile is prepared with amalgamated zinc, water acidulated with 8 per cent. of sulphuric acid, and carbon reaching above the porous pot, and having its projecting part covered with paraffine. After a month M. Borlinetto found that the pile was not disturbed by the acidulated water, nor did the zinc present any exterior alteration. Our friend Major Waterhouse has recommended the use of this developer for intensifying wet collodion negatives. Two negatives fixed and washed are immersed in a ten per cent. solution of bromide of copper, which gives them a light citron yellow tint. After washing, they are plunged in the ferrous oxalate, when they assume a deep olive colour. This is one advantage over the pyrogallic developer.

Modification of Phototype Process combined with Letter-

press.—I have modified this process as follows. A plate after being rubbed with French chalk, is coated with normal collodion of $1\frac{1}{2}$ grammes gun-cotton in 50 grammes of alcohol, and the same quantity of ether. When dry, this receives a film of bichromated gelatine, and is allowed to dry in the oven. The gelatine can then be cut round the edges, and the pellicle is raised and exposed to light from the back before fixing to a block of the same height as the type. By this means a very solid film is obtained, which may be used as a typo-graphic negative, except that the prints are more delicate, and more care must be taken in the inking suitable to it than to that of the letter-press, as that is sure to go right.

I terminate this letter by wishing all my readers a happy New Year, and hope that the year 1883 may be rich in fresh and striking photographic progress.

LEON VIDAL.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

CHAPTER V.—THEORY OF PHOTO-LITHOGRAPHY, AND GENERAL CONSIDERATIONS—*continued.*

THE general correctness of Swan's theory has been confirmed by Dr. Eder, who has made a most exhaustive examination of the reactions of chromic acid and the chromates on organic matter, in a paper which gained the gold medal awarded by the Photographic Society of Vienna, and is replete with matter of interest to the photo-lithographer. An abstract of it will be found in the NEWS, vols. xxii. and xxiii.

The generalresult of Dr. Eder's investigations appears to be as follows:—The change resulting from the exposure to light of a mixture of gelatine and bichromate of potash in a dry state depends primarily on the reduction of the excess of chromic acid of the bichromate, and an oxidation of the organic substance. Under the influence of light the yellow chromated gelatine turns brown, and by continued action of the light the brown parts become green, showing clearly the formation of chromate of chromium, and finally of chromic oxide. The first effect of the light is apparently to produce chromic oxide, and this again enters into a close combination with some of the chromic acid of the bichromate, which is always in excess, thus forming chromate of chromium; and it is this latter substance which, combining chemically with part of the gelatine, renders it insoluble. The remainder of the gelatine is decomposed by the liberated oxygen, and converted into formic acid and other oxidised bodies which are soluble, and do not contribute to the formation of the insoluble residue forming the picture, because analysis shows that this consists entirely of unchanged gelatine and chromic oxide.

The action of the bichromates upon gum is similar to that on gelatine, the insoluble substance formed being a compound of gum and chromic oxide. With albumen, however, it would appear that an oxidation of the organic matter really does take place, as albumen is not rendered insoluble by chromic oxide.

The decomposition which causes the insolubility of chromated gelatine, &c., may also be brought about without the influence of light by heat or by long keeping in the dark. The action in the latter case is slower, though heat and moisture, and particularly both combined, favour it. Sensitized papers or plates, &c., can therefore only be used within a few days of their preparation, and must be kept dry and in absolute darkness, for the action of light, though it may be slight, once set up, continues even in darkness. This fact is sometimes taken advantage of when light is dull and full exposure cannot be given. By keeping the under-exposed print in the dark for a few hours, the image may be developed of the same strength as if it had received a full exposure.

For the same reason sensitized paper should not be exposed to too great a heat in drying, which might render it insoluble, and liable to retain ink on the ground, whether washed off or inked up.

In most of the photo-lithographic processes depending on the use of chromo-colloids, the colloid material is by preference gelatine or a mixture of gelatine and albumen, especially for the transfer methods. The gelatine is easily applied to paper, and gives a good substantial coating, which is not penetrated by the transfer ink when inked in the press. Its insolubility in cold water gives it an advantage in those methods in which the photo-lithographic image is developed by inking-in with a roller on the damped gelatine surface.

On the other hand, gum and albumen are readily soluble in cold water, and the manipulations are simplified. Those substances are, however, generally used for coating stones or metal plates in the direct methods. For this purpose and also for coating paper, albumen is generally preferred to gum, as giving a more resisting coating, the images formed with gum being inclined to be broken and rotten. Albumen is, by some workers, preferred even to gelatine in the transfer methods for fine work, where great sharpness and delicacy are required. For working on the large scale gelatine will, on the whole, be found the most convenient.

