The Butler Book

The History of Italian Sculpture.*

THE author of "Tuscan Sculptors" has now completed a history of sculpture in Northern, Southern, and Eastern Italy. He has divided his subject into seven parts, or chapters, for the purpose of making the necessary geographical distinctions; and in each of these divisions he has given a very complete, if not exhaustive, notice of the works of the principal sculptors. As we might expect from an expert workman who has the best of materials before him, and good tools with which to set to work, he applies himself to his task with the shortest preface. On his first page we find ourselves in the bright land of wine and fruits, art and song.

We see the same plains radiant with oranges, lemons, citrons, pomegranates, almonds, and other fruit rare to our northern clime; the same blue waters, the same hanging woods, the same mountains glorified with marble, alabaster, jasper, and porphyry, as the Crusaders saw as they marched hurriedly to the seaports whence they were to sail for Palestine; the same purple and gold horizon the Greeks and Lombards saw as they fought and fell; and, looking southwards, the scene of the prowess of successive bands of Norman knights, the last of whom overran the whole of that portion of Southern Italy once known as Apulia, and during the period of their rule erected buildings that we now look upon as legacies of price. Mr. Perkins tells us there is a visible change, however, in the aspect of this southernmost country so far as its social development is concerned. The magic iron rods, called railroads, have performed their usual wonders here. He says, "the ports whence the followers of Peter the Hermit embarked for Palestine, are being widened and deepened; Brindisi has renewed her relations with the East, and the track which, Horace followed in his

memorable journey to that long-neglected haven, will soon be familiar to tourists. They will gaze with wonder upon the noble churches of Apulia, with their storied gates of bronze, their portals covered with mystical sculptures and Oriental ornament, and their pulpits and bishops' thrones resting upon Saracen prisoners, lions, or elephants; and upon her Mediaeval castles, one of which still stands in such perfect preservation, that were Frederic and his infidel hosts to return to earth, they might again find shelter within its marble halls." When this time comes, the tourists hastening to tread in the steps of Horace, will be all the better prepared for an appreciation of the art-wonders they will see by the way if they make themselves acquainted with the information Mr. Perkins has collected and digested. Meanwhile thinkers and workers, more than pleasure-seekers, will find matter of great artistic interest in his pages.

The historian of Italian sculpture takes us up, as we have indicated, in Southern Italy, and from Apulia and the Ahruzzi, conducts us northwards to Naples, Rome, Lombardy, and Venice; and thence crossing Northern Italy westwards, carries us to Verona, Vicenza, Padua, Mantua, Brescia, Bologna, Ferrara, Modena, Reggio, Parma, and Piacenza; and thence to Genoa and Carrara, where he sets us down. The southernmost portion of Italy has this peculiarity. Whereas in Rome we may trace remains of the kingly republic and imperial epochs, and then again of Mediaeval and Renaissance days, showing the successive phases of art in many centuries, in Apulia we are limited only to a short period for the chief stores of art-work, and this brief space is strongly marked by foreign influences. In the tenth century Apulia was ruled by the emperors of the East in the person of a Greek officer deputed by them, and was a frequent prey to the incursions of Saracens who had located themselves at Malta and Sicily. At the beginning of the eleventh century, when pilgrimages to the Holy Land were the order of the day, a band of Norman knights on their way home from Jerusalem landed at Salerno at a critical time. A fleet of Saracen ships approached the coast and landed a force large enough to intimidate the inhabitants, who, with their Duke Guinar III., would have complied with their demand for ransom from pillage, as on similar occasions, but for the interference and protection of these Normans. Many of the marauding Saracens were massacred, and the survivors were put to flight. About ten years afterwards a second band of pilgrim Norman knights arrived in Italy at the right time to assist the inhabitants in their endeavour to throw off the tyrannical rule of the Greek catapan. Unlike their predecessors, they did not depart when their work was accomplished, but they established themselves in a fortress near Naples; and, reinforced by frequent arrivals of adven-

tarous spirits from Normandy, maintained their position for nine years. This was about twenty years before the conquest of England by a larger body of Normans. In those days there was a Norman knight, Tancred de Hantville, who had twelve sons. Three of these brothers joined their countrymen in their stand against the Saracens and Greeks, and within three years after this accession to their strength the Normans became masters of the whole of Apulia, with the exception only of Bari, Brindisi, Otranto, and Tarentum, which were still in the hands of the Greeks. They divided their conquests among twelve Norman counts, and established a seat of government at Melfi. Walter Guiscard, a fourth son of Tancred de Hantville, soon joined his brothers, bringing with him his famous son Bohemund, afterwards the first prince of Antioch, whose name still glitters as brightly as ever the sun shone on his lance as he led on the European hosts to the walls of the Holy City. It is to this short period of strife between Greek, Saracen, and Norman that the most important of the art-work of Apulia belongs. The sculpture is chiefly found in the façades and portals of the churches built at this time, and bears evidence of Greek, Saracenic, and Norman impressions upon the minds of the sculptors. It consists principally of bas-reliefs representing Scriptural personages or scenes from holy writ placed in the lunettes and upon the architraves and side-posts of the doors, and of ornaments carved in relief upon the archivolts of the portals, or sculptured in the round and half set into the walls. In the former there are Byzantine influences to be traced; in the latter we may see Oriental and Classical elements blended. Many of the Apulian churches have suffered in the hands of restorers, who have substituted, Mr. Perkins affirms, false glitter for solid splendour; but the marble work has been more fortunate; much of it has been left untouched. The famous grotto on the summit of Monte Gargano, which drew so many pilgrims after the Archangel Michael notified, to the Bishop of Sipontum, in the fifth century, that it was to be henceforth sacred to himself and the angels, now contains nothing of artistic interest but its bronze gates cast at Byzantium 800 years ago, and a marble catædra of twelfth-century workmanship, enriched with Arabic ornaments, of which the seat is supported by crouching lions. The duomo at Bari, founded by a Greek bishop about 500 years after the consecration of the grotto, has been still more unfortunate. The ciborium, made for the successor of the founder by Alfansa da Termoli, and the pulpit made shortly afterwards for a subsequent bishop, have been both removed, and the edifice "restored" in the "very worst modern taste." At the neighbouring church of San Nicolo, erected early in the twelfth century, there is, however, a ciborium, the details of which correspond almost

* Italian Sculptors: being a History of Sculpture in Northern, Southern, and Eastern Italy. By Charles C. Perkins. With Etchings, by the Author, and engravings on wood, from original drawings and photographs. London: Longmans, Green, & Co. 1863.

exactly with the descriptions given of that of Alfano. It is described as having a pyramidal roof divided by colonnettes and upheld by marble columns, the capitals of which were sculptured with angels, leaves, branches, climbing serpents, and deeply-cut ornament, and inscribed with the artist's name and laudatory verses. One of the illustrations on the first *planche* is a capital from the San Nicolo ciborium, in which somewhat ill-proportioned angels are represented kneeling upon large leaves which droop as with their weight. Mr. Perkins points out, "What strikes us most in this Apulian marble-work is its firm, decided character, and we are led to observe that the artist, though apparently ignorant of the first principles of form, deals as boldly with the human figure as he does with the leaves and animals which he has studied from nature." A *cattedra* placed in the same church by its founder is supported in front by two grotesque Arabs who are kneeling, and a standing figure of a man with a staff, and at the back by a lion holding a man's head in his paws. On the portal and facade of the same edifice are bas-reliefs of Samson and the lion, lions and syrens, vines and arabesques, and presentations of various heads encircled by winding lines springing from vases. Two angels fill up the portal arch, bulls standing upon consoles are placed below the cornices, and a seated sphinx tops the gable of the facade. Richer still is the facade of the cathedral at Traja, built in the last years of the eleventh century. The "most bizarre of all Apulian facades" must be described by Mr. Perkins. He says,—

"Not only is it peopled with all created things, but its surface glows with yellow and green stones, after the fashion of the Sicilian churches, uniting the sharp-cut, clear-lined sculpture of the East with the polychromatic decoration of the Saracens. It is divided into two parts by a cornice, richly carved with heads of men, lions, and leaf-work. In the upper one is placed a great wheel window, encircled with a row of rudely-sculptured heads, and surmounted by the figure of a man seated upon the back of a nondescript animal. Eleon, elephants, porcupines, and apes protrude from the wall on each side. Four columns, with lions above their capitals and the last bases, support a plain round arch above the window; and six smaller arches, with dentellated archivolts and leaf-work capitals, are set against the wall in the lower portion of the facade, on either side of the great central arch over the portal. The slabs of marble which decorate the central arch are covered with Arabic ornament, and the reliefs on the architrave are composed of rudely-chiselled figures, of a Byzantine type, representing Christ enthroned between the Virgin and St. John, SS. Secundinus and Eleutherius, and the symbols of the Evangelists, in medallions; while in the lunette of one of the lateral doors, whose side-posts and architrave are sculptured with ornament, is a bas-relief of Christ treading on the lion and the dragon, with two rudely-carved angels of a Byzantine type. The varied and elaborate capitals of the many columns, which divide the nave from the side aisles, furnish another example of rudely-chiselled heads, surrounded by rich and tasteful ornaments, whose patterns are intricate, but never confused in line."

We must content ourselves with this presentation of the art-work at the disposal of Bohemund and his contemporaries. The church built by this Norman hero at Canosa on his first return to Italy from the East, contains a characteristically designed *cattedra* and pulpit; and the Grave Chapel adjoining it, built to his memory by his mother, is treated with similar feeling. This is surmounted by an octagonal drum pierced with round-headed windows. Around the exterior of the chapel run a series of pilasters with carved capitals connected by round-headed arches. The entrance is closed with bronze gates, which bear, besides various decorations and the name of their maker, Roger from Amalfi, Latin inscriptions setting forth the exploits of the illustrious dead. Bearing true witness to the mixed foreign influences of the day, these gates have discs filled with Arabian ornament in the upper panels, while below them are figures, standing and kneeling as unmistakably Byzantine in character, as though formed in a Byzantine MS. In like manner these conflicting elements illustrate the life of the hero, whose thoughts were so constantly in the East, that as he stood upon the altar-steps at Chartres with his bride, the daughter of the French monarch, by his side, he turned to the spectators of his marriage, and preached a new crusade, promising "castles, cities, and rich possessions in Asia to all who would follow him.

In Naples Mr. Perkins finds only one instance of marble-work previous to the middle of the thirteenth century. This is a set of bas-reliefs in the chapel of San Giovanni a Fonte adjoining the cathedral, which originally formed part of a pulpit made for the old church of Sta. Reparata, and in which the figures are as minute as those upon an ivory casket. In the cathedral of neighbouring towns there are some early sculptures, as at Salerno, where there are two twelfth-century marble pulpits on which mosaic work is

introduced; and at Ravenna, where there is a third pulpit of similar workmanship, and still handsomer design, made by Nicolo di Bartolomeo. The dawn of Mediæval art in Naples has a veil of the supernatural thrown over it, as is the case in other instances. Just as Jupiter, in the old Greek legend, condescended to assure the sculptor that his representation of his form met his royal approval, so a crucifix by an early Neapolitan master is said to have spoken. The name of the artist of this miraculous crucifix has been handed down; but one of his pupils, Masuccio I., enjoys considerable local reputation. In former years many works were attributed to this sculptor which are not now to be found, or which have been proved to have been executed by other hands. He is said to have designed the *duomo* and the church of S. Dominic Maggiore. His godson enjoys still more popular regard. De Dominic, indeed, goes so far as to accredit him with every church and tomb of this epoch. Mr. Perkins attributes to this godson, who was the pupil and namesake of Masuccio, the monument of Pope Innocent IV., which has been pointed out by Neapolitan writers as the elder master's work. This was several stages high, and ornamented with mosaics and bas-reliefs, but all that remains of it now is the effigy of the pontiff lying upon the sarcophagus. Our author also accepts Masuccio II. as the sculptor of the tomb of the Duchess Catherine of Austria at San Lorenzo, which is a quadrangular structure having a pointed roof supported upon spiral columns, in which the sarcophagus is raised sufficiently high to admit of a doorway affording access to the choir being placed below it. An effigy lies upon the sarcophagus, and SS. Peter, Paul, Catherine, and Louis of Toulouse stand at the head and feet of it. The spirals of the columns, the pinnacles at each end of the architrave, and the lunette, are enriched with mosaics; and the front of the sarcophagus is ornamented with roundels containing half-figures in relief of the Madonna, SS. John the Evangelist, Anthony of Padua, Francis and Santa Chiara. The fourteenth century is filled with the name of Masuccio, although, says Mr. Perkins, the inscriptions and documents of the time make no mention of him, "and no better proof of his ever having existed is to be found than vague tradition and bold assertion, which fix the date of his death in 1387, at the age of 96." In some of the works ascribed to him our author perceives a Tuscan character, which he thinks proves them to have been executed by the Tuscan artists who are known to have resided in Naples in the fourteenth century. This Tuscan influence is especially remarkable in the Angevine monuments in the church of Sta. Chiara, which appear, indeed, to have been modelled after the type of the monument of Queen Maria, widow of Charles II. of Anjou, in the church of Sta. Maria Donna Regina, executed by Maestro Tino or Lino da Camino. But all these monuments are alike attributed to Masuccio by Neapolitan writers, although Tino da Camino was appointed in conjunction with Gallarudo da Sermona, in the last will and testament of Queen Maria to make her monument. Mr. Perkins sees at least six distinct styles in the sculptures at Sta. Chiara, not one of which could be that of Masuccio. His pupils, Andrea Ciccone and Abbatè Bamboccio, hold nearly as high a place in popular regard among fifteenth-century artists as he did among those of the previous age. The first of these built the churches of Santa Marta and Monte Oliveto, and the latter the facade of San Giovanni a Pappacoda and the portal of the *duomo*, both being, as was most frequently the case, architects as well as sculptors. They were both, also, the authors of several monuments. We will describe one that is attributed to Ciccone in Mr. Perkins's words, as a specimen of the taste of the day. It was executed at the command of Queen Joanna II., to the memory of her brother King Ladislaus, for the church of San Giovanni a Carbonara:—

"It is a towering pile, three stories in height, rising above the door which leads from the choir into the sacristy. Four colossal statues of Temperance, Prudence, Justice, and Fortitude, flank this doorway, and serve as caryatides to support an open-arched gallery, within which are placed six seated statues of life-size, representing King Ladislaus and his mother, Royalty, Charity, Faith, and Hope. Above this gallery is a certain recess, which contains a sarcophagus, bearing the recumbent effigy of the king, watched over by curtain-drawing angels, and figures in relief of the king and queen, and two other royal persons. Upon the topmost pinnacle of the structure Ladislaus is again represented, seated upon his war-horse and holding a sword in his right hand. The eyes of the statues and statuettes are coloured, their hair and robe borders are gilded, and they are relieved against backgrounds painted blue, and adorned with gilt fleur-de-lis."

From this gaudy, though doubtless, to some extent, imposing monument, with its statues, statuettes, arched gallery, gilding, and colouring, we turn to the great centre of art-work, Rome. "How can you," writes Petrarca to Pope Urban V., "sleep peacefully upon the banks of the Rhone, beneath ceilings fretted with gold, while the Lateran, mother of all churches, lies roofless upon the ground, exposed to wind and rain, while the houses of the Holy Peter and Paul tremble, and while the temple of the Apostles is a ruin, a shapeless heap of stones, fitted to extort sighs from breasts of stone?" Notwithstanding this extreme desolation pictured by the sweet-hearted poet, we need not say Mr. Perkins finds many noble specimens of sculpture in Rome that must have been there then. With bare mention of the widely-known fourth-century monument of the Prefect Janus Bassus, the fifth-century bronze statue of the titular Saint, cast in commemoration of the deliverance of the city from Attila; and the sixteenth-century statue of St. Hippolytus, in the Lateran Museum, he shows us some of the earliest Papal tombs, now reposing in the crypt of St. Peter's, but which were originally in the interior of the basilica before the rebuilding of the edifice.

Among these, and peculiarly interesting to Englishmen, is the large Roman sarcophagus of the one English Pope, Nicholas Breakspear. The lid of this monument is carved with masks, and its sides with festooned ox-skulls. Of more artistic interest is the tomb of Boniface VIII., which is as removed from the showiness of the Neapolitan monuments as it is from the homine simplicity. It is a sarcophagus, with a fringed and embroidered altar-cloth falling in folds over the front, on which lies an effigy of the deceased wearing his pointed tiara with a double crown, embroidered gloves and slippers. This Mr. Perkins identifies as the work of a member of the Cosmati family, successive generations of which wrought at Rome for a hundred and fifty years, dating from the middle of the twelfth century. He finds in the course of his survey of Roman sculpture no artist's name mentioned in any inscription between the fifth and ninth century.

In the tenth century Magister Christianus placed his name on a monument to a Cardinal Peter, and his example was followed by many marble-workers in Rome, and within a range of fifty miles around it. "These inscriptions," says our author, "are engraved upon arches, friezes, and monuments, as well as upon the pulpits, bishops' thrones, and ciboria." After Magister Christianus, come the names of Giovanni and Guido, inscribed upon the architrave of the ciborium of the church of Santa Maria di Castello, at Corneo; and after them the names of a family, consisting of father, four sons, and grandson, the father's and sons' being found upon the architrave of the choir of San Lorenzo, and that of the grandson, Nicolo di Angelo, upon the paschal candlestick at St. Paul's. This candlestick is one of the most curious remains of Mediæval work in Rome. It is a marble column, about 18 ft. in height, sculptured in relief with subjects from our Lord's life, resting upon a quadrangular base, having animals like sphinxes at the corners. No fewer than five peters are made out in various inscriptions, one of whom is the Peter le Orfever, who, with an artist named Odericus, accompanied Abbot Waro to England, and executed the mosaic work in Westminster Abbey. These bring us to the Cosmati family; and here we must stop for the present, the value of the book justifying another article.

THE METROPOLITAN DISTRICT RAILWAY.

THE works upon the first section of this important line, namely, those between South Kensington and Westminster Bridge, have been completed, and the line was opened for passenger traffic the day before Christmas. The designations of railways commencing with the word "Metropolitan," and which are intimately connected with the Metropolitan underground system, are a little perplexing to the uninitiated, and a few words of explanation as to their relations may not be thought needless or out of place. The continuous railway girdle of London, so often referred to as the inner circle, is already constructed, or is to be constructed, under Parliamentary powers granted to two companies,

the Metropolitan and the Metropolitan District. The portions of the inner circle belonging to the Metropolitan Company commence, or will do so, at Trinity-square, Tower-hill; and, taking the northern and western portions of the circuit, embrace about two-thirds of the whole distance. This portion of the communication includes the Metropolitan proper from Moorgate-street to Paddington; the Metropolitan Extensions from Paddington to Brompton, opened a few months since; and the Extension in the East from Moor-gate-street to Trinity-square: this last, about a mile in length, is the only portion of the Metropolitan system now remaining to be executed, the works not being as yet commenced. The remainder of the circuit, which runs mainly east and west on the southern side, is in the bands of the Metropolitan District Company, and fills up the space between Trinity-square and Westminster Bridge. The first portion of this line upon which the running will be taken up, so to speak, from the Metropolitan, commences at South Kensington, and, for the present, terminates at Westminster Bridge. A short length of the Metropolitan Extension, from Gloucester-road Station to South Kensington, has also been completed since the line was opened from Paddington to Brompton, so that the communication is now complete from Moorgate-street round to the north and west, and, turning southwards and eastwards, reaches at Westminster a point considerably to the east of the centre of the whole distance, and leaves only about a fourth of the whole distance in the south-eastern quarter remaining to be executed and opened. This inchoate portion of the Metropolitan District line will pass under the Thames Embankment to Blackfriars Bridge: thence it will be carried under the new street in progress, from the intersection of that street with Cannon-street, from which it will be carried along Cannon-street, and by way of Eastcheap to Trinity-square. The other "Metropolitan" works outside of the circuit are, the double line of the Metropolitan District between South Kensington and Brompton Stations, and a double junction which the same company is providing between the inner circle at Kensington and Gloucester-road Stations, and the West London line at West Brompton and Hammersmith-road. The other tangential adjuncts, as they may be called, of the Metropolitan, are the Metropolitan and St. John's Wood line, in which the Metropolitan has a joint interest, and the Metropolitan and Hammersmith and City line, leased jointly by the Metropolitan and the Great Western Companies, at 5½ per cent. All the lines referred to are worked by the Metropolitan Company, which will also supply the engines and rolling stock for the Metropolitan District Line; and will, further, take the receipts upon that line, of which it will hand over to the District Company 55 per cent. of the gross takings, for local traffic and the proportion of through traffic carried upon it. The train service over the Metropolitan and the Metropolitan District Lines will be one and the same, excepting the extra trains that are thrown off for St. John's Wood and Hammersmith.

The works upon the additional portion of the circuit now completed; the design and finish of the stations and booking-offices; the form of the covered ways; the character of the retaining walls; the rails and fixings of the permanent way; the system of signalling employed, and other features of the line, are all similar in the main, and the same description applies generally to them, as those of the last section opened. In a railway of such a peculiar character as a metropolitan underground line, however, a variety of difficulties is presented by streets, roads, and buildings aboveground, and by communications of various kinds underground, that are not met with in the construction of an ordinary line, and that necessitate a resort to a variety of expedients and modifications, and to numerous novelties in engineering practice. The new portion from Westminster Bridge to South Kensington, and thence over the Metropolitan Extension to Gloucester-road, Brompton, is about 2½ miles in length. The Westminster booking-office is a temporary erection, as it is in contemplation, we believe, to erect upon the site, at some future time, a more imposing and extensive building than a railway booking-office. The permanent platform has been provided at Westminster Bridge, which will be a terminus for a time. It is situated at the west end and inner side of the Thames Embankment. From the station the line passes under Bridge-street, obliquely, and onwards to the front of Westminster Hospital, and thence along by the back

of the Westminster Palace Hotel to the Broadway, where there is a station within a short distance of Birdcage-walk, St. James's-park. The covered ways are generally of the same form throughout,—elliptical,—the strength at different places being regulated by the superincumbent weight to be borne,—namely, from five to as many as ten courses of brick. Extra strength, again, is obtained in particular situations by strong cast-iron girders at short distances between centres, and jack-arches thrown across between them. Under the operation of a feeling of reverence, a padding of peat, 3 ft. thick, has been packed behind the wall of the covered way for about 300 ft. on the side, and in the part of its course, nearest to Westminster Abbey. The Broadway Station is similar in character to the others already described; the same effective elliptical roof, ornamented and coloured as the others are; the same regulation platform, 300 ft. long by 14 ft. wide, adequate for a train of six carriages of the extra size run on the Metropolitan. There are galleries for entrance and exit in this, as, indeed, in all other cases. Of stations and works generally, it would seem that the engineers, Messrs. John Fowler, engineer-in-chief of the Metropolitan system, and T. Marr Johnson, have bestowed much care and forethought in fixing designs, sections, and types, in the outset, and have adhered to these as closely as possible, and with only such modifications as peculiar circumstances in the different situations may have suggested. Westminster station has a provision for required at all the stations,—a gas-holder for the supply of the trains; and the Broadway station has another special provision—a short side tunnel at each end of the station for spare locomotives. There is no refreshment-room at the Broadway station, but it, in common with the others, has a convenient cloak-room, waiting-rooms, closets, &c., on the ground level; the accommodations for passengers being properly arranged that the booking-office has to be passed through in reaching the rooms and closets. In passing generally, it is satisfactorily evident that the engineers have been able to construct a much larger proportion of the line open to the open intervals are comparatively numerous, many of them 100 ft. long, and upwards. The retaining walls, when so deep as to require it, are supported by cast-iron cross struts. The walls have in many instances a thickness at the base of about 10 ft., of which about 2.5ths is concrete, and the remainder brickwork. Between the retaining walls, as well as in the covered ways, inverts are introduced wherever the line is carried through watery or unstable material. The Victoria station is exceptional in its arrangement, a mezzanine floor being introduced for the booking-office, which is on a level, about half-height between the platforms of the Brighton and the Chatham companies and the street, for the more easy access of passengers from these lines. The Victoria Station is extra commodious, and is well adapted for the traffic likely to be done in that locality. The galleries and booking-office are here also across the west end of the station. The galleries are across the west end of the next station, which is at Sloane-square, and across the east end at South Kensington, or the last, exclusive of the present station at Gloucester-road. The South Kensington Station is also of extra size, being a joint station for the Metropolitan and the Metropolitan District, which, from that point, duplicates the line to Brompton Station with the West London line. The platforms at South Kensington are 400 ft. long. Among the special difficulties presented in the execution of the works were the treacherous nature of the stuff which had to be passed through, and the copious water-springs that were encountered. Pumping-engines were kept at work night and day during the progress of the works. The water taken up was about 4,000 gallons a minute. Permanent pumping-stations will be established at South Kensington, Sloane-square, and Victoria: from all other points the line will be drained by gravitation in the ordinary way. In this section some very lofty and heavy buildings overhead have necessitated great caution in the execution of the works, and resort to roofs for the covered way of enormous strength. As illustrations, we may mention Messrs. Elliot, Watney, & Co.'s brewery in Pimlico, part of which stands over a portion of the line, and also the lofty houses

in Victoria-street, the backs of which are almost perpendicular with one side of the covered way. No injury has been sustained by any of the buildings over the line. The most remarkable obstructions met with were probably two main sewers which the line had to be carried under, but not so far below them as to leave them undisturbed. In each case lengths of the sewer brickwork the width of the line had to be removed, and the sewer service carried on by temporarily placed wooden troughs. These, in turn, gave way to cast-iron cylinders, supported by side wrought-iron girders, which were fitted to the brick work of the sewers at each side. One of these conduits, 9 ft. diameter, carries the Ranelagh sewer in an oblique direction across the Sloane-square Station, leaving headroom for the engine funnels and no more. The other, the King's Scholars' Pond Sewer, is of much larger dimensions, and the 14 ft. diameter in passage is oval in form, and 14 ft. diameter in one direction,—the horizontal,—by 11 ft. in the other. Both of these sewers are tide locked. The Ranelagh Sewer crosses under the Metropolitan Extension line at Baywater.

For assistance in obtaining these particulars we are indebted to the polite attention of Mr. T. Marr Johnson.

It is not yet quite determined at what intervals trains will be run; a commencement has been made with a ten minutes' service. The trains travel the distance between Moorgate-street Station and Westminster Bridge in forty-five minutes, stopping at all the stations.

DESIGN IN RELATION TO MATERIAL.

AMONG the anomalies resulting from the system of architectural reproduction which has now for so long a time prevailed amongst us, the rehabilitation of this or that extinct form or manner of design in place of thoughtful original invention, it has come to pass that we have become singularly indifferent as to the relation which should subsist between the texture and peculiar capabilities of any given material and the artistic form which is to be impressed upon it. During the cold reign of the pseudo-classic tendency, when the mere repetition, in any material, of the leading features of Greek architecture formed the Alpha and Omega of our art, it was, of course, all in the natural order of things that there should be columns formed from channelled segments of wood glued together into a cylinder, and that imitations of stone-coffered ceilings should be artfully attained by the aid of plaster and bracketing. These things were openly done, and no one raised an eyebrow or lifted a shoulder at them. But when there arose the spirit of modern Gothic, mighty, as we were assured, to the pulling down of the strongholds of plaster capitals and wooden plinths, *ad id genus omne*, then was it confidently prophesied that the spirit of "sham" had been demolished, and great were the paeans sung over the demolition. Nor let us by any means question, in the main, the received opinion that much good fruit has been borne by that notable movement. If it was connected with much of blind and bigoted exclusiveness and copyism, it at least brought us back to study a style which on the whole was verily a style of *building design*, of design capable of accomplishment nowhere save in building, and in no material save stone; and the treatment of this grandest of architectural materials was concerned, the teaching of the Mediaeval monuments was an exceptional one. They belonged to a time when men may be said to have literally thought in their material to a degree never attained since. Yet from this very fact it arose that the stone type of design took such possession of the minds of the old builders, that they could not shake it off even when working in other material, and much of their treatment of woodwork became only so much stone design dignified, if we may coin a word. To the enthusiastic revivers of Mediaevalism there could be no such thing as error in Gothic work, and accordingly they complacently imitated and reproduced the wooden battresses which resisted no thrust, the wooden arches cut from the solid, and all the other little anomalies consequent on the translation into this material, of design formed in a totally different one. The style was to be reproduced with reverence, faults and all, just as it was found. The particular result just alluded to is, however, only a single instance of the manner in which this enthusiastic copyism

mitated against thoughtfulness in design. It is to be feared that, independently of such partial and inevitable results, the copying system which has so long prevailed has acted much more widely than this, in inducing a carelessness and want of thought as to the æsthetic use of materials, and habituating us to a sort of routine method of treating them, rather in accordance with pre-existing examples than with considerations of the nature and quality of the material, and the special treatment demanded thereby. The effects of this want of consideration are apparent all round us. We may endeavour, however, to indicate some of the forms in which it is most prominent.

Stone, which may be considered, in spite of all newly applied materials that are coming into fashion, to be *par excellence* the architect's medium for design, is a material best used under compression, very weak under cross-strain, and which in general can only be used in superimposed blocks of a limited size. These conditions would seem to indicate unmistakably enough the proper and architectural method of using stone. We should naturally conclude that an arched form of construction should be the rule in a stone building, or that if a lintel form be adopted, the width of the opening should not only be limited, but that as much as possible of the material should be left in the lintel, which should on no account be weakened by cutting away from it for so-called ornamental purposes. Yet we constantly see buildings in which both these obvious conditions are utterly disregarded. There are positions, indeed, in which a lintel construction becomes desirable in stone, as when no sufficiently secure abutment can be obtained, or when a row of window-heads are ranged immediately under a horizontal cornice. But a fashion has now sprung up, and is gaining ground greatly among the architects of the new Gothic school, the absurdity of which cannot be too strongly insisted upon. A lintel construction is adopted, but in order to assimilate the lintel with what is supposed to be the Gothic spirit, it is cut up into the form of a shallow arch, pointed or otherwise. Thus the lintel is materially weakened, and a large portion of the stone literally goes to waste, along with the labour expended on it. We have actually seen a full half of a stone lintel cut away in this manner, to a horizontal line, the ends being left in the form of brackets turning down upon the brick jambs of the opening. Where a soft stone is used, this may increase the difficulty, but the effect it is to have it would be difficult to say. One of the very worst forms in which we have seen this absurdity was in the case of a building where the lintel was cut into the form of an ogee arch (a very bad form as it observed, at the best), the point of the ogee slitting up the centre of the stone of course, in a charming manner; we almost expected to see the split go right through the lintel as we looked at it. The capabilities for effect, again, resulting from the necessity for arranging the material in courses, are not nearly enough considered in walling. There is hereby a natural opportunity presented for the use of a selection of stones of varied tints, but of similar texture and formation; and also for obtaining a picturesque character in the walling, which can be imparted by varying the depth of the courses, or by here and there a thinner course, exactly in the manner best calculated to bond the walling securely; so that here construction and effect go hand-in-hand, as in all true architecture they almost invariably do. The capabilities of wall-surface, in this kind of way, are not by any means made the most of at present. A current vulgarity in wall-treatment, on the other hand, is the use of panelling, which is also an example of the sin of appropriating a method of treatment originating in the qualities of another material. When we see a panelled wooden cabinet or side-board, or a panelled door, the system appears perfectly natural and satisfactory; because we know then that we are dealing with a substance of a fibrous texture, sufficiently tough to cohere even when sawn into very thin layers, and which will consequently bear joining by tenons and other such contrivances. A panelled door, therefore, is a fitting and economical method of applying the material used; but it is an absurdity to apply panelling, merely as such, to a wall-surface, thus conveying to the eye the idea that it is framed of thin slabs and angle-pieces, when we know the material is, in fact, too friable for any such treatment. The

only legitimate application of panelling to stone wall-surface is introduced (a raised panel of marble veneer is introduced (a proceeding, however, which on some grounds is questionable), or when the panel mould is merely introduced as the boundary-line of some decorative carving, in which case the sinking should not be so deep as to conceal any part of the ornament, but merely sufficient to mark it off from the plain wall-surface adjoining. But the placing of new panelling over the surface of a building, as ornament, is always evidence of poverty of designing power and want of perception of the true requirements of architectural design. The constant use of it was one of the great blots on the Italian Renaissance, many of the best buildings of this school being deprived of a great deal of their effect, and almost taken out of the category of architecture altogether, by their being covered over with a feature which masked their real construction and gave to the whole an æsthetic, quite alien from the effect which a construction of solid blocks of bonded stone ought to present. A similar error is the employment of that hideous feature, as it appears to us, a rusticated column. Where the column is really built up of isolated parts in shallow courses, this method is constructively far inferior to the use of a monolith, where one can be obtained; and if the column is really a monolith, artificially rusticated, the case is worse, as involving a waste of material to produce a sham.*

As to wood, there is no end to the misuse that has been made of this useful and pliable material; the misuse in the majority of cases resulting from the imitation of stone treatment. It is made into sham pilinths and surbases, put together with much careful joinery; ineb pieces are "boxed" into the imitation of a solid cornice or soffit; it is twisted round, under the influence of steam, into sham arches; forms foreign to its erection very nature. The absurdity is, that a kind of imitation of separate pieces is often made, when a single solid piece would have both looked better and been more durable. In erecting large stone gate piers, it is a natural plan to foot the shaft of the pier on a plinth stone larger than itself, and to crown it with a heavy projecting cap. But for smaller piers, where a monolith is easily obtainable of sufficient size, it is an absurdity to do this, as the monolithic gate-pier on this scale will be far stronger than a built one; and the absurdity is still greater when (as we have seen) a monolith is used, and the greater part of the surface chipped away 2 in. deep all round, in order to get a sham plinth at the base. The same sort of blunder is constantly made with stair-newels. A newel should be a solid piece of wood, to receive the handrail and notch-board, and should be so treated, any ornamental finish worked out of the solid. But in many cases it should imitate a large pier, and so a cap and round the bottom, and the cap nailed on the top. In due course of time the plinth shows signs of separating from the core to which it is attached, and the head gets loose; whereas the simple post might have lasted for generations. A common misuse of wood is found in such erections as summer-houses and conservatories, especially in buildings of a Classical tendency; where, instead of the upright stiles being treated as wood and moulded solid, they are developed into apparent pilasters, composed of 1½ in. stuff, with all the insignia of caps and bases, and "everything proper." We have actually seen such a thing as a kind of handbox pedestal elaborately framed round iron columns, which, in fact, went through the floor on to a hollow square box with plinth, surbase, and all adroitly put together. This is, perhaps, a flagrant case; but the shams that have been perpetrated in wood are such as to make one doubt sometimes whether there is such a thing as architectural principle at all. The Gothic school are certainly foremost in deprecating such things as we have just alluded to; but they have their own little shams in the treatment of woodwork, too. The wooden buttress is now, indeed, going out; but in the "firework" designs for bookcases and organ-cases, with inlaid and variously-coloured wood, which we constantly see, there is frequent use made of the

* We speak, of course, of columns of moderate dimensions, such as would occur in an entrance porch; a situation in which rusticated columns have been a good deal used.

shab and arch, on a small scale, which is simply a stone feature translated into wood. In such pieces of furniture the quality of wood as a material, its resistance to cross-strain, and its comparative softness and facility for carving, point to its suitable employment in square and diagonal moulded bracing, and in carved brackets, while its cobesiveness in thin layers authorises, as we before remarked, a panel construction; and panels, let us note, may be made highly ornamental in cases where *bonâ fide* carving is too expensive, by being simply pierced through in some carefully-designed flat pattern,—a source of decoration which might have been made more of and been more artistically developed than it has been. As to the "centre-bit" style of decoration, so much in fashion, formed by piercing round holes in the wood every where, it is only worthy of very young children. We say nothing of designs for roofs, for there timber is, so to speak, master of the situation; if you do not treat it on true "wooden" principles, the roof will revenge itself upon its clumsy constructor by falling, and pushing out the walls.

The sententious ejaculation of Butler,—

"Ah, me, what perils do environ
The man who meddles with cold iron!"

may apply to architectural as well as to military aspirants. So far as construction is concerned, we need scarcely, we hope, at this time of day, urge that iron when used constructively in the form of girders or columns, should be shown as such, and not be masked by a *quasi* stone or wood construction. Nor does the treatment of wrought iron in ornamental work call for special comment here, so far at least as principles of design are concerned. Wrought iron is so peculiar a material, and demands so much arduous labour in the treatment of it ornamentally, that there is little fear that it should ever be used except to produce those effects which are peculiar to it, and which nothing else can well imitate. It is when we come to that too often pernicious compound, cast-iron, that our critical spirit is aroused: *hæc opus, hæc labor æst*—or rather the *saving* of labour. As to the use of cast-iron for ornament generally, perhaps the best advice to those about to use it would be comprised in one word,—*"Don't!"* There are cases, however, where much money cannot be spent on ornament, and where a certain amount of decorative effect can be attained by the aid of cast-iron; but then it must be designed with due regard to the deficiencies of the material. Let no one suppose that highly ornamental carved work, when once executed in wood, can be reproduced *ad infinitum* in cast-iron, with any but the most lamentable and poverty-stricken results. It is in the attempt to get too much out of cast iron that the material has been so vulgarised and misused. It must be remembered that we are here dealing with a material coarser than sandstone, which is utterly incapable of giving sharp cuttings and under-cuttings, delicate surface-work, or anything which goes to produce that crispness necessary to the proper effect of elaborate carved designs; yet we see foliated capitals and leafage ornament perpetually attempted in this material, sometimes cast from models themselves coarsely executed in lead, the coarseness being necessarily exaggerated in the casting. This sort of cast-iron ornament is alone sufficient to remove the stamp of art from a building, and throw over it a flashy, tradesman-like appearance. What can legitimately be attempted with cast iron in the way of ornament is whatever depends on simple lines and square decided sections, without aiming at delicacy of surface-work. Brackets, for instance, with pierced ornamental spandrels, the ornament produced merely by the flat perforations in the material, without any attempt at a moulded edge, will generally have a satisfactory result. Similarly, capitals to cast-iron columns may be designed, consisting of simple flat leafage forms, defined only by the sinking between them, and not attempting to take the place of the carved foliage ornament, which can only be satisfactorily executed in wood or stone. In designing capitals of this kind, suitable for the material, there would be scope for some novel treatment of the crowning feature of a shaft or column. As to the kind of so-called ornament we meet with on our iron lamp-posts and area-railings, the leaves, and wreaths, and festoons, with their details only half made out, straggling, as it were, to show themselves through the coarse material, year by year more choked and filled up with paint and dust,—with regard to such things the only consolation (if it

can be called so) is that the design is generally worthy of the material in which it is attempted.

What we have said about cast iron will also apply in great measure to that other material for cast ornament, plaster. A growing distaste for this perishable though showy vehicle of ornament is one of the main things for which we have to thank the modern Medival movement, though the pioneers of this movement carried the matter too far, in the inclination which they showed to ignore even the efficacy of plaster in rendering the interior of a building comfortable and warm, and to return to bare brick or stone walls. And plaster has also its legitimate uses as an ornamental material,—uses which, in a future number, we may endeavour to define more minutely. But, though more dnoitic than cast iron, it can never have the sharpness and crispness of actual carving; and therefore all attempts to execute elaborate and delicate ornament in this material must result in a sort of pie-crust effect, and be classed with that sort of ornament which may be designated generically as *flummery*.

We have indicated a few of the leading and most obvious points in which the relation between material and design appears to us to be habitually and constantly overlooked; to those among our readers who are accustomed to think before they work, many others will doubtless occur. We would draw attention, in conclusion, to the importance of such considerations as regard the future of architectural art. The simplest path in art is often the truest, and leads most directly to the goal; and we cannot but think that in the present day there would be less diversity as to what really constitutes good architecture, less confusion and jumbling of old styles, and a better chance of arriving at the "new style"—that mirage constantly hanging before the eyes of the modern architect, and ever receding from his grasp—if architectural designers would often adopt the simple plan of considering, first, what material will be practically best for the building they are to erect; and, secondly, what is the nature and property of that material, in what method it can be constructively used so as to insure its utmost efficiency, and what class of ornament its peculiar texture and surface render it fitted to give full value to.

METROPOLITAN ASYLUM COMPETITION.

THE Metropolitan Asylum District Board having decided to erect additional hospitals in the different districts of the metropolis for fever and small-pox cases, purchased land for the purpose at Hampstead, at Stockwell, and at Homerton.

For the Hampstead Fever Hospital, as we have before mentioned, six architects were invited to submit designs, and the first and second premiums were awarded to Messrs. Pennington & Brigen, of Manchester, and Mr. J. H. Fowler, of London.

Certain alterations and modifications of these designs have, however, been required by the Board, and the plans have not yet been sanctioned by the Poor-law Board. The original estimate of the successful plan was 15,500*l.* The number of patients accommodated here is a little over 100.

For the Stockwell Fever and Small-pox Hospitals, which are to accommodate about 150 and 90 patients respectively, the following gentlemen submitted designs—Mr. Marrable, Messrs. Pennington & Brigen, Mr. Worthington, Mr. T. H. Wyatt, Messrs. Nesfield & Shaw, and Messrs. Beeson & Co. The first premium for the Fever Hospital has been awarded to Mr. Marrable; the second to Mr. T. H. Wyatt. The first premium for the Small-pox Hospital has been awarded to Mr. Wyatt and the second to Mr. Marrable. The estimate for the Fever Hospital is about 33,000*l.*, and for the Small-pox Hospital about 25,000*l.* The plans are now before the Poor-law Board for their approval.

Of the Homerton competition we speak more at length, under a separate heading.

Designs are being prepared for a sick asylum for the Newington district, to accommodate 600 patients, on a site purchased at Peckham-rye, six architects having been invited to compete—Messrs. John Giles & Biven, Mr. T. E. Knightley, Mr. Jarvis, Mr. Lepard, and Mr. D. Barton. The plans are to be sent in on the 14th of January.

It is to be hoped that as one of the competitors has been long connected officially with the parish, the managers will, for their own sakes, take the opinion of some qualified person on the

designs. Either some architect well acquainted with hospital plans, or the inspectors of the Poor-law Board, would assist them materially in arriving at a just decision, and relieve them of the grumbings of disappointed candidates. The *Lambeth* managers have invited the before-mentioned gentlemen and others to submit designs for a similar building.

THE FEVER HOSPITAL AND SMALL POX HOSPITAL, HOMERTON, COMPETITONS.

METROPOLITAN ASYLUM DISTRICT.

SIX architects were invited to furnish designs for the proposed Fever Hospital and the Small Pox Hospital, at Homerton. With reference to the first, a premium of 200*l.* was offered for the best design, and 150*l.* for the second best; the successful competitor, if required, to carry out the works for a payment of 1,000*l.* less the amount of the premium; but not to be entitled to any premium or payment unless a substantial contractor undertake the work at a price not being more than 10 per cent. above the estimate of the cost sent in with the plans.

For the Small Pox Hospital, the premiums were 150*l.* and 100*l.*; and the payment to the successful competitor, if he carry out the work, 700*l.* less the amount of premium, and under the same condition as to estimate as the former.

The Fever Hospital to have 182 beds; the Small Pox Hospital 102. The instructions prescribe pavilions, not more than two stories in height, placed, if practicable, north and south; 2,000 ft. cubical space to each case; Parian cement or other impervious material for the walls; open windows reaching to the ceiling; ventilating stove-grates to bring in fresh warmed air; outlet shafts; hot-water pipes in some of the wards; double-action lifts; staircases of iron with wood treads and fire-proof landings; and that no expense is to be incurred for any kind of ornamental work. The names of the competitors and the estimates they sent in stand thus:—

	£	s.	d.	£	s.	d.
Mr. Gilbert Scott, jun., for the Fever Hospital	42,000	0	0			
Ditto, for the Small-pox Hospital	22,000	0	0	64,000	0	0
Mr. E. L. Bracebridge, for the Fever Hospital	29,800	0	0			
Ditto, Small-pox Hospital ..	21,700	0	0	51,500	0	0
Messrs. Giles & Biven, for the Fever Hospital	27,000	0	0			
Ditto, Small-pox Hospital ..	17,000	0	0	44,000	0	0
Mr. T. H. Watson, for the Fever Hospital at	25,000	0	0			
Ditto, Small-pox Hospital ..	16,800	0	0	42,700	0	0
Mr. A. Wilson, for the Fever Hospital (A)	26,000	0	0			
Ditto, Small-pox Hospital (A) ..	15,350	0	0	41,350	0	0
Ditto, for the Fever Hospital (Alternative Plan) (B)	24,000	0	0			
Ditto, Small-pox Hospital (B) ..	14,350	0	0	38,350	0	0
Mr. T. E. Knightley, for the Fever Hospital	19,950	0	0			
Ditto, Small-pox Hospital ..	13,050	0	0	33,000	0	0

The committee arrived at the conclusion that the designs submitted by Messrs. Giles & Biven and Mr. Wilson best carried out the instructions and displayed a very improved arrangement of the several wards and the administrative department; they therefore recommended that the premiums of 200*l.* for the best design for the fever hospital, and of 150*l.* for the best design for the small-pox hospital, be awarded to Messrs. Giles & Biven, subject to the terms and conditions contained in the instructions; and that the premiums of 150*l.* for the second-best design for the fever hospital, and of 100*l.* for the second-best design for the small-pox hospital, be awarded to Mr. Andrew Wilson. This recommendation the Board have, we believe, confirmed, nor are we disposed to question it.

The designs by Messrs. Giles & Biven have some excellent points, and are generally good. The staircases which lead to the upper wards have no communication with the wards, a gallery, open on both sides, completely separating them in each case. Again, the "administration," which forms the centre of each hospital, well away from the wards, is divided into four distinct blocks of building,—the medical and official, the attendants' department, the store and kitchen department, and the laundry department, which are all unconnected, except

by the ground-floor corridor, open on both sides if required. The plan of the small-pox hospital is particularly compact, the two pavilions for each sex radiating from the two ends of a short corridor, the administrative blocks, divided as before, being in the centre.

Mr. Wilson's plans resemble those we have already mentioned more nearly than the others; but he lessened his chance of adoption by using well-ventilation, so to say, in one part; that is, ventilating by an area surrounded by buildings. In both Mr. Knightley's plans this same error, to a larger extent, is obvious. Mr. Scott, jun., has brought the administration into too close proximity to the wards. The design has several meritorious points, and the same may justly be said of the designs by other competitors not specifically mentioned.

PRICE-BOOK FOR CIVIL ENGINEERS AND CONTRACTORS.*

THE plan of this work is well conceived, and it appears intended to supply a definite and well-ascertained want. There is nothing, as it truly implies, in which the professional reputation of the engineer and architect, and the interest of the contractor, are more directly concerned than the preparation of estimates for public works; and "there are very few duties which require greater consideration of almost innumerable subjects and conditions, varying with localities and circumstances, all of which affect labour and materials."

The book is divided into two sections. The first consists of tables or price-lists for various works and materials, accompanied by some railway specifications; and the second contains a good compendium of the legal liabilities of engineers, architects, builders, contractors, and workmen.

The price-lists in the first section are in the main correct, according to the present London standard; yet we regret to be unable to speak of this section with wholly unqualified commendation. It is, in our view, a serious deficiency in it, that no attempt is made to furnish the data upon which the prices are based; such, for instance, as the rate of wages assumed to be paid, which is never once alluded to. This defect is the more noticeable, as no date of publication is stated on the title-page, so as to give the book the appearance of referring to any year or period, notwithstanding the great fluctuation in wages which is constantly occurring.

Moreover, the price-lists, though correct in the main, are not wholly free from error. Thus, under the head of "Earthworks" (Table 1), a barrow-run is assumed at 25 yards, whereas the practice in London is to confine it to 18 yards, or three 18-ft. planks, which invalidates any calculation founded on the author's assumption. Again, the item given for pumping (No. 12) is absolutely useless. The cost of pumping cannot be arrived at in any average way, and can only be estimated from the experience acquired in any given locality. In fact, it varies in practice from 3*d.* to 5*s.*, or more, so that the table in this respect is more calculated to mislead than to inform. The cost of timbering the sides of excavations, though not referred to in the table, is alike an important item; the cost of which has been found to vary from 3*d.* to 2*s.* per yard, according to the nature of the soil and the quantity of water.

We would also refer to the item of carting. Without objecting to the prices given by the author in No. 13, it must be seen that they are almost wholly dependent on the rate of wages paid, and liable to mislead if that rate be not stated. It is found in practice that a horse will travel about fifteen miles a day, and this independently of the length of lead, as, with short leads, and consequently more frequent rests during the filling of the cart, a horse will walk faster than on long leads; so that the distance of his daily travel is nearly the same in either case. For example, assuming half a mile lead, and the cart to hold a cubic yard, there would be 15 cubic yards per day carried; which, at the wages of 6*s.* 6*d.* for horse, cart, and driver, would be 6*d.* per yard for cartage; and with an addition 1*d.* per yard for filling, depositing, plaut, and profit, the entire price for transport would be 11*d.* per yard.

The concrete prices also show clearly the lead.

* Atchley's Civil Engineer and Contractor's Estimate and Price-Book. By W. Davis Haskoll, C.E.

ing defect of the book to which we have alluded. Given the proportion of gravel and lime, the price of concrete varies according to the separately varying values of ballast, lime, and labour; and the cost of ballast alone has varied around London from 1s. to 8s. per yard, according to locality and demand. Fixed prices are also given in the tables for the cost of coffer-dams; whereas the labour of pile-driving alone, even when the rate of wages and materials is unaltered, varies from 1s. to 4s. per foot of pile driven, according to the nature of the soil.

The culvert quantities given in Table 2, and also the tunnel estimates in Table 3, are of great practical utility and convenience. We would recommend, however, that the bottom of the excavation for culverts should be got out horizontal rather than following the curve of the invert as shown in figs. 20 to 29; the curvature of the invert bottom being made up to the required form out of either a concrete or brickwork bottom, instead of by cutting it out of the natural soil. Thus in brick culverts, where concrete is not used, we would, in ordinary soils, lay two clear level courses under the invert.

In the prices for brickwork given in Table 4, the assumed cost of bricks is stated, but no further particulars are supplied as to the data on which the value of labour, mortar, plant, and profit are assumed, so as to enable the tables to be used under varying circumstances. It is due to the author to state, however, that the prices of both brickwork, timber, and iron are fairly applicable to present rates.

This book, on the whole, possesses the merit of great comprehensiveness, and of present correctness and utility to the classes for whom it is designed, especially in London. But it appears to us worthy of the author's attention to produce a work on an extended basis, which would have a wider and more lasting application. By tabulating, as far as possible, materials and labour as well as money; or, in other words, by stating the known proportionate quantities of materials used and daily work done, the engineer and contractor would from these quantities and the known rate of wages and materials in any given locality, be able to form their estimates with confidence, and with a degree of convenience hitherto unknown. Nor is there any peculiar difficulty in such a task; the materials for which are either known or can be gathered from observation by any one who has the opportunity of observing the progress of engineering works.

HOSPITAL BUILDING.

ARCHITECTURAL INSTITUTE OF SCOTLAND.

At the first meeting for the new session, held on the 23rd ult., Mr. Jas. Gowans read a paper on "The Edinburgh Infirmary and its Site," a subject just now greatly interesting the people of Edinburgh. In the course of his paper Mr. Gowans said.—In designing any building, the primary consideration of an architect is to plan it so that it may in the fullest degree be suitable for the purpose for which it is intended; and the most prominent requirements in a hospital appear to me to be the following:—

1st. That the buildings should have a full supply of light and pure air.

2nd. That they should be detached from each other, and classified for the particular diseases for which they are to be used.

3rd. That the ward buildings should be constructed so that they might be easily taken to pieces, and removed to other situations; or if they are constructed in a permanent manner, they should be built of material which would prevent as far as possible the absorption of diseased air.

4th. That the drainage should neither contaminate the building itself nor those other buildings which may be in the neighbourhood.

As to the first. No one can dispute but that plenty of light and pure air is of the greatest importance for the healing of the sick or hurt, and large windows on either side of an apartment afford the best means of their receiving both. A south-easterly exposure for chambers appears to me to be the most conducive to health, as the air that comes with the rays of the morning's sun is always the freshest and best; and just as you would place the bedrooms of your dwelling-house in that direction, so should they be in the wards of an infirmary.

As to the third. Following out the camp or

cottage idea, the structures could be made either of iron, in pieces that would be easily detached and removed when necessary, or to attain the same ends, and have more permanent buildings, they could be constructed of stone, and lined with concrete, cement, or other inside casing, which would prevent the absorption of those gases leading to the various diseases which stick to hospital buildings after they have been used for any length of time. The sort of apartment I aim at is one that could be only affected by bad air so long as the immediate cause existed, which could be thoroughly expelled by the through and through ventilation of the opposite windows, and the thorough cleansing by water ejected from the hose of a fire-engine. In fact, I would have it as easily cleansed as the drug bottle of a chemist, and I see no difficulty in doing this, as the walls, floors, ceilings, ingoings of windows, and other surfaces, could be altogether made of some vitrified substance; and as I believe the timber of floors, doors, and finishings, absorb these unhealthy gases, I would have no finishings about either, but have the framing-work made of iron, with opaque glass for panels. The windows also I would have of iron frames, so that, at least as far as I know, the work would have nothing about it admitting of the least absorption.

If the drainage from the hospital is allowed to pass without being treated in some manner so as to destroy the contagion it necessarily carries, the drainage of the houses connected with detrimentally affected; and if there should be the slightest leakage in the drains, or any failures in the cesspools (which is often the case), the inmates of such dwellings would run great risk of contagion. The ventilation of the drains is also another matter that should not be overlooked. The outlet, therefore, of the drainage of a hospital should not be of a sluggish nature, but should have fall enough to carry it off as rapidly as possible.

A great consideration is, to provide such buildings and such devices as will aid our surgeons in the successful issue of their operations, or the medical men in the treatment of those diseases which often baffle the skill of the highest in the profession on account of the absence of such aids.

It would be as idle to expect that the surgeon could go through with his operation satisfactorily, unless he had the help of the best of instruments, or the medical man to cure without being provided with the best of drugs, as to expect that they can do all that is required of them in the old hospitals, which we are now about to remove. Again, if we can aid our physicians or surgeons in this way, we are aiding ourselves as well as others, because that, apart from the success which our diseased poor get in infirmaries, the contagious diseases which now and then come across such cities as ours must be checked, and kept from our own doors, by the removal of the afflicted to within the walls of a hospital.

To come down to a commercial view of the whole thing, I think it will pay the community to provide all that is best. If it is possible, by the aid of sanitary and other contrivances, to cure the patient in eight days instead of eight weeks, there must be a gain; so why not invest a little more money now that we have the opportunity of doing the right thing, and saving as we go on? I believe, from all that I have heard, that the result of the operation of the surgeon, or the means adopted by the physician for the cure of the sick, is not what either dread; what they dread is, the baneful influences which seem to adhere to the walls of the building itself, or the want of the restoring atmosphere which should come from the outside.

The Chairman (Mr. Peddie) invited discussion on the paper.

Mr. Lessels, architect, thought that if the buildings were to be temporary, it would be better to put up glazed buildings made of fire-clay and white on the surface. They could build the walls hollow, and the interior walls could be made of glazed fire-bricks, which could be quite impervious, and could be washed perfectly clean. For himself, however, he confessed that he should not like to see any building of that temporary nature erected in this city. He thought it would be quite possible to design a permanent building so as to meet the requirements of an excellent hospital. The difficulty as to bad gases might be overcome by lining the walls with fire-brick, and coating them with cement.

Sir James Simpson said he thought that Mr. Gowans's suggestion of building on a raised platform on the present site was most valuable,

because the building would then have the best ventilation and exposures far as the circulation of air was concerned. Sir James proceeded to refer to the question whether the buildings should be temporary or fixed, repeating the views which he expressed at the meeting of the Medico-Chirurgical Society in favour of having the administrative portion of the buildings fixed, and the buildings for patients of a temporary kind, made of iron, which could easily be taken down and put up again. He referred to statistics which he had prepared two years ago, showing that out of a million of midwifery cases treated in the hospitals throughout Europe, the proportion of deaths was 1 in 29; while out of a million of similar cases treated in their own homes, the proportion of deaths was only 1 in 210. He also contrasted the results of amputations in the Edinburgh Hospital with those of amputations performed in the country, stating that out of upwards of 400 amputations performed by country practitioners there were 40 deaths, or 1 in 10; while the statistics of the Edinburgh Infirmary three years ago showed, that out of 70 or 72 operated upon, 30 died, or 1 in 2½—the mortality being thus three times greater in the cases of the operations in the hospital than in those in the country. That was a startling fact, he said, and what was true of amputations was true of all other operations, and of the treatment of other diseases. He did not think it would be sufficient to wash the wards, because the large new hospital in Paris, where the walls were of Parian imitation of marble, and where there was the utmost cleanliness, was found to be the most deadly in Paris. No one had yet succeeded in getting rid of the miasma that seemed to gather in old hospitals, and they might succeed if they would build hospitals of some material that could be built readily, and put up again. After suggesting that iron might be used with advantage, and that layers of charcoal might be placed to operate as a disinfectant in interstices of the iron walls, Sir James concluded by insisting on the necessity of providing a hall for the patients, and of providing a large number of rooms with one bed, to prevent patients retarding the recovery of others, maintaining that it was better to treat one hundred patients perfectly and kindly than two or three hundred imperfectly and to the destruction of their health and lives.

Dr. Stevenson Macadam said that whatever might be the mode of construction of the hospital, the introduction of charcoal would render it more healthy than it would otherwise be, owing to the value of charcoal as an absorbent of gases.

Dr. Dunsinure said that Sir James Simpson's statistics were calculated to injure, not only their hospital, but hospitals in general. He did not call in question the rates of mortality Sir James had quoted, of 1 in 3 in hospitals, and 1 in 10 in country practice; but as an old hospital surgeon he thought it was not fair to compare the two at all. In the hospital a great many persons, who had met with severe railway accidents, were brought from a great distance, bleeding for hours before they got to the hospital. Dr. Dunsinure went on to say that he approved of hospitals being built of iron, though he did not think they could be built of that material for large towns. He also approved of the suggestion made as to the use of charcoal. He saw no reason why the washing of hospitals should not be attended with benefit; and, referring to the remarks of Sir James Simpson on the mortality of the Paris hospital, he said that might be accounted for by the fact that it was ventilated artificially instead of naturally.

Dr. Alexander Wood wished some scientific gentlemen, with Sir James Simpson at their head, would endeavour to ascertain what this miasm was that lurked in hospitals; for if no amount of washing would remove it, he confessed he was a little sceptical of any great effect being produced by the unscrewing of iron bolts and laying the iron upon the grass. Before advocating the substitution of iron for stone and lime, he would like some more certainty about the end justifying the means.

The Chairman said that in Paris the large new hospital to which Sir James Simpson had referred had 612 beds, and it required the whole space of about ten acres. St. Thomas's Hospital in London would have 638 beds, and required six acres; and it was to be built four stories high in consequence of the limited space. In these circumstances they might safely say that five acres of infirmary ground would not properly accommodate 500 beds.

THE HEALTH OF PLYMOUTH.

PLYMOUTH is, perhaps, the largest and the most important English town of which the Registrar-General does not publish weekly returns of births, deaths, and mortality. The information bearing upon its vital statistics recently prepared and presented by Dr. A. C. Hingston, Senior Physician of the Plymouth Public Dispensary, is therefore a welcome contribution to sanitary intelligence.

Plymouth may be said to comprise the three registrative districts of Plymouth, Devonport, and East Stonehouse, and to include a population estimated by the Registrar-General to the middle of this year at nearly 140,000; but Dr. Hingston's return deals only with Plymouth borough, which, at the census of 1861, contained 62,599 persons, and is now estimated to have 71,373 inhabitants. The element of population in the necessary calculation for obtaining the death-rates in towns is but too often a source of much difficulty and probable error. The interval of ten years between one census and the next may not be too long between the numbering of the nation at large; but ten years in the life of a town may be as eventful as fifty years in a rural district. The rise of a fresh branch of trade, or the decline of another, not infrequently so changes the rate of increase of population in a town as to render the use of the rate which prevailed between 1851-61, for instance, worse than valueless for the greater part of the decade 1861-71. The question of a quinquennial census of all town districts is one of sufficient importance to deserve the attention of the Royal Sanitary Commission, for a reliable estimate of the population is necessary to lend preliminary value to vital statistics. To return to Plymouth. Dr. Hingston does not, unfortunately, state the population upon which his calculations are based; but from local inquiry there appears no reason to doubt the accuracy of the estimate given above, founded upon the rate of increase between 1851-61, and it is probably this which has been used. It is to be somewhat regretted that the returns relate to the three months September, October, and November, instead of for one of the more usually recognised quarters, as useful comparison with the returns published by the Registrar-General for other large towns is thus rendered almost impossible.

During the three months ending November last, 334 deaths were registered in the borough of Plymouth, against 364 and 339 in the corresponding three months of 1866 and 1867. These deaths give an annual rate of mortality during those three months of 19 per 1,000, against 23 per 1,000 last year. During the same period the death-rate was 20 per 1,000 in Bristol, 23 in London, 24 in Birmingham, 29 in Liverpool, and 33 in Manchester; indeed, Plymouth was healthier during that period than any one of the large English towns furnishing weekly returns, Bristol coming nearest with 20 per 1,000. In explanation of this result, Dr. Hingston says,—"We may consider the town as definitely assuming a more healthy condition, which is clearly due to the improved drainage, and other sanitary arrangements which have been carried out during the last few years."

Many of our large towns have recently been suffering from the prevalence of zymotic disease, resulting in excessive death-rates. Different forms of fever have been very fatal in Manchester, Liverpool, and Leeds; scarlatina in Manchester, London, Birmingham, and Newcastle-upon-Tyne; and small-pox in Sheffield. Plymouth, however, has been unusually free from this class of diseases: there appears, indeed, not to have been a single death from scarlatina in the town during the past five months. During the three months ending November, of the 334 deaths recorded, only 48 resulted from zymotic diseases; whereas, in the same period of 1867, 73 were so returned out of 339 deaths. Perhaps the most conclusive evidence of the improvement in the health of the town is the steady decline in the proportion of these deaths from zymotic, or, as Dr. Hingston plainly calls them, preventable, causes in recent years. In the three months of 1865 ending November, 33 per cent. of the total deaths were referred to this class of disease. In the same period of 1866 this proportion fell to 25 per cent.; in 1867, to 22; and in the corresponding three months of the present year the proportion has been but 14 per cent.

Of the 48 deaths from zymotic disease, no less than 19 occurred from diarrhoea, mostly infantile; 15 were fatal cases of fever, and one

of small-pox; the only death resulting from this disease in the past two years. This speaks well for the efficient performance and general adoption of vaccination, as seaport towns are especially liable to the importation of the disease from other places, with the spread of infection if this precaution be neglected. Hull has recently been suffering from this cause.

We are glad to see that the most influential of the local papers, in noticing Dr. Hingston's report, has taken the opportunity to urge the advisability of appointing an efficient medical officer of health. It is but too often the case that such a measure is not mooted in a town until some epidemic, by its fatality, spreads death and terror among its inhabitants; and the trite saying, "Let well alone," is too frequently urged against taking any important sanitary step if it can be proved that other towns are worse off, and suffering from higher death-rates. The inhabitants of Plymouth should, however—the rather encouraged by the success of what has already been done—still further show their earnestness by making a judicious appointment of a medical officer. The improvement in the health of the town would then probably continue, and we should no longer have to chronicle even 15 fatal cases of fever in three months, with their probably five times as numerous cases of attack with subsequent recovery. It is well worthy of local consideration whether Plymouth, Devonport, and East Stonehouse could not, for sanitary purposes, be formed into one district, with one medical officer of health. The duties of such an appointment are always more efficiently performed if they are sufficient to occupy the whole time and attention of an efficient officer.

CELTIC, ROMAN, MOORISH, AND OTHER REMAINS IN ALGERIA.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the last meeting of the Institute, Professor Hayter Lewis gave some particulars of a recent visit to Algeria. The time which he could afford allowed him to make but few sketches, which had been enlarged by Mr. Taverner Perry, the Messrs. Hensman, and Mr. Hanson. The country described comprised the town of Algiers and the districts around it, the geographical position and topographical features of which were pointed out on a map, after which the author gave a succinct history of the various races by whom the province was successively peopled, from the ante-Christian era down to the middle of first century, when it became a province of Rome. The Vandal conquest led to the coming of one of the great regenerative nations of Mediaeval times, the Byzantines. About a century after that the power of the Vandals was destroyed by Belisarius, the famous general of Justinian, and they henceforth and for ever disappeared; but it was different with the Byzantine. Wherever he had gone his mark had been left, and all over the province something for ever cropped up to show that this half-Greek, half-Persian, had been there. The Byzantine power was short-lived; for, little more than 100 years after their conquest, occurred the advent of the religion and conquests of Mahomet. In A.D. 612 the Saracens invaded Northern Africa, and in thirty years more they had overrun and conquered the whole, and for 1,200 years it remained, in the main, Mahomedan. It was not, however, till 1050 that the conquerors summoned their countrymen from the deserts of Arabia to people those of Algiers. With them there came, of course, another style of architecture, which lasted well nigh to our own day; but it was seriously modified at various times, chiefly under the Turks, who had entire possession of the Government from the sixteenth century. In 1830 the French landed at Sidi Feruch, and destroyed the government of the Algerine Beys. In 1837 they stormed Constantine, and from that time Algeria had been a half-civilized province of France.

Of the various works of all these different peoples he took, first, those usually termed Celtic or Druidic, for want of a better name. Of these works vast numbers exist in Algeria, and many of a most curious kind, particularly in the northern French village of Gnyotville. These old monuments were little prized by the men who have just preceded us; but the French Government has now awakened to the calls of its savans. The remains at Gnyotville are simple cromlechs, formed of large rude unworked stones, set up edgewise, so as to make a small

chamber, which is covered with one or more large stones at top. That these were sepulchres there could be no doubt, as bones have invariably been found in those newly opened. He could neither see nor hear of any trace of a tumulus over any of the cromlechs, and none of them bear any mark or moulding, or possess even a tradition to tell of their authors or dates.

He now came to a very great advance indeed. On the top of a hill in the Sahel range, rising there 850 ft., is the famous Khour-el-Mouria, or Tomb of the Christian Lady, which can be seen for an immense distance along the plain or from the sea, standing holly out above the range of the Sahel as a great conical tumulus. The site is now utterly desolate, and up to the time of the present Emperor's visit to Algeria it was an entirely confused mass of stones. The lower part having been buried by the rain of the upper, his Majesty having provided the requisite funds, the work of clearance was begun in 1865, under the direction of Messrs. Berbrugger & MacCarthy. The clearance occupied eight months. The author proceeded to give a minute description of the architectural features of this monument, and exhibited specimens of the stone. Of the purpose of it nothing could be discovered. There were no records on the walls: the chambers were all empty,—no sarcophagus,—no skeleton,—no trace of sepulture or shrine. A few beads of a coral necklace and some trinkets of Egyptian make were all that the most careful search could find. The openings broken in the porticulis communicating with the central chamber were barely large enough to admit a man, and no sarcophagus could ever have been removed through them. It must, therefore, be supposed that the chambers had contained the ashes only of the dead, easily removed, and now scattered by the winds. As to the date of this very grand work the whole of the details gave one the idea of their having been copied by Roman artists from Greek originals, and Mr. Berbrugger assigned the structure to Julia II., who died A.D. 19, and to his queen, Cleopatra, daughter of the celebrated Egyptian.

Of a similar type to the above, but of somewhat smaller size, is the tomb (still it is thought unrisen) in the eastern province, near Batna, known as the Medracen, a name of which no probable meaning or derivation has yet been given. This monument, which stands upon a lofty hill commanded for a long distance from the plain, is also utterly without inscription or tradition to assign its date, origin, or purpose. The more probable purpose seemed to be that it served as a royal mausoleum for the kings of Numidia as the Kolea edifice did for those of Mauritania. Structures similar to the foregoing were met with in the south-east province of Oran, the existence of which he believed was not known until 1842. These were three in number, built of large stones on a square base, with a pyramidal top formed of steps as in the Medracen and Khour.

The above were the only remains of Roman or earlier art which seemed to the author so peculiar to the province as to require special notice. Between the time of the Romans and Byzantines there was nothing architectural to remark; but amongst the records of this date in the museums are several of great curiosity.

At Tipasa were said to be the ruins of a large church, now filled up by the huts of an Arab village; but the author was by an unfortunate accident prevented seeing them, nor could he meet with any description of them. At Bon Ismail he found the lower part of a building which appeared clearly to be the ruins of a very early church, with some very curious features still remaining in a totally perfect state. At Constantine there are the remains of a church said to be those of the original one founded in the time of that emperor; but the ruins are very scanty, and there was no assurance that the church had not been rebuilt over and over again since its foundation.

He now came to the Arabs. Their works, so far as he could personally speak of them, are chiefly in the town of Algiers, the whole of which was really comparatively modern, and its architecture, whatever its style, could date only from about the same period as that of the chief Renaissance architects of Italy. It is built on the side of a steep hill, in a wedge-shaped form, starting from the harbour at the foot, and finishing with the Turkish citadel of the Kasba at a height of 387 ft. above the sea. There is nothing in the Arab part that we could fairly call a street, nor any part through which a carriage of any kind could be drawn. The thoroughfares

are mere alleys winding about the sides of the hill, in paths so tortuous and irregular that a stranger has but one means of discovering his way of escape from them, viz., by persistently going down-hill, wherever that may lead, by which means he must of course at last find himself at the bottom of it. The houses, mosques, and palaces, their domes and minarets are white. Their roofs are flat, with no gable or slanting covering, to mark from a little distance one building from another, either in outline or colour; so that the general appearance of the city from the sea is really that to which it is likened, as a stone quarry. The most ancient and interesting of all its buildings is the grand mosque, the Djama Kahir. It stands close to the sea, and is common enough looking outside, being a simple square-walled building, with a few small apertures in it for light. A lofty minaret above proclaims to the stranger that this building, which it crowns, is one of the great native edifices of Algiers. [The author, by the aid of a sketch, described the principal features of this building.] All this, he said, was genuine Arabic, as its date would show, the mosque having been built in 1000, and the minaret in 1322. The author then proceeded to give a description of another mosque close by,—that of the Fishery, or the new mosque, Djama Dejedid, which he said was evidently the work of a master mind, and well carried out externally, as shown by the sketch exhibited, the outlines declaring to the eye of the architect that they were designed by a Christian architect of Greek extraction, who, as tradition recorded, was either bewitched or burned to death by the Turks in the sixteenth century.

In walking through the Moorish quarters one sees nothing whatever of the interior of the houses, and the narrowness of the streets allows little enough even of the exterior to be seen. In the Jewish quarters it is different: there the doors of the houses are constantly left open, and in the various other parts of the town so many houses and palaces are now occupied by the French for public and private purposes of various kinds, that a good idea of the old arrangements can be easily obtained. He then called attention to a sketch of the archbishop's palace, whose exterior, he said, was one of the finest specimens of Moorish work in Algiers, which he described. He knew nothing more beautifully designed or worked out than the small domes of the archbishop's palace or of the beautiful palace of the governor. A curious circumstance struck him, which was this,—that nearly every doorway he saw throughout the town was of the same identical pattern.

The doors inside and outside the houses, no matter where or of what size, were of this same identical pattern, or so near it as to show that it was copied from the same original. The columns, he added, are well nigh as curious. They are nearly always of marble, and the capitals and mouldings very well and boldly carved. None that he saw were antique, or copies of the antique. In the corridors the columns, which are necessarily short, have spiral shafts, as also many of those to the colonnades, as also many of the latter are octagonal about one-third up, and spiral above. The same pattern of tiles, too, is seen everywhere. The design of the large windows is equally curious with the other parts, as they are as invariably square as the doors are circular, and almost always have wide architraves, with ornamental scroll-work. The construction of the houses and marques is simple enough. They are built chiefly of bricks, very hard, about 4½ in. square, and are much better than the bricks now made. When the walls were very thick, each side was of brick, and the interior filled in with rubble. The mortar used was red earth, with a very small portion of lime. The floors and staircases were formed of wooden joists, on which a second boarding was laid. On this was a thick layer of the red earth, then a flooring of stone, marble, or tiles. In the common houses the joists were of round logs only; in the better class they were squared, and the chief beams were moulded. The joists projected through the walls to carry the overhanging parts, and the ends were supported by round slanting timbers, which effectively carried down the thrust to a low level, but without any attempt at ornamental effect. The tiles were of coarse earthenware of a light tint, which was covered with a very thick white: on this the pattern was painted, and then lined in (all by hand), and the whole glazed over.

In respect of modern Algiers he need say but little; for, although there have been great works

done of late years, there is little to interest the architect. The whole of the buildings on the seaboard of the town are new, and most of them erected by our countryman, Sir Morton Peto, to whose zealous officers, Mr. Jackson and Mr. Akman, the author was deeply indebted during his stay, as also to our English chaplain, the Rev. Mr. Guisberg. The steep shelving shore, which till lately existed, has been transformed by them into a series of magnificent terraces, which rise boldly up from the harbour, and which form the roofs of warehouses of great size; the whole producing a combination of grandeur and utility unequalled in effect by that of any commercial town he knew.

He wished if it were only in gratitude for the great good the French have done in Algiers he could say a good word for their architecture, but he really could not; and those who wished to see good specimens of it need not travel so far. One thing he would say, in conclusion: whether the modern Algerian architecture be good or bad, it is clearly French. However, in carrying with them to a foreign land an architecture of their own, the French had gone on the right path, and would leave their mark to succeeding times, as the Turk, the Roman, and the Celt had done before them. But in their ecclesiastical works the French had given up this principle. The cathedral erected on the site of an ancient mosque, and the costly Notre Dame d'Afrique, which overlooks the sea and the town from a most conspicuous eminence, have been built in the likeness, so far as the altered services of religion would allow, of the mosques the place of which they have supplied.

SCHOOLS OF ART.

The Maidstone School.—The attendance at the distribution of prizes in this school was not large. The walls of the ancient room in which the meeting took place were hung with drawings made by the pupils. The Rev. H. Collis read the report. From this it appeared that the school was opened upon the 29th January, 1867, under the care of Mr. J. B. Williamson. Three classes had been formed from the commencement, and 127 students had passed through the school, sixty-two being now under instruction. Builders, clerks, bricklayers, ticket-writers, upholsterers, carpenters, engineers, masons, apprentices (various), schoolmasters, Bluecoat boys, shoemakers, hakers, and surveyors had attended the school. The numbers presented in free-hand drawing were 45—passed, 35; models, 22—passed 18; geometrical drawing, 4—passed, 2. Two of the artisans had obtained two prizes each. The first examination was held in March last. The Government grant had been 14l. 10s., but from the first the school had been self-supporting. The teaching in the school was thorough, and therefore slow,—real progress being aimed at, and not the gratification of unskilled eyes. The report closed with a suggestion that prizes should be offered by the townspeople. Mr. Monckton, in seconding a resolution that the school deserved support, remarked that Woollett, the eminent engraver, had been a pot-boy at the Turk's Head public-house, and commenced his artistic labours by engraving upon a pewter pot. In the Town-hall would be found also the name of Jeffreys, the painter, another native of Maidstone, who painted the altar-piece which formerly stood in All Saints' Church, but was now in the Museum.

The Lincoln School.—The annual exhibition of drawings, paintings, and designs executed by the students of this school has been opened for one week. The number of works exhibited was about 500, exclusive of elementary drawings, hung in groups to economise the room. The distribution of the prizes has also taken place. The mayor presided. The room was well filled by the pupils and their friends, and the general public. Mr. Taylor the headmaster's report said,—“Commencing with the results of the different competitions and examinations conducted by the Science and Art Department, extending from March to August, the following prizes were awarded to all the Schools:—National competition of all the Schools of Art in the United Kingdom,—One national bronze medal, two Queen's prizes, and nine works selected in London for the National Art Competition; nine free studentships to students in the advanced section, admitting them free to all the advantages of the school; eight prizes for light-and-shade drawings from the

cast, &c.; nine prizes for drawings executed within one hour in freehand, geometry, perspective, model, and mechanical drawing; forty-nine certificates for the same; two full certificates.” “The attendance has been for each class,—morning, 29; afternoon, 35; evening, 106; pupil teachers, 26; total number of individual students, 180.” The report of the committee stated that “some alterations in the building have been made during the past year. The staircase has been very much improved, and the ladies' cloak-room also. Considerable additions have been made to the art-library.”