As regards the quality of the gelatine suitable for photo-lithography, there is not much to be said; any good quality will answer. For photo-transfers it should not be too soft and soluble, otherwise the coating of the paper will be too thin, and the ground liable to be stained with ink. On the other hand, it should not be too hard and insoluble at moderate temperature, otherwise very hot water will be required for washing, and this may cause the ink to clog up and thicken on the lines. For general purposes I have found Nelson's opaque gelatine answer very well, but in hot weather the addition of a little of the harder fine cut of the same maker is desirable.

For transfers to be rolled up, or for the preliminary coatings of washed transfers on an insoluble basis, the gelatine may be somewhat harder.

The bichromate salts usually employed for sensitizing photo-lithographic transfer paper, &c., are the bichromates of potash and ammonia. The potash salt is the one most commonly used, and answers all purposes, though bichromate of ammonia is preferred by some as giving more sensitive films, owing to its greater solubility, and the consequently larger quantity that can be combined with the colloid material without its crystallising out.

Finally, with regard to the mode of applying the photographic image to the zinc or stone, either directly or by transfer, the choice is to be guided by much the same principles as rule in ordinary lithography, where the design may be produced on the stone either by transfer from a drawing made on prepared paper with the special resinous, soapy, so-called "autographic" ink made for this purpose, or by drawing directly on the stone with a similar ink or solid crayon. In the one case the drawing is made upon paper, in its correct position, and is in a convenient form for moving about. It is, however, liable to be made coarser, and thrown out of scale, by the operation of transfer. In the other, the drawing is made on the stone or zinc plate itself; it must be reversed, and the stone or zinc, if large, cannot readily be moved about; the drawing may, however, be made as fine as the draughtsman can make it, and be perfectly true to scale.

In photo-lithography, also, the transfer methods offer many conveniences in the greater facility and certainty of the manipulations, the power of joining up several sections of a subject, and they give a strong image on the stone or zinc, which will yield a large number of copies. This image is, however, as a rule, coarser than the image obtained by the direct methods, and is liable to distortion by the process of transfer, just as is the case in ordinary lithography.

In the direct methods, on the other hand, the scale of the original is accurately preserved, the work is cleaner, and the lines sharper than they can ordinarily be obtained from paper; there is also a considerable saving of time and material, the coating of the stone being very thin, and taking only a few minutes to dry.

In these methods, however, the size of the work is limited to a single negative, and this must be taken reversed specially for the purpose. With negatives on glass it is difficult to obtain perfect contact between the surface of the stone and the glass, and the latter is liable to be broken by the pressure required. This difficulty is much increased with large stones or plates, which are, further, very inconvenient to carry about in and out of the dark room. In some of the direct methods the printing ink is not in actual contact with the stone or plate, but separated from it by a film of gelatine, which is easily worn away in the press, and consequently the work will not give many good impressions.

The collo-chromate transfer methods, being in many ways the most convenient for all ordinary work, are the most generally used, and we shall therefore consider them first.

(*To be continued.*)

Notes.

Our little supplement, "Waiting to go on," will be remembered by many in the Pall Mall Exhibition of 1877. The *Pictorial World* of the same year issued an engraving of the photograph, by our permission, as their Christmas picture, entitled "Our Baby Clown," but it was scarcely a satisfactory reproduction. Of the present print, by the "ink-photo" process, we may say that, if not perfect, it has, at any rate, all the original merits and demerits of the photograph.

In our "By-the-Bye" last week we mentioned the circumstance that expression on the human face could be counterfeited by applying electricity to certain muscles of a "subject," thus causing them to move mechanically. Curiously enough, the subject was also alluded to last week by Mr. Preece, in lecturing before the Society of Arts on the subject of Electric Exhibitions in general, and that of Munich in particular. Touching the latter, the lecturer said:—"Among the curiosities exhibited there, I was able to secure only one. It is an instructive and amusing series of photographs, taken by Dr. Von Zeemssan, a celebrated electro-physiologist of Munich, of the face of the same man, who has involuntarily been compelled to assume expressions of various emotions by the application of currents of electricity to various nerves of the face."

We amused ourselves on the shortest day in making a few drawing-room pictures. Our room is favourably lighted from the east, and a pale tint on the walls helped the photographic operations materially. Ordinary commercial plates were employed, and a small rectilinear lens, and it says something for the quality of the former when we mention that fifty seconds proved too long an exposure with the normal developer recommended by the makers, but by adding water to the extent of one-third the volume of the developer—certainly the easiest plan of modifying a new formula—we secured some well-lit photographs, without a trace in any portion of them of under-exposure. This is doubtless a very ordinary feat to accomplish now-a-days, but at Christmas five years ago it would have been nothing less than phenomenal.

We spoke the other day of the Swan lamp employed as a star-light in a fairy's diadem at the Savoy Theatre, and we described the manner in which this striking novelty was evidently managed. We can now, however, speak with authority. As we opined, the battery is fixed on a plate between the wings of the fairy, and held by two straps round the arms. It is a secondary battery that is used, consisting of three cells, and weighing about four pounds. Consequently the tripping *coryphée* is a little handicapped in her movements.

Dr. Koenig, of Berlin, has re-discovered that by straining an incandescent lamp a highly actinic light, similar to that of the arc, can be produced; and his experiments also confirm our observation that a lamp thus strained gives very much more light in proportion to the current passing. This, as we stated last week, is just the way in which the star-lights in the fairy ballet are managed at the Savoy Theatre.

Another case of re-discovery. Our rough-and-ready method of making a screen with tinfoil, so as to partly cover the incandescent lamp, and at the same time act as a reflector, has actually been re-invented, and made the subject of a recent patent.

Mr. C. Ray Woods, in confirming our experiments with electric printing, mentioned, as a drawback to the operation, that the silver prints are red in colour, and do not easily take a nice tone. This is quite true, and we cannot help thinking the cause is to be traced to the lack of penetrating power of the electric light; it appears to have a more superficial action than sunlight, and although numbers are readily registered on a photometer scale, sufficient chloride is not reduced to yield a rich and vigorous tone.

We have made experiment with some "cherry" fabric, sent to us by Messrs. Law Brothers, of Foots Cray Mills. Being of a much lighter red than ruby, and consequently permitting the passage of more light, we were at first somewhat prejudiced against the new dark-room fabric; but, strange to say, a twofold trial proved it to be exceedingly advantageous. Taking two commercial plates at random, from one of the last packages to hand, and another pair from those longest in stock—about fifteen months—we tried the "cherry" against some ruby calico in use in our dark room. Each plate was put in a printing frame behind a Warnerke sensitometer and a single thickness of fabric, and then exposed for five minutes to a fish-tail burner some four feet off. On development with a standard ferrous oxalate solution, the two plates exposed under "cherry" showed but the squares Nos. 1 and 2, while in the other plates two rows of figures were more or less

H BADEN PRITCHARD COPYRIGHT.

" WAITING TO GO ON."

legible. Still, as the fabric for the dark room is a matter of importance, and the testing of it is so easy, we recommend all photographers to experiment for themselves, and to remember also that whether the colour is cherry or ruby, it is liable to fade in time.

Mr. Belt and Sir Hardinge Giffard, in the recent libel action, were loth to permit the casting of the bust modelled in court, owing to the fact that the casting operations would materially alter the features for the worse. It never occurred to them that by photographing the bust with a stereoscopic camera from a few different points, it would be possible to secure reproductions, which, to the eyes of a spectator, would present all the relief and plastic character of the original. Views of the photograph seen in the stereoscope would at once show if the bust had suffered in casting.

The arrest of the Russian Prince Krapotkine on French territory has shown the existence of an International Police organization, of which a branch is said to exist in this country. Whether this is so or not, it is very certain that on the Continent the registry of outlaws and Nihilists is most complete, and with the aid of photography the secret police of every European capital is supplied with the most perfect information regarding suspects. When we visited the Paris Detective Department some eighteen months ago, we found the photographic staff in the *Rue de Jerusalem* very busy in printing and sorting portraits of such personages, the pictures being many of them copied from photographs received from St. Petersburg, Vienna, Berlin, London, and elsewhere.

As we looked over these portraits—to a man, almost, unshaven and unshorn, and in appearance very much like artists or German students run wild—it occurred to us how easy it would be for a Nihilist to disguise himself. These dark, hairy individuals in *negligé* attire would never be found by the police if they took but two precautions—a clean shave, and the assumption of the garb of respectable citizens, would at once make ordinary beings of them, and put the chance of recognition beyond all possibility.

By-the-bye, we see that many of our English newspapers speak of Thonon on the lake of Geneva, where Prince Krapotkine was arrested, as being in Switzerland. At the last exhibition in Pall Mall, we remember seeing a picture of the spot similarly labelled, while several photographers showed prints of Mont Blanc and Chamonix ticketed "Swiss Views." To show how deeply rooted in the minds of Englishmen is the idea that Chamonix is in Switzerland, we may mention that on the occasion of our last visit, all the letters in the hotel letter-box awaiting British tourists were thus addressed, with a single exception, which was in Dr. Vogel's handwriting, and bore the superscription, "Haute Savoie, France."