The Manchester School.—The annual meeting and distribution of prizes in connexion with this school have taken place in the Lecture Theatre of the Royal Institution. The chair was occupied by Mr. Thomas Bazley, M.P. The secretary read the annual report, which stated that in the financial affairs of the Institution there was a considerable deficiency, the annual subscriptions, from deaths and other causes, continuing to decline in amount, not a single money donation having been added during the past two years. It was painful to the committee to have to make continued appeals to the public, whilst the internal working of the school, under the judicious and effective management of the headmaster (Mr. Mackley), continued in so satisfactory a state. During the past year Mrs. Abel Heywood had presented the munificent donation of 500l., the interest of which was to be annually distributed in prizes.

Mr. Mackley, in course of his report, said,—

“With reference to the new regulations of the Department, and the establishment of art studentships, I am sorry to say that the measure does not appear to apply to this school, as no inquiries for the privilege have yet been made. At the national competition which took place in London this year, we were so fortunate as to obtain a larger amount of first-class prizes than any other school in the United Kingdom, although the number attending this school is not nearly so large as several others which competed. Many of the students are now applying themselves to art with the sole object of becoming draughtsmen. At the second-grade examination, which took place here in March last, fifty-nine ‘passed,’ and twenty-five obtained prizes; and at the national competition held in London, one gold medal, four silver medals, three bronze medals, and five third-grade prizes were awarded.”

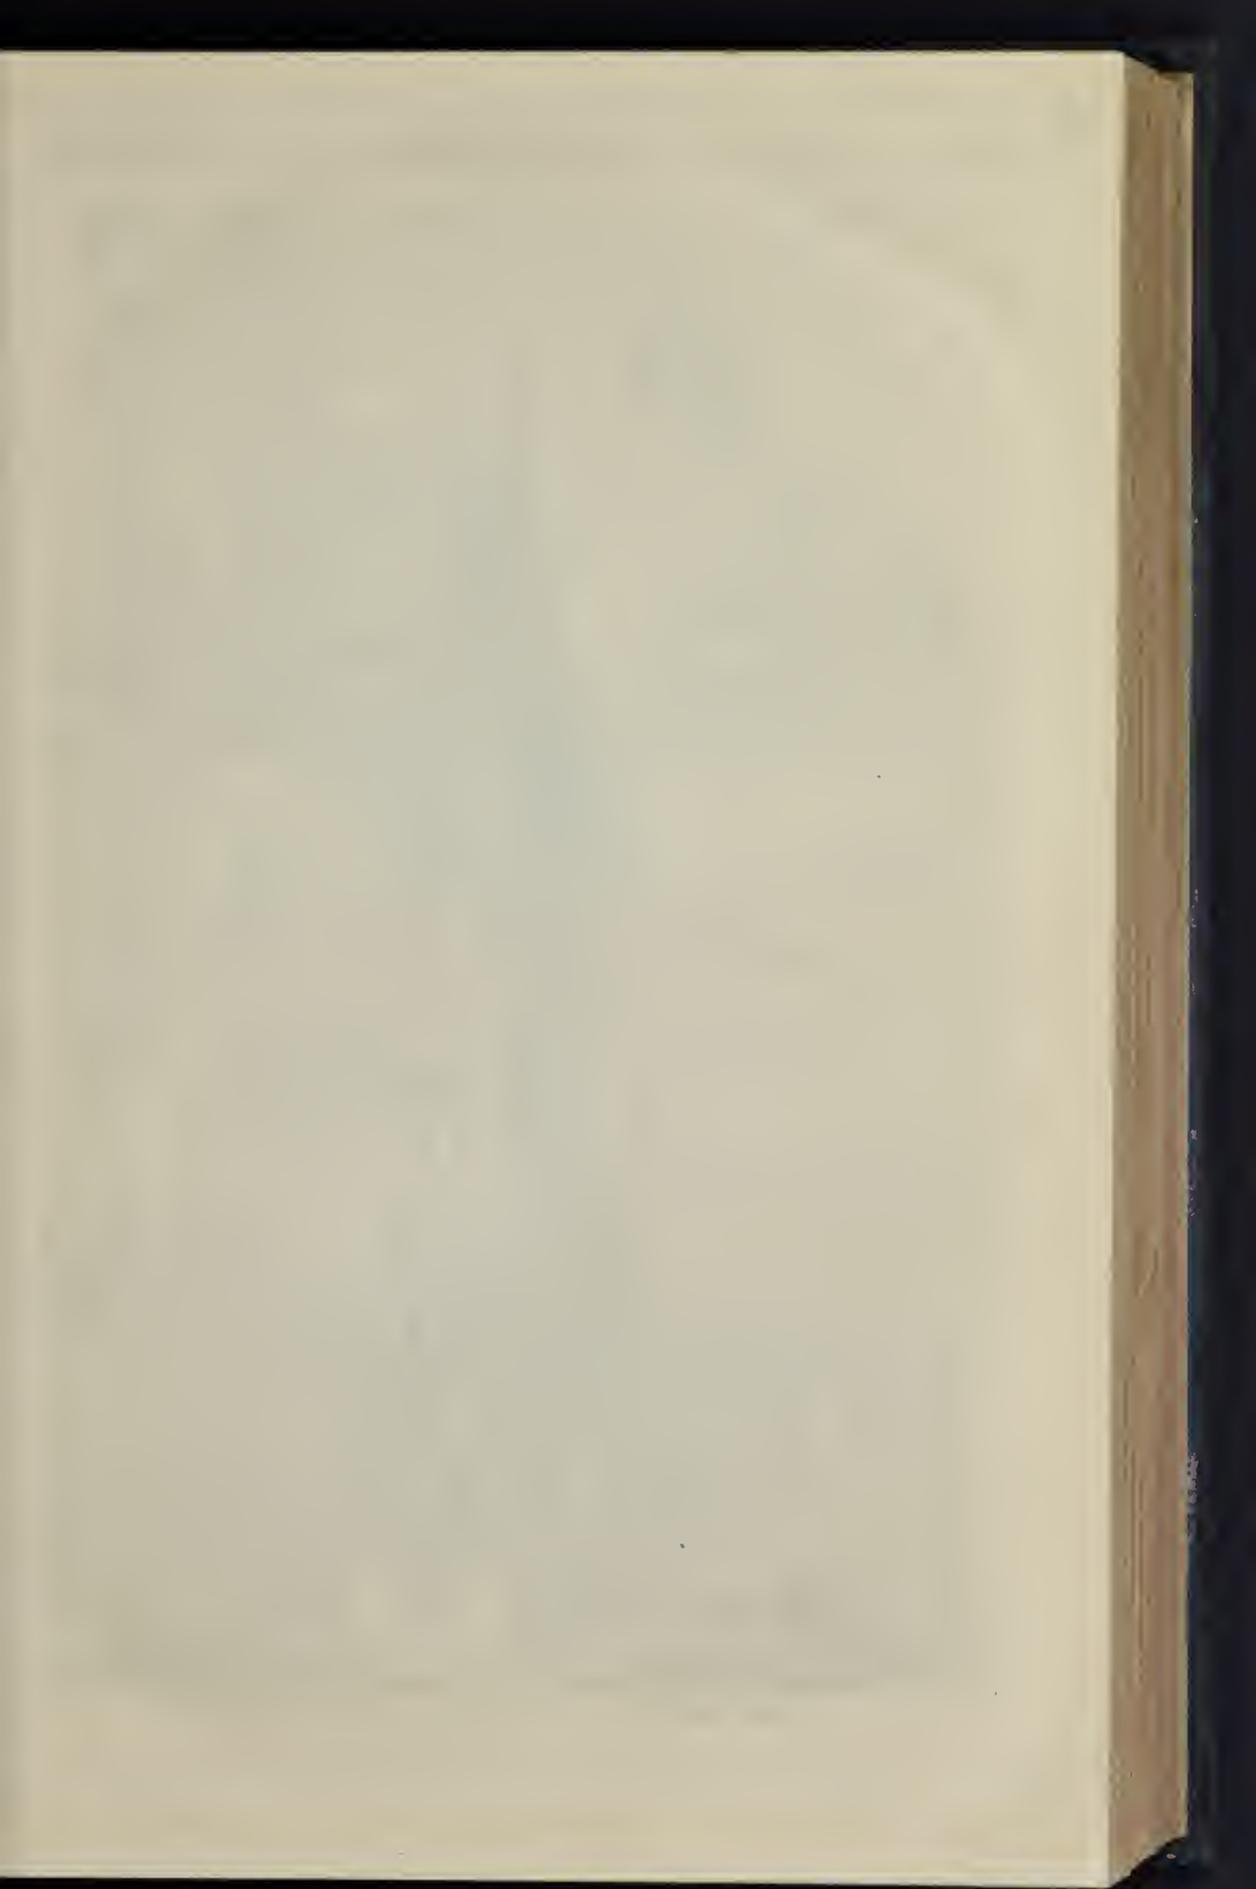

MEMORIAL CLOCK TOWER, LEICESTER.

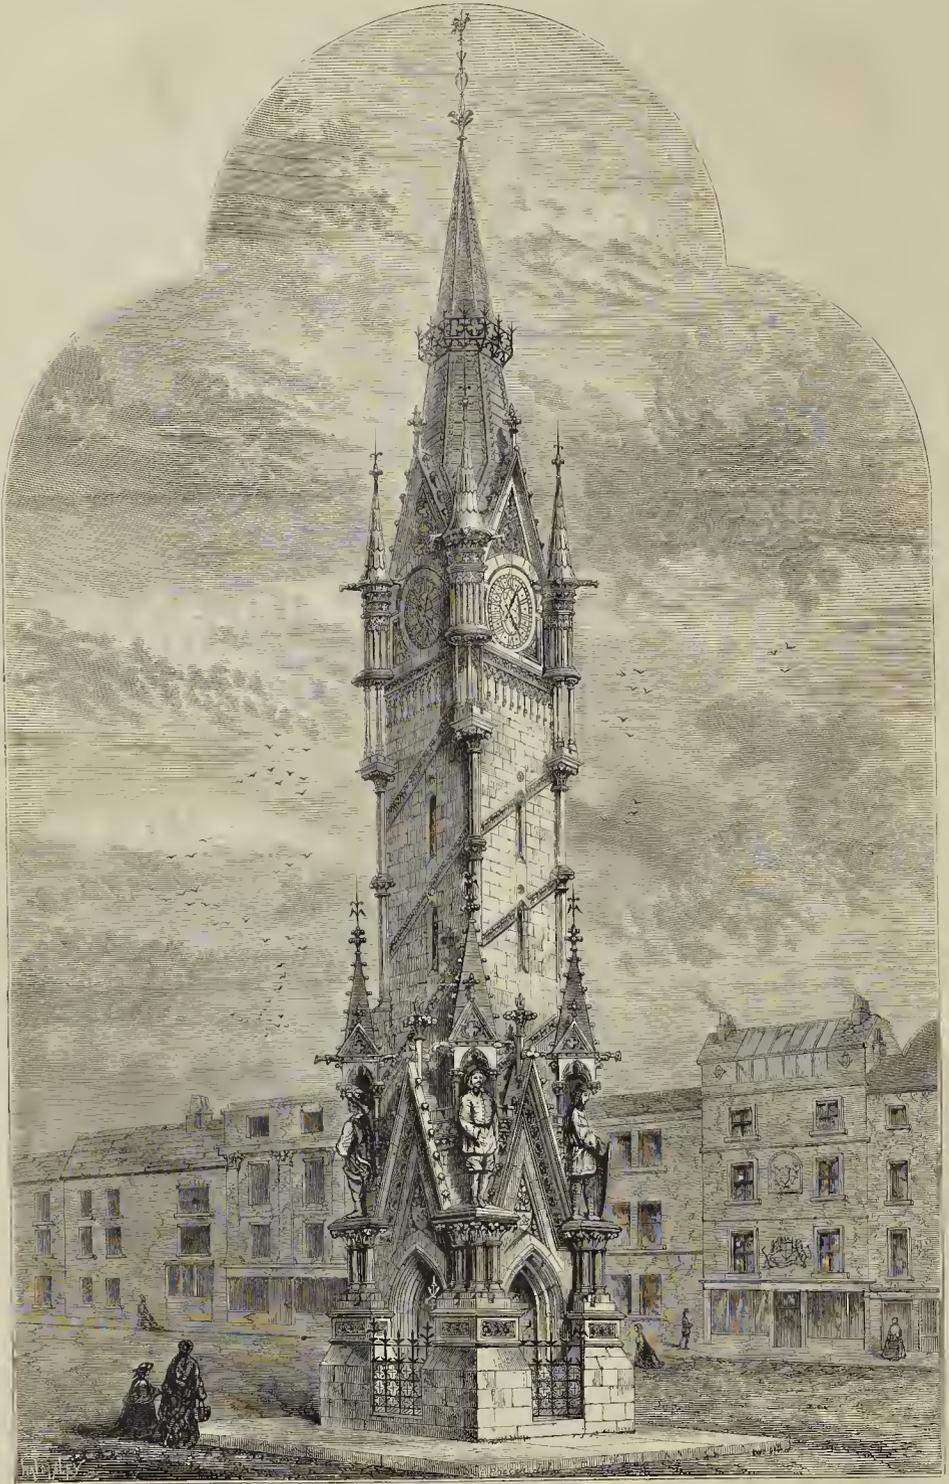

About a hundred designs were sent in competition by architects for the above work, and were publicly exhibited. The town-council having consented to supply the clock, lamps, foundation, and lighting, the subscribers' committee felt it was due to that body that they should have a voice in the selection; the committee, therefore, adopted three designs by ballot, and from these the council selected the one by Mr. Joseph Goddard, of Leicester, architect. The total height of the tower is about 80 ft. The figures are 10 ft. 8 in. from the platform, and 7 ft. in height. The larger shafts are of polished granite, and the smaller ones of polished serpentine marble. The base is of Mount-Sorrel granite, with hammer-dressed face. The figures are of Portland stone, and the remainder of the edifice is of stone from the Heiton quarries. The style is Decorated Gothic. The four benefactors represented on the building are Simon de Montfort, Earl of Leicester; William Wigton, the founder of a hospital for aged men and women; Sir Thomas White, whose monetary loans to tradesmen are still granted yearly; and Alderman Gabriel Newton, founder of the “Green-coat School.”

But a little more than a year ago some half-dozen gentlemen met by invitation, when a small committee was appointed, with a working honorary secretary, the pecuniary results of whose exertions show receipts by subscription of over 872l. The total cost will be about 1,000l. The corner-stone was laid on the 16th of March last, and the top stone fixed on the 8th of June. The work has been executed from the designs and under the superintendence of the before-mentioned architect, by Mr. Barfield, of Leicester. The clock, which is understood to be a good piece of work, was made by Messrs. Gillett & Bland, of Groydon.

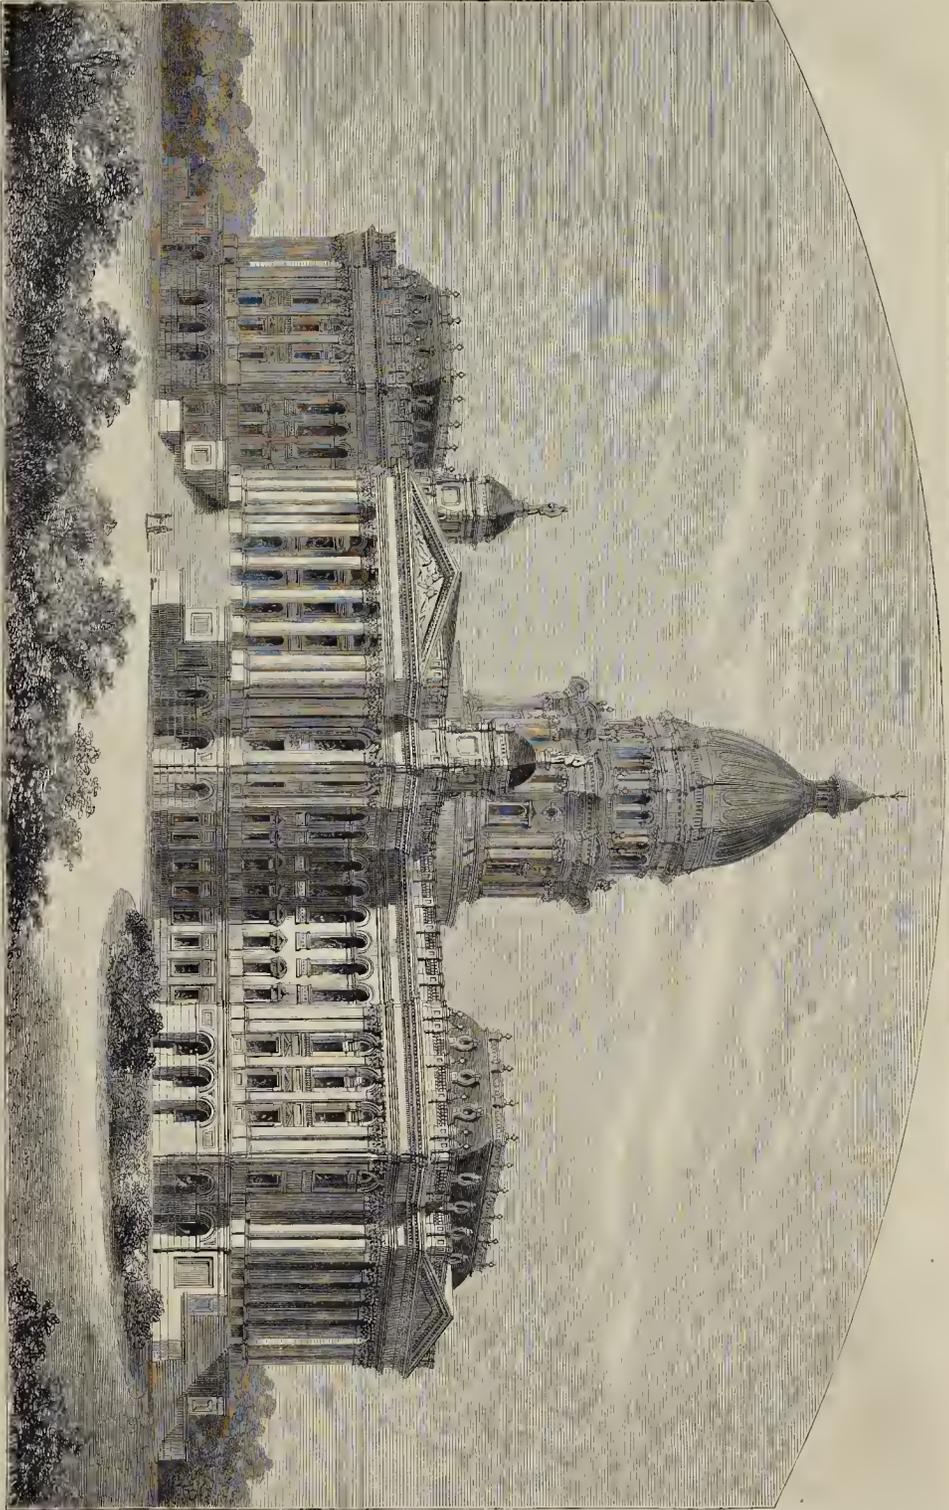

Progress in the United States.—“First-class New York residences” now contain a billiard-room, a chapel, and a theatre or concert-saloon.

The spire of the new cathedral in Pittsburgh is to be surmounted by a hollow iron cross, 14 ft. in height, which is to be illuminated by 300 gas jets.

MEMORIAL CLOCK TOWER, LEICESTER.—MR. JOSEPH GODDARD, ARCHITECT.

THE ILLINOIS STATE CAPITOL: SPRINGFIELD, UNITED STATES OF AMERICA.—Messrs. COCHRANE & GARNSBY, ARCHITECTS.

THE NEW STATE CAPITOL, ILLINOIS, AMERICA.

WE give a view of the New State Capitol now in the course of erection in Springfield, the capital of Illinois, in the United States of America. The ground plan of the building is that of the Greek cross, arranged to present four fronts of similar style. The order adopted is the Corinthian. The north, east, and southern fronts of the superstructure are each to be supplied with a portico of eight detached columns in front, the outer two on each side being coupled. The western façade presents the same exterior, except that when entering the building you pass into the basement through a stylobate, the portico not projecting as far as on the opposite front. The tambour of the dome comprises two stories, the first ornamented with disengaged columns in pairs; and the second with pilasters. From the top of the latter springs the dome, surmounted by a lantern. There is a balustrade on the top of the entablature of the first story, consisting of pedestals and balusters. The height from the ground to the top of the lantern is 254 ft. The dome at its base is 83 ft. in diameter, outside the walls. The building is 354 ft. long by 240 ft. wide; the height is 95 ft. The interior is to be finished in the same elaborate style. Messrs. Cochrane & Garnsey, of Chicago, are the architects; Mr. J. W. Ackermann (late of London), acting as draughtsman. The corner-stone was laid with Masonic ceremonies on the 5th day of October, 1868. The whole structure will cost 3,000,000 dollars.

THE TECHNICAL INSTRUCTION MOVEMENT.

THE Workmen's Technical Education Committee, appointed at a conference held at the Society of Arts, have just issued a report. The committee express a decided opinion that there is at present no provision in the metropolis for scientific and detailed instruction to workmen, the fees charged at the School of Mines, the Royal School of Chemistry, and the evening classes at King's and University Colleges, being beyond the means of those receiving weekly wages, and the artisan class being practically excluded by the lectures being given in the daytime. The committee, admitting that the Department of Science and Art encouraged the formation of science classes, complain that it does not provide the means of instruction. The committee recommend the establishment of science and art classes in the industrial quarters of the metropolis, the formation of technical schools for instructional detail where work shall be actually produced, and central schools for foremen and managers, like the *École des Arts et Métiers* in France, as well as a normal school for the training of science teachers, in connexion with the existing Science and Art Department. Finally, the committee strongly urge the paramount importance of establishing museum schools. Having obtained the services of Mr. J. C. Buckmaster in organising such classes, the committee urgently appeal for aid to all classes of the community, and also to Government, while they express dissatisfaction with the report of the recent select committee of the House of Commons on the subject.

MANCHESTER ARCHITECTURAL ASSOCIATION.

THE opening meeting of the Session was held in the Society's rooms, Corporation-street, December 15th, the president, Mr. Isaac Blackwell, in the chair. Mr. Darbyshire, the Honorary Secretary, read the annual report, which reviewed at some length the operations of the Association during the past session. Several interesting papers had been read, including one by Mr. Horner, of the Liverpool Society, which paper had been printed and circulated among the members. The report referred to the Students' Class, recently established in connexion with the Association; and from the report presented to the Council from the Student's Class Committee, it would appear that the efforts made some twelve months ago to establish these classes have been attended with a success scarcely expected by those most interested in their formation. The class for design and construction is presided over by Mr. J. Battye; Mr.

Gregory conducts the modelling; Mr. J. Redford the free-hand drawing; and the services of Mr. Bagot have been secured for instruction in water-colour drawing. The classes are well attended. An exhibition of the students' production has been held, and it is hoped that the study and instruction these classes afford will be of considerable benefit to the younger members of the profession located in Manchester.

The president read his inaugural address, which touched upon matters of local interest, and referred to the facilities now offered by the association for the study of those branches of an architect's education not to be had in the routine of the office.

GLASGOW ARCHITECTURAL SOCIETY.

THE SEWAGE QUESTION.

THIS Society met in their rooms, 138, Bath-street, last week, Mr. Campbell Douglas, president, in the chair. Mr. John Honeyman, jun., read a paper on the sewage question, in which he advanced the opinion that the most obnoxious sanitary defects would not in any measure be remedied by the purification of the river. The question, as he understood it was, "What are we to do with our sewage, and especially how are we to deal with it in the earlier stages of its existence, so as most effectually, and comfortably, and healthfully to get rid of it?" The fact was the sewage had done its worst before it made its appearance at the harbour at all. In its long and, it might be, sluggish course it had become almost completely oxidised, and had contributed its quota to those poisonous products of putrefaction which, unsuspected, carried sickness and death to many a home. Arrived at the river it was comparatively harmless, though still offensive. The purification of the river, therefore, might be safely left alone till we had overcome the more serious defects of our system—want of proper arrangements for flushing, ventilating, and trapping the sewers. Having made sure of this, we should go on to provide for the ultimate disposal of the sewage. Although he denied that there was any danger in continuing to send the sewage into the river, he considered such a course to be exceedingly objectionable. While free to make as much use as possible of the river, we were not free to abuse it—we were bound to let it pass on through the city undefiled. If the water-closet system were retained, we must make up our minds to provide a suitable outfall for the sewers. But this was probably necessary in Glasgow in any case. He thought the scheme proposed by Messrs. Bateman & Bazalgette ought to be carried out, and he had every confidence that in such hands it would prove thoroughly satisfactory. It was of course a difficult and very expensive undertaking, but most really good things were expensive, and he hoped that in this they would be preserved from any "cheap and nasty" substitute.

SANITARY MATTERS.

Kilderminster.—The present state of the public health here causes considerable anxiety to the inhabitants, who naturally inquire how far the alarming increase in the rate of mortality is due to the want of sanitary precautions by the local authorities. An official report by Mr. Stretton, the medical officer of the Poor-law Union, presented to the Board of Guardians, throws some little light on the subject. This document calls attention to the bad water and inefficient drainage of the town. No attempt, it seems, has been made by the local governing body to remedy the former, but the medical officer bears willing testimony to the fact that where any efforts have been made to improve defective drainage, they have invariably been followed by a decrease of sickness in the locality. He suggests that, as the town authorities have so long disregarded "the constant gratuitous admonition of the medical profession" on this vital question, a special commission of inquiry should be obtained from London. He reports that from 1st October to 21st December last there occurred at least 350 cases of preventable diseases; and at least fifty have died, while "very many poor wretches have been left deteriorated in health for life." The Board of Guardians, though apparently also slow to move, have consented to appoint a deputation to urge

upon the Town Council the desirability of introducing an efficient system of town drainage and water supply.

Bromley.—A system of drainage is now being agreed upon by the local Board of Works, who have purchased 10½ acres—part of Holloway Farm—to which the whole of the sewage of Bromley is to be conducted, and used on the irrigation system. Whether it is to be conveyed there by gravitation or pumping, is not decided upon. Mr. Lawson, C.E., is in favour of the former; and Mr. Jacobs, the engineer and surveyor to the Board, of the latter. The Board have left these two gentlemen to agree between themselves, and by their opinion the Board will be guided.

THE TRADES MOVEMENT.

THE strike of masons at Aberdeen has terminated, and an arbitrator has been appointed mutually by the masters and workmen to decide upon the wages question. Parties have been named as witnesses by the operatives, and the chairman of the operatives has, in the name of the combination, formally declared the strike at an end.

A case of considerable interest to the building trades, though only involving a small sum (£s. 2d.), was brought before Mr. Boushara, in the North Shields County Court, lately. A joiner summoned Mr. Addison Potter, of Willington Quay, for the recovery of the sum mentioned. The plaintiff, with some other men, had been engaged in out-door joiner work in Mr. Potter's factory, and a day's work in such circumstances is from daylight to dark. Mr. Potter has a workshop where joiner-work goes on before daylight and after dark by gas, or from six to six. The plaintiff, with some other men, had been working in the open air; but between two and three o'clock in the afternoon, the material necessary to keep them employed ran short, and the foreman of the joiners told the plaintiff he must go into the workshop and get some doors ready. He went, but at dark he knocked off. Next morning he returned, but there was no employment for him, and he had to go home. He summoned Mr. Potter for the quarter day he lost. The Judge maintained that he was entitled to it. It was quite clear that the plaintiff was employed upon a definite class of work, viz., in the open air, the time for which was from day-break to dark; and the defendant having failed to keep him supplied with material, it did not entitle him to order him into the workshop to get ready material that should have been got ready for him, except in the time for which he had been working previously. He gave judgment for the plaintiff with costs, and his day's pay as a witness.

A deputation of working men who are shareholders in a "Mutual Land, Emigration, and Colonisation Company," have waited upon the American Minister for the purpose of soliciting his advice and co-operation with reference to an emigration scheme which has been devised by that company, with the view of ameliorating the condition of the artisans of this country. The deputation wish to found a colony in Nebraska, the land to be held on Communistic principles; but Mr. Johnson could not assure them that they would be allowed to do so in any part of the United States. He promised to communicate with the Governor of Nebraska, and further their object in any other way within his power.

NEWS FROM MELBOURNE, VICTORIA.

ABOUT six miles from Melbourne, beyond Hawthorn, lies the small but rapidly-increasing village of Camberwell. Five years since some members of the Anglican Church commenced the erection of a small edifice for public worship there. In a very short time it became necessary to enlarge this building. Then followed the erection of a parsonage and a common school. It has become necessary to enlarge the church again, and there is no room for the children attending the Sunday-school, who exceed 120 in number. Plans have been prepared by Mr. Billing, architect; and if the works are completed as proposed, it will make Camberwell one of the prettiest villages in the suburbs of Melbourne. The Rev. C. Isaacson, the present incumbent, has already raised a large sum towards the building fund. The Melbourne Meat-preserving Company's works, at Marlybroug, on the Salt-water River,

near Melbourne, consist of a group of buildings, some old and others new. The establishment is capable of disposing of 3,000 sheep and 50 head of oxen per week. In a room, 90 ft. long by 30 ft. wide, the slaughtered animals are cut up into joints. They are then sent to the kitchen adjoining, where they are cooked. Over the cooking-up room is the tin-shop, capable of accommodating forty tinsmiths, where tin is soldered into canisters, at the rate of about 12,000 per week, by twenty tinsmiths. Adjoining is a machine-room, where the tin is cut up, rolled, stamped, &c. The meat is put into the canisters in the kitchen, and carried up by a lift to the preserving department to be soldered down, a hole being left for the extraction of the air, after which they undergo other processes, such as cooling the canisters, testing, &c. The whole of the alterations, new buildings, &c., have been carried out under the inspection of Mr. A. Purchas, by Messrs. Piggem, contractors, North Melbourne. The boilers and engine have been supplied by Mr. Enoch Chibber, while the preserving apparatus, soap-vats, &c., have been constructed by Messrs. Robison, Brothers, of Flinders-street, from designs supplied by Mr. Ritchie, the manager of the company.

The Duke of Edinburgh, as captain of the *Galatea*, has reported very favourably of the meat prepared by this company, and the Government is giving it a trial. We may here add, that it is to be hoped the spicing of meat, such as that which has been prepared in Australia and sent home since we urged this as one available form of preserving Australian mutton and beef, will be more skillfully done than that lately sent home, which the writer has tried, and found to be quite unfit for human food.

The Colony of Victoria.—The area of the colony is estimated at 56,644,160 acres, or 80,944 square miles. At the commencement of the year 1867 nearly 7,500,000 acres had been parted with in fee simple, and the roads, &c., in connexion therewith made up the quantity to 7,710,438 acres; 2,571,172 acres were let on lease for agricultural purposes at a rental of 2s. or 2s. 6d. per acre per annum, and roads, &c., in connexion therewith made up the quantity to 2,699,758 acres; 226,150 acres were held under license for residence and cultivation in the vicinity of the gold-fields at a rental of about 2s. 6d. per acre; 1,848,444 acres were occupied as commonage, principally around the various gold-fields; 20,848,623 acres were available land held under pastoral licence by squatters for grazing purposes at a rental of 2-0-7d. per acre; 6,850,000 acres were unavailable land held by squatters in connexion with the above; and 15,463,747 acres were waste lands unoccupied. The Crown parted with the fee-simple of only 104,684 acres in 1867.

IMPORTANT DECISION ON A CLAIM AGAINST A BUILDER FOR HOARDING IN.

At the last sitting of the County Court at Margate, before Mr. W. C. Scott, the judge of the court, a claim was tried by Mr. W. Hills, a partner, against Messrs. Brown & Sons, of Margate, builders, for the sum of 50*l.*, for loss of trade and damages suffered by the plaintiff, by reason of the defendants having erected a hoarding, and carried on certain building operations contiguous to the shop occupied by plaintiff, &c.

Mr. Towne, of Margate, appeared for plaintiff, and Mr. John Thomas Moss, of London, for the defendants. A large number of witnesses were called on each side, and the case occupied several hours before the court.

Plaintiff's case was, that defendants were employed as contractors to erect certain maltings and brewery premises for the eminent brewers, Messrs. Cobb & Co., in Trinity-square, Margate, under the direction and superintendence of Mr. W. Lane Sear, the architect to the firm; and that the hoarding erected by defendants, and the dust blown by the building operations, kept away custom from the shop, and damaged his stock and business to the amount of 50*l.*

The case was somewhat peculiar from the fact that the respective premises stand at right angles to each other, in the form of the letter *L*, the short leg of the *L* representing the front of the cutter's shop, and the longer leg the maltings; the entrance to the shop being in the internal angle formed by the two buildings, and the hoarding having been erected parallel to the longer leg, to the distance of 10 ft. from the plaintiff's shop-window, whence it was returned in a slanting direction to within 3 in. of the shop door.

For the plaintiff it was contended that his shop-window having been blinded by this hoarding, for some three months, and much carting going on in front of his premises, which were also damaged by dust, he had of necessity suffered in his trade, and that such damage having been occasioned by work carried on by defendants, they should be held liable for his loss.

For the defendants, Mr. Moss contended himself with calling evidence to prove that no special negligence was

to be imputed to the defendants, who used the customary mode of hoarding, and turned it inward (at some inconsiderable distance from the site), at such a distance from plaintiff's window as to allow reasonable access to his shop window and door; and contended that the carrying away of some rubbish, caused by pulling down an old building, which occupied part of the site, and the dust caused thereby, were not matters in respect of which (although, no doubt, very inconvenient and annoying to the plaintiff), the defendants should be held liable to make compensation in damages.

The court, without any hesitation, adopted this view, and held that no special negligence or carelessness having been proved against the defendants, the case must be dismissed with costs against the plaintiff.

Verdict accordingly.

THE "ART MUSEUM."

In continuation of my notes, in the *Builder* of December 19th, let me add the following remarks on the South Kensington Museum. But, first of all, Why such a long name as "South Kensington Museum?" As this most delightful of all collections is now constantly in everybody's mouth, it would be only kind to give the said "everybody" a rather smaller mouthful. The South Kensington Museum is, *par excellence*, the Art Museum of London; then why not call it so? "The Art Museum" would be sufficiently definite for all general conversation, directing to servants, carriages, and so forth; and when a more precise address were needed it might be worded, "The Art Museum, South Kensington."

There is an abbreviation of the long title creeping into use, which must not be tolerated, namely, "the S. K. M." This is too suggestive of skim-milk, and is, therefore, altogether inappropriate as applied to our art-museum, where everything is *crème de la crème*.

I remember some years ago, when two utterly incongruous things were going the round of the London papers,—the *Great Eastern* that would not start, and the clergymen who would not stop in their silly practice of sounding as a separate syllable that detestable, sanctimonious "ed" at the end of their words throughout the Church service,—an amusing computation was made in an article in the *Times*, to the effect, that if all the muscular energy which was annually wasted throughout Protestant churches in pronouncing the exploded and silent "ed" could have been hrought to bear on the *Great Eastern*, it had moved her from her moorings long before.

Soon after that article appeared, most clergymen had the good sense to drop the objectionable termination, greatly to the increase of the manliness and good taste of their elocution; and now, I am thankful to say, it but seldom offends the sensitive ear, that is as keenly alive to the musical inflections of the human voice as to the sweet notes of a fine-toned organ: the best of both of which, by the way, is not too good for employment in God's house. The application of this long digression is that I hope the *Builder* will raise its powerful voice to spare all of us the present useless "waste of muscular energy" required for repeating the long title, "South Kensington Museum," and transform it into the short, sharp, and appropriate cognomen, "Art Museum."

In my former notice I was too hurried to do full justice to the case of exquisite specimens made at and lent by the Royal Porcelain Works, Worcester. The centre jewelled vase, or wine-cooler, resembling an adaptation of Henri Dent ware, is a charming thing, of elegant form and proportions, and the admirable, high-relief heads, on deep blue plaques, call to mind Sansovino's beautiful bronze sarcophagus door in St. Mark's, Venice. The helmeted head is especially pleasing. The large pilgrim-bottle, with a nicely-drawn miniature in greys,—*"Orfèe aux Enfers"*, I presume,—is another gem; the gilded, winged, semi-figures at the junction of the body and neck of the vase have a beautiful seraphic expression on their perfectly original faces. Another lovely thing is the tall, delicately-shaped jewelled jug, with the broad grey band around it, on which is painted most exquisitely a procession of coloured figures, the subject being, as the inscription under the lip of the jug tells, "Diogenes seeking for a Man" (Quæry: seeking for an honest man). The handle is formed of a terminal figure gilt, with flowered blue drapery, of a singularly metallic, or rather unmetallic appearance; and the stem and foot have a delicate scrollwork in black, running over a gold ground, relieved by four bosses of foliage in light blue, harmonizing with the

drapery of terminal figure. The ewer and tazza, with Limoges grey designs on deep blue ground, taken from the Art-Union work "The Norman Conquest," has been already mentioned. Pity Mr. Macleise did not place his kneeling Harold in a less distorted attitude, and that the proprietors of the Worcester works did not select a more pleasing illustration from that fine series for the decoration of their otherwise so elegant ewer, the tazza of which is very beautiful. In an entirely different style the tea-service, with delicate garlands on white ground, and dark medallions, containing charmingly painted heads, is well worthy of notice and commendation.

Before closing, I must draw attention to the magnificent slab of Roman mosaic, mounted as a table, and lent by Mrs. T. Hope. It stands immediately on the left, after descending the three or four steps that lead into the grand hall of the Art Museum. The ground is white, covered with most delicate scroll-work of conventional flowers and leaves, with two large masks; three medallions are placed along the centre of the slab, each bearing an elegantly-shaped vase or brazier. A volume of smoke rises from two braziers, formed of so minute tessera, and of such tender gradation of shade and colour, as to seem almost impalpable, and to deceive the beholder into believing the vapour is in motion, and that the slab is seen athwart the curls of smoke. The bordering of this slab consists of a cleverly-involved double fret, the two frets being elongated, and an open box-form inserted between, which has a novel and singular effect. At the corners where the frets join, and especially at the lower corner of the right-hand side, the pattern is very well arranged, and forms beautifully sharp angles. It is singular that, possessing such great manipulative skill, the mosaicist was ignorant of perspective, as witness the laurel wreath—which looks as if standing up, instead of leaning against the brazier—and the front leg of the tripod.

Apreros of tripods, how excellently the three human feet and legs, with the classic short skirt forming the junction, support the bronze Etruscan and lamp, lent by the Hon. A. G. Ponsenby, and which will be found in one of the glass cases wherein the Lowestoft china was lately exhibited.

ART-LOVER.

"HOW TO KEEP OUT THE WET."

ALLOW me to make a few "practical" remarks upon this subject, and in reply to the letter from "Anti-Sham" in your last paper, as I can speak from experience in nearly all the counties of England.

1st. The house built by "Anti-Sham," with a fire-brick outside facing to a "slaty-rubble" stone wall, may be said to be built *inside* out. Bricks, generally speaking, and fire-bricks in particular, are of a porous nature, and the wet coming against them will travel both vertically and horizontally; whereas a "slaty" formation of stone must necessarily be of a laminated texture, and will only allow of wet travelling horizontally; and if the outer edge of the stones have a willing inclination downwards, the wet will not run in at all.

2nd. Where a blue brick, like those made and used in Staffordshire, with a glaze on them, can be met with, it will do as an *external* facing to a stone wall.

3rd. If stone of a flinty nature or glazed bricks are used as an external facing, it is essential to attend all the more carefully to the pointing, both as to form and quality, in order to keep out wet, and to have the walls lined with common bricks or porous stone internally, to prevent the condensation which would otherwise occur on the plastering during changes of atmosphere.

4th. The pointing, whether of Portland cement or stone-lime (mixed with clean sharp sand) has much to do with keeping out the wet. It is frequently made too wide, overlapping the edges of stonework or brickwork, so that every drop of rain is caught in the tiny fissure, which will, in such case, occur at the upper edge of such pointing.

It is difficult to get bricklayers and wallers to point a joint back *behind* the face-line of the wall; but it should always be insisted upon in exposed positions; the upper edge of each point should be pressed inwards, the lower edge coming forward to the face of the brick or stone below it. To all practical men this is known as "weathered" pointing.

5th. After all the care that may be taken in

the construction of solid walls, wet will sometimes penetrate. The only safety is in the hollow wall, banded with twisted iron ties; or still better, with Jennings's glazed ware bricks, at all points of contact between outer and inner portions of walls, not excepting the jambs to windows and doorways, and the angles of the building. Over the lintels to doors and windows slates bedded in cement, and cemented over, should cover the backs of all relieving arches where exposed to droppings of wet in the cavity of the walls.

Gth. A difficulty with the stonework used in cills, jambs, mullions, and heads, still occurs, which should have some effectual coating applied externally.

I have, during the past autumn, and in previous years, had ocular demonstration of the wet striking quite through 9 in. and 10 in. thickness of Box ground, Bath, and other stonework, turning green and mouldy on the inside, as well as causing dampness to joinery attached, and to plastering or internal jambs, &c.

W. H. ESPENETT.

FALL OF HOUSES, LIVERPOOL.

SIR,—In a new street called Fullford-road, at Fair-field, a suburb of Liverpool towards St. Felix's, were two double-fronted houses in course of erection. These adjoined each other, and were the beginning of that side of the street. They were up three stories above ground, and nearly ready to receive the roof. The front and back walls were up to the eaves, the party-walls up and topped, and it only remained to bring up the internal walls. This was being done from a scaffold loosely piled up off the top floor. We were had a great deal of rain here lately. On Saturday evening it began, and rained hard and continuously till Monday at noon, and again for two hours very heavily during Monday night. The work was done on the walls during Monday; and on Tuesday morning, before it was fairly light, four bricklayers, with three labourers, attended to their work, and had not well begun the whole of the internal walls when a heavy rain fell, and the poor fellows were precipitated a depth of at least 30 ft. amongst the falling joists andrickwork. One was got out dead; another, I fear, died during the last night; and others are severely injured that they are not expected to live.

The cause of the accident was undoubtedly the looseness of the walls, and the want of bond. In the basement the wall was 9 in., but from the ground-line to the roof it was only 4½ in., with no bond of any kind, although the joists of therick rooms rested in it. The joists of the front rooms are laid in the other direction parallel to 4½ in. wall. This wall, then, with the other, forming one side of staircase, and which was 30 ft. high in 4½ in. work, seems to have yielded like a sheet of paper, and fell.

Work in London is bad enough, but dry-work here is worse. There is, I believe, a surveyor for the district, which is outside the boundary!

G.

BOSTON CHURCH CHIMES.

SIR,—I read in your valuable paper of Dec. 18th a letter from Mr. Thomas Walsley, highly complimentary to the Boston Church chimes, and I was much interested in such matters, and I determined to visit the town and hear them, realising myself a great treat, and expecting, from the tenour of his letter, to hear music of the highest good citizens of Boston might be justly proud of. I much regret to say that my gratification was in reverse ratio to my expectations. I was a jumble, I venture to think, was never in music before; and on all sides I heard numerous expressions of disappointment, not very disgust. The tone of the bells is undoubtedly very fine, with the exceptions, as pointed out by Mr. Walsley. This much every one allows. Having very carefully studied the subject, and being fully convinced of the practical value of the principle contained in Mr. Walsley's patent, I was anxious to see so large an application of it, and, upon asking, was courteously admitted to the machinery-room. My opinion of the value of the principle was confirmed by my visit; but I venture to think that the mode of applying is most defective and faulty. The result, without other con-

siderations, would certainly bear me out in this assertion. Your correspondent seems to imply in his letter that the barrel ought to be made of horizontal bars of metal, between which the pins could be shifted by loosening the screw-nuts underneath, and not of mahogany "pricked" as now, and that therein lies the great fault.

This, to my mind, is one of its greatest recommendations, that with pins no larger than ordinary pins for domestic use, bammers of 3 cwt. and 4 cwt. can be discharged upon bells with the greatest precision, and that any number of barrels can be pricked and momentarily applied and the previous one preserved; whereas metal barrels, as he desires, would be much larger; and when once the pins were shifted, the same tune could not be played again until the pins were readjusted.

I will, in a future letter, if you will kindly allow me, state my reasons for thinking that the present result is so very unsatisfactory, and thereby endeavour to assist those who are desirous to see introduced into this country open-air bell-music which it shall be a pleasure to listen to, and not, as notably at the Royal Exchange, and Cryptologic Church, London, and St. Patrick's, Dublin, miserable failures. To show you how much dissatisfaction is expressed in Boston, I will state that I was asked by persons who have subscribed largely to the fund for supplying the chimes, to take the matter up on public grounds, and see whether something cannot be done to get them some music fit to listen to for the large sum of money expended, or stop the public nuisance altogether.

G. L.

WET THROUGH WALLS.

SIR,—About two years and a half since I applied the soap and alum process, as recommended by you, to different parts of three houses much exposed; in each case it has been a failure, the heavy rains having beaten completely through the walls, which were only 9 in. Nothing else could be expected. Time and weather will wear out anything,—nothing will entirely resist the weather. The owner of one of the houses called my attention to this matter last week, and I examined the walls. At the top of the house, under some brick and mortar were plastered, and run down as if it had been poured from the roof of a water-pipe. I advised him to give the brickwork and Bath stone dressings a coat or two of linseed oil when sufficiently dry; but even this will not last for ever, as the water and atmosphere will destroy its resisting qualities, and then the process must be renewed. A little more attention to the battening of walls is, I believe, desirable, the battens should be kept at greater distance, and less mortar than between the laths. Some plasterers are not so particular in this as they might be. It was evident at the house in question that the key of the work was in some places in contact with the wall.

With regard to "Anti-Sham" in your letter, he must not be surprised. In the winter season of 1865-6 there was much rain. I was working at a new house at Moreton, near Dartmouth (see exposure to Dartmouth is no joke), the walls were 20 in., or 21 in., built of granite rubble masonry with granite sand, much harder stuff it is difficult to find. The incessant rain beat completely through, streamed down, and settled on the floors in pools. In this case it did not come through the stone; the mortar, I take it to be, was the vehicle that conveyed the water through; nor do I believe any walls impervious to wet. Mortar, make it of what you may, will absorb moisture; and hence, if the moisture be continued for a sufficient time it will penetrate the mass.

I recommend "Anti-Sham" to try the oil; it will, perhaps, alter the colour of the freestone, but there is no spoil and all the evils attendant. I should not put any colouring with it whatever, and in a little time the alteration of colour will not be so visible. I believe the soap and alum will answer if repeated every two years, but care is required in laying on to prevent froth. The solution should be used as hot as possible, directly it cools it becomes frothy, and should be reheated; a thin flat brush is the best to lay it on,—better than a two-knot; it should not be worked to and fro, but dip the brush into the pot and work it upward with a pressure, which will cause the solution to run down and fill up the pores; yellow bricks will show it least.

NATHANIEL BESLEY.

"OYSTERS O!"

WHITTABLE and oysters have been noted for their plumpness and pearly lustration in our. Poor, lean, insipid oysters are brought from Jersey, and other places, and deposited at the bottom of the sea off Whitstable and the Isle of Sheppy; and in a short time they, too, acquire the same flavour and agreeable flavour. What is the cause of this? It may be owing to the healthy nature of the sea water, or to the sea-water by the locality. This blue clay is of the same character as that which overlies the bed of chalk under London. If this theory be right, would not the oysters, sold in the oyster-shops, be better fed, and improved in flavour, by putting a lump of this blue clay in each tub over night? The experiment is simple and worth trying. In the event of success, probably some pool-natured oyster dealer would be kind enough to forward the writer a barrel of them for the suggestion.

J. P.

ARCHITECTS' ACTIONS.

Liverpool: Fisher v. Jackson.—This was an action for commission, brought by the plaintiff, an architect and surveyor, against the defendant, Mr. Jackson, a landed proprietor at Birkenhead, and formerly M.P. for North Derbyshire.

Mr. Quaife, Q.C., and Mr. C. Russell were for the plaintiff; Mr. Hoiker, Q.C., and Mr. Leofric Temple for the defendant.

Plaintiff's claim was for 150*l.*, which he grounded on a special contract. It appeared that it was the defendant's custom, in selling his land to builders for villa or other sites, to advance the buyers' money while the buildings were in course of erection. In April, 1864, the contract out of which this suit arose was entered into between defendant and plaintiff, whereby it was agreed that the plaintiff should act as surveyor to the defendant, it being his duty to inspect the buildings so being erected on Mr. Jackson's property, and report to him their value, so that he might know what money advances he might safely make.

Plaintiff's account of the terms of his engagement was that defendant promised him 5*l.* for each report so made on each villa, cottage, and shop.

The defendant's version was that payment was to be made not on the rate alleged by the plaintiff for all buildings, but at that rate for villas only, and that for a bare report on a shop he was to receive 2*l.*, and on a cottage 1*l.*, and that he had been paid on that basis. This was the whole point in dispute.

The jury, after having been looked up for some hours, returned into court, having been unable to agree, and were discharged without giving a verdict.

CASES UNDER METROPOLITAN BUILDING ACT.

SEPARATE BUILDINGS UNDER ONE ROOF.

At the Woolwich Police Court, on Tuesday last, Messrs. Oxford & Whillier, contractors, appeared to answer a summons on the complaint of Mr. Collis, the District Surveyor for Charlton, for an infringement of the regulations as to the construction of buildings enacted by the statute 18 and 19 Vict. cap. 122.

The defendants were represented by Mr. Samuel Poynter, barrister, instructed by Messrs. Boys & Tweedies.

Mr. Collis deposed that he had received notice from the defendants, as required by the statute, of the erection of four tenements under one roof, intended to be used as almshouses, on a piece of land adjoining Charlton Church; that on inspection of the structures he found that the several tenements had separate entrances from the street, but that the party-walls dividing them had not been carried up through the roof to a height of 15 inches above the gutters, as required by the 17th section, read in conjunction with the third paragraph of the 27th section: he accordingly gave notice to the builders, requiring the provisions of the statute to be complied with. This notice having been neglected, the present proceedings were taken.

On cross-examination by Mr. Poynter, the witness said that the internal party-walls had been constructed, so far as they were built, in the manner required by the statute, and that communication by internal doors had been established between each of the tenements, all of which were under one roof.

Mr. Poynter submitted that Mr. Collis had mistaken his remedy. This was a penal proceeding intended to compel owners of property to see that their builders executed work conformably to certain regulations which the Legislature had deemed necessary to secure the public safety; so far it was a penal statute, and must therefore be construed strictly. The Act had itself indicated against whom it intended the penal clause as meaning the person for the time being in the receipt of the rents and profits. Mr. Poynter, therefore, contended that the test as to whether this non-compliance constituted a penal offence, was whether there was a beneficial occupation; because, if not, the Act had pointed out another mode of securing compliance with its constructive regulations. Now, what were the facts of this case? About the year 1825, a benevolent old Dutchman built by will certain funds to provide lodging, light, and fire, and to pay a weekly allowance to some poor infirm elderly people connected with the Dutch Church in Austin Friars. Under that will certain almshouses had been erected and tenanted until they were required by a railway company, and in consequence of their demolition it became necessary to erect new buildings. The trustees of the Dutch Church, who had the administration of the funds, had purchased an acre of ground adjoining Charlton churchyard, and had contracted with the defendants to erect a building capable of accommodating a certain number of old married couples, entirely separate and detached from any other building, the designs for which had been furnished by Mr. William Wignatton. The effect of an enforced compliance with Mr. Collis's requisition would destroy the harmony of the elevation, besides cutting heavy and entirely unnecessary expense, without giving any additional security. It appeared, without giving any additional security, that the building in paragraph 2 of clause 3, and intended to be an almshouse came within the contemplation of the Act *quodam generis* with the word hospital. Here the tenancy was by a superintendent, who had apartments provided for him, and who was, in fact, the head of what might be considered one family, inasmuch as there was a

perfect internal communication with every room. The Metropolitan district surveyors had evidently taken this view of the statute, as they had not compelled the builders of the Peabody Model Lodging-houses to carry their party-walls through the roof, and this was a much stronger case for the defence, for here the occupation, so far from being even remotely beneficial, was of the nature of providing fire, light, and lodging, and paying the lodgers for living there. Thus, the learned counsel contended that this was a public building, and that a difference of opinion as to construction of a public building, being in his opinion as to construction of a public building, should be submitted for the arbitration of the Metropolitan Board of Works.

The magistrate, after having inspected the plans and elevations, said he thought that the counsel's objection must prevail. His only difficulty was supposing the Metropolitan Board refused to arbitrate?

Mr. Poynter said the Court of Queen's Bench would compel them by writ of mandamus, but it was not to be apprehended that that would ever become necessary. In fact, in this case, he considered that he was in reality fighting the battle of the superior Board by contending that their jurisdiction should not be encroached on.

The magistrate said he thought that this was a public building analogous to a hospital, and that therefore the mode pointed out by the 39th section of settling a difference of opinion as to construction must be adopted. It was for the Metropolitan Board of Works to decide between the architect and the district surveyor. The summons must therefore be dismissed.

MONUMENTS OF REMOTE AGES.

A WORK "On Tree and Serpent Worship, or Illustrations of Mythology and Art in India in the First and Fourth Centuries after Christ," by Mr. Jas. Fergusson, is announced. The sculptures of the Buddhish Topes at Sanchi and Amaravati will supply the illustrations. Mr. Fergusson writes:—

"The earlier of these two monuments is that at Sanchi, near Bhopal, in Central India. Its gateways belong to the first century of the Christian era, and are covered with sculptures which represent the worship as principally addressed to the *Dagoba* itself, or to trees, and only occasionally to other Buddhish emblems. The serpent is but rarely worshipped, and Buddha himself is nowhere represented either as receiving homage or even as an ascetic. No priests appear anywhere, and asceticism as such afterwards understood certainly formed no part of the religion when these sculptures were executed."

The *Topes* at Amaravati belongs to the fourth or fifth century, and the sculptures of its wall represent a state of things much more nearly approaching to what we find in books than those at Sanchi. Buddha does appear as an ascetic, both preaching and receiving homage. Priests are occasionally present, and many of the legends of the *Lalita Vastara* are represented there; but the whole is mixed up with Tree and Serpent Worship to an extent not hitherto suspected, though the sculptures are still far from most of the absurdities of modern Buddhish literature."

A work "On the Stone Monuments, Tumuli, and Ornaments of Remote Ages; with some Notes on Early Irish Architecture," collected and described by Mr. Waring, is preparing for publication. This book will consist of more than a hundred plates, each containing on the average four or five subjects. About seventy plates are dedicated to the class of subjects called Druidical.

PRIZE PLANS FOR LABOURERS' COTTAGES.

Royal Agricultural Society of Ireland.—With reference to the designs in competition for the prize offered by his Grace the Duke of Abercorn for the best plan and specification of a labourer's cottage, the council have selected that sent in by Mr. Thomas Mallinson, marked "Experience," for a double cottage, as combining a due regard to economy with the most suitable accommodation in a class of buildings the improvement of which is so desirable in this country. The plans will be issued as soon as possible.

The Salopian Society.—We have received, with a packet of papers and plans, the following letter from Dr. Stryp, of Shrewsbury:—

"The directors of the Salopian Society for Improving the Condition of the Industrial Classes having, as they believe, good reason for dissenting from the opinion enunciated by the council of the Society of Arts in their letter of the 23rd November, as to the originality of Mr. Birch's designs, published in the *Agricultural Gazette* of December 23rd, 1837, venture to trouble you with the correspondence, and the plans therein alluded to; and will feel greatly obliged if you will kindly undertake to examine and compare them."

The directors regret the necessity for adopting such a course, but feel that the council's unsatisfactory communication of the 11th December leaves them no alternative but to solicit the opinion of a professional tribunal; hence their appeal to the *Builder*."

The correspondence enclosed to us includes a letter from the secretary of the Society of Arts, saying in reply to Dr. Stryp:—

"Whilst the council admit a certain similarity of plan in the two designs, they do not consider that it amounts to more than might naturally arise from independent minds applied to the solution of a problem, the conditions of which did not admit of great variety of treatment; and they see no reason to believe that Mr. Birch has in any

way copied the design of the Salopian Society. The council are, therefore, not prepared to reopen the question of award."

Going beyond our province, we have examined the plans, and consider the council of the Society of Arts were right in declining to reopen the question. It seems to us that the recipient of the Denton premium was not more indebted to predecessors than was the designer of the Salopian Society's cottages. We have by us plans made by ourselves years ago which both the plans in question strongly resemble, though never seen by the designer of either. It is as well we should state that the design published by the author in the *Agricultural Gazette* (December, 1837) is not the design originally submitted, and to which the premium was awarded. This will be found in the *Builder* of December 31st, 1834.*

EXAMINATION PAPERS, PUBLIC WORKS, INDIA.

THE examination papers for competitive examination of candidates for appointment in the engineer establishment of the Department of Public Works in India, held at the India Office, London, in December last, were set by Mr. George Preston White, C.E., and are now before us. They are not very practical, so much so that questions are a separate examination in science is required. A very good examination on these papers might be passed by a man who does not know the multiplication table. The headings are "On Cement, Concrete," "On Building Materials, Brick Stone, &c.," "On Suspension Bridges, and Screw Piles," "On Architecture and Building," and "On Iron and its Applications." The papers are so much easier than those set by the same Examiner in June last, that we are curious to learn if the results on that occasion showed that the latter were too stiff. Mr. White is particularly anxious "to direct attention to the importance of the study of architecture and design in building," and we applaud him for it; but a better example should be placed before the candidates for description than that which accompanies the papers. This is an "original design for a range of public buildings," with three domes, in the worst style of the green-house builder, a campanile with doors in the upper part of it leading into the air, and detached columns round the building carrying nothing but blocks of the entablature which crowns the front.

A MORTUARY FOR MARYLEBONE.

THE vestry of the parish of Marylebone have erected a large public mortuary in the burial-ground at Paddington. The mortuary has been formally opened. The building is in the Egyptian style, and has been built by Messrs. Temple & Foster, of Paddington, from drawings prepared by Mr. Browning, the vestry surveyor. Within, there is a row of four ornamental cast-iron columns down each side, which not only help to support the iron bearers fixed into the walls to hold shelves for the reception of a large number of dead bodies, but they also sustain the girders which uphold the roof, from the centre of which the room is lighted with gas on a new principle.

ACCIDENTS.

Weem.—An accident occurred at Weem, near Aberfeldy, on the 22nd, by the falling of a portion of the wall of the new Episcopal Chapel in the course of erection there, whereby four men were injured, two of them fatally. It appears that the gable at the west end had been completed, and the workmen were engaged re-erecting the scaffolding, when, by the overhanging of some beams which rested horizontally on the bottom of the end window, the whole of the wall above the window was thrown inward, falling upon the men.

Colchester.—On Sunday and Monday the wind blew a perfect hurricane at Colchester. On Monday evening a portion of the spire of the Lion-walk Congregational Church fell with a loud crash, breaking through the roof and doing considerable damage to the interior fittings.

* Vol. xlii., pp. 951, 952.

This church, Gothic in style, has been built only five years, at a cost of 5,000*l.* The damage done can hardly at present be accurately estimated, but it will probably amount to several hundreds of pounds.

Gateshead.—The bridge in connexion with the road leading from Rowland's Gill railway station, to Burnopfield, Gateshead, and crossing over the river Derwent, has fallen. Happily, no one was upon the structure at the time.

It appears that some large holes in the centre of the structure had fallen in to the extent of about a yard. The bridge, it is stated, for some time past has presented large cracks; and the strong and rapid flow of the water, after the recent heavy rains, had caused the serious collapse which has now taken place. The bridge is an old stone structure, situated on the township road to Burnopfield, at the foot of a steep hill, spanning the river Derwent with two stone-built semi-arches built into the rock, and the land abutments built into the pier, and the land abutments built into the pier. The heavy rains had washed up the surface of the bridge, thus letting a great weight of water into the hearting of the structure, which, unfortunately, is only sand and soil. As this material subsided it acted as a wedge, forcing one side of the Burnopfield arch into the Derwent, leaving only about 3 ft. of footpath on the other side.

Rochdale.—A shocking calamity occurred at Rochdale on Sunday. The wind blew in fearful gusts. In a new street off Spottland-road a row of houses had just been completed, and two of them are so constructed as to answer the purpose of a Sunday school, or it could be altered into two houses. Mr. Bewick, of Manchester, was the contractor. On Sunday the place was open for divine service for the first time; and in the afternoon Mr. John Ashworth, author of "Barrage Tales," preached. There were present about 400 persons. Shortly after the congregation had met, one of the windows was blown out by a gust of wind. Little notice was taken of it, and the service proceeded, when another violent blast lifted up the roof, the gable end fell in, and the two side walls fell inward, after which the roof crashed in upon the whole. A distressing scene of confusion and horror ensued. Strange to say, no one seems to have been killed, but various persons were seriously injured.—The front wall of a Methodist New Connexion Chapel, in course of erection in John-street, Rochdale, was also blown down on the same occasion; as also was the top part of a factory chimney; and the bricks penetrated the roof of a cottage in Dawson-square, but fortunately none of the occupants were injured.

KEIGHLEY MECHANICS' INSTITUTE, AND SCHOOL OF ART.

A PROJECT long contemplated is now in progress of realisation. Involving the sale of the old building, 5,000*l.* have been obtained. Accordingly, plans have been prepared by Messrs. Loeckwood & Mawson, architects, of Bradford near London, the carrying out of which, exclusive fittings, will cost above 10,000*l.*; and the whole of this, it is hoped, will be obtained before the new institution is completed. The building is to be in the Gothic of the thirteenth and fourteenth centuries; and a prominent feature will be a spire. The site is one of the best in Keighley, a plot of ground at the corner of Cavendish street and Skipton-road. The foundation stone of the new edifice has been laid by Mr. I. Hold of Oakworth Hall. The basement story will entirely devoted to class-rooms, except the curator's house and the retiring-rooms for the ladies. The windows and floor all round will be completely out of the ground, so that it will be basement floor only in name. The ground-floor will be approached by the principal entrance the Skipton-road, and, at this point, will rise to a height of nearly 100 ft. To the left the entrance vestibule will be the large room lectures, &c. The hall will be 87 ft. long 44 ft. wide, and will accommodate more than 1,000 persons. To the right of the vestibule be the reading-room, 28 ft. by 18 ft.; the library 23 ft. by 15 ft.; the patent-room; the penk; and the secretary's office. Immediatly opposite to the principal entrance in Skipton road is the grand staircase leading to the roof devoted to the School of Art. These rooms an important portion of the building. They consist of the painting-room, lighted entirely the north, which will be 30 ft. by 18 ft.

modelling-room, casting-room, mechanical-room, and masters' room, with a convenient retiring-room. Attached is a large exhibition-room, lighted from the top. The cost of the land and buildings will be about 12,000*l.*, and the works are being executed almost entirely by Keighley contractors. The contractors and amounts of contract are as follow:—Mr. John Smith, mason, 5,850*l.*; Mr. Robert Sngdon, joiner, 1,860*l.*; Mr. John Scholefield, plumber and glazier, 503*l.*; Mr. Benjamin Dixon, plasterer, 371*l.* 12*s.*; Messrs. Clapham, Brothers, ironfounders, 367*l.* 9*s.*; Mr. Thomas Wilson, slater, 314*l.* 10*s.*; and Messrs. Briggs & Mensforth, painters, 167*l.* 12*s.* 6*d.*

HARBOUR WORKS.

Carnarvon.—The first stone of the proposed additional harbour works at Carnarvon has been laid by the Mayor. The proposed new harbour is on the north side of the town, near to the station of the London and North-Western Railway Company. The improvement of the present harbour is also contemplated. The estimated cost of the portion of the plan now about to be carried out is 24,000*l.*, which will be obtained from the Public Works Loan Commissioners. The estimated cost of the entire works is 50,000*l.* Mr. Frederick Jackson, C.E., supplied the plans, and the contractors are Messrs. Bughrd & Jones.

The Lizard.—The Board of Trade have received an application for a provisional order to constitute a Harbour Authority to alter, deepen, and improve the harbour, or cove, usually known as Million Cove. These improvements, as at present contemplated, are sought to be effected by the construction of three breakwaters, a quay or landing-place, and slip. The first breakwater is to be 630 ft. long; the second, about 25 ft. long; and the third, 55 ft. long. The quay is intended to be 130 ft. long and 20 ft. wide. The slip will be 90 ft. in length and 10 ft. wide. Money is to be borrowed on mortgage of the dues.

St. Just.—An application is to be made in favour of St. Just-in-Penwith to the Board of Trade, it being proposed that a company shall be incorporated to make a harbour and pier, to occupy the site of Porenven beach, between Bolloval Cliff on the north, and Letcher Cliff on the south. On the west pier or breakwater is to be erected, extending from Bolloval Cliff for 70 ft. towards Crow Rock. Another pier, 120 ft. long, will extend from Letcher Cliff towards a southern extremity of the first pier. On the north 225 ft. long, east 230 ft. long, four wharfs, the respective lengths of 225, 230, 250, and 200 ft., are to be erected adjoining the piers. From the south end of the pier, extending from Letcher Cliff, another pier with a south face of 10 ft., and a north face of 225 ft., will spring in a westerly direction; four piers 700 ft. long will extend from under Bolloval Cliff in a southerly westerly direction.

GENERAL MEETING OF THE INSTITUTION OF CIVIL ENGINEERS.

At the annual general meeting, held on the 1st of December, the report of the council was read, with respect to the new building, upon which it was determined to retain the existing house, with the addition of the lack part of an adjacent house, as recommended by the council, and was taken for ninety-nine years of each year two properties, for 450*l.* per annum in the case of No. 25, Great George-street, with the option of purchase within ten years for 12,000*l.*; and in the case of the lack part of No. 24, Great George-street for 208*l.* 13*s.* 4*d.* per annum, and a like power of making it freehold for 11*l.* 13*s.* 4*d.* It was mentioned that the two last named were the net amounts which should have to be paid, after making allowance for the very liberal gifts of two of the owners, the entire of Mr. G. R. Stephenson's interest, one-third, and 500*l.* in diminution of Mr. Stephenson's interest, also of one-third. At the same time the specifications and cost-estimates for the works were prepared with such alternative conditions; one for their completion and delivery in five months, so as to be ready for opening of the present session; the other for their performance in eight months. The tenders were received from several builders, and that of Messrs. Holland & Hannen being the lowest was accepted. That firm undertook to finish the

building according to the architect's designs in five months for a sum of 11,650*l.*, and in eight months for a sum of 11,100*l.* The contract was based on the first-named alternative, and had been duly fulfilled. In maturing the details of the plans of the new building several important modifications had been made, the principal being the addition of a newspaper and tea room on the ground floor, by which the area of accommodation for the general use of the members had been doubled.

The council were enabled to state that, whereas the estimated outlay, including all contingent expenses of moving, furniture, &c., amounted to 14,810*l.*, they fully believed the actual cost, including some furniture not yet delivered, would not exceed 17,250*l.* To meet the liabilities of the building fund, being the accumulations of fees received from members and associates on joining the Institution; next to realize the unconditional bequest; investments made from time to time out of surplus income. The first two sources would, of course, be entirely exhausted, but as far as the council could judge, when hand of the nominal value of about 3,000*l.*, to provide for the Miller bequest of 2,000*l.*, the Errington bequest of 1,000*l.*, and the Locke bequest of 2,000*l.*, would hereafter disappear from the accounts, but the names of these benefactors would be held in grateful remembrance as connected with the erection of the new building.

A notice had recently been served on the Institution the evening session for an Act, under the title of "Public Offices Consolidation (Acquisition of Lands)," to empower the Commissioners of her Majesty's Works and Public Buildings to acquire the property held by the Institution. The council had, in reply to this notice, intimated their dissent to the proposed undertaking.

The council, having decided to institute an inquiry as to the systems of engineering education (other than military and naval) in different countries, the cost to the student and to the respective Governments, and the effect, or profession, of such preparatory training upon the technical establishments and private individuals abroad and at home. This circular had previously been presented to a mass of materials which yet remained to be arranged, but which it was hoped would in due time be presented to the members.

During the past session forty-five members and 105 associates had been elected, while the deceased, resignations, and emsures together amounted to 116, or at the rate of 7.41 per cent. on the present number of members of all classes. It was shown by the abstract of accounts for the year ending the 30th of November, 1868, that the income proper, exclusive of all receipts from life compositions, building-fund fees, and dividends of every kind, had amounted to 5,633*l.* 3*s.* 3*d.*, while the ordinary disbursements had only been 3,677*l.* 4*s.* 8*d.*, thus leaving a surplus of 1,956*l.* 18*s.* 7*d.* But when to this sum was added the above excluded items, still disregarding all trust moneys, the surplus became 3,210*l.* 8*s.* 6*d.*

PROVINCIAL NEWS.

Burnham.—A market-house is to be erected here, by a company formed for the purpose. On the ground floor will be the market, also Board of Health and other rooms. Above this is to be a town-hall. The corner stone of the building has been laid.

Worcester.—The new Orphan Asylum at Upper Henwick, which the friends and supporters of that institution were enabled to erect chiefly through the munificence of Mr. T. Padmore, late M.P. for this city, who presented 4,000*l.* to the funds, is now nearly completed. A site was secured on a large piece of elevated ground near the Henwick railway station, and the building has so far progressed as to be now receiving its roof. The architects are Messrs. Wtakin, of Lincoln, and Walker, of Nottingham; builders and principal contractors, Messrs. Slinm & Vickers, of Nottingham. Materials, brick, with Bath stone facings; style, mixed Gothic. The front facade, which faces Henwick-road, has three projecting bays, with gabled tops, the central bay being on an arcade forming the porch. Two stone circular columns support the front of the porch, and the back rests on strong carved corbels inserted in the wall. These columns, which are of red Mansfield stone, have capitals carved by Mr. Legge, representing stiff conventional foliage and male and female heads, with dog-tooth moulding; the capitals, ribs in centre of columns, and bases, are of Bath stone. Above the porch is a semi-circular apartment, forming part of the central projecting bay, the two side bays here named being flat. The windows are square-headed, with mullions and transoms; the dormers and bottom windows in front having canted heads. The building has three stories in front

and two behind. The roof is steeply pitched and slated. The building is divided into two equal parts by a central passage or corridor leading straight from the porch to the dining-room. The apartments on the right will be entirely appropriated to the girls and those on the left to the boys. Two corridors, running at right angles with the central passage, divide each compartment or wing of the building. The larder is an octagonal building in the centre of the area, and is approached by a covered way. The dining-room is 20 ft. wide by 40 ft. long, and has a doorway leading to the girls' wing; another to the boys'; and a third to the central passage communicating with the front porch. In each wing of the building are school and class rooms. The plan of both wings is exactly alike. The upper stories are occupied with dormitories, baths, &c. The honorary-wall runs close at the back of the building, and at the front and sides will be gardens. The whole will cost some 5,000*l.*

Shiffnal.—The new Assembly-room and Market-hall building has been opened. The architect was Mr. George Bidlake, of Wolverhampton; the builder, Mr. Clark, of Shiffnal.

Finedon.—The new Temperance Hall and Institute, which has been for some time in course of erection here, has just been opened. The grand front consists of dwelling for hall-keeper, entrance and two wide staircases to upper room, reading-room, large club-room, kitchen, and offices. The upper room covers the whole area; is lofty, well lighted, and has an open-timbered roof, which makes it admirably adapted for music. The platform is reached by a private staircase at the upper end of the hall, communicating with an ante-room below. The building, which is Gothic, and has a row of buttresses on each side, is of Finedon stone, with Box stone dressings to the doors and windows. A cloak has been placed at the south end, by subscription, and is from Bennett's, of Cheapside. The works have been executed by Mr. W. Henson, builder, Finedon, from the designs of Mr. R. W. Johnson, of Melton and Leicester, architect.

MANCHESTER FIRE BRIGADE.

From the annual returns just issued by Mr. A. Toyer, the superintendent of the Manchester fire-brigade, it appears that during the year ending September 29th, 1868, there were 301 fires exclusive of false alarms. Of these thirty were classed as serious, or more than one-sixth destroyed.

The brigade consists of one superintendent, two engineers, two assistant engineers, thirty-four firemen, two coachmen, and one messenger. There are sixteen stations where men are on duty at various parts of the city. The apparatus is as follows:—Six engines (manual), three horse hose-carriages, nine hand hose-carts, seven fire-escapes, with hose, &c., and thirty-seven hand pumps. The original cost of the apparatus was 3,523*l.* 17*s.* 1*d.* The insurance companies contribute to this brigade nearly a third of the amount they pay to the London fire-brigade; this fact alone showing how the insurance companies appreciate the efficiency of this brigade.

CHURCH-BUILDING NEWS.

Appleton Roebuck.—A new church, situated at Appleton Roebuck, in the parish of Bolton Percy, and about nine miles from York, has been consecrated by the Archbishop of York. The site is the gift of Sir W. E. Mitner, bart. The edifice consists of a nave, chancel, bell-turret, south porch, and vestry. Its inside dimensions are—nave, 56 ft. by 25 ft., and chancel 25 ft. by 17 ft., or a total internal length of 81 ft. The material employed in its erection is Bradford stone for the walls, which are lined inside with red brickwork exposed to the view. Ancaster stone has been used for the dressings, and the structure is covered in with grey tiles. At the west end of the church is a bell-turret, rising above the extremity of the nave gable, and supported by a buttress. This turret is 60 ft. in height. The east window is of three lights; those pierced in the north and south walls of the chancel are of single lights; and the west wall contains two windows of the same character as those in the nave, the buttress of the bell-turret separating the two. All the windows have geometric traceries heads, and

ting wings, two of which will contain a stone rising to ascend into the upper part of the ceiling. Above the staircase, and in the other gables, will be constructed class-rooms, committee-rooms, &c. The large school-room will have an open floor, the timber being painted and finished. The material which is to be used in the erection of the building is Horsforth stone. The cost of the building, it is estimated, will be about 2,000l. In the new building accommodation will be provided for nearly 500 day scholars and a larger number of Sunday pupils.

STAINED GLASS.

Trinity Chapel, Brighton.—A committee of gentlemen has been formed with a view to the erection of a window in this chapel to the memory of its late minister, the Rev. Frederic Robertson. This, we believe, will be only a portion of a larger memorial to him in Brighton.

Great Church, Worcestershire.—A window has been placed in the chancel of this church, subscribed for by the tenants on the estate of Mr. Thomas Henry Hope Edwards, of Great Worcestershire, and Nettle Hall, in memory of a late Captain William J. Hope Edwards, of the 5th Shropshire Rifle Volunteers. It consists of three lights. In the centre is our Saviour, and on the side lights are St. Matthew and St. Mark. The whole is in keeping with the ancient character of the church. The window was superintended by Mr. John Robinson, of Shrewsbury and Warrington.

Wiford Church.—In addition to a stained window and medallion bust in memory of the late Kirke White, this church has been further adorned by a window to the memory of Mr. Thorpe, the late rector. The Kirke White memorials have been raised by public subscription, but the window in memory of Mr. Thorpe has been put in at the expense of that gentleman's nephew, the Rev. H. J. Beach, of Tutbury. As Mr. Thorpe's window occupies the post of honour, viz., the east end of the church, it ought first to be described. The design is the resurrection of our Lord, the centre compartment being devoted to the figure of Christ, just descended from the tomb, and those on either side worshippers. The Kirke White window is on the south side of the chancel, and represents the scene of Bethlehem. In the upper part of the principal light are the Magi on their journey to Bethlehem, and in the lower they are worshipping the Child. The upper part represents the Resurrection. At the base are the words, "In memory of H. K. W." Mr. A. W. H. O'Connor, of London, was the artist. The medallion head of Kirke White, to which we have referred, is in Carrara marble, from the studio of Mr. W. T. Cole, medallist of the Royal Academy. It is a representation of the poet's features as gathered from a picture in the possession of some friends at Nottingham. The medallion is 20 in. by 16 in. and has been placed in the chancel under the direction of the artist.

Books Received.

Historic Ninetins: a Book of Curiosities, where Old and Young may read Strange Matters. By JOHN TIMBS. London: Lockwood & Co. 1868.

How clever fellow, such as those Mr. Timbs here often quotes, is ever and anon knocking down some old and popular idea, or setting up a new one of his own in its stead. In many cases these clever fellows are quite right, but they are, as I doubt, sometimes wrong; and not a few of them are much more bent upon the display of their own ingenuity than upon either knocking down the wrong idea or setting up the right one; and had the right one been the ninetins that was in these clever fellows would here exert themselves quite as diligently and ostentatiously in knocking down that one as the other, or in setting up the other in its stead. There is just such a severity in science, sometimes, as well as in history. Mr. Timbs has here made a curious and interesting book on "historical ninetins," as he quaintly calls it. The items are condensed and concise, and I much of the matter seems to be not mere repetition from historical or other sources, but well written, so as to give the kernel of a story in nutshell. It is evident, on the whole, from a great store of examples, that much we call

history is mere fiction, even as regards not very ancient times. The "strange stories" told us here by Mr. Timbs relate to a great variety of subjects, including characters and chronicles; doubts and difficulties; fictions and fabulous histories; ifs and incredibilities; legendary stories, marvels, and misrepresentations; myths and mythologies; parallels and periods; popular errors; prophecies and guesses; prehistoric times; reckonings and refutations; tales and traditions; universal history and readings with new lights.