We notice that at the last meeting of the French Photographic Society, Colonel Sebert presented a note taken from the *Scientific American* of the 28th October last, concerning some photographs of the results of a submarine explosion secured by the United States Engineers. As a matter of fact, the note in question appeared originally in these columns some months previously, as our readers may remember. It is not this circumstance, however, but rather a remark of the gallant colonel's upon the information we gave, that causes reference to the subject once more. The height of the column or jet of water sent into the air by the violent detonation of the dynamite measured 180 feet, and during the period of the experiment, four photographs, it will be recollected, were taken at certain times fixed by a chronograph.

Colonel Sebert thinks there must be a mistake in the records of the times taken, for while one photograph showed the column at its full height, in another picture, taken two seconds afterwards, the column had disappeared. As it takes more than two seconds for a body to fall 180 feet, the gallant Colonel pronounces the exposures to have been *mal determinées*. Now we are not going to defend the scientific corps of the United States Army, although we may mention that a chronograph in practised hands is not given to making mistakes; but we simply confine ourselves to pointing out how Colonel Sebert himself may be mistaken when he says the figures quoted *sont certainement erronés*. We have witnessed many submarine explosions of the nature photographed by the United States Engineers, and we have always remarked that when a powerful explosive like dynamite or gun-cotton is employed at no great depth, and the water consequently thrown into the air to a very great height, the upper portion of the column consists of fine spray, which, if the spectator happens to be to leeward, may wet him to the skin. Two seconds would be ample, with the least air stirring, to convey this spray to a distance, and hence its absence in the field of the photograph is perfectly explained without any reversal of the laws of nature or mistakes on the part of the chronograph.

Patent Intelligence.

Application for Letters Patent.

6114. Stephen Henry Emmens, of Soho Square, in the county of Middlesex, Actuary, and John Munro, of West Croydon, in the county of Surrey, for an invention of "Improvements in photometric apparatus."—Dated 22nd December, 1882.

Patents Sealed.

3072. Gerard Wenzeslaus von Nawrocki, Proprietor of the firm of J. Brandt and G. W. v. Nawrocki, Patent Solicitor and Civil Engineer, of 124, Leipzigerstrasse, Berlin, Germany, for an invention of "A new or improved process for the manufacture of hyposulphite of soda."—A communication from the Verein chemischer Fabriken, of Mannheim, Germany.—Dated 29th June, 1882.

3491. Edward Gardner Colton, of Southampton Buildings, in the county of Middlesex, for an invention of "Improvements in the method of producing photographic images and an apparatus applicable therefor."—A communication to him from abroad by William Kurtz, of the city, county, and state of New York, United States of America.—Dated 22nd July, 1882.

Specifications Published during the week.

2277. H. J. Haddan, for "Producing pictures on glass, stone, metal, &c."—A communication from E. Godard.

This invention has for its object to reproduce images and drawings by means of vitrifiable colours on glass of any shade or colour. This process may also be applied to wood, marble, and other stone, on canvas or paper prepared for oil-painting and to other solids having polished surfaces, for instance earthenware, porcelain, and copper. The original drawings or images should be well executed and drawn on white or preferably bluish paper similar to paper used for ordinary drawings. In the patterns for glass painting by this process one marks the place to be occupied by the lead, before cutting the glass to suit the various shades which compose the colour of a panel, as is usually done in this kind of work, the operation changes only when the glass cutter hands these sheets over to the man who undertakes the painting. The sheets of glass are cut according to the lines of the drawing, and, after being well cleaned, they are placed on the paper on the places for which they have been cut out. If the window to be stained is of large size and consists of several panels, only one panel is proceeded with at the time. The glass is laid on the reverse side of the paper (the side opposite to the drawing) the latter having been made transparent by saturating it with petroleum. This operation also serves to fix the outlines of the drawing more distinctly, and to give more vigour to the dark tone of the paper. When the paper is thus prepared, and the sheets of glass each in its place, they are coated by means of a brush with a sensitizing solution on the side which comes into contact with the paper. This coating should be as thin and as uniform as possible on the surface of the glass. For more perfectly equalizing the coating a second brush is used. The sensitizing solution which serves to produce the vitrifiable image is prepared as follows:—As much bichromate of ammonia is dissolved in water till the latter is saturated, 5 grammes of powdered dextrine or glucose are then dissolved in 100 grammes of water, to either of these solutions I add 10 per cent. of the solution of bichromate as described above, and filter the resulting mixture. The coating of the glass takes place immediately afterwards in a dark room, the coated sheets are then subjected to a heat of 50 to 60 degrees in a small hot chamber, where they are laid one after the other on a wire grating situated 35 centimetres above the bottom. Care should be taken not to introduce the glass under treatment into the hot chamber before the required degree of heat has been obtained. A few seconds are sufficient to dry each sheet, and the wire grating should be large enough to allow of the dried glass being laid in rows on one side where the heat is less intense. For the reproduction of the pictures or images a photographic copying frame of the size of the original is used. A stained glass window being for greater security generally divided into different panels, the size of one panel is seldom more than one square metre. If the picture to be reproduced should be larger in size than any available copying frame, the prepared glass sheets are laid between two large sheets of plate glass, and part after part is proceeded with by sliding the original between the two sheets. A photographic copying frame, however, is always preferable, as it presses the glass sheets better against the original. The original drawing is laid flat on the glass of the frame. The lines where the lead is to connect the respective sheets of glass are marked on the drawing with blue or red pencil. The prepared sheets of glass are then placed one after the other on the original in their respective places so that the coated side comes in contact with the said original. The frame is then closed. It should be borne in mind that the latter operations must be performed in the dark room. The closed frame is now exposed to light. If the operations are performed outdoors, the frame is laid flat, so that the light falls directly on it ; if indoors, the frame is placed inclined behind a window, so that it may receive the light in front. The time necessary for exposing the frame depends upon the light and the temperature; for instance, if the weather is fine and cloudless, and the temperature from 16 to 18 degrees, it will require from twelve to fifteen minutes. It will be observed that the time of exposure also depends on the thickness of the paper used for the original. If, however, the weather is dark, it requires from thirty to fifty minutes for the exposure, in which case several frames may be proceeded with at the same time, which saves time, for while one frame is exposed, another one may be prepared, and so on. It will be observed that if the temperature is above 25 degrees the sheets of glass should be kept very cool and be less dried, otherwise, when exposed, the sheets are instantly metallised, and the reproduction cannot take place. The same inconvenience takes place if the temperature is beneath 5 degrees. In this case the sheets should be kept warm, and care should be taken not to expose the frame to the open air, but always behind a glass window at a temperature of from 14 to 18 degrees. The time necessary for the exposure can be ascertained by taking out one of the many pieces of glass, applying to the sensitive surface a vitrifiable colour, and observing whether the colour adheres well. If the colour adheres but slightly to the dark shady portions of the image, the exposure has been too long and the process must be recommenced ; if, on the contrary, the colour adheres too well, the exposure has not been sufficient, the frames must be closed again, and the exposure continued. To save time and trouble, the time necessary for the exposure may be ascertained by first proceeding with a small frame containing only two small sheets of prepared glass when the exact time for exposure can be ascertained and operations with the large frames can safely commence. When the frame has been sufficiently exposed, it is taken into the dark room, the sensitized pieces of glass laid on a plate of glass or marble, with the sensitive surface turned upward, and the previously prepared vitrifiable colour strewed over it by means of a few light strokes of a brush. This powder does not adhere to the parts of the picture fully exposed to light, but adheres only to the more or less shady portions of the picture. This operation develops on the glass the image as it is on the paper. I then add 30 to 40 grammes of nitric acid to 1,000 grammes of wood-spirit such as is generally used in photography, and dip all prepared pieces of glass into this bath, leaving them afterwards to dry. If the bath becomes of a yellowish colour, the same must be renewed. This bath has for its object to remove the coating of bichromate, so as to allow the colour to adhere to the glass from which it has been separated by the layer of glucose and bichromate which would prevent the vitrification. The bath has also for its object to render the light parts of the picture perfectly pure, and capable of being easily retouched or painted by hand. The application of variously coloured enamels and the heating are then effected as in ordinary glass painting. The same process may be applied to marble, wood, stone, lava, canvas prepared for oil painting, earthenware, pure or enamelled iron. The result is the same in all cases, and the process is the same as with glass, with the difference only that the above-named materials are not dipped into the bath, but the liquid is poured over the objects after the latter have been placed in an inclined position. Having now described the invention as communicated to me by my foreign correspondent, I wish it to be understood that I do not bind myself to the exact proportions of materials for the sensitizing solution as stated in the above specification, and that the details of the process may otherwise be varied without departing from the principle of this invention. *Claim*—1. The process of producing images in vitrifiable colours on glass, wood, marble, metal, and other surfaces, substantially as described.

2403. P. M. Justice, for "Frames for printing photographs."—A communication from G. S. Street.

This invention relates to that class of frames which are employed for photographic printing, and particularly to the frames for direct photography or blue printing. The invention consists in the means or arrangement of parts whereby the tracing cloth, paper, or other material may be readily arranged and held closely in position during the operation of printing. I effect this desirable result by the application of a water or other pressure cushion in the place of cross bars and set screws as ordinarily used, and by the improved arrangement and combination of parts all as hereinafter described and set forth. The advantages gained by the use of my invention are :—First, the pressure applied is uniform, and lessens the liability of breakage to the glass ; second, the pressure can be applied instantaneously ; third, the apparatus is entirely self-contained, there being no parts which it is necessary to remove to accomplish the work on hand.*

Patents Granted in France.