MORE ALMANACS.

WHITAKER'S Almanac for 1869 contains a very large amount of necessary information, with a wider range of subjects than hitherto included in such works. Readers will learn to realize the fact that the British dominions extend far beyond the British Islands, and that there are other important countries in the world. Much attention has also been given to financial matters, showing how the national income has been expended. The commercial, scientific, and Parliamentary summaries, are also new features.—"The Dramatic and Musical Almanac for 1869," by J. W. Anson (of the Adolph), includes several amusing articles, and a large number of dated events connected with actors and the stage. Mr. Anson would make his Almanac more useful by adding the names of committee and officials of the various societies and funds connected with the Stage, Dramatic Authors' Society, Dramatic College, General Theatrical Fund, and so on, with particulars of their purposes and statements of accounts.—"The Art-Union of London Almanac for 1869" contains, like all its predecessors, information on matters of art and art-societies not to be found elsewhere. The meeting days of all the societies are given, and room is afforded for noting engagements. For the current year every subscriber will receive a *fac-simile* of "Mulready's Wedding Gown."—"Young England's Almanac and Naturalist's Calendar" is well calculated to foster the study of Natural History, — and a valuable study that is.

VAMORUM.

Report of the Metropolitan Board of Works, 1867-8. The annual report of the Metropolitan Board of Works has just been published. It treats of numerous subjects, of much interest to the ratepayers of the metropolis, and shows them what they have had and are having for their money. Of the progress of the works we have already treated from time to time; but we may here summarise them from the conclusion of this annual report:—

"During the twelve years which have elapsed since the constitution of the Board, they have expended large sums in carrying out the objects contemplated by the Local Management Act of 1855, and various other statutes passed in subsequent years, under which largely extended duties have devolved upon them; and these sums have been uniformly raised by local taxation on the occupiers of property within the metropolitan area, the only exceptions being the coal and wine duties, the Government contribution of 10,000l. per annum, and the annual amount received from fire insurance companies in aid of the fire brigade. There is no doubt that, in return for this taxation, the inhabitants of London and its suburbs have received great benefits from the works of the Board, amongst which, as the most prominent, may be mentioned the system of main drains, the embankments of the river, the formation of new thoroughfares, the establishment of parks, and the preservation of open spaces. Beyond these there are many other improvements which the Board have from time to time aided the local authorities in carrying out by granting pecuniary contributions. But notwithstanding that much has been done during the past few years for improving the condition of the metropolis, it is clear that its growing requirements will be very far from met unless additional facilities for traffic are provided, common and open spaces secured, and other works executed, which will necessarily involve a large expenditure. . . . The Board entertain a hope that the attention of the Legislature will shortly be directed to the important question of readjusting the taxation between the owners and occupiers of property in the metropolis, and that ultimately the requisite revenue will be placed at the disposal of the Board without the necessity for imposing additional burdens on those who are already so heavily taxed."

—"Sewage Irrigation," by Michael Scott, C.E., London. Maclehose, Glasgow. 1868. This is a second letter, addressed to the Lord Provost of Glasgow, on the city sewerage question. Mr. Scott here compares his own scheme, of which we have already spoken, with that of Mr. Bateman and Mr. Bazalgette, and shows in what respects he regards his own as preferable. The cost of the rival plan Mr. Scott states at 1,253,256l. and that of his own at 850,000l., thus effecting a saving by his plan of 403,256l. The annual charges on the Bateman and Bazalgette plan

would be 55,000l.; and on Mr. Scott's, 35,000l.; thus effecting a saving of 20,000l. a year; at least, Mr. Scott says so.—"Woman's Work in the Temperance Reformation, London," published for the National Temperance League, by W. Tweedie, Strand. However stale and unprofitable in the eyes of some, the temperance reformation movement is a most important one; and it is regarded as becoming every day of more and more importance on account of the sad fact that intemperate practices are privately spreading to a fearful extent amongst our women of every class. Mrs. S. C. Hall, in an able and womanly introduction, does not hesitate to state this as a fact, in her own knowledge; and in the papers, prepared for a ladies' conference, held in London, May 26, 1868, of which this little volume is made up, the abhorrent fact, of society being defiled with the prevalence of tipping and drunken women, is quite as plainly declared. This is a shocking state of matters; and a fearful look-out for the rising generation, many of whom, even while children, are absolutely taught to tipple and look for their daily wine or beer as eagerly as their elders. There are medical men, too, who obviously pander to the growing propensity in women for stimulants, and it is not seldom under the guise of medical "orders" that both women and children indulge the abominable habit. In these regards the little volume under notice is well adapted to arouse the public attention to the evil and to lead to its correction.—"The Agricultural Labourer" (No. 2). By J. Bailey Denton, C.E. This pamphlet contains a reprint of a series of letters, which first appeared in the *Daily News*, on the general condition of the agricultural labourer. They treat of village water-supply, drainage, earth-closets, and cottage-gardens; cottages; wages; beer, and cider; education and technical instruction.

Miscellanea.

Bedfordshire Architectural and Archaeological Society.—The general meeting of this society for the present year has been held, Lieut.-Colonel Stuart in the chair. Mr. Wyatt read a paper entitled "Bedford and the Olden Time," which formed a continuation of the author's "Glance at Saxon Bedford" (read before this society and published in the volume for 1865), bringing down the sketch to the close of the last century. It was illustrated by some large drawings in water-colours of various objects of interest. Mr. Hurst next read a poetical version of the legend connected with the lady whose tomb and effigy are to be seen in the south wall of Oakley Church. Mr. Haddock then read the report for 1868, which was adopted.

Value of Property in Brighton.—An opportunity of forming an opinion upon the value of freehold property in the best part of Brighton was afforded last week, when Mr. George Attree submitted to public competition the block of freehold mansions facing the sea, numbered from 1 to 5, Junction-parade; together with the property known as No. 1, King's-road, forming the western end of Junction-parade. Lot 1 comprised No. 5, Junction-parade, let on a repairing lease at 200l. a year, determinable on the 1st of September, 1873. Taken at its present rental, Mr. Attree estimated its value at 4,000l.; but he put its value at 250l. a year, which might readily be obtained in five years' time. The first bidding offered was 3,000l., on which an advance of 500l. was immediately made. Another 100l. was offered, and from this point the biddings were increased by fifty till they reached 3,850l., at which price the lot was knocked down. Lot 2 adjoined lot 1 on the west, and was of similar elevation, but less extensive frontage and accommodation. It was let to the same tenant for 150l., and possession could be obtained at nearly about the same time as the last lot. The biddings for this property, which opened at 2,000l., were more spirited, and rose 50l. at a time till they reached 2,850l., for which sum the property was bought by the same party that had secured lot 1. Lot 3 adjoined lot 2, and was let to the same tenant for 170l. a year, but upon a yearly holding. The entire front, it was stated, had, within the last twelve months, been reconstructed, at a cost of 350l., to correspond with the two lots just sold. The biddings opened at 2,750l., at which price it was sold, to a Brighton gentleman; the others having fallen to strangers.

A New Masonic Hall for Durham. — The foundation-stone of a Freemasons' Hall has been laid with Masonic ceremonial, at the south end of Old Elvet, Durham. The architect is Mr. T. C. Ebdy.

Free List of Portraits in the National Portrait Gallery. — A list has been printed of the portraits in the Exhibition at 23, Great George-street, Westminster, and is presented gratis to those visiting the Exhibition, which is open to the public on Mondays, Wednesdays, and Saturdays, from ten to four o'clock; admission free.

The late Sir Richard Mayne. — It is to be hoped that the death of this valuable servant of the public was not expedited by the howl of ridicule and abuse directed at him for his endeavours to lessen the danger of unowned dogs and the nuisance of hoop-trundling in the streets, — excellent and much-needed steps. Some of our journalists, and so called, dramatists, ought to feel thoroughly ashamed of themselves.

King's College Chapel, Cambridge. — We understand that Mr. F. E. Stacey, of Llandough Castle, Glamorganshire, and formerly Fellow of the College, proposes to fill the great west window of the chapel with stained glass. The donor expressed his wish that the new work should harmonize with the magnificent windows now in the chapel, towards realizing which result it would be his endeavour to secure the services of the best artists and glass-stainers to be found either in England or upon the Continent. Here is a fine chance for fame or contempt for some one. We advise Mr. Stacey to treat the design and the execution of the glass as two separate events.

Working Men's Club and Institute Union. A meeting of representatives of workmen's clubs in London, took place on Tuesday evening, at the offices of this society, with a view of conferring with the council on the various questions which affect the success of those institutions. Among others the subject of connecting the clubs with all popular organizations, such as the co-operative, trade, benefit, and temperance societies, was carefully considered; also the question of rendering workmen more independent of public-houses in the matter of refreshments, and of making the clubs more attractive, under the heads both of recreation and of instruction. At the close of the meeting, a motion for a further conference, to be held shortly, was unanimously agreed to.

Luncheon on Australian Meat in the City. — About eighty guests assembled on Tuesday in the central depot of the Australian meat agency, Norton Folgate, London, at the invitation of Mr. Tallerman, the manager, in order to test the qualities of various forms of preserved meat from Australia. On this occasion the chief form presented was meat salted in Australia and prepared in various ways in this country. Mr. Warrenner, inspector of cookery for the army, superintended. It is reported that the result was sufficiently satisfactory to warrant the public in giving some encouragement to the undertaking. Preserved meats, hermetically sealed in tin vessels, are to form the chief ingredients of another banquet. The company were of opinion, as we are, that the successful introduction of meat into England from Australia was a matter of the highest importance.

The Great Bell for Worcester Cathedral. — The long-expected bell has arrived from Loughborough, conveyed upon one of the Midland Railway Company's wagons, drawn by three horses gaily decked with ribbons, to the cathedral. This bell, which is 6 ft. 4 in. in diameter, is not to form one of the peal in the cathedral tower; but is to be the clock bell, to strike the hours. The motto on it is "Surge qui dormis, et exurge a mortuis, et illuminabit te Christus!" — that is, as in the English version, — "Awake, thou that sleepest, and arise from the dead, and Christ shall give thee light." This motto appears round the crown of the bell. Round the waist there are coats of arms. Below there is the following inscription: — "In usum Ecclesie Cathedralis Christi et beate Marie Virginis in civitate et comitatu Vigorniensis, Johannes Taylor, Loughboro'. Fudit A. D. 1868." which may be Englished thus: — "For the use of the Cathedral Church of Christ and the blessed Virgin Mary, in the city and county of Worcester. John Taylor, Loughborough. Founded A. D. 1868." There are round the bell four rows of Gothic ornamentation.

Monument at Alnwick. — A monument to the memory of the late Dr. Hedley, of Alnwick, in the form of a memorial cross, of Sicilian marble, upon three large stone bases, has just been erected in the cemetery, Alnwick. It is 11 ft. high, and was designed by Mr. Thomas Gibson, architect, Newcastle. The work was executed by Mr. D. McMillan, monumental sculptor, Alnwick.

Local Improvements in Glasgow. — The unwholesome and overcrowded closes are being cut into by the Improvement Committee, who are gradually destroying them, with some consideration as to the temporary want of dwellings which such operations necessarily produce. The death-rate of the districts which are being opened up have been appalling, — 40 to 45 per thousand. Clearances for a new street are being made across many of the closes, extending from Bell-street to Spirling-street, and also across others, stretching from St. Andrew's-street to Steel-street. The tall tenements thus disclosed present a most wretched aspect.

Destruction of Wick New Harbour Works. A hurricane of great violence has been experienced in the North, and has been attended with considerable destruction to property. The new harbour works at Wick were so completely destroyed that only a few upright sticks remained of several hundred yards of piling and staging, and the whole stonework of the past season disappeared, being thrown into the bay. All along the shore, on both sides of the bay, large quantities of timber were stowed, and the immediate vicinity of the works presented mixed masses of stone and debris, which had been thrown ashore during the night. The break-water staging, where not entirely demolished, was here and there twisted, broken, and otherwise injured, and 250 ft. of sea-wall which had been built this season were gone. The damage is variously estimated at from 10,000, to 30,000. At least twelve months' work has been destroyed, and it will take more than another twelve to bring the works to the state which they were in. The end of the sea-wall was closed up, as formerly, for the season, some time ago; the stones being firmly embedded, and secured by powerful iron clamps in a manner that justified the hope of the works being able to resist all inroads of the sea.

TENDERS.

Table with 2 columns: Item description and Price. Includes tenders for alterations and additions to Whitelebury House, Highgate, for Mr. G. H. Brown, Messrs. W. G. Habershon & Pite, architects; and for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel.

Table with 2 columns: Item description and Price. Includes tenders for the erection of new buildings in the Iron Gate, Derby, for Mr. John Smith; and for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel.

Table with 2 columns: Item description and Price. Includes tenders for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel; and for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel.

Table with 2 columns: Item description and Price. Includes tenders for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel; and for alterations and repairs to No. 15, King-street, Chesham, for Mr. Gabriel.

For the erection of a shop and dwelling, and alterations to the Ten Bells, Spitalfields, Mr. W. E. Williams, architect: —

Table with 2 columns: Name and Price. Includes Langmaid, Symonds & Wilder, Hyde, and Maris.

For alterations, Nos. 49 and 50, Hooplanditch, Messrs. John Young & Son, architects: —

Table with 2 columns: Name and Price. Includes Cohen, Heaps, Ashby & Merritt, Hart, Reid & Son, and Chessum.

For Loughborough village roads and sewers. Mr. A. R. Pite, architect: —

Table with 2 columns: Name and Price. Includes Wigmore, Harris, Johnson, Potter, Strickson, Turner & Cole, Cowland, King, Crockett, Kilduff, Reid, Crofts, and Gardiner.

TO CORRESPONDENTS.

Terms Copying. — Several manufacturers, who were not present at the recent discussion on this subject at the Institute of Architects, write saying their names consequently do not appear, and they wish us to rectify the omission. We are unable to comply.

We are compelled to decline pointing out books and giving addresses.

All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

Normal. — The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

IMPROVED MACHINERY, combined with STEAM POWER, is employed by J. W. BENSON in the Manufacture of Church, Tower, Stable, and Tell-tale Clocks, Sun and Wind Dials, Perpetual Calendars, and every description of Clock and Watch Work. Architects, Builders, Committees, &c. can be promptly supplied with estimates. A descriptive Pamphlet on Church and other Clocks, post-free, 2d. J. W. BENSON, by special appointment, Watch and Clock Maker to His Royal Highness the Prince of Wales. Steam Factory for Clocks and Watches, 65 and 60, Ludgate-hill; Showrooms, 25, Old Bond-street, London.

ARCHITECTURAL ASSOCIATION, 9, COVENTRY, W. The ASSOCIATION, JANUARY 29, 1869. The LIBRARY for which the Frazee of the Association were awarded will be held by the respective authors.

IN THE UPPER SCHOOL, PECKHAM, S.E. every boy well grounded in English, made to write a hand for business, and to be able to speak a second language and to be able to read and to be able to write in French and German are spoken daily. The admission fee for day and board is 10s. per week. The school re-opens JANUARY 19, 1869.

ORARY'S INN ROAD. — To Builders, Cabinet Makers, and Others. MR. LERREW will SELL BY AUCTION, on the PREMISES, between 10 and 11, MONDAY, JANUARY 4th, 1869, at TWELVE for ONE, a quantity of iron, steel, and brass, prepared for building, machinery and other work, dry cut stuff, wide plank, mouldings, and boards, of all kinds, poles, ladders, old materials, &c. Auction Office, 2, Cannon-street, Strand, near Euston Station.

NOW READY, price 6s. by post 4s. 4d. LANTON'S BUILDERS PRICE BOOK, for ARCHITECTS, ENGINEERS, BUILDERS, CONTRACTORS, SURVEYORS, and all the BUILDING TRADES. For Fifty Years this Book has held the position with the Building Trade. The present issue has been very carefully revised and improved, and will be found a valuable as a guide as a price book.

TO ENGINEERS, ARCHITECTS, BUILDERS, &c. STANHAUS'S TABLES OF ANGLE and THE SQUARES of the Sines, Cosines, Tangents, Secants, and other trigonometrical functions, per Linear Foot of every Section required for Roof, Orders, Bolvers, &c. and will be found invaluable to any one engaged in Estimating for Wrought-Iron Work generally. Price 1s. 6d. by post 1s. 9d. Publishers, VIRTUE & CO. 25, Ivy-lane, London.

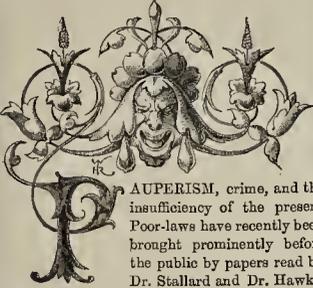

QUANTITIES MADE EASY. A quick and accurate method of taking out quantities from plans of buildings, with or without a specification. Sent free by post for 20 stamps. — Address, A. G. 16, Redway-lane, Tottenham, Upper Lee-street, Newmarket, S. & C.

GWILT'S ARCHITECTURE, illustrated with more than 1,100 Wood Engravings. Revised, with alterations and additions, by WYATT PATWORTH, Fellow of the Royal Institute of British Architects. Additionally illustrated with nearly 100 Wood Engravings by H. J. Swait; and more than 100 other Woodcuts. London: LONGMANS, GREEN, & CO. Paternoster-row.

The Builder.

VOL. XXVII.—No. 1353.

Pauperism and Crime.—The Boys' Refuge at Bisley, near Woking.

PAUPERISM, crime, and the insufficiency of the present Poor-laws have recently been brought prominently before the public by papers read by Dr. Stallard and Dr. Hawksley, in the one case at a meeting of a department of the Social Science Association, and in the other in the rooms of the Society of Arts, under the auspices of the London Association for the Prevention of Pauperism and Crime, Lord Shaftesbury presiding. At the Social Science meeting, Mr. J. Morley, M.P., was in the chair; and on both occasions the subject was discussed at considerable length by a number of gentlemen who have long given attention to it. Startling facts, affording evidence of the rapid growth of pauperism, were adduced, and the public seem to be aroused to the importance of the matter. Let us hope that some real advantages will follow. Dr. Stallard's paper and the reports of the discussion upon it have been referred to the Council of the Social Science Association, with the request that they will "take such steps as they may deem best to promote reform in the administration of the Poor-laws." They must go

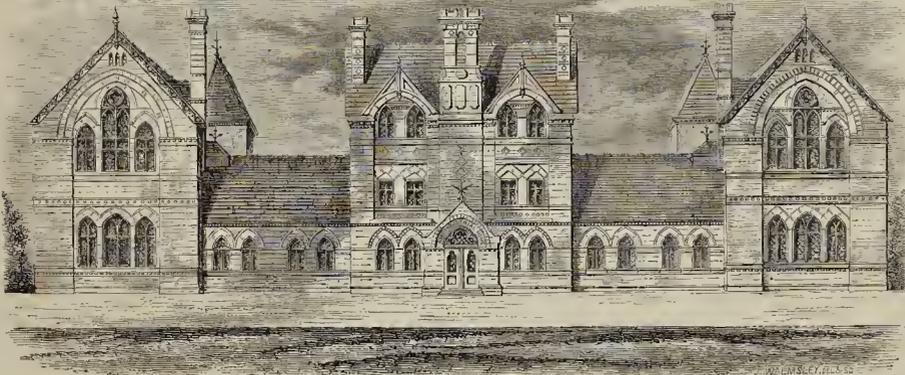

farther than this, and obtain legislation on other points if the advancing evils are really to be stopped and remedied. With the deepest interest in the object at heart, we must express regret that a fresh society has been formed to effect what the Social Science Association has long more or less actively urged, and is at this moment specially engaged upon. It would surely be better if the efforts of all interested in it were concentrated, and a more speedy result might then be expected. No trifling efforts will be needed to stop the spread of pauperism. Individuals are getting richer, masses poorer; and many causes are in operation tending to bring this about. Besides some that have been dwelt on, we must regard the present enormous amount of Imperial taxation and the inequality of local rating as powerful agents. Whole parishes are being pauperised by these causes alone.

In the exceptionally taxed parishes the small shop-keeper finds it impossible to pay his way, falls out of the rate-paying class into the aid-receiving body, and thus increases the fatal pressure on those who are still struggling. What sound reason can be given for forcing a man who lives on one side of a street to pay 4s. or 5s. in the pound for the relief of the poor, while his neighbour on the other side of it, perhaps even his rival in trade, is not called on for more than 1s. or 1s. 6d. in the pound? The only argument that can be adduced is one of selfishness. It is to be hoped that efforts for a remedy of this evil will be persevered in. Such injustice cannot much longer endure. It is simply a question of time. Again, our system of building on short leases is gradually transferring all house property to a few persons,—handing over the accumulated savings of thousands to the comparatively few land-owners. This same system has given us miles of ill-built, ill-ventilated, insufficiently-drained, fever-producing piles of rubbish, which, at the expiration of the short lease on which they have been "run up," will have to be repaired and set in order by the unlucky then owner before delivering them up. If this system do not produce a convulsion one of these years the teaching of history is worth nothing. We hear

of one well-known nobleman who can tell the date of the year in which his descendant's income from property in the metropolis will be a million a year, and no one able to say what he will do with it. A promising young nobleman, with some 400,000*l.* a year *already*, has recently put himself under the guidance of an alien church; the coming men of a million a year each may prefer an alien king, or, at any rate, spend their wealth without any reference to the well-being of those who have placed it on their land for them.

One result of this system is that shelter gets dearer; houses grow worse and worse. Overcrowding destroys the stamina and self-respect of their occupants, and produces a population of sickly paupers and evil-doers. If we would prevent the spread of the evils we are deploring the children must be taken in hand. There are 100,000 children in the metropolis alone uncared for who may be made either a curse or a blessing to society, just as society chooses. An enormous responsibility this, surely. Education and industrial training must be afforded to all, and insisted on from all. Parents who will not give their children decent training must be made to do so. This should be one of the first works of the new parliament. The opposition to such legislation would be much less than some seem to fear. Notwithstanding the enormous sums we spend annually in alleviating poverty and punishing the criminal, we do comparatively nothing to prevent pauperism or crime. Calculations that we made some little time ago, and which have been confirmed by the statements of Dr. Hawksley and Dr. Stallard, show that the money expended on the poor through the agency of charitable societies, parochial bodies, and private donors must be at least eight millions *per annum*: the punishment of crime, according to official statistics, costs about four millions, and we estimate the cost of crime to the public, the extent to which the criminal class destroy instead of producing, at six millions, making, in the whole, an expenditure of *eighteen millions of pounds sterling annually*.

Against indiscriminate almsgiving we wage war. Indiscriminate medical relief is the first

The Boys' Refuge Farm School, Bisley, near Woking, Surrey.—Messrs. Habershon, Brock, & Webb, Architects.

movs towards destroying self-dependence and showing the recipient the way to the workhouse. Of discriminate charity we cannot have too much; the charity that knows, and aids at the right time; that prevents the break-up of the home; that inspires with fresh hope; that shows the field for profitable exertion. The able-bodied should be forced to work, if they would eat; and they should be made to do work that will pay. The work-in-vain system is wasteful, demoralizing, and abominable. We want the result of every man's labour. The payment should be by piece-work. The making and maintenance of roads, embanking rivers, draining, the manufacture of clothes for the poor, for the army, and for the navy, and above all the reclamation of waste lands, are works to which such labour might be fairly applied. There are millions of acres of uncultivated land in England and Ireland on which labour might be profitably employed. We shall want legislation to enable public bodies to employ the destitute. Aid might be given to those who would emigrate—not to the colonies or another country, but to these waste lands at home, there to bring up their children in habits of industry and self-dependence, and to make the desert smile. With less of indiscriminate almsgiving, as we said before, we want more real intelligent charity, personal help, and Christian sympathy;—sympathy—

"Which hath an operation more divine
Than breath or pen can give expression to."

Above all things let us take up the children. The strong feeling we have in that direction leads us to make this an opportunity to bring before our readers the last step taken by those who manage what are known as "The Refuges for Homeless and Destitute Children," whose head-quarters are in Great Queen-street, Holborn.

The house there was found too small to receive the crowds of orphans that came for succour. In 1866 the *Chichester* training-ship offered the means of training for a seafaring life some 200 boys, but the mission still grew, and it was determined to erect a house at Bileys, in Surrey, to which it is proposed to transfer the young and weakly boys from the London Refuge, so that they may be trained to look after cows and pigs, grow vegetables, till the land, and thus be fitted for service at home or in the colonies. To so good an enterprise we wish the best success. The new building consists of a centre and two wings, connected together by corridors. The centre contains the committee-room, store-rooms, living-room for the master, and separate infirmaries. The left-hand wing contains workshops for several departments, and a broad open dormitory over. The right-hand wing contains the dining-room, with a similar spacious dormitory above. In the rear the kitchen and proper offices are erected as separate buildings; and again in the rear of each of the wings are swimming-baths and lavatories. The total frontage of the building is about 160 ft., and the entire cost 5,775. The architects are Messrs. E. Hatherston, Brock, & Webb; and the builders, Messrs. Carter & Son, Horseferry-road, Westminster. The style, it will be seen, is a sort of Gothic, with bands and patterns of coloured bricks, and walling of red bricks. The dormitories have open timber roofs, and accommodation is made for 150 boys. The farm consists of 88 acres. Mr. W. Williams, the hard-working secretary of this association, said, at the opening of the new building last month, that in the previous year there were gathered from the streets into the refuge no less than 246 boys, and up to the end of November 310 had been received, and for the twenty-one days of this month 50 more had been received, and still they came heaving to be received. We need not enlarge on the advantages accruing to the public as well as to the boys themselves in so large a number being rescued from misery and vice, instead of being allowed to drift into the criminal and dangerous class. The advantages are apparent to any one who will give the subject a moment's thought. At the present time there are 160 boys on board the *Chichester*, being educated and trained for the Royal Navy and Merchant service, 166 boys in another refuge, and 50 at the country home, and upwards of 100 inmates in the two refuges for girls. With a view of further converting the "waste" going on in the human material and turning it into useful labour, the committee have raised the building we now illustrate, and to which they purpose transferring the young and weakly boys from the London Refuge, so

that they may be fitted for service at home or in the colonies.

While urging this immediate necessity for larger and more comprehensive measures to stem the advancing tide of pauperism and crime, we point with admiration to what is being done by this particular association.

THE HISTORY OF ITALIAN SCULPTURE.*

In the fourteenth century Marcus Romanus was the one sculptor, of whom Rome can show any proof, and this is only in one work, a statue of Saint Simon, the prophoe, behind the high altar of the church dedicated to him at Venice. Some writers have attempted to divide this century between Marcus Romano and Pietro Cavallini, the scholar of Giotto. Vasari, for instance, names Cavallini as the sculptor of the crucifix at St. Paul's, which is said to have spoken to St. Bridget; and Horace Walpole says, that it was he who made the shrine of Edward the Confessor, and designed the crosses which marked the resting-place of Queen Eleanor's body. Mr. Perkins, in the book we are now noticing,† denies both these statements. There were, however, two sculptors in the fifteenth century, Paolo Romano and Gian Cristoforo. They were both goldsmiths as well as sculptors. Antonio Filarete mentions that Paolo helped to make the silver statues of the twelve apostles for the altar of St. Peter's, that were destroyed in the sack of 1527. His principal works are the statue of St. Paul on the Ponte Sant' Angelo, the tomb of Fra Bartolomeo Cavallini in the church of the Miraltes di Malta, and the monument of Cardinal Stefaneseh at Santa Maria, in Trastevere. The sarcophagus of Fra Bartolomeo is divided into panels by twisted columns, containing his arms and a mortuary inscription in Gothic letters; and on the top of it lies the knight dressed in armour and grasping the handle of his sword. The cardinal's tomb consists also of an effigy on a sarcophagus, but it has the addition of a marble canopy, with a frieze of coloured mosaics. Gian Cristoforo was the scholar of Paolo, and like his master was a goldsmith, as, with the assistance of two more scholars of his master, Niccolò della Guardia and Pietro Paolo da Todi, he made the twelve silver statues of the apostles for the Papal chapel at St. Peter's. He is also mentioned as the sculptor of figures and busts at Sta. Maria, in Trastevere, and as one of the artists employed upon the tomb of Gian Galeazzo Visconti, at the Certosa, at Pavia. Mr. Perkins gives two Roman sculptors to the sixteenth century, Giovanni Battista and Andrea Romano, the first of whom accompanied Giulio Romano and Primaticcio to Mantua, the last being also employed in the same city. In connexion with this paucity of local sculptors our author makes the following remark:—

"When we remember that Rome in the early part of this century was the home of some of the greatest foreign artists, it seems incredible that their example and teachings should not have developed native talent. From Niccolò Pisano down to Benvenuto Cellini all the great Tuscan sculptors went to Rome; some, like Donatello, Ghiberti, and Brunelleschi, to study ancient remains; others, like Simon Donatello, Filarete, Rosellino, Mino, and Michelangelo, to reside and work there. All were received, honoured, and employed by the Pope, the city became their chosen place of residence, being then, as she still is, the most sympathetic and the most attaching of all places to those whose lives are devoted to art in any form. Everywhere at Rome we find that the works of merit are by foreign artists. At St. Peter's and St. Pietro in Vincoli they are by Polignolo and Michelangelo; at Sta. Maria del Popolo and Sant' Agostino by Andrea and Jacopo Sansovino; and in the deserted cloister of the latter church by Mino and Mino's imitators; at Sta. Maria del Popolo and the Pantheon by Lorenzetto; at Sta. Maria dell' Anima by Tribolo and Michelangelo Senese. Indeed, with the exception of the pulpits, ciboriums, and tombs of the Cosmati, and the works of Paolo Romano, which hardly rise above respectable mediocrity, there are no Roman sculptures of interest in the many churches of the Eternal City."

The history of the Comacine architects forms an early feature in the account of sculpture in Lombardy. For twenty years an island in the Lake of Como held out against Alboino and his followers. It contained numbers of fugitives from all parts of Italy, some of whom were the skilled workmen known as the Maestri Comacini, and subsequently as "casari," builders of houses. There is evidence to show that the Lombard kings enfranchised the members of this guild, after the island submitted, and allowed them the privilege of making contracts. King Rotari, especially, in his code of laws, protected the

Maestri Comacini, whose free jurisdiction, explains Mr. Perkins, was recognised by the name of Free-masons. Although the miserable state of the country, owing to war and pestilence, prevented any considerable structural operations, for some time after the conquest, Queen Theodinda soon appears upon the scene, employing the Magistri Comacini to build the duomo at Monza, and recording the conversion of her husband Agilolph in a bas-relief over the portal representing the baptism of our Lord. A century after this other Comacine masters were still building in the same style, which is debased Roman with strong Byzantine tendencies. There is an octagon font in the duomo at Cividale, erected by St. Calixtus, bishop of Aquileja, which well illustrates its peculiarities. "Its roof is supported upon slender columns, with rude Corinthian capitals. Their intermediated spaces are spanned by round arches, whose spandrels are adorned with clumsily-represented Christian emblems. The bases of the columns rest upon a marble parapet sculptured with figures symbolical of the four evangelists, each holding a book, inscribed with verses by Sedulius, a Latin poet of the fifth century, and an ornate Greek cross, with candelabra and palm-trees executed in relief by lowering the surface of the stone around their clumsy outlines, within which the details are indicated by furrows dug out in the stone." Milan so heartily patronised the arts that the fourteenth century saw no fewer than 2,000 monuments in its churches, according to the statement of a chronicler of that period; but a decree of the Council of Trent led to many of them being taken down. About this time we first meet with the Campionesi, a company of architects and sculptors so called, from the district of Campione. Five sculptors, known as "da Campione," were engaged upon the duomo at Modena in the thirteenth century. Two others, Matteo and Bonino da Campione, were accorded the title of famous. Area di Sant' Agostino at Pavia, which took twelve years to complete, in this structure "the effigy of the saint, covered with a winding-sheet held up at its corners and sides by six angels, lies upon a mortuary couch seen through the open arches which support its second story. The statues of the apostles are placed, two by two, in compartments around the lower or basement story, separated from each other by pilasters faced by statues of the Virtues. Above them smaller statues of saints and prophets stand against the pilasters of the second story, upon which rest consoles supporting seated figures of saints and martyrs. A row of pointed gables, decorated with crockets and finials, runs round the uppermost story, upon which is a series of bas-reliefs, representing incidents in the life of St. Augustine, separated from each other by twenty statues." One of these artists was the sculptor of the monument that Bernardo Visconti erected to the memory of his wife, in which, curiously, there is no effigy of the lady, but an equestrian statue of himself, clad in armour and biton in hand. And the elder of the two was appointed architect, first of the duomo at Monza and then of that at Milan. At Monza there is a mortuary tablet, set into the outer wall, which says, "Here lies the great architect, the devout Master Mathews da Campione, who built the facade of this holy church as well as its pulpit and baptistery, and who died in the year of our Lord, 1396." The first architect of the cathedral at Milan was Marco Frisone da Campione, who with four Campionesi formed a body of architects and sculptors, attached from this beginning to the "Veneranda Fabbrica." The contemporary building, the Certosa, however, was placed in the hands of Bernardo da Venezia. This building Mr. Perkins, with others, considers surpasses the duomo in artistic interest, for it is a perfect museum of sculpture by the best artists of the Lombard school. He says of it,—

"Few Italian churches, indeed, can compete with the Certosa, whose stiltiness is broken only by the hushed tread of some white-robed monk, who passing on, leaves the visitor to an undisturbed enjoyment of the objects around him. After scanning every rich detail of the facade, he enters through the sculptured portals into the nave, examines the paintings and marbles in the chapels, the tombs that lie the transepts, the expensively sculptured doorways of the sacristies, the bas-reliefs and terra-cottas in the vast cloisters, the richly carved capitals and cornices, and carries away with him a sense of harmony and completeness only to be derived from a series of works which belong like these to one school and to one time."

Early in the fifteenth century we find Jacopino da Tradate working for the "Fabbrica del Duomo." He was called upon by the Duke Filippo Maria

* See p. 1, ante.

† Italian Sculptors. Longmans & Co.

to commemorate the entry of Pope Martin V. into Milan, by erecting a colossal statue of him in the duomo. This admirable figure, which is more than twice the size of life, is seated on a draped throne, in full pontifical, holding the keys in one hand and giving the benediction with the other. Jacopino was also the author of the half-figure of God the Father in bronze in the centre of the roof of the apse of the duomo, and the reputed author of the tomb of Pietro Torello at Sant' Eustorgio. Before his death he removed to Mantua, to work for the Duke Francesco Gonzaga. The school of the Campionesi characterized by "simplicity and extreme quietness of action in its round-surfaced, short-proportioned statues and bas-reliefs" was now supplanted by that which came in with the Renaissance, remarkable for its "violent action, intense facial expression, hardening on grimace; clinging draperies, great length of limb, and very flat treatment of surfaces." A transitional style appears to have been used by the brothers Mantegazza, in the first part of their career. They did so much work at the Certosa for the Prior Filippo de' Ranacate, that their pay amounted to nearly the cost of a house at Milan, which he made over to them as a discharge of his debt, stipulating that its value over and above their account should be made up in future work. Some of their later work is marked by the exaggerated gestures and expression we have just quoted. Giovanni Antonio Amadeo, or Omodeo, who worked with them, on the Certosa, is considered the most remarkable of the Lombard sculptors. He was the son of a farmer, living near the Certosa. When he was nineteen we find him with his brother Protasio, at work upon sculptures for this building; and in 1490 we read he received the appointment of head architect to it, and designed and carried out the façade. He erected the monument to the daughter of Bartolomeo Coleoni, at Basella, near Bergamo, spoken of as one of the most charming works of the kind in Italy: delicate, simple, and beautiful. The slender figure of the deceased, in an embroidered robe, lies with her head upon an ornamented pillow, upon a sarcophagus, enriched with statuettes. There is a string of jewels upon her head, and a necklace round her throat. Her eyes are closed, and her arms folded upon her bosom in serene repose. Her father commissioned Omodeo to build a family chapel at Bergamo, immediately after its completion, which he designed in the richest Renaissance style. At Cremona he worked upon the shrine of the Egyptian martyrs; and in the family chapel of the Borromei on the Isola Bella he executed two monuments which show his delicate touch and artistic eye to considerable perfection. But when he undertook the crowning of the Milanese duomo with a cupola he resigned all other engagements and removed to Milan. Mr. Perkins considers Omodeo would have ranked with the Tuscan Quattro Centisti had his style been less mannered and more elevated. After him come his rival Cristoforo Solari, some time head architect of the Milanese duomo, with his scholars Giovanni Dentone, Giovan Giacomo della Porta, Girolamo da Novara, and Andrea da Fasina; the latter of whom figures in the records of the Fabbrica, poor unfortunate, as continually asking for money in advance. It is, perhaps, some clue to this inability to meet his current wants with his current industry to be told that his work was "tasteless and clumsy, though smoothly and skilfully executed." After this brief little is known beyond the names of the sculptors, who clustered "like bees" about the duomo in the last half of the fifteenth century, and stored up their work in it. The Fabbrica held out great advantages, which were appreciated to their fullest extent. The young were taught their art and the old were pensioned; which privileges were forfeited by seeking work elsewhere without permission. Mr. Perkins gives full accounts of the labours of other Milanese sculptors not employed on this great work; but who have materially enriched Lombardy with their works. We learn from them the lesson that we need not grieve because our work is not displayed in the high places of the world. They teach us "to labour and to wait." Recognition is sure to come, if our work be worthy of it.

We must give the pretty piece of word painting with which our author limns in Venice. He says the Venetians had more feeling for colour than for form, and accounts for this preference by their relations with the East, and the situation of their city between the formless sea and everchanging sky—

"When we look around us at Venice we see colour expressed in every object which meets the eye. St. Mark's, with its marbles and mosaics, is all white with it; the Ducal Palace is toned like the inside of a sea shell; the façades of the stately buildings which line the Grand Canal are variegated with disks of serpentine and porphyry; and the sails of the fishing-boats vary in tint from a golden yellow to a deep amber; the water in the side canals, which as we emerge from them into the Giudecca or the Lagoon expands into the broad sea, is as pure as those long strips of sky between the black chimney-tops, which in like manner widen out into the measureless heavens. Seen from afar through the early morning haze Venice looks like some 'saporoso amethyst,' and at sunset, when the flaming heavens above her are reflected in the smooth waters, her towers and palaces grow grey upon a pavement of fire, like ashes resting upon glowing embers. City and sky and sea are then all visionary, all indistinct in outline, and we feel why a great school of colourists rather than a great school of sculptors grew up at Venice. Venetian sculpture was always strictly decorative, and the artists who practised it were rather marble-workers than sculptors, men skilful in carving statuettes and arabesques, but incapable of raising their art out of its Medieval dependence upon architecture."

All the leading Venetian sculptors for three hundred years were architects. In this span of time three styles of architecture prevailed—Gothic, Renaissance, and Baroque, and the sculpture was adapted to each with like skill. The Gothic was practised by Filippo Calendario, the Massegne, and the Bons; Andrea Rizzo represents the Lombardi; Leopardi the Renaissance; and Alessandro Vittoria, with his followers, the Baroque. Up to the thirteenth century, Byzantine influences predominated, as many details on St. Mark's prove, especially the central bronze door, which hut for its Latin inscriptions and saints might be taken for Byzantine work. The first indication of less formalism is pointed out by our author as the beginning of a national style, is shown in the scriptural bas-reliefs upon the marble columns of the ciborium, and in the baptistery, and in the little figures at the base of the columns in the Piazzetta. The Niccolò di Barattieri who raised these columns and sculptured the figures, a Maestro Donato, and Johannes di Venetia are the only Venetian artists who are known to have flourished before the fourteenth century. After the new century came in, we find Bertuccio casting the external gates of St. Mark's, and two anonymous Venetian sculptors at work, the one making an ancona of wood for the altar of the duomo at Murano, and the other carving the Madonna della Misericordia above the Ponte del Paradiso at Venice. A third is heard of at Genoa. These, with the bas-reliefs of the second half of the century, are exceedingly rare compared with the contemporary sculpture of Tuscany. The Ducal Palace sculptures are so perfectly adapted for the places they occupy, are so complete as a series, and harmonize so well with the scheme of the building, that Mr. Perkins considers they must have been designed by the architect Filippo Calendario, and not, as some writers have endeavoured to show, by the Bons a hundred years afterwards. This Calendario was originally a sailor or shipbuilder at the fortress of Mirano, and by his talents and industry at last occupied the post of superintendent of public works. Mr. Perkins accounts for his acquiring the necessary skill to maintain such a position by suggesting that Andrea Pisano must have given him some instruction. He is, let us hope he may ever be, the solitary example of an architect being hanged. He was implicated in the conspiracy of Marino Faliero, or supposed to be so, and the Council of Ten sentenced him to death, gagged him, and hanged him from the red columns of the balcony of the ducal palace he had beautified. His work undergoes an appreciative criticism in the work before us. Instead of examining it minutely, we must proceed with a more general survey of the stores Mr. Perkins has collected. He describes the type of tomb common at Venice upon which so many of her sculptors spent their best thoughts, as the most perfect of any, because it is beautiful to the eye as well as solemn and appropriate. The sarcophagus is generally set high up against a chapel wall under an arched canopy. Its front is divided into two panels full of bas-reliefs, by a statuette of Christ, or a group of the Madonna and Child under a little baldacchino; and at each end there are figures of the Angel of the Annunciation and the Virgin. He says the recumbent figure of the deceased is placed upon the sarcophagus as though it was laid out in church before burial, and angels are placed to guard it, either holding back curtains that fall from the canopy above, or standing by with censers in their hands, or supporting the cushion on which the head is placed. The tombs of the doges afforded ample opportunity for the sculptor's chisel and fancy.

A Renaissance tomb, by Pietro Lombardo, consists of a sarcophagus resting on a projecting base, supported upon consoles, having strong holding vases in their hands, rich leaf-work and an eagle with spread wings on its front, and has a frieze so exquisitely sculptured that a needle rather than a chisel seems to have been the implement used in its execution. It is, however, upon buildings that the chief works of the Venetian sculptors are to be sought. After Jacopo Sansovino's forty years' reign in Venice, during which period nothing was undertaken without his sanction, his defects were exaggerated by his successors into the style called Baroque. War was declared against the straight line, ornament was heaped on regardless of construction, limbs twisted into impossible attitudes, and draperies hollowed out, to look as though honeycombed from natural causes rather than by the chisel. This illogical, thoughtless, capricious sort of work is not to our author's mind, who, accordingly gives it no prominence in details, and closes his account of Venetian sculpture with a sketch of the life of Alessandro Vittoria, under whose auspices it commenced its eccentric rule.

In Verona we find Magister Uro and his scholars Gioventius and Giovanò, from the Isola Comacina, at work upon a ciborium, on the church of San Giorgio di Val Pulicella. Then comes a gap with only Maestro Pacifico, through which several centuries rolled away. In the twelfth century there was a little band of sculptors at work upon the church of San Zeno, making the bas-reliefs that cover the walls of the façade on either side of the great portal. One of them Adamans, carved his name upon a capital of a shaft at the entrance to the crypt; so we may conclude that it was he who sculptured the centaur hunting a stag, the dead fox hanging on a staff carried by two cocks, imaginary animals, and such droll conceits, upon the architrave above. The first great Veronese artist, our author asserts, was Victor Pisano; for before that period, if the lords of Verona wished to build a tomb they were obliged to send to other cities for artists. But it would be difficult, he continues, to find more delicate shades of modelling, greater truth to nature, and more exquisite taste in the use of costume and arrangement of drapery than are to be found in some of Il Pisanello's work, though he looks upon him as a medallist rather than as a sculptor. Among the cinque-cento sculptors our author mentions Girolamo Campagna, the author of the clever bas-relief, relating the story of a murdered man resuscitated by St. Anthony, that he might testify to the innocence of his father accused of his death, in the Cappella del Santo at Sant' Antonio. Neither of the sculptors of this period, however,—not Giulio di Girolamo della Torre, the ex-lawyer,—nor Giovan Battista, who made the crucifix for the duomo at Mantua Vasari praised so highly; nor Alessandro Bassi, who made the statue of San Bernardo Abate for the church of Sta. Maria at Carrara, made anything so exquisite as the marble candelabra in the duomo, ascribed to an unknown Paolo (detto delle Breze) from Rome.

Vicenza, the birthplace of Palladio, sent a sculptor to Padua in the first half of the fifteenth century, to carve an elaborate pilaster for the Cappella del Santo in the church of Sant' Antonio. A hundred years after this, another Girolamo da Vicenza was making the tomb of Pope Celestine V., in the church of Sta. Maria Collemaggio at Aquila, in the Abruzzi, and another Vicentine sculptor, Rocco, was executing marble works for the Collegiata of Sta. Maria Maggiore at Spello. Two other sculptors left Vicenza to work elsewhere, and left the field free for Palladio's fame.

Padua, associated with the work of many renowned Tuscan sculptors, has also produced a few artists of eminence. First among these was Fra Clarello, monk, sculptor, architect, and standard-bearer, in the army of the Pope, that marched to Padua to put down Ezzeolino, but his works have all perished. Bartolomeo Bollano is the next. He worked for Pope Paul II., at the Palazzo di San Marco, and was employed at Perugia in casting a bronze statue of him for the outside of the duomo. His pupil, Andrea Briosco, called Riccio or Crispio, from his curling hair, is more famous. He was the author of two clever bas-reliefs, in the choir of Sant' Antonio, which have been said to contain lessons enough to make a modern sculptor; and of the bronze candelabra, of which his patron Gian Battista Leon wrote, "Well may the city be proud of a work so admirable in every part, so beautiful in

form, and so perfect in execution," and of which Mr. Perkins gives an etching and full details. There were several other Padoan artists who did good work, but his fame eclipses them all.

Mantua dedicated herself to Virgil when the illustrious poet had made his birth-place famous. His name was upon her banners and on her coins, and when the magistrates wished to celebrate a victory they decreed that his statue should be erected in a niche above the Piazza that he might appear to be taking share in the events of the day, and the joys and cares of his compatriots. This statue proclaims the condition of art to have been but rude when it was erected. Twenty years afterwards a marble alto-relief was made of him, the execution of which is somewhat better. These and all the earliest sculptures at Mantua are anonymous. Three men, Mantegna the painter, Alberti the architect, and Sperandio the medalist, influenced much of the subsequent work at Mantua. Mr. Perkins says of the foremost of these three that he Christianized Paganism, and of Giulio Romano that he Paganized Christianity.

Most of the cities in Central Italy hold high places in the history of art as fields on which good work has been done, and great artists produced. Bologna stands foremost in virtue of Francia and the Caracci; then comes Parma, made famous by Correggio. Their sculptors are not quite so world-known. But Bologna boasts her beautiful and gifted sculptress and vixen, Propertio da Rossi; Ferrara can claim Alfani, Lombardi; Modena is proud of Guido Mazzoni and his scholar Antonio Begarri; Reggio of her two Clementis; and Parma of Benedetto di Antelamo. Throughout his attractive volume Mr. Perkins gives illustrations of the chief works of the most celebrated artists. Thirty-nine etchings, some of them of great beauty, are given, and upwards of a dozen woodcuts. Opportunity has, of course, to a great extent, guided their selection; although there are none included that do not specially illustrate some peculiarity, there are necessarily many sculptors left unrepresented altogether. Of the works of the artists just enumerated, only one is illustrated, which is a group from a mortorio in the church of San Giovanni Decollato at Modena, by Guido Mazzoni. Those who would qualify themselves for looking at sculpture with some knowledge of its chief sculptors and their styles, those who would enlarge their sources of interest in their fellow-workers and their appreciation of their works, would do well to read every page of Mr. Perkins's book.

METROPOLITAN EXTENSIONS OF THE SOUTH-WESTERN RAILWAY.

In addition to the important extensions that have been recently completed and opened to the public, in connexion with the railway systems of the metropolis, others—the last, probably, for a considerable time to come, excepting the East London line only—have again to be announced, namely, the new line of the South-Western Company from Kensington to Richmond, and the new direct line of the same company between Wimbledon and Kingston. The new lines, the successive openings of which have been most recently noticed in the *Builder*, the Metropolitan extension from Paddington to Brompton, and, next, the Metropolitan District from Brompton to Westminster Bridge, are parts of the inner circle, the precise course of which was definitively settled by Parliament in 1864. The Kensington and Richmond line and the metropolitan system are intimately related in two distinct aspects. The principal of these is, that the Metropolitan has running powers at mileage rates over the new line, upon which the company may run trains by a working junction at Hammersmith, from Moorgate-street, or any other station on the inner circle, through to Kew, Brentford-road, or Richmond. For the present the Metropolitan Company will book passengers to any of the stations on the new line, but will not probably take advantage of the running powers till spring or summer, when the pleasure traffic sets in. The Metropolitan Company has just completed a greatly enlarged new station at Hammersmith, which will continue to be used as a terminal station for that locality. The station of the new line is close to that of the Metropolitan, but on a higher level; a covered stair and gallery communicates between the two stations. The course of the new line from its start at a point a little

to the north of the West Kensington Station, on the West London line, is by a bend of nearly a semicircle to the north and west, the springs of the arch being at the West Kensington station on the east, and the Hammersmith Station on the west. In its course the line passes under the Metropolitan line (Hammersmith and City), and bending round to the west, rises to the high level station, close to the Metropolitan station, the high level having been necessitated by the headway required for the Grove-road, which passes under the line close to the two Hammersmith stations. The junction between the Hammersmith and City line, and the Kensington and Richmond line, is effected between the point where the last-named crosses under the other and the station. The booking-offices and stations on the new line are all more compact and promising for the comfort of passengers than that at Hammersmith, which straggles, with a variety of angles and curves, over what seems to be, but possibly is not, an unnecessarily large aggregate area. Abundant platform accommodation has been provided at this as at all the other stations indeed, but it is to be regretted that the chief advantage of planked platforms—their being warmer than stone or asphalt—has been sacrificed here, from considerations of economy it may be presumed. The long platforms, about 15 feet above the ground level, and open to the bottom, are laid with undressed planks, and five-eighths or three-quarters of an inch open at the joints. The planks will, of course, last much longer with the air playing between the edges; and will discharge the rain that falls upon them more readily than a close surface, but stone or asphalt would have been preferable for comfort, during dry cold, in such a situation. The line is carried over the public road by a wrought-iron girder bridge of 90 feet span, very much askew. The floor of the bridge is of double planking, and wrought-iron buckle plates, packed between, to deaden the sound of passing trains, with Barnetized saw-dust. From this point the line curves round on a viaduct of about a mile in length, and pursues a course nearly straight, and almost due west, for about three miles, to Brentford-road. About midway there is a station for the service of Turrham-green. The course of the viaduct is nearly parallel with the London and Brentford rail; the average height of the work is about 20 feet to the rail level; the arches are of 20 feet span. There are ten wrought and cast-iron bridges in the viaduct of from 76 feet span downwards, all waterproof and packed to deaden sound. The line crosses Acton-green upon a falling gradient of 1 in 120, and at the west side of the Green enters a cutting of considerable length and depth, in which the line passes under the Brentford-road, which is carried across on a wide skew bridge. In this locality, also, the mains of the water and gas companies, which serve the district, are borne across the line between plate girders of wrought-iron.

At Brentford-road the line curves to the south, and reaches the station for Brentford in the course of the curve. The station here is large and commodious, with four lines of rails, and ample platform accommodation. The up platform is about 24 ft. wide, and covered the whole width. There is from this station a short branch connecting the line with the North London, by which trains may be run from any of the stations on the North London line to Kew Gardens and Richmond direct, instead of, as now, by the long detour by way of Barnes. There is also a junction here with the South-Western loop-line, giving communication with Brentford, Hounslow, and other stations to the south-west. At a short distance from the Brentford Station the new line crosses over the South-Western loop-line and immediately afterwards over the Thames by a bridge with cast-iron piers and lattice girders. The bridge has five spans of 108 ft. 6 in. each clear, with about 20 ft. of head-way at high water. The cylinders are square, with small three-quarter columns at the corners, the columns cast solid. The cylinders are let down deep in the London clay, the base of the foundation excavations being filled with concrete. The cavities of the cylinders are filled with brick-work and cement. The upper portions of the piers rise considerably above the upper edge of the girders, and show deeply-indented panels filled with alto-relievo ornamental work. They show semicircular heads on the faces, and are surmounted by globular lamps. The abutments are of red brick, and relieved with pilinths, columns, and caps, of Portland stone.

The most important work between the river

and Richmond is the station opposite the new entrance to Kew Gardens,—a station at which doubtless a large pleasure traffic will be done, for which provision has been made in platforms and sidings. In its onward course the line passes under the Richmond-road and Sandylane by a tunnel-bridge of 150 ft. long, and a little further on bends round and runs alongside of the Richmond and Windsor line to the new station, close to the old one at Richmond, which will be used in common by the South-Western, the Metropolitan, and the North London Companies. Passengers will here change for the Windsor, Reading, or Kingston trains. The line is about seven miles in length.

The extension from Malden to Kingston is important in itself, in passing through about 2½ miles of exceedingly pleasant new country, admirably adapted for residence, but is even more important in the connexion it opens with the London, Chatham, and Dover and Brighton systems. In addition to the new line between Malden and Kingston, and the new station thereon at Norbiton, near Kingston-hill, the South-Western line has been doubled between Malden and Wimbledon, and there is now a regular service between Ludgate-hill, Blackfriars, and Camberwell-road stations *via* Hone-hill, Tulse-hill, Streatham, Tooting, Wimbledon, Malden, and Norbiton, and Kingston. Numerous other advantages, in interchange of traffic between north and south, east and west, have been secured by the opening of these new lines, and the train arrangements that have been entered into between the various companies. The changes and enlargement of service consequent upon the opening of the lines, involved the addition of about 300 trains daily from New Year's day, when the new services were entered upon with the opening of the lines.

The works were designed and carried out under the superintendence of Mr. W. R. Galbraith, engineer to the South-Western Company. Messrs. Brassey & Ogilvie were contractors for the Kensington and Richmond line; and Mr. P. Mortimer, resident engineer. Messrs. Aird & Sons were contractors for the Kingston and Wimbledon line; and Mr. A. McDonald, resident engineer.

THE ANTIQUITIES OF PARIS.

THERE is sad work going on amongst the relics of old Paris. The Paris correspondent of the *Telegraph* relates a circumstance to illustrate this. M. Récapé, a well-known amateur and dealer in works of art and *ébrés*, having heard that a considerable quantity of carved wood had been sold as rubbish, hurried to the spot. One glance at the confused heap in a corner of the yard was enough for M. Récapé. The contractor asked 1,200 francs for the lot, and the amateur paid the money down. On examination, this huge pile of firewood turned out to be an inestimable treasure—no less than the whole of the woodwork which had decorated the old reading-room in the "Bibliothèque Impériale," a marvel of artistic workmanship, supposed to have been designed and carved for the great Colbert. When the woodwork had been cleansed of all impurities, even Récapé himself was astonished. The carvings were voted, by competent judges, to be among the finest productions of the reign of Louis XIV., and were purchased soon afterwards by M. Mailet du Boulay, a rich amateur, for the sum of 8,000. Another instance of like enormity happened three years ago. A wrought-iron balustrade was taken down from the grand staircase of the same "Bibliothèque," and was also sold by weight to some *Auvergnat*. A goldsmith of Genesee saw it, and became a happy possessor for the sum of 1,200. On being told of the affair, the inevitable M. Récapé went immediately to Genesee to make himself, at any cost, master of the balustrade, which is said to be one of the most wonderful specimens of wrought-iron in existence.

Quiet "Practice on the Piano.—The Paris journal *Le Ménestrel* mentions a new invention which should earn for its author the gratitude of millions. It consists of an apparatus, which, applied to any piano, will deaden the sound emitted. There are few persons who have not been sometimes distracted by the "practising" of some too persevering player, and who would have paid any price for such a "mute" as that described. But will the players use it?

THE DEAD YEAR.

Among the duties which fall to be performed by the public journalist at this "festive season," is the mournful task of reviewing the losses which the world has sustained by death. He is once more called upon to chronicle a long roll of public characters, distinguished in the various walks of professional life, who have closed their earthly career during the past twelve months. Some had attained to greatness, others had but given promise of becoming great when the fell destroyer came; but of one and all it may truly be said that they died and left the world better than they found it. Many eminent names are inscribed in the general obituary of the year; the church, the senate, the army and the navy, literature, the law, and the medical profession, each has lost a number of notable representatives both at home and abroad. It falls more within our province, however, to record the losses that science and art have sustained. Here we have to mourn many bright ornaments in our own and in other countries. The year 1868 will be chiefly memorable as that in which died two of the most renowned men of any age or country. The great natural philosopher—the discoverer of the law of polarization of light by reflection—the inventor of the kaleidoscope—the founder of the British Association for the Advancement of Science.—Sir David Brewster breathed his last at his seat near Melrose on the 10th of February, at the patriarchal age of 87. His illustrious friend and countryman, Lord Brougham, followed on the 7th of May, at the still more advanced age of 90. In the deaths of Brougham and Brewster, Scotland lost two of her most illustrious sons, and the world two of its greatest benefactors. Science and art, as we have said, have suffered numerous and great losses. Baron Marochetti departed with the old year, having died in Paris on the 25th of December, 1867, aged 63. About his merits as a sculptor there is a diversity of opinion; while he lived he enjoyed a considerable reputation, and we are content to respect the old maxim *de mortuis nil nisi bonum*. With the dawn of the year—on the 2nd of January—passed away John Doyle, better known as "L. B.," the celebrated political caricaturist, whose works caused an extraordinary amount of public interest forty years ago. His likenesses of Sir Robert Peel, the Duke of Wellington, and other public men, have never been excelled. He was father of the artist who designed the inimitable and familiar frontispieces of *Punch*—the well-known "Dicky Doyle" of "Pips, his Diary," and "Brown, Jones, and Robinson," celebrity. Within a few days after died M. Claudet, the eminent photographer, of Regent-street, who first introduced into this country the old daguerreotype process, in the year 1839, and made various useful discoveries in connexion with his art. Also Theodore Rousseau, one of the most celebrated landscape painters in France. M. Rousseau died at his beautiful retreat at Barbizon, on the skirts of the forest of Fontainebleau, whence he drew his inspiration. He was 55 years of age. On the 24th of this month the death was recorded of Dr. John Davy (born 1790), an able chemist, geologist, and physiologist, and brother and biographer of the celebrated Sir Humphrey Davy. In February, William Herapath, the well-known chemist and toxicologist, of Bristol, was taken from us in his 72nd year; and in the following week, singular to say, another member of the Herapath family, John, proprietor of *Herapath's Railway Journal*, and author of "Mathematical Papers," died at the age of 78. The death of Ball Hughes, the sculptor, took place at Boston on the 5th of March. Born in London in 1806, he was a pupil of Baily for seven years, during which time he gained several important prizes in competition. The Royal Academy gave him a silver medal for the best copy in bas-relief of Apollo, and the Society of Arts awarded him a gold medal for an original composition, "Pandora brought to Earth by Mercury." Mr. Hughes emigrated to America in 1829, and executed a large number of works in the States, some of them of great excellence. M. Charles Méryon, the famous French etcher, who died also in the beginning of March, was principally known by his admirable etchings of Parisian streets and buildings. Towards the close of this month was announced the demise of Bernard Mhlenin, a distinguished miniature-painter, of Dublin, and president of the Royal Hibernian Academy; as also of M. Picoi, the veteran historical painter, of Paris, aged 82. He obtained the first prize of L'École des Beaux Arts with his "Mort de

Jacob," so long ago as 1813. Herr Vandernael, the eminent architect, of Vienna, died in April, and Mr. Carmichael, a well-known English landscape painter residing at Scarborough, in May. The end of this artist was painfully sudden. He had been out walking, and on his return to his studio was seized with a fit, which terminated fatally in a few minutes. Mr. Carmichael was 68 years of age. At the close of May we had to speak of the death of John Burnet, engraver, painter, and writer on art, the friend of Sir Walter Scott, and of Wilkie and Allan, the painters. A descendant of the famous Bishop Burnet, he was born in Edinburgh in 1785. His engravings of Wilkie's pictures are well known. Many of his engravings are from Burnet's own pictures, or illustrations of his own books. Among the former are "The Greenwich Pensioner," the original of which was purchased by the Duke of Wellington; "Feeding the Young Bird," "The Draught-players," and "The Mouse." His literary works include, "Hints on Painting," "Landscape Painting and Oil Painting," and lives of Rembrandt and Turner. Louis Royer, the celebrated Dutch sculptor, died at Amsterdam, on the 5th of June, aged 75. This day month (on the 5th of July) Italy lost Giovanni Bastianini, a young sculptor of undoubted genius. He produced busts in terra-cotta of marvellous truthfulness and grace: of one of which at the South Kensington Museum we have recently spoken. Unfortunately for his reputation, his price being high, his line of labour was confined to the pseudo "antique;" that is, presenting as ancient works the productions of his own hands, washing the marble of his busts and statues with tobacco water until they became so discoloured, that even the most suspicious could not pronounce with any degree of positiveness, by merely looking on them. Bastianini was the son of a poor stonemason, of Fiesole, and began life as a worker in the quarries. Through the patronage of the Chevalier Inghirami, he learned the rudiments of the art of sculpture, and afterwards was employed at a small remuneration by Freppa, a well-known dealer in curiosities, to execute for him those works in terra-cotta which have since found their way into great national collections as the recovered masterpieces of Early Italian art. One of them, the celebrated bust in terra-cotta of Benivieni, which was bought for a trifling sum by the Florence dealer, and afterwards sold for 13,000 francs, at a public auction in Paris, is now deposited in the Louvre. This promising genius fell a victim to typhus fever, in Florence, at the early age of thirty-eight. America had to lament one of her most widely known painters, Emanuel Lentze, who died of congestion of the brain, at Washington, on the 20th, aged fifty-two. He was of German extraction, and became a pupil of the famous painter Lessing, of Dusseldorf. Lentze produced a series of pictures from English and American history, which are remarkable for their character, spirit, and fidelity. Among the best of his earlier works may be mentioned "The Court of Queen Elizabeth;" "Henry VIII. and Anne Boloy;" "Cromwell and his Daughter;" and the "Tea-noclast." Of his paintings representing subjects taken from American history, the most important and popular are "Washington at Monmouth," "Washington crossing the Delaware," "Sergeant Jasper," "Washington at Princeton." All these works are widely circulated throughout the United States; and though the last named may be said to be the most popular among art critics, engravings of "Washington crossing the Delaware" can be seen in almost every cottage in that country. At the time of his death Lentze was engaged on a large cartoon representing "Civilization," to be painted in one of the panels of the Senate Chamber at Washington. Our own country lost an unusually large number of distinguished professional men this month. The versatile and accomplished artist, George Honsman Thomas, was snatched away suddenly at the age of 44; and George Cattermole, in his 68th year. In the death of Richard Hassall, South Kensington lost one of its chief designers and sculptors, a man of great promise. Another designer and modeller at Kensington, Mr. Gibbons, was accidentally drowned. James Thomas Hixon, the water-colour artist, died of consumption, at the island of Capri, in the Bay of Naples. He had recently been elected an associate of the Institute of Painters in Water-colours, and exhibited four drawings at its last exhibition. Mr. Hixon was only 32. In August Cicóri, the great French scene-painter, passed away full of years and honours. His career was curious.

Having begun life as a musician, he used, at fourteen, to play his part on the violin in the "Séraphin" orchestra. Subsequently he took to painting, under one of the architects to the king, and ended in being the most eminent artist in his line. As far back as 1810 Cicóri, by order of King Jerome, restored the great theatre at Cassel, and in 1825 he superintended the coronation festivities of Charles X. The decease, on the 25th of this month, of Charles Elliott, deprived America of her most distinguished portrait-painter. He was the son of an architect, and was born in Scipio, New York, in 1812, where he studied art under the well-known American painter, Trumbull. Also in August died Professor John Millington, an English chemist of reputation, in the United States, aged 89. He was a practical miner, and in early life was associated with Macadam, the celebrated road-maker. George Maccallum, a young Edinburgh sculptor of much promise, pupil of Brodie, R.S.A., and afterwards assistant of Steel, her Majesty's sculptor for Scotland, was cut off suddenly in the beginning of September, in his 27th year. On the 15th, E. H. Wehnert, a clever and popular artist, several of whose works have been engraved, died at Kentish-town, aged 54. He was closely followed by Hippolyte d'Orschwiller, the French painter, about the same age. Next, Antonio Vechte, the *repousseur*, passed away, to the regret of all who are interested in art-workmanship. This accomplished craftsman and able designer was born in France in 1799, and lived in this country for a number of years. His works now enjoy a European reputation; but few men have made a nobler struggle for recognition than Vechte. On the 27th of October, the death was announced of Herr Edward Hildebrandt, a distinguished landscape-painter of Berlin.

Other names besides those we have enumerated deserve record—of individuals who have departed during the year, less distinguished or less known, perhaps, than the above, but whose useful labours in the cause of science, art, and architecture are nevertheless not without interest to our readers. Among architects we have lost George Guillaume, of Southampton, who died on the 15th of February. He enjoyed a high provincial reputation for nearly thirty years, and, in addition to numerous works in ecclesiastical and domestic architecture which he designed and executed, Mr. Guillaume was an able writer on architectural subjects, and a man of no mean powers as a mechanical inventor. On the 23rd of May Mr. Pritchett, architect, York, closed a useful life at the venerable age of fourscore years, having been in actual practice on his own account for the long period of 55 years. In the end of July William Clephane, architect, of Stockton, died; and about the same date, after a long and painful illness, as our readers know, George Rowden Brnell, in his 64th year. The other day we announced the death of John Burlinson, who for a quarter of a century was the confidential and valued assistant of Mr. G. Gilbert Scott. Several able engineers have also disappeared from our midst, including Thomas Duncan, the water engineer to the Liverpool Corporation. His death happened also last month. The Society of Arts has lost one of its oldest and most valued members in Harry Chester, who will be missed from the councils of that and various kindred associations. Nor ought we to omit the name of Channace Hare Townshend, who departed at a good old age in February. He was an elegant poet, an accomplished musician, and a skilful painter. But he will be chiefly remembered as a collector of works of art, of rare judgment and exquisite taste, and for having with equally rare liberality bequeathed his venerable collection to the South Kensington Museum for the benefit of the public.

Since this notice was written Mr. George Lowe, the well-known gas engineer; Mr. Edward Goodall, engraver and father of painters; and Mr. Abraham Cooper have left this life. Abraham Cooper died at Greenwich on Christmas-eve, aged 81. This notable painter was born, we believe, in Red Lion-street, Holborn, and sprung from a very humble position. His first exhibited picture, "Tam O'Shanter," sent to the British Institution well nigh sixty years ago, was purchased by the Duke of Marlborough. Mr. Cooper has been ever since a constant exhibitor both at the Royal Academy and the British Institution. His works consequently are very numerous, and he painted too long for his fame. Among the principal are "Blincher at the Battle of Ligny," "Cromwell at Marston Moor," "The Death of Harold," "The Battle of

Assaye," "The Battle of Shrewsbury," "The Battle of Waterloo." He was elected an associate of the Academy in 1817, and R.A. in 1820.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE HOLY LAND.

The fortnightly general meeting of the above Institute took place on Monday evening, the 4th inst., Mr. James Edmeston in the chair. Mr. John Clarkson, of 36, Great Ormond-street, and Mr. Thomas C. Ebdy, of Darham, were balloted for and elected associates of the Institute. The decease, on the 16th of October, at Hong Kong, of Mr. John Clark (member), formerly of 2, Great James-street, Bedford-row, was announced by the chairman.

A communication from Professor Donaldson, giving a hasty sketch of that gentleman's visit to the Holy Land, with passing remarks upon the intermediate places visited; by the Professor and his party, was read. It was in the form of a letter addressed to Mr. C. C. Nelson, and was couched in the characteristic graphic style of the writer. Speaking of his visit to the Suez Canal, Professor Donaldson states—"The southern portion between Ishmaella and Snez is excavated to half its depth only, and one harbour at one mouth has to be completed. It is a marvellous realization of a prodigious project, and does justice to the daring of its projectors. As you steam along its channel 300 feet wide, with sufficient depth to receive the largest merchant vessel, you cannot but feel impressed with the extent of this great sea-channel. But its maintenance [continued the writer] will be the greatest difficulty of all: to preserve the depth from being choked up by the sands, whether along the canal itself or in the port, is even now a matter of anxiety and care. While we were upon the spot a French vessel of war was expected, and they were employing many gigantic dredgers to secure a channel. In the basin of the harbour there were several vessels of considerable size. The piers to enclose the harbour of Port Said are constructed of enormous blocks of concrete, a couple of metres or more in each direction thrown over and left to take their places *à la nature*; but it has been found that this will not do, for the waves force themselves between the crevices and interstices with such force as to move them, and they are now considering how to produce more cohesion between the blocks than by their mere weight; and if they are obliged to adopt the combination of the masses by regular construction, as in our Dover pier, it will cause an enormous expense, for the dykes or piers extend out miles into the Mediterranean." From Port Said the party proceeded to Jaffa, in an Egyptian coaster, the journey thence to Palestine being continued on horseback. Jerusalem was reached in a day and a half. "Jerusalem itself," writes Professor Donaldson, "caused me the greatest disappointment and pain. It is a vast store for religious traffic, occupied by religionists of every shade of Christian doctrine, each scrambling and fighting for the pre-eminence. . . . Each sect seeks to appropriate as specially its own this or that spot as the true site of each sad event in our Saviour's life. The Holy Sepulchre could never have been where its representation is now located; but Latin and Greek, Armenian and Copt, fight and scramble on the soil, and the Turk, as guardian of the sacred spot, as it is supposed to be, is obliged with bastinadoes to keep the furious superstitious antagonists in order." The sanitary condition of the city was described as the worst possible; for it is without sewers, and is supplied with water from cisterns which receive the surface waters, too often impregnated with cesspools and drains. The architectural features are few and difficult to trace. The structure most deserving of notice is the new dome to the Holy Sepulchre, nearly completed, the entrance being decorated with paintings which were described as being of too pale a tone to be effective.

The Holy Sepulchre itself was mentioned as a most dramatic assemblage of churches, chapels, oratories, and sanctuaries; some on the general level, others going up, several going down into the rocky caverns, and with the ceremonies of the various religionists carried on at the same time the mind became bewildered, "and one wondered whether this could be a true temple for the worship of the living God, or a very Bahel or Hense of Baal for the sacrifices of superstition."

Jericho, Bethlehem, and Samaria were in their turn visited. The main tour in the Holy Land occupying the party three weeks. Hardly any traces of Jewish buildings remain, but there are some noble ruins of the times of the Herods and the Romans. Two days' ride from Caesarea Philippi brought the party to Damascus, "one of the world's Paradieses of the Turk and Moslem." Thence a portion of the party visited Balbek, and after an examination of the stupendous ruins there, were joined by their friends, and proceeded thence to Athens. The Professor is now on his way home, and will, no doubt, on a future occasion communicate to the Institute an account of his subsequent trip.

Professor Kerr took occasion to call attention to the subject of the New Building Act about to be brought before Parliament, and expressed a hope that before any decided step was taken on behalf of the Institute on so important a measure, a general meeting would be convened by the council.

Mr. Seddon said the subject had been under the notice of the Professional Practices Committee, and a series of resolutions on the Bill had been drawn up by Mr. Digby Wyatt, which had been referred to a special committee. The last action taken in the matter had been to request Mr. Chas. Barry and Mr. Marrable to confer with Mr. Tite, the president of the Institute, who had charge of the Bill in Parliament with respect to several of its more important provisions.

The paper appointed for the evening was "A Descriptive Sketch of the New House at Innewood, county Wicklow," by Mr. White. Illustrations of this structure, with a description, having appeared in the last volume of the *Builder*, it is unnecessary to repeat the particulars which constituted the paper laid before the Institute.

A brief discussion followed the reading of the paper, in the course of which additional particulars were furnished by the author with regard to the construction of the flat of the roof, being in this instance of cement and tile, in contradistinction to lead—an experiment which the architect believed would be successful in all respects. The arrangement of the gutters, which was of a peculiar and novel character, was also the subject of conversation.

In reply to inquiries, Mr. White said he had omitted to give the details of the construction of the central flat between the two main roofs. This, he said, was effected by a course, first of all, of Staffordshire red tiles laid upon the joists, with a fall sufficient to carry off the water. Then followed a course of slates laid dry; upon these was a layer of cement, and upon that a course of plain tiles, likewise jointed in cement, so that there were three courses of tiles and one course of slate, with a body of cement between, which, in his opinion, formed an excellent and permanent flat, more durable than lead; the objection to the latter material being the frequent repairs required. The surface of the flat was of tiles, and he considered the cost of that mode of construction was not much beyond that of lead. The total cost of the building was 15,000*l.*, including the stables, &c. He added, that the joinery work was undertaken by an English contractor, who had sawing and planing mills in this country, and the work was sent out ready to be fitted together on the spot.

LEEDS.

Sanitary Progress.—An increasing death-rate has long given rise to a feeling of uneasiness respecting the sanitary condition of Leeds, and the arrangements for preserving the health of the town. Many improvements, involving a heavy expenditure, have been carried out, and others equally costly are projected with the view of removing the causes to which epidemic disease and premature death may be traced. Confined localities have been opened up, and stagnant atmospheres rendered comparatively harmless by admittance with purer air; foul privies and pestiferous cesspools have been swept away; unhealthy dwellings have been either closed or brought to a better condition; the habits of negligent and slatternly householders have been corrected as far as is possible; and the sanitary state of the town has been further improved by scavenging and a main drainage, so far as the latter has been carried out. But while much has been done to promote the public health, there are still many adverse influences at work. Not the least potent of these are the back-to-back houses which con-

stitute so marked a feature in the domestic architecture of Leeds; all with cellar kitchens, some so much below the level of the street as to render them as unfit for human habitation as diminished light, damp and steaming walls, and imperfectly-trapped sinks can make them; while the peculiar plan of such dwellings renders a thorough ventilation of the sleeping-apartments a problem which the opening of windows seldom succeeds in solving. The operations of speculative builders also have not been favourable to the hygienic condition of Leeds. Streets have been run up, and footpaths and roadways left in the state in which the carriage of building materials, the digging of foundations, and the laying of gas and water pipes have left them. Happily the disgusting aspect of the backs is being rapidly changed. The backs which have already been improved are Dow-heck and Hol-heck, the works connected with the former having been completed, while the greater portion of Hol-heck has been finished, and additional powers are sought by the corporation in the Improvement Act Amendment Bill, of which notice has been given, to enable the backs committee to undertake the remainder. All that has been done up to the present time in reference to Sheeps-crook has been the removal of a large quantity of the mud which had accumulated in its bed; but it is expected that its turn for improvement will come before long. The excellent effect which the works have had, so far as they have proceeded, fully justify the anxiety of the backs committee to push them forward; and, in what has been done, their views have been ably carried out by Mr. A. M. Fowler, the borough surveyor. The first improvement contract which the corporation intend to let in the spring, embraces that portion of Sheeps-crook or Lady-heck extending from Nether Mills, on the river Aire, to Broadhead's Mill, in Mabgate; the next contract will take in the part extending from the last-mentioned mill to Woodhouse Carr. It is not proposed to cover over the large streams, such as Sheeps-crook and Hol-heck. The watershed of Sheeps-crook is upwards of 12,000 acres.