149,048. Brunot, for "An apparatus for obtaining instantaneous photographs by electric action, or a so-called 'lightning screen.'"—Dated 20th May, 1882. Class 17.

149,120. Street, for "A photographic press."—Dated 23rd May, 1882. Class 17.

149,221. Candeze, for "A revolving diaphragm for instantaneous photographs."—Dated 26th May, 1882. Class 17.

* From the detailed description which follows it is difficult to clearly understand the exact points of novelty claimed. Perhaps the most novel and extraordinary features are the adaptation of a *safety valve* to the air-cushion of a printing-frame, and the proposal to use water instead of air. Printing-frames with air-cushions as padding have not hitherto been received with much favour.

Review.

DIE PLATINOTYPIE, von Josef Pizzighelli und Arthur Baron Hübl. (*Dr. E. Hornig, Vienna and Leipsic*).

IT may be remembered that about a twelvemonth ago, the Vienna Photographic Society distinguished with the gold Voigtländer medal a memoir on the subject of platinotype printing by Captain Pizzighelli and Lieutenant Von Hübl. These gentlemen have pursued the investigation then published still further, and now give to the world, in the compass of a useful little volume, the whole history and process of platinotype printing. The earliest experiments with platinum salts by Herschel, which date as far back as 1832, are mentioned, as also those of Döbereiner and Johannsen, the authors quoting from Hunt's *Researches on Light* to show how much interested in these salts were the early photographic experimentalists.

Willis's later experiments and eminently satisfactory results are next discussed, for, as our readers are well aware, it is to him that we owe platinotype printing as a practical photographic process. The authors do not, however, content themselves with a description of Willis' beautiful method as it stands at present, but enter very thoroughly into the why and wherefore of the reactions that take place and result in producing the delightful engraving-like pictures, of which a magnificent specimen appears by way of frontispiece. To all photographers, who are German scholars as well, we warmly recommend *Platinotypie*, for it expounds well and thoroughly one of the most permanent, as it is one of the most pleasing and recent, printing processes.

THEORIE UND PRAXIS DER PHOTOGRAPHIE MIT BROMSILBER-GELATINE. Von Dr. J. M. Eder. Zweite Aufgabe. (*Dr. E. Hornig, Vienna and Leipsic*).

THIS recent edition of Dr. Eder's work on gelatino-bromide, although termed the second, may in some respects be considered the third, for "Modern Dry Plates" was published between the two German issues. Be this as it may, Dr. Eder has now, to all intents and purposes, given us a new work on the subject, for the book has been almost entirely re-written, and now contains no less than fifty-eight illustrations. A more perfect history of gelatino-bromide it would, indeed, be difficult to prepare, for we find therein a very succinct and complete account of all the improvements that have of late been contributed by photographic experimentalists in this country, no less than in other parts of the world. As one might expect, we find the PHOTOGRAPHIC NEWS laid under contribution pretty heavily, a most convincing proof that the worthy author keeps abreast of the times, and allows nothing to escape his keen eye and ever-recording pen.

Dr. Eder's volume—albeit it treats only of the gelatino-bromide process—now includes 250 closely-printed pages, and, on glancing through them, one knows not which to admire more—the author's wonderful power of observation, or his indefatigable efforts in seizing the salient points of all that comes under his eye. Moreover, a copious contents and exceedingly clear index make it possible for the reader to derive full value from the volume, in respect to which we wish the author every success.

AUSFUHRLICHES HANDBUCH DER PHOTOGRAPHIE. Viertes Heft. By Dr. Josef Maria Eder. (*Halle a/s, Wilhelm Knapp.*).

ANOTHER volume from the pen of Dr. Eder comes to us, forming the fourth part of that gentleman's great work on photography, which, so we are told, is to be complete in ten or twelve parts. The present volume, numbering nearly 150 closely-printed pages, treats more especially of the photographic camera, and aids to exposure, and it is the more interesting for being very copiously illustrated. Not only are there descriptions and drawings of the various kinds of cameras and dark slides that have been employed and imagined since the days of Daguerre, but of shutters, stands, and other apparatus connected with the camera, there are sketches innumerable. Some of these we have ourselves contributed from the PHOTOGRAPHIC NEWS, but these latter represent but a small proportion of the many interesting pictures scattered throughout Dr. Eder's pages.

In a word, we may say that Part IV. of Dr. Eder's Complete Photography—for this is, perhaps, the best translation of the title—fully sustains the reputation of the previous issues of his wonderful work.

Correspondence.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Please allow me to remind your readers that the Popular Lantern Meeting of the above Society, to be held at the Society of Arts, on Thursday next, January 4th, commences at *seven* o'clock; and also that I hope intending contributors will kindly send me a list of their slides as early as possible,—Yours truly, F. A. BRIDGE.

9, *Norfolk Road, Dalston Lane, London, E.*

[Mr. W. Brooks also writes in explanation of error as to time in his letter last week, and reminds our readers that the doors will be open at 6·30.—ED.]

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on Thursday, the 21st inst., Mr. LEON WARNERKE in the chair,

Mr. F. W. HART produced a negative from a batch from Honolulu, and most of which were marked over nearly all the plates the same, as shaded with an irregular yellow stain which quite destroyed the negative; the negatives were perfect at one edge, the colour being a blackish one; he attributed the discolouration to paper having been in contact with the film.

Mr. W. M. ASHMAN thought it was due to the hyposulphite not being thoroughly eliminated; he accounted for one edge being clean by presuming that had been uppermost when draining.

Mr. A. L. HENDERSON thought that the original colour of the negative had been yellow, the darker colour being the stain, and produced by oxidation.

Mr. DEBENHAM said if this were so, a yellow patchy-looking negative had by the action of the air been converted into the usual black deposit.

Mr. HENDERSON said sea voyages had been found to produce a very marked effect upon gelatine plates; Mr. Tunny, of Edinburgh, had found a voyage to New Zealand completely remove the image from some exposed plates, and none could be developed on them.

The CHAIRMAN'S experience was the reverse of Mr. Henderson's; he had developed in Russia plates exposed in California three years before, and found them as if just exposed.

Mr. A. J. BROWN thought that the fact of an image not staying on the plate was due to the presence of free bromine.

Mr. HENDERSON said that one of the largest plate makers left free bromide in his plates; he had prepared plates which could not be detected from those referred to by adding to the washed emulsion a small quantity of bromide of potassium.

Mr. BARKER had found that the haloid salts all had the property of removing the action of light from the film.

Mr. A. COWAN had prepared an emulsion according to a recently published formula, by which green fog was said to be prevented, and he produced two negatives on plates prepared from the same, one of which was badly green fogged, in the other there was no fog; this result had been obtained by diluting the developer for the latter to one-fourth; it would seem therefore that green fog could be produced by the developer, as well as by the emulsion.

The CHAIRMAN had prepared an emulsion from a solution of metagelatine, handed him by Mr. Henderson. After keeping a few hours he found the emulsion slow, but by heating it to 180°

and keeping the vessel containing it covered, thus causing it to take several hours to cool, he obtained a good quality plate, giving 21 or 22 on the sensitometer.

Mr. Henderson had noticed, on looking through one of Warnerke's sensitometers, that a higher figure could be read when one side was presented to the eye than with the other, and that when a sensitive plate was exposed from the wrong side, two numbers less were shown than when used in the regular manner: and he passed round plates showing that this was so; he attributed it to the colour of the glass.

Mr. Debenham thought it was due to the fact that the higher numbers were very faint, and could only be seen by their sharp definition against the covered part, and the plate being reversed, this sharpness was blurred sufficiently to remove the faint image which was scarcely visible when sharp.

The Chairman thought that the light diffused by the dead surface of the gelatine might account for the variations in the indications.

Talk in the Studio.

Christmas, 1882.—

The strides of Science travel fast,
Our Art has through a crisis passed,
In four short years, 'tween sun and ice;
Our Banner bears the strange device—
Emulsion.

Though we've to work in gloomier light,
Our Studio floors are always bright;
Though in dark-room no sunshine's shone,
Yet from our lips escapes no groan—
Emulsion.

The Nitrate Bath's a cloud beneath,
Our Silver Dipper's in its sheath,
The death-knell of Collodion's rung;
We all now speak the well-known tongue—
Emulsion.

Leave not the Bath, Collodion said;
Be sure there's danger overhead.
Exposure's latitude's not wide.
Let's try, at any rate, replied—
Emulsion.

Oh stay! Collodion said, and rest
Thy head contented on my breast;
New fangled things are all my eye.
Still came the answer, with a sigh—
Emulsion.

We know not how this tree will branch
That's come down like an avalanche;
The Bath may fairly say good night.
The voice still cries, far up the height—
Emulsion.

Sometimes it proves a faithless hound,
Its weak points are in summer found;
But, with a good supply of ice,
We still can make our strange device—
Emulsion.

So in the Twylight, cold and gray,
Our friend Collodion must lay.
We look upon him from afar,
Bewail his fate—a Fallen Star—
Emulsion.

With apologies to Longfellow.—A.C.