The new Hotel.—The new Central Station Hotel, mentioned by us some time ago, has during the past eighteen months sprung up in one of the busiest thoroughfares of the town. It is being erected by the Great Northern Railway Company. The directors invited a limited competition, and the plans of Messrs. M. E. Hadfield & Son, of Sheffield, being chosen, the necessary drawings and contracts were prepared. It was at first intended to erect the hotel upon the precise spot of the old Wellington Inn, but the great disadvantage of having to cross Aire-street suggested the possibility of removing that street, and so placing the hotel in direct communication with the station. The result shows the change to have been most desirable, and the hotel, as it now stands, may be said to present four fronts, with ample streets for light and air on all sides, whilst the broad and spacious railway corridor will afford a passage in all weather from the carriages to the interior of the hotel. The style of architecture chosen may be described as "Romanesque," studied from the domestic buildings of Germany and Lombardy. The general outline of the exterior is well defined by four pavilion roofs of high pitch which spring from the general cornice, thus surmounting the formidable difficulty of the square block which the site imposes with reference to architectural effect. The building occupies a site of about 160 ft. by 90 ft., the principal, or entrance, front being towards Wellington-street, but the façade opposite the station, being of greater extent, presents a more striking elevation. The hotel is very nearly completed, ready to receive its decorations and furniture, which it is proposed shall accord with the style adopted for the architectural details of the building, colour being freely used wherever it can be made useful in heightening the effect of the interior. The contractors are Messrs. Sbafoe & Barry, of York, and Mr. Daniel Falcher has acted as clerk of works. The stone carving of the exterior, with exceptions, is by Mr. Earp, of London, and has been executed from the architects' sketches and direction. The tile pavements are by Messrs. Maw, of Broseley. The marble chimney-pieces and stove-grates have been supplied by Messrs. Dennis Lee & Welsh, of Leeds; and the metal balconettes and staircase balustrade by Messrs. Longden, of Sheffield. The hot and cold water service, hoist, heating, bells, gas-fitting, kitchen range and cooking houses, &c.,

have been fitted up by Messrs. J. & C. May, of London; and the Vieille Montagne zincwork of the roofs has been executed by Mr. Fox, of Limehouse. Messrs. Garlick & Son, of Leeds, have executed the plastering.

WORKS OF UNKNOWN ARTISTS.

THE FAIRFORD GLASS.

In commenting on some similarities between the Dantzig picture and the Fairford west window in the *Standard* of October 8th, I remarked that the picture was by H. Van der Goes. In your journal, on the other hand, Mr. Weale's authority was quoted in favour of Dierich Stuerhonts. This led me to ask Mr. Weale if he had made any more recent discoveries than those with which I was acquainted, and he tells me that the story of his having discovered the Dantzig picture to be by "Boots" is a canard invented in Berlin about April 1st, and thence copied into some English papers. This will account for the error. The coats of arms on the back of the picture and other evidences (which, I believe, Mr. Fuller Russell is about to publish) make the testimony in favour of Van der Goes as the artist very strong. Enough, I think, has been said and written against the attribution to Dierich of the Fairford windows; and it is very palpable to any person conversant with the art of the fifteenth century, especially in glass, that he could neither have painted nor designed the whole of them, if he did any.

After some months of research in various ways for a clue to the artist, I was looking again over the Brussels gallery in company with Mr. Weale, and came across a picture which *prima facie* so resembled the Fairford work that I was arrested by it. On examination, I found much corroboration of the identity between the artist of the east windows of Fairford and the picture before me. The picture is numbered eighty-four in the catalogue, and is a representation of the Crucifixion; with other scenes in the background. I give some of the most evident points of similarity:—

First.—It has the A of the Fairford work, on a blue banner, on the dexter side (not the A of Albert Durer, or Aldegrever, as given in the article in the *Gentleman's Magazine* by Mr. Tom Taylor).

Secondly.—Our Lord on the Cross has the same style of floriated nimbus.

Thirdly.—It has the good and bad angels over the thieves.

Fourthly.—The plumed and rough wood crosses.

Fifthly.—Arrangement of hair on angels' heads, plain to the ears and then commencing to curl, and the manner of their draperies nearly identical.

Sixthly.—The face and figure of the Blessed Virgin with her costume very similar in character, &c.

Seventhly.— Armour and costume alike.

Eighthly.—The same sentiment, tone of colour, and style of composition mark both works.

The artist seems to be amongst the unknown, or rather as yet no name has been identified with the work, either by the connoisseurs of Germany or Belgium. At one time the picture was attributed to Aldegrever, on account of its signature. This every critic now acknowledges to be a mistake, and I have some sketches from glass designed by that artist, which bear no resemblance whatever to the picture. It was once also, I am told, attributed to Durer. This was found to be as untenable as his claim to the Fairford work, and affords a capital parallel; in fact, if Mr. Holt can identify the picture as Durer's, to my ideas he will have gone a great way to prove the glass also to be his, and *vice versa*. It was in the collection of M. Weyer, of Cologne, and sold at his sale to the Brussels Gallery at the same time as the beautiful *Mentling* was purchased for our own National Gallery. There is a long notice and description of it in the account of Mr. Weyer's collection, a work useful to every picture collector. I translate the following portion for the benefit of your readers:—

"This composition is very remarkable. The groups, especially the cavaliers to the right of the Cross, and the Holy Women, are disposed with great ability, and show the original genius of the author. If the drawing falls short in its anatomical proportions (the heads being large and the arms short), the draperies and details leave nothing to be desired. The colour has a marvellous brilliancy, dazzling in its splendour, and the deep sentiment that reigns throughout, makes this picture worthy to occupy a high rank amongst the productions of the school of the 'Bas Rhin.' At the commencement of the present century it ornamented the church of Richterich, near Aix la Chapelle, when from ignorance of its value it was sold to General Ruhl von Lillenstein, who left it to the Minister von Schleitens, from whom M. Weyer purchased it."

* Its title is, "Notice sur la Collection de Tableaux anciens faisant partie de la Galerie de M. J. P. Weyer, &c. &c. Par W. H. J. Weale. Bruges. Lodon. J. Barthes & Lowell.

Mr. Weale, at Mr. Weyer's sale, tried to persuade Sir Charles Eastlake to purchase it for our gallery. Sir Charles, however, did not think it the class of picture desirable. And it was sold to the Brussels Gallery for the trifling sum of 185*l*. In a letter received but a few days since from Mr. Weale, to whom I had shown some drawings of the Fairford work, occurs the following remark:—

"Since I saw you I have seen the carved retables of Verney now at Tongres; the canopies are of a similar design to those at Fairford. I have no doubt that the artists who executed the Fairford work [by some of it], belong to that part of the Netherlands. Richterich is between Aix la Chapelle and Hertzogenrath."

These contributions will be, I hope, useful to those who, like myself, take an interest in the works of unknown artists, and their name is legion, for the works identified with their authors bear a small proportion to those not recognized or of doubtful attribution.*

N. H. J. WESTLAKE.

THE STAIRCASE IN HAMILTON PALACE.

Sir,—Allow me to correct your correspondent "J. S. R." in some of his statements about the staircase in Hamilton Palace, "built entirely of black marble."† He says that this "is not the principal one in the palace, and that it was erected by the late duke." It was erected by the late duke's father, viz., Alexander, the 10th Duke of Hamilton, who made the latest additions to it, and it is the principal staircase in the palace; but to one not acquainted with, and getting perhaps a hurried look through, the house, such a mistake might easily arise.

The older portion of the palace forms three sides of a quadrangle, the entrance-hall being on the ground-floor, with the entrance-door in the centre of the inner face, facing the east. On this floor, also, were the principal rooms. The addition faces the west, and this became and is now the main front of the palace. In the centre of this front, and on the first-floor level, is the new entrance-hall, approached through a portico on the same level, and reached by a double flight of steps, somewhat like Blenheim. All the state-rooms are on this level, alongside the new entrance-hall to the north, and its use is this. Should visitors be set down at the western entrance, instead of ascending by exposed outside stairs leading to the portico, in wet weather, they go inside at once, to a lower hall, communicating with the old one on the same level; and if arriving by the old entrance, the black marble stair becomes the main approach to the principal floor, the steps being only carried up to this level.

The staircase, instead of being of black marble, is lined with a warm-tinted and beautifully veined freestone; so also is the new entrance-hall. The latter magnificent apartment, the floor of which is laid with coloured marbles, is the whole height of the principal and bed-room floors; while the staircase has the additional height of the ground-floor.

The masonry of these two apartments is of the most exquisite kind. Not only the faces of the stones, but the top and bottom beds and end-joints also were polished; and instead of this being done in the usual way by rubbing them with the polisher, the parts to be polished were laid on the polisher, and in this way rubbed until they were perfectly true.

The steps of this stair-landing, balustrade, and skirting, are of polished black marble, as also are the jambs of the doors at either end of the landing, the one leading into the new entrance-hall, the other into the state bed-rooms. The landing is supported by two Atlantes, I forget whether of bronze or marble. I think, speaking from recollection, that the steps at the centre flight are 8 ft. long, and the return ones 6 ft. The steps are moulded on the back and all polished. The balusters are carved, and stand on a moulded base, raking with the steps.

With regard to the cost of this staircase and stair, I think no one could possibly give a guess. The freestone was from one of the duke's own quarries. The workmen were in his own employ and paid by the day. The workmanship had to be of the best, and the men were allowed their own

* As respects the Fairford windows specially we have received a number of letters, including one from Mr. Martin Underwood (with various drawings, both from Fairford and Nuremberg), and a further communication from Mr. J. G. Waller. We must, however, wait for a fitting opportunity to bring the matter forward again with the prospect of a useful result.—Ed.
† Vol. xxvii, p. 948.

time. As the lower portion of the walls of the staircase is chamfered rustic work, and every arris had to be perfectly true, no idea can be formed of the cost of this part of the work. The steps, plats, and balusters were contract-work, and I think were executed in London. I cannot believe in a single baluster costing 27*l*. for the polishing; but the entire cost of one might reach that sum or even more.

To satisfy your correspondent "K. K." as to the date of erection, I may state that I was engaged at intervals at the drawings for this staircase and other parts of the house, while in the office of the late David Hamilton, of Glasgow, who was architect to the duke (see his obituary notice in the *Builder*, vol. i, p. 537) from 1837 till his death in the end of 1843, at which time it was not quite finished.

I suspect "J. S. R." has mistaken the stair known as the duchess's (also a very fine one), for the principal stair. It is so to the bed-room floor, but it is not the principal stair in the palace. JOHN BAIRD.

ST. PANCRAS INFIRMARY.

This Infirmary is now being erected at Highgate on a site containing about 3½ acres of land. On the highest or north side of the ground is placed the central or administrative block, extending from north to south. In the front portion are placed the porters' rooms, and immediately joining them are the male and female receiving-rooms, with water-closet and bath in each. Right and left of these are the dwellings of the resident surgeon and assistant surgeon, and matron, with bed-rooms, &c., in the floor above. On the other side are the Board and waiting rooms, with lavatory attached. The matron's linen-room, &c., are on this side also.

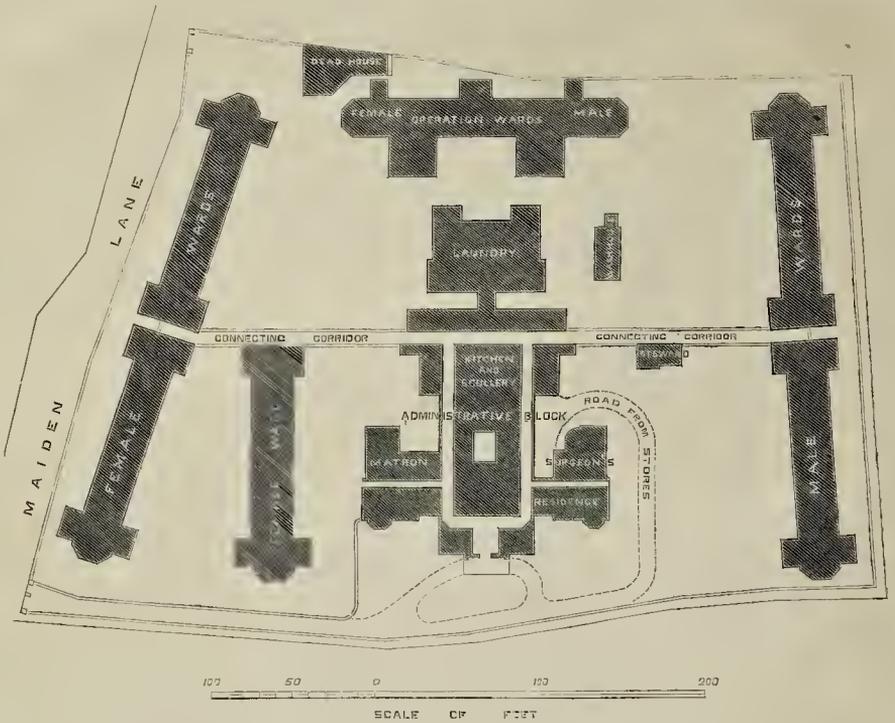

The centre is occupied, as will be seen on reference to the plan, by the store department, with steward's office overlooking. By the natural fall of the ground ample space is obtained for wine, beer, and other cellars beneath without excavation. The kitchen, scullery, and larders are adjoining, and occupy the centre of the entire range of buildings.

On either side of the corridors are the steward and male servants' mess-rooms, and the matron's and female servants' mess-rooms. The steward has a separate and a distinct house on the right of the main building, overlooking the entrance to the stores. The dispensary and operating-rooms are situated on the side of the intersecting corridor, between the male and female block; on the other side of the door dividing the cross corridor is the boiler-house, with stairs to coal-store below. A patients' clothes-store is close at hand here, entered from the covered way outside the building, which leads to foul wards.

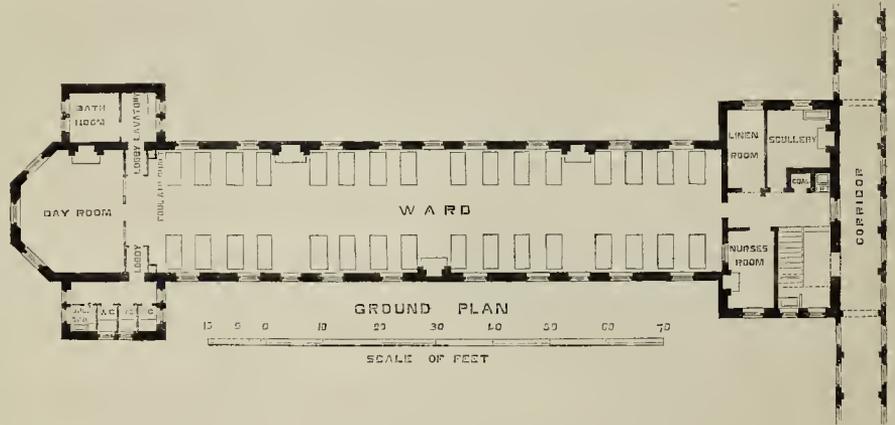

The laundry is approached by steps necessitated by the fall of the ground; these steps are divided in the middle from the male and female sides. Dry-houses for drying the clothes are provided for, and in addition a spacious drying-ground adjoins the laundry. All these buildings are lofty, and ventilated by top draughts. Beyond this laundry, and entirely detached from the rest, is a wash-house for foul linen, with fumigating-room, under which is a large tank for storage of rain water. W.C.s and urinals in convenient positions are placed throughout the buildings.

The patients' blocks are placed on either side of the main block—the three blocks for females on the left, the two for males on the right. Accommodation for 256 females is provided in two wards of three stories each and one of two only—32 beds in each ward. For male patients there is one block of three floors and one of two, providing for 160 patients. The wards are 22 ft. wide and 13 ft. 6 in. clear height, and are lighted by windows on either side, reaching within a foot of the ceiling; the upper part of the window is made to fall open for ventilation. Open fireplaces are used for warming, the air before passing into the wards being heated by circulation round the stoves. Each ward has a staircase, with nurses' room overlooking ward and ward scullery, sink, and lift from corridors below for linen, food, &c.; a linen-store and nurses' W.C. at the one end of it, and shuttes and dust for foul linen. At the other, on one side are a bath-room and lavatory for patients, and W.C.s in the other, thoroughly ventilated by through draughts. At the extreme end is a day-room for the use of convalescent patients, with easy access from ward.

ST. PANCRAS INFIRMARY, HIGHGATE.

Block Plan of the whole Establishment.

Plan of One of the Wards.

The four wards are entirely isolated, and contain accommodation for 54 patients of each sex, or 108 in all. They have lavatories, W.C.s, nurses' rooms, and sculleries for each particular class.

The dead-house is at the south-east corner of the ground, with the necessary *post-mortem* rooms, &c., and removals can be made without the necessity of going near the main buildings.

The staff of nurses will, we understand, be provided by the Nightingale Training Institution.

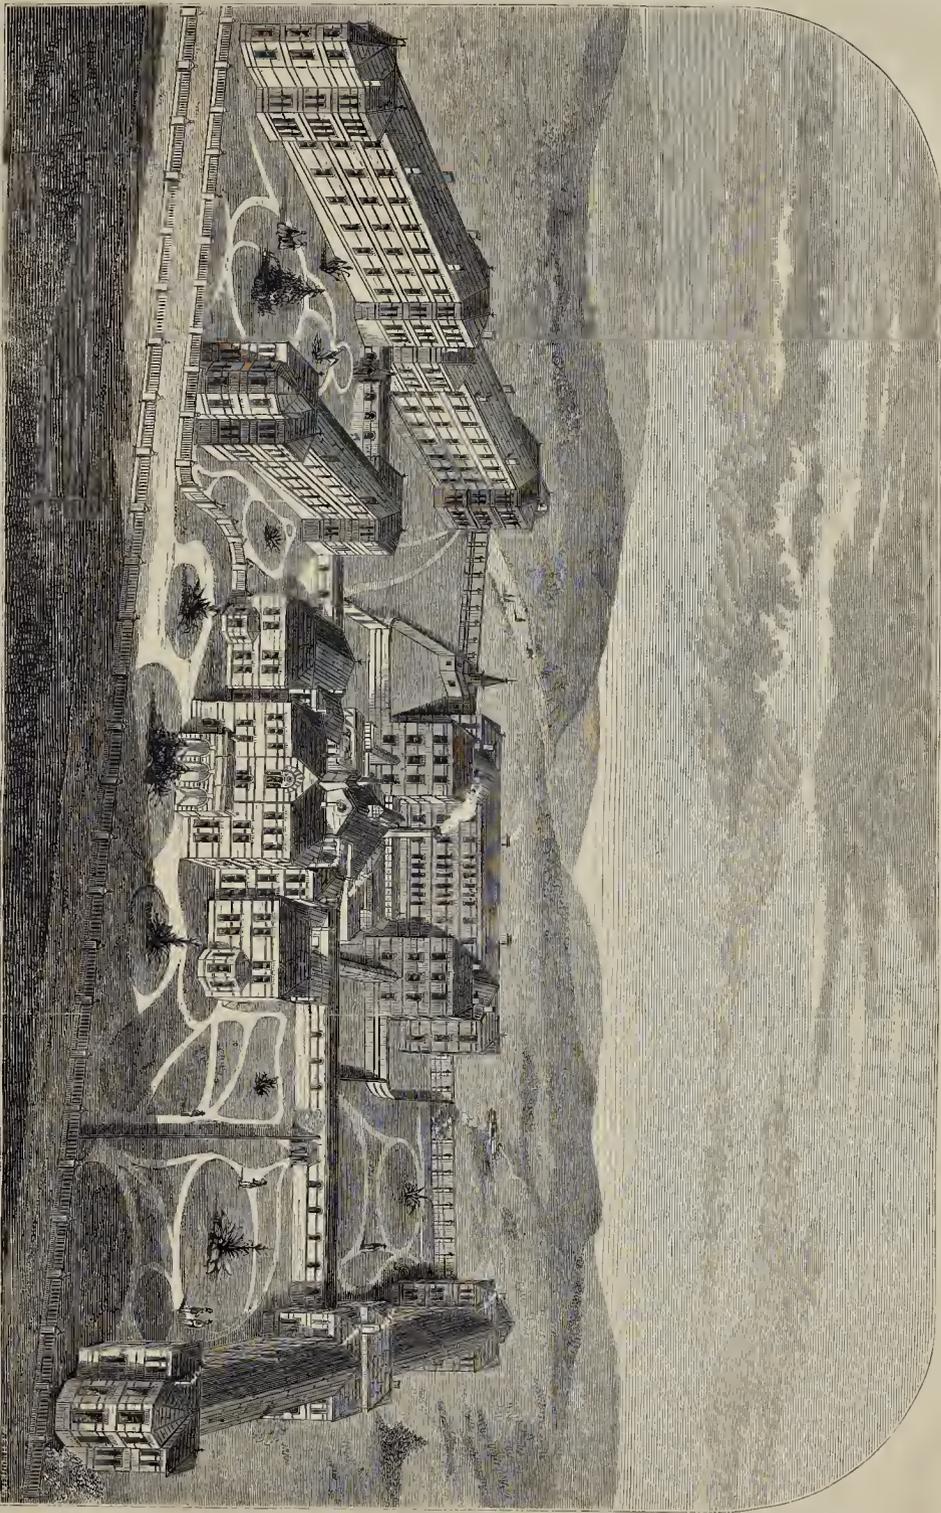

This infirmary is being erected for the St. Pancras Board of Guardians, of which Mr. W. H. Wyatt is the chairman, from the designs of Messrs. John Giles & Biven. The contractor is Mr. W. Henshaw, whose contract amounts to 36,000. The clerk of works is Mr. Culverhouse.

THE STREET SIGNALS IN WESTMINSTER.

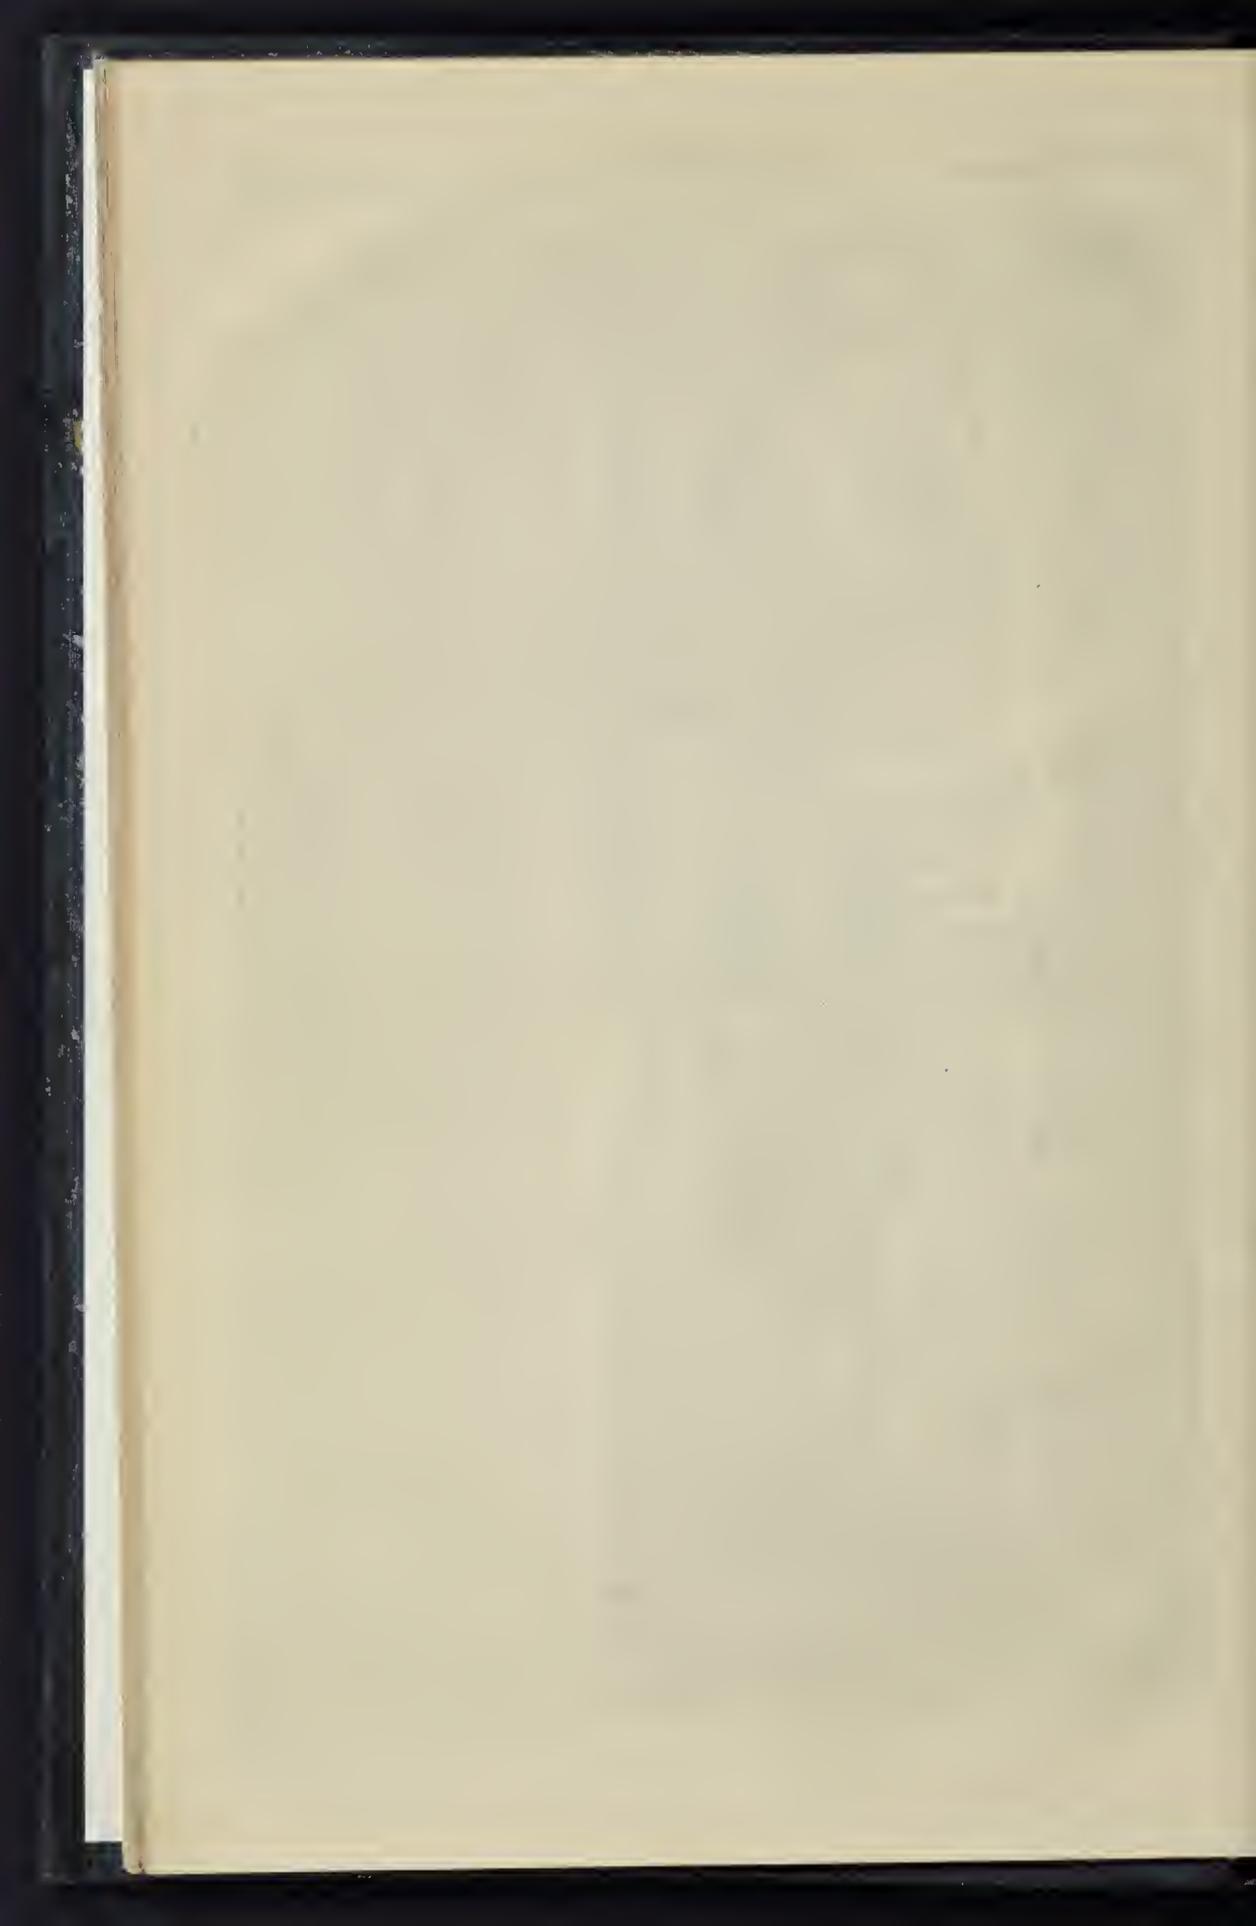

The police report favourably of the working of the Semaphors signal pillar, recently erected at the corner of New Palace-yard, Westminster. The pillar has had the misfortune to sustain two accidents from gas explosions, for which its designers, or makers, are in no way chargeable. It appears that some of the mains near the pillar are in such a state, that the gas escapes freely from them, to saturate the earth, or escape how it may. A quantity of this leaked gas found its way into the hollow signal pillar, and caused a violent explosion on Saturday night, when the constable opened the small door with the intention of turning off the gas from the signal lights. The policeman had not any light, but the gas

probably ignited on the admission of the air, the lights never being quite extinguished. Pending inspection and repair of the mains, an attempt is made to protect the signal pillar by loosening the road round its base, that the gas leakage may be discharged into the atmosphere, and not allowed to accumulate in the cast-iron signal pillar, which is nearly air-tight.

A Statue of Grattan.—A movement is about to be set on foot for the erection of a statue in College-green, Dublin, to the memory of the illustrious Henry Grattan. The site will be opposite the building which was the scene of the orator's triumphs, and in the immediate vicinity of Foley's statues of Burke and Goldsmith, in front of "Old Trinity."

ST. PANCRAS INFIRMARY, HIGHGATE.—MESSRS. JOHN GILES & BYER, ARCHITECTS.

ROAD MAKING.

Sir,—Notwithstanding the attempt at logic and argument of "Pro," I am still of opinion that a strong foundation of concrete, &c., (which he admits in places) is a *struqum non* in making or renovating a road; and I think instead of carrying out the plan as advocated, of sprinkling over the surface just a stone thick, it would be better, in most cases, and great economy, to completely renew the road-surface, put in a good foundation, and cover the surface with the best and strongest stone that can be procured, properly prepared, and carefully laid on, and we should hear little of bad roads.

I have known roads so constructed of a pitched foundation covered with a 6-in. coat of Hartsill stone, last for six years without applying fresh material, under the heaviest traffic of any road out of London, and the broken stone that was prepared for its renewal had become covered over with grass in the depôts. That shows the advantage of a well-made road in the first instance.

If "Pro" wishes to know the expense of repairing roads in the neighbourhood of London, that might be obtained from the Secretary of State, who receives the annual returns of expenditure, &c., on every trust, and these are fully and fairly made out, and are trustworthy data for those who are anxious to acquire information on the subject.

"Pro," who appears to be a new shining light, seems to think that all that has occurred before his advent is chaos and confusion worse confounded, but he labours under a slight mistake. Certainly we are not improving so much as we ought from the precepts and examples of our predecessors, simply because we are too prone to endeavour to establish a standard of our own.

For instance, "Pro" advocates the use of hot coal-tar, &c., as a panacea of all the ills applied to the loose coating of stone spread over the surface by means of an old water-cart, constructed on low wheels, and afterwards rolled.

The application of gas-tar and pitch to road surfaces "Pro" must understand is not new. In 1842 I used it at Nottingham, and it is used in many places; but it is not applied in the manner proposed: indeed, it would not be practicable. The stones are first properly broken, and the tar and pitch are spread over, and mixed amongst them in the heap, and the heap is turned over and over, so that every stone becomes more or less covered with the tar and pitch. The material is then applied to the road surfaces, and consolidated in the usual manner. But I have found in practice that, in the first place, it is not cheap, being more expensive than "binding;" it does not stand up to the durability of the roadway, because in all the summer months the heat sets injuriously upon it, softens it, and produces friction and abrasion amongst the metal of the roadway, and forms, in addition, a very soft, elastic, and yielding surface for the draught of carriages, and therefore adds seriously to the force of traction.

As to moisture or rain penetrating the crust of a well-constructed roadway, it is not the fact except when it is only a stone thick: with proper curvature the rain runs off. I have broken up old roadways in large blocks, thoroughly consolidated and cemented together, that were difficult to separate, and moisture could not penetrate, except slightly at the surface; so that the argument about moisture percolating through falls to the ground.

"Pro" condemns my 12 in. of material put in one coat, and yet in another place he recommends slag or cinder for a foundation, 6 in. or 8 in. thick (just as I applied the 12 in.); but this thickness is insufficient for heavy traffic, even if protected with the heavy coat of 2 in. as top covering!

If cinders are not to be had, he suggests 3-in. zones, 6 in. or 8 in. deep, covered with the fressad coat of 2 in. These will not act as proposed, as they would inevitably work up to the surface, and form a rough road, and would not require lifting to make a smooth surface. As to my remarks about lifting, "Pro" misunderstands me. If an old roadway had rough stones, if many inches deep, I should just lift or clarify the surface, without disturbing the foundation, so as to improve the cross section, and tick out the large stones; then I should break and add to them additional metal, so as to strengthen the surface, and not lift and take

out the rough stones, break and apply them to another part, as is sometimes the practice.

I have lately had several opportunities of examining the street surfaces of some parts of the metropolis, and I must say I do not find much improvement in the mode of repairing them. The Poultry, in which so many experiments have been made, is still far from being a perfect street surface. The cross section is too flat and defective; it is sunk in holes in places where mud and water accumulate in wet weather. This, I believe, arises originally from a defective foundation, and the imperfect way the stones are set, and perhaps the quality of the stone may have something to do with it.

In extending my observations westward I found them most properly breaking up the Macadam road at Charing-cross, and substituting for it a pavement.

They were using a foundation prepared of concrete, and upon that they were laying sets of apparently good depth and suitable thickness; but I do not quite approve of the plan adopted, nor do I believe it is one calculated to make a strong and durable roadway.

The concrete did not appear of sufficient thickness for such a thoroughfare of heavy traffic, and the ballast of which it was composed was too fine, as coarser ballast would make a stronger and more durable concrete for such a purpose.

The sets are also placed in transverse rows, close together, and the joints filled in with fine concrete in the form of grout; and this I consider a defect in the mode of paving, as I believe an open transverse joint of 1 in. or 1½ in. wide, well and solidly crammed full of gravel or ballast, would form as good a surface, and at the same time afford a better foothold for horses.

I observed in many cases where the streets are paved with the narrow sets, that horses are continually slipping and falling, and I think this may be obviated to a considerable extent by the open joint suggested. I do not think it would at all deteriorate from the strength and durability of the roadway, while it would add much to the safety of the traffic.

B. BAYLIS.

SCHOOLS OF ART.

The Bath School.—The annual distribution of the prizes took place at the school premises, 33, Paragon. The mayor presided. He said he hoped the school would be self-supporting. During last year 102 pupils had attended the mechanics' and artisans' class, the average attendance for evenings being forty-five; 133 pupils had attended the morning classes, the average attendance being sixty-two. Dr. Puckett (the head-master, whom he eulogised) had also succeeded in establishing a sketching class, which numbered twenty-three pupils. Then, in addition, 2,000 of the pupils belonging to the poor schools of the city were taught the elements of drawing, and this they hoped to continue. It was an almost incredibly large number, and they could not expect them to be very elaborately taught; but the teaching was sufficient to enable them to obtain prizes from Government.

The Penance School.—The prizes awarded the pupils of this school by Government have been handed to them by the Mayor of Penance. Many of the visitors, who filled the school, saw for the first time the improvements which have recently been effected—the substitution of an arched way for the north wall, and the addition of a second room 18 ft. long. By this arrangement better light, as well as more space, has been secured. A large number of ladies were present. The head-master is Mr. Geoffroy, who has conducted the school since its commencement, sixteen years since, when it began with twenty artisans. There are now 900. The school is considered to be in a successful state, and it is now a school of science as well as art.

The Cork School.—The annual distribution of prizes to the students of this school took place in the Athenaeum. The mayor presided, and there was a fair attendance of spectators, but not at all what might have been expected to be present on such an occasion. Mr. Brennan, the master of the school, read the committee's report, which stated that, during the past year, the total number of persons receiving instruction in the Central School had been 187, being a slight increase over the number attending last year, in addition to which the children from the National Schools, St. Stephen's Bluecoat School, &c., continued to re-

ceive instruction either in their own schools or at the School of Art. The Department examinations in freehand drawing, geometry, modelling, &c., were held early in the month of March. About fifty-six persons presented themselves for examination, of whom twenty-nine were successful, being an increase of nine over the number last year. Two of the students passed in all the subjects of the "second grade," entitling them to receive their certificates. A considerable number of advanced and elementary works were sent up to the annual competition in London. The Department reported favourably on the character and rendering of the works sent, and the works of thirteen students were selected for national competition; two received "honourable mention," and three students received their grade prizes.

STAINED GLASS.

Batley Church.—To the east window of the chancel we have already alluded. In the principal part of the centre light is a life-size representation of our Lord as the "Good Shepherd," leading into the fold a stray sheep. In the upper part of the same compartment is a jewelled mosaic cross, within a vesica. In the two compartments on the dexter side of this is a large group, representing the Nativity of our Lord, and the visit of the Magi. In the two compartments on the sinister side, the group represented is that of little children brought to our Lord. Both these groups are surmounted by mosaic shrine work, founded upon ancient examples in Westminster Abbey. The tracery is filled with a treatment of our Lord in Glory, and St. Peter and St. Paul, and a host of angels, with musical instruments, and palm branches, &c. The window has been presented by Mr. Sheard, the architect of the church, in memory of his daughter; and the artists, as formerly noted, were Messrs. O'Conner, of London.

St. Mary's, Nottingham.—Two more stained windows have been placed in the south side of the chancel of this church. There is a similarity in the design of the windows. The subjects dealt with by the artist in the window erected by the Wright family are chiefly connected with the earlier events in the history of the Saviour, extending to St. Matthew iv. The window in memory of Sir C. Fellows is illustrative of the first six or seven chapters in Matthew and John, including the miracle of walking on the water, and the driving of the money-changers out of the temple. There is a representation of Christ praying in the wilderness.

Kibworth Church (Market Harborough).—A second memorial window has just been put in the church of Kibworth. The window is placed on the north side near the east end of the aisle. The window contains three openings, and the subject is Christ raising to life the son of the widow of Nain. In the centre light is our Saviour holding the hand of the young man; the widow is standing at the end of the bier, while the Saviour, commanding those who carried it to stand still, said "Young man, I say unto thee, arise." The other figures in the group are the Apostles and other attendants. The canopies and bases are formed of the lily foliage, and the figures of St. Wilfred, the patron saint, and Faith and Hope, are introduced on either side. In the tracery are angels bearing scrolls. The window was designed and executed by Messrs. W. Holland & Son, of Warwick.

St. Michael and All Angels, Brantree.—The east window of this church has just been filled with stained glass at the expense and in memory of the late Mr. Richard Lacey. The artists were Messrs. Clayton & Bell. The window consists of five lights, each divided into two parts; the upper containing a full-length figure surmounted by canopy work; the lower, on a smaller scale, the representation of some scene in the sacred life, in an especial way connected with the holy person represented above. In the first light is the Virgin Mary, holding in her arms the infant Jesus, and bearing the lily; beneath is the Nativity.—Mary, Joseph, and the Babe lying in a manger. Next in order, is St. John the Baptist in raiment of camel's hair, bearing the cross and pointing to a medallion Agnus Dei; beneath is the baptism of our Lord by the great forerunner. The centre light contains a figure of our Lord in the act of blessing; beneath which is the crucifixion, with St. Mary and St. John. The next division contains a representation of St. John, bearing the palm of victory, and a chalice,

whence issues a dragon, in reference to the legend which tells how the apostle was once warned of a poisoned draught by such an occurrence. Beneath is the last supper, our Lord seated with the twelve. St. Peter occupies the next light, bearing the golden key of heaven in his hand, and the scene beneath is that in which the risen Lord appears, bearing the print of the nails. The tracery in the upper part of the window is filled with coloured glass, an angel occupying the centre space.

SCHOOL-BUILDING NEWS.

Whissonsett.—A new school building in connexion with the Church of St. Mary the Virgin, Whissonsett, Norfolk, has just been completed, from the designs of Mr. C. J. Moxon, architect. The main building consists of a school room 51 ft. by 20 ft., a classroom, communicating with the former by open arches, and separate porches for boys and girls. The roofs are all open-timbered of a very substantial and ornamental character, and the material employed in the building is flint, with red brick dressings. The whole is warmed by a patent Garney stove, so placed as to serve for school and class-room. The builder was Mr. George Brown, of Whissonsett.

DISSENTING CHURCH-BUILDING NEWS.

Whissendine, Rutland.—A few days since a new Congregational chapel was opened in this village. The building, which is of Gothic character, is constructed of red and white bricks, arranged with stone. It occupies a prominent site in the heart of the village. Mr. J. Berridge is the architect, under whom the works have been carried out by Mr. John Fast, of Melton Mowbray.

Chard.—A new Congregational church has been erected in the High-street of this town. It is Early English, and of parallelogram form, divided, by iron shafts and the construction of the roof, into nave and aisles. There are a tower and lofty stone spire at the south-west angle. The principal entrance is in the centre, and having a traceried window over, filled in with stained glass. The apse at the east end is relieved by the diaper work and passages of Scripture. The architect was Mr. Stent, Warminster; and the builders were Messrs. Hawker & Harbour, Chard. The total cost is about 3,000l.—On Wednesday last a preparatory Congregational church was opened in the Kent-road. A limited competition resulted in the design of Mr. Stent, of Warminster, being accepted for church, school and class rooms, &c. The schoolroom has been erected and dedicated as a preparatory church during the erection of the other buildings. Mr. A. Smith, of Portsea, is the contractor.

North Shields.—A Scandinavian Lutheran church has been opened here. It is situated in the Borough-road. The edifice is built on an irregular shaped piece of ground a short distance from the New Quay. The congregation will be chiefly composed of sailors. Owing to the peculiarities and the smallness of the site, the west façade of the church is built at an obtuse angle with the adjoining curvilinear ordinary ecclesiastical position, is much less than would otherwise have been the case; and it was necessary to build a gallery at the west end. The staircase to this gallery is enclosed in the circular turret at the south-west angle of the building, which forms a feature in the external appearance. Two lancet lights, with shafted jambs, and a large sexfoil window complete the west gable. The church is 47 ft. long by 26 ft. wide. The east window is of stained glass: it is of three lancet lights set in polished stonework. In the centre light is a representation of the Crucifixion, with St. John and the Virgin in the side lights. The artists were Messrs. Heaton, Butler, & Bayne, of London. This window is the gift (among other embellishments) of Mr. Borries, the Norwegian and Swedish Vice-Consul, at Newcastle-upon-Tyne. The chancel floor is laid with encaustic tiles. The pulpit is placed in the south-east corner of the nave; and open pews fill the rest of the church. There are all of deal, slightly stained and varnished, and will accommodate 230 persons. The church is heated by means of a Gill stove in the basement. The work has been executed under the direction of the architect, Mr. F. R. N. Haswell, of North Shields. The contractors, with the exception of the iron-

founder (Mr. W. H. Walker, of Newcastle), are all Shields men,—viz., Messrs. Campbell, mason; Conlson, joiner; Place, slater; Twizell & Sons, plumbers and gasfitters; and Frazier, painter and glazier.

Olney.—The Baptist chapel, having undergone considerable alteration and renovation, has been reopened. The pulpit, pews, ceiling, and galleries have all been removed, and the building is now fitted up with a platform. The new benches fall back about 4 in., and to each there is a door about 18 in. or 20 in. high to protect the occupants from draught. The renovation has cost about 345l. The contractor for the work was Mr. Cunnold, builder, of Ipswich; the plans being those of Mr. Barnes, of the same town, architect.

CHURCH-BUILDING NEWS.

Gamblesby.—The new church here has been opened for divine service. It has been built on a concrete foundation about a yard in depth, and is of red stone. The ground connected with it is enclosed by a wall of the same material. The exterior of the church measures 72 ft. by 22 ft., and the interior 66 ft. by 18 ft. It contains thirty-two pews, which represent 130 sittings. The pews are all open, and of stained wood. At the west end of the church is a slated spire. The roof of the church is ornamented by a stone ridge. The architect was Mr. Charles J. Ferguson, who, when his design was chosen in 1865, was a pupil of Mr. G. G. Scott, and is now of the firm of Cory & Ferguson, of Carlisle. The builders were Messrs. Watson & Son, of Kirkoswald. The contractors for the building were,—for the stonework, Messrs. A. Watson & Sons, Kirkoswald; joiner work, Mr. Pollock, Penrith; plumbing and glazing, Mr. Porter, Penrith. The stained-glass windows at the east end of the church were from Mr. John Scott, of Carlisle. The total cost of the church is estimated at about 1,900l.

Gatesgill (Carlisle).—The chief stone of a new church has been laid here. It will be dedicated to St. Jude, and will be built in the Early English style of architecture, and consist of a nave 45 ft. by 24 ft., with centre aisle, and a chancel 21 ft. by 14 ft., adjacent to which will be a side chapel, vestry, and organ-chamber. The principal entrance will be by a porch on the south elevation. The north and side elevations will be coupled lancet windows, with projecting buttresses, relieved with gables to vestry and organ-chamber. The west gable will be pierced with circular and lancet windows. The hefrly will be erected at the south-west angle of the west gable, with gill terminal 42 ft. high. The roof will be of high-pitch, and covered with slates of varied tints and ornamented with ridge cresting. The total cost will be about 1,100l. The contractors for the building are Messrs. Bregg, Wilson, & Baty, of Gatesgill; for the carpenter and joinery work, Mr. Ward, of Raughtonhead; slating, Mr. Hanson, Carlisle; plumbing and glazing, Messrs. Thomson & Sons, Carlisle; plastering, Messrs. Johnston, Brothers; ironwork, Mr. Wm. Corbett, Carlisle. Mr. John Love, of Manchester, architect, has supplied the design for the building. The church will be built of stone from quarries in the neighbourhood.

Yoxford.—The church here has been reopened, after a renovation of the interior. The two galleries have been removed, and the dormer windows in the roof blocked up. The church has been rebentched with New Zealand Kawrie pine. The chancel floors are paved with tiles. The walls have been scraped and cleaned. An organ, built by Mr. Green, of Ipswich, has been presented by Mr. Green, of Ipswich, has been presented by Mr. J. W. Brooke, of Sibthorp, has presented the new north door, curtain, &c. The door was built under the superintendence of Mr. R. M. Phipson, architect, of Ipswich and Norwich. The rest of the work has been carried out by Mr. Charles Nunn, of Friston, builder, the execution of the work having been performed by him, jointly with Messrs. Clayton & Cotton, carpenters, Yoxford. The whole cost of the restoration, exclusive of the organ, will be upwards of 600l.

Nevington.—The restoration of the chancel of the church here, with the exception of a little decoration, has been completed. The temporary window is of white, hordered with red. The reredos is not finished, as the wall is too damp for illuminating. The alabaster tomb of Sir John Brook has been restored by Messrs. Houghton & Co. The gallery has been removed.

Kendal.—The parish church restorations have been completed. The present restoration will

cost about 2,500l. This added to 6,400l. spent in 1850-2, and 2,200l. in 1863-4 amounts to more than 11,000l., the greater part of which was raised by voluntary contributions, and is exclusive of several presentations. The works have been carried out under the designs furnished by Mr. J. S. Cresswell, of Manchester, who has been the architect on all the several occasions. The contractors for the carpentry were Messrs. John Fisher & Samuel Compton; for the masonry, Mr. Robert Shaw; for the plumbing, Mr. Robert Winder; for the staining and varnishing, Mr. William Jackson; and for the plastering, Mr. Joseph Steel, all of Kendal.

Hertford.—A meeting of the committee for rebuilding St. Andrew's Church has been held to consider the steps to be taken with reference to the plans and estimates for the new church. The contracts sent in by different builders, it was stated, were all considerably in excess of the architect's estimate, and they were rejected. It was then referred to Mr. Johnson to find, within a specified time, a builder to carry out the works at the cost he stipulated. This he had done, and Messrs. Dove, of Ilkington, have offered to take the contract for 3,215l., omitting the heating apparatus. They at first offered to do the work for 3,450l., and then omitting the heating-chamber (which would cost 60l.) for 3,390l. Since then they had sent in another estimate, offering to carry out the plans, building walls of 2 ft. thick, instead of the thickness figured on the plans (which was 1 ft. 3 in.) for 3,215l. The sub-committee recommended Messrs. Dove's estimate of 3,215l. to the general committee for their adoption, subject to the question of finance; and the general committee agreed to this.

Sawlingham.—The church here has been reopened. There is a new aisle, equal in area with the nave, and separated from it by an arcade springing from five pillars, and surmounted by a new roof. The windows (five in number) are similar to those in the churches of Shelton and Alburgh, which latter is supposed to have been built by the same architect as the church was restored by. The central one, of Birmingham, Messrs. Hardman, of Birmingham, illustrates the story of the "Good Samaritan." Parallel with the aisle has been erected a vestry, opening into the chancel by the north wall. The alterations in the nave consist of the windows and roof. The former have been enlarged perpendicularly; the latter, which of late was flat and almost resting upon the beams, has been replaced by one of greater elevation, with cornices and diversified spandrels. The narrow archway leading into the tower has given place to one extending to the full breadth of the tower, through which is seen a window erected over the new stone doorway, which leads from without into the ringing-chamber. The church is laid throughout with black and white tessellated pavements. The pewing is of oak, moulded and surmounted by poppy-heads. The contractors were Messrs. Rust, Devoreux, & Barrell, of Norwich; and Mr. Benest was the architect.

PROVINCIAL NEWS.

Newcastle-upon-Tyne.—The foundation stone of the new hospital in connexion with the Newcastle-upon-Tyne Poor Law Union Workhouses was laid on the 9th inst. The hospital is intended for the accommodation of 200 patients, being sick and infirm inmates of the workhouse; and the estimated cost of its erection is 14,000l. The building forms three sides of a quadrangle, the latter being open towards the south. The east and west wings will be two stories in height, each containing two sick wards, 94 ft. long, 24 ft. wide, and 14 ft. high. The range on the north side of the quadrangle will also be two stories in height, and contain two wards on either side of the centre building, 88 ft. long, 24 ft. wide, and 14 ft. high. The centre building will be three stories in height, and is appropriated to nurses' rooms, sculleries, surgery, committee-room, &c. The walls will be of stone, and the style may be called Domestic Gothic. Mr. Robert Robson, of Wideopen, is the contractor; the architect, Mr. S. Oswald; and the clerk of Works, Mr. George Nixon.

Havreboer, South Devon.—A cottage residence has been just erected for Mr. Wm. Eastlake. It is in the parish of Buckland Monachorum, and is surrounded by fine moorland scenery. The walls are of Lee Moor white brick. The more exposed dressings are of wrought granite, the rest of freestone. The lower portions of win-

dows are glazed with plate glass; the spaces above the transoms with stained glass in lead. The furniture of the cottage will be chiefly of oak. Mr. James Hine, Plymouth, is the architect.

Preston (Lancashire).—A new workhouse has been opened for the purposes of the Preston union. The building has cost between 40,000*l.* and 50,000*l.*, and has been designed by Mr. Leigh Hall, of Bolton. The site is at Enlwood, about a mile from Preston. Hitherto there have been five workhouses in the union, but the new establishment will do away with them all.

West Bromwich.—A meeting of the committee appointed to consider the various plans forwarded for the hospital about to be erected in West Bromwich, in place of the present inconvenient dispensary, has been held at the Infirmary Board-room, High-street. Designs for the building were received from Mr. Y. Thompson, of Bennett's-hill, Birmingham; Mr. G. B. Nichols, West Bromwich; and Messrs. Martin & Chamberlain, of Birmingham. The sub-committee ultimately decided to recommend the Infirmary Board to decide the plans of the last-named gentlemen. The plans provided for the erection of forty beds, but at present it is only intended to build so as to have room for twenty, though the administrative offices will, of course, be designed for the whole number of beds. The site of the proposed building will be on the Lodge Estate, West Bromwich, in Edward-street, at right angles to Lombard-street, and the ground contains 6,000 square yards. It is hoped the work of excavation will be commenced in March. This total sum at present raised is about 2,350*l.* The amount includes a subscription of 215*l.* from the workmen of Messrs. George Salter & Co., and from those of Messrs. P. D. Bennett & Co., 126*l.*, both of which are payable by small weekly instalments extending over three years. The building will cost between 5,000*l.* and 6,000*l.*

FROM IRELAND.

St. Mary's, Crumlin-road, Belfast.—This church is the first of five churches which were to be built to supply the great need of church accommodation in the suburbs and manufacturing districts of Belfast. It has been consecrated by the Primate of all Ireland. It is from the designs of Messrs. Slater & Carpenter, of London. It has a lofty wide nave, with side aisles nearly as wide and lofty as the nave, following in this respect the idea of the great church of Austin Friars, in London. The tower is central, with transepts and chancel. The nave arcades are simple in character, with alternate voussoirs of Carlisle and white Scraho stones, resting on shafts of red Scotch stone. The roofs are simple. The ornrod braces of the nave roof rest on the ends of the tie-beams of the aisle roof, which are brought through the wall, thus forming a continuous tie across the chancel. The windows are lancets in triplets and complets. The complets in the aisles have large crossed circles over them, under one great inclosing arch on the inside. The nave has a traeroised roof on the gable. The chancel is apsidal, with crossed lancet windows. The tower rests on four moulded arches of red and white stone, rising from stone piers, two of which are engaged in the chancel and transept walls. Above these is a lofty lantern stage open to the church, with four lancets on each side, richly arcaded outside, resting on shafts of red Carlisle stone, with carved capitals. Above is a similar and much more lofty stage, for the bell-chamber. The angles of the tower have pilaster buttresses, with shaped angles. The spire is of timber, slated, and has on each of its cardinal faces rich spire-lights of oak, with lofty pointed roofs. The whole height of the tower and spire is 120 ft. The church is built of hassat faced with white Scraho stone, red Scraho and Carlisle stone being introduced in the arches and bands. The paving is of Dungannon stone, and the chancel is tiled. The builder was Mr. Henry, of Belfast.

St. Patrick's, Ardagh, County Monaghan.—This chnroh, or rather part of a church, has just been consecrated, and has been built by Mr. E. P. Shirley, from Messrs. Slater & Carpenter's designs. It is a simple oblong building, with an apsidal sanctuary opening out of it by an arch at the east end. The whole is to form the chancel of a much larger church, but for the present it will be used for the parishioners. It is four bays in length, and has lancets moulded on the inside. The chancel arch is built up in the west wall, and encloses a traeroised rose-window, with a

temporary door and porch under. The roof is of timber, with arched principals. The sanctuary is apsidal, with a moulded lancet in each side. The roof is of solid stone, arched on the inside, and weathered on the outside. The walls are lined with polished alahaster. The floors are of rich tiling. The sanctuary is raised seven steps, the Shirley vault being formed in the crypt below. The windows are all filled with stained glass, by Messrs. Clayton & Bell; the rose-window illustrating the life of St. Patrick; the sanctuary windows the Passion of Our Lord. The other windows are of simpler design. The marble work is by Sibthorp, of Dublin, and the builder was Mr. Parks, of Carrickmacross.

SANITARY PROGRESS.

Sanitary Inspection of Shipping.—The Sanitary Act of 1866, which the *Builder* had previously done its best to show the necessity for, especially as regarded the sanitary inspection of shipping, as well as in other respects, has been acted on by the City authorities in the supervision of the sanitary state of the shipping within its limits; and the report of Dr. Letehely, the medical officer of health for the City, on that important subject for the last two years, has just been issued, and we now give an abstract of its contents:—

"Small as the City district is, it affords ample proof of the necessity for proper inspection of all the shipping in the port of London; and it indicates, moreover, the kind of work which, and for during the last two years, there have been 3,223 inspections of the ships and vessels within your jurisdiction, and on 149 occasions it has been found necessary to amend their sanitary condition. This number includes nearly the craft which are under your control, and the chief improvements required have been the cleansing and better ventilating of the forecabin. As a rule, your officer makes about forty inspections a week, and he takes the opportunity of visiting the ships directly they arrive in port, in order that he may see their actual working condition.

From what I have seen of the state of the vessels in the river, and of the opinion that the appointment of a sanitary inspector of shipping has been productive of much good; and it is to be regretted that a like appointment has not been made by the other local authorities having jurisdiction over the shipping of the river; for it is manifestly an inconsistent thing that the whole port of London, only about a thousand yards of it, on each side of London-bridge, should be subject to sanitary supervision.

That there is great necessity for this is admitted by all who are acquainted with the sanitary condition of our mercantile marine; for over and over again it has been shown that fever and scurvy and epidemic diseases are not only very prevalent in the vessels which trade with this port, but that they are also directly referable to defective sanitary arrangements. This has frequently been a subject of remark by the medical officers of the Dreadnought hospital-ship, and of the customs. . . . Nearly all the cases of fever admitted into the hospital-ship are of the typhoid class, which indicates bad sanitary arrangements. . . . It is open to inquiry whether the inspection of vessels should not extend beyond the mere lodging of the crew, so as to reach the nature and quality of their diet; for if, as Dr. Barnes asserts in his report to the Medical Department of the Privy Council, half of the men received into the Sailors' Home at Poplar are, at the time of their admission, suffering from sea-scurvy, and if, as he also states, it is not uncommon for from 20 to 70 per cent. of a ship's crew to be diseased at one time, it is highly necessary that inquiry should be instituted as to the cause of such mischief; it concerns the health and well-being of upwards of 170,000 British sailors. Laws have been made, and notably the Merchant Seaman's Act for 1835, for the purpose of obviating this, but they are practically inoperative.

Inspections of this nature might properly be made by the sanitary officers of the port, whose duties would then extend to the whole sanitary condition of the ship. At present, however, there is a lamentable failure of all such proceedings; and even in respect of the partial supervision of our mercantile marine, in so far as the provisions of the Sanitary Act of 1866 are concerned, there is an open disregard of the law. . . . It is expedient, as well as imperative and necessary, that the several nuisance authorities on the two sides of the River Thames should agree on some mode of co-operation, whereby a proper inspection of all the shipping in the port of London shall be regularly and systematically performed, in accordance with the provisions of the Act of Parliament."

Stamford.—The Marquis of Exeter has presided at a public meeting in the lecture-room of the Stamford Institution, for the purpose of considering the sanitary state of the town. There was a numerous attendance of the clergy, medical men, and chief inhabitants. After some discussion the following resolutions were carried unanimously:—"That it is desirable to take steps to adopt a more effective system of drainage in Stamford, with a view to improve its sanitary condition." "That a memorial from this meeting be presented to the town council, requesting them to adopt the Sanitary Acts in Stamford." In course of the discussion it was remarked by Mr. Phillips that the drainage of the town might be materially improved, and that the impurity of the water supplied from the public wells was the great cause of preventible disease amongst the inhabitants. Mr. Heward mentioned that diarrhoea of a very serious type was prevalent in the town during the past autumn, and that

many deaths occurred. Mr. Paradise said that the cost of draining Grantham had been "about 6,000*l.*"

UTILITY OF THE NORWEGIAN COOKING APPARATUS TO WORKMEN AND OTHERS.

A SUBSCRIBER, of Newcastle, Ballymahon, Ireland,—Mr. L. H. King Harman,—writes us on this subject. He gives the result of three successful trials made under his own superintendance. In one case, he states:—"Having a shooting party of seven gentlemen at this place, I had a proper quantity of Irish stew made in the usual manner, put down on the hot hearth in the largest of the tin vessels, when it came to a boil in thirty minutes; it was then kept boiling fifteen minutes longer, when it was rapidly taken from the hearth, and placed in the machine, with a quantity of extra potatoes, in the other two tins, which last tins came to the boil in about half the time of the larger one. The box was then locked up, and sent in a cart after the shooters, when in two hours and a half, after being opened and turned out, the gentlemen found all the contents most perfectly cooked, steaming hot, and most excellent. This afforded as much as the seven could eat, and was also sufficient for an excellent dinner for the head keeper and some of his assistants. This machine will cook anything which can be boiled, as meat, fowl, vegetables, dumplings, &c. I considered it a most complete success, and that it will prove a useful companion to all persons obliged to move about, and not able to be at home for comfortable, hot, and regular meals, as railway guards, land agents, on inspecting expeditions over the properties under their charge; shooting parties, commercial men, pic-nic excursionists, &c.; and last, not least, it would prove of the utmost value to our army, and when made on a large scale it would do well to accompany the new water-transport cart, and afford excellent refreshments to our soldiers after a heavy march, an exhausting field-day, and a well-fought battle, when a hot and comfortable meal would go far towards restoring the strength and maintaining the life in many a wounded man. The great utility of these machines will plead my excuse for trespassing on your columns. They only require to be known and properly tested, in order to be highly prized and valued. The smallest size would prove most useful to tradesmen, as carpenters, stone-cutters, &c., working on buildings, &c., far from their own homes, before leaving which, when at their morning meal, their wives or children could prepare their dinner, which they could find well cooked, hot, and comfortable when required."

Were the apparatus made cheaper and better than at present, it would come into general use among workmen and others. Its present price, 12*s.* 6*d.*, is too high, and the way in which it is put together far too slight. A first-rate tradesman informed Mr. Harman that they could be made properly at 5*s.* each in a large quantity, and leave a good profit to the maker.

RAILWAY CRUELTY.

Sir,—I have just been seeing my daughter off by the twelve o'clock train for Leeds. As the journey is expensive for poor folks, she took a second-class ticket; but nothing would induce the porters to let her have a hot-water tin,—not on payment or any way. They said they had strict orders only to put them gratis into first-class carriages. They might surely let poor second and still more, third-class passengers have had little comfort on a long cold journey at a small fixed price. It is most arbitrary and insulting, I call it, to those who cannot pay the high first-class charge: the second is high enough. Fancy nurses and children, or a delicate young governess, going all the way to the North in the depth of winter, and being refused such a thing, whilst they see them given away where they might be paid for. I hope you share my indignation.

AN ARTIST.

. We do share our correspondent's indignation. Independently of the cruelty of the thing, it is utterly stupid. Directors know well enough, now, that it is from the second and third classes that they derive the bulk of their revenue, and yet they have not the sense to see the desirability of rendering travelling as agreeable as possible to those classes. It is an utterly short-sighted policy.

BRICKMAKING IN SCOTLAND.

A WRITER in the *Weekly Scotsman*, on Manufacturers in Native Clays, says,—“The number of bricks made in Britain in the year 1802 was 714 millions; in 1840 it was 1,725 millions; and in 1850, the year in which the duty was abolished, it was 1,563½ millions. The number of bricks made in Scotland annually was 154 millions in 1802, and 47½ millions in 1840. If the great increase in railway and other works, the rapid enlargement of towns, and other recent causes leading to a more extensive use of bricks be considered, the number now made in Scotland cannot be less than 200 millions a year.

There are in Scotland 122 manufactories of bricks, tiles, and articles of a similar nature; and in connexion with these from 4,000 to 5,000 persons are employed. The manufactories are widely scattered over the country, the farthest north being at Banff, and the farthest south at Dalbeattie; but the greater number are in Lanarkshire and Fifehire, in which counties valuable beds of fire-clay exist. The most extensive manufactory is that of the Garnkirk Fire-clay Company, situated on the Caledonian Railway line, about six miles east from Glasgow. The company was originally formed to work coal, but, finding that extensive seams of fire-clay existed on their property, they took to manufacturing that material, which now almost exclusively engages their attention. The principal seam of clay is 7 ft. in thickness, and lies at an average depth of twenty-eight fathoms. Its quality is considered equal to that of the best Stourbridge clay. The manufactory covers upwards of six acres of ground, and is surrounded by thirty tall brick chimneys, which give it an extraordinary appearance. Raw material is brought in, and finished goods are sent out, by branch railways, the traffic on which never ceases from one week's end to the other. Two hundred tons of clay, and about an equal weight of coal, are used every day. Upwards of 300 men and boys are employed by the company, and these are aided by three steam engines with an aggregate of 150-horse power. This is exclusive of the power employed to bring the clay and coal out of the pits. The clay is of a dark colour, owing to the presence of a small proportion of bituminous matter; but when that is dispelled by the action of fire, only silica and alumina remain, and it is the presence of these substances in certain proportions that decide the value of the clay. As it comes from the pits, the clay is entirely devoid of cohesion or plasticity; and in order to bring it into working condition, it has to be ground very fine, and then mixed with water. Several powerful mills are used for this purpose. They consist of great iron rollers, which travel round a circular trough, and pass over the clay. Several hundred-weights of material are operated on at once, the time for which the grinding is continued depending on the quality of the articles to be produced.”

SNOW AND THE VESTRIES.

I VERY much wish to be permitted to ask whether our vestries, district boards of works, and like bodies, are at all thinking of what to do in case London should be visited with a snow-fall of anything like the greatness of that which came upon us in the first week of January, 1867? I have read a number of local papers in order to discover any indication of preparation or thought on the question, and I confess I have found no indication.

“We know not when the storm may come,
But 'tis coming in the air;
And this is the warning of the drum,
Prepare! Prepare! Prepare!”

I was perhaps wrong in saying that no local body had given any attention to the snow problem. The City of London, the localist of our local bodies, made some stir in the matter during the whole of the year 1867. Its Engineer, in a report dated January 17 of that year, that is, about a fortnight after the great fall, detailed “the measures taken for cleansing the streets of the City after the snow-storm on 1st January, 1867.” This report, with some additions, was subsequently issued in pamphlet form, and no doubt is still procurable at the office of the Engineer of Sewers, Guildhall.

On October 31, 1867, the City authorities offered, by advertisement in the public prints, premiums for “plans and suggestions as to the best mode of effecting the removal of snow from streets and places within the City.” This mode of the magistrates (the premiums offered were beggarly in the extreme, 30 guineas for the best plan, and 20 guineas for the second best) resulted in the chief clerk, Mr. Jay, receiving by the appointed day, November 26, 1867, 157 replies, some with drawings, and some few with models illustrative of the schemes. These were severally referred by the committee to the Surveyor, to arrange and classify. They were arranged in classes as follows:—1. Snow to be melted by furnaces, boilers, or steam jets, &c.; 2. Snow to be carried away to vacant places, River Thames, &c.; 3. Snow to be thrown into yards, railways, or to minor streets; 4. Snow to be thrown into sewers, down existing inlets, or by new inlets to be constructed; 5. Snow to be dissolved

by salt, salt and water, manganese, or other chemical agents; 6. Snow to be heaped into ridges in centre on sides of carriage-way to melt gradually; 7. Snow to be rolled by steam or horse power.”

On Thursday, December 19, 1867, the Streets Committee presented their report to the Court of Common Council, which met on that day. The committee had met on several occasions after the completion of the classification by the surveyor, and had carefully examined the schemes separately, and had selected several of them for further consideration. They proposed that sundry experiments should be made, with a view to test the practicability of some of them. They avoided, therefore, giving an opinion upon the merits of any until the result of such experiments had been ascertained. But considering that snow might fall before these experiments had been tried, they had carefully considered the best course to be adopted, and had given the superintendent such instructions as they believed would greatly assist in mitigating the inconvenience of a heavy fall of snow in the City.”

This report, as I have said, was presented on December 19th, 1867, now more than a year ago. We had scarcely any snow in London last winter, and so, of course, no “experiments” with the new modes were tried.

Thus, then, stands this grievous snow question.

On the 3rd of January, 1867, one of our great difficulties wrote:—
“London woke up yesterday morning to find the streets and pavements covered with three or four inches of snow. To all appearance we could not have been more surprised if we had all been asleep since the hottest day in last August. Nobody seemed to expect the snow, and nobody was prepared to meet it.”

Let us not deserve this stinging reproach again. Let our local boards at once form “snow committees”; let them estimate, and, if not best, make their forces to the advantage of the time. Let each local surveyor take a journey to Guildhall and ask permission of Mr. Hayward, Secretary to the Commissioners of the Metropolitan Board of Works, to inspect the numerous and a half of plans sent in by the very experienced engineer of the Commissioners, and by the extremely patient hundred and a half of planners; let the local surveyors meet together and compare their own experiences and arrangements with those of the Board, and then it will not be said again—as was said with strictest truth of the snowstorm of the 1st of January, 1867—“Nobody was prepared to meet it.”

EXEMPTIONS: METROPOLITAN BUILDING ACTS.

Sir,—I should feel greatly obliged if you could give me information on the following matter:—

Amongst the buildings exempt from the operation of the Metropolitan Building Act (vide Part I. Sec. VI.) are, “all buildings not exceeding in height thirty feet, as measured from the footings of the walls, and not exceeding in extent one hundred and twenty-five thousand cubic feet, and not being public buildings, wholly one occurrence street or alley, whether public or private, and at the least thirty feet from the nearest buildings, and from the ground of any adjoining owner.”

1. Does this clause justify any person in erecting two or more houses on his own ground less than 30 ft. apart, if more than 8 ft. from any other building, and at least 30 ft. distant from the ground of the adjoining owner, without the interference of the district surveyor?

2. If the district surveyor chooses to inspect the premises to ascertain whether or not they are exempt from the Act, is he entitled to any fee?

A case raising the first question was before the magistrate at the Woolwich police-court some few weeks ago, but was not completed on the first day of hearing. It was adjourned to, I think, the 12th or 14th of November, but I have been unable to ascertain how the matter was settled. As, however, the question is of some importance to builders, and the public generally, some of your readers may be able to inform us of the magistrate's decision.

“* * * We do not know how the case in question was settled, but are quite certain the clause quoted does not ‘justify any person in erecting two or more houses on his own ground less than 30 ft. apart, if more than 8 ft. distant from the ground of the adjoining owner, without the interference of the district surveyor.’ The clause requires for a building to be exempt, that it be at least 30 ft. from any building, no matter to whom it belong, and at least 30 ft. from the ground of any adjoining owner. If it did not do so, whole rows of houses belonging, as they often do in the first instance, to the same owner, might be built without the control of the act. In reply to question 2, no fee is allowed by the act to a district surveyor for ascertaining that a building is exempt.”

NORTH RIDING OF YORKSHIRE BRIDGE-MASTER.

Sir,—Some weeks ago exception was taken in your pages to an advertisement issued by the magistrates of this riding for a bridge-master. The effect of that advertisement was to bring not less than fifty applicants from engineers. This number was reduced to eleven by a committee, and the appointment will take place by vote at the Quarter Sessions held this week. A most active canvass is proceeding by the selected eleven. From my own experience, I can safely say that a bridge-master who attends, not only to the building of new bridges, but the repair of present ones (in a Northern climate, where sudden and great rises of waters occur), the roads 100 yards on each side from the crown, the parapets and railings, the gaol and police courts and cells, &c., will have plenty of work to attend to, and to his practice.

RAILWAY COLLISIONS.

Sir,—Will you allow an old correspondent to mention a circumstance which may at least appear curious, if not startling? Some twenty-five years ago he really believed he possessed a “secret,” though a “civil engineer” (with mutual friend) must afterwards have had a very similar one, and expected vast advantages from it, to infallibly

neutralize, or “paralyze,” railway collisions, if at highest speed, and within a few feet of contact, by the shaft-wards encountered, or at least the writer did, an overlooked circumstance, which sadly damped their aspirations. The “shocks” of instantaneous stoppage, which perhaps they could not have achieved, covered by a lateral correspondent three or four years ago, to “fall from a height of 80 ft.,” might “half kill” nearly all the passengers in a train, near and far. The “other” contingency, still, with respect for after judgment, could not something more be done there by means of sounds? I do not mean “temporary” “fog signals,” or even constant “shriek” of whistle; though that would be infinitely preferable to mutilation or death, of which we have had such terrible examples, and even social and religious warnings issued. But a regular announcement of approach at sufficient distance for safe measures. With sole drawback of some “noise” which safety to “life and limb” might not weigh very near, front, and “sharply” struck, by machinery once in three or four seconds, or otherwise, though capable of being stopped in “one.” If the “bell” were carefully tuned to a “high” or “altery” tone, the effect might not be so bad; perhaps in the country rather “lively.” And this, I expect, could be distinguished when prepared for in almost any weather at about or near the distance of a mile distant.

COMPENSATION CASES.

HENRY ABRAHAM V. THE CORPORATION OF LONDON.

This case (Lord Mayor's Court), a compensation claim, arising out of the works of the Holborn Valley Viaduct, came on for hearing, on the 4th inst., before the learned Plaintiff, Mr. Henry Abraham, is a glass-cutter, lead merchant, &c., and carries on a large business at No. 55, Snowhill and 1, Farringdon-road. The original claim sent in some time ago for 19,850*l.*, but was amended to the sum of 8,857*l.*

Mr. J. H. Lloyd and Mr. Litter (of the Common Law Bar), instructed by Messrs. J. & M. Pontiff, appeared for the claimant; and Mr. E. F. Fox, and the Hon. F. P. Threlker, instructed by the City Solicitor, appeared for the Corporation.

From the opening speech of the claimant's counsel it appeared that the value of the neighbourhood of the claimant's was daily increasing in value from the enormous pedestrian and vehicular traffic in Holborn, and more especially so the claimant's premises, in consequence of their fine central position; and evidence of the claimant and his surveyors (Mr. E. Fox, Mr. O. A. Young, and Mr. Samuel Green) showed that the sum claimed was not in any way exorbitant one.

After several other witnesses had been called on behalf of the claimant and severally cross-examined by the counsel for the Corporation, the jury was discharged in consequence of the sum of 8,857*l.*

MESSERS. THORN V. THE METROPOLITAN BOARD OF WORKS.

This claim, under the Lands Clauses Consolidation Act, for compensation for compulsory removal from offices which the claimant rented, and which were required for the Thames Embankment, &c., and the new street to the east of Mansion House, was heard on Tuesday at the Guildhall Police-court, before Mr. Alderman Finnis.

Mr. Murphy, instructed by Messrs. Braddon, appeared for the claimant; and Mr. Philbrick, instructed by Mr. Ward, for the Metropolitan Board of Works.

Mr. Murphy said that the claimants were the contractors for the construction of Blackfriars Bridge, and the compensation they sought was out of the ordinary course. In 1841 Messrs. Thorn took the contract for the bridge, and immediately took the second and third floors of the claimant's premises, in consequence of which they were required to close the new street to the east of Mansion House, so that they could always keep their eyes on the workmen. The top floor they left off to Mr. Bryant, their resident agent for the claimant, and the compensation they sought, in September last the premises were required for the new street from the Mansion House to the Thames Embankment, and Messrs. Thorn had to give up the second and third floors on the opposite side of Chatham-place, No. 4, where they were unable to have a view of their works or the men employed upon them. There was a great loss accruing to the claimants from the fact that they were unable to employ a sufficient supervision over them. That loss was difficult to arrive at, from the exceptional character of the case. Some had estimated so much a day, and the new street to the east of Mansion House thought it the fairest way to take a percentage on the wages they paid weekly, and they had done so. They had put down their loss at the moderate sum of 5 per cent., but he was bound to say that that was only a speculative item, for they had no data upon which to arrive at any definite sum.

The claim put in was 1,500*l.* for the loss on the men's time by want of supervision, 40*l.* for increased rent, 20*l.* for fixtures, 20*l.* for reinstatement, 16*l.* for loss of clerks' wages during removal, and 5*l.* expenses of removal; making a total of 1,601*l.* Evidence having been given in support,

For the defence Mr. Philbrick called Mr. E. N. Clifton, architect, who said he had constructed building such as Greenhall House and East India-avenue, and paid about 3,000*l.* a fortnight for wages. Supervision for a man, such as that spoken of, was not superfluous, and the profits of a contract. There was no value in Mr. Thorn's interest in No. 13, for he paid a rack rent; but where a tenant was compelled to move, it was customary to give him a week's notice.

Mr. Trist, of the firm of Norton, Trist, & Watney, thought that 150*l.* would cover every expense and liability of the Board of Works, and be a little allowance to Mr. Bryant, who was the claimant's resident agent, the chief clerk, to consult on the matter, and on returning into court awarded Messrs. Thorn 400*l.* compensation, and 30*l.* costs.

BOOKS FOR THE SCIENCE CLASSES.

Sir,—I think if each of the science schools was provided with a circulating library of first-class scientific works, it would greatly facilitate the spread of scientific knowledge. A committee should be appointed to collect the most valuable and practical works, and place them at the disposal of the students, for the payment of, say 1*l.* per week. Surely the Government could accomplish this; and I think it would be highly creditable by the working classes of England, who wish to improve

themselves. It would render the technical phrases and terms familiar to the ear of the student, and save a considerable amount of the teachers' time. For I am certain there are many that join the sciences classes that do not understand a single term of geometry; and they commence drawing without really understanding what they are doing. They do not succeed because success is impossible, and the teachers very rarely give them any encouragement, and they become discouraged, and ultimately leave the school. And I also think there is room for amendment in the appointment of teachers, for I have actually seen a teacher in one of the London schools puzzled by a simple problem in descriptive geometry, and also very inattentive to the students; such as spending thirty or forty minutes in a friendly chat. I think every teacher should be thoroughly conversant with the science that he is paid to impart to his pupils. Moreover, he should pledge himself to execute his duties, and take a kindly interest in his vocation, and his attendance should be regular and punctual, which, I am sorry to say, it is not in the school mentioned above. After considering the above facts, can we wonder that so few pass the examination? I hope the Authorities at South Kensington will take this into consideration.