Celestial Phenomena for the Year 1883.—The coming year will have no very great attraction for the astronomical world. There will be four eclipses, two being of the sun, and two of the moon. One of these only is to be visible in England, and that only partially. Of the meteoric showers the brightest displays are to be seen in April, August, and November; these will prove an interesting study for the amateur as well as the practical astronomer. The first heavenly phenomenon of any note in the forthcoming year is a partial eclipse of the moon while in zenith on April 22, which will be a very small affair, for at the time of the greatest phase a portion equal to only about one-tenth of the moon's diameter will be obscured. This eclipse may be observed from the western parts of North America and in Australia, but will not be perceptible at any point throughout the British Isles. The second will be a total eclipse of the sun, commencing on May 6, but will not be visible here. The central line of this eclipse passes across the South Pacific Ocean, thus rendering this phenomenon visible in the eastern parts of Papua and Australia, New Zealand, Central America, and the north-western parts of South America. The next eclipse, part of which will be observable here, occurs on Oct. 16, when the earth comes between the sun and the moon, thus partially covering the latter and hiding it from the sun's light. The first contact with the earth's shadow occurs at about six o'clock in the morning, and the last about an hour and fifty minutes later; but as the moon sets at Greenwich at thirty-one minutes past six a.m., only a very small portion of this eclipse will be visible here. The last phenomenon of this description occurring next year is an annular eclipse of the sun on October 30 and following day. Although not visible here, it will be generally perceptible throughout the whole of the North Pacific Ocean, Japan, China, the Corea, the most eastern parts of Siberia, Russian America, British Columbia, California, and the more western provinces of the United States of America. Other beautiful celestial phenomena may be seen in the meteoric showers, which are exceptionally fine in 1883, the following being the days on which the brightest displays will be observable:—January 2 and 10, February 6 and 28, April 17, May 16, June 14 and 18, July 15, 18, and 27, August 1 and 5 to 11, September 8 and 29, October 21, November 7 to 9, 11, 17, 26, and 29, and December 6 to 12.

To Correspondents.

*** We cannot undertake to return rejected communications.

*** Contributors' Copies of Year-Book.—There are several contributors to our Year-Book who have not yet received copies, owing to the circumstance that we have not their addresses. The publishers will be glad to hear of any omission of this nature, in order that it may be rectified as soon as possible.

W. L. Berry.—Burslem, Staffordshire, is sufficient address.

W. E. Dailla Jones.—They are Edison's lamps, not Swan's. It would probably involve an outlay of about two hundred pounds, after which the cost might perhaps be about the same as gas. Perhaps, however, the company will supply the plant on the hire system: write to their office on the Holborn Viaduct.

W. E. Crag.—1. It interferes to a certain extent, but all you have to do is to allow more time for the precipitate to settle down. 2. Certainly; run it into an old pan, and add a few grains of protosulphate of iron to each batch. 3. He is not right, as the gold is actually deposited in the prints. 4. A decomposition is liable to take place when very hot water is used.

Combination.—The pamphlet is no doubt out of print, but you might be able to meet with a copy by chance.

W. Richards.—The additional slots would be cut for you by any philosophical instrument maker.

F. K. Thompson.—Our Year-Book contains full and practical directions.

Arthur Klosterer.—1. The initials simply signify that the gentleman is a member of the Chemical Society, and is considerably proud of the circumstance. 2. Our impression is that it was communicated to the Royal Society about 35 years ago. 3. No doubt it can be more thoroughly separated by the second method, but this advantage is probably counter-balanced by the length of time required for the completion of the process.

H. G. H.—1. The paper is of a very bad quality, and largely adulterated with sulphate of lime. 2. A mere trace of chrome alum will harden it to the required extent—say half a-grain dissolved in a drachm of water, and then added to your usual batch of the mixture.

Fred Ambrose.—1. The cleaning of the glasses must have been very carelessly carried out, as a microscopic examination revealed fragments of old and discoloured collodion film under the stratum of gelatine. 2. Vogel's mixture of bichromate of potash and sulphuric acid is as effectual as anything we have used, the proportions being one ounce of bichromate, 2 ounces of sulphuric acid, and a pint of water. Soak the plates in this for a few days.

Oxford Street.—The pyroxyline has decomposed so far as to be absolutely useless. If kept loosely in paper it may be preserved without change for many years, but it rapidly changes even when preserved in a stoppered bottle. 2. We have never found it necessary, the commercial article answering well in our hands.

Doubtful.—1. Certainly not. Some of the most interesting and valuable appliances now in general use by the photographer were first shown at those meetings. 2. There is only one in each year.

Harrison James.—Daylight is not only better, but more convenient, and there are not ten days in the year when such work is impracticable, excepting as far as the extremely large plates are concerned.

Several answers are unadvoidably crowded out this week.