A. WORKING MAN.

HOLLOW WALLS.

SIR,—Can any of your correspondents inform me whether, in the case of a dwelling-house built with hollow walls, any openings (as air-bricks, &c.) are necessary from the external air into the chamber between the two thicknesses of the wall, and, if so, what number in proportion to wall length, and in what position they should be placed?

A. B. C.

FLOWER POTS.

SIR,—Is it not possible, in this age of window gardening amongst all classes, to manufacture a better sort of earthenware flower pot than is usually sold,—say a section of a column, with two ribs on the upper part and two ribs on the lower, with two lip side handles such as are commonly seen on the old red earthenware pan. We should then have a flower pot with a solid base, not so top-heavy. I cannot afford china pots, marble squares, or decorative tery. I want a good, besides not being so well adapted for the growth of plants as earthenware. I think if gullion and peck pots were so made they would have great sale.

CIVIS LONDINENSIS.

BOSTON CHIMES.

SIR,—Writing in a strictly independent yet temperate spirit, I gave a descriptive account of the bells and chimes at Boston in the *Builder* of the 19th ult. How far "G. L." in your last impression has fairly represented the scope and tenour of my remarks, let your readers decide.

I might reply at some length touching the suggestion and proposal of your correspondent. I will, however, merely say on the present occasion that if he will refer your readers—I do not myself require such information—to any set of large bells on which the capabilities of a machine constructed upon the principle which he advocates have been, or will be, fairly tested, much time and trouble will be saved.

THOMAS WALSLEY.

NEW METROPOLITAN MARKETS.

SIR,—The ultimate erection of new markets for the accommodation of the more crowded districts of London is no doubt certain, either under central or local authority, but in the mean time much may be done to make the existing centres of retail business more convenient on the working man's great marketing night, Saturday.

My suggestion is that such streets as have by custom become regular markets, and are in consequence practically impassable for horse traffic on Saturday evenings, should be closed at each end from say six till twelve o'clock, the district scavenger ordered to cleanse the street thoroughly from end to end, and the stall-keepers placed back to back in the centre of the road.

In many streets like East-lane; The Brill, Somers-town; New-cut; Westminster-broadway; Narrow-street, Limehouse, even this arrangement would leave little enough room; but the two comparatively wide paths on either side of the street, and the stoppage of vehicles, would be preferable and more convenient to both seller and buyer than the present disorganized condition of these necessary resorts. The parish surveyors and the police might easily initiate the system, and, working in harmony, could not fail to add to the comfort of all concerned.

A. M.

NEWS FROM MELBOURNE.

The warehouse of Messrs. Warne & Webster, Flinders-lane, Melbourne, is a five-story building, recently erected in this lane of large warehouses. It is being erected for a firm of importers and clothing manufacturers. The space occupied is 27 ft. frontage by a depth of 90 ft., and 52 ft. in height from footpath to the top of blocking. The half-ank basement is of bluestone ashlar to the level of the ground-floor, and thence, to the top of the building, of brick, each floor being lighted by windows on both sides. The floors are 12 ft. high, with the ex-

ception of the basement, which is 10 ft., and the attic, which is 9 ft. to underside of tie-beam of roof. Goods are raised by a hydraulic lift to the several floors. Each floor is supported on wrought-iron girders stretching across the whole width from wall to wall. The front towards Flinders-lane, from the footpath to the level of the ground-floor, is fine sized rusticated hne stone, with plinth and capping, angles rounded, and segmental-arched window-heads. The superstructure is cemented, the ground-floor having a cornice and semicircular-headed entrance-door, and windows springing from the impost, the vousoir of arches being vermiculated with moulded archivolt between the vousoir, the jambs rusticated, and the rounded angles rusticated and broached to receive the square quoins above. The object of rounding the angles is to prevent drays from injuring the building. The two ranges of windows above the ground-floor cornice and below the main cornice have, in each floor, three windows with regular entablatures, moulded jambs, sills, &c., and rusticated quoins up the angles, the whole surmounted with a very plain adaptation of Vignola's grand hock cornice. Over the cornice is an attic having rusticated pilasters with vertical raised panels and rusticated quoins; and the three windows are finished with architraves; and over all an attic cornice and cincture blocking.

Books Received.

Art of Constructing and Repairing Common Roads. Weale's Rudimentary Series. London: Virtue & Co., Ivy Lane. 1868.

A fourth edition of this volume of Weale's Rudimentary Series, with additions, has been published. It includes a "Survey of the Metropolitan Roads," by S. Hughes (which might be left out without much loss); the "Art of Constructing Common Roads," by Henry Law; "Remarks on the Maintenance of Macadamised Roads," by Sir John Burgoyne; and a note by Mr. Robert Mallet on the causes of the apparent failure of macadamised roads in certain localities. Mr. Mallet regards asphaltic macadamising as the very best material for the street surfaces of populous cities. A large amount of valuable instruction is given.

A Descriptive Treatise on Mathematical Drawing Instruments. By WILLIAM FORD STANLEY. Second Edition. London. 1868.

In the second edition of this Treatise, already as originally published favourably reviewed in these pages, Mr. Stanley has given some additional matter, including illustrated accounts of a tray for holding wood blocks on which drawings are to be made; a copying-table; a set square for section lines; a full description of planimeter for computing areas; a gauge for cutting off drawings, and some few smaller matters. The book will be found useful in every office.

An Elementary Course of Plane Geometry. By R. WORMELL, M.A. London: Thos. Murby.

Mr. WORMELL feels, with others, that sticking to Euclid, pure and simple, is not the way to teach properly the practical bearings of geometry; and he has, therefore, compiled this text-book for beginners, with reference to utility. The advantages that have resulted from the introduction of the system in the City middle-class schools, enable him to speak with some confidence of its value. Many of the illustrations are drawn from architectural subjects, which leads us to say, by the way, that the view of a cottage, on page 67, is in faulty perspective. Nevertheless it is a good little book.

The Art-Journal.

The *Art-Journal* begins the year with the first of a series of illustrated papers, headed "The Stately Homes of England (occasionally open to the people)," by the indefatigable editor, Mr. S. C. Hall; Mr. Llewellynn Jewitt contributing the antiquarian notes and details. Alton Towers is the first "stately home" treated of. The number is altogether a very good one, and includes a view, and some engraved details of the Paris Opera House. Mr. Jas. Dalmore again takes up his valuable series of papers on "British Artists," and illustrates well the works of Sir Joseph Noel Paton.

Miscellaneous.

House Blown Down near Huddersfield.—The ravages of the recent hurricanes are everywhere perceptible in some of the villages in Yorkshire. A house belonging to a farmer at Thurstonland, a wild, romantic district, was blown down, and is now a mass of wreck and ruin. The farmer's wife was completely buried among the debris, and when extricated, a task which occupied over half an hour in its accomplishment, it was found that she had sustained very severe injuries and bruises, caused by the descent of bricks and rafters. A cradle in which the child lay was overturned, but the occupant was not hurt. Babies always escape, somehow. One hears, now and then, of them tumbling out of railway-carriages running at high speed; but who ever heard of one of them being killed? They are scarcely ever even injured.

Proposed Rural Hospital at Ashford.—A scheme is under consideration for the establishment in the neighbourhood of Ashford of one of those excellent institutions which have been found so valuable at Cranleigh, Tewkesbury, and elsewhere. Sir Edward Hoare, bart., Mr. C. Pemberton Carter, and Mr. John Furley are prepared to undertake the establishment of a hospital of this kind at Ashford, and it is to be hoped that their benevolent exertions will be crowned with complete success. The last report of the trustees of the Cranleigh Village Hospital contains the following statement:—"The simplicity of the domestic arrangements and the comfort of being within easy reach of relations and friends, as well as the quiet of a private room, and the home feeling which prevails throughout the hospital, add materially to the popularity of the institution in its own immediate district; and, combined with a certain amount of liberty, more than can be accorded to the inmates of larger hospitals, has an influence which certainly aids in the recovery of many of the patients."

Mr. Holman Hunt a Sculptor.—Mr. Holman Hunt is in Florence. He finds so much difficulty in getting his design for his wife's mausoleum executed that he has taken lessons in sculpture, and is himself carrying out the work.

Mdlle. Nilsson a Sculptor.—According to the *Vigaro*, Mdlle. Nilsson is exceedingly clever as a sculptor. The next Exhibition (it adds) will probably contain a statuette executed by her.

Manufacture of Building Material.—Among the trades lately introduced on the Tyne, the manufacture of concrete for building purposes is mentioned.

Gloucester Cathedral.—The nave of this cathedral was lighted with gas for the first time on Christmas-eve. The effect, it is said, was good. The lighting is effected by about 500 jets, projecting from the string course above the Norman arches, the main pipes being concealed from view. It has been ascertained that the cost of lighting is about a guinea each service.

Master Builders and Trade-Unions, Manchester.—A circular calling attention to the relative position of builders, brickmakers, and bricklayers has been issued. The persons and firms by whom it is signed include some of the most influential in the city. Their complaint is:—"The arbitrary laws of the unionists unwisely shorten the hours of labour; limit the quantity of work to be performed in a given time; advance the rate of wages; increase the cost of all building without improving the workmanship; keep down the skill and condition of the workman; augment the difficulty of his becoming a master; and injure most the very class supposed to be benefited. To remedy this evil they suggest the employment of non-unionist workpeople and members of the Free Labour Registration Society; and that they themselves be encouraged to take apprentices from the non-employed youth of our large towns; by which means they would have an opportunity of adding considerably to their weekly wages, and thus a constant and well-regulated supply of labour would always be available, and contribute much to the general good of the public as well as to all parties connected with the building trade."

Charge against the Accountant of the Metropolitan Board of Works.—Mr. Hughes, the accountant of the Metropolitan Board, has been taken into custody and brought before a police magistrate on a charge of defalcations to the extent of about 2,000.

More Alpine Railways.—Mr. Fell, the English engineer, has offered to the Swiss Federal Council to undertake the construction of three railroads, over the Alps for a guarantee of interest of 600,000*fr.* annually. He estimates the cost of that over the Simplon at from 11 to 13 millions; of the St. Gothard, at from 13 to 14 millions; and at 15 to 18 millions for the Luckmanier.

Intensification of Gas-light.—Mr. James Allison Hogg, gas engineer, Edinburgh, practises a method of producing intense light with coal gas. A mixture of gas with atmospheric air is lighted after passing through a tiasse of iridio-platinum wires at a determinate pressure. In a few seconds the metal becomes heated up to a white heat, the flame disappears, and an intense white light is the result. An enlarged picture has been taken by its aid on prepared photographic paper. The light will burn in a gale of wind, it is said, without any protection round it, and a downpour of rain will not affect it. The use of platinum to increase the intensity of gas-light has been long known; but this seems to be an improvement.

The Cheap Railway Fare Scheme.—A paper was recently read at the Inventors' Institute, London, by Mr. R. Brandon, on his scheme for the "Consolidation of Management of Railways, and Uniformity of Fares for all Distances." At present, he said, the fares average 1*s.* for each person; but by his plan the fares would be 1*s.* first-class, 6*d.* second, and 3*d.* third; and he calculated that the number of passengers would be increased sixfold. He would propose, however, that all luggage should be paid for. By this plan, taken as a whole, he expected the following results:—Single tickets, 17 millions sterling; annual, 18 millions; express trains, 11 millions; 3*d.* fares, half a million; luggage charge, four millions; saving in management by amalgamation, 3½ millions; total contemplated revenue, 55 millions, being an excess over the present gross revenue of 38 millions sterling. He had not entered into any calculations as to goods trains, as he did not think they would be much affected by the proposed change. He preferred that Government should take the whole of the railway capital at a value based on a seven years' average of quotations, and that the interest should be 4½ per cent. Deferred shares and bondholders would be paid out of the surplus revenue after the payment of the above charges. The chairman (Mr. H. Williams) whilst inviting discussion, demurred to Mr. Brandon's calculations. He denied the analogy between the carriage of letters and of passengers altogether. A discussion followed, in which Mr. Varley, Mr. F. W. Campion, and others took part; and the proceedings terminated with a vote of thanks to Mr. Brandon.

The French Atlantic Cable.—For the past four months the manufacture of this line has been actively going on down at Greenwich. The cable is nearly similar to those laid down in 1865 and 1866, with the exception of the core in the present being larger, and weighing 100 lb. of copper more per mile. The object of this enlarged core is to attain a greater speed of transmission. The cable is very strong, its actual strain being 7½ tons. Sir James Anderson, who superintends the whole work on the part of the company, has recorded his opinion that by keeping up the Milne Bank, and around the southern edge of the Grand Bank, there can be no possibility of injury to the cable from icebergs. It is a well-known fact that the icebergs never "bottom" in over 90 fathoms of water; and, by acting upon Sir James Anderson's advice, the line would never be out of 500 fathoms of water. The *Great Eastern*, now lying off Sheerness, by next March will once again have resumed her telegraphic attire.

Progress of Montreal.—Upwards of 1,000,000 dollars have been spent in building in Montreal in the year 1868. In 1856 the value of assessed property was but little over 25,000,000 *dols.*, and the revenue of the city from all sources 285,000 *dols.* Now the value of assessed property is computed at nearly 100,000,000 *dols.*, and the city's revenue has increased to upwards of 700,000 *dols.*

Alarming Accidents at Churches in Liverpool.—Those assembled in St. John the Baptist's Church, Toxteth Park, on the Sunday before last, were alarmed by a noise produced by the top stone of one of the turrets falling on the roof over the south side of the nave of the building.

A gale of wind was the cause. Happily the stone, though making a hole in the ceiling, rested on it. One of the churchwardens (a ladder) shortly afterwards advised the clergyman to suspend the service as the wind was blowing very hard, and a similar downfall of some of the other minarets might occur. The service, therefore, was prematurely closed. A precisely similar accident occurred about the same time in St. Paul's Church. In this case the broken piece of the spire fell through the roof and landed on the organ, but without doing more injury.

The Thames Embankment.—The planting of trees on the Thames Embankment (north), as recommended some few weeks since at a meeting of the Metropolitan Board of Works, has been commenced, nearly fifty trees being now in the ground. The trees are placed at intervals of about twenty feet from each other, and already nearly half the line of ground between Westminster-bridge and Hangerford is ornamented. The three new piers now in course of construction on the river—at Hangerford and Waterloo-bridges and the Temple—are fast approaching completion.

Hydraulic Cements: The French Academy.—Paris, December 21st.—M. E. Fremy presented his second memoir, "On Hydraulic Cements." These cements, he said, were produced, as Vicat established, by the calcination of argillaceous limestones. It is generally admitted that the result from the action of lime on clay is three salts—silicate of lime, silicate of alumina and lime, and aluminate of lime, which become hydrated on addition of water, and so form cements. M. Fremy's researches have been made with a view to putting these theories of hydraulicity to the test. In his first memoir, he demonstrates that the theory of hydraulicity founded on hydration does not apply to all the bodies formed during the action of lime on clay. By producing silicates of lime and silicates of alumina and lime under the most different conditions, he proved that these salts never hydrate nor solidify in contact with water unless they contain some free lime. Following up the five experiments of M. M. Rivot and Chaptou, he has demonstrated that of all the bodies which result from the calcination of an argillaceous limestone, aluminate of lime is the only one which has the power of solidifying and forming a hydrate under the influence of water. In the memoir now before the Academy he expresses the following opinion:—"The 'setting' of an hydraulic cement is always due to a pouzolanic phenomenon; consequently an hydraulic cement should always be formed of two different parts, the pouzola and the lime bases."—*Scientific Opinion.*

Explosion of Gas in a Concert-room.—An explosion, causing some damage to property, but, fortunately, unattended with injury to life or limb, recently occurred at the Co-operative Hall, Darwen. The large room of the hall, lately used as a theatre, was set apart for an entertainment to be given by Miss Emma Stanley, the veteran actress, as we might call her, were it not unallant to speak of a lady as a veteran. About six o'clock on that evening she went to the hall along with her manager, Mr. Harrison, for the purpose of seeing that all things were in proper order. A strong smell of gas at once arrested their attention. The hall-keeper sent for a gas-workman, who went underneath the platform foolishly with an open light in his hand. The consequence was, that the gas immediately exploded with a loud report. The platform was shattered, and one of the pillars was entirely blown to pieces. The workman, almost miraculously, escaped unhurt; but the concussion had such an effect on Miss Stanley's nerves that she was incapacitated from performing that evening, for which loss, it is said, she intends to claim damages.

TENDERS.

For a villa residence at Putney. Mr. G. H. Page, architect. Quantities supplied:—
Eaton Brothers £1,257 0 0
Lathey Brothers 1,230 0 0
Aries 1,264 0 0
Merret & Ashby 1,291 0 0
Bass 1,190 0 0

For the erection of a villa residence on the Bromham-road, Bedford, for Mr. James Edward De Gruchy. Mr. John Usher, architect. Quantities supplied:—
Edey & Waldman £1,165 0 0
Smith 1,153 13 0
Moore 1,145 0 0
Dey 1,138 10 0
Dickens 1,124 0 0
Carvin 1,115 0 0

For pipe sewers, &c., at Springfield Park, Lewisham:—
Hilton £992 0 0
Hutchings 711 0 0
Trevorson 669 0 0
Jones 688 0 0
Phillips 569 0 0
Reed 510 0 0
Blackburn 500 0 0
Crockett 495 0 0

TO SUBSCRIBERS.

We give with our present Number, as a supplement, an INDEX and Title-page to the Volume of last year. A COLOURED TITLE-PAGE can be had, gratis, on personal application.
THE TWENTY-SIXTH VOLUME of "THE BUILDER" (bound), for the year 1868, will shortly be published, price One Guinea.
CLOTH CASES for binding the Numbers are NOW READY, price Two Shillings and Nine-pence each.
SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of Three Shillings and Sixpence each.

IMPROVED MACHINERY, combined with STEAM POWER, is employed by J. W. BENSON in the Manufacture of Church, Turret, Stair, and Tell-tale Clocks, Sun and Wind Dials, Perpetual Calendars, and every description of Clock and Watch Work. Architects, Builders, Committees, &c. can be promptly supplied with estimates. A descriptive Pamphlet on Church and other Clocks, post-free, 2*d.* J. W. BENSON, by special appointment, Watch and Clock Maker to His Royal Highness the Prince of Wales. Steam Factory for Clocks and Watches, 58 and 60, Ludgate-hill; Showrooms, 25, Old Bond-street, London.

The Builder.

VOL. XXVII.—No. 1354.

The Church of St. Mark, Venice.

UNITE alone in architecture stands the Church of St. Mark in Venice; it belongs to no style, it is a style in itself; it is without antecedents, it has remained without imitations,—perhaps, we may say, it is incapable of being imitated, for the scale is part of the style, and the richness of the decoration no less so; in its completeness it is an architectural resultant of the long history of Venice, and the history of Venice is too peculiar to have had parallels, or to be likely to be repeated.

It is usual to ascribe much of the peculiarity of the building in plan, construction, and decoration to Byzantine influence, and to consider that in this way its riddle is explained,—its evolution accounted for,—but little, indeed, is to be made out in this way on accurate comparison; we may recognize Byzantine details, features, processes, ornaments, but at last the renunciations, and the protests against any Eastern prototypes we know, are more important than the adoptions and adaptations.

We shall do better justice to the subject by leaving aside at the present time the attempt to affiliate the structure by inconclusive or insignificant family resemblances,—a view of the subject sure to be well taken care of elsewhere,—and by taking well to heart the manifest fact that whencesoever the designer of St. Mark's may have collected hints, as whencesoever he may have gathered his materials or his workmen, it was due to his own energy of organization, to the vivacity of his own fusing and remodelling imagination, that their ultimate form and arrangement, their harmonized unity and truly original effect, are to be ascribed. This is one of the cases where the enjoyment of art supercedes, or, at least, subordinates the interest of archaeology. *Materia superavit opus*; the idea of the architect dominates the materials he works with and works upon, even when sometimes he seems to adapt them in their very crudest form. The name of the architect of St. Mark's is unknown,—his very age is uncertain within a century; but whatever may have been the date at which he commenced his work, or put on sufficient record the leading lines of his conception, his spirit seems to have been continued to many of those who went on with his work, whether they may have been merely putting into execution his own intentions, or were moved to apply enhancements that almost invariably harmonized in effect.

The church, if we would describe its leading characteristics most summarily, is in plan—apart from some interior modifications—a Greek cross, with aisles on either side of both nave and transept, the nave and its aisles terminating eastward, in semicircular apses, with niches at their ends and sides. Over each arm of the cross, and over the intersection, is a hemispherical dome; five, therefore, in all. The western

arm of the cross is enveloped by a portico northward and westward, which is returned on the south side as a series of external chapels, including a baptistry. The interior of the church has its walls encrusted up to a certain height with slabs of veined marble, and where they cease, the decoration is taken up by a covering of mosaics of Scripture subjects with inscriptions, in colours on a ground of gold mosaic. These cover the whole surfaces of the vaults, the domes, the archivolts; below, the pavement is composed of elaborate patterns, in tessellations of most variously coloured stones, and the columns that are introduced are massive monoliths, often of the rarest and most costly marble.

At present a great deal of the pavement is in a state of ruin, and even some large surfaces of the mosaics of the vaults are stripped for reparation. The marble walls are discoloured, whether by mere dirt, or whether their brownish hue may be the more inveterate result of time and exposure. Tarnished are the silver lamps, and dulled the glitter of the heavy compound crosses that hang suspended from the roof, but still the effect of the interior is gorgeous in the extreme, with a gorgeousness that is majestic even at a disadvantage, and in its earliest freshness could have been by no means tawdry. All the minor fittings are of like magnificence. The smaller shafts that support the two pulpits are most beautiful, and so varied as to exhaust the vocabulary of the lapidary; rich slabs form the sides; the screen and all the furniture of the choir, and apse, and altar, has the same character, whatever their ages, of elaborateness, costliness, splendour. We should wish to convey this liveliest conception of this accumulation of costly elements of splendour, that a due impression should be prepared for of the value of the true artistic management by which they are brought under control, and made to subserve a gradual culmination of a larger effect.

The same principles of decoration and the same lavishness are continued in the portico with some new variations, and thence again to the exterior. Walls, vaults, and niches are again encrusted with marbles and historical mosaics, and the pavement with tessellations; the porches also and the intervals on the western wall are now still further clothed by double superposed orders of small columns of various marble, and with capitals as varied; this style of enrichment is still further extended on the western exterior and its recessed porches. These clothing colonnades reach up to the springing of the archivolts, and then are succeeded by covering slabs of marble, with sculptured or more brightly-coloured slabs inlaid, the enclosed semicircles above the portals being occupied by brilliant mosaics, and repeated by others with the same costly embellishments above.

On the gallery above the central porch stand the four bronze horses, so called, of Lysippus—but Greek in any case—transferred originally from Chios to Constantinople; and behind them rises again the range of five archivolts, with intermediate pinnacles, and crested by a richly but elaboration of foliated crocketing, rising to its highest apex to enclose the emblazoned lion of St. Mark's.

The foundations of the present church of St. Mark's at Venice date from A.D. 977; but they occupy the site, and very probably follow the lines of the earlier ducal chapel destroyed by fire, which is dated A.D. 826,—a century and a half earlier. Thirteen years previously the Venetians had acquired—an ancient inscription in a side chapel says frankly that they stole (*Marcum furantur Kanairii vociferantur*)—the relics of St. Mark from Alexandria. The interest of Venice in Cyprus quite explains her peculiar attachment to the evangelist whose history connects him with the island, and the readiness with which the patronage of the city was transferred to him from San Teodoro.

The main building was completed in 1071, and repaired, after injury by fire, again in 1106. The incrustation, with marble within and without, came later. The bronze horses which now stand above the portico, were brought from Constantinople in 1205, but probably found their present places later, for it was not until quite the end of the fourteenth century—that is, after 1380—that some of the window openings received traceries, and the upper archivolts and pinnacles were added and decorated. The high domes are also work of the late Middle Ages; while the foliated crockets, with intermingled and cresting statuettes that enhance so remarkably the grace and glory of the façade, are as manifestly works of the Renaissance as any of the dated mosaics of the seventeenth century.

The unity of effect which nevertheless results is certainly very remarkable; it is so far successful that the combination of styles is very constantly overlooked here as completely as in the Dog's palace, and thus are betrayed some who, lavish of praises without qualification for mediocrity in its purity, have no words hard enough for that revival which, whatever it revived, was very largely a revulsion from abuses of a style that was effete. Whatever is most peculiar in the building is at the same time most beautiful and most predominant, and whatever is less original seems by very force of its association to have put on so much of special character as to harmonize by producing agreeable relief rather than to shock by an incongruity.

The five external cupolas have a bizarre effect that adds no little to that peculiar richness of fanciful variation that is often styled Orientalism; but their value tells rather in remoter views than as contributing to the composition as it presents itself from Piazza and Piazzetta. The plainness of their surfaces would conflict with the general enrichment of other parts if they were more obtrusive; to the extent to which they appear their numbers and fantastic outline at least give evidence of the extent of the building behind and intimate sympathy with the multiplied variety of the façade.

This façade is not perpendicular to the main axis of the piazza, nor is this large square indeed even nearly a regular oblong, while still the sides are not so far divergent as to attract ordinary attention. The variety thus given to the presentation of the structure is an immense advantage, whether the result of design or not; the sacred temple seems to assert independence, and, at the same time, escapes an air of contemptuous disregard; it is neither the slave of its position nor forgetful of its responsibilities.

The exterior of the building carries more marks of alterations than the interior; perhaps instead of alterations, we should say of successive additions and completion at intervals; and yet this comparatively few changes and additions that have been made within derogates much more from the general value of its effort. To this point, however, I shall return.

The effect of the façade has been made the subject of glowing and picturesque descriptions which it would be vain to emulate and a little ungracious and unwelcome to criticise; indeed, they involve so much of truth that we may accept the exuberance of ornament like the extravagances of some of Turner's Venetian scenes, as in this sense faithful—they express the effects of the original on enthusiastic imaginations, and may surely therefore be credited to the excellences of the original.

The fundamental plan of the church of St. Mark may assuredly be described as the Greek cross, and it would seem to have been by a slip of the pen that Mr. Fergusson substitutes so distinctly the Latin cross. The full outer breadth across the transepts, including the walls, is as nearly as possible equal to the length from the first step by which we enter the church slush with its front wall, to the outside of the eastern

wall beyond the apse. The numerous recurrences of the Greek cross among the mosaics and upon the sculptured capitals of most archaic style of any in the church vindicate the claim of the form to primary consideration by the designers, who, whatever the freedom with which they treated it, returned to it in distribution of horizontal spaces, as we shall see, over and over again.

The front wall is of double thickness, to admit the introduction of staircases to the upper plan, the entrances to which are on either side of a covered porch, open towards the narthex or covered portico.

We take as the basis of observations the plan of St. Mark's given in the Atlas of Giognara. It verifies so many logical adjustments that the author was in no way cognisant of, that its general accuracy seems to us to be sufficiently approved. It agrees also very exactly with the later outline by Kreutz.

The thickness of the internal incrustations is given, on what authority for exactness we know not, by a lighter shade or hatching. Whether this enrichment was contemplated from the first or not, the distribution of the interior neglects it and follows proportionate dimensions taken up to the unclotted wall.

The church proper, as we have shown, may be enclosed in a square.

The centre of the central dome on horizontal plan is midway between the back of the extreme niche of the apse and the internal line of wall by the entrance; a transverse line, therefore, through this point gives us the axial line of the transepts.

A central circle equal in diameter to one-fifth of full breadth of inclosing square, includes the horizontally-projected plan of the dome.

The nave dome is of the same diameter as the central dome, and its centre is fixed midway between the interior line of west doorway and the margin of central circle; the interval between dome and dome is thus equal to that between western dome and entrance wall.

The projection of the western dome is flanked on either side by a triplet of columns; the distance from axial line of these columns to centre of nave equals the distance given in the other direction to the flank wall; thus is decided the width of the aisles and the complete internal width of the body of the church.

These lines are ruled through across the transepts with the result of giving a broader interval on either side of plan of central dome than divides it from the nave dome.

The limit north and south of the domes over the arms of the transepts, is now obtained by the dimension from centre of plan to western margin of nave dome; in other words, a circle struck from centre of building will just touch on their remote margins and thus include, the horizontal projections of the nave and of the transept domes.

The breadth of the transept has already become deducible, and consequently the plan upon which its aisles and dome are to be distributed.

A transverse line tangential to eastern margin of nave dome projection, cuts the line of the wall of nave aisle; a column is placed in the aisle upon the line in front of this intersection, and the interior line of transept wall is made to range with the eastern margin of this column on plan.

The semi-breadth of the transept is thus diminished, and becomes less than the semi-breadth of central dome taken with interval between it and nave dome.

The semi-breadth of the transept thus obtained, is now to be halved, and this will give the axial line of an intermediate colonnade, here of two columns only, and by deduction of the semi-diameters of the columns, the diameter of the transept dome.

This diameter appears to have been brought by design exactly to 28 Venetian feet against 36 of the central dome, showing a loss of 4 ft. on each side by the contraction ensuing on the inserted colonnade.

The result—anticipated and aimed at—is most important in subordinating the transepts to the central nave; this is still further pursued by the reduction of the full spread of the transept on plan, by the occupation for closed chambers of so much of the space of full breadth of building as extends beyond the external margins of the transept domes to the north and south. These chambers, however, are not permitted to curtail the breadth of the church absolutely, for they have only the height of a ground story, and support a continuation of a gallery open to the

church; and on one side the light of the southern sun is admitted through a large rose window—of later design—above them. This peculiar feature is still more remarkably treated at the western extremity of the church, where the gallery in question is not only extended over the double wall of the entrance, and the inclosed staircases, but this open upper story is extended even over the west porch or atrium, and light is thus admitted into the body of the church through the great window immediately above the advanced west portico. It is this arrangement which gives a certain appearance of increased length to the church, and vitiates so far the primary proportion of the Greek cross.

The lines of the transept ruled through on the eastern side touch the margin of the projected plan of the choir dome. The diameter of this is apparently about 30 Venetian feet, as against the 36 of the centre—the span being contracted as in the transepts, by beavings for an archivolt within the lines of the piers of the centre; the eastern semi-circular cove is struck immediately beyond the projection of eastern dome upon a diameter again reduced on the same principle.

When we glance over the general appearance of the plan thus brought out, we see that it starts from a single principle of arrangement, then develops by repeated applications of the same principle to successive extensions, and lastly, sets a limit to this process of development, and gives coherence and unity to all comprised within those limits, by subordinating all members to one chief culminating position of interest, by modifying each subordinated member in accordance with speciality of function, and by marshalling all in appropriate sequence and order.

Nothing can well be more alien from the system on which this—systematically enough—is effected, than that rule of planning, on equal squares—*pari-quadrato*—that has sometimes been vanned as a royal road, at least it were an easy one, to the mastery of noble effects. Assuredly it is no easy problem for the balance to be held between irregular fancy and mechanical coldness in design. Regularity is the very soul of that rigid law of discipline that architecture can never relinquish with impunity; by which alone it can retain mastery over the manifold and immense assemblages of members and materials it contends with. But strictest discipline must needs be administered with that discretion of which the equivalent in design is quick apprehensiveness of safely admissible—of absolutely indispensable, adaptation; with that lightness of hand, that treatment with feeling, that can venture from time to time—nay, even constantly as the work proceeds,—to desert the dry perceptive lines of the broad and hard general rule; that can revert to qualifications which, although only admitted at first instinctively, deserve welcome as inspirations; these will constantly be found, on further study, to be themselves amenable to laws as eternal as the one rule that they appear at first to contravene, whereas they in effect cooperate with it.

The general plan of the church, then, as we have seen, is the Greek cross, with arms of equal spread from the centre; but the east and west arms are allowed a more liberal width than the transepts north and south, and thus the dignity of a nave is asserted in this direction. Moreover, while the lengths of the transepts are curtailed on the floor level by assignment of their extreme portions to closed chambers, the eastern arm receives a distinction that shows it as noble above all its fellows,—by an exceptional apsidal termination.

The cross of the general plan has a very marked expression in the void space of nave and transept, which remains after the reduction of the plan by the cross lines that partition off the lateral and transverse aisles. The hemispherical dome over the grand crossing rests on the keystones or rims of the extrados of four great arches that are continued as barrel vaults in the four directions as far, generally speaking, as the edges of the great quadrangle which mark the breadths of body of the church and of the transepts. The transition from the square central plan to the covering circular dome, is effected by coved spandrels or pendentives. This central dome has thus the effect of being the centre of a Greek cross of its own, of which the short and almost equal arms are the pairs of oblongs, north and south, and east and west, that are roofed by the barrel vaults.

The north and south arms of this cross are now appalled severally as arms of, again, a northern and southern Greek cross dependent on a domed centre in either transept.

The transept domes, like that of the centre, rest on the rims of four barrel vaults, of which three extend as far in each case as the outer wall of the church, and the fourth as far as the grand crossing. The eastern arms of the crosses thus formed on either side, are appropriated as chapels with altars, out of regard to which, as it appears, the opposite arms of the cross are left clear; the north and south arms, as we have seen, are closed below, but are open above to a late Gothic wheel-window on the south, and on the north to the extramural wall, which is clothed with a rich mosaic. Galleries extend over the closed portions, of which that on the south is divided by a passage giving an entrance to the church from the piazzetta.

The western arm of the central cross becomes in like manner the eastern arm of another majestic cross of which the nave dome covers the centre,—the north and south arms extending to outside walls of the church proper, and the western as far in the first instance as the wall pierced by the entrance door.

Above this western limb, which is not like the corresponding member in the transepts curtailed below, receives the farther extension already noticed, and includes under its prolongation of vaulting a gallery over the portico or vestibulum, as far as the line of the large west window and the wall behind the projecting outer porches, and their external gallery.

The piers which present an angle at each corner of the square of the central dome, and bear at right angles the barrel vaults across the transepts, and across nave and presbytery, are pierced by arches north and south, and east and west, to give passage to the direct and the transverse aisles, and become thus on plan divided, in fact, into four piers; here again the projected plan gives a small secondary Greek cross; with arms included in each case between the three massive quadrangular piers, and the pier attached to angle of nave and transept wall; the perforation is in two stories,—a loftier opening is below a smaller of more window-like proportions above. The analogy to the large central arrangement is supported by each of these small squares, having again its domical ceiling or cupoletta resting on extra dos and coved spandrels.

The barrel vault of the western arm of the nave cross descends on parallel walls that are pierced with arches again like those that bear the eastern; only the north and south walls of the church, instead of being perforated, are merely clothed with shallow arches; but the square voids in the angles still assert their analogy, and receive each its proper domical vault.

The eastern arm of the central cross becomes the western of another domed at the crossing and above the high altar, in like manner, but in place of a rectangular eastern arm, it recedes in this direction a semi-circular apse of full span; its semi-domical head of this is wall visible throughout the full length of the church, and is occupied by a colossal mosaic of the seated Saviour on a blazing ground of gold. Below are three smaller niches with semi-domical heads,—that to the left is fitted at the back with the bronze doors of Sansovino that give entrance to the sacristy. It is at this point that the differentiation of the primary type of arrangement is most declared. These eastern domes rest, as in other cases, on grand arches of its full span, but below, to the right and left, the eastern halves are walled up, affording towards the choir backs and seats for stalls, and serving to enclose small chapels at the ends of the north and south aisles; these have apsidal ends eastward and three smaller niches in the thickness of the wall below, reductions, therefore, of the main termination of the church. Above the dividing wall runs the gallery that accommodates organs and orchestra.

The main effect of a grand crucial plan might easily have been distracted by the importance of the large secondary cross vaults; that it is sufficiently salient on first entrance into the church, is due to the skill with which the differences of the upper and lower plans are blended, to the well-regulated gradation in dignity of enrichment of the several arms of the cross, and the vigour with which certain well-accentuated lines of decorated detail are carried round the interior throughout at identical elevation, binding all together in unity.

The line of nave, east and west, is well-decided and kept distinct from the north and south arms of the cross under its special dome by the insertion of three columns in the interval, which

carry a connecting gallery only, and for the rest declare themselves simply as standards of a line of demarcation. The moderation of their intervals is moreover most useful in bringing down a scale for comparison of magnitudes; and the space under the central dome gains in magnitude by contrast with the oblongs of the aisles that are so cut off from it.

By a like arrangement in the transepts, the eastern and western arms of the domed crosses are divided from the main transept, running north and south by pairs of columns in opposite sets, bearing a continuation of the galleries which wind round the interior of the small squares of pier-crosses, and so round the church, connecting the covered extremities of both transepts and nave. This passage has thus much analogy to some forms of the so-called triforium, but that it was ever extended, or intended to be across the aisles, I do not believe.

The capitals of these columns are gilt, and very varied in design, but even when not exactly paired, are usually treated with a distinct intention to match in general effect. Some are pretty literally Corinthian, and some Composite, never exactly executed; others belong fundamentally to either one or other of these forms, but betray a definite attempt to work out a novel combination, and usually under a predominant Byzantine feeling. We seem to be provided here with examples of two forms of innovation in style. Innovation is sometimes little better than innovation of malice aforethought, when it is prompted by no welling up of new imaginations, but is a mere assertion of brute independence, a resolution to be different in any case, different for the sake of difference, right or wrong.

It is impossible not to perceive in other cases that it was through the degradation of an originally pure if not perfect form, that novelty has been evolved more honestly at least, and of better promise. A type that might have been fixed and immutable for ever, by the conserving energy of its very beauty, had it never been unworthily executed, has been superseded at last by designs of most contrasted character, that still took their origin from its own dehailed exemplars. When refined beauty lapses, it may easily be into something worse than primitive crudity; ill executed specimens then become incitements to regeneration, to remodelling that does not retrace the steps of the ages to a departed purity of which the traditions may be absolutely lost, or that otherwise may be too elaborate for resources, for patience, or for skill. Many Byzantine capitals have much the air of being cheap or random completions, one how or another, of capitals that had been found blocked out to receive Corinthian foliage. The attempts of indifferent workmen in this way at last suggested motives that were developed by livelier imaginations, abler hands, but equally exempt by education from reverence for correct classification. This, however, is subject to the transformation of species architectural, that deserves to be worked out independently, and invites abundant illustration; parallel phenomena are to be found in those changes of language by which degraded provincial Latin became the Italian of Dante, the French of Montaigne, while dialects less divergent from their original, remained hazy Medieval Latin, or became obsolete.

The columns of the interior of the church, of porphyry, verd-antique, Oriental and African marbles, have invariably monolith shafts, and in their enrichments, as in their ordination, there are but exceptional traces of that irregularity that is so striking in the vestibule and the external porches. In the interior there is scarcely a trace of admission of incongruous associations for the sake of finding a place at any risk for fragments of value in themselves, but with no pretensions to match; here every column and capital has the appearance of having been made for its place, and designed with regard to its associates and its surroundings. The six in the nave proper are of marble, as indeed are most of the rest; but these, in deference to the dignity of their position, are cut in the expensive direction—transversely to the veining of the stone. The central capitals of the triplets on either side are tolerably accurate Corinthian, and contrast by heightened decoration with their companions on either side, which again match their opposites, but are of style of plainer finish.

Every abacus above the gilded capitals is enriched with an elegant inlaid pattern in black and white; this is continued at the same level round the plain massive piers; it is repeated

with extra and very beautiful elaboration above the capitals of the granite monoliths, that are in pairs against the walls and at the angles of the transepts to receive the broad archivolts of the pier-crosses; from these capitals the simpler pattern of the nave abacuses is continued as a string-course along the walls, and it thus makes the circuit of the entire church,—nave, transepts, presbytery, choir, with a value in effect that is far beyond its immediate conspicuousness.

The positions of other parallel string-courses above are governed by the distribution of the design, as it is shown by a longitudinal section.

It is futile to attempt to follow out the process of distribution of a truly artistic design through one single line of deductions. The very principle of harmonious combinations implies the ultimate concurrence of several motives of arrangement—the equilibration of various concurrent momenta. But the concurrence at last is only brought about by independent examination and pursuit of the tendencies of each; by the discovery of agreements arrived at from different points; by the concession of compromises recognised as unavoidable after scrutiny from most varied aspects. The height of the crown of the central dome from the pavement is as nearly as possible equal to one-half the interior length of the choir as already taken; this, however, does not give us the height of the dome itself—the level of the springing of the hemisphere. This is necessarily one-half of the diameter of the dome, of that circle which, as we have seen, is given by one-fifth of the full length or breadth of the church. This agreement, however, may be but an undesigned coincidence, or it may have been considered, and even rendered exact, in consequence of its observed approximation to a dimension brought out by another process. Thus, let us say that the architect decided first, that his greatest interior height should equal half his extreme interior length; by halving this height again we find that our section of the church is again divided into a lower portion, comprising the vertical walls of rectangular outline, and an upper which contains only the vaults, domes, and semicircular heads of walls under the vaults. This line well marked runs through from end to end of the church, interrupted only by the later wheel window of the transept: it is confluent with the abacus of small column of upper story immediately below the spring of vaults and archivolts, and is returned at the eastern end to mark the base of the semi-dome of the grand apse.

The upper division or half is now divided between two semicircles of equal span,—that of the large central dome and that of the barrel vault of the nave below it. That the diameter of these semicircles is not equal to half the height of this upper division is due to the circumstance that a certain space is occupied by thickness of construction between the base of the dome and the intrados of the barrel vault. By making this deduction, on whatever principle, it is clear that we should bring out the diameter of the central dome by reference to the continued bisection of interior length, and irrespective of its division into fifths. The lines of height of barrel vault and dome springing again, run through from end to end of the church, to finish upon the crown of the grand eastern apse.

Thus we have, first, the level giving the base of the domes throughout; then that of the barrel vaults and semicircular archivolts; the joint height of these divisions being equal to one-half the full height of the church, or one-fourth of its full interior length. By halving the height from the base of the dome to the floor, we obtain the line of bases of paired columns that in an upper story carry the archivolts of the transepts of the choir and apse; it is returned round the transepts as the moulding of the halustrated gallery over the arcades, round the tribunes, houses within the great piers, and so passes entirely round the church. At one end it accentuates the elevation of the gallery over the entrance, and at the other crowns the lower division of the grand apse above the secondary niches. The proportionate height is continued to the choir, where the raising of the floor below is counterbalanced exactly above by the thickness of the sub-archivolt.

Apart from the noticed deduction for constructional thickness, it is clear that the height of this division and of the colonnettes it includes would be exactly one-eighth of the full height of the main dome; as it is, they are somewhat

in excess of one-sixth of the height of vault of nave, the reduced dimension.

The smaller paired columns upon this level already adverted to, have great merits in themselves, and the highest value in effect. Here again is exemplified most strongly the distinction that must be admitted between the treatment and design of San Marco in the interior and on the exterior. All these columns are alike in design, adjusted originally to the dimensions of their position and of well-studied elegance. Their shafts of dark marble are octagonal prisms, with graceful diminution upwards, and they blend below into an accurately moulded base of elegant profile with an ease that may well put to shame mediaevals who never learnt to spare the jar of a harsh transition from abruptly broken shaft to base-moulding.

The abacus is rectilinear in profile, and the intermediate capital, of uniform type in every case, and of very decided Byzantine character, is accommodated to the outline of the shaft by cutting off the angles of a cubical block from the corners of the abacus above to a line matching the inclined side of shaft below.

The more numerous and closer introduction of the colonnettes in apse and presbytery assists very greatly that effect of gradual focalization of interest that is favoured by general increased enrichment ensuing upon contraction of the general spacings and rise of level upwards to the eastern extremity.

This line, then, coincident with their capitals, and at exact midheight between pavement and springing of cupolas, marks the lower point of the pendentives under all the domes, and the limit of the vertical piers and sidewalls throughout the church; and its importance is acknowledged accordingly by a white marble moulding, richly carved, but still of no such projection that it may not consistently be returned as an abacus moulding above the capitals of smaller paired columns that, on the upper story bear the advanced archivolts.

The line of the bases of these small columns gives another continuous division marked by a light plain moulding of small projection; it is continued below the vertical windows of the apse in one direction, and in the other it is returned round the transepts as the moulding of the halustrated gallery over the arcades, and so it reaches ultimately the like position above the arcades of the nave, and the tribunes housed within the great piers.

This is the leading line that determines the distribution of the gorgeous internal enrichments of the church. The soffites of the arches of the arcades are indeed enriched with mosaics of figures, compositions, and patterns; but except for these, and a few figures on walls of the nave aisles, the enrichment up to this level throughout the church in nave and transepts, depends entirely on incrustation with long vertical slabs of veined marble returned symmetrically upon their sections. The general character and tone of colour of these is pretty uniform, and has a certain warmth that is not inharmonious; besmirched, however, as the entire surface appears high and low wherever not brightened here and there by attrition of heads or shoulders of worshippers, the original tint may easily be misinterpreted through adventitious dinginess. The comparatively plain yet not neglected walls, only broken and relieved by the attached and intermediate shafts, are thus interposed between the elaborate mosaic pavement of the floor, and the gleaming and storied walls of the upper story above the level of the galleries, and then of the vaults and archivolts, the pendentives, and the domes. We must reserve the remainder of our observations for another article.

MEMORIAL OF THE LATE HENRY KIRKE WHITE.

THROUGH the earnest efforts of the Rev. E. Davies, rector of Wilford, near Nottingham, which place was the favourite resort of Henry Kirke White, a memorial of the youthful poet has, at length, been placed, by public subscription, in the chancel of Wilford Church. The memorial consists of a painted window, illustrating Kirke White's ode, "The Star of Bethlehem," which has been produced by the Messrs. O'Connor; and also of a medallion portrait of Kirke White, sculptured in white marble by Mr. W. T. Hale, of London, and which has received approval for its truthful resemblance to the existing portraits of the poet.

THE BIRMINGHAM AND MIDLAND BANK.

We publish a view and plan, in our present number, of the Birmingham and Midland Bank, which is now in course of completion. The commercial needs of the great midland metropolis have induced the proprietors of the chief banking establishments to rebuild or extend their premises, and amongst the foremost in taking that step were Messrs of the Birmingham and Midland Bank, whose offices in Union-street have been enlarged from time to time till, more accommodation still being required, the directors wisely determined to build on a more extensive site more convenient premises fitted with recent improvements.

The building is from the designs of Mr. Edward Holmes, of Birmingham and London, and stands at the junction of New-street and Stephenson-place, opposite the Exchange Buildings, which were erected from the designs of the same architect, and illustrated in our pages a few years back.

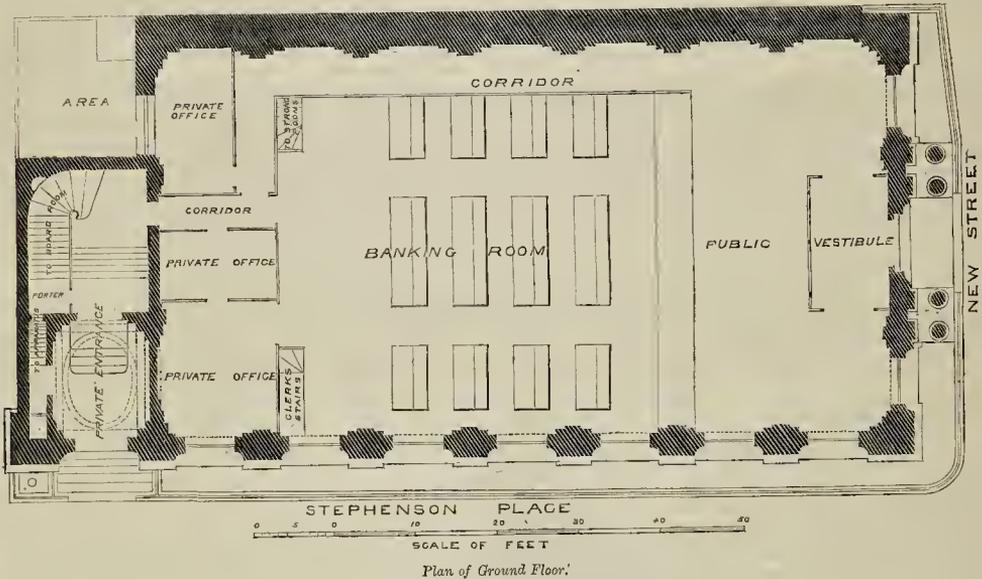

* See p. 47.

As will be seen on reference to the plan, the whole of the site, with the exception of the private entrance and stairs to Board offices, is occupied by the banking room, a fine apartment 92 ft. long, 49 ft. broad, and 30 ft. high, the private offices being shut off by screens of polished mahogany and embossed plate-glass. In addition to nine lofty windows, a central lantern gives light to the bank. This lantern is 37 ft. by 18 ft. 6 in., and is filled with ornamental glass by Messrs. Chance, Brothers. The strong-rooms, with the dining and coat rooms for clerks, occupy the whole of the basement, which is well lighted. On the first floor are placed a board-room, 48 ft. long, 26 ft. 3 in. wide, and 25 ft. high, with windows in both fronts, and ante-rooms, dining-room, sitting-room, and bed-room for resident clerks, lavatory, &c. There is a private room for the manager on the Mezzanine floor over the private entrance, and a gallery which may be used for clerks over the private rooms at end of bank. The second floor, lighted from the roof and from area for central lantern, is occupied by the kitchen, offices, and bed-

rooms: a light from coal-cellars communicates with the former. The upper stories are carried by wrought-iron large box-shaped transverse and longitudinal girders, each of the transverse girders weighing about 18 tons.

The style of the building speaks for itself: it is somewhat severe in character, the architect being instructed to avoid all unnecessary ornamentation, but the result is an edifice at once dignified and bank-like. The two fronts are executed in Portland stone, the four columns of the portico being of Cornish grey granite polished, each a monolith. The walls internally are finished with Martin's cement. The ceiling is divided into nine compartments, round each of which there are cornice and cove: each division is cofered. The bank fittings are of polished Spanish mahogany. The private rooms and board-room are being warmed with hot air by Mr. W. W. Phipson, C.E.; the massive iron railings are in the hands of Messrs. Hart & Son; and the other works have been carried out under the direction of the architect by the contractors, Messrs. J. Crosswell & Sons, of Birmingham.

THE BIRMINGHAM AND MIDLAND BANK.

Plan of Ground Floor.

A PLEA FOR STONE.

Among the theories set up by sundry architectural prophets, upon which to ground the formation of a new style, and indicate with precise and irrefutable logic the form which such style must take, the most prominent is that which takes for its basis the comparatively recent introduction of iron as an important constructive element in building. We have had this view of the matter, in fact, dimmed into us *ad nauseam*. All young lecturers and readers of "papers," who wish to appear very philological, tell us that this is the "iron age," a metaphor which seems inexhaustibly attractive. "A pound of wire will do as much as a ton of stone;" we are to have no more such wasteful and clumsy expedients as arches and abutments. Tension, tension is the thing. According to a well-known and very clever writer, the lintel and the arch styles, representing cross-strain and compression, have had their day, and the *tensile* style is the style of the future. We have no intention here of "setting the battle in

array" upon the question of our future style. Heaven forbid that we should add a line to the reams of theorising which have been written on the subject. To us, indeed, one building carried out with thorough honesty and straightforwardness as to material and design is worth more than a whole shelf of books of prophecy. But one can understand how comforting it must be to the minds of a certain class of designers to have a neat concentrated theory upon an apparently practical basis; and how exhilarating must be the visions conjured up of all the new and elegant forms which building design is to take after we have become naturalised with the new material, and have made it as important an element in architectural history as stone was made by our forefathers. And even if we decline to contemplate the possibility of a purely iron style, still, if we are to accept Mr. Garbett's tensile style of arches without abutments, it is clear that iron must play the most important part in the practical construction thereof, and a millennium for the ironfounders be the inevitable result.

Our ironical anticipations on this head, however, were rudely interfered with the other day by the contemplation of a small piece of iron 2 ft. long, which some years back had been inserted in the masonry of a spire when under "restoration" to tie one of the angles at a weak point; that is to say, the material was stated to be iron by those who were bound to know—a statement which, in the face of the unsightly ragged mass of oxidation presented to us, had to be accepted in faith only. Of course, it has been a currently admitted fact for some time past that iron is very unsafe material to use in conjunction with stone, and that under such circumstances it is always liable to go; in fact, that in admitting iron into masonry you are introducing an element of decay, or even of destruction. Yet this knowledge is very often set aside and practically ignored. We are acquainted with one church built by an eminent architect, and deservedly an object of admiration in its neighbourhood, the "crossing" of which professes to be covered by a solid stone dome springing from four main piers. It was originally

intended to be so, but (being in the confidence of the contractor) we obtained the information that the pendentives were in fact supported by iron girders across the spigots, concealed in the masonry. We represented that this was, in fact, tying an edifice up, not building it, but were met by the assurance that the girders in question would last "till the millennium," which, not knowing the date of that era, we could not dispute. But, waiving the question whether such proceedings are really in accordance with the art of architecture properly so called—whether it is not a very lame and mean sort of expedient to represent a building as constructed of masonry when, in fact, it is supported by concealed bands of a tensile material—what we wish specially to call attention to is the fact that iron, even when used in the most favorable positions, and with the greatest care to exclude from it the action of weather, has not yet had the test of time to determine its capabilities of endurance as an architectural material. It is very well to talk of an iron style, and to declaim against the prejudices of those old-fashioned people who look cautiously askance at the idea; but it must be remembered that it has heretofore been one of the chief glories of architecture as an art, one of the qualities which render it in its highest forms most attractive to the best minds that have been engaged upon it, that its productions have been more or less monumental in their character, and have claimed both by their magnitude and stability a kind of dignity and importance on the earth beyond that which attaches to smaller and more perishable works of art. Now, even setting aside the question of artistic appearance, we have no proof as yet that structures principally or wholly of iron will last in this way as monuments to future generations, since time is the only test in such matters; but, from what we know of the material, we have every presumption that it will not so last. Knowing as we do the rate at which iron gives off its substance in the form of rust, a source of decay which becomes more felt in proportion to the increase of external area; knowing the extent to which it alters its conditions under change of temperature, and the difference of the conditions of wrought and cast iron in this respect, which yet must often be used in conjunction; remembering also the thousand and one weak points which are liable to make themselves felt in a structure all the parts of which have to be joined by bolts, screws, and such-like contrivances; under all these circumstances, it is impossible not to feel that the claim for iron as a leading material in the architecture of the future is even practically a very doubtful one, and that buildings dependent in any way on such a material, though invaluable for temporary purposes, must lose nearly all that enduring character once supposed to belong peculiarly to architectural designs, and have small chance of carrying down the memory of their designers to posterity.

Nor is the case for stone, as against iron, less strong in an æsthetic than in a practical point of view. Consider for a moment the remarkable distinction between the *rationale* of the two materials. They do not stand by any means on the same footing. In using iron, we are using a material which is to some extent artificial. It does not show itself above ground; and when it has been laboriously dug up and brought to light, it is not in a state for use, or even recognisable at once by those who only know it in its artificial state; nor is it till after much mystery of smelting, puddling, and other treatment known to the initiated, that it comes forth "prized and meet for the master's use." But in using stone, we are using a natural material in its unaltered state, so far as texture and quality are concerned,—a material concerning which we have had previous experience, before we used it, in its powers of resistance. We see it before us in the quarry, cohering in vast masses, and resisting a compression of many tons, and we take it as it is, merely cutting it to the required sizes, and set it, as it lay before, "on its quarry bed" (if our object of the works attends to his duty properly). We expose a great amount of its surface to the weather; but otherwise, if our building is properly constructed, we do not alter the condition under which the material existed in its natural state, and consequently are saved much of the doubtful and experimental proceedings which are forced on us in dealing with artificial materials. A more important consideration, in an æsthetic point of view is, that we are here using the material which we see visibly around us, which forms part of the ground we tread;

we are causing the "great globe itself," visibly and ostensibly, to furnish the means whereby we may erect those "cloud-capped towers, gorgeous palaces, and solemn temples" which have formed some of its noblest adornments. It is this which has given much of their impressiveness and effect to the great monuments of the architecture of the past; that they have appeared not so much as independent erections or constructions upon the earth's surface, as actual growths from it, homogeneous with it, in substance and texture, and thus appearing to form part of the landscape amid which they stand. Sir Charles Barry, indeed, is known to have made this latter effect a special object whenever circumstances permitted, his delight having been to "connect the house with the landscape," by happily-contrived terraces and gardens, diminishing in artificiality as they receded from the edifice and mingled with the open country. Nor can we ignore the immense value of the mass and weight of material necessary to a stone building, and necessarily precluded in an iron one, when architectural effect is to be considered. After deducting all the effects of previous habit and prejudice, after showing that a nation long habituated to seeing its principal structures of iron would come to look on that material with far more respect than we now do, and become used to its rigid lines and thin forms, it is nevertheless impossible for a moment to admit that structures resting upon thin metallic shafts and roofed with a web of spider-like framing, can ever have that effect on the mind which has been produced upon all beholders by the temples of Karacac and Philæ, the Parthenon, and the great cathedrals of the middle ages. In the "iron age" all that has constituted the majesty of architecture would disappear. That aspect of enduring immobility, which seemed to connect the structure with the ground it stood upon, the broad play of light upon the piers, the depth of shadow in recesses and roofs, the aspect of mystery which pervades a grand interior on a large scale—all this would go, and leave us instead a barren framework of thin lines, standing nakedly out, devoid of all the magic of chiaroscuro, and suggesting nothing save economy of space and material. Unless architecture is to be a lost art, stone must still be the main material for the architect to work with.

Brickwork has indeed been putting forward great pretensions of late, and, in buildings where economy has to be considered, must always take precedence of stone; but we have instances, not a few, of late years, in which brick has been, and is being, voluntarily preferred for large and expensive churches, and buildings of a similar class. We take this to be a foolish piece of fashion; a change for the sake of change, or in the vain hope of thereby achieving originality. All our church architecture having for so long, more than any other branch, run into copyism, the original models have been exhausted, and the copyists were at a dead lock, when the lucky discovery was made that the Mediceval builders of the North of Italy had produced admirable structures, after their manner, of brick and marble, to the adequate illustration whereof one of the most talented English architects lent himself with a will. Here was a new field, the marble, indeed, might be difficult to obtain, but the brick was feasible; whence a springing up of brick churches, as aforesaid, with square jambs in lieu of splay or mouldings, and traversed by divers bands of black. This may be all very well for a change, but as to appearance there is no comparison, except in the eyes of prejudiced persons. It is very difficult to get brick of a decent colour at all for a large building, and when the best is obtained, it is far inferior to the natural tint of fresh stonework; and being an artificial tint, moreover, does not harmonize with the landscape around it: while the forced and strongly pronounced polychromy obtained by different tints of brickwork is far inferior in effect to the natural play of colour and tone in stone walling. Then carved ornament cannot be introduced, except by the insertion of stone in which to carve it; though the enthusiasm of some of these modern "bricks" has led to the resuscitation of moulded ornament in brick,—a device which costs nearly as much as stone carving, without having one-fourth the effect, and which was originally used in localities where no stone easily carved was procurable, but which is now voluntarily substituted for freestone, where the latter is plentiful, merely for the sake of fashion. Of course, good brick is a very fine material where expenditure must be limited; what we protest against is the pretence

of preferring it to stone on artistic grounds. And there is one very strong reason for using stone, when building in the country, even for small houses, viz., that it can be made to harmonize with the landscape of the district in which the house is erected. In introducing brick into a landscape, we are in almost all cases introducing a discordant element of colour. But in using (as should always, if possible, be done) the stone of the neighbourhood, not only are we using, as before said, a natural instead of an artificial material, but we are using that which is the basis of the landscape around, and from which the latter takes its prevailing tone and character; whether it be a limestone or a sandstone district, or whatever formation it may be, we are thus carrying the tint and character of the landscape into the walls of our house, which seems to become part and parcel thereof. This is not sufficiently attended to; and sometimes stone is brought at additional expense from a distant quarry, to satisfy some whim of the architect, when the stone of the neighbourhood would have had a far more satisfactory effect in comparison with the surroundings of the building.

In making this plea for the use of stone as *par excellence* the architectural material, we may be met by the objection that the order of things, and consequently the tenure of building property, is no longer characterised by the same stability which belonged to ancient periods, when the current of life moved at a slower rate, and when the uses and requirements and value of a building did not change for centuries after its erection. It may be said that we have no longer occasion, in our towns especially, for those monumental structures which were seen built to last for ages, seeing that we know not when the demands of a shifting and increasing population and a changing polity may render such edifices, after a comparatively brief time, no longer suitable or useful. But the idea arises from a too partial view of the course of human affairs. As Mr. Froude observes in the opening of his "History of England," the history of nations has always presented an alternation of epochs of change with long periods of settled and established ideas. We are now in a period of change; steam has revolutionised our domestic polity, and some time may elapse before we settle down into the new form of life and manners towards which we are, however, rapidly moving. It may be wise, therefore, not to stereotype any of our present wants or partialities in the form of expensive buildings of a monumental and enduring character. We are now in the condition of the man described by the Roman satirist:—

"Diruit, ædificat, mutat quadrata rotundas."

We are changing our forms of building and our forms of life, and the iron architecture does well enough for the temporary needs of such a period of change, and will last about as long as it is likely to be wanted. When we shall have settled alike our great lines of railroad and our great lines of life, and grouped our habitations accordingly, we shall once more find stone the fittest and best exponent of an architecture which we may trust will not be inferior to that of the great periods which we have left behind us.

A FRENCH BOOK ON HEATING AND VENTILATING.

THE author of a treatise upon heating and ventilating French private houses and supplying them with water, recently published in Paris, cries out bitterly against the prevailing system of false luxury in French houses, which provides appearance before comfort.* Every sanitary arrangement, he declares, is sacrificed to secure handsome reception-rooms, which give to their occupant a semblance of being something more than he really is; and if the architect entertains any other consideration, it is how to impart an air of luxury to the façade. Where an English landlord advertises, "Well-aired beds," a French one announces "*Appartements ornés de glaces.*" M. Joly, the writer in question, has made a long residence in foreign parts; "where taste is sometimes at fault, but where domestic comfort is studied better than in France," which we presume he is too polite to name more particularly. But it is easy to see that it is with

* *Traité Pratique du Chauffage, de la Ventilation et de la Distribution des Eaux dans les Habitations particulières: à l'Usage des Architectes, des Entrepreneurs, et des Propriétaires.* Par V. C. Joly. Paris: J. Baudry, 16, Rue des Saints-Pères. 1869.

the widely-spreading adoption of sanitary appliances in English houses that he contrasts the almost utter absence of water and ventilation in French habitations. In his enumeration of what he calls the vice of French domestic buildings, he speaks of low ceilings, of water-closets badly lighted, badly ventilated, and placed close to the kitchen; of the absence of ventilation, baths, and water; of nurseries looking upon the unwholesome courts into which the spots carrying away the foul waters of the house discharge themselves; and of chimneys which waste the heat they should economise, as evils the French tolerate with complacency, if not with approval; and after dwelling at some length upon the discomfort and misery of these shortcomings, he strenuously urges the adoption of the habits of "propriety" common to the English, Dutch, and Americans. Posterity, he continues, will be scarcely able to believe, that in Paris, the eighth wonder of the world, men and women can be seen at the present day *attelés à des tonneaux*, and carrying water upon their shoulders to the upper stories of houses. Cold water within the last few years has found its way into French kitchens, but hot water is still unprovided there, and both are entirely absent in the upper stories, as is the health-giving bath. A French bed-chamber, he deplures, let it be ever so richly decorated, contains only a bed, a secretaire, and a few chairs: no convenience for the performance of ablutions is in sight. He would have a bath at the side of the bed, a choice of site we cannot endorse, however much we approve of the general use of this source of cleanliness and health. A bath in a bedroom is a mistake, because the steam from the hot water is a source of damp to the bedding. It is much more advantageously placed in a room opening out of the sleeping apartment, when, by the simple plan of closing the door between them, the steam is confined to the bath-room. Having shown the great desirability of more attention to sanitary matters, especially the need of a proper water-supply in French private houses, he first points out the best methods of carrying the last-mentioned reform into execution, after owning that learned engineers have spent much time in disentangling the difficulties of providing water, ventilation, and heating for barracks and prisons, and adding, "Thanks be to Heaven, every one does not live in these," as a reason why private dwellings should also be considered. He next turns his attention to the best modes of heating and ventilating, illustrating his subject with upwards of a hundred and fifty diagrams, and supplementing it with a list of the principal works relating to it, dating from the year 1400. Each division of these important measures is minutely treated; for instance, water supply is discussed in its various stages of collection, filtration, distribution, heating, purification, and utilization; and its application to baths is shown in views and sections embracing the modes in use in ancient Rome and Pompeii, as well as in England and America at the present day. He terminates his description of the different systems of heating baths with an account of that which he calls French, because he has not seen it in use elsewhere, and, he says, it seems to him admirably adapted to the many-storied French houses. This is merely the plan which utilises the surplus heat of kitchen or other stoves instead of wasting it. The reservoir of water is furnished with a number of pipes, through which the waste heat from the stove, generally the kitchen stove, circulates, and these heated pipes raise the temperature of water in which they stand to their own. In summer, when large fires are not so certain to be in constant use, gas can be applied with equal facility to the same apparatus.

M. Joly's chapter on the heating of apartments is agreeable reading, for it treats the subject cosmographically, if we may say so, and is rich in illustrations of the stoves of the world. Chinese, Persian, ancient Roman, and Mediaeval heating contrivances are well represented, as are the more modern Continental stoves. He names as the best kinds in use in France those known by the names of their inventors, as "l'Appareil Foudet" and "l'Appareil Mouserson," both of which are furnished with hot-air chambers. A third management of the means at disposal may be described as an ordinary wood fire upon the hearth, the smoke from which ascends an iron pipe in the chimney-flue, leaving the extra space in the chimney as a chamber in which external air is heated by the pipe, and made to distribute itself into the same room in which the fire is placed, near the

ceiling, by orifices provided for the purpose. Heating by water is only used in France in greenhouses and hospitals.

Ventilation is treated by M. Joly as the twin-sister of heating. He gives the preference to natural ventilation, but enters fully into the various artificial means, as well as into the history of *l'aération*. The ventilation of mines first occupies his care, thence he passes to that of hospitals, and thence to that of churches, theatres, salons, concert-halls, schools, and buildings of many stages in height, successively, the various systems being clearly illustrated. We pick out for especial mention a plan for warming and ventilating a building of the last-mentioned class, which resembles in its most essential features one recently illustrated in these pages. M. Joly shows a four-storied house with a basement, in the centre of which is placed the heating apparatus. There are three ventilating shafts in communication with the *calorifère*, one ascending straight up from it through the entire height of the house to the outside of the roof, the other two being placed on either side of it, at some little distance, so that they pass through the rooms to the right and left of those in the centre of the house before passing likewise out of the roof. At every ceiling there is an opening into one of the shafts to carry off the vitiated air, and in each room near the floor there is another opening, through which hot air, conveyed by pipes from the central apparatus below, is introduced into it. Like others, M. Joly urges that the most simple, economical, and effective way of ventilating a private house, both in summer and winter, is to imitate the method used by Nature for the circulation of the blood in the human frame; that is to say, to place the moving power and principal arteries in the centre, with branches directed towards the extremities. In a house the principal artery should be a shaft in some useless angle of the staircase, as near as possible in the centre of the building. This would be the seat of the circulation of the air of the interior. Hot-water pipes ascending from the basement for the service of the rooms above could be also placed in it. If the waste heat of the kitchen fires was not available for the displacement of air in it, a stove could be placed at its base for the purpose, which could be further utilized by making it heat a circulation of water that could mount to the top-most floor, and serve the baths and lavatories upon every story on its way up. In a section devoted to a consideration of the ventilation of the rooms occupied by working men, the author asks whether their cases should not be thought more of than that of criminals, for whom so much trouble is taken in the ventilation of prisons. After picturing the upright workman coming home to his modest habitation, which is probably without water, ventilation, warmth, and salubrity, he suggests that in those instances where his house forms one of a row adjoining a factory, there should be a vast horizontal conduit running through it and the rest, carrying into each chamber fresh air in summer, and hot air in winter. This plan has been pursued by some manufacturers, who have been recompensed by the vigour and activity of their workpeople, as well as by the decrease of cases requiring pecuniary assistance. When the house is not so situated he recommends another cheap plan of securing fresh air and heat, which appears to be an exceedingly ingenious one. Taking it for granted that the workman will have a stove and not an open fire, he says this stove should have suspended over it a small iron-plated and lined reservoir or cistern, which is to be heated by the smoke, and by a circulating boiler. The flue of the stove on its arrival at the ceiling ought to find there an enlargement or opening, in the middle of which the smoke-tube is to pass out, the remaining space being filled with a moveable register, shut when the fire is afloat, but open throughout the night. The disadvantage of turning flues into ventilating shafts with us is the descent of soot. With wood fires this might not be so insurmountable; moreover, the pipe for the smoke, made perhaps of glazed earthenware, might be carried up the full height of the flue, where there could be no deposit of any kind in the latter. This is not the only ingenious conclusion urged upon French landlords. In conclusion, M. Joly observes progress is slow, especially in a country like France, full of routine; but it is sure; and what is a luxury for the few to-day will be, in twenty years perhaps, a necessity for every one. We commend his work; it is comprehensive as well as foreseeing.

THE LATE MR. GEORGE SMITH, OF MERCERS' HALL.

We mention with regret the death of a much-respected member of the old school of surveyors, Mr. George Smith, which took place on the 5th inst. Mr. Smith was born at Aldenham, in Hertfordshire, on the 28th September, 1783; came to London in early life, and was afterwards articulated to Mr. Brettingham. We have heard him remark as a curious fact, that he and another pupil were the only students there who afterwards followed the profession, the rest having joined the army. He afterwards went as clerk to Mr. Alexander, and was largely connected with the dock business; subsequently he was with Mr. Beazley, a relative of the late Samuel Beazley. Mr. Smith eventually settled in London, living in the neighbourhood of St. Paul's, and quickly came into a large practice.

He was appointed district surveyor of the southern division of the city of London, in the year 1810, an appointment he held until the time of his death; being, we have heard, the second surveyor who had held the appointment since the passing of the Building Act. In 1814 he was elected surveyor to the Mercers' Company, and held this appointment also to the time of his death.* He formerly held the appointment of surveyor to the Coopers' Company; this he resigned to take his place on the court, and he served the office of master twice. Mr. Smith was a very early member of the Royal Institute of British Architects; became a member of the council; and was the appointed chairman of the committee who drew up the report on dilapidations.

During his time he was much engaged in the heaviest references, in connexion with his old contemporaries Roper, the elder l'Anson, Montague, Higgins, and some more, who have all passed away, as well as with Mr. Lockyer, Mr. Hoil, and others, still pursuing an active career. Among his works as an architect, may be mentioned St. Paul's School, the New Corn Exchange, the tower and entrance of the old Royal Exchange; the Whittington's Almshouses, at Highgate, for the Mercers' Company; the church in Blackheath Park; Hornsey Church, except the tower; Gresham College; Mercers' School; and numerous private residences. He also made designs for Sellers' Hall, where he took but with right consideration declined to carry them out, and insisted upon the company's own architect being employed. He was a member of the Surveyors' Club from the year 1807, and a trustee of their charitable fund. He was also a Fellow of the Society of Antiquaries, and connected with some other public bodies. A few years ago he married a young wife, who, however, died before him, and he had recently built for himself a house, "Newlands," at Cophthorne, in Sussex.

THE EDINBURGH MEDICAL HOSPITAL.

EDINBURGH is at this moment in a sort of fever about the rebuilding of a medical hospital. It appears that the ancient institution which has flourished now under the name of the Royal Infirmary for a period of nearly two hundred years, has survived its usefulness, and has become antiquated. What is more, it turns out to be positively injurious to the health of the unfortunate patients who are forced to seek admission within its portals. Notwithstanding the most strenuous efforts to improve it and add to it, the original defects of its construction appear to be incurable; it has been tried in the balance of hospital statistics, and found wanting; and during the course of last year it was formally condemned by the proper authorities, and ordered to be razed to the foundation. Of course, as a necessary consequence, a new hospital has to be built; and on this question we may say a few words.

It is hardly necessary to tell our readers that Edinburgh is the seat of a most ancient and celebrated medical school. Genoa is not more distinguished for its velvets, nor Lyons for its silk manufacture, than Edinburgh is for the profession of medicine. It may be said that in a city from which all political and even literary glory has gradually departed, the profession of

* His very active partner, Mr. George Barnes Williams, who, first as clerk and then as partner, has been connected with the subject of our notice for the last thirty years, and for some time past has done all the work of the company in consequence of Mr. Smith's failing health, is a candidate for the appointment, and would seem to have strong claims to support in his application.

such a school of medicine is not to be disregarded. To do them justice, the citizens of Edinburgh are in nowise guilty of neglecting this circumstance; and accordingly they have entered heart and soul into a movement to provide the necessary funds for erecting a building worthy of the city and the profession. Upon the Medical Hospital, of course, the wide reputation of the Edinburgh Medical School is based, has been reared, and will, no doubt, be extended; it is in fact, if we may venture to use an old metaphor, the corner stone of the building.

The doctors, as far as we can discover, were the first to complain of the present building. This was, indeed, no more than their duty; but the most important initiative steps in the work were taken by the citizens themselves.

During the month of April last year a great public meeting was held in Edinburgh. The Lord Provost took the chair. Lord Dalhousie, Lord Hamilton, Lord Polwarth, the Lord Advocate *in esse* (Gordon), the Lord Advocate *in posse* (Moncrieff), the President of the College of Physicians, and the President of the College of Surgeons, together with an eminent publisher, Mr. Boyd, and a famous paper-maker, Mr. Charles Cowan, addressed the meeting. It was announced that 100,000*l.* was the sum needed; and of this sum the managers could supply 40,000*l.* from their own funds, chiefly derived, it would appear, from former legacies. The response was hearty and immediate: 25,000*l.* were subscribed on the spot. An influential committee of citizens was appointed to conduct the public subscription. A benevolent widow lady, Mrs. Buchanan, of Moray-place, first of all contributed 1,000*l.*, and then soon afterwards amended her donation to 5,000*l.* The Earl of Moray gave 1,000*l.*, the Earl of Wemyss also gave 1,000*l.* There were in all ten names followed by the same magical complement of one numeral and three cyphers. The high constables undertook a domiciliary visitation of the working-classes, who, to say of them what is only fair, have always been faithful supporters of the institution. Collections were made at the same time in those curious brass plates which stand on tripods at the doors of the city churches, and the result of this and more was, that towards the end of July the sum of 67,000*l.* had been raised, which sum, added to the 40,000*l.* we have mentioned of Infirmary stock, make up 7,000*l.* more than the stipulated capital required for the rebuilding of the new hospital. We cannot tell as yet how far this continued appeal has met with success, for the subscription is still in progress.

Hitherto "the movement" had been one of uniform success, peace, concord, and good-will. But we must now turn over another leaf in the history; and this, we are sorry to say, is by no means so full of sunshine, or rather of azure and gold. The best of "movements" somehow or other never will run smooth; the apple of discord is sure to fall to the surface sooner or later; and in the present case the split has arisen on the question of *site*. This is a vital question, and its importance cannot be over-estimated, but the considerations which should determine it are so simple, the condition so elementary, and the necessities so easily understood, that we are totally puzzled to discover the reasons for such a stormy and protracted warfare as it has caused in the newspapers and public meetings of Edinburgh.

It may be desirable to explain here that the Infirmary of Edinburgh consists of two hospitals, the medical and the surgical. The medical hospital is the ancient institution we have referred to above, and the *bens* of the surgical consists partly of the old High School of Edinburgh and partly of a comparatively new suite of buildings which were erected in the year 1852. The old High School contains the wards and class-rooms of Professor Syme; the new buildings those of Professor Syme. Further, it may be added that this noble charity is under the management or supervision of a board of directors, partly elected annually from the body of contributors and partly composed of the Lord Provost and magistrates, who are managers by virtue of their office. The duties of the managers seem to be rather indefinite. But to proceed: the gentleman who played the part of the Goddess of Discord on this occasion was Professor Syme, a surgeon of long practice and high standing, who honourably fills the chair of chemical surgery to the university of Edinburgh. On the 16th day of November last year he addressed a circular letter to each of the subscribers; and in this letter he asserts, and shily supports, the six following propositions:—

"1. That the managers had resolved to spend nearly the whole of the money in the purchase of property adjacent to their own, 69,000*l.*

2. That they had also resolved to rebuild the medical hospital partly on its present site and partly on the site so acquired, which consists of the shops and houses in South Bridge, facing the College gates.

3. That a larger, healthier, more salubrious, and cheaper site could be got in the grounds of Watson's Hospital.

4. That the managers only proposed a new medical hospital.

5. That there was as much need, if not more, for a new surgical hospital.

6. That if the new infirmary he erected on the present site, all the existing buildings must be removed before the foundation-stone could be laid. In that case, Edinburgh would be without a hospital for at least three years."

We will only quote two sentences from Professor Syme's argument under his fifth proposition, in order to illustrate their character:—

"Although the ordinary surgical wards are not so bad as they were, still that terrible pyæmia—the scourge of unhealthy hospitals—is distressingly frequent, together with other indications of imperfect ventilation, It is therefore with no pleasant feeling that I receive the visits to our hospital so frequently paid by members of the profession from all parts of the world, who must necessarily make injurious comparisons of the spacious, convenient, and well-ventilated wards seen elsewhere, with the narrow, rank, and altogether incoherent arrangements of our surgical department."

It is hardly necessary to say that this letter made at once a powerful impression on the contributors and the public. We do not see how it could operate otherwise; for the facts seem to us indisputable and the arguments unanswerable. But it is an unfortunate characteristic of our medical schools, that their doctors differ in their opinions, and still more in their practice. Edinburgh, we are sorry to say, is no exception to the rule. Indeed, if we are to credit all we hear, we believe that diseases of the antagonistic and pugnacious type break out there with uncommon virulence and intensity. Since the days when Dr. Sangrado pulled his opponent's ears there has been no such scene witnessed as one professor of the same college publicly burning the pamphlets of another professor in his class-room. Our readers, therefore, will not be astonished to learn that within a week another doctor of the same school, Professor Spence, professor of surgery proper, also published a letter in reply to that of Professor Syme, in which, if not with equal skill, at least with more command of statistics, he urged the following counter-propositions:—

"1. That Professor Syme's letter contains statements regarding the sanitary condition of the surgical hospital which, if allowed to pass unchallenged, must prove injurious to the reputation of the institution, and of the medical school of Edinburgh.

2. That he (Spence) knows these statements to be incorrect as regards the department under his charge.

3. That he, as the senior acting surgeon of the infirmary, had never made or joined in such complaints; neither had the acting surgeons as a body.

4. That he had had actual experience in every ward of the surgical hospital. Professor Syme never had charge of any one of them. He might, therefore, feel justified in calling in question his (Syme's) competence to pronounce an opinion.

5. That the statistics of amputations for disease during a long period, as given in the published reports will compare favourably with those of any great city hospital.

6. That he holds strong opinions as to the advantages of the present site."

We have no room, even if we had the inclination, to wade through the terrible mass of newspaper controversy which followed on these rival letters,—

"Strow'd were the streets with milk-white reams,
Flow'd it all the Canongate with inky streams!"

All the great Edinburgh writers—medical, legal, ecclesiastical, mercantile, economical, municipal, and architectural—seem to have exhausted their wit and invention in fetching arguments and digging up sites. One writer recommended that the hospital should be put beyond the boundaries of the city, after the fashion of the ancient Jews,—and very wisely too. Another suggested the city poor-house; a third, the cattle-market; a fourth, George Herriot's Hospital; a fifth, the Queen's Park. One doctor, obviously half-eccentric, proposed an iron bridge over the Cowgate to a site among the lowest slums of the High-street; and another doctor of equal eminence proposed that there should be no hospital built at all, only a provision of movable pavilions constructed with cast-iron plates. The medical profession, as far as we can judge, are about equally divided in their opinions; and, in fine, the question as between the two professors is substantially unaltered. But when doctors venture, who shall decide? We need not disguise to answer the question. With regard to public "movements" of this sort, the proverb is something musty. The science of public health, for example, is perhaps more indebted in our generation to the engineer than the physician; but,

at all events, no man in his senses will be governed in his opinions by the statistics of one department of a hospital. Professor Spence's statistics may be, and are, doubtless, correct, so far as they go. But no statistics in the world will make a plain man believe that the site of Christ Church Hospital, in Newgate-street, is as salubrious as the site of St. George's Hospital at Hyde Park Corner. And such—or nearly so, we believe—is the analogy between the present site of the Royal Infirmary at Edinburgh, and the site which Professor Syme recommends at George Watson's Hospital, which lies with a southern exposure, on the northern slope of the Edinburgh meadows. We cannot choose but support the view which gives the suffering inmates of a hospital the chances of more sunlight, better ventilation, and purer atmosphere.

We hear that Mr. Ryce, the architect to the Royal Infirmary, has been requested to report on the comparative merits of the two sites. This ought to have been a preliminary step. It is unfortunate that the managers have lodged their bill, and scheduled the property on the old ground, without the least reference to another bid, it may be, improved site. However, better late than never.

COLOGNE CATHEDRAL.

It was not until the spring of last year that the works and restorations upon other parts of this venerable pile were thought sufficiently advanced to allow of some progress being made with the two western towers; and this being at length determined upon, much had to be undone in consequence of decay, and other reasons, before the work could be satisfactorily proceeded with. Mechanical appliances were for the most part as uncouth and imperfect in the middle ages as they probably were in the time of the Egyptian Pharaohs. In those days it was the work of an entire day to raise a block of stone weighing some 40 or 50 cwt. from the ground to a height of 100 ft., and this was mostly done by soldering a powerful ring into the stone and raising it by means of a huge crane to the top. Some twenty stones have this been found upon the northern tower, of the "Dom," each still provided with its lifting-ring, which it was not thought worth while to remove at the time when the works were stopped. Last spring the task of completing the towers was put in hand, the first thing to be done being to remove the time-honoured ponderous old crane we all know so well, if not from an actual visit, at any rate from all the Eau de Cologne bottles we have ever seen. All joints, mortises, and joggles, were found utterly rotten, and a special scaffolding was necessary to take down the huge timbers that once had formed the crane. A careful examination into the condition of the masonry was then made, when it was found that much had utterly decayed, and would have to be taken down before continuing the new work; for in the upper parts of the towers, at least, much of the local soft sandstone appears to have been used, and this was in parts so weathered away, that in one instance the roof of a creeper was followed down to a depth of 20 ft. before it could be extracted. As the annual tourist this year approaches what Mr. Spurgeon calls (like Coleridge before him) the City of a Thousand Smells, and the fine old tower gradually looms into view, he will find that his old friend has disappeared, and the puff of white steam will tell him that here as everywhere the steam-engine has superseded manual lifting-power. A stationary engine of 8-horse power will be at work, lifting in four minutes what in days gone by would have taken two days. Both towers are in hand at the same time, the progress of both being the same; and being connected by means of a light iron bridge fitted with rails, the stones can be moved, when up, to any required spot. The pecuniary means whereby these works are carried on are twofold,—namely, first, by voluntary aid (his Majesty the King of Prussia heading the list with a handsome annual contribution), and, secondly, by the questionable proceeds of a lottery, which produces to the Dom Committee an annual income of about 37,000*l.* It is thus hoped that the second story of both towers will be completed in two years and a half, the octagonal part in two years and a half more, and the whole work by the year 1877. After perusing the above paragraph, the reader will be amused to learn that Bishop Bertholet, of Air-la-Chapelle, in a report on the cathedral at

the beginning of the present century, actually advised Napoleon I. to have the whole structure raised to the ground, as it was "positively unsafe to walk under it!"

MICHAEL FARADAY.

The last number issued of the "Proceedings of the Royal Society" (No. 106, vol. xvii.) contains amongst the Obituary Notices of Deceased Fellows an interesting and important narrative of the chief events of his personal history, "with such indications of his character and opinions as may be read in his written correspondence and private memorials." It has been put together by Dr. Benze Jones, F.R.S., occupies 68 pages, and is full of delightful teaching. The way in which Faraday acknowledged, on many occasions, his obligations to Mrs. Marcet's well-known "Conversations" will interest on several grounds. He thus wrote to M. De La Rive on the occasion of that lady's death:—

"Your subject interested me deeply every way, for Mrs. Marcet was a good friend to me, as she must have been to many of the human race. I entered the shop of a bookseller and bookbinder, at the age of thirteen, in the year 1804, remained there eight years, and during the chief part of the time bound books. Now it was in those books, in the hours after work, that I found the beginning of my philosophy. There were two, especially helped me, the 'Encyclopædia Britannica,' from which I gained my first notions of electricity, and Mrs. Marcet's 'Conversations on Chemistry,' which gave me my foundation in that science.

Do not suppose that I was a very deep thinker, or was marked as a precocious person. I was a very lively, imaginative person, and could believe in the "dark night" lights as early as in the 'Encyclopædia'; but facts were important to me and served me. I could trust a fact, and always cross-examined an assertion. So when I questioned Mrs. Marcet's book by such little experiments as I could find means to perform, and found it true to the facts as I could understand them, I felt that I had got hold of an anchor in chemical knowledge, and clung fast to it. Thence my deep veneration for Mrs. Marcet; first, as one who had conferred great personal good and pleasure on me, and then as one able to convey the truth and principle of those boundless fields of knowledge which concern natural things to the young, untaught, and inquiring mind.

You may imagine my delight when I came to know Mrs. Marcet personally; how often I cast my thoughts backwards, delighting to connect the past and the present; how often, when sending a paper to her as a thank-offering, I thought of my first instructress; and such-like thoughts will remain with me."

A life of continuous unselfish work was that of this "blacksmith's son from Jacob's-Well-mews, full of inborn religion, and gentleness, and genius, and energy, [who] searched for truth and trusted to facts in his experimental researches, and thus left to science a monument of himself that may be compared even to that of Newton."

A VOICE FROM THE CRYPT OF ST. PAUL'S.

Sir,—Will you allow me to appeal to you, as one of the recognised guardians of our public buildings, to prevent the desecration and the great injury which the annual assembly of the charity children within St. Paul's Cathedral does to the sacred edifice itself, and to the various national monuments it contains? This assembly of the children has hitherto taken place in June, so that if the subject were brought forward now, there would be ample time to investigate the matter and to make other arrangements.

For some time before the day of meeting, load upon load of heavy timber is carried into the cathedral, and a host of workmen sent in to erect the staging necessary for the accommodation of many hundreds of children and of spectators. To say nothing of the interruption to the ordinary services of the cathedral, and violation of the tranquillity which should reign in this national mausoleum, just think of the danger and the actual damage done to the monuments of those whom the nation delights to honour, and which have cost, individually and collectively, vast sums of public money. The sculptured effigies of our great countrymen are out of reach of ordinary visitors, which clearly shows that the injuries they have sustained must have been caused by careless workmen, and be the result of these heavy timber erections. And after these huge halks of timber and immense loads of planking have been crowded in, so as to occupy the whole area of the noble dome, what then? All this expense, labour, risk of fire, fuss, and trouble, are incurred for the mighty grand purpose of allowing some hundreds of educated people to listen to the performance of an enormous number of ill-instructed charity children, singing psalms and hymns in a way to illustrate the

lamentable deficiency of musical tuition in this country. And then come several more days of hammering and wrenching apart; the staging is taken down, and the loads of planking and timber are huddled out of the cathedral.

Now, I ask you, Mr. Editor, *est homo*? If it be desirable the charity children should have an annual gathering, why not let it be held in Exeter Hall, or the Crystal Palace? Both of these places are already prepared for such exhibitions; but the latter especially recommends itself as a means of sparing the poor children much suffering and inconvenience; and after the performance is concluded, they could enjoy some recreation and amusement.

With the meeting at St. Paul's as now arranged, the access to the children's seats being very limited and exceedingly inconvenient, the poor little creatures are obliged to be in their places some hours before the time of performance, and there they must sit, hungry and weary, for many of them have walked long distances to the cathedral; and when, as is frequently the case, a girl faints from the heat and from sheer exhaustion, she has to be lifted out over the heads of her companions.

A third point is, what becomes of the money collected at this festival? On the day of rehearsal it may be small in amount, but on the "grand day" it must be considerable. The whole affair is in the hands of "The Society of Patrons," who are supposed to help the parochial schools from the funds so collected. Who has ever seen an account of the receipts and disbursements? The writer, some twenty years ago, filled a public office, and was then told it was right for him to go to this celebration. At the cathedral and at the dinner afterwards, to which he was invited, he gave about 25*l.* The following year he was invited to the sumptuous dinner at the London Tavern, the few gentlemen constituting the "Society of Patrons," being in all their glory. Since then he has heard nothing of them or their doings, nor of their society, saving the notice in the public newspapers of the meeting of the charity children in St. Paul's.

Who constitute the Society of Patrons? Why are not the accounts sent to subscribers? Where are the said accounts to be seen? Who are the donors? And what good has the whole thing done? A SHADE.

SANITARY MATTERS.

Kidderminster.—In compliance with a request by the local board of guardians, Dr. Roden, medical officer for the No. 2 district, Kidderminster, has presented a report embodying his views on the sanitary state of the town. Mr. Stretton, medical officer for No. 1 district, had already presented a report on the same subject. Dr. Roden remarks at the outset, that he quite agrees with Mr. Stretton that, although the town would never be placed in a secure state till proper drainage and water works were carried out, there were, nevertheless, many local causes of disease not connected with such works which required prompt removal or amelioration. He could safely say that scarcely a death from fever or other zymotic disease had occurred in his medical district, that he could not almost immediately trace to some cause capable of amendment or entire removal. Pigstyes were scattered in all directions at the rear of rows of houses, and in crowded streets and alleys throughout the densely populated parts of the town, and generally so near the houses as to be a constant source of disease. Privies and open ashpits were generally still nearer to the houses, and so constructed that the roof shuts the rain-water into the ashpit, thus giving rise to pestilential vapours, and dealing out death and disease to the entire neighbourhood. Doubtless, [he said] the proper remedy for this state of matters would be the adoption of earth closets; but, as he imagined it would be next to impossible to carry out such a system in large towns, some plan of amelioration should be attempted. Besides scarlet fever, which has latterly been the cause of the increased mortality, the population had been visited by almost every form of exanthematous and zymotic disease, including measles, erysipelas, gastric and typhus fevers, whooping cough, croup, diphtheria, diarrhoea, &c., and under such conditions it was easy to understand that bronchitis, consumption, rheumatism, and other blood diseases were not only engendered, but their victims were, in many cases, rapidly hurried to a premature grave; while, as regarded scarlet fever, the disease has assumed

the most malignant type—it was, in fact, nothing less than the putrid sore throat of hygone times. Dr. Roden suggested various remedies which should be adopted without further unnecessary delay. First and foremost, he would advise the early adoption of the Public Health and Local Government Acts. The application of these Acts he thought ought to be compulsory on towns of a population of 10,000 and upwards, as should the appointment of medical officer of health in all cases where the Act is applied. A complete system of sewerage and waterworks could no longer be delayed, or the town might lose the opportunity of controlling the expenditure. The council should adopt Mr. Torrens's Bill for providing better dwellings for artisans and labourers, which, he remarked, would be of incalculable benefit to the town.

Sheerness.—The town of Sheerness, once reputed to be a most unhealthy place, appears now to be one of the healthiest towns in England. The number of deaths registered in the year 1868 for the sub-district of Minster, in Sheppy, including Sheerness and Queenborough, was 304. The population of this sub-district was 17,000 in 1861, and is now at least 20,000. Hence the death-rate of Sheerness is only fifteen in the thousand—seven less than the death-rate of England and Wales, ten less than that of London, and lower than that of any watering-place in England except Eastbourne. This surprising improvement in the health of Sheerness is not exceptional, the death-rate of 1867 being nearly as low. The great improvements effected during the last ten years in the sanitary regulations of the town, with the natural salubrity of the fresh sea-air to which Sheerness is exposed, have tended to produce this favourable result. The want of additional and better class houses is much felt, and extensive building operations are contemplated during the coming summer. A large public hall, with reading-rooms, &c., is in course of erection. The Government has been induced to dispose of a quantity of land for building purposes to meet the local want of houses.

THE TEMPLE OF HEROD.

LIEUT. WARREN has recently addressed some speculations on this subject to the Palestine Exploration Committee. He says:—"From our present knowledge of the Haram area, we may draw the inference that the southern wall is that spoken of by Josephus as the south wall of Herod's enclosure; for we have the Ophel wall joining in at the south-east angle, at what would have been the eastern cloisters, and we have the arches of Robinson and Wilson on the west; and the great difficulty now is the dilemma about the dimensions given by Josephus; for, while on the one hand, he leads us to suppose that the Temple enclosure of King Solomon was in compass four furlongs, and that the area was doubled by Herod, yet, on the other hand, he gives us six furlongs as the compass of Herod's enclosure, including Antonia: so that it is an open question as to what the exact measurements were.

We have, however, in the present walls, certain conditions given to us in Josephus's account of Herod's Temple, and it may be interesting to apply to these Haram walls a plan of that ancient enclosure. For this purpose I have taken the plan of the Temple, constructed by the Rev. John Lightfoot, D.D., in 1684, because it was made (by his own account) entirely from the ancient writings, his mind being unbiassed by any knowledge of the present Haram enclosure. I have taken his southern wall, and applied it to the south wall of the Haram area, lengthening it until they coincide, and at the same time increasing all the parts to scale. We have then a plan of Herod's enclosure occupying the southern part of the Haram area, and being a square of about 900 ft. a side, its compass being six furlongs."

The writer then goes on to note the results, pointing out relations and discrepancies, and showing that there are between Dr. Lightfoot's plan and the present Haram area a number of points of resemblance, which are sufficient to draw serious attention to the matter; but out of them there are two or three points which tell almost equally in favour of those plans in which the altar is placed near to the *sakhra*.

His remarks may be useful to those who are interested in locating the Temple enclosure; but we seem to be a long way yet from fixing the position with any degree of certainty.

HOUSE BUILDING.

In the course of the discussion at the Institute of Architects last week, on the description given of Humewood,* in the county of Wicklow, Ireland, Mr. T. B. Smith said it was natural that some differences of opinion should arise on the subject of building. One was as to the treatment of granite. There appeared to him to be great advantage to the architect in the use of granite, inasmuch as it was a material of that refractory character which would not allow him to be run away with by all sorts of fancies; and much of the effect of the recent works in Dublin, he thought, was mainly due to their having been executed in a material which would only bear a treatment of great breadth and simplicity. Any description of fine moulding in granite was out of place, unless it was polished, and then they got into great expense. He would be glad to hear the criticism of the meeting with regard to the arrangement, as in the instance before them, of placing the kitchens and other servants' offices in the basement, beneath the principal floor of the house. They had been led to believe that in country residences, where there was more space at command than in towns, there was advantage in having the offices on the same level as the house, and that the drawback of a long corridor was compensated by the freedom from noise and odours arising from the basement. At the same time, in the present case, no doubt there was great economy in the arrangement of the servants' offices beneath the principal floors.

Professor Kerr said the question of placing the domestic offices in the basement, or on the same level as the house, was one very much to be decided by the tastes and habits of the family occupying it. In the case before them it was obvious that the garden front of the mansion was overlooked from the servants' offices. This would be an objection with some people; but such an arrangement of the offices as had been carried out at Humewood was, no doubt, highly economical. With regard to general convenience much, no doubt, was to be said on both sides. To some people the carrying of dinners up a staircase was objectionable, and principally affected the servants themselves. The question of the casements of the windows instead of sashes was one on which they might rest a little. He thought they might take it that in this climate the sash window was the only known contrivance which would keep out the weather. No casement he had ever heard of was effective against a thorough wet wind in England; and it must be still less effective in Ireland. In his own practice he ventured to introduce sash windows in every case, even in millioned windows, and the suggestion which occurred to one's mind that the sash had an unpleasant external appearance was not borne out in fact if they got a sufficiently deep reveal. He would like to receive a little more explanation with regard to the gutters. The construction of the tile and slate flat described was, he thought, rather a novel thing, but he did not think there would be persuaded to adopt it in preference to a lead flat. The gutters were, perhaps, as remarkable in their way as the flats, and he would like to ask Mr. White how the down-pipe acted which was inside the wall. He (Professor Kerr) said he believed most people made it an invariable rule to have the down-pipe outside the wall; and in his younger days he received a lesson with regard to inside down-pipes which led him to avoid them thereafter. His apprehension in the present case was, that when the pipes stood full of water, the water would find its way through some unexpected place in the wall.

Mr. C. F. Hayward thought the question of basement offices and the arrangement of the same accommodation on the ground-level could only be practically answered by saying it was entirely a matter of taste on the part of the proprietor interested in the subject of the roof flat, because he had a belief in the tile flat in opposition to the lead flat, and he saw no reason why it should not answer in the present case. There were certain disadvantages in lead slate—one of which was the frequency with which they required to be repaired, and the little parloinings which went on during those repairs, and the frequent shovelling off of snow was liable to damage the lead. In this respect he felt Mr. White had done good service in having entered upon this particular experiment, and it was one which was deserving of consideration; and on this point he would be

glad to have some information as to the comparative cost of the two modes of construction. He thought there were very good grounds for adopting such a plan as this in opposition to the lead flat, and he hoped the experiment in this instance would be successful. The question of casement versus sash was one of importance, inasmuch as upon the determination of it depended the arrangement of the curtain and other decorations of the room.

Mr. Brooke suggested that the objection to basement offices on the score of their overlooking the garden front could be obviated by the use of roughed plate glass in the windows.

Mr. White, in concluding the discussion, said, with regard to the arrangement of the domestic offices in the basement, beneath the principal living-rooms, he should be better able to give an opinion in two or three years time, and he should then be happy to communicate to them what the experience in this particular residence was. But the question here was that, inasmuch as there must of necessity be a basement of 8 ft. or 10 ft.—in the first place, for the sake of getting out of the cold and damp, and secondly, for the sake of the prospect, it would have been an enormous waste of space if it had not been utilised for the servants' offices. As arranged in this instance, he thought there was the minimum of inconvenience from the adoption of that plan. He conceived that all these offices being brought into such very available communication with the living part of the house was a great advantage. In a residence on a smaller scale he might hesitate to place the kitchens, &c., on the basement. With regard to the overlooking of the garden front from the offices, it was to be remarked that it was at a point of the ground which would never be much used by the family or visitors, as it was the way to the stables and other parts of the out-premises, and the windows were glazed to the height of six feet with roughed glass. With regard to dinner-lifts he believed they were only lifts that smells all over the house, from what he had heard of places in which they had been adopted. With regard to the question of sashes and casements, he could say he had seen as much wet come through the former as the latter, and he had seen casements which were impervious to rain and wind in the most exposed situations; and he had also seen sashes which did let in a vast quantity of both. Casements, on the other hand, he regarded as best adapted for the display of fine scenery and prospect. With regard to down-pipes within the walls, he thought Professor Kerr, in the case he referred to, must have used pipes which were insufficient for the overflows. The pipes at Humewood, he said, were 6 in. diameter, and were placed between the outer and inner casing of brick-work which lined the house. With regard to the true curves of mouldings, of course it was impossible to explain or define why one curve was better than another, and why one point which was simply artistic should have a more pleasant effect than another. All they could aim at was the result to be derived from them as a whole.

NEW CONGREGATIONAL CHURCHES.

"THE Congregational Year Book for 1869" * shows, as our own pages have already done, great activity on the part of the body it represents in building churches, chapels, and schools. It shows that there have been fourteen new churches formed in England, three in Wales, and two in Queensland. The foundations have been laid of thirty chapels in England, of four in Wales, one in Canada, and one in Madagascar. Fifty new chapels have been opened in England, eleven in Wales, three in Scotland, seven in the colonies, and one in Paris. The foundations of four schools have been laid, and twenty new schools have been opened. The Year Book contains descriptions and views of a number of the buildings erected, and of these we give two:—

Trinity Congregational Church, Huntingdon.

This church is a large structure of the early decorated style of Gothic architecture, with tower and spire at the south-west angle of the front; the total height of the latter being 190 ft. The church stands 45 ft. back from the High-street, the open space being inclosed. The plan of the church is cruciform, having a total length of 114 ft., 49 ft. wide across the nave and aisles,

* The Congregational Year Book, 1869. Containing the proceedings of the Congregational Union for 1868, and general statistics of the denomination. London: Hodder & Stoughton.

and 60 ft. across transept. The height of the church, from floor to ceiling, is 48 ft.; and the average height of the aisles is 24 ft.

The arches, separating the aisles and transeps from the nave, are of moulded Bath stone, and support a clearstory, having double-light windows, with tracery heads. The columns are of cast-iron, bronzed. The ceiling of the nave is continued the full height, over the apse, and terminates in an octagonal form. The trusses of the roof rest on dwarf stone columns, having sculptured oaks and corbels; the wall space, beneath the windows of the apse, is covered with arcading, unornamented by a corbel table—the whole forming a reredos. The panels are fitted with Irish marble, having Scripture texts. This decoration has been erected to the memory of the Rev. W. Wright, the first pastor of the church, by his son, Mr. Samuel Wright.

The floor of the apse is raised about 18 in. above that of the church, and choir-seats are placed on each side. The organ-chamber is on the left of the apse, and opens into it and the aisles by stone arches and columns. On the right side of the apse is a corresponding arch fitted with a wood screen. The tower entrance has a stone-vaunted ceiling, with moulded ribs and sculptured corbels. Beneath the church is a large school-room, 60 ft. by 31 ft.; infant school-room, and seven good class-rooms, beside a library, warming-chamber, large lavatory, and other conveniences. The height of the basement is 12 ft. The warming apparatus consists of hot-water pipes, which run up the centre, and round the sides of the church. The church is at present arranged for about 720 sittings on the ground-floor. Mr. John Tarring is the architect.

Congregational Church, Ancoats, Manchester.

Amongst the illustrations in the Year Book of 1866, was one of a new church at Pin Mill Brow, in Ancoats, Manchester. Very shortly after that building was opened, the Midland Railway Company obtained powers for a line to a new goods depot, which necessitated its purchase. It still stands, but has not been used for worship since then. With the proceeds of the sale of the property, the trustees purchased the only available plot of land in the township, viz., the site of the old gas-works. The accompanying engraving shows the structure, as now in progress. The river is about 25 ft. below the road; and, after allowing for floods, the depth at that end admits of a large room below the church floor, 47 ft. by 30 ft., and 15 ft. high. This will be temporarily divided, and used for infant and elementary class-rooms. The interior of the building is 88 ft. long, by a mean clear width of 50 ft. Galleries are provided on three sides, and two spacious staircases thereto. Underneath the galleries will be class-rooms, ten in number; temporarily separated from the central portion of the body of the church by lath-and-plaster partitions.

It is intended to fit up the galleries with pews, for appropriate sittings for the congregation, and to use the ground floor for school purposes at present. The entrances are so arranged that access to the galleries is exclusively confined to the congregation.

The body of the ground floor will contain movable forms, capable of seating 300 adults, which, added to the sittings in the galleries, will give accommodation for a congregation of 650 persons.

The roof is supported by wood pillars, in a line with the side-gallery fronts, connected by framed spandrels above. All the timbers will be exposed to view, and stained and varnished. The walls are of brick, with stone dressings. The roofing will be covered with Knaehell slates.

Provision is made in a cellar-basement for Haden's heating-apparatus. The cost of the building proper is 4,710l., which is the amount of the builder's contract. This includes 500l., at least, for extra foundations, the whole of the walls having to be taken down to the level of the bed of the river, between 20 ft. and 30 ft. below the ground surface. The lighting, heating, and movable furniture, boundary fences, and architects' commission, will swell the total outlay to about 5,800l. The architecte are Messrs. Paull & Robinson, Manchester.

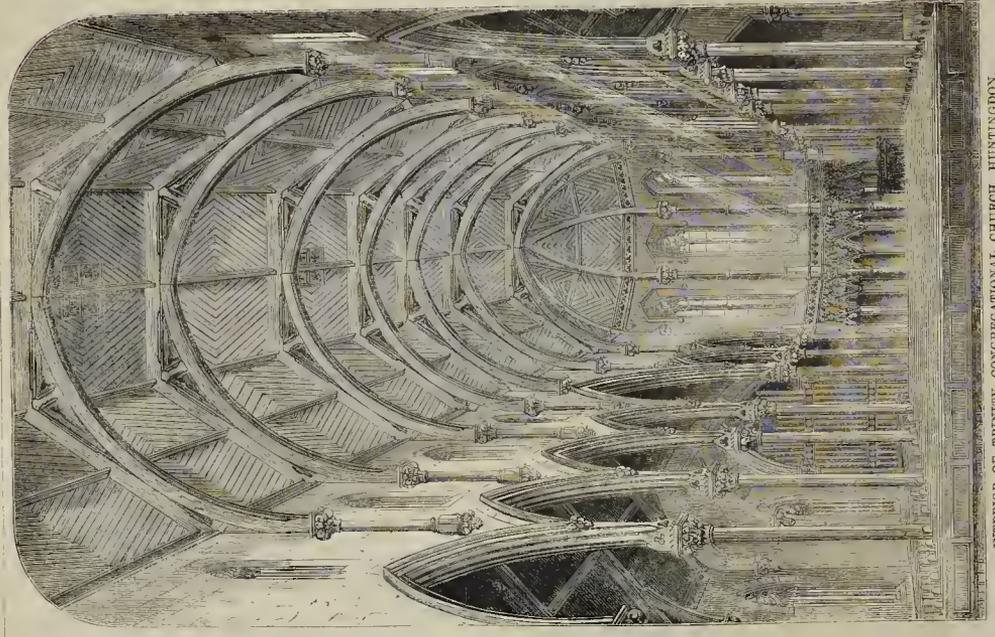

Society of Engineers.—At the meeting of this society, to be held on the 13th inst., the president will present the premiums awarded for papers read during the year 1868, and the president for 1869 will deliver his inaugural address.

* See p. 26, ante. View, plan, and description of this mansion will be found in our Vol. xxvi., pp. 657, 658, 659.

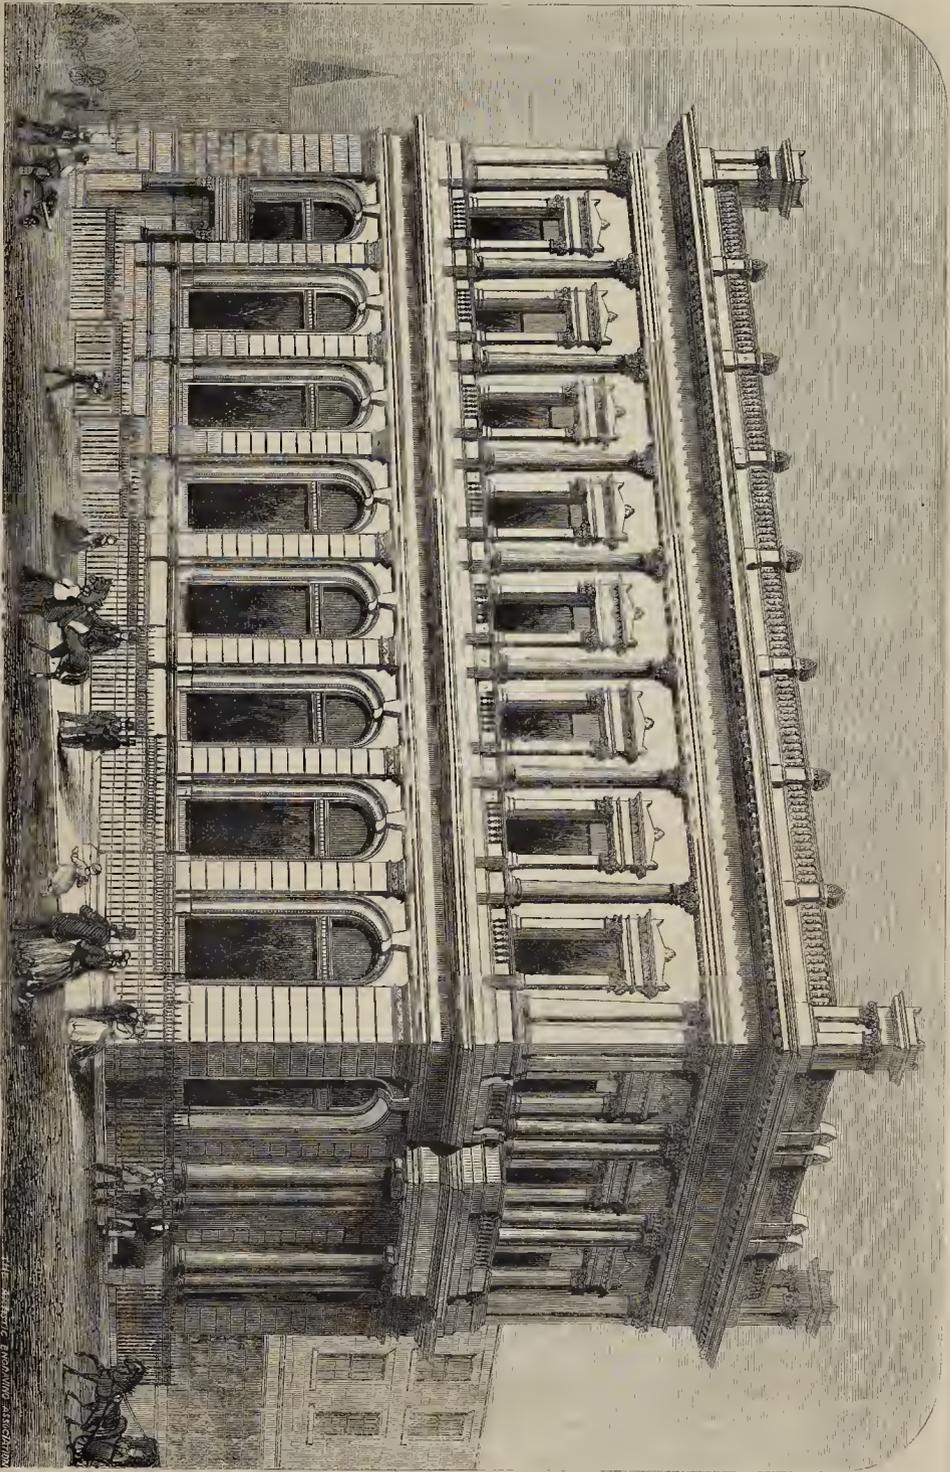

CONGREGATIONAL CHURCH AND SCHOOLS
 MANCHESTER
 ARCHT. BY WILLIAM AND ROBINSON

THE BIRMINGHAM AND MIDLAND BANK, NEW STREET, BIRMINGHAM.—Mr. Edward Holmes, Architect.

[See page 11.]

ARTERIAL AND AGRICULTURAL DISTRICT DRAINAGE, AND THE LAWS CONNECTED THEREWITH.*

The term "arterial" has been applied to the rivers and streams of a country in consequence of their similarity to the arteries for conveying the blood through the body, and the appearance of a map and of a drawing of the arteries of the body are precisely the same.

In this paper it is proposed to advocate the principles of arterial drainage by pointing out the great benefits that would ensue from a more extensive adoption of the system, and by giving an account of the results in those cases where some combined systems or district drainages have been carried out.

Before an institution consisting, as this does, of persons practically acquainted with the management of land, and who are fully alive to the improvement of which it is often capable, by the application of engineering works, it would seem unnecessary to occupy time in discussing questions so familiar to them. Nevertheless, as an inspector under "The Land Drainage Act, 1861," having had a better opportunity of forming an acquaintance with the subject, perhaps, than most persons, I have found that the advantages of such works, particularly in some parts of England, are not appreciated as they ought to be, and I hope that the influence and intelligent spirit of the members will be exerted to recommend the adoption of the facilities offered by this Act. As an illustration of the works that have been carried out in training and forming the courses of rivers through marsh lands, we need only refer to the fens in the counties of Lincoln, Cambridge, and Norfolk, to understand what can be done by combined systems of drainage in reclaiming land, and in preparing it for cultivation.

The necessity for district systems of arterial drainage has, it is well known, arisen from the great increase of pipe drainage, and the better clearing and opening of ditches and drains of late years, thereby causing a more rapid and an increasing discharge of water from the uplands into the valleys, and overloading the rivers and streams, so flooding them more frequently, and to a larger extent, than was experienced in former times; besides which, those valley lands being subject to floods, or the water constantly lying within a few inches of the surface, have their crops frequently destroyed, and are available as pastures for a much shorter period in each year than they really ought to be.

The difficulties that formerly arose, from the state of the law, in constituting any combined action to remove obstructions in rivers, to deepen, straighten, and improve them, and to form proper outfalls through the lands of hostile owners, or of those who were indifferent to the improvement of their own land, or unwilling to give facilities to others, have been, to some extent, removed by an alteration and extension of the powers of the old sewers laws.

I read a paper on "Arterial Drainage and Outfalls," at the Institution of Civil Engineers, in 1859-60, after which Sir George Cornewall Lewis, then at the Home Office, prepared a Bill extending the powers of the laws relating to the Commissions of Sewers. In 1861, the Act called "The Land Drainage Act" was passed. The main features of that Act are that it enables commissions of sewers or district drainage Boards, as the promoters may elect, to be formed in river valleys, or in marsh and low lands, by those who may be interested in them, by combining under either of the above forms to carry out works in making new watercourses and improving rivers, with the necessary outfalls, and to take the lands benefited by these means within a properly defined jurisdiction, sanctioned by the Inclosure Commissioners, but extending into valleys in the interior, and not limited to the areas marked out by the level of the tides, as the old commissions are. The Act also provides for the reclamation of land from the sea, irrigation, &c.

Mr. Theodore Thring has published a manual of the Act, which I beg to recommend to any one who wishes to be informed of its various powers.

The number of cases under the Act, amount to twenty-two, of which I have inspected twenty-one, and these districts comprise, in all, about 770,600 acres.

* From a paper by Mr. R. Bovall Grantham, C.E., read at the Ordinary General Meeting of the Institution of Surveyors, January 11th, 1869. The President in the chair.

The following is a list of the districts which have been formed:—

District	Acres
Morden Carrs, Durham	4,000
Wormbrook, Hereford	1,974
Wissey, Norfolk	8,240
Ladden Brook, Gloucester	957
Longdon and Eldersfield, Worcester	3,835
Langorse, Brecon	1,953
Masey, Northampton	7,918
King's Sottingham, Norfolk	5,913
River Idis, Nottingham	6,000
Stammer, Somerset	876
Currymoor, Somerset	1,820
Dysynay, Merioneth	2,554
Staunton Common, Hereford	1,454
Winterton, Norfolk	1,055
Chedzoy, Somerset	2,412
Alter Moor, Somerset	2,154
Frodsham, Cheshire	4,217
Northmoor, Oxford	2,384
North Moor, Somerset	3,235
Haddiscoe, Norfolk	1,628
Muckfleet, Norfolk	1,404

Some of these have been carried out most successfully, and others are in progress, and some have not been commenced. The areas of each district vary, as will be seen, from 591 to 11,259 acres.

The cost of putting the powers of the Act into operation has been on an average 50l. in each case.

I do not know that I can illustrate the subject better than by describing the practical results of different methods of carrying out a combined system of arterial drainage. For this purpose I have selected a district drained by gravitation; another by means of pumping; and a private drainage, also by pumping.

The first is that of the Leaden, which is a river rising in Herefordshire and Worcestershire, with a watershed of about 120 square miles. The district was formed under a Commission of Sewers in 1861, and the works, which are confined to the jurisdiction, were completed, as far as they could be then executed, in 1867.

The commissioners, in order to inform those who are interested in the improvement, lately published a statement of their proceedings, with an account of the expenditure. The account shows the total expenditure; but it should be remarked that the purchase of the water rights and compensations absorbed more than half of it.

The Leaden flows into the western branch of the river Severn, about 1½ mile from Gloucester. There were formerly two mills upon it—one, the Over Mill at the Severn; and the other, Radford Mill, about 2½ miles above it—by which the water was penned back for upwards of 5 miles. The water-power of both mills was purchased by the commissioners, who were thus enabled to deepen, widen, and straighten the river where requisite; and the effect has been to lower the water towards the outfall 5 ft., and at the upper end 4 ft. The jurisdiction of the commissioners, which includes a branch river in the parish of Tibberton, extends over about 1,400 acres.

From the Severn to the archway under the Hereford and Gloucester Canal, which is 4½ miles, the work consisted for the greater part of a new cut, and the remainder in deepening and taking off bends only. Both sides of the new river, for a mile and a half in length up from the Severn, as well as along the bank parallel to the Severn, were embanked, to keep out the tides and its flood-waters, and also to confine the floods of the Leaden itself, which flow down from the upper country about two days before those of the Severn arrive at the same point. From the Hereford and Gloucester Canal through Tibberton parish, being about 1½ mile, the brook was deepened and widened in places, and in others the banks were dressed off and the bushes cleared. From about the fourth mile on the main river it was deepened, cleared of bushes and weeds, and the banks dressed off for about 2 miles, making altogether nearly 7 miles,—the cost of which amounted to about 3,070l., including superintendence. The remainder of the outlay was for obtaining the commission, raising money, office and legal expenses, &c. The money has been borrowed, and will be paid off in twenty-five years. The rate for the repayment of this and interest, together with the annual expense of clerk, varies from 9s. to 11s. per acre, assessed upon the land according to the benefit conferred. For the first two years after completion of the main cuts for the river, the repairs and clearing the bottom and sides cost only 10l. The practical result has been that the floods caused by the river Leaden itself have not overflowed its new channel, and the floods and tides of the Severn itself have been so confined within its own banks as to prevent them overflowing the adjoining land, and their duration is very much reduced.

The floods have never since injured the growing grass, nor carried it away when out, as was formerly the case in about one year out of four. The quality of the grass is very much improved, and cattle and sheep can remain on the pastures nearly all the year. The under-drainage can be better carried out, and the river is as nearly as possible under the control of those who are interested in its proper action. To conclude the description of this work, I cannot do better than quote a letter written to me by Mr. William P. Price, the member for Gloucester, and chairman of the Leaden Commission, who lives in the neighbourhood, and has a large area of land within the jurisdiction:—

"November 29th, 1868.
The result of our Leaden drainage may be stated in a very few words.

We can now drain effectually all the lower level, which we could not have done before; and the floods are much fewer in number, and when they come do not hurt us, because they are off again directly.

The drainage has done all I ever expected of it. It is difficult to speak of the commercial value. The rates may be taken to be about 7s. 6d. per acre, putting the rest for redemption of capital outlay. Is the improvement worth this 7s. 6d. to the tenant?

In the first place, I don't think any one of them denies it. But if they did, I should not believe them.

In the second place, one hay crop saved in every four years would pay it for them; and summer floods destroyed the crops at least once in four years.

But, apart from this, we can now keep cattle in the leas always, except during the very short duration of a flood, which we rarely experience now, except when the cattle are all in the folds. W. P. PRICE.

Note.—The average cost per acre which Mr. Price refers to is that which is chargeable to the tenant, being the interest, the landlord generally paying the difference, which is the redemption of capital outlay.

The next case which I propose to describe is that of a district in Norfolk, in the parishes of Winterton and Somerton, about 10 miles north of Yarmouth, and which is drained by pumping. This district, containing about 1,100 acres, is comprised within a watershed of about 2,500 acres, and lies in a basin, formed by high land on the south side, and bounded on the west and north sides by Martham Broad, or Lake, and the Hundred Stream, the levels of which are from 3 ft. to 4 ft. above the area: on the east side are sand hills on the sea shore.

The soil at the eastern side consists of sand, yielding much water from the sand hills; it then, as we proceed westward, becomes peat of some depth in places below the bottoms of the drains; farther west still, the clay locally called oze, or houlder clay, underlies the peat, and appears on the surface; and then, at the extreme west, there is peat again to a small extent.

The land, previous to the formation of the Commission, was drained by a windmill, driving a scoop wheel, which was destroyed in a gale of wind; and also by a small steam engine, driving another scoop wheel, which was too small by itself to drain the lands.

The area was, in fact, a marsh; for, although the wheels lifted the water out, floods occurred, and the drains were seldom free from water, the level of which was within about 2 ft. of the surface of the land, which produced little more than rushes and water weeds, and cattle could remain on the lands a few months only, even if the weather was fine. The marsh lands are generally let with the uplands in proportion to their extent, and, therefore, no definite rental is charged upon them exclusively; but I have always considered that an average of 10s. per acre was as much as they were worth. In 1864, a commission of sewers, under the "Land Drainage Act," was issued, called the "Winterton and Somerton Commission of Sewers."

The object of the work was to collect the water by a main leading drain at one point, from which it could be pumped into the Martham Broad, or lake, a lift of 5 ft. to 7 ft.; and, in 1865, an Appold pump, worked by steam, was erected for this purpose.

It should be mentioned that the natural fall of the country was towards the sea, and that the hundred stream formerly discharged itself into the sea, through what are now high hills of sand, so that the drainage of the eastern portion has been diverted westerly against its natural direction; and it was therefore necessary to cut the drains through a summit in the district to make the water flow to the pump, which caused deeper cutting for the drains than would otherwise have been required. The different parts of the work were done by contract, completed in July, 1866, and the following is a summary of the cost:—

Earthworks	£1,422
Pump and engines	1,301
Bridges and culverts	512
Engine-house	625
Engineering and other costs	423

£4,183

There are other items of expense, the amounts of which I am not acquainted with, but I consider that the whole cost has not much exceeded 4,500*l.*, or about 4*l.* per acre. At first, owing to the land having been for all time full of water, and several springs existing, which came from the northern high land and sand hills, frequent pumping was necessary to keep the water in the drains low; but the subsidence of the peat lands, and the draining kept up by the pump, have very considerably reduced the necessity for its use. The rate, including the repayment of the borrowed money, is about 8*s.* per acre. In this case the rate is levied equally on the acreage, and not in proportion to the benefit conferred.

A great part of the area has been ploughed up, and the remainder has become firm pasture, which, in the course of time, will be improved by the disappearance of rushes, flags, and water-weeds. The nearest value that I can arrive at is, that the parts which have been wholly reclaimed are worth, to rent, 30*s.* per acre, and the remainder, 2*l.* per acre at the present time; and this value will doubtless increase. . . .

The "Land Drainage Act, 1861," has hitherto not been applied so extensively as might have been expected, considering the great scope of its powers, and the advantages which result from them if properly called into action. It is, doubtless, well known to you that the old sewers laws could not be made available for the improving and advancing the interests of agriculture in the present times. They certainly impose but light burthens upon lands by way of rates; but the powers are so restricted, the jurisdictions are so undefined, and the governing bodies so varying and irresponsible, and, generally, unconcerned, that they are almost useless for the exercise of extended operations.

But the "Land Drainage Act, 1861," requires amendment in some particulars, with the addition of provisions to make it more applicable to the purposes of agriculture, and that only. The old sewers laws are applicable, as far as they go, both to the drainage of towns and of agricultural districts; for it was not contemplated when they were framed that any distinction between the two would have been necessary; but, of late years, towns and populous districts have well-defined laws of their own, applied under the sanction of a department of the Government, by which the mode of proceeding and method of rating are regulated, and other useful provisions are exercised; but the legislation for agricultural drainage purposes is surrounded by great difficulties and uncertainty; in fact, well-defined provisions are required for many purposes, and

the chief of these is the mode of rating, in which there exists much doubt and difficulty. In my experience of this question of rating I have met with a great variety in the practice and opinions of the several valuers with whom I have come in contact; one has adopted the poor-rate as the basis of the rate; another, an equal acreage rate; and one or two, a rate according to the benefit conferred. Cases of appeal to Quarter Sessions have been referred to me; but I think there ought to be a special rule for this kind of rating. The only Act which in any way refers to this question is the 4 & 5 Vict., cap. 45 (which was merely an amendment Act of 3 & 4 Wm. IV., cap. 22), but in so indefinite a manner as to throw doubt upon it. The correct principle, in my opinion, is that it should be in proportion to the benefit conferred on the various lands by the works; and in Ireland, where the question of drainage and rating is unlogged by sewers laws, the matter is better understood; and at the time of the famine, in 1847, when large arterial works were carried out, they adopted such a system, which is illustrated in the table below.

There is another important question, and that is the power and the means of taking land for new works, or removing mills and obstructions in rivers; but the regulations laid down in the law are most cumbersome and uncertain. There are many other matters, which it would be tedious to enumerate, each requiring amendment; and I am in hopes that in the next Session of Parliament, an inquiry will be instituted into all the laws relating to drainage, and that we shall have a well-defined and simple system of law established expressly for agricultural, arterial, and outfall drainage.

It would be very desirable to include, in any new Act, provisions for irrigation and storage of water, so that they might be either conjoined with or separated from drainage districts; and powers to charge either water rates or rents according to the systems adopted. The system of irrigation is extensively carried out in France, in the districts of Alpes-Maritimes, Haute-Garonne, and Basses-Pyrénées; in Spain, in those of the Canal de Esla, Canal de Henares, and Canal de Logrono; and in Italy, at Milan, &c.

A discussion ensued, in which Messrs. Ryde, T. Marr Johnson, and others took part.

The next meeting will be held on Monday, the 25th inst., when the discussion on Mr. Grant-ham's paper will be resumed; and a paper will be read, entitled "Parochial Assessment," by Mr. Edward Ryde.

found, on the contrary, that it was capable of consuming more smoke than in fact it did; but it was urged in defence that to use the means provided for that purpose would render it impossible to carry on the trade with the furnace in question. The defendant was convicted, but the Court of Exchequer quashed the conviction on the ground that (assuming the furnace to be properly constructed) the words in the local Act "as far as possible" meant as far as possible consistently with carrying on the trade in which the furnace was employed.—*Cooper v. Woolley.*

Liability respecting Footways.—By the Ryde Improvement Act (which incorporated the Towns Improvement Act) commissioners were appointed to carry the Act into execution and were empowered to levy rates and to apply them to specified purposes. By the Towns Improvement Act the management of streets is vested in the commissioners, who are thereby made surveyors of highways. They are by the same Act guilty of a misdemeanour for neglecting to repair any public footway within the limits of a special Act, and are liable to be indicted in the same manner as the inhabitants of a parish. In a case where a person met with an injury caused by a footway within the limits of the local Act being out of repair, the commissioners were held liable to an action, and it was decided that it was not necessary to aver in the pleadings that they had funds applicable to the care of the footway.—*Hartnall v. The Ryde Commissioners.*

Construction of the Words "Tenement" and "Inhabitant."—A manufacturer of edge-tools in Birmingham resided out of the town, but occasionally took his meals during the day at the factory, where his servant-man resided. He applied, under the Improvement Acts, to the town commissioners of Birmingham to remove the ashes, dust, and rubbish arising from the manufactory, but they refused to do so. It was decided by the Court of Exchequer that they were obliged to remove ashes, &c., made from the manufactory. The manufactory was held not to be a "tenement," and the owner was held not to be an "inhabitant" within the meaning of the Improvement Acts.—*Lyndon v. Stanbridge.*

THE CABINETMAKERS OF LONDON.

SIR,—In your issue of the 26th ult. you gave a selection from the speech delivered by the Marquis of Bute before the members of the Cardiff School of Science and Art, in which he makes an indelicate charge of incompetency against the cabinetmakers of London. I allowed another number of your invaluable journal to appear hoping to find some one more competent than myself had replied to the charge therein made, but was disappointed; herein is my excuse for troubling you.

Now, notwithstanding the general excellence of the noble marquis's speech, I must enter my protest against the above statement. I have an intimate knowledge of the London cabinet-makers, and have had years of experience amongst them; and, instead of the above charge being correct, I can testify to numbers of them possessing practical knowledge of detail to carry out any job entrusted to them. I have often found the designs given to the workmen are not practical, and they have to be altered to the requirements of the job,—I do not mean sketches, but as working drawings. I have as workman had the honour and extreme pleasure of carrying out designs in different styles, wholly solid and others richly inlaid, principally Gothic, by Mr. Welby Pugin, Mr. Burges, and others, yet I have never had a single complaint of the jobs whilst in execution or when finished, and for years I have seen art works executed with the same result. Yet, withal, I am perfectly satisfied there is room for great improvements, to produce satisfactory results. It is necessary there should be improved relations between employer and employed—a reciprocity of feeling; but if the employer requires a foreman he advertises,—he selects one from the number of applicants. Cupidity too often prompts him to select the man possessed of effrontery, and the men feel that he is placed over them to extract all that is possible from them. He is generally ignorant of the speciality of the business. He is invested with full power, and he carries it out to the letter. I have seen the best men in a shop discharged without one moment's notice, and no reason assigned to them for the act, yet each and every one of those men mentally and morally were his superiors, and he knew it, never regard-

THE "BUILDERS'" LAW NOTES.

Execution of Public Works.—A certain local Act of Parliament authorises a local corporation when any street not being a highway is not sufficiently sewered, levelled, paved, flagged, and channelled, to give notice to the respective owners of the premises fronting such street, to sewer, level, pave, flag, or channel; and if the requirements of the notice were not complied with, the corporation might execute the works referred to in such notice, and recover the expenses from such owners. In a certain case the corporation gave notice to owners of premises in a street not a highway to "repair, form, and pave the same." It was held by the Court of Queen's Bench, on appeal, that the notice was bad as it did not sufficiently specify the works required to be done, and the order of justices for the payment of expenses was accordingly quashed.—*Parkinson v. The Corporation of Blackburn.*

Ratable Value of a Railway Goods Station.—A certain borough Improvement Act authorising a rate to be levied enacted that the occupiers of any land used only as a canal or a towing-path for the same, or as a railway constructed under the powers of any Act of Parliament, should be rated at one-fourth only of the net annual

value. Certain sidings and turntables, occupying about ten acres of land, were used for loading trucks or carriages with goods, and also as a standing-place for laden and unladen carriages, and were found in a special case to be necessary for conducting the traffic of the railway. It was decided that this land might be virtually considered as part of the railway, and it was accordingly only rated at one-fourth of the net annual value.—*Midland Railway Company v. The Corporation of Birmingham.*

Consumption of Smoke.—Under the provisions of the Towns Improvement Clauses Act, a penalty was imposed on persons so negligently using a furnace as not to consume the smoke arising from it. The Birmingham Improvement Act incorporated this provision, but with the reservation that the words, "consume the smoke," should not in all cases mean "consume all the smoke;" and that the penalty might be remitted if the person summoned had so constructed or altered his furnace as to consume, as far as possible, its smoke, and had carefully attended to the same, and had, in fact, consumed the smoke as far as possible. An information was laid against a manufacturer for so negligently using his furnace as not to consume its smoke. It was not shown that the furnace was improperly constructed; it was

ing his employer's interest. By such treatment men get demoralized, which often causes them to take any advantage that arises. He not being conversant with the details of the style of work necessary to be carried out, is continually thwarting the workman in his attempts to carry out what is so necessary, and plays so important a part in good work. Now, what could he more simple than to select the best man in the shop to fill the office who understands all the requirements of the business? By so doing, there is a stimulus given to men to perfect themselves, and act as a member of the firm, in hope of promotion. Your journal has often insisted upon the necessity that all art-workmanship should bear the names of the producers; but for the full development of art-principles and art-workmanship it is necessary the workman should have a share in the profits, and feel himself a *bona fide* member of the firm, partaking of the honours and emoluments, or losses and disgrace, which his own actions would create or destroy. In your volume of 1865, pages 365, 386, and 514, you treat upon the relations of capital and labour, which would be to the advantage of all to study seriously. Mr. Hughes states, at page 366, "The old relations of master and men have passed away; they will never be satisfied without a share in the profits, and some voice in the internal management of the workshops. But it is to M. Leclair that I should like attention to be drawn, page 514, wherein your readers will find how completely the interests of art are interwoven with amicable relations existing between employer and employed.

WM. WARREN.

CHURCH-BUILDING NEWS.

Birmingham.—The new church of St. Gabriel, situated in Barn-street, in the parish of St. Bartholomew, has been consecrated. The cost of the edifice, including fittings and lands, has been 4,200l. Of that sum 3,000l. were contributed by the Ryland Fund, and the remainder has been defrayed by voluntary donation. The architect was Mr. J. H. Chatwin; and the builders were Messrs. Wilson & Son, of Soho, Birmingham. The whole of the gas-fittings, the church bell, and the communion-table were manufactured by Messrs. Blews & Sons, who were at the same time donors of a brass lectern, a metal reading-desk, and the chairs used in the church.

St. Paul's (Cornwall).—The parish church of St. Paul has been consecrated. The whole fabric was put in repair more than twenty years ago. Some portion of it was then rebuilt, and the same process, as the *Cornish Telegraph* points out, might very well now be applied to the south-west angle, especially after the improvements which have just been effected in the church. In the spring of the year the vicar had a new reredos erected by Mr. Earp, of Lambeth; the style is Perpendicular, in accordance with that of the church. The design comprises a central gable canopy over the holy table, flanked on each side by an arcade of sunken panels in Caen stone, separated by buttresses of two stages. The canopy is cusped and crocketed, and surmounted by a finial. The material is alabaster, the veining being sufficiently light to admit of contrast with the red Plymouth marble of the supporting columns and super-altar. Within is a panel of Salvati's mosaic, having, on a gold ground, the sacred monogram in a vesica, and passion-flowers with their tendrils and leaves on either side.

Warkworth.—The church here has been renovated by the liberality of Miss Horton, the Lady of the Manor, at whose sole expense the restoration has been effected. Mr. Franklin, of Deddington, was the builder employed in the work, under the superintendance of Mr. Charles Driver, Messrs. Heaton supplied the stained-glass window.

Bristol.—The body of Emmanuel Church was built and licensed for divine worship about two years ago; the congregation has continually increased, and so additional accommodation was rendered necessary. Funds (for want of which the designs were curtailed) being provided, the church has been so far completed as to justify its consecration, and the ceremony has now taken place. The additions, says the local *Times*, consist of a chancel and two transepts. The foundations are laid for a tower, 130 ft. high, with belfry story; a west porch and south chapel are also contemplated. Five months ago Mr. Diment, the contractor, commenced the new portion, and now it is completed. Accommodation has been provided for about 230 people more than could previously find room in the

church. Of 614 sittings 100 are free and unappropriated. The fabric, which was designed by Mr. Norton, of London, now consists of a chancel, with an apse, 39 ft. by 28 ft.; two side chapels, 22 ft. by 13 ft.; transepts, 21 ft. by 14 ft.; nave, 84 ft. by 28 ft.; and north and south aisles, 63 ft. by 14 ft. each. It is constructed of local stone, with Bath stone dressings, relieved by bands of red sandstone; and the walls are strengthened with buttresses. The walls are surmounted by a parapet, with a carved cornice. Above the apse is an iron cross and finial, and on the transept gables are stone crosses. Mr. Alderman Proctor gives a tenth of the cost of the additions. The north chapel has been built mainly through the instrumentality of Mr. James Poole.

South Weald.—The parish church has been reopened for divine service. The nave, south aisle, and upper portion of the tower were taken down. The tower was originally built with Kentish rag, and has been restored with the same material, keeping the old lines and details. The body of the church consists of nave and chancel, south aisle, and lay rector's chancel. The additions to the church are the new chancel, organ-chamber, and vestry. The length of nave and chancel, 105 ft.; height to apex of roof, 40 ft.; south aisle, length, 90 ft.; height, 37 ft.; organ-chamber, 14 ft. by 8 ft.; vestry, 15 ft. by 14 ft. The walls throughout are built of flint rubble, with Ancaster stone dressings. The windows are all of the same material. The roofs are of Dantzic fir, quite open. The nave and chancel roofs are of ornamental character. The south aisle roof has been so arranged as to open out the tower arch. The seats are of English oak, plain, and are all open seats. The carving of pulpit, prayer-desk, and stall ends has been executed for the contractor by Mr. Polley, of Coggeshall. Of the stone carvings, which consist of a choir of twelve angels, in white Mansfield stone, several bases and heads were executed by Mr. Earp, of Lambeth, for the contractor. Mr. Earp has also prepared a new reredos, consisting of a series of nine arches, filled in with texts of Scripture. The arches are of alabaster. A new oak porch is erected at the main entrance. The church is heated with hot water by Messrs. Goddard & Massey, of Nottingham. The bells have been re-hung on new oak frames, &c., by Messrs. Mears & Stainsbank, of Whitechapel, London, who have also supplied a new chiming apparatus, to enable one man to chime the whole of the bells. The building is of the Decorated period, and Mr. T. S. Fenton, of London, is the architect; Mr. James Brown of Braintree, the contractor; Mr. Thomas Cressy, the clerk of the works. The works have cost about 7,000l., and have been defrayed by the vicar, lay-rector, &c.

ARCHITECTS' LIABILITIES.

SIR.—Will you kindly favour me with your opinion in your next issue on the following points?

Upon a church restoration there is an architect's clerk of works employed, with the usual powers as to construction of the building, quality of the materials, &c., &c. In the course of the work it is found that a beam would be placed in what the contractor's foreman considers dangerous proximity to a flue, and he called the attention of the clerk of works to it, who gives instructions for the casting of the beam to be delayed until he can see it done. He (the clerk of works) is present on the scaffold, when the beam was cased under his personal supervision, and the work is left (as is supposed) perfectly safe. In a short time after, the church is burnt down from the defective casing of this very beam.

1. Upon whom does the responsibility rest?—the architect, the clerk of works, or the contractor?

2. If an architect, in giving a final certificate for balance of contract and extras, is or is not bound to give an account showing how the balance is made, if it should be demanded from him by the contractor? FAIRPLAY.

* * * If this statement be correct, the contractor is clearly not to blame, but the clerk of the works, for whose acts, if he were appointed by the architect, the architect would probably in law be deemed responsible. This responsibility, however, is a very serious matter, and should have the consideration of architects as a body.

The reply to question No. 2 would depend on the conditions of the contract. Such an account is usually given.

THE NEW MEAT MARKET, SMITHFIELD.

How praise great Jones's work, where men Have coolly swept away each pen? But that this sarco-phagus may endure, From the first butcher's stall I seize a skewer, To tell how Jones, the genius, waved his wand, While Browne and Robinson * obeyed command Like bricks—with bricks. The butchers' palaco
rose
Where once unsavoury odours smote the nose; And for a structure grand, and no Aladdin-myth, Browne, Jones, and Robinson, nurlped the field of Smith!

ACCIDENTS.

Fire at Messrs. Chance's Glass Works.—A fire recently broke out in the glass-works belonging to Messrs. Chance, at Spon-lane, Birmingham. Efforts were at once made to prevent the fire spreading from the box-room to the store-room, next to which is another pile of buildings, said to contain goods worth 20,000l. The place where the fire began was entirely gutted, and the roof of the goods warehouse completely destroyed. The damage is roughly estimated at about 3,000l. The works of Messrs. Chance cover about thirty acres, employ 1,700 people, use nearly 1,800 tons a week, make their own gas, have their own saw-mills, pot-rooms, and clay-mills.

Fall of a Warehouse Floor at Ipswich.—A serious accident has occurred at a new seed warehouse, at the corner of Bridge-street and St. Peter's Dock. The warehouse has not been long completed, and is used for the storage of linseed. It is three stories in height, and consists of a centre and two wings, and it was to the first floor of the centre that the accident occurred. The space below the floor is that into which wagons with loads of seed are drawn, and where they are unloaded, and the main supports to the floor were two wooden beams, each strengthened by an iron girder down its centre: the ends of these rested on four piers of brickwork, two on either side of this part of the building, and the load it was calculated that each beam would support was 200 tons. Several cargoes of seed had arrived, but the quantity placed upon the floor in question did not much exceed half the weight calculated as its full load. Without any warning the iron girders of both beams gave way, the beam furthest from the entrance-gates snapped in two, and that half of the floor with its load of seed fell in, carrying with it the upper part of the two piers, and a small portion of the brickwork of the end wall, but the seed slipping off the other portion of the floor it remained in its place. The accident is supposed to have arisen from defects in the iron girders.

Fall of Two Houses in Liverpool.—In Jamaica-street, Toxteth Park, the Corporation have in course of demolition a block of buildings the removal of which is requisite for certain improvements to be carried out. While the men were at the work of piecemeal destruction, the outer wall of one of the houses suddenly came down wholesale. The remainder of the block fell immediately afterwards, and in the general wreck one of the workmen was buried and severely bruised.

Fall of a Railway Embankment.—On the London and South-Western line, at the western end of the Exeter tunnel, several tons of earth and rock recently fell upon the up-line, which was blocked up during the night. The disaster had been expected for some days previously. Some men were then working at the Honiton tunnel, where a similar catastrophe occurred some weeks ago.

Fall of a Chimney.—On Sunday last two men, named respectively James Fields, brick-layer, and John Flynn, labourer, were killed in Glasgow, by the falling of a chimney-stalk, between 90 ft. and 100 ft. high, connected with the works of Messrs. Robert Fields & Co., Parliamentary-road. The stalk had been deemed insecure, and the men who have been killed were employed, with two others, in lightening the structure by taking 20 ft. from the top. For this purpose cross-stays were erected inside the stalk, by means of which Fields and Flynn ascended to the top, where they removed the bricks, and dropped them down the inside, whence they were removed by the other two men through an aperture which had been formed

* The builders.

of about 5 ft. high and 3 ft. wide. While they were so engaged on Sunday last the stalk suddenly gave way at the bottom.

"CHOOSING THE WEDDING-GOWN."

ART-UNION OF LONDON.

THAN this picture, by Mulready, it would be difficult to find, in the entire range of modern art, and so work more pre-eminently combining skilful composition and drawing with thorough knowledge and masterly exposition of the theory of colour, whether exemplified in harmonious gradation or bold contrast. Though coloured on the warmest scale, the reds are so skilfully toned and so counterpoised by cooler tints, that the whole produces a rich mellow effect on the eye, analogous to that of a judiciously-planted flower-bed of bloom and foliage combined.

The sentiment and composition are no less excellent than the colouring. The exquisitely easy pose of the bride's figure, the *bonhomie* of the old mercer, and the interest with which the young parson watches his betrothed, are all admirably given. The work is full of valuable instruction, both for the draughtsman and the colourist.

When this picture was exhibited in 1846, it was felt that Mulready had given new interest to an old story. That the popularity of the subject has not waned is proved by the number of copies constantly being made of the original in the South Kensington Museum, and the crowd of visitors always attracted to it. Though the "Vicar" says he chose his wife not "for fine glossy surfaces," but "such qualities as would wear well," we must allow him to have been exceptionally fortunate in getting thrown into the bargain the graceful form and sweet face of the damsel before us.

This picture the Council of the Art-Union of London has had reproduced in chromolithography for the subscribers of the current year, and, looking at the extreme difficulty which necessarily attends the production by mechanical means of such a work, we must allow that great success has been achieved by Mr. Vincent Brooks and his assistants. No little artistic knowledge and able management of colour are required to produce, by printing from stone, a similar effect to that of colour laid on by the brush, and when it is known that no less than thirty-four tones have been used for as many different gradations of colour, and that every printing must coincide to a hair's-breadth with all that have preceded, the difficulty of the work can scarcely be over-rated. We may certainly congratulate the members of the society on the opportunity thus afforded them of getting for the amount of the subscription so faithful a transcript of this masterpiece of England's great colourist, besides the chance of prizes.

It is announced that the impressions will be ready for the subscribers on the 1st of February.

DECORATION OF THE GREEK CHURCH IN LIVERPOOL.

At the Liverpool Court of Passage an action has been tried, in which Lazarus Syreloff, a Greek artist, sued Mr. George M. Papsayanni, of the well-known firm of Papsayanni Brothers, of Liverpool, merchants and steamship owners. The declaration in the pleading alleged that the plaintiff was induced by the defendant to come to Liverpool, at great expense, upon the promise that on his arrival there he would be employed to execute paintings for the Orthodox Greek Church now in course of completion in Parliament-street, but that the defendant had refused to perform his promise. There was also a claim for work done. The defendant pleaded, amongst other things, that he had not agreed as alleged, and that the agreement was subject to a condition which had not been fulfilled by the plaintiff. The defendant is one of the committee of subscribers by whom the erection of the church is being superintended. It was thought desirable by these gentlemen to secure the services of a Greek artist for the decoration of the church, and the defendant accordingly communicated with a gentleman residing in the Levant, who recommended the engagement of the plaintiff, then living at Chios. The defendant then wrote to the plaintiff, offering him a free passage to Liverpool, and agreeing, according to the plaintiff's case, to engage him on his arrival here to paint ten large paintings and some smaller ones for the embellishment of the church, and to find him a passage home again at the conclusion of his work, which was to be accomplished by the 1st of July, 1867. The plaintiff came to Liverpool in 1868, in one of the defendant's steamers. On his arrival there he painted a picture for the approval of the defendant and the other subscribers, which the plaintiff asserted was approved by them, but the church not being ready for the reception of the pictures, the plaintiff was not employed. The defence was that Mr. Papsayanni acted only as one of the committee, and not on his own responsibility. It was said that the plaintiff entirely failed to please the artistic taste of the committee. Mr. Basilio Papsayanni, the defendant's brother, then offered him a free passage home, and promised to obtain subscriptions for him. He also

entertained the plaintiff at his own house for six months.—The jury returned a verdict for the defendant, but expressed their opinion that Mr. Papsayanni should give the plaintiff a free passage home. A passage, it was stated, would be at the plaintiff's service any time when he chose to avail himself of it.

THE CHIMES AT BOSTON.

Sir,—I am sorry to notice in your valuable periodical the publication of letters which have for their object an attempt to depreciate the carillons of chimes lately set up at Boston by Messrs. Gillet & Blaud, of Croydon. Being a most disinterested party, I may perhaps be allowed to express my view of such hostile conduct.

As an amateur, I went to Boston last June purposely to see and examine these pebbles. Unfortunately the work was not finished; but I saw quite enough to warrant me in saying that I fully concur with Mr. Denison in what he says as to "the magnificent machinery which has been constructed for producing the chimes—infinitely superior to everything else of the sort for promptitude, certainty, and regularity of action." Indeed, I will go further, though a country parson, from circumstances which need not repeat here, I happen to know the difference between good workmanship and bad—and I question whether it is possible for any parties to turn out a more masterly production. I had no opportunity of seeing the barrels at work, nor of hearing the bells sounded in concert, but I examined the details of the machinery, and tested the tones of the bells individually, and they appeared to me to be of admirable quality and of very sweet tone. If, as it is stated, the big bells and the little ones do not blend together in perfect harmony, the fault may be with the founder, if he has cast the whole set from the same alloy, instead of graduating the proportions of metal according to the size. Be that as it may, and whatever may be said by any hostile critics, I have not the slightest doubt but that eventually the Boston chimes or carillons will not only be the first, but the finest in the kingdom.

It was a saying of my friend, the late Sir Mark Lambard Brunel, whose inventive powers were perhaps never surpassed. "Ah! it is very easy to invent a thing, but very difficult to make it do; and when you have, after much labour and anxiety, succeeded, some ill-natured, jealous person will be found ready enough in endeavouring to run it all down; but, never mind—what is good will prevail, and that's enough for me."

H. T. ELLACOMBE, M.A.

* * * We have from "G. L." a reply to Mr. Walsley's note, but do not think it necessary to print it.

AIR TO HOLLOW WALLS.

Sir,—In last week's *Builder*, I observe a letter from "A. B. C." (page 35), inquiring the best mode to supply air to hollow walls. If we prepare a large quantity of our Patent Damp Proof Course for this very purpose, by connecting holes on the upper side of the slab (beneath the hollow in the wall) with the longitudinal hole running throughout the entire length of slab. The vitrified course thus answers three purposes,—1. Prevents the damp rising; 2. Admits air to hollow walls; 3. Prevents dry rot in the floor timbers. CHASLES LUGGER.

Sir,—In reply to your correspondent "A. B. C.," who asks "if air bricks are necessary to the construction of hollow walls?" I beg to say they are not. A house should not only be dry, but warm in winter, and cool in summer. To insure this the internal temperature should be beyond the influence of external change. An air space hermetically sealed is an effective non-conductor of heat or cold. The introduction of air bricks would promote circulation within the air space, and thus destroy that uniformity of temperature which is so much to be desired. GEORGE JENNINGS.

THE FEVER HOSPITAL AT HAMPSHIRE.

Sir,—With reference to your notice, in the *Builder*, of the hospital about to be erected at Hampstead from our plans, we wish to say that the original estimate was "15,000, exclusive of engines, boilers, and machinery," the cost of which, together with providing for six additional patients, for which we received the instructions of the committee, has raised the total estimated outlay to 17,400, and not to 19,000, as stated. Moreover, no "alterations" have been made in the plans, except those necessitated by this increase in the accommodation, and they are now before the Poor Law Board. The cost will not exceed "172, per bed," but for the purpose of comparing this hospital with other projected buildings of the same class, it must be borne in mind that the "cost per bed" will always have reference to the number of patients under the same "administration," and that as the latter increase in number the cost will be in a diminishing ratio; also that four of our pavilions are "one-story buildings," which, we need scarcely remark, adds to the cost, as does the very considerable fall in the levels of the land. PENNINGTON & BINGHAM.

PROPOSED RESTORATION OF CHRIST CHURCH CATHEDRAL, DUBLIN.

The Dean and Chapter, at last taking steps to put this very interesting building into a decent state, applied to Mr. G. E. Street to advise them as to what should be done, and that gentleman has accordingly made a report on the subject, and illustrated it with plan, section, and elevation of part of the north side of nave. Examining the crypt, he is led to believe that its age is uniform throughout; or, at any rate, there is very little difference. The pointed arch occurs in its construction throughout; and the square piers which support the vaults are almost all chamfered, and the chamfers have an ornamental stopping which is certainly not earlier than the end of the twelfth century.

It follows from this, in Mr. Street's opinion, that no part of the old Irish Cathedral built by Bishop Donat, now remains; and that the Church which we have contains nothing earlier than the work of the English artists who followed the invasion of Stronghow, and who left so many marks of their presence in the beautiful works which they erected throughout the Pale.

"At first sight the planning of this crypt looks so much more like that of a Norman work than of a Pointed building, that it is important to insist upon the fact that, in point of date there is very little difference between the completion of the crypt and the erection of the Church above, and that whatever Church existed on the site before the time of the English Invasion, was entirely removed in order to provide the necessary foundations for one on a large scale. I see no reason whatever to doubt that the whole of the Choir was erected on the same plan as the Crypt, and that from the beginning of the thirteenth century to the middle of the fourteenth it stood unaltered."

The unsatisfactory choir being sound, he proposes to confine the new works to the nave, which is very bad; to build up large buttresses opposite each of the principal columns of the nave to support the clearestory; and to rebuild the south aisle. The estimate of these and other works necessary stands thus:—

"1. I estimate the cost of the south aisle and south arcade and clearestory complete, as shown in my plans, at a sum of.....	47,000 0 0
2. The cost of the alterations in the west end, the new door, window, coping, gables, &c., &c., estimate at.....	1,265 0 0
3. The whole of the works in the north aisle and north side of nave.....	5,000 0 0
4. The groining, &c., of nave (in wood).....	1,320 0 0
5. The cleaning and repairing interior of transepts.....	500 0 0
6. The paving of nave and aisles.....	263 0 0
7. The paving of transepts.....	250 0 0
Total cost.....	£15,935 0 0

Mr. Street's proposition to finish the walls of both aisles and clearestory "with the characteristic Irish battlements" seems to us worth reconsideration: this rude sort of finish scarcely agrees with the fine thirteenth-century work of the fabric.

COMPETITIONS.

Eaton Suburban Church, Norwich.—In reply to invitation seventeen sets of drawings from architects residing in various parts of the kingdom, were received. From this number the committee selected four sets,—two from London, one from Edinburgh, and one from Norwich; and at a meeting of the committee, held on the 7th inst., it was determined to adopt the design of Messrs. Brown & Pearce, of Norwich.

Lincoln County Prison.—The magistrates received twenty designs in reply to their advertisement, and after several meetings reduced that number to three, and then referred the selected plans to Mr. Barnard Hartley, the county surveyor of the West Riding of Yorkshire. Ultimately the design of Mr. Frederick Peck, architect, London, was selected. The committee recommended that a grant of 100l. be made to Messrs. Jones & Lee, architects, London, whose plan appeared second in merit, and 50l. to Mr. Moffat, architect, Edinburgh. The prison is to be built at Lincoln, and will be commenced as early as possible.

Wesleyan Chapel and Schools, Pill, near Bristol. In a limited competition for this work, the designs by Mr. E. A. Lansdowne, architect, were chosen.

DIAPER BRICKWORK.

We have inspected with great pleasure a number of bricks with diapered surfaces, also string courses, and columns, produced under Peter's Patent. Ancient examples of diaper work in brick are well known, but hitherto the few attempts to approach the object have failed, from the great expense of ordinary moulding, and the very prohibitory exorbitant duty formerly imposed on such work. By machinery patented by Mr. H. Pether, bricks with elaborate designs, either in delicate hold relief, can be produced at a moderate cost (6l. a thousand), either from patterns now prepared by him or from designs furnished by architects. Many of these will admit of the introduction of ceramic colour, or the insertion of gilt or other glass. Mr. Pether obtains a small joint, by the contrivance of a recess or kick on all other sides of the brick to receive the bulk of the cement, thus forming a strong union and key.—The Barkham material is particularly sound, and most of the designs already prepared are very artistic. We are disposed to think good use may be made of this invention.

RAILWAY INTELLIGENCE.

Progress of the Railway in the Thames Embankment.—At the meeting of the Metropolitan Board of Works last week, in answer to a complaint by Mr. Shaw, the engineer stated that he had no hesitation in saying that the works of the railway company on the Thames Embankment, if carried on at the present rate, would not be completed in six years. The works in the new street from Blackfriars to Cannon-street had not even been commenced. The interest on the money due had not been paid. Mr. Newton said it was quite time pressure was put on the railway officials to force them to carry on their works. The subject was referred to the works committee for report.

A Dangerous Railway Platform.—At the *Secondaries' Court*, before Mr. Secondary Potter and a special jury, the case of Walker v. The Great Eastern Railway Company has been heard. This was an action in the Common Pleas to recover compensation for personal injuries at the Lea Bridge Railway Station, through, as alleged, a "rotten platform." The damages were laid at 2,000l. The plea was withdrawn and judgment suffered by default. Plaintiff was walking along the platform from a train when he fell into a hole in the platform. He was much hurt, and had since been, and still was, unable to work. The jury assessed the damages at 250l.

PROGRESS IN BELFAST, IRELAND.

ACCORDING to a report made to the Town Council at their last meeting, it appears that since the Belfast and County Antrim Borough Act was put in force the 1st July, 1866, there had been 302 private streets formed and completed—paved and paved—under the Borough Surveyor's superintendence. Since 1861, when the last census was taken, 10,078 houses had been erected, and of these 1,602 had been built during the year which had just expired. The valuation of property had increased in the borough. In 1861, the valuation of the borough was 278,807l., while at the end of the year which has just closed it was 417,329l., showing an increase during the last seven years of 138,522l. The surveyor has been able to accomplish a great many improvements in the other streets of the town. During the year 1,487 new houses had been erected on the County Antrim side, and 1,135 on the County Down side, making a total of 2,622.

PROVINCIAL NEWS.

Bristol.—The new white Lion Hotel, in Broad-street, has been opened for business. The building was erected from designs by Messrs. Foster and Wood, of Bristol, architects; and the structure above the principal floor occupies three sides of a square, so that the rooms enjoy as much natural light as possible, Christ Church, at the top of the street, forming the fourth side. The principal entrance is in Broad-street, where a flight of steps leads to a vestibule and hall, 70 ft. by 20 ft., covered by a glazed roof supported on bays of arches, with pillars and carved capitals. The panels below the roof have been decorated by Mr. Lang, of London, with designs representing the seasons. On the right of the entrance are the coffee-room, 42 ft. by 28 ft.; clnh-room, 47 ft. by 21 ft.; bar, still-room, offices for the manager, &c. On the left is provided a capital commercial-room, 50 ft. by 28 ft., with writing-room and lavatory attached; a restaurant, 48 ft. by 26 ft., approached from a side entrance, with bar and service-room adjoining, fitted up by Messrs. Llewellyn & James. The coffee and commercial rooms abut on the terraces in front of the hotel. Behind the hall, and separated from it by a secondary entrance and passage, is the billiard-room, which can also be reached from Wine-street; the apartment measures 42 ft. by 24 ft., and is fitted up with two of Thrston's best club tables; the scoring apparatus is of the most perfect kind. Adjoining the billiard-room are a smoking-room, lavatory, &c. All the principal rooms on this floor are 16 ft. high. The principal staircase, which is of stone throughout, commences behind the commercial-room. On the first floor are a ladies' coffee-room, 25 ft. by 10 ft., numerous suites of sitting-rooms, and some few bedrooms. The second floor, and also the third, are devoted to bedrooms. The floors are all fireproofed by Dennett's patent construction. At the top of the building, on the lower corner, is an immense tank, filled with

water, which will be available in case of emergency. There is a luggage lift from the bottom to the top of the house, and another for the conveyance of provisions from the kitchen to the bar. An apparatus for supplying hot water all over the house is provided. There are over 200 rooms and about 560 windows in the hotel. The contractors were Messrs. Warburton, of Manchester; Mr. Boulton has done the carving.

Cannock.—The covered market, which has been erected by a joint-stock company, and has been built, at a cost of about 1,300l., by Mr. M. B. Anderson, of Cannock, from designs by Mr. T. Lloyd, of Wolverhampton, has been thrown open to the inspection of the public.

DISSENTING CHURCH-BUILDING NEWS.

Dovenby.—A new Congregational chapel, which has been erected at Dovenby, near Cockermouth, has been opened for divine service. The chapel has been built from the design of Mr. T. L. Banks, of Cockermouth, architect, and is in the Gothic style of architecture, with a high-pitched roof and a semi-octagonal ceiling. The building of the edifice was commenced in the course of last summer, the masonry being let to Mr. Henry Grave, of Aspatia, and the joiner's work to Mr. P. Robinson, of Cockermouth. The chapel has cost about 200l., and is capable of accommodating between eighty and ninety persons.

STAINED GLASS.

Holy Trinity Church, Worcester.—The centre window of the five in the apse of this church has just been filled with a design in stained glass by one who, having had a legacy left him as one of the executors to a gentleman lately deceased, has devoted it to this purpose. The window is by Mr. Wailes, of Newcastle. It is in the Decorated style, and includes three principal lights, each between 9 ft. and 10 ft. high, and stone tracery under the arch. The entire window has been filled with stained glass, the subject being that of the Ascension of our Lord. The figure of the Saviour occupies the upper portion of the central compartment; in those on each side are represented choirs of jubilant angels; while the eleven Apostles and the holy women are variously grouped below. Each light is terminated by a canopy, worked with foliage upon a ruby background. The tracery under the arch is filled with a running wreath of foliage glass in various tints, upon background of ruby and purple.

Miscellanea.

Proposed Margate Pier and Harbour Company.—A Bill for the incorporation of the Margate Pier and Tranway Company has been published. The proposed capital is 12,000l. in 12,000 shares, of 10l. each. The Bill applies for the carrying out of many improvements and the use of certain new powers of various kinds, including power to make specific charges for persons and goods passing along the pier. The Corporation are neutral in the matter. The Commercial Union have resolved that a requisition be sent to the mayor, signed by the burgeses, asking him to convene a public meeting for the consideration of the project.

Lead-poisoning on the Tyne.—The *Lancet* says,—"A valued correspondent reminds us of a fact of which we were not altogether ignorant—that there is a great amount of lead-poisoning involved in the various works on the Tyne. He says 'it is pitiful to see the number of young girls suffering from lead.' It is not improbable that this subject of lead-poisoning will be brought before Parliament. It is of sufficient importance to be a matter of inquiry, whether we consider the suffering involved in lead-poisoning, or the frequently early disablement of the sufferer in various ways."

Gas.—The Staines Gas Company have declared a dividend of 7½ per cent., free of income-tax, for the past year. They are extending their works.—The Bewdley gas consumers complain both of the price and the quantity of their gas, or its quality. The price is 6s. 8d., and they have nothing for that but darkness made visible. This they cannot understand considering the position of Bewdley with reference to coal.

The Liverpool Free Public Libraries Report.—This document has been issued in printed form. It states that there is nothing of special interest to report during the year just expired. The Institution has pursued its career of usefulness, increasing as its treasures increase, and is at present in a thorough condition of efficiency. The Committee regret they cannot report much further progress towards the erection of the permanent Gallery of Art. The Council have sanctioned the outlay of 10,000l., provided the interest and redemption fund can be met out of the penny rate levied under the special act. During the past year the average number of books issued from and returned to the Reference Library has been 1,982 per day, the yearly circulation numbering 565,344 volumes, against 573,774 during the previous year. During the year, 1,973 volumes of books have been added to the Library, viz., 1,686 by purchase, 119 from the Commissioners of Patents, and 68 volumes by donation. From the Lending Libraries, 423,547 volumes have been lent. The total number of volumes in these libraries is 39,035. The circulation has been equivalent to lending each volume ten times in the year; and each reader has had 50 volumes, or nearly one a week. The works of music issued, viz., Operas, Oratorios, Masses, &c., number 3,492 volumes. As regards the Museum, compared with the average of five years, the total number of visitors in 1867-8 is very nearly 10,000 in excess, as shown by the following figures:—Total number of visitors in 1867-8, 463,851; average of the five years preceding 1867-8, 453,914; excess in 1867-8, 9,937.

Manchester Academy of Fine Arts.—The ninth annual general meeting of the members, associates, and students of this Academy has been held in the council-room of the Royal Manchester Institution; the president, Mr. W. K. Keeling, presiding. There was a numerous attendance. The hon. secretary (Mr. Selim Rothwell) read the annual report. The council remarked that they had again the satisfaction of stating an increased success, and a considerable addition of associates and students during the past year. There were twenty-eight members, eight associates, and ten students. The report having been adopted, the president and secretary were again re-elected; Mr. Crozier as treasurer, and Mr. Hadfield literary secretary.

The Law Courts and Thames Embankment.—Mr. Tite, M.P., at the Metropolitan Board of Works, has given the following notice of motion:—

"Whereas it appears by certain public documents emanating from the Commissioners for building the New Courts of Justice that the actual cost of the site purchased in the Strand will amount to 785,000l., and that the additional land now proposed to be purchased, according to Mr. Pownall's estimate, is 668,000l., so that the total cost of the ground will be 1,453,000l., and the expenditure on land and buildings together, as appears from a same document, will be 34 millions, of which 1,385,100l. are proposed to be advanced by Government at 4 per cent. on the security of a redeemable annuity; and whereas the Equity, Common Law, and other Courts could be accommodated on the site already purchased by the Commissioners, that the Probate Court, Masters' and Registrar's offices could be placed on the site afforded by the Thames Embankment, with such supplementary acquisitions as the nature of the proposed building may require, by which means a considerable reduction would be effected in the cost of the land to be taken, and a position would be obtained superior to any in regard to free circulation of air, unimpeded light, and in the facility of access by road, river, or rail,—that it be referred to the Works Committee to consider the extent required for the suggested buildings, the area at present at the Board's disposal, and what additional property would require to be taken adequately to provide for the several offices enumerated; and that the committee be authorized to confer with her Majesty's Government as to their willingness to negotiate for the acquisition of such a site for the purposes above indicated."

Ahley-mills Pumping Station.—The Metropolitan Board of Works has appointed Mr. Usher, who has been engaged in superintending, under the direction of the engineer and assistant engineer, the erection of the machinery, to the office of superintendent of the station, at a salary of 250l. per annum, with house-rent, coals, and gas, and he is to remain on the premises. The Board also determined that the staff at the station and weekly wages to be paid to each shall be as follows:—Four engineers, 36s.; two firemen, 24s.; two coal trimmers, 21s.; four cleaners, 21s.; two oilers (yonths), 15s.; two fishers, 24s.; one smith, 36s.; one hammerman, 24s.; one clerk, 30s.; one lodge-keeper, gardener, and messenger, 24s.; one night watchman, 21s.

Destruction of the Prince of Wales Theatre, Glasgow.—This theatre died the natural death of theatres on Wednesday night last.

Masons Insisting on the Help of Stone-dressing Machinery.—About two months ago a strike was the result of Messrs. Beauland, of Bradford, attempting to use stone steps dressed by machinery at the Idle quarries, near Bradford, and the men returned to work on their employers allowing the men to re-dress, by hand, work already dressed at the quarry by machinery. Messrs. Beauland ultimately insisted on their men dressing the stone for the steps entirely by hand; but his men now insisted that the stones should be partially prepared by machinery at the quarries, and finished by hand-labour at the new buildings. The stone from Idle had, in fact, been found too hard for the labour, in dressing by hand, to be remunerative. The result is a strike on the part of the masons against the use of stone wholly dressed from the quarry.

Presentation of Bells to St. Julian's, Shrewsbury.—Mr. J. J. Peele, town clerk of Shrewsbury and a churchwarden of St. Julian's, has just presented a peal of six fine bells to the parish. The bells were cast by Messrs. Mears & Stainback, and have been hung in the tower of the church, in lieu of a like number of bells anciently placed there and requiring renewal. The mottoes inscribed on the several bells are,—

- No. 1.
"Peace on earth," &c.—Luke, chap. ii.
"My gentle note shall lead the cheerful sound;
Peace to this parish, may goodwill abound!"
- No. 2.
"Our voices tell when joy and grief betide:
Mourn with the mourner, welcome home the bride."
- No. 3.
"May all in truth and harmony rejoice!
To honour Church and Queen with heart and voice."
- No. 4.
"Prosperity attend old England's shore;
Let Shrewsbury flourish, now and evermore."
- No. 5.
"For mercies undeserved this peal is raised;
So may Thy name, O God, through Christ be praised."
- No. 6.
"With deepest tone I call to church and prayer;
And bid the living for the grave prepare."

The New Magdalen Hospital at Strat-ham.—The extensive range of buildings for the new Magdalen Asylum recently erected at the rear of the railway asylum at Strat-ham is now nearly completed, and the inmates at present located in the old hospital in the Blackfriars-road will be forthwith removed to the new institution. The new hospital extends over eight acres of land. A church has been built within the grounds, for the public in common with the inmates.

"The Architecturesque."—At the next meeting of the Institute of Architects on Monday evening, the 18th inst., Professor Kerr is to treat the subject of "The Architecturesque," in continuation, we are reminded, of a preliminary lecture to the Architectural Association fully reported in the *Builder* of March 7th and 14th last.

Schools for St. Luke's District, Gloucester. It is proposed to erect these schools in, and facing, the Stroud-road. The buildings will consist, on the ground-floor, of boys' schoolroom (70 ft. by 20 ft.); girls' schoolroom (50 ft. by 20 ft.); and infants' schoolroom (65 ft. by 20 ft.); with class-rooms attached to each, and with separate entrances; accommodation is afforded for over 450 children. A house for the master is attached to the schools, with offices and yard. The house will contain parlour and kitchen on the ground-floor, and three bedrooms on the first-floor. This portion of the buildings (though entirely separate from the schools as far as communication is concerned) has been made to form a feature in the group. Open and spacious playgrounds are provided. The schools and class-rooms will be 12 ft. high to the wall-plate from the floor, and the timbers of the roof, which are to be exposed to view, will be stained and varnished. The building is intended to be of red brick, with bands of ornamental coloured bricks. The design was prepared by Mr. Alfred William Maberly, architect, Gloucester, under whose superintendance the works are to be carried out; and the estimated cost is 2,000l.

The Slade Bequest to University College. A meeting of the Graphic Society was held at University College, on the 11th inst., the president, Mr. Foley, R.A., in the chair, when several resolutions were passed acknowledging the value of the Slade bequest, and the meeting adjourned with a view to further action. We had intended to refer to the subject of this bequest at greater length, but are forced by press of matter to defer doing so.

The late Dr. Robert Hooke.—We are told that the vicar and some influential inhabitants of St. Helen's, Bishopsgate, have formed a committee for the purpose of obtaining subscriptions for the erection of a stained-glass window in their church, as a memorial of Dr. Robert Hooke, a brief account of whose inventions and discoveries appeared in our columns a few weeks ago.

Viaduct across the Solway.—The Solway Junction Railway is now near completion. The permanent rails between Kirtlebridge and the Solway viaduct are laid, and the station-houses are being erected. The viaduct, which is a fine specimen of engineering, is now finished. The river Wampool is crossed on a viaduct of seven bays. The viaduct is similar to the one over the Solway.

The Institution of Civil Engineers.—At the meeting of this Society on Tuesday evening, the 12th instant, fourteen candidates were elected, including two members, and twelve associates.

Rotherhithe Drainage Contract.—At last week's meeting of the Metropolitan Board of Works, tenders were received for the construction of new sewers in Plough-road, Swing Bridge-road, and Trinity-street, Rotherhithe, and the diversion from the river of the sewage from the Durand's wharf outlets, which varied from 25,450l. to 14,750l., and the lowest, that of Mr. Nicholson, was accepted.

The Builders' Benevolent Institution.—The annual ball for this excellent charity will be held at Willis's Rooms, St. James's, on Tuesday, the 26th of January, under the immediate patronage of the Lord Mayor and the Lady Mayoress. Mr. G. F. Trollope is the President, and Mr. G. Plucknett the Treasurer. Mr. Joseph Bird takes the ball, as usual, under his special care, and will receive applications for tickets up to the 22nd. Such of our readers as like an evening of the sort promised will enjoy it the more, knowing that the profits of the entertainment will go towards rendering easy the last days of distressed age.

Science Classes.—On Friday, the 8th inst., a public lecture was given at the South-west London Science School, Arthur-street, Chelsea, on the "Physical and Chemical Properties of Water," by Mr. Bickerton, head master of the science classes held there; Mr. H. J. Coles in the chair. The lecture (admission to which was 1d. to non-members) was given as the preliminary lesson for the present year to the chemistry class, the object being to show the interesting nature of scientific study and the pleasure and advantages to be derived from it.

A Covering for Staircases.—The wear of staircases is often a serious matter. Whether of wood or stone, with much usage, they soon go. M. Cazean says he has found a durable covering in thin plates of aluminium bronze. It is for the column of the Place Vendôme that M. Cazean proposes his covering. He says the experiment has been made in a factory, where plates of common bronze on the stairs 1 1/2 in. thick were worn out in six weeks, while plates of aluminium bronze 1/2 in. thick remain just the same as when new, after 11 months of service. Aluminium bronze, it would seem, is not so expensive if it will bear this amount of usage. It is merely copper, with from 8 to 10 per cent. of aluminium.

TENDERS.

For pulling down and rebuilding house, for Mr. J. S. Gower, City Horse and Carriage Repository, Barbican. Mr. R. Walker, architect. Quantities by Mr. W. E. Stoner:—

Lark	£1,765 0 0
Brass	1,615 0 0
Hurdley	1,650 0 0
Sewell & Son	1,650 0 0
Prince	1,479 0 0
Kilby	1,358 0 0
Turner & Sons	1,339 0 0

For house, at Upper Norwood, for the Rev. R. Birch. Mr. Sextus Dyball, architect:—

Perry (accepted)	22,500 0 0
------------------------	------------

Accepted for four houses, offices, &c., at Bulrush Mills, Bately, for Messrs. Talbot, Senior, & Talbot. Messrs. Sheard & Hanstock, architects:—

Mason's Work	£613 14 0
Farrar	236 12 0
Iberson	18 0 0
Senior	31 0 0
Hey	

For a cottage, for Mr. Thomas Brown. Mr. John Usher, architect. No quantities:—	
Dickens	£270 0 0
Lawson	230 18 6
Richards	208 18 6

For new infirmary, &c., Stratford-upon-Avon Union Workhouse, for the Board of Guardians. Mr. Thos. T. Allen, architect:—	
Bennett	£2,379 0 0
Dixon	2,195 0 0
Naden & Sons	2,169 0 0
Bayly	2,068 16 0
Hilton	2,065 0 0
Clark & Smallwood	2,000 0 0
Green	1,883 0 0
J. & G. Callaway	1,868 17 9
Holtom & Price (accepted)	1,965 11 6

For new waterclosets, lavatories, drainage, &c., Stratford-upon-Avon Union Workhouse, for the Board of Guardians. Mr. Thos. T. Allen, architect:—	
Denner	£285 10 0
Porter & Co. Callaway	340 0 0
Ham, Martin, & Edwards	385 0 0
Holtom & Price	390 0 0
Horseman & Martin	321 0 0
White (accepted)	286 0 0

For the Acton Main Drainage, Contract No. 6. Mr. E. Monson, C.E., Surveyor to the Acton Local Board. Quantities supplied by Mr. Young:—	
Forrick & Son	21,020 0 0
Smith	779 0 0
Brunsdon	765 0 0
Williams	760 0 0
Robinson	755 0 0
Bloomfield	729 0 0
Robinson	696 0 0
Cricket	650 0 0
Young	613 0 0
Parker (accepted)	603 0 0
Reed (too late)	573 0 0

For proposed villa residence, for Mr. Wm. H. Wishall, in the Fortincales-road, Wandsworth. Messrs. Lee, Brothers, & Pain, architects. Quantities supplied:—	
Nicholson	£4,040 0 0
Van Vliet	3,569 0 0
Edbs & Sons	3,777 0 0
Alastair & Sons	3,669 0 0
Avis	3,669 0 0
Thompson	3,260 0 0

For villa residence, at Calne, Wiltshire, for Mr. G. Harris. Mr. John Watson, architect:—	
Bladwell	£9,128 0 0
Pinnegar	8,269 0 0
Call & Fethick	6,518 0 0
Light & Smith	6,484 0 0

Tenders for Bridge at Moerdijk.—According to the Bulletin for pipe tenders sent in for the construction and erection of the metallic part of a great bridge over the Hollandsche Diep, at Moerdijk, on the Dutch State lines, was that of Messrs. Vriesingen & Van IJel, of Amsterdam, 1,947,471. Among the English tenders sent in for this work may be mentioned the Newcastle-on-Tyne Iron and Coal Company, 241,000l.; the Butterley Company, 224,000l.; Messrs. T. Brassey & Co., Birmingham, 165,322l.; Messrs. Vigoules, of London, 168,750l., &c.

Radnorshire Gaols.—Messrs. B & A. Hamer, builders, Kingston, obtained the contract for enlarging and altering the Radnorshire county gaols at Freestige, for 1,853l.

Springfield Park Estate.—Mr. James Bloomfield says his tenders for pipe sewers was 343l. 2s. 2d., as printed. The rightful discrepancy in the tenders for this work (see p. 36, ante) calls for some explanation. The highest was 992l., the lowest 200l.

We are compelled to decline putting out books and giving addresses. All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. Note.—The responsibility of signed articles, and papers read at public meetings, rests of course, with the author.

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent Garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher."

The Publisher cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES ONLY should be sent.

Advertisements cannot be received for the current week's issue later than THREE o'clock p.m. on THURSDAY.

The Builder.

VOL. XXVII.—No. 1355.

Underground Life.*

VISIT to a coal mine is always extremely interesting, and even exciting, to a novice. The underground workings are reached by the shaft; in a bucket suspended from a rope in some collieries, but on a well-arranged platform with a cage and shield overhead, the whole travelling in guides, in others. An unpleasant feeling is experienced at starting, in the sensation of vacancy which the going down a shaft always produces. The bucket rubs against the walls; the space is narrow, and appears still more so than it really is, on account of the darkness. It is but dimly lighted by the lamps. Water filters through the rock drop by drop, in a fine rain, and now and then the thought occurs that a stone might fall from the wall and smash your head; that the rope, stretched by the weight it supports, and whose oscillations are perceptible, may also break, or the bottom of the bucket come out. In the middle of the shaft the thought occurs of a collision, or of a possible entanglement; but when the obstacle is escaped you breathe more freely, and soon reach your journey's end, happy to have escaped with so little trouble. Visitors sometimes decline to go down the mine in this way, while others cover down at the bottom of the bucket, where they remain motionless through fear, and on reaching the bottom it is actually necessary to turn the bucket over to get them out, and they only recover their senses with difficulty. The miners, on the contrary, make this journey twice every day without a thought of danger; and they laugh and talk in going down, just as an old soldier goes under fire without shrinking, and gallily faces the shower of grape-shot.

Two or three times every four-and-twenty hours, but usually twice, morning and evening, the fresh turn of hands enters the mine. The sight is a curious one; the men press forward in a hody; then, at the sound of the bell, they disappear in crowded groups in the tubs and cages, or down the ladders. They are heard talking on first leaving; but the sound of their voices is soon lost in the shafts, until it becomes merely a hoarse murmur, and only the pale glimmer of their lights is distinguishable.

Prayers are offered up in some Continental mines by the miners before going down; in most mines, however, this is neglected. When they arrive at the bottom of the shaft they separate, and every one goes to his place of work.

In the stalls and working-places where the noise is heard, and where the smell of gunpowder is perceptible, the miners are getting the coal; in the levels the rolly-boys and horses are crowded together, and trains go and come; at the bottom of the shaft it is the noise made in hooking on or unhooking tubs which is heard, and the shouts of the hookers on to the landers

at the pit-mouth. The lamps only shine at certain points, lighting up the faces of the men, the shape of the wagons, and the coal which glistens here and there; the rest is cast in shadow, and yet the whole effect is animated and startling.

The galleries cross each other in all directions, like the streets of a town with many turnings. There are cross-roads and squares; each road has its name and destination, but as there are no sign-posts, a stranger loses his way at first, soon finding it, however, by practice. Some of the galleries, which are long, wide, and well ventilated, form the principal thoroughfares and great streets, constituting the fine quarter of the mine. The others, which are sometimes low, narrow, tortuous, ill supplied with air, kept in bad repair, and liable besides to be only in temporary use, are like the old quarters, which will soon have to disappear. This underground town is inhabited night and day; it is lighted, but with lamps. It has railways, traversed by horses and locomotives. It has streams, canals, and fountains—strong springs of water which, in truth, could be very well dispensed with. There are even certain plants and living creatures which are peculiar to it; and life, as has been said, seems to assume special forms in it. It is the black and deep city, the city of coal, and the lively centre of labour. The inhabitants only live in it part of the day or night to do their work; and the crews or shifts relieve each other two or three times in the course of the four-and-twenty hours. There are not, as might be supposed, either promenades, shops, or houses, and still less resident miners who never see day. Light again when they have once entered the works. The horses only, in some districts, never leave the mine.

Some authors have spoken of men who spend all their lives underground, who are horn and die there, painfully subjected to the labours of the Troglodytes. There are two mines in particular on which the imagination delights to brood—those of Wieliczka and Bochnia, in Austrian Galicia, where they do not work coal, but a rich mass of rock-salt. At the intersection of the galleries the miners have carved out of the solid rock obelisks, columns, statues, and even a chapel. There was no need to pretend that there were in these salt-mines houses several stories high, bazaars, theatres, coffee-houses, hotels, springs and streams of fresh water, and even a windmill! It has been stated that the miners never left these dismal abodes, that they were born and died there. All that is pure fiction. It is not the less true that a large mine in active work resembles in some respects in appearance, and by the animation which prevails in the working-places and the levels, an actual town.

The dangers to life in coal mines are varied and numerous, as every Briton well knows. One of the most fatal is fire-damp; but on this we need not here enlarge. In some collieries it used to be the custom, before the safety-lamp was invented, to light the fire-damp every night. The time is still remembered at Rive-de-Gier, in France, when a man came every evening to set fire to the gas in the mine—to provoke the explosion, in order that the working stalls should be accessible again the next day. Wrapped in a covering of wool or leather, the face protected by a mask, and the head enveloped in a hood like a monk's cowl, he crawled on the ground before firing the explosive mixture, to keep himself as much as possible in the layer of respirable air; for the fire-damp, being lighter than the atmosphere, always ascends to the upper parts of the levels. In one hand he held a long stick, with a lighted candle fixed at the end of it, and he went alone, lost in this poisoned maze, causing explosions by advancing his lamp, and thus decomposing the noxious gas. Having fired any mixture of fire-

damp, he naturally changed his position and walked upright, since the carbonic acid produced by the explosion rapidly formed the lowest layer of air. He was called the *pentitent*, on account of the resemblance of his dress to that of certain religious orders in the Roman Catholic Church. In other mines this brave collier was called the *canonier*. When the fire-damp killed him on the spot, it was said that the canonier died at his post on the field of honour, and that was all his funeral oration. The same person in English mines bore the expressive name of *fire-man*.

Coal mines are liable to take fire and burn even for years. The ignition of the coal, especially in Staffordshire, where, from the peculiar nature of the coal, combustion is not uncommon, has produced surprising effects of alteration in the measures containing the coal. The sandstones have become vitrified, baked, and dilated by the fire, the banks of plastic clay hardened, and changed nearly into porcelain.

In the environs of Dudley there was formerly a coal-mine on fire. The snow melted in the gardens as soon as it touched the ground. They gathered these crops in a year; even tropical plants were cultivated; and, as in the Isle of Calypso, an eternal spring prevailed. It is by somewhat similar means that early fruit and vegetables are grown in the depth of winter in some of the gardens round Paris, where the temperature of the soil and the surrounding air is artificially raised by means of currents of hot water made to circulate in pipes underground.

In another Staffordshire colliery, the firing of which dates many years back, and which is called by the inhabitants *Burning Hill*, it was noticed, as at Dudley, that the snow melted on reaching the ground, and that the grass in the meadows was always green. The people of the country conceived the idea of establishing a school of horticulture on the spot. They imported colonial plants at a heavy expense, and cultivated them in this kind of open-air conservatory. One fine day the fire went out, the soil gradually resumed its usual temperature, the tropical plants died, and the school of horticulture was under the necessity of transferring their gardens elsewhere.

Subterranean ignitions generally only trouble the miner by the mephitic vapours which they give out, and the high temperature which they cause in the stalls.

Falls of ground may be ranked amongst the greatest perils which the miner has to guard against. If the shock be direct, the man is crushed on the spot; or if he escape, it is at the cost of a limb. Masses of rock from the roof, bell-moulds, as lumps of ironstone are called in the figurative language of the colliers, sometimes become suddenly detached without the least warning, from the shales or friable coal forming the roof. These lumps, frequently of great size, falling on the head of the miner, often kill him outright.

In other cases, the wallings and timberings give way under the enormous pressure of the ground.

The danger of underground inundations is as formidable as that of falls of ground. The water accumulates in the mine, in a body, in basins, in actual lakes. The miner keeps it there by dams made of cement or clay—by wooden framework, the different pieces of which are geometrically put together like the stones of a wall or a vault. Equally cleverly devised masonry has been built up in the shafts; and yet the pressure of the water is sometimes so great as to overcome all these obstacles. An old English collier, who believed the earth was alive, compared the veins of water met with in mines to the veins and arteries of the human body.

The proportion of accidents and lives lost to

* *Underground Life; or, Mines and Miners.* By L. Simonin, translated, adapted to the present state of British mining, and edited, by H. W. Brastow, F.R.S., of the Geological Survey. Illustrated with many plates, including chromolithographs. London: Chapman & Hall, 1863.

the number of persons employed, and the tons of coal raised, in 1868, according to our author, was as under:—

The number of accidents involving loss of life in the collieries of the United Kingdom was	837
The number of lives lost by those accidents was	1,484
The number of collieries in the United Kingdom was	3,192
The present quantity of coal raised	1,011,654 tons.
A life was lost for, of coal raised	69,484 tons.
Tons of coal raised per separate fatal accident	117,837
Persons employed per separate fatal accident	374
Persons employed per life lost	216
The number of coal-miners in Great Britain	329,663

The accidents, when analyzed, are annually as follows:—

By explosion of fire-damp	149.6
By falls of roof	44.9
By falls, &c., in shafts	147.9
By sundry causes	190.1
	1009.3

It is remarkable that in the confined and sunless atmosphere in which the coal-miner lives half his time, he contracts few special maladies; nevertheless, in the course of time the bad air impoverishes his blood and causes anæmia, while the dust arising from the coal produces dangerous affections of the chest and lungs. On the other hand, the miner is sheltered from the inclemency of the weather, from cold, wind, and rain, and is more favoured in that respect than the out-door labourer. He has, nevertheless, to be careful not to take cold on leaving the mine, and to observe certain precautions when he has to work in water. Now that the long ladders have been nearly all done away with in coal-mines—though not so in metallic mines—and with them the serious lung-diseases which they induced, it may be said that, accidents excepted, the most formidable enemy of the miner is rheumatism. It is accidents only which expose the miner to a thousand perils, and which cause death, as it were, to marob incessantly by his side.

The managers of collieries generally watch over the safety of their men with a paternal solicitude. Sick-funds are everywhere established, and supported by subscriptions, and by the produce of fines, which are imposed at every mine whenever any of the standing rules are broken.

The sick-clubs, which are now generally being introduced into the collieries of this country, are under the management of the miners themselves.

The coal production of the globe in 1866, according to M. Simonin, was as under:—

United Kingdom (England, Ireland, and Scotland)	101,630,544
Other countries of Europe	17,000,000
Prussia	11,200,000
France	12,000,000
Austria	4,000,000
Saxony	4,500,000
Hesse, Bavaria, Hanover, Russia, Spain, Italy, &c.	4,000,000
North America	50,800,000
Other countries of the globe	15,000,000
India, China, Japan, Australia, &c.	3,000,000
	68,800,000
Total	170,430,544

See England (2) (continues M. Simonin). "Coal does not merely furnish the indispensable aliment of the factories; it serves beside to freight ships. Should coal fall elsewhere, England alone could supply the world. She exports at this time more than nine million tons, the eleventh part of her entire produce. It is by means of their coal depots that the modern representatives of the old Phœnicians mark their maritime hitting places on the globe; and it is partly for the supply of their steamers that they transport coal from one hemisphere to the other. In the Mediterranean they are everywhere, especially at Gibraltar, Malta, and Alexandria; in the Red Sea, at Suze; in the Indian Ocean, at Aden, the Mascarets, Natal, Mozambique, and Zanzibar; then at Muscat, Bombay, Madras, Ceylon, Calcutta, Rangoon, Singapore, and the stations in the China and Japanese waters; in the Atlantic Buenos Ayres, Monte Video, Rio Janeiro, Bahia, Pernambuco; and at the Azores, Madeira, the Canary Islands, Ascension, Saint Helena, the Cape of Good Hope, on the coasts of Guinea and Congo. All these stations, all these anchorage, have stores of English coal; so has the entire archipelago of the Antilles, especially Cuba, Jamaica, Saint Thomas, and Colon-Aspinwall. Along the coasts of North America—at Quebec, Halifax, Boston, and New York—the British Colonies and the energetic Yankees compete with each other in supplying coal. In the Pacific it is Panama, Guayaquil, Callao, Arica, and Valparaiso which the coal-ships visit; and on the opposite parallel in the northern hemisphere, San Francisco, the Queen of the Great Ocean, the Gulf between the Indian Ocean and the Pacific it is the great island Australia, which of itself forms a section of the globe. The globe now belongs to those who can supply her with coal; and, as a celebrated statesman said in the House of Commons, all the nations which are without combustible minerals are the vassals of England.

Europe, even, cannot dispense with the services of the United Kingdom. If nature in the formation of coal-fields has favoured England at the expense of the other countries of the Old World, the greater number of the latter are, notwithstanding, possessed of Carboniferous deposits, which they work with greater ardour; still, what is required to make the production equal to the consumption is derived from England. Here, again, we see the British coal-ships make their appearance, not in the Mediterranean only, where we have already followed in their wake, but along the coasts of the Atlantic, of the English Channel, of the North Sea, and the Baltic. France herself is in this respect the tributary of Great Britain."

The excellent work of M. Simonin treats chiefly of coal-mines, but also to a considerable extent of metallic mines and surface works; and the volume is concluded with a briefer account of mines and other works which yield precious stones.

In speaking of metallic miners, he says:—

"The miner in metal, like the coal-bearer, occupies a distinct place, and is marked by peculiar characters in the great family of workers. He constitutes the true type of miner, a sort of subterranean pioneer, a type more varied, and of yet greater originality than that of the collier. In coal-mines a certain sort of family likeness prevails, the same discipline distinguishes the works, the strictness of the regulations in force in each district is the same, and these deprive the workman of a portion of his local habits and customs. In metal-mines, on the contrary, the depôts are dissimilar, and each of them has a special mode of occurrence, necessitating different systems of working; and the discipline also is less exact. Lastly, while the ordinary way of mining for coal is scarcely a hundred years old, some of the metal-mines have been worked for ages as they are now worked. In each of them the workman has retained, as it were, the stamp of the ground—peculiar manners and customs."

It may be useful to quote the following passage from remarks on the purity of gold:—

"Analyses of some Specimens of Gold from Mines."

	Composition in a thousand parts.		
	Gold.	Silver.	Iron, copper, &c.
Siberia ... {Altai,	980	20	—
Ural,	950	50	—
Australia	940	60	—
Northern mines	900	100	—
California {Central mines	800	198	2

This table shows how the character of the gold varies with the country which produces it, and how it often differs from that of the gold which is coined or worked. The standard gold coin in England, by an Order in Council issued in the reign of her present Majesty in 1855, is made of an alloy consisting of twenty-two parts of pure gold and two parts of alloy, the alloy being an indefinite proportion of silver and copper. The standard for gold used by jewellers and goldsmiths (hence called jewellers' gold) is 18 parts of pure gold in 24 parts of alloyed metal (called gold of 18 carats fine); but articles of plate and jewellery may also be wrought of 9, 12, or 15 carat pure. In France the proportion is 9 parts of pure gold to 1 of copper for gold coinage, and 7½ of pure gold to 2½ of copper for the gold employed for jewellery and goldsmiths' work. It need scarcely be added that the object of alloying the gold with copper is to make the precious metal harder and less liable to wear.

Like most metalliferous substances, precious stones are generally met with in veins or simple fissures, and even in cavities, which either traverse or occur near eruptive rocks. Sometimes they are found disseminated through the rock itself. Most gems are considered to have been produced, like metallic ores, from aqueous solutions and hot vapours. Time, repose, and the means being favourable, sparkling crystallizations are the result, and the gem slowly appears, crystallizing itself out from the surrounding rock in which it originated. Volcanic lavas have given birth to some gems.

The British public are in no small degree indebted to the translator of this instructive and valuable work for adapting it to the present state of British mining; and also for reducing the somewhat high-flown and romantic style of the original, which nevertheless gives a minute and practical account of mining throughout the world by an experienced miner.

The work is well printed, on excellent paper, and contains 10 fine chromo-lithographs of metallic and other minerals, precious stones, &c., with 100 uncoloured engravings on wood, and 20 valuable geological maps.

THE RAILWAY PROSPECTS OF 1869.

The railway returns of the Board of Trade afford to any one who is at the same time practically familiar with the subject of railways, and apt at analysis, the means of arriving at very important results. To a very great extent inductions and analyses have been already brought

before the public in the pages of the daily press. There is one mode, however, of investigating the subject which no publicist, so far as we are aware, has attempted. It is one that leads to very important conclusions. We are happy to add that they are little less encouraging than they are important.

Eighteen years of railway history are summarily compared in the analyses of the report. In the year 1849, when the comparison commences, the sum, in round numbers, of 230,000,000 sterling had been expended upon 6,000 miles of railway, which had then been constructed at a cost exceeding 38,000l. per mile. The gross receipts for that year were hard upon 12,000,000l. sterling, or 1,957l. per mile, and the number of passengers carried was nearly 69,000,000.

At the expiration of nine years—that is to say, in 1853—the capital had been increased 41 per cent. The length of line open had been increased 53 per cent. The gross receipts had doubled. The receipts per mile had increased 35 per cent. The passengers had rather more than doubled.

At the close of the second period of nine years, or in December, 1867, the capital had increased 54 per cent. on that of 1853, or 111 per cent. on that of 1849. The length of line open had increased nearly 60 per cent. on that open in 1853, and 136 per cent. on that open in 1849. The gross receipts had increased 64 per cent. on those in 1853, and had more than trebled (333 per 100) those of 1849. The earnings per mile had increased 91 per cent. on those in 1853, or 45 per cent. on those of 1849. The passengers had increased 106 per cent. over those of 1853, or 315 per cent. on those of 1849.

The great difference in the rate of increase, in every item, between the first and the second of these two periods, is much more striking when we compare the cost at which the additional mileage was constructed in either case. The 3,500 miles constructed in the first nine years averaged 27,400l. per mile, and reduced the cost of the entire net of railways to 34,300l. per mile. The 4,700 miles constructed between 1853 and 1867, cost 37,100l., almost exactly 10,000l. per mile, or 36 per cent. more than those of the former period; thus increasing the total cost of the entire system to 35,300l. per mile.

It is thus plainly evident that the railways of this second period were at once more expensive and less remunerative than those of the first. They cost within 1,000l. per mile as much as did the railways prior to 1849, by the construction of which we had to obtain our knowledge of an entirely new system of engineering, and in the cost of which the price of that experience was included. It is true that the heavy cost of the expensive metropolitan termini, and internal links, is included in the latter term. But while this will do much to account for the increased outlay, it may, on the other hand, be expected to have contributed in equal proportion to the increase in the sum total of receipts, and in the numbers of passengers.

During the second period, therefore, from 1858 to 1867, the 4,700 miles of railway, constructed at the price of 37,400l. per mile, while increasing the running length of some by 60 per cent., only increased the gross receipts by little more than the same proportion. A closely similar proportionate increase of length (53 per cent.) during the former period, at the cost of a third less per mile, had allowed the receipts earned at the commencement of the time to be doubled. How much this difference was attributable to circumstances beyond the direct control of the projectors of the various lines, it is not now our purpose to inquire. The facts themselves are sufficiently striking.

Had we been destitute of the experience due to a more sober period of constructive industry, the fact that in eighteen years, by increasing our railway net to the extent of 136 per cent., we trebled the receipts, and more than trebled the number of passengers carried at the commencement of that period, would be enough to lead us to form no contemptible idea of the energetic growth of the great industrial interest identified with the new system of transit. The facts are of extreme significance; and the deduction that, if wasteful extravagance is avoided, a gradual improvement in the returns and dividends of the railway property of the country will take place, is hardly to be avoided.

There is another aspect of the question, of even more immediate practical interest, as to which the returns now before us do not afford the means of so complete an analysis; but to which it is not easy to attach too much impor-

We have seen that the present mileage returns of railway traffic results in an average loss, regard being had to the interest proper to be paid on capital. We see further that the traffic now actually carried on may be grouped into four classes, namely, the three classes of passengers, and the goods, minerals, and cattle; and that, in approximate numbers, these groups earn the respective rates of 30s., 15s., 8s. 8d., and 3s. 6d. per ton. It is true that to obtain the full value of the experience of 1867, we should take into account the mileage both of passengers and goods, as well as the total numbers of the former, and the tons weight of the latter. But without going into this nicety of detail (which the anxious manager will, no doubt, do for himself), it is palpable that there is a very remarkable connexion between the character of the traffic and the net earnings of the railway.

Taking the cost of 6s. per train mile as normal, we have given reason for estimating the mileage of the express trains at 8s. 1d. per mile for the speed of 40 miles per hour, and 10s. 3d. per mile for a speed of 50 miles per hour; these prices to cover deterioration of property and 5 per cent. dividend. Allowing for the extra quantity of tare per ton of first-class passengers, it is pretty evident that there could be no loss in conveying them at express speed, if trains were especially devoted to their service—a point which it is clear that some of the companies have endeavoured to establish. The disproportion between the fares and the accommodation of the first and second class passengers is one of the greatest anomalies in our present system. The difference in the cost of conveying the two classes, at the same speed, is, on some lines, inappreciable. Again, on other lines, the distinction between the second and the third classes is little more than nominal, except in fare. That the public are arriving at a similar conclusion is indicated by the fact that the second-class traffic has diminished $\frac{3}{4}$ per cent. during the year 1867, while the first-class traffic has increased $1\frac{1}{2}$ per cent., and the third class has increased 5 per cent.

If, then, we cannot regard the first or second class traffic as conducted on such disproportionate terms as to cause loss to the shareholders, the question lies between the third-class traffic and that in goods, minerals, and the like. It is only necessary to compare the earnings per ton of each class of traffic in order to see where the really weak point in our system lies. The conveyance of a ton of third-class passengers, on the gross average, produces for the carrying company 244 per cent. more than the conveyance of a ton of goods. The tare on the conveyance of the former is more than on that of the latter, but all other elements of expenditure are less in the former case. Yet it is this important traffic which it is the general object of railway management to discourage as far as possible, with the futile hope of driving passengers to pay higher fares; while the exertions of the traffic agents in obtaining goods to transport have been so successful as to cumber our railway lines with 54 per cent. of entirely unremunerative traffic.

The subject presses for the attention of every railway shareholder, more especially from the fact (to which we have before alluded as imminent) that not a few of the main trunk lines must shortly be doubled, if they are to continue to increase both their passenger and their goods traffic. It is difficult to come to any other conclusion, from the facts before us, than that the bulk of the mineral and goods traffic is carried on at a loss. Canals in some parts of the country are falling into ruin, which might resume their former activity, to the great profit of the proprietors of the railways, who are, in many cases, also proprietors of the neglected canals.

Without attempting to dilate upon individual instances, without saying more than that the figures of the Board of Trade returns indicate certain points as demanding very careful and very honest investigations, we invite our readers to draw their own conclusions from our analysis. The entire railway traffic of the country is now worked at a loss, considering the fair rate of interest on the money expended. More than half of that traffic, measured by its money returns, involves the transport of five times the net weight of the traffic that earns the other 46 per cent. Making an allowance for the tare, and considering that the extra price, which now, in a somewhat invidious manner, is charged for a cushion or an arm-chair, may be fairly and properly proportioned to the speed at which the traveller chooses to be conveyed, the

disproportion is startling. To reverse the system of the late period of railway decline; to cease to strangle the legitimate canal traffic with the donkey result of ruining the canals and impoverishing the railways; to regard the third-class passenger as the staple customer of the latter, when conveyed at a moderate speed, are the points which seem, as it were of their own accord, to emerge from the sea of figures presented by the report of the Board of Trade.

The increase of traffic receipts in 1867 over those of 1868, is 1,315,000l. This is accompanied by an increase of mileage. But, as we have before seen that, in eighteen years, an increase of 136 per cent. in mileage was accompanied by an increase of 333 per cent. in receipts, we are justified in calculating on an average increase of 3 per cent. per annum, independently of any augmentation of mileage. This is equal to an annual increase of 1,200,000l., of which, according to the experience of 1867, 600,000l. would go to dividend. But all the ordinary railway stock existing at the end of 1867, amounted only to 233 millions sterling; 269 millions of capital existing in the form of preference stock and debentures. It is not, indeed, the case that the whole of this preference stock now receives its guaranteed dividend, and the profits of several years may be swallowed up before the condition is fulfilled. Still, it is to be noted that a steady increase of earnings, applicable as dividend, at the rate of 600,000l. per annum must exert a very transforming influence on the value of railway property and lower the rate of interest on all terminable loans. Apart from any increase of profit which may be anticipated as likely to result from a revision of the traffic system, such as above suggested, the natural growth of income will, in little more than three years, add nearly one-half per cent. to the gross amount of dividend. In nine years that average dividend promises to amount to fully 5 per cent. That the net income applicable to the existing railway capital of 502 millions will amount to 5 per cent. by the close of the year 1876, is one of those anticipations on which we are as fully justified in relying, if we experience no return to our past insanity, as on any inference to be drawn from the analysis of carefully-collected statistics.

SPECIAL INSTRUCTION IN ART.

FELIX SLADE'S LEGACY.

The late Mr. Slade, of Lambeth, has left to trustees and executors 45,000l., in trust, that with so much of that sum as may be sufficient for the purpose, not exceeding altogether the sum of 35,000l., they may found and endow, within two years after his decease, three or more professorships for promoting the study of the fine arts, to be termed the Slade Professorships of Fine Arts; one of such professorships being founded and endowed in the University of Oxford, another in the University of Cambridge, and one or more in the University College of London, the amount of the sum to be expended in founding and endowing each of such professorships being in each case at the discretion of the trustees; it being also at their discretion whether the sums shall be equal or unequal in amount. They are also, out of the same sum of 45,000l., to found and endow, within two years after his decease, six exhibitions or scholarships of fine art, to be called the Slade Exhibitions or Scholarships, each to be of 50l. per annum in amount, and to be in connexion with University College, London, and to be given to students in the fine arts, under nineteen years of age, for proficiency in drawing, painting, or sculpture; and to be held by each student to whom an exhibition or scholarship shall be so given, for not more than three years. Any surplus of the sum of 45,000l. bequeathed, the trustees, within five years after his decease, are to apply in such manner as they shall think fit for the encouragement, benefit, and advancement of the fine arts in England; and every part of such surplus which shall not be so applied within the same period of five years, is to fall into his residuary personal estate.

The University College committee having referred, the trustees were informed of the considerations which pressed upon the committee, as thus:—

"1. Our Committee considered that the acceptance of Mr. Slade's bequest, and particularly of that part founding scholarships for students in drawing, painting, and sculpture, would impose on the College the duty of affording such instruction as ought to be given to students who are following the fine arts as a profession.

2. We thought that the academical education in Uni-

versity College of professional artists would require the establishment of a separate faculty or department. We have now two faculties, those of literature and of medicine; we should then require a third, a faculty of fine arts, with its separate classes and teachers.

As we now find to some extent, with reference to our present two faculties, we should certainly then find to a much greater extent, with reference to a new fine-arts faculty, that many of our existing chairs (or professorships) would be eminently fitted for giving instruction to fine-art students on subjects important to such students, and yet at present not taught to them at all, or very insufficiently taught. Indeed, it seemed to our Committee, as far as we at present understand the matter, that a faculty, or college, or school, for the education of professional artists, could scarcely be well carried on unless in connexion with complete schools of literature and medicine, such as University College aims at maintaining."

Mr. Edwin Field, on the part of the committee, set forth various points that presented themselves for consideration, and asked as an immediate question:—Will the executors be disposed to found a "Felix Slade Faculty of Fine Arts" in the College for the education of professional artists, the schools of this faculty to have their own appropriate buildings, such buildings hearing of course Mr. Slade's name?

"Such a faculty in connexion with complete schools of literature and medicine does not, I believe," says Mr. Field, "exist in Europe. In the eyes of artists it would be a most noble and useful institution." The difficulty seems to the committee to be this, that while the single professorships to which each of these Universities is confined, would certainly be each a professorship, not for the instruction of artists, but one aimed at inducing the general students of those Universities to take a greater interest in art; the provision pointing at an indefinite number of professorships at University College, and at an unequal division of the funds, and also at the scholarships to be established at University College, points at the institution of a complete system of fine-art education at the college. Mr. Field thinks it necessary to point out (though probably it is not material where the executors have such large discretion as Mr. Slade's have) that architecture may seem to have been omitted by Mr. Slade from the benefits of his bequest:—

"Our Professor of Architecture (Mr. Hayter Lewis) rightly suggests, however, that it should be pointed out that drawing (one of Mr. Slade's three objects) is as necessary for the architect as for the painter. He tells me that there is a great desire on the part of many eminent in their interest for promoting architectural education, that students in architecture should study drawing from the living models, and receive a more artistic education generally; for which purpose a committee has recently been appointed by the Royal Institute of Architects."

Some of the artistic bodies of the metropolis have already passed resolutions, as our readers have been informed, recognising the importance of the bequest and the desirability of securing it. At the meeting of the Graphic Society Mr. Cave Thomas spoke on the broad question. Some of his observations we may usefully reproduce. He said: "It appears to me that if the Royal Academy could have in any way joined issue with the great objects of the Slade bequest, it would have been one of the greatest events of modern times, no less than that of initiating a great educational reform. For it is not only in its important special educational hearing that I regard the Slade bequest, but as offering the means of introducing the training of the most important of the senses into the curriculum of a general education. Consider for a moment the vast amount of impressions received through the sense of sight, and yet that our established system of general education takes no cognizance of the importance of training the eye to observe, to see correctly. True education is not to ' cram ' all kinds of information into a student, but to educe, to develop the true human nature, the whole manhood. This, therefore, appears to be our very strongest ground of appeal to the executors. For although we may all feel the great novelty and importance of the boon which the Slade bequest offers specially to the Fine Arts, we must also acknowledge the equal or greater boon which it offers to the cause of general education. And my own opinion with reference to the policy which University College should adopt with reference to the bequest is, that the educational motive should be its starting point; for in effecting a reform it behoves us to be political economists,—to effect the change we desire gradually, so that the inconveniences of change be reduced to a minimum—not, however, for a moment losing sight or grasp of the ultimate purpose. The sudden establishment of a great school of art solely for the education of painters, sculptors, and architects, notwithstanding it should offer greater advan-

tages than other schools, might have the effect of raising more artists than the State requires, and he the source of great disappointment; for where, at present, is the work demanding this highest education of the artist? You will, perhaps, agree with me, that as yet it does not exist. But why does it not exist? I answer, for this simple reason, that æsthetic training has no standing in our accepted educational system. Make art an element of education by utilizing the Slade bequest at Oxford, Cambridge, and University College, and the foundations of our appreciative feeling for art will be laid, which will create the demand for that monumental art which requires the highest education of the painter, sculptor, and architect. Meanwhile, the art student would gradually learn the advantages of pursuing his special and general studies *parsi passu* under one dome. Thus, by a system of gradual development and growth, facilities of the fine arts would by-and-by be established without exciting that animosity and opposition for which great pretensions, no matter how reasonable or well founded, are often, unfortunately, the mark in this too jealous country."

The first point is for the University to secure the bequest. Mr. Field's remarks seem to suggest the probability of a delay that might endanger it. An opportunity to advance the artistic education of the country now offers itself that ought on no account to be missed.

PROFESSOR KERR ON THE ARCHITECTURESQUE.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The adjourned meeting of this Institute took place on Monday evening last, Mr. Charles Barry, vice-president, in the chair.

The chairman announced in terms of deep regret the decease of Mr. Arthur Ashpitel, past vice-president and member of the council, the intelligence of which, he said, had only reached the council during their sitting that evening; also of Mr. Geo. Smith (follow), of Frederick's-place, Old Jewry, who was personally well known to many members of the Institute. Among the donations announced was that of Mr. James Fergusson's folio work "On Tree and Serpent Worship," illustrative of mythology and art in India, presented by the author, a sumptuous book, embellished with numerous photographs. A letter from Mr. Fergusson was read, announcing his resignation as member of the council of the Institute, the retention of which office he considered incompatible with the appointment he had recently accepted of secretary to the Board of Works. The chairman took occasion to remark, that the appointment of Mr. Fergusson to that office could not but be most satisfactory to the public, and was an event of peculiar interest and gratification to the architectural profession at large.

Mr. Abel G. Clifton, of Great George-street, Plymouth; Mr. James Joy, of 112, St. George's-road, Southwark; and Mr. George Vials, of 15, Great James-street, Bedford-row, were elected associates of the Institute.

A conversation took place (introduced by Mr. Chas. Fowler) relative to the steps proposed to be taken by the council in connexion with the amended Building Act, to be introduced in the next session of Parliament. It appeared that a report had been made to the council by a special committee, to whom the provisions of the Bill had been referred for consideration, upon which a draft report had been prepared by the council, with a view to its being submitted to the Metropolitan Board of Works, in accordance with a communication from that body. Mr. Fowler, Mr. David Brandon, and other members, thought it desirable, that before any formal step was taken on the subject in their corporate capacity, the Institute should be made acquainted with the views of the council as embodied in their draft report, and that an opportunity should be afforded them of discussing the provisions of the Bill at a special meeting to be held for that purpose. After some talk it was agreed by resolution of the meeting that the draft report of the council, together with a report adopted by a committee of district surveyors, should be printed and circulated to the members, and that the subject should be discussed at the next meeting of the Institute.

Professor Kerr then proceeded to deliver a discourse entitled "A Development of the Theory of the Architecturesque," in continuation of a preliminary lecture to the Architectural Associa-

tion (*vide Builder*, March 7th and 14th, 1868). The Professor commenced his address by remarking that during the last twenty-five or thirty years, as was well known, one speculation after another had been submitted to the public and the architectural profession with the view of determining the proper principles of architectural art, and of supplanting certain other principles which were supposed to prevail. Those speculations at first were grounded upon the supposition that we previously possessed the material with which to deal in design; that is to say, that the rules of the examples of antiquity, and the precedents of former practice, were to be regarded as the data. Later in the day they had a different idea set up: they were called on to look to nature and set aside mere precedent. They were called on to repudiate copyism, and to design for themselves. They had even been invited off-hand to devise any number of new styles to suit any number of occasions. Little came of all this: and more lately still they had had an entirely new character of speculation set up, which he might call the poetic sentiment; and they were now invited to discard gross and every-day notions, and to rise to sublimated and refined ideals, while those who called upon them to do so were not always able properly to explain. On this point he contrasted the dicta of two celebrated advocates of a new state of things in order to start the subject he had to lay before them. He found in the edition lately published by their friend, Mr. Wyatt, of the old *Gwilt* of early days, an apparently excellent dissertation on Medieval architecture, and what he wished to lay before them was what appeared introductory to the principles of Pugin on one page, and those of Ruskin on the other. Having quoted these passages, Professor Kerr went on to remark that they had here the views of two muscular writers, both thoughtful men, well versed in strong language, and hard hitters. In one they had the views of the practical architect, in the other those of the speculative enthusiast. The contrast was singular, and would serve to illustrate with effect the argument he had to use.

Some present might be reminded that not much more than half a century ago a somewhat similar bewilderment existed in the sister art of painting, and it was a singular fact that that bewilderment was very much dismissed by the apparently simple proceeding of the introduction of a new phrase. It often happened that a word which it promotes an idea and becomes accepted, served to bring disputed points to a distinct and definite issue; and he thought in the present condition of architectural philosophy they were in a position to introduce a corresponding phrase to that which was introduced on the former occasion in the art of painting, and by the using of the word "architecturesque," if they could understand and agree upon its meaning, to simplify the position as regarded the art as much as the word "picturesque" had served to simplify matters in the art of painting in this country.

The question he had to propound this evening was this. Is there in the art of architecture a certain artistic essence which is peculiarly its own? They would look at a building—suppose it a perfect work—the structure all that could be devised for propriety, and in accordance with the advancement of the age; and yet, when looked at by the artist, that building should happen to be simply dead, devoid of everything like vitality, and dumb with regard to anything like speech. But the artist should put his pencil over it, and, like an enchanter's wand, it should produce in every touch a manifest vitality, until at the last that which was dead was instinct with perceptible life, and that which was dumb spoke a positive and fascinating language.

Now what was this that was added? That upon which this process had been performed was building, the result architecture. Between the two lay something, and that he called the architecturesque. They might call it "dress." Not that he desired to suppose that architecture was clothing. It was an immaterial dress—call it embellishment. A few months ago he had occasion to deliver a lecture before a kindred society, and he chose this subject, and he then contented himself with endeavoring to establish the necessity for the recognition of this special artistic quality and the propriety of defining it by his phrase for the sake of formula. He did this, he said, in order to introduce it to the architectural reading public, to see if it was contradicted before he presumed to introduce his theory in a more advanced state. He had hitherto not been contradicted, and therefore he considered he

was so far entitled to their indulgence if he considered he was permitted, in the absence of contradiction, to use the word "architecturesque" without further definition or explanation.

His next step was to point to a few examples of the introduction of the architecturesque, or the expenditure upon building of that desire which was implanted in the human intelligence for ornamentation—that desire which of itself more than any other separated man from the lower animals. Professor Kerr proceeded, by illustrations exhibited, to point out the gradual stages of the introduction of the architecturesque as shown in the development of the column from the rude trunk of a tree up to the Greek Doric order, which, he said, might be regarded as almost the simplest of all architectural contrivances, yet so refined that it still retained its hold upon them as one of the most perfect. He next proceeded to point out the development of the architecturesque in the arch. The origin of the arch, he said, was not generally properly understood. Most people supposed that the curve of the circle was the form that originated the structure of the arch. Nothing was a greater mistake. The origin of the arch was simply in timber strutting. The same principle was exhibited in stone struts, and he was of opinion that the pointed arch as a principle was older than the semi-circular arch; he did not mean as an ornamental detail, but as a principle of construction. The development of the cornice and the stylobate was also followed out.

Before proceeding next to trace the development of architectural design, or the architecturesque historically, he would say a word on what he called spurious architecturesque. This, he said, was emphatically their present fault as architects, and it was this which was bringing down upon them one new broom after another, proposing to make a clean sweep of all of them, and set up something else. The reason for this was that they had been educated in the superficial rather than the substantial; and this was a state of things which would take a longer time to remedy than many supposed. Dealing historically with the question, he would now point out that there were three great schools of architecture,—the ancient, the mediæval, and the modern. The ancient world in origin be Oriental; the mediæval, Boreal—if he might be allowed the old-fashioned term;—and the modern, Occidental. The ancient having the elegance of the Eastern nations; the mediæval having the force of the North; and the modern the many-sidedness of the Western intellect. Again, the first was of large stones, the second of small stones, and the third of any stones or no stones at all,—sometimes, perhaps, "compo"! The first was trabecation (structural), the second arcuation (still structural), the third superficialization (post-structural, and too often counterfeit);—the first peculiarly architecturesque, the second intentionally picturesque, the third merely æsthetic. And if we were ever to recover the life and spirit of design it must be by superficialism giving place to substantialism.

After some critical remarks upon the historical development of the Greek orders, also upon that of arcuation as the sole basis of the system of Gothic architecture, Professor Kerr proceeded to remark that, after all he had said on the subject, those whom he had addressed would expect some kind of indication of a scheme or system for the architecturesque, and he had prepared the following in a tentative way only. First, the subject was building, with its adjuncts; secondly, the purpose was embellishment (beauty, ornament, decoration)—embellishment in pursuance of that natural law which was an essential element in the constitution of the human mind—the desire for "dress," the desire for ornament, the desire for producing art; and, thirdly, the purpose being embellishment, what was the limit of that purpose? Nothing short of infinite novelty. That was a principle involved; from which there was no escape; for that which forced the human mind to ornament everything which it produced, forced it, also, to perpetual effort for novelty. The next point was the means by which architecturesque effects could be produced, which were traceable under four heads. Then came the sources of suggestion,—structure, proportion, and imitation. Another point was the influences by which these suggestions should be governed, amounting to little more than the reaction of the same principles upon each other. Lastly, the conclusive effects would be three—viz., grace, style, and character; the multifarious results of

which one could scarcely instance, except by a few haphazard selections.

Coming, then, to the special application of the architectesque principle, he would, in the first instance, take the case of the steam-engine. Some present might remember the time when it was a serious subject of consideration how to combine the steam-engine architecturally—how to apply any of the five orders to it. The question was, which of them was most suitable, and it was generally decided in favour of the Greek Doric. But the steam-engine was a thing it was impossible to architecturalize. It was a mechanical matter, and not a thing to which the architectesque could be applied. Then take the case of a bridge; which was now considered to be the work of the engineer. How seldom did we see a bridge artistically treated. There were some approaches to ornament; but the spirit in which ornament should be applied to such structures was the architectesque, and was not understood. Looking at the Thames Embankment, what a noble opportunity it afforded for treatment by the architectesque; but the opportunity had been lost. Again he looked for a moment at the Crystal Palace. It was not in itself an ornamental structure. It was no doubt well built, but the question of ornamentation was avoided for sufficient reasons; but it served to raise the whole question of the application of the architectesque to iron work. When they heard declamations about new styles they ought to remember that at least a new material required a new style, and if there was one circumstance which attached more discredit than another to them as architects—and they would excuse him stating his opinions very boldly, even when they were against themselves—it was this—that architects had been so long in possession of the new material of iron, and had yet to take the first step towards the treatment of it in an artistic manner: and this showed the slow growth of any new style; for educated as they had been, he had no doubt it would take ages to effect the introduction of a new style, even with all the advantages of new materials. Having spoken at some length on architectesque sculpture, the learned Professor concluded by remarking that he had taken upon himself to confess a great deal—perhaps too much—on their behalf, but it was well not to be stingy in confessions. But if they, as architects, were guilty of so much that was spurious, was there not here and there in other matters besides architecture a good deal of what might be called spurious sentiment? Did we not live in an age of spurious sentiment? Our history, our philosophy, our law, our politics, our poetry,—was there not a good deal that was spurious in every one of these? If we came to our faith, our hope, our charity, was there not too much that was unconventional at the very core? And if they as architects had the custody of an art, whose essence depended upon its reflecting the character of the times, if they reflected that character all too faithfully what less could they do?

On the motion of Sir Digby Wyatt, seconded by Mr. J. P. Seddon, a unanimous vote of thanks was accorded to Professor Kerr for his paper. The lateness of the hour at which it was concluded prevented any discussion upon it on this occasion.

"THE ARCHITECTESQUE."

SOCIETY is singularly capricious in its reception or non-reception of a new word. It occasionally happens that an expression, happily hit upon by a popular writer, will receive sudden and almost immediate currency, and be recognised at once as a convenient shorthand expression (so to speak) for some class of ideas which formerly floated indistinctly through complicated ramifications of speech, with no set term whereby to define it. At other times a word equally happy and equally needed will, nevertheless, fall dead upon the public ear, or only force its way into recognition through a system of repeated manifestoes in its favour by those who have originated it. Probably the explanation may be found in the fact that in the one case the subject with which the new word is connected is one widely understood, or at any rate sympathized with; and that in the other case it may be one which, though perhaps equally important, has not laid hold of the sympathies of people at large. This is not a pleasant conclusion for those interested in the art of architecture, for there can be no question that the contrast hinted

at above is illustrated by the two words "picturesque" and "architectesque," which were placed side by side by Professor Kerr in his recent elucidation of the latter term at the Institute meeting. The first-mentioned expression appealed at once to a large circle of more or less educated persons; for though the highest qualities of the art of painting have been, and perhaps always will be (like all high things) "caviare to the general" yet at the time the word "picturesque" came into use there was undoubtedly, as there is now, a wide-spread interest in the productions of this branch of art, fostered to a great degree, no doubt, by the dicta of fashion, which impelled both gentlemen and ladies periodically to congregate where

"The Exhibition stares with annual pictures."

No such public interest attaches, so far as we are aware, to the introduction of the word "architectesque," hit upon by Professor Kerr; and as the word is similar in its etymology to its progenitor "picturesque," and as it certainly expresses, very aptly, a quality for which there was no concentrated expression before, we can only regard the indifference with which it has been treated as one more indication of the want of public interest in architecture as an art, and the ignorance of what really constitutes it as a separate branch of art.

It is really, however, a very important thing that we should define, more clearly than has hitherto been done, wherein architecture as an art really consists, seeing that in the eyes of one class of critics it is coming to be largely identified with engineering, and with another class it has for some time back been looked upon only as the framework for the exhibition of sculpture and ornamental design. We owe a good deal, therefore, to one who has introduced an expression, the recognition of which (should it come to be recognized) will be in itself a tacit acknowledgement of the fact that architectural design does actually exist as an independent art. We shall owe still more to any one who will define clearly for us wherein the "architectesque" consists. It was on this head that some of those present must have felt, as we did, that the lecture which has given rise to these remarks was, as it was, perhaps, intended to be, rather suggestive than exhaustive. The grouping of all previous and present architecture into three schools, the 'architectesque, picturesque, and conventional,' characterised respectively by aruation, trabecation, and *superficialisation* (another new word) was very comprehensive; though we should doubt whether the architecture of the present (represented by the third term of the triad), can rightly be called a "school" at all, its predominant characteristic being the absence of all distinguishing characteristics. And, to our thinking, Professor Kerr gives a more important place to what he somewhat vaguely calls "the desire for the beautiful" in originating architectural features than we should be inclined to concede. Observe, we say, in *originating* them; the decoration of them afterwards is another matter. For instance, we cannot accept the idea of the origin of the plinth from a desire to carry off the abrupt angle formed by the wall with the level ground. We imagine the plinth, like the cornice, to be purely constructive in its origin (which, indeed, the Professor in the latter part of his lecture by implication admitted), and to have arisen simply from the perception of the advantage of a broad and heavy base line of masonry in distributing the pressure of the wall, or the line of piers or columns, which it supported. Nor do we feel the nature of the architectesque to be much more clearly defined by referring it to "proportion," or its decorative part to "the imitation of the beauty of Nature." It may be that it is scarcely possible to define further; still we think the gist of the matter lies in the question, *how* are we to imitate Nature? At the risk of being, in our turn, found fault with for vague speculation, we would suggest that the essence of the architectesque consists in its being a generalising of those principles of beauty of which the plastic arts of sculpture and painting are more definite but less general expressions. A picture tells us a definite story, gives us a definite idea, but it also pleases us as much, sometimes much more, by its general effect of chiaroscuro, just as a group of sculpture pleases us by the balance of mass and form, independently of the subject. In architecture we have all the definite expression eliminated, and the attention wholly directed to the general broad effect of light, shade, and balance of form. Again, in nature we admire certain flowers for their special beauty, but in truly architectesque

ornament we do not directly copy any special vegetable form, however beautiful in itself; but we observe what common qualities they are which originate more or less the beauty of all these forms,—we recognise the principle of growth, of the springing of smaller parts from a central stem, and upon this we base such ornamental features as the Classic anthemion and the Gothic fleur-de-lis. We throw this out as a hint of the direction in which we suspect the truth to lie, as to what constitutes the essence of the architectesque. To the consideration of the difference between the really architectesque and the picturesque schools in architecture, and their relative value, we may return hereafter. In the meantime it is to be hoped that the introduction of the subject may give rise to some valuable hints in future discussion.

LIFE AND DEATH MAPS.

It would be difficult to confer a greater benefit upon sanitary science than that which is rendered by the preparation of clear topographical delineations of the path, or of the home, of disease. We urged this in past years, and the seed bore fruit in a few places. In Keith Johnstone's "Physical Atlas," a sheet is devoted to the subject of the distribution of health and disease over the surface of the globe, and much credit is due to Dr. Bryson for what that gentleman did in this direction when he held the post of Deputy Inspector-General of Navy Hospitals.

The general idea of the importance of graphical illustration of facts statistically collected, is one of which it is not easy to exaggerate the importance. The value of any single fact, be it more or less when isolated, is incalculably increased by co-ordination with other and similar facts. In all forms of study or of teaching this is admittedly the case. But when graphic illustration is appealed to, information which is entirely unexpected, will sometimes make its appearance on the chart. Not only does the process of plotting make what is already known more clear to the mind of the describer, and thus to that of the reader or observer, but it not unfrequently indicates the existence of some unsuspected law, or some previously unknown relation.

Take, for instance, the case of the elaborately drawn map of the cholera districts of London, which is to be found in the ninth report of the medical officer of the Privy Council. The actual rate of mortality during the cholera outbreak of 1866, is represented on this map, the greater or smaller number of cases in each district being represented by a greater or less intensity of dark shading. It is impossible for any person who has the slightest acquaintance with charts or plans, to look at this map without acquiring an amount of information for which he would have to toil through many columns of letterpress, or to consult an unwieldy table. Time is thus saved to no small extent. But this is not all. Those who will study reports, or consult tables, are the persons who already take an interest in the subject discussed. But a clear plan has the result of *creating* that interest. It brings the matter home to those who would otherwise care or know little or nothing about it. And to grasp the attention of the non-professional reader on any point regarding the operation of the great laws of health, is to render more prevalent the exercise of enlightened sanitary precaution.

The distribution of the darkly-shaded spaces which indicate the most fatal activity of the choleric poison, so markedly and persistently coincides with a certain river valley, and with the district supplied with water from certain clearly ascertainable sources, that the lesson is unmistakable. No surveyor, no architect or engineer, no physician, could look at the map for a moment without having his attention drawn to the probable exciting cause of the disease. No educated person could look at it without becoming aware that a means of warding off one of the most dreaded scourges of the time was, at all events, indicated to him, and so indicated, as to be to some extent within his reach. Thus, that which is only an elegant and convenient memorandum for the officers of health, becomes a striking medium of information and of instruction, for those who have neither the time nor the habit of thought that would lead them to the perusal of reports. A man looks at the map from curiosity. He draws from it wisdom unawares.

Genuine admiration, without question, is due to this careful method of graphical illustration

We have pleasure in calling attention to the further progress of this study evinced by a description of the map communicated by Dr. Haviland to the Medical Society on the 30th November last. It is one of an entirely new series of charts, which cannot fail to contribute to that which is one of the first objects of the architect and of the engineer, human health. In the old maps of the last century dangerous localities were indicated often by the lineaments of some grotesque monster. Somewhat in the same way the series of charts which Dr. Haviland is now preparing will tell all those who may be conscious of a liability to any specific form of disease, what districts they should shun. Rheumatism and heart disease, and the terrible scourge of cancer, are the maladies which have been just selected as the topics of graphical display.

To a certain extent the medical map will correspond with a physical sketch of country. Elevation is a prime element in the distribution of disease. Mountain slopes and summits, table lands and elevated plains, mountain valleys, which are the cradles of streams and torrents, fertile river valleys and basins, and districts swept by the sea breeze, each have their distinct value in the map of health. In fact, each element has a specific relation to each distinct type of disease; so that a genuine medical map, when complete, will be almost too complicated for distinct plotting. It is an atlas rather than a map, which we expect from the new delineations of the new medical survey.

We are familiar with the use of cartography as a means of presenting the results of statistical inquiry to the eye at a single glance. Many interesting plates of this nature are to be found in every physical atlas. The rain map is one of the most striking of this series, the greater or smaller depth of annual rain-fall being represented by a corresponding depth of shade. Some time ago some very clear diagrams were published to illustrate the operations of the Post Office, in which, instead of shade, proportionately drawn lines were employed, to indicate the density of population. Charts of tidal phenomena, of winds and cyclones, of isothermal and isochimical limits, of the paths of eclipses, of the districts ravaged by earthquakes and volcano, are familiar to every student of physical geography.

Dr. Haviland, drawing experience from the labours of his predecessors, is not content with showing the actual presence, or plus-indications, of the subject of his inquiry, and leaving the plain blank paper to represent the absence of disease. He uses two colours, instead of a simple shade, and represents in blue and in red the positive and the negative value of a district. We are not sure that this method is theoretically correct. If we consider health to be normal, we may take the tinted paper as its best exponent. Still there are advantages to be secured by another mode of treatment, and the balance of those advantages is a fair subject for discussion.

As far as cancer is concerned, the lesson to be derived from Dr. Haviland's map is simple. Damp seems to be the predetermining cause; damp, connected with alluvial soil and depressed level. The pressure of the barometric column appears to enter into the list of predisposing causes. Many persons are aware of the depression of feeling caused by residence in river valleys, or even by passing a short time on low levels, not excepting the sea-shore itself. In this depression of spirits may be detected the indication of at least one of the disturbing causes that tend to generate cancer.

Rheumatism and heart-disease are, topographically speaking, close neighbours of cancer. But there is a difference between these two forms of ill health which becomes very apparent in the map. In cold, upland valleys rheumatism prevails. The barometric elevation, or some other cause, is unfavourable to the development of cancer. On the other hand, the sea air appears to have a directly preventive influence as to the progress of heart-disease. This sanative power does not extend to cancerous affections.

One of the most striking results that springs from the chartological investigation of disease is the positive direction which we are thus led to see that Nature herself affords as to the location of hospitals. A hospital for cancer, it would seem, for example, should be erected in the very spot which would be most unfavourable for the position of a hospital for phthisis, or lung disease. The insular position which would be the most favourable for a hospital for patients affected with

disease of the heart, would be most fatal for the patients suffering from cancer. By the wise selection of the appropriate locality of hospitals for each specific form of disease the *vis medicatrix nature* will be brought most directly to the aid of the physician.

It is this view of the subject which is naturally the most important to the architect. The question of site, indeed, is not always within the competence of the professional adviser. Too often all that the architect can hope to do is to make the best structural use of a given spot for a fixed purpose. This is frequently all that lies within the limits of his duty. Such is the case, for the most part, in city or suburban buildings, or in cases of reconstruction. But when a wider range is allowed to the professional adviser, he may obtain the most valuable aid from charts such as those to which we refer. If it be the mark of a man of genius to select a site for a great building, which shall be the best for picturesque and structural reasons, no less will it enhance the future fame of the builder of a great hospital, that he has been guided by sound sanitary knowledge. The success or failure of the treatment of the majority of cases of any specific disease, which are brought to a hospital, skill and care being alike, will depend entirely on the fact how far the site of the building is suitable to the recovery of that particular class of patients.

To draw an illustration from a case under our immediate notice. A noble building is rising opposite to the Palace of the Legislature at Westminster, to receive the patients of the former St. Thomas's Hospital, — a building to be known by that long respected name. Now, with whatever detail the architect may have been expected to enter into the distribution of the several wards, he may draw one lesson from the map of Dr. Haviland. He need make no provision for cancerous patients. The river-side hospital is no place for them. Highgate, or Hampstead, or Sydenham, would, according to this view, be the proper locality for the successful treatment of that formidable malady. An indication of this nature is of no little value, both to the architect and to the physician. On the other hand, no general idea of the advantages of a fine healthy situation should be allowed to influence the selection of an elevated site for a hospital intended to receive patients suffering from pulmonary complaints. In the same way we are taught how most surely to exorcise the familiar household demon known to our country population as the "rheumatiz," and how a sea-side sojourn may be favourable to evils affecting the heart, without resorting to the heroic remedies of the Lesbian poetess.

One other important question will be illustrated by the completion of a good series of medical maps. It is that of the influence, whether chemical or electric, of the actual elements of the soil. Hitherto it has been difficult to distinguish between the physical and the chemical elements of climate. Those persons who have been able to give much practical attention to this subject, are the most aware of its importance. Thus, a volcanic soil, composed of ash, produces an amount of fatigue to those who walk over the surface, which, under the same latitude, and at the same elevation, and the same time of year, is unfelt by those who walk over limestone. Something of this electric depression and volcanic fatigue may be realised in Paris or in London by persons who walk on an asphaltic pavement. In London itself a sensible difference of elasticity and buoyancy of spirit is experienced by some persons when they pass from a clay soil to a gravel, or the reverse. We have known instances of an almost entire loss of sleep during a residence on the alluvium of Bordeaux, in spite of the comparative cleanliness of the city and the careful structure of the houses. In South Wales, over the wide district that consists of what is called "rab" (a sort of indurated clay), a sense of fatigue and depression is normal to some strangers, which is entirely lost when they pass on to the red sandstone of the neighbourhood. These are a few out of, no doubt, very numerous instances of a climatological effect which is not dependent either on elevation, on temperature, or on the presence or absence of fadings from sea breezes, in the air. Medical men will do a great service to the profession, and to the health of their countrymen, by aiding in the investigation of this obscure part of the science of therapeutics.

The ample field that yet remains for the illustration of statistics by well-designed maps, is

worthy of the best attention of the profession of the civil engineer.

The cholera map to which we have before referred, as issued in the report of the medical officer of the Privy Council, is an example of clear, intelligible, shading, which may safely be taken for a pattern. In any attempt to combine the charts of the various diseases, it is evident that the adoption of two colours to express the *plus* and the *minus* state of affection would be impossible. On the other hand, it would be quite practicable to give a large amount of definite information as to the natural distribution of distinct forms of disease on the same plan, by the use of a single tint to denote each malady. For this reason we are inclined to the opinion that the introduction of two colours to indicate the prevalence or the reverse of the same disease is less advantageous than the adoption of a single colour, with a deepening intensity of tint. For the purpose of a public lecture indeed, where the greatest amount of distinctness has to be studied for a large audience, and where a separate chart can be produced for each separate branch of inquiry, the plan adopted by Dr. Haviland has great convenience. But whatever may ultimately prove to be the best mode of working out the details, there can be no doubt in the mind of any educated man of the great advantages to human health which may be expected to follow from the development of the comparatively novel study of medical cartography.

While speaking on this subject, we must not omit to call attention to the valuable report of Dr. Buchanan, on the distribution of phthisis as affected by dampness of soil, appended to the tenth report of the medical officer of the Privy Council. The annexed geological map of the South-east of England, reduced from the Geological Survey, is as clear as can be expected from so small a scale as 10 in. to the mile. The map showing the registration districts is less to be commended. Perhaps a certain indistinctness may be thought to give more force to the sensible remarks of Dr. Buchanan as to the scientific utility of the parochial boundaries, and as to the necessity for following the physical geography of a country, rather than its civil geography, in medical maps. We hope that Dr. Buchanan's researches will not slacken until he presents us with a phthisis map of England, shaded like the cholera map to which we have referred. In the mean time, too much attention cannot be given to the ultimate conclusion of Dr. Buchanan's report, "That wetness of soil is a cause of phthisis to the population living upon it."

THE VENTILATION OF SEWERS.

Sir,—I very gratefully acknowledge that, for many years past, I have derived a good deal of information from the pages of the *Builder* on different branches connected with the drainage of towns. Amongst all the other matters that have been discussed, that of ventilating sewers has come in for its share of attention since its importance has been felt. In order to accomplish this purpose, various modes have been adopted, none of which, however, seem fully to answer the purpose intended, and, may I be permitted to say, that in my opinion, for this simple reason—that they have not been in accordance with the teachings of nature. I may venture to state that engineers have failed to reason out this matter in any satisfactory way, almost uniformly adopting the method which includes charcoal as a deodorizer. In the report of the engineer respecting the drainage of Canterbury, however, he stated that this mode had been found to be a hindrance to ventilation and promotive of escape into houses through shallow and imperfect traps; and open pipes above the roof were chosen as the only safe way. And for this purpose, many engineers have adopted the rain-water pipes of high houses; but the fallacy of trusting to this arrangement has been ably exposed by Dr. Carpenter, of Croydon, in his pamphlet on "House Drainage."

That a considerable amount of good has been effected even by these means, that are now acknowledged to be imperfect, there can be no doubt. Indeed, the present President of the Society of Engineers, in his opening address before that society, gives two instances of *ascertained* saving of life as far as statistics can show it; one at Croydon, and the other at Liverpool. I think, however, that a much more certain and effective mode of ventilating sewers would be, to consider the difference in the temperature of the sewers and of the external air, and to con-

struct ventilators accordingly. To expect rain-water pipes or any kind of shaft exposed to the night air to be effectual, is not to found our expectations on the operations of Nature's laws. For do not the laws which produce atmospheric movement teach us a lesson in this respect? If the principal cause of those currents of air called winds is the disturbance of the equilibrium of the atmosphere by the unequal distribution of heat, if when one part of the earth's surface is more heated than another, so that the air becomes lighter, and rises up, from being expanded, does not the cold air rush in and take its place? But we need not appeal to Nature in her grander movements when we may be made sensible of this fact any day. Stand, for instance, just inside of a lecture-hall or other assembly-room when there is neither fire, nor gas, nor audience, and there is no rush of air into the room; but let the gas be burning freely and the room well packed with people; and then take up a similar position, when the heated air is rushing up through the ventilated ceiling, and there will be a convincing proof that the cold air is rushing in to take its place.

Assuming, then, that it is a settled point in the operations of nature, that a great cause of all atmospheric motion is the unequal distribution of heat, I conclude that when the external air is colder than the air in the sewers, neither the charcoal ventilators, nor the rain-water pipes, nor the ventilating shafts recommended in the ninth clause of the report of the Royal Engineers, as to the drainage of Oxford, Eaton, Windsor, and Abingdon, will fully answer the purpose intended; but may sometimes, and especially at night, occasion a downward draught, and thus force the foul gases through the sink and close traps into the warmer atmosphere of living and sleeping rooms. Now, sir, I am well aware that the *Builder* has on many occasions pointed out the importance and necessity of heat in some form or other for the effectual ventilation of sewers; but what seems surprising to me is, that drainage engineers appear to ignore it altogether. In the early part of last year I had nearly a dozen schemes of drainage to examine and report on, and in all of which I found the proposed ventilation to be unsatisfactory, being either by means of the charcoal container or the rain-water pipes.

About two years ago I prepared and submitted to a local Board a method of ventilating, which I described in the following words:—"The other set of ventilators I propose for night only, to be formed by passing an iron tube up a lamp column, which is to be fitted up with a spreading reflector forming a cone, and the gas to be in four jets, causing a greater warmth over the aperture of the ventilating-pipe than exists in rooms or closets at night-time, when doors and windows are closed, and when the ordinary out-of-door ventilators are not sufficient to prevent the gases passing through water-traps into the warmer temperature of cooking and sleeping rooms. A lamp so fitted up I propose to be placed as near as convenient to the highest part to which the different public drains extend."

I have fitted up such a ventilator myself, in connexion with a large cesspool, on premises in the occupation of some of my own family, and am satisfied that it acts beneficially. Mine is simply a cooking gas-burner placed on the upper part of a gas-column, with the addition of a spreading cone, with the ventilating-pipe protruding through and upwards, so that by the series of small blue jets of gas the whole atmosphere above has a glow of heat; and as it is so placed as to be available for the purposes of light, it is sometimes turned on sufficiently strong for that purpose, and which, of course, causes the ventilator to be much more heated.

I was glad to read the very sensible remarks on the subject of sewer ventilation, signed "V," which appeared in the *Builder* of November 21st, 1868, and am quite of his opinion that any system which is likely to meet with acceptance must be self-acting, or, at any rate, not attended with much trouble, and such I consider the plan which I suggest to be.

I proposed that a charcoal doodriser should be placed in the pedestal of the lamp-column, so as to use the one by day and the other by night, if desirable.

SURVEYOR.

Poets' Readings.—Mr. Robert Buchanan is to give the first public reading from his own works in the Hanover-square rooms on Monday, the 25th inst. The programme naturally includes some of his best pieces.

FROM AUSTRALIA.

Melbourne.—An immense structure is in course of erection in Flinders-lane, upon the site of the old Prince of Wales Hotel, and towering in a most conspicuous manner above all the surrounding buildings. It is to be a warehouse, although the ornate nature of the architecture renders it dissimilar to the generality of such places in Melbourne. The style of architecture is the Romanesque, which has been employed in embellishing a vast oblong shell, constructed with the main object of providing an amplitude of room, none of which can be sacrificed to considerations of beauty. Messrs. Reed & Barnes are the architects. The building measures 156 ft. long by 48 ft. wide, and its height to the top of the parapet which surmounts the walls is 76 ft. It is divided into a basement, a ground-floor, and four upper stories, the basement walls being of stone, and the superstructure of bricks cemented. The most conspicuous ornamentation in the Flinders-lane front is bestowed upon the centre first-floor window, which is of Venetian form, with a projecting balcony and pediment. The remaining front windows on the different floors, and those along the sides, are arranged in clusters and groups, the group openings being separated by small capped columns. Communication between the various levels, for the transit of goods and persons, will be afforded by lifts and ample staircases from floor to floor. As a rule, the workers employed in the warehouse will ascend and descend by the lift. The contractor for the building is Mr. John Wood, and the clerk of the works Mr. Wallace, while the plastering has been done under the supervision of Mr. Parry. The item of plastering is a pretty considerable one in the contract, since the walls of the building are plastered inside throughout, and are to be finished off with architraves and other ornamentations. Between eighty and ninety men have been employed upon the work, including the bricklayers, plasterers, masons, carpenters, and laborers. The entire cost of the building will be about 15,000l.

An addition to the Sailors' Home is now in progress, and nearly completed. The new dining-hall, now being erected, is 56 ft. long by 22 ft. wide. When completed, the Home will accommodate 125 men. The total cost of the institution, including both the old and the new portions, will be about 10,000l.; that of the new being 4,300l., although the present contract only amounts to 3,050l. Messrs. Martin & Peacock are the contractors for the additions, and Messrs. Smith & Watts are the architects. The foreman of the works is Mr. Greig.

Additions have been made to the Wesleyan Church at Emerald Hill. Messrs. Crouch & Wilson are the architects. The additions comprise a transept 70 ft. by 40 ft. internally, orchestra and small class-room, with two large vestries underneath, and two porch entrances. The new walls are built for a tower. The church will now accommodate 1,000 persons. The fittings have been supplied by Messrs. Bell & Butt, of Richmond, who also prepared those in the old portion. Messrs. Danks & Dempster also again attended to the gasfitting. The nave measures 73 ft. 6 in. by 40 ft.; the transept, 70 ft. by 40 ft.; the walls are 23 ft. high, and the mid-ceiling 35 ft. 6 in.; the height to ridge is 53 ft. All the passages and lobbies are laid in cement, the flooring being raised some 5 in. or 6 in. higher. The pulpit, &c., are of cedar, French-polished.

Fitzroy Gardens, Melbourne.—Melbourne is abundantly provided with public parks and gardens. The Fitzroy Gardens are second only to the Botanical in extent, beauty, and general attractiveness, while they are nearer to the city. The public are indebted to Mr. Hodgkinson, Assistant Commissioner of Lands and Survey, for the conversion of what was not long ago a waste blank into a delightful retreat. The ground is tastefully laid out, stocked with all sorts of ornamental trees, reticulated with running water, which keeps the grass ever green, and the shrubs umbrageous, and is intersected in all directions with broad and well-kept avenues.

Ballarat.—A large bell, cast here for the Free Church of England, attracted to Mr. Higgins's foundry a large number of ladies and gentlemen to witness the process. The St. David bell, as it is called, is the largest ever cast in Ballarat for church purposes, its weight being a little over 2 cwt., and its dimensions 26½ in. at bottom, with a height of 23 in. A smaller bell, cast at the same time, weighed about ½ cwt. The next largest bell cast here for church use is that of St. Peter's, in Sturt-street, which weighs about

120 lb., and was cast nearly two years ago at the Victoria Foundry, by Messrs. Hunt & Opie. The same firm cast the largest bell yet made here—namely, the bell cast six or seven years ago for the Ballarat Fire Brigade, which weighed between 5 and 6 cwt. Mr. Higgins, the caster of the St. David bell, is also the donor of the bell to the church.

MONUMENTAL.

The statue of Lord Palmerston, by Mr. Woolner, which is to be erected in Palace-yard, Westminster, is now so nearly completed that the model is in the hands of the bronze casters. The figure is somewhat larger than life.

The municipality of Missolonghi are taking measures to raise a monument there to Lord Byron, who contributed so much to Hellenic independence before he died in their town in April, 1824. A statue is to be erected to the poet on the spot where he breathed his last.

The total sum subscribed by the metropolitan police for the erection of a monument to the late Sir Richard Mayne, K.C.B., chief commissioner of police, is 574. 18s. 9d.

The young sculptor Dantan has received the commands of the Emperor to execute a marble bust of Rossini for the library of the Institute.

THE JOINT COUNTIES ASYLUM AT CARMARTHEN.

ARCHITECTS' RESPONSIBILITIES.

SOME few months since we gave a short article upon "False Economy in Building," in which we had occasion to refer to the large structure at Carmarthen known as the Joint Counties Asylum. We now learn that at the Quarter Sessions lately held the subject was brought before the three courts of Carmarthen, Cardigan, and Pembroke, when a report was presented from the Committee of Visitors to the Asylum. In this report the committee regretted to state, that "in consequence of defective workmanship and materials used in building the asylum," it had been "found necessary to renew a considerable portion of the work, and extensive repairs had become indispensable." The committee stated that they had been compelled in September last to call upon the treasurers of the three counties to pay 400l., so as to enable them to proceed with such repairs, but the committee found that they were now "compelled to make a similar order for the sum of 1,200l." The committee express the hope that this sum—1,600l. in all—will be sufficient to place the buildings in thorough repair. They also state that a "case" had been submitted to counsel to advise whether or not they had a remedy against any person, and whom, for such defective workmanship and bad materials used in the erection of the asylum; and in pursuance of the "opinion" given they had resolved, subject to the approval of the Courts of Quarter Sessions for the three counties in union, to take proceedings against their late architect for the damages they have suffered, and were sure of being subjected to, by his having given his certificates, from time to time, to the contractor, and thereby passed defective workmanship and materials used in building the asylum. The matter was discussed at the Quarter Sessions in the three counties, and at the Carmarthenshire Court, the Earl of Cawdor explained the position of affairs. He said the committee had not been properly treated. They put their trust in their architect, and he had certified that the work was properly executed, but they now discovered many defects. The committee had submitted a "case" to an eminent counsel,—Mr. Field,—and they had just received that gentleman's "opinion," which was to the effect that the committee could proceed against the architect, to recover damages for the defects. Earl Cawdor's individual opinion was in favour of this view. It was stated in the discussion that followed, that a precedent for proceeding against the architect was furnished in the case of an action which arose with respect to the large structure at Colney Hatch. However, the Quarter Sessions of the three counties,—Carmarthen, Cardigan, and Pembroke,—have all decided upon confirming the proposal of the Asylum Committee to take legal proceedings against the architect. The case will be anxiously looked forward to. It is far from clear whether the action should be taken against the contractor for not fulfilling the terms of his contract, or against the architect, for signing certificates when the work was not properly executed.

THE LATE MR. GEORGE SMITH,
ARCHITECT, F.S.A.

To the brief but comprehensive sketch, in the last number of the *Builder*, of the professional life of the late Mr. George Smith, architect, permit an old pupil to add a few unprofessional details, if only to show how well his success was deserved by the means he took to secure it, and by the generous use he made of its fruits.

Mr. Smith had always been sincerely attached to his profession, and perseveringly followed it. In all that he did he was extremely careful and painstaking, and wisely thought that whatever was worth doing at all was worth doing well. The specifications which, as a student, he wrote out were admirable examples of neat and elegant penmanship.

His drawings were done with great care and attention. The early habit thus formed never deserted him. In advanced age I have seen him, at his country house, occupy himself in drawing out a humble plan and elevation with as much carefulness and exactness as if the world were still all before him, and he had his fortune to make in it. His writing, like his drawing, was always his best. The slow and careful way in which he invariably signed his name was something remarkable, and showed the importance he attached to doing it well. His measuring-hooks were models of neatness and even elegance; so also were his calculations for estimates; there was nothing of a hurried or hasty character about even the most insignificant of his papers and notes. His heart was in his business, and thus business became his chief pleasure.

In the most solemn act of his life, his first marriage, business came second to the ceremony itself. I have heard his eldest son, George, long since deceased, say, that after the wedding in the morning, his father went down to Windsor to measure some work. Windsor was then a much longer distance in time from London than it is now. The lady he married was a Miss Howel, a daughter of a City functionary, the water bailiff, who on going once to consult the eccentric Abornethy, and stating who he was, the latter replied,—"Water bailiff! sir, water bailiff! you mean the brandy-and-water bailiff!"

Mrs. Smith had a cultivated literary taste, but did not indulge her inclination for writing to the detriment of maternal duties. They had a numerous family—five sons, two of whom are in the church, and two daughters, the eldest of whom died early. The present oldest son is the Rev. Sydney Smith, M.A., perpetual curate of Werth, in Kent. Mr. Smith lived to a good old age, and retained to the last much of that constant cheerfulness and gaiety of mind for which he had all through life been distinguished. Those who have had the pleasure of meeting him only on business, and those who have been privileged to witness the expansion of his heart and his sportiveness in the bosom of his more serious family, will never forget either that genial courtesy and pleasantry which made him a constant favorite, especially with the gentler sex, nor that unchilled juvenility which often led his loving wife laughingly to exclaim, "Now, is he not the youngest of them all?"

Mr. Smith had a natural turn for humour, and a talent for selecting the comic points of a story and representing them with dramatic effect. An ordinary narrative would thus in his hands become transformed into a humorous description that made the gravest hearers laugh heartily, though he himself rarely joined in such noisy demonstrations.

As Mr. Smith rose in his profession he became the benefactor of his family, and though he may not have left the world a wealthy man, in the common acceptance of the word, yet he died rich in good deeds, and of him it may be truly said, in the words of holy writ, he rests from his labours, and his works do follow him.

The writer of this short tribute to the memory of his once honoured master, entered Mr. Smith's offices as an artiled pupil in 1822; they were then in Bread-street Hill, and a Mr. Thomas Nichols was the head-clerk. Nichols was a good draughtsman and mathematician, and perfectly well understood construction: he made the drawings for St. Paul's School, and for the tower of the late Royal Exchange.

His successor in that situation was Mr. A. B. Clayton, who had taught painting in the family. Clayton came from Mr. Roper's offices, and was a person of a very different stamp to the pleasant Tommy Nichols, as his predecessor used familiarly to be called. Clayton had de-

signed the new Church of St. Mark, at Kennington, and the tall monumental shot-tower by the side of Waterloo Bridge. He was an artist, and introduced a new style. It was shortly after this that the offices were removed to Mercer's Hall, where they now are.

Of the several pupils his contemporaries, the most distinguished was William Grellier, of Wormwood-street, Bishopsgate; he subsequently obtained the prize awarded by the Gresham Committee for the best design for a new Royal Exchange. He was a most exemplary and persevering student; received in 1829 the gold medal in Architecture of the Royal Academy, and in 1831 was one of the most efficient members of the Architectural Society of London, and for four years was honorary secretary. When, in 1842, that society was merged in the Royal Institute of British Architects, William Grellier received a piece of plate and a memorial, in testimony of his valuable services. A premature death deprived the profession of one of its rising brightest ornaments. The principal edifice with which William Grellier's name is associated is that handsome structure in Liverpool, "the Royal Insurance buildings." Another fellow-pupil was James Barr, recently deceased, the author of "Anglican Church Architecture." To give, however, even a brief account of the pupils of the late Mr. Smith, both before and since the writer's own time, would fill a volume. How several entered the Church, how others entered the army, how some followed one calling, some another, and some no calling at all, would serve to show what a good practical foundation this study affords for a variety of subsequent professions, and that in the intermediate and undecided stage of life which succeeds to boyhood, there is nothing better for a young man to do than to court *La bella Architettura*, who says to all her suitors, "Love me, love my sisters also."

H. C. BARLOW, M.D., F.G.S.

SANATORIUM FOR HARROW SCHOOL.

In the year 1861, the Sanatorium for Harrow School, of which we give illustrations in our present number, was commenced. Previously to this each boarding-house had a set of sick-rooms, where illness of every sort was attended to, and where every precaution was always taken to prevent the spread of infection, though by such means alone it was not always possible to provide against the communication of disease. Even now the same series of sick-rooms exist at each house, and the same care and attention are given personally to all ordinary forms of illness, but all cases of infectious diseases are removed to the Sanatorium.

It is difficult to imagine how such a large school as Harrow, with 500 scholars, was able at all satisfactorily to get on without such a safeguard against extraordinary, and it is indeed greatly to the credit of the masters, and a strong proof of their care and attention, that the school was able so long to exist wanting an asylum of this kind against those insidious and fearful visitations which, spite of care and attention, seem to come to all communities alike, but which are peculiarly obnoxious to such large numbers of young people as are gathered together at a public school.

It was principally owing to the indefatigable exertions of the present—then the new—head master, Dr. Butler, that all the unavoidable difficulties of the new arrangements were overcome, and the means provided for the prosecution of the work.

We quote from the architect's report on the subject in 1863, to show the original intention, before we speak of how it has been carried out:—

"I may remark first as to the building itself (for it deserves somewhat upon the character which it is to assume what will be the best site) that it would probably not be desirable to make it a very conspicuous object, nor too prominent amongst the other school buildings at Harrow, either by its position or its architecture. Yet at the same time I presume it must be conveniently situated, and large enough to contain the accommodation mentioned to me the other day. As to the rooms or wards themselves, they need not partake too much of the character of a hospital, though obviously they should have all the conveniences of one, and possess sufficient cubical capacity and ample means of ventilation.

Attention should be paid not only to the aspect of the rooms, with a view to obtain sunlight and air, and shelter from cold winds, but also to secure a cheerful prospect, and one associated with the everyday enjoyments of school life.

Bearing all this in mind, I have made a small (though imperfect) sketch, in order to show the various require-

ments could be satisfied and the several rooms grouped into a block, which could be erected in a simple style of architecture and in an economical manner.

The ground-floor might contain the beds for miscellaneous disorders—the matron's room, kitchen, &c.; while, supposing the building were placed on the side of a hill sloping considerably towards the south and east, the various outbuildings might economically form a basement under the central wing.

The upper floor might be appropriated solely to the class of disease prevailing at one particular time, and some of the rooms be reserved for more desperate cases, with nurses' rooms attached, while two or three extra rooms might be obtained in the roofs of some part of the building as extra sleeping-rooms for servants, or store and lumber-rooms, if required.

The architectural appearance of the building would be simple, very little stone being used; but the character of the school building; generally kept up, in the use of red bricks, with a few black bricks introduced, and tiled roofs. The interior might be finished partially with stained and varnished deal.

Most of the sick-rooms would contain 1,000 cubic feet for each patient, and each room an open fireplace as one of the best possible ventilators. All the windows should be made to open, if required, and placed in such a way that by opening the door and the windows of the passage a thorough draught could be secured to purify the rooms. At the same time everything like a draught should be generally preventible by a system of warming and ventilating the passages as well as the rooms. For this purpose a system of what may be called "artificial" ventilation should be adopted to assist what may be termed the "natural" ventilation of doors, windows, fireplaces, &c.

The site itself was costly, and the building, owing to its position and special requirements, could not be a cheap one; yet, a great deal of accommodation has been obtained on an appropriate site, and, as will be seen, at a moderate outlay, viz., about 3,500*l.*, exclusive of site, fencing, and a few items not necessarily belonging to the building. It is, however, only right to add that the fitting up of the laundry, &c. (which we shall describe), with the hot-water coils in the hall, was executed by Messrs. Bonham and others at a cost additional to the above. The whole works have been carried out under the superintendance of the architect, Mr. Charles Forster Hayward, F.S.A., in a style consistent with other works by that gentleman at Harrow, and somewhat also in accordance with the local traditions of the spot, viz., in red brick, with a sparing introduction of stone dressings, ornamental pateras of black headers, and with tiled roofs.

It should be stated that the building is smaller than was at first intended, and the site larger than was actually required for the present; and the roadway had to be made as well as considerable special works for drainage. The advantages, however, are commensurate; for perfect isolation at the end of a long private road, yet with a cheerful view of habitations not too near, a magnificent prospect extending to Windsor Castle in one direction, and, at the same time, openness to all health-bearing breezes, with shelter from the coldest quarter, have been secured,—at a distance not too far from the business of the school.

Advantage has been taken of the steepness of the ground to obtain a good basement,—the living-rooms in which look upon a terrace high above the remainder of the site, which is laid out as a garden; while the chief entrance is on what would be called the ground floor.

The accommodation afforded by the basement is as follows:—Kitchen, scullery, servants' room, larder, cellar, knives and boots, and coal places; and there is an entrance on the terrace level. In communication with these rooms, but with a chief entrance on the exterior and on the opposite side, are a laundry, purifying-room, and the heating apparatus, which serves both these, as well as the warming of the hall by hot-water coils. The purifying-room, which is a most important adjunct, is vaulted and capable of being heated to a very high temperature, and therein is placed all linen, &c., to be thoroughly cleansed,—and, if not reused, consumed. All the steam and smell are, of course, carried off by the great draught of the furnace flues, and the articles are got rid of in the shortest possible time, and with the least amount of handling—by no means an important matter. On the basement level, also, is the carriage-house, containing the special vehicle, which alone is allowed to be used for the conveyance of the infected.

The entrance-porch, doorway, and hall, are made sufficiently wide for the entry of this carriage into the building; and the staircase is made unusually wide, and easy of tread, to allow of patients being carried up in their beds when necessary, though, of course, it would seldom occur that a patient arrived in such a state of prostration. It must be remembered no accidents or surgical cases are brought to the Sanatorium; its use is strictly confined to the treatment of infectious diseases.

Once in the hall, the general arrangements are clear: a short, wide corridor gives access, on the right, to a convalescent room, a surgeon's room and dispensary, a bath-room, and at the end a "double ward;" while adjoining, on the other hand, are the W.C., &c.; the back staircases, down and up, and the lift, which is fitted with noiseless gear, and is built in a solid brick shaft, with only the actual necessary openings to it. The short passage-way, lighted from the side (at one's back on entering), conducts to the matron's rooms, and the stores immediately under her care; and for her use there is a private access to the back staircase and the rest of the building.

Ascending the staircase, which is of oak and pitch pine,—unenclosed in any part, the underside of the stairs being as visible as the upper, and all finished to show the woodwork,—we find the upper floor a counterpart of the arrangement thus described, except that the two rooms below used for the doctor and for convalescents, form the largest ward for three patients, or more if necessary. The bath-room on this floor is also fitted as a nurse's kitchen, with small range, &c., and the rooms over the matron's rooms are quiet wards. Advantage is taken of the position of the hot-water cistern on this floor, to form an airing-room for linen.

The larger wards we have spoken of were designed for one or two beds each, generally only one, but with a door of communication between them, for the sake of taking advantage of the feeling of companionship in youth generally, and making cheerfulness an assistance to convalescence, as it would be in the many cases of the mildest character, to be treated in the building, while isolation or at least separation was adopted for the more seriously affected patients.

The wards are separately ventilated from the ceiling by Watson's double tubes running up to, and enclosed in, a turret on the roof; at the same time open fireplaces are used, and open windows are available if required. By closing the passage-way, these rooms can be made a complete set for the treatment of a different disease from that attended to in the remainder of the building.

At Eton, the wards are a series of small rooms for single patients—a system corresponding with that of the school generally; but in the building of which we are speaking there is only one room unable to accommodate more than one patient; if occasion should require, but provision is made for enlargement at any time, so that desirable rooms could be added if it were found desirable. The total number of beds now provided for is fourteen, or eighteen when the house is quite full. The sick-house at Rugby is used, we believe, as a sort of general hospital for all kinds of illness, and is very popular amongst the boys; and the same can be said of the Harrow sanatorium, as, indeed, the cessation from lessons and ordinary school discipline, with the substitution of special care and attention, with often no great feeling of debility, is likely to make it.

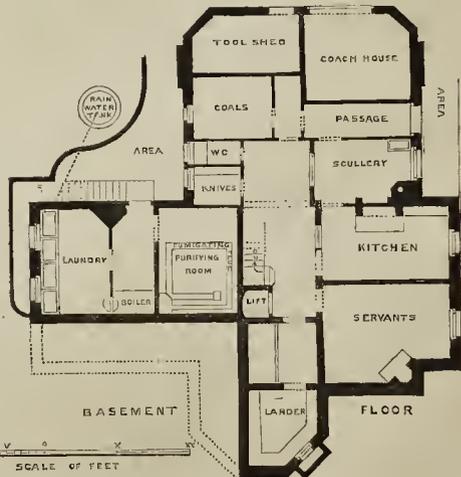

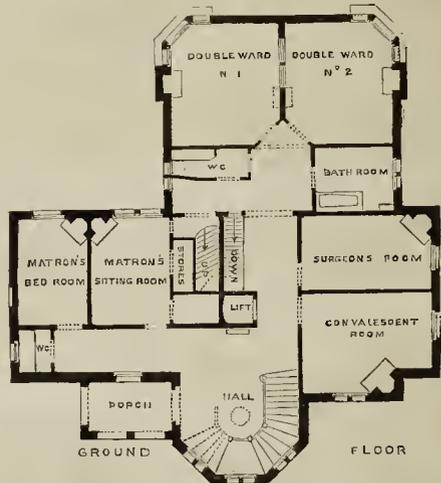

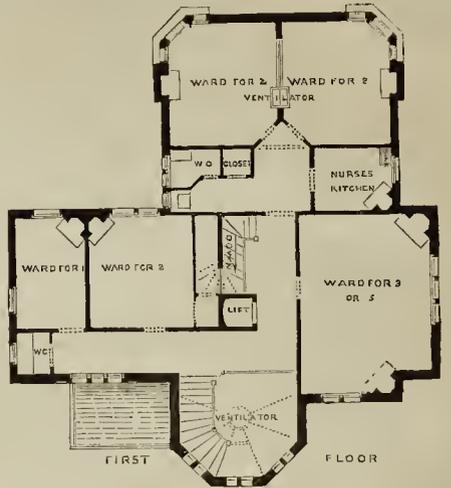

The ventilation of the rest of the building is carried out by a large Watson ventilator in the turret over the principal staircase. Over each doorway is a set of louvre openings, which, communicating with the upper part of passage-ways, carry the foul air that passes in this direction at once to this exit; while open fire-lump stoves and sash windows afford additional assistance. The part of windows above the transom is hinged also, and works by cords and pulleys, so that the upper part of the room can easily be filled with fresh air. The rooms are 12 ft. high, and each ward allows 1,200 cubic feet of space to each patient when the rooms are full—otherwise, about double this quantity. Of course, the haseiment is cut off from the rest of the building for ventilation.

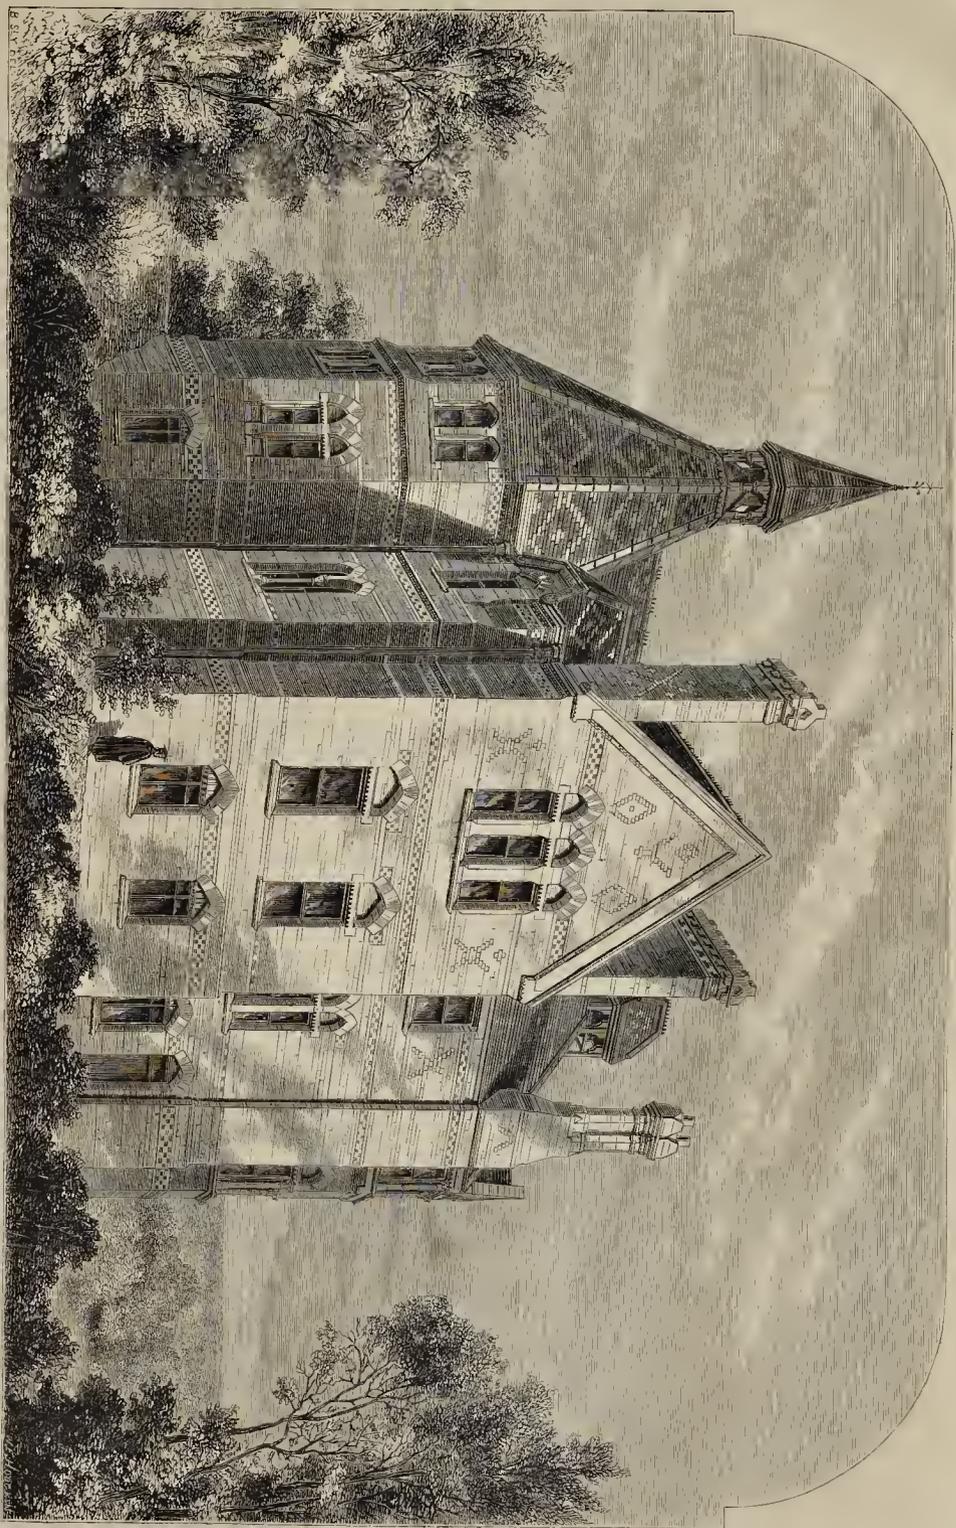

The furnishing of the interior has been carefully attended to, and carpets and curtains avoided as much as possible. The walls are all painted. The hall is paved with tiles partly, and the floors are stained and varnished. The works were carried out by a local builder; and its usefulness has already been put to the test, and its importance proved as one of the institutions of the flourishing school founded by old John Lyon at Harrow-on-the-Hill.

We have only to add that the Sanatorium is under the care of Dr. Hewlett and Dr. Bridgewater; a lady presiding over the establishment.

St. Mary's, Newington.—Mr. Charles Hardy, Assistant-Surveyor of the borough of Leicester, has been appointed Surveyor of Sewers to the parish of St. Mary, Newington.

THE HARROW SCHOOL SANATORIUM.

SANATORIUM FOR HARROW SCHOOL.—MR. CHARLES FORSTER HAYWARD, ARCHITECT.

THE SEWERAGE OF BIRKDALE.

Those who know anything of Southport will hardly have failed to notice the rapid increase of the neighbouring township Birkdale. Some few years since what is now occupied by a considerable population was then merely rabbit warren. Numerous residences have been erected, and the care and expense the proprietors have been at in forming gardens upon the barren sand, in most cases the whole, show the soil having to be brought from a distance, show how the seaside is appreciated by the inland manufacturing population, from whom, among the substantial classes, both Southport and it are mainly fed. Southport and Birkdale have attained considerable reputation for mildness of climate, which has not failed to influence their prosperity; about five years ago Birkdale adopted the Local Government Act, and in consequence of the formation of new roads, and the rapid extension of property within that time, after considerable discussion, the Board have finally decided to give their district the benefit of a comprehensive system of sewerage, in lieu of the absorbent cesspool system now in vogue. The question of a suitable outlet formed one of the main difficulties to be dealt with; as the objection to bringing outlet pipes on to the shore being insuperable, an arrangement for a disposal of the sewage inland became of prime consequence. These preliminaries having been settled, the Board have entrusted the preparation and carrying out of a sewerage scheme to Messrs. Keade & Goodson, civil engineers, of Liverpool.

Among other things, Birkdale will possess suitable gardens when the new portion of the Birkdale Park Estate (the property of Mr. T. W. Mandell) is completed.

COLUMNS IN PUBLIC BUILDINGS.

It has often occurred to me that in churches & other public buildings they might now substitute for those heavy, massive stone pillars now used, which are so expensive, tedious in erecting, and so much obstruct both the seeing & hearing, strong iron pillars, and then encase them in thick coloured glass, by which means they could give them the most beautiful polish, either plain or fluted, of the most varied and attractive colours. No two of them need be alike, if it was considered advisable. I think the manufacture of glass has been brought to such perfection in this our day, that you would experience little if any difficulty in getting what I propose and suggest, in the most perfect and satisfactory manner, and, by so doing, secure six most desirable things in this go-ahead age of ours,—namely, beauty, lightness, roomy, space, efficiency, and time.

St. JOHN S. BRODERICK.

NEW WING OF COUNTY GAOL, CHESTER.

This work is now near completion. The old buildings having been removed, says the local Chronicle, the foundations were found to be defective, and this unexpected obstacle had to be surmounted by excavating the entire surface to a depth of 14 ft., the foundation walls being raised from a bed of concrete 4 ft. 6 in. deep, which involved an outlay of £1,375. On the 10th of November, 1867, the first stone was laid, and from that time the building progressed satisfactorily to the present. The form it takes is a section of an octagon, the front presenting two oblique angles, corresponding to the projecting angles of the chapel at the south-west end of the goal. The entire length of the building is 140 ft., the width 46 ft., and height at the ridge 43 ft. The front is of stone, double-faced, and taken from the old buildings, at the exception of the plinth course. The entrance is by a porch beneath a tower, or projection shaft, which is 61 ft. from the ground, and which is attached a lightning conductor, half-inch copper wire, with glass insulators. The entrance, under the tower, is secured by a iron-plated on the inside and at the edges, and beyond this are ordinary sliding-doors opening into the main corridor. The width of the arch is 12 ft. 6 in., and the height to the ornamental cornice at the springing of the arch, 12 ft. On either side of the corridor are the cells for the prisoners, 84 in number, in three rows of 14 on each side. Each cell is 12 ft. by 8 in., and 9 ft. 6 in. high, and is furnished with a table on ornamental brackets, a stool, wash-tub, and water-closet, while at one side

of the table is a roller to which the hammock is strapped, the other end being secured by hooks to the wall. The different tiers of cells are reached by an ornamental iron winding staircase in front of the main entrance, with perforated treads and risers, there being four flights and two landings, and is lighted by six windows, 5 ft. 6 in. by 3 ft. 6 in. From these landings there are balconies with ornamental iron fronts, resting on scroll brackets, which extend the length of the corridors on both sides and give access to the two upper tiers of cells. In the tower, and easy of access from this second landing, is the officer's day-room, and above that his sleeping-room, and from his position he can see down to the angles on either side of the corridor. In each cell there is a handle which, when turned, strikes a gong near the officers' rooms, and throws out an indicator at the cell which requires attention. There is a jet to give a certain amount of light to each cell, while the corridor is lighted by jets from the scroll brackets supporting the railings. The heating is by means of hot air, to obtain which there is a saddle boiler under the corridor. A main is carried the entire length of this, and from it a pipe is carried to each cell, the prisoner being able to regulate the temperature by letting in cold air if he chooses. Besides this, the hot blast can be regulated by the admission of cold air, and for close and sultry weather there is a stove in the extraction shaft for increasing the current of cold air. The water for the use of the prisoners is supplied from two large cisterns fixed above the corridor arch in the roof: each prisoner obtains what he requires from a tap in his cell. The architect is Mr. R. Griffiths, of Stafford; the clerk of the works, Mr. C. Smith; and the builder, Mr. H. Lovatt, of Wolverhampton, who has the contract for the new county asylum at Macclesfield, and has been engaged in prison alterations at Stafford, Coldbath-fields, and elsewhere. The total cost of the work, less 658L. 4s. 6d. for old materials, was 3,956L. 1s. 11d., and the personal superintendence of it is, for the most part, due to Mr. F. F. Foxall and Mr. Elsdon, the foremen of Mr. Lovatt.

THE DESTRUCTION OF A GLASGOW THEATRE BY FIRE.

We last week announced a telegram notifying the total destruction by fire of the Prince of Wales's Theatre, Glasgow. It was situated at the junction of Main-street, Cowcaddens, and Stewart-street, the front entrance facing the Established Normal Seminary. At a quarter past eleven o'clock on the Wednesday night, at the conclusion of the performance of the pantomime of "Valentine and Orson," the audience was dismissed. About five minutes after twelve persons in the street gave the alarm that the theatre was on fire, flames coming from the roof above the gallery and that part of the stage nearest to Stewart-street. Ere the engines reached the scene of the fire the flames had got complete mastery over the building, and were bursting forth from the back of the stage onwards to the rear of the gallery. The fire brigade had then to direct their efforts in the way of preventing the flames from spreading to the contiguous buildings, and particularly to a tenement, part of which forms the corridor which led to the stalls and boxes. These efforts were successful, but it was not till near three o'clock that the flames had subsided. In fact, the fire did not cease raging till it had burned up everything that was combustible. The building was insured by the proprietor, Mr. Hannay. Mr. Davis, the tenant, is insured for 2,000L.; but the value of his scenery and other properties is estimated at 8,000L.; so that his loss is 6,000L. The actors, carpenters, and some musicians have lost their all—their dresses, tools, and instruments,—and may be a considerable time out of employment.

This is the fifth theatre in Glasgow which has been destroyed by fire. The first—a stone building—was the Queen-street Theatre; the second, the theatre—a brick erection, built by Anderson, the Wizard of the North, in the Jail-square; the third, the Adelphi, also in the Jail-square, built of wood, and tenanted by Mr. Miller; the fourth, the Theatre Royal, in Dunlop-street, a fine stone building, which belonged to Mr. Alexander, who also managed the theatre for himself; and the last, the Prince of Wales's. Mr. Cook's Circus, in the Jail-square, also met with the same fate.

The Prince of Wales's Theatre, which was opened on the 3rd of August, 1867, was built on

the site of the Old Colosseum, in Stewart and Cowcaddens streets. It had a neat but unpretending appearance. There were two tiers of galleries, one of which was set apart as boxes, and the other for the accommodation of the "gods." The gallery was seated for 1,000, pit and stalls for 1,600, while in the boxes sitting-room was provided for 700. The stage was 40 ft. in length with 33 ft. of proscenium. The theatre was lighted with a large crystal sunlight gaselier, situated in the centre of the roof.

THE PHYSICAL

COMMOTIONS THROUGHOUT THE GLOBE.

THERE is something really alarming in the persistency with which "earthquakes in divers places" have for some time been manifesting themselves. In Iceland last month, numerous shocks were felt, not a few of them more or less violent. At Tauras, in Rungia, a violent earthquake was felt on the 3rd of the present month: its direction, as in so many other cases, was north and south. Distinct shocks have been felt at Weston-super-Mare, and in the east of England itself: there, too, the direction was north and south. A clergyman complains that he was sadly maltreated by what he calls a typhoon, while walking between Winscombe and Axbridge: he was struck on the back all of a sudden by a whirlwind, and dashed along "like a stone from a catapult" for 100 yards, and even rolled over and over after being dashed to the ground. Intelligence from Mexico announces that an earthquake took place on December 20th, in the cities of Colima and Manzanillo. Several persons were killed, many houses were destroyed, and nearly all the buildings in both places were more or less damaged. On November 12th, too, an earthquake destroyed several houses in the state of Coshula, and continued for two days with recurring shocks, fifty-eight in number. The country had previously been deluged by floods in the river Nazas, causing great distress: many people were drowned, houses were swept away, and vast quantities of provisions destroyed. A private letter received from Taranaki, in New Zealand, states that during the recent earthquake there the earth seemed convulsed by a perpetual pulsation for six hours, and for forty-eight hours afterwards sleep was hardly possible, as the constantly-recurring shocks were very violent. There were no less than forty shocks. To other earthquakes which have occurred in India and elsewhere, even since this article was prepared, we have no room at present to refer.

In a recent discussion at Melbourne, Australia, before the Royal Society there, relating to the South American earthquake, it was stated that the great wave which rolled on the coasts of New Zealand and all the eastern and southern shores of Australia, on August 15th, must have rolled over the Pacific Ocean in eighteen hours, or at the rate of 383 miles an hour. We are no disciples of Dr. Cumming; but when a matter-of-fact practical paper like the London Times, under present circumstances, quotes Scripture as to "earthquakes in divers places," one need not much fear making a little more particular allusion to predictions which may relate to cosmical and social laws of progress, which we as yet know little about, as we certainly do about the cause of these earthquakes, and which were, no doubt, seen clearly and appreciated by the inspired predictor. In the first place he alludes, as do Old Testament seers, to "the latter days" as the opening of a great summer, though attended by notable cosmical and other disturbances. Thus, in the Book of Amos, the seer, speaking of a vision he had, says,—“I see a basket of summer fruit.” Then, said the Lord, the End is come upon my people; and in accordance with this we find the following passage in Matthew. “Now learn a parable of the fig-tree. When his branch is yet tender and putteth forth leaves, ye know that summer is nigh; so likewise ye, when ye shall see all these things, know that it is near, even at the doors.” “These things” related not only to “earthquakes in divers places,” and “the sea and waves roaring” but to “stars falling from heaven,” the sun being darkened and the moon not giving light and becoming “as blood,” or, in other words, to a total eclipse of the sun, after the “trifling of those days” with “wars and rumours of wars,” “perplexity of nations,” and yet “knowledge increased,” and great “running to and fro,” &c. Was there ever a time in the memory of man when “all these things” were so concentrated in any one year as in last year, when there

were "earthquakes in divers places," when the falling meteoric showers excited great interest; when there was an eclipse almost unprecedented for its totality; and when the blood-coloured prominences which surrounded the disk of the moon while it darkened the sun, might well be regarded as the true meaning of the passage in Revelations relating to the sun becoming black and the moon as blood? What all these earthquakes, at least, betoken, is a very grave problem for men of science to solve. No sneering can extinguish this fact.

THE DECAY OF STONE IN PUBLIC BUILDINGS.

SIR,—For many years I have looked with grief upon the decay of stone in several of our large buildings, especially in such noble buildings as the Houses of Parliament, and many others which are ornaments to our metropolis. It seems a pity that after so much pains, anxiety, and expense has been bestowed upon these, they should in so short a space of time crumble to decay.

Now, as this decay must result from some cause, it is necessary that the exact cause be arrived at. It has been said on good authority, and by some of the cleverest men of the present day, that it is the smoke of London acting on the stone causes it to decay.

The principal object of this paper, then, will be to show that the decay of stone does not result from this cause, and in order to substantiate this I will mention a few plain facts which will tend to show that the smoke does not act upon the stone in sufficient force to decay it.

I have been to a great many quarries in various parts of Great Britain, and therefore have had the opportunity of noticing the stone on the spot from whence it is obtained, and I find there is a certain portion of stone that will perish in its own native air, and on its own soil, away from all smoke and soot; for instance, I have seen the Cheshire, Yorkshire, Lancashire, and Derbyshire stone, also the Glasgow white stone, and granites at various quarries, all perish in their own native air, and at most of these places there has been no smoke or soot to act upon them.

Again, there was a large building erected in the west of London, and one of the late eminent judges of stone was appointed to examine the quality of the stone. Now after this gentleman had passed the stone for the West-end building, a great quantity of it perished before the roof was on. This must at once prove to our minds, and not only to us but to architects and engineers, that it is not the soot that causes the stone to decay in our public buildings, but the inferior quality of the stone that was used. If the above proofs are not sufficiently convincing, allow me to mention one or two still more so. If we will but take the pains to look at some of our buildings, we find in many instances a sound stone adjoining a decayed one. How can this be accounted for? If the smoke had such an effect upon these stones that are decayed, why did it not act in the same manner upon the adjoining ones that are sound? Thus we again see that an inferior quality has been mixed with a good.

I have myself removed the accumulated soot from the face of stone, and on examining, found it to be quite sound and perfect. These simple facts ought to convince any practical man, and also our geologists, that the smoke is not the cause of the stone decaying.

The largest quantity of stone used in London is of the Portland. I have walked through these quarries and examined the stone at this place and found it to perish in large quantities (remember this stone has not been subjected to the smoke). The stone then is brought to London, and used in the construction of buildings, and, as may be expected, before the roof is fixed will be found to be in an advanced state of decay, and not only before the roof is fixed, but even after the stone has been used only two or three months; then our scientific men say it is the smoke acting upon the stone causes the decay, whereas if proper judgment had been used, and the stone of the right quality, the smoke would have had little or no effect upon it.

A great quantity of the Portland stone that is used in London perishes far sooner than the Bath. As a proof of this I will refer to the entrance gateways to the park at Hyde Park Corner. These are of Portland stone; nearly all this stone has perished, and is still perishing as fast as time will permit. Now the adjoining building

to these gateways is Apsley House, which is of Bath stone, and the stone of this building stands far better than the so-called Portland at the gateways. The exterior of the Grosvenor Hotel is mostly of Bath stone, and has been erected some seven or eight years, and not a single piece of this stone is decayed. And why? Because it was carefully selected. If it had been of a bad quality it would have perished before now, and thus, while this Bath stone building stands, some Portland ones have perished in less time than that above mentioned.

This stone, then, that decays, is simply an inferior quality, which, if placed in any buildings, whether in town or country, will decay; and not only will decay, but has already done so. For instance, many large buildings in the city of Oxford were erected out of stone obtained in the neighbourhood, without any regard being paid to the quality of that stone, and the result was as may be expected, in a few years these buildings went to decay. Had this stone been of a good quality, it would have remained sound and perfect, because some of the good quality obtained from the same neighbourhood was used at the same time as the above, and is as perfect now as when used.

The above example must not be confined to Oxford only, for it is the same with our noble Houses of Parliament. It appears to me that two qualities of stone have also been used in this building, namely, a good and bad. The fault is not so much in the stone decaying as want of judgment in selecting the same; because if stone be carefully selected, I am confident there will not be that decay there now is.

When we take into consideration the various kinds of stone that are sent to London, and all different in quality, we will see that careful judgment ought to be exercised in the selection of the same. I will here mention a few of the many sorts of stone. There are six distinct sorts obtained from Portland, five from Bath, and fifteen from Yorkshire and Derbyshire. In the neighbourhood of Penryn, there are about sixty or seventy granite quarries, the granite differing in a great many of them both in colour and quality.

We also obtain eight different sorts of granite from Aberdeen and its neighbourhood, viz.,—three sorts from Peterhead, two from Mull, five from Dalhousie, and three from the north of Ireland. We thus see that great care and judgment ought to be exercised in the selection of the proper quality, but that judgment has not always been correct; for instance, the before-mentioned judge of stone condemned two large loads of Portland stone at some works for which Mr. Kelk was the contractor. I said at the time this stone was good and would stand the weather. As a proof of this we afterwards used the whole of these two large-loads at the same works, and up to the present time not a single stone has perished. And here I cannot help remarking that some of our great men have a name which sways all before them, but have not the correct judgment which is absolutely necessary in respect to the quality of stone; for we here see judgment had been passed upon this stone and it proved the reverse.

It has also been mentioned that the granite at Waterloo Bridge is passing under the same process of decay as our stone, caused by the smoke: this is not the cause, for it is well known that the granite which was brought to London at the time Waterloo Bridge was being built was of an inferior quality compared to the granite used at the present day. I have seen granite almost as soft as grit stone, and possessing all the elements of decay. I have also seen granite in the neighbourhood of Aberdeen decayed in the inside of a new building, where it has been screened from smoke and the weather.

Thus, I have endeavoured, in the first place, to show it is not the soot that decays our stone; and, secondly, that this stone that decays is of an inferior quality.

It must not be supposed from the above that there are no good stone buildings in London, as several are now passing before my mind, but time will not permit me to offer any comment on these.

WILLIAM CROSS.

Manager of the Prince Consort Memorial.

** We willingly allow Mr. Cross, as a practical man of good experience, to express his opinion. What he says is to a great extent correct, but it is not wholly so. The decay of the stone of the Houses of Parliament (and which, by the way, is usually described as more extensive than it is), is not a case of selected and

unselected blocks. This is proved conclusively by the circumstances that the decay is most apparent in particular positions all round the building; for example, under the base moulding throughout, and under the first string. The stone in these long lengths would necessarily present a fair average of the quarry. The gentleman to whom our correspondent refers is obviously the late Mr. C. H. Smith. We have no right to doubt the assertion that his judgment failed on the occasion stated; but knowing well the experience he had had, and the extent to which he had studied the subject, we may confidently ask, who knew more about stone than he did? and if he failed, in whose judgment can we even now place faith?

ACCIDENTS.

A PORTION of the embankment of the Bridgewater Canal, at Trafford Moss, has given way, flooding a large extent of land in the neighbourhood. It happened on the left or north-east side, near Barton-on-Irwell, opposite the Trafford Moss Farm. In a few hours the Irwell had received nearly the whole of the escaped water. It was found that the bank had given way at a place where a culvert has recently been constructed, which passes beneath the canal and drains the moss.

At Petersfield the floors of a malthouse belonging to Mr. Crafts, in the Dragou-street, fell to the ground-floor below, containing a quantity of malt and barley. Fortunately no one at the time was on the premises. The cause of the accident appears to have been from the beams resting in the walls having withdrawn from their bearings. The old building was burnt down in March last. The new malthouse was erected in the summer.

A fire has occurred at the Town-hall, Crewe. A workman who was about to do some repairs, on opening the door of the news-room, was met by a volume of smoke. The fire brigade and engine of the London and North-western Railway Company attended without delay. The flames had by this time made their way into the large hall above. Some little delay occurred in getting a good supply of water; but upon securing it, the exertions of the fire brigade were speedily rewarded by the abatement of the fire. The damage, fortunately, was not very extensive. A large space of the flooring of the hall is burnt out, a couple of doors or so downstairs are destroyed, and some of the flooring there also and the smoke-room papering and paint are damaged, as, indeed, is the paint in the hall as well. The fire would appear to have originated in the passage leading from the news-room to the smoke-room, in which passage the firewood, &c., is kept. The origin of the fire is unaccounted for.

A singular accident has happened in Flat-street, Sheffield, by which two men were seriously injured. Messrs. Rodgers & Sons, the well-known cutlers, have lately added further workshops to their large large chimney, 33 yards high, has been erected. The whole of the works and the chimney were completed without an accident, but, the chimney being finished, it became an object of curiosity to go up it, and on Saturday afternoon many persons ascended. The apparatus used in the ascent was the same as was used in the course of building the chimney—namely, a wooden box, drawn up inside by a rope extended from "legs" at the top of the chimney to a crab in the yard. A mason and a bricklayer, among others, went up, three other men being at the crab, two of whom were accustomed to work, but the third was lending a hand, and it is supposed that he rested his left hand on a bar at the top, and by so doing disengaged the "catch" which locked the spindle of the crab into its place. At all events, the catch did become disengaged, and the effect of this was that the spindle got out of its place, a small cog-wheel at the end of it, which worked into the big cog-wheel of the drum, coming away from the larger wheel altogether. There was then no check on the drum round which the rope was coiled, and of course the weight at the other end caused the rope to unwind with great velocity, the two men in the chimney coming down like stones. The crab being thrown out of gear, the men at the handles had no control over it, as the revolution of the drum did not affect the handles in any way. When the accident happened the two men were within two or three yards of the top, so that their fall was about 30 yards. One had a leg broken, and the

other a serious scalp-wound, but neither was killed outright. The contractor for the chimney and works was Mr. John Wilson, of Sheffield.

A terrible accident occurred at Delhi on December 5th. Some masons were employed plastering an arch of the new bridge across the branch of the river between the fort of Delhi and Salimgruh parallel with the railway-bridge, when the arch fell in, burying the men beneath its ruins. Out of ten men extricated from the mass of masonry, only one was found to be breathing, and he died soon after.

THE METROPOLITAN BOARD OF WORKS.

MONEY MATTERS, LEICESTER-SQUARE, OXFORD-STREET UNDERGROUND, &c.

The usual meeting of the Metropolitan Board of Works was held on Friday in last week. The financial statement presented showed the total cash balance in the hands of the treasurer on the 11th of January to be 234,929l. 17s. 11d. Dividends were ordered to the amount of 9,396l. 18s. 3d. The sinking fund now amounts to 110,882l. 2s. 5d. New Three per Cent. Annuities.

The Chairman said he had received a communication from Mr. O'Beirne, M.P., stating that a proposal had been set on foot to build on the vacant piece of ground in the centre of Leicester-square. The amount proposed to be raised for building purposes was about 80,000l. It was resolved that a communication should be sent to Mr. O'Beirne, to the effect that the Board would do all in their power to prevent the open space from being built upon.

A deputation from the vestry of St. Marylebone and residents in the locality of Park-road, in Regent's Park, attended the Board to present a memorial with reference to the application of Messrs. White & Sons for erecting buildings in front of the present line of frontage in Park-road, as laid down by the superintending architect. The memorial was referred to the Works Committee for consideration and report.

A memorial was presented from the Board of Works for the Strand district against the proposed Oxford-street underground railway. This memorial was also referred to the Works and Improvement Committee for report, but it is said the bill has been withdrawn.

The clerk to the Board presented a report from the Finance Committee, which recommended certain payments to be made, and amongst the items were the following:—

Mr. Wilkinson, J.—Counsel's Fees, May and June, 1868.—	
Woolwich and silverdown Drainage	245 3 0
Cattle Market	150 13 6
Subways	150 13 6
Thames Embankment Approaches	195 16 6
Chelsea Embankment	150 13 6
Metropolitan District Railway Company	50 8 0
	4743 8 0

Mr. H. L. Taylor drew the attention of the Board to the enormous charges for counsel's fees paid to Mr. Josiah Wilkinson for two months only. Mr. Dalton (chairman of the Finance Committee) said Mr. Smith, the solicitor to the Board, used his discretion as to the counsel he employed, and for his part he could see no reason because Mr. Wilkinson had been a member of the Board he should not be employed. He believed that the House of Commons had laid down the charges to be made by counsel. The report of the committee was ultimately approved, and the money will be paid.

A report was presented from the Finance Committee stating the result of a negotiation for a loan of 150,000l. for the purpose of completing the Whitechapel, Holborn, and Kensington improvements, and the formation of Finsbury and Southwark Parks, and recommending that the offer of Mr. Pepper to obtain the advance of that sum for a period of five years at 44 per cent. be accepted. This recommendation led to a long discussion, Mr. Roche expressing his great dissatisfaction at the way in which this money was proposed to be raised. He saw no reason why they should not go to the fountain-head in the money-market; and by issuing bonds for small amounts, they would be readily taken up when it was known that those who advanced the money had the entire rates of the metropolis as security for the payment, and they would be content to receive a very much lower rate of interest than has then been proposed to be accepted by the committee in their negotiations with Mr. Pepper. He moved an amendment, which was negatived by a majority of 21 to 14, and the original recommendation of the committee was put and agreed to.

WIDFORD CHURCH, HERTS.

The parish church of Widford, like many others of the Hertfordshire churches, had fallen into a bad condition. A year or so ago, however, the vicar and some of the leading inhabitants, took the matter up, funds were raised, and the church having been restored, was reopened for service on the 14th inst. The bishop of the diocese, Rochester, preached on the occasion, and the village kept holiday. It deserves mention that one of the lady residents assisted in raising the fund by sketching and lithographing views of a number of the churches in the country, and which found sale in the neighbourhood. Readers of Charles Lamb will remember that Widford is the scene of his tale "Rosamund Gray;" and from the churchyard, looking across the valley of the Asbe, is seen the Wilderness, formerly a *pleasance* of the old mansion at Blakesware, where a relative of Charles Lamb was housekeeper, and which he often mentions in his writings. The works at the church have been done under the direction of Mr. G. E. Pritchett, architect, by Messrs. Bell & Son, of Cambridge. The tower has been thrown open by the removal of a gallery and modern boarded inclosure. The whole church has been reset and paved with encaustic tiles. The roofs have been restored and panelled. All the masonry and buttresses have been repaired, leaving the original stonework untouched as far as possible. A vestry has been added on the north side, and the church has been warmed with hot-water pipes supplied by Mr. Waller, of London.

Three ancient wall paintings in the chancel have been preserved. One of these, on the north side of the chancel, is particularly interesting, as it represents the Saviour seated in judgment on a rainbow; swords proceeding out of his mouth; his feet and hands pierced; there are figures around him (probably of angels) blowing trumpets. Another of them is on the eastern wall, probably representing St. Peter in Eucharistic vestments; and a third shows an ecclesiastic mitred pronouncing a benediction. Dandruff makes mention of these paintings. The chairs in the chancel are the gift of Miss Hamond. The altar-cloth was presented and worked by the Misses Palmer; and Mr. Spencer Lewin presented a new flagon and alms-dish, and restored the ancient chalice. The piscina and sedilia were both blocked up, but were found when the works were going on; also a Norman capital, which was embedded in an old buttress. The heltry is in course of renovation; there are five bells, one of which being cracked, has been sent away to be recast.

THE ABBEY OF AFFLIGHEM.

The ancient Abbey of Afflighem, near Alost, which has been in ruins for sixty years and more, is, we understand, about to be restored to its original uses, and has again passed into the hands of the Benedictine Order. At the period of the dissolution of the religious houses in Belgium, which took place at the commencement of this century, the Abbey of Afflighem was one of the most magnificent establishments belonging to the Order of St. Benedict, in the "Low Countries." Originally founded in the year 1063, it had been several times rebuilt. The earliest portion of the buildings then in existence was the nave of the church, which was erected between the years 1122 and 1144. The church was of great size, and consisted of a long nave and aisles, with two towers at the west end, transepts with an eastern aisle, and a very spacious choir, without spires. The nave was Romanesque, the transepts Transitional, and the choir, which was erected in 1204, was fine Early point. Unfortunately, the interior of the church was entirely modernized in the year 1762, under an architect of the name of Dewez, who covered the grand old Romanesque arches and pillars with wretched "Rococo" ornaments in stucco. Most of the abbey buildings were also re-erected by Dewez, and although very magnificent in their way, were quite out of keeping with the church and other ancient portions of the monastery. A very interesting little "bird's-eye view" of this abbey as it appeared at the end of the seventeenth century is to be seen in the "Brabantia Sacra." This engraving is by Harewijn, and represents the church crowned with curious "inlombs" spires. The cloisters appear to have been very extensive, and to the west of them was a large building with Gothic windows, and a large porch on the

upper story, which was approached by an external flight of steps. The west front of the church had evidently been modernized, even at that period, and most of the gables had been deformed by scrollwork.

The remains of these buildings are not very extensive, as they have been destroyed at various times, and the materials sold. However, a considerable portion of one of the nave arcades exists, with several of the monastic offices.

We have not been informed what portions are rebuilt, or whether a thorough restoration of the whole building is contemplated.

FALL OF WALL, LIVERPOOL.

SIR.—Human life is cheap, that is, under certain circumstances. Another bricklayer has succumbed to the injuries he received when he fell with his fellows at Fairfield, and is dead. An enlightened British jury, under the direction of the borough coroner, have sat upon him, and have delivered a verdict similar to those already given by juries on the two others who died from the same cause previously, viz.—"Accidental death, caused by the rains," a verdict equivalent to the old one of "Died by the visitation of God," and one which I utterly repudiate as being false, for if ever there was an accident which might have been predicted and prevented this was one.

I have visited the fatal spot again, and see nothing to alter in the account which I gave you at the time of the accident, an account which I shall leave your readers to compare with the verdict, and I have no doubt many will concur with me in my opening remark, that "Human life is cheap."

But, sir, I fear that this accident, of which I have told you, is not the only one on the same spot of which I shall have to make report. Not only are the remaining internal walls so bulged and shaken that they will have to be taken down, but the front of the house has collapsed, and the party-wall, which contains the chimneys of that side of the house, and of the other which is to be built against it, has formed itself into a fine curve outwards, of some 6 in. or 8 in. rise, and is also likely to fall. But the builder is sanguine, and hopes yet to save his carcass, and so he is getting in the foundations of this new house, which is to form a prop and support to the disabled one. Workmen meanwhile working in and about the building, the district surveyor also calling occasionally, and looking on.

This seems to me a very wrong state of things, and one calling for immediate alteration. Does the district surveyor do his duty, or is the law which he executes insufficient? Houses here are usually run up with 9-in. outside and party walls of inferior bricks and mortar, and very inferior workmanship, and without bond or wall-plates, and yet they are expected to stand. That they do not stand when any great strain is put upon them is well instanced by the fall of three houses on this same estate on Sunday, 27th of December last. These three carcasses were built in a row and adjoining, with good sized plan and four stories high, and were ready to receive the roof. A gust of wind came and levelled them with the ground, leaving only a small part of the back of the last house standing.

It is high time that some protection should be given to tenants, who are often compelled to inhabit the houses they occupy, but who are now liable to plague, pestilence, and sudden death from the want of previous supervision.

E. G.

ST. MARY'S, WARKWORTH.

The Church of St. Mary, Warkworth, Northamptonshire, was reopened on Tuesday, the 5th inst., by the Bishop of Peterborough, after renovation. It is of the late Decorated period, and was probably built on the site of the chapel of the Old Castle of Warkworth (the ruins of which were removed within the last few years). It has suffered much from alterations made at the end of the seventeenth century, and also from a "restoration" carried out about thirty years ago, when the greater part of the beautiful carved oak fittings for which this church was noted were either removed or destroyed.

At the commencement of last year, Miss Horton, of The Holt, Middleton Cheney, the lady of the manor, determined to restore the church as far as possible to its original beauty,

and generously provided the whole of the necessary funds for that purpose. The works are now completed, at a cost of about 2,500*l.* and have been carried out from the designs and under the superintendence of Mr. C. H. Driver, of Westminster. Messrs. Franklin & Sons, of Deddington, were contractors for the work generally; Messrs. Heaton, Butler, & Bayne supplied the stained glass; Messrs. Minton & Hollis the ornamental tiles; and the altar-cloth has been worked by Miss Draper, of Banbury.

The principal works executed have been:—Rebuilding the chancel on the old foundations (in place of the barn-like structure of the seventeenth century); building south arcade to nave; re-roofing the whole of the church and reseating it with oak seats, using the fine old ends that remained in the chancel; lowering the floor to its former level, and resetting in stone slabs the two fine brasses found under the floor of the Lady Chapel; cleaning the beautiful thirteenth-century altar tomb to Sir John de Lion from the whitewash which disfigured it; and restoring the porch to its original form. A vestry has been also built, the oratory warmed, and the churchyard properly drained.

COMPETITIONS.

Hull: St. Silas Church Competition.—This church, according to the conditions issued by the committee, is to hold 650 adults; the cost, including foundations for the tower, is not to exceed 3,500*l.* The premium for the selected design is 25*l.* and for the second best design 10*l.*; the competition was confined to local architects, and from whom the committee received eight designs. The design bearing the motto "Argus" has been selected for the first premium, and "Why not?" for the second. The church is to be built of red brick, with stone dressings; the arrangement of plan shows a nave of four bays, with north and south aisles, and a chancel with south aisle, the latter to be used for vestries and organ. The tower will be at the south-west corner of the nave, the first stage forming the porch and south doorway. The seating, of red wood, varnished, will accommodate 676 adults in the nave and aisles, also 40 seats in the chancel for choir. The author of the design selected for the first premium is Mr. R. G. Smith, of Guildhall Chambers, Hull.

Everton Hospital for Infectious Diseases.—The committee of this hospital having advertised for plans and specification for the erection of a new building upon the present site, received designs from sixteen competing architects. With the aid of a committee appointed by the members of the Liverpool Medical Institution, two plans have been selected—the first by Mr. Thomas Cook, of South Castle-street; the second by Mr. Joseph Ivimey, of Bunston-square, London; to whom the first and second premiums of 50*l.* and 25*l.* respectively will be awarded on the committee being satisfied that the building can be completed for the sum specified. The committee do not bind themselves to carry out either of the selected plans.

Dover Priory Competition.—The design marked No. 1, London, which gained the first premium (52*l.* 10*s.*) was sent by Mr. F. A. Klein, of Cannon-street, London. The design marked L. S. D., which gained the second premium (21*l.*), by Mr. A. G. Hennell, Southampton-buildings, Chancery-lane. There were seventy-five designs sent in.

PATENTS CONNECTED WITH BUILDING.

APPARATUS FOR INCREASING, REGULATING, AND CONTROLLING THE HEAT AND DRAUGHT IN STOVES, &c.—A. Middlemist. Dated 27th January, 1868. This invention consists in the adaptation to the back part of the range, stove, or fireplace of a rectangular or other formed box or case, provided with a damper or valve to be employed in connexion with the grate, stove, or hearth, so as to regulate the passage of the air, heat, and smoke within the chimney, and accelerate or diminish the draught to or from the fire by means of a mouth or opening. The apparatus whereby this is effected may be formed of wrought or cast iron or other material, and fitted or adapted to any or all of the various descriptions of grates or stoves at present in use; or new grates or stoves may be so constructed as to have the invention combined therewith.

WINDOW SUN BLINDS.—W. E. Newton. A communication, Dated 30th January, 1868.—This invention is not described apart from the drawings.

ORNAMENTAL TILES, &c.—J. Walker. Dated 17th February, 1868.—According to this invention the patentee perforates the absorbent mould in the parts where it is recessed, in order to form the pattern with small holes, which serve to supply the air more freely between the die or mould and the moulded tile, and cause the two to separate more readily. Also, in place of filling the mould as usual, he forces it upon a hat or slab of clay or clay by means of a press or otherwise, and the requisite impression is thus formed on the hat or slab of clay or clays, the holes giving free escape to the air and allowing the clay to penetrate into all the recesses of the mould afterwards in the usual way. The hollows in the moulded slab or hat of clay or clays are filled in with clay of another colour or colours, and the tile is finished as heretofore. The same process of manufacture is applicable to slabs, bricks, and other articles.

PORTABLE STOVES.—J. & J. Hinks. Dated 18th February, 1868.—Stoves made according to this invention are especially suitable for burning petroleum oil or petroleum spirit, but other liquid combustibles may be employed. The patentees construct a portable stove in the following manner:—the body of the stove consists of a hollow perforated cylinder of metal, the bottom of which has an opening sufficiently large to permit of the cone of the burner being passed through it. The said body is supported above the lamp at the required distance by means of arms or brackets on the lamp-stand. The lamp is supported on a stand provided with handles, by means of which the stove may be carried about. A short distance above the flame of the burner a sheet metal, up which the current of heated air and products of combustion from the lamp pass, and on the top of the perforated cylinder a hot-water reservoir or boiler fits. The hot-water reservoir has a conical tube passing through it, up which the current of hot air from the lamp rises and passes into the room. The cover of the hot-water reservoir and conical tube is so formed that the heated air in passing into the room carries with it a portion of steam rising from the water, and this keeps the air of the room sufficiently supplied with moisture. By means of a tap hot or boiling water may be drawn from the boiler. The lower part of the body may be made of glass, so that the lamp serves as a source of light as well as heat. When the body of the stove is of metal, the patentee inserts near the bottom a piece or pieces of talc, through which the state of the flame can be observed.

MANUFACTURE OF COMPRESSED BRICKS.—H. Chamberlain. Dated 18th February, 1868.—This invention consists essentially in pressing the brick two or more times, and each time in a fresh mould, so that the second pressure which is exerted upon a brick delivered from the first mould in the more or less defective state usual in dry brick moulding, perfects the article by completing the expulsion of the confined air and equalising the density of the brick, which, according to this invention, is turned over or reversed whilst passing from one mould to another, and, consequently, becomes equally pressed on the top and bottom surfaces.

MACHINERY FOR EXHAUSTING AIR, SUITABLE TO BE USED FOR VENTILATING MINES, &c.—J. G. Jones. Dated 19th February, 1868.—Here the patentee constructs a casing which is mounted on a central axis, and around the axis, on one or on both sides, are apertures for the passage into the casing of the air from the mine or other place to be exhausted. The casing has two or more hollow arms formed upon it, which spring from the central portion of the casing approximately in a radial direction opposite to that in which the casing is driven. The end of the arm is open, and forms the exit for the exhaust air from the mine or other place. On the leading or convex side of each arm there is formed a hood to take in air. It has a wide opening in its mouth, which receives the air standing in its course, as the hood is carried round with the other parts of the casing. From the mouth the air-passage in the hood gradually diminishes in area in passing outward along the arm until at some distance from the center end of the arm the hood opens into the air taken in by the hood consequently enters this passage and acts as a blast to force forward the current of air issuing from the mine or other place through the arm. When the apparatus is required to work under varying conditions it is desirable that the plate which separates the exhaust-air passage in the arm

from the blast passage in the hood should be made adjustable.

PULLEYS FOR SUSPENDING WINDOW FRAMES.—F. Ryland. Dated 12th March, 1868.—The patentee claims making on the inner sides of the frames or boxes of the said pulleys bushes or annular projections, and forming the shoulders of the axes of the bowls or wheels, or the central bosses of the howls or wheels of the said pulleys, in the same planes as the sides of the bowls or wheels for the purpose and substantially in the manner described.

ORNAMENTING SLATE, &c.—J. S. Gee. Dated 16th March, 1868.—Here the patentee first prepares the design correctly in accordance with the effect desired to be produced upon a sheet of prepared or lithographed transfer paper, or paper cloth, or other suitable material, prepared on one side or face thereof for the purpose of receiving the colours which are afterwards intended to be removed therefrom in a body. The surface of the slate or other material to be ornamented having been cleaned and prepared to receive the coloured ornamentation, the sheet of prepared paper, cloth, or other fabric or material, having the surface of the design first coated with a thin layer of cement or adhesive liquid, is then applied to the surface to which the ornamentation is to be transferred, and upon the application of friction and pressure to the back of the sheet, with the aid of water or other liquid to discharge the coloured design or ornamentation from the sheet, the coloured design is readily transferred. The slate, marble, or other material treated is then stoved or baked, and the colour or colours having been thoroughly dried and hardened, the surface is afterwards coated with varnish, and again subjected to heat during a sufficient period. When prepared it may be repeatedly varnished and stoved alternately, and finally polished in the manner at present practised in producing enamelled slate.

ARBITRATION CASES.

WHO IS WRONG?

The Liverpool corporation some time ago obtained the sanction of Parliament to appropriate the water, known as the Riddleworth Compensation Water, amounting to 8 cubic feet per second, during twelve hours per day. The claims of thirteen out of the fifteen millowners and riparian proprietors had been satisfied some time ago, but it was found impossible to arrange amicably with the remaining two, Mr. John Park and Mr. Rodgett, and these cases had therefore to be referred to arbitration. Mr. C. E. Cayley, M.P., acted as arbitrator on behalf of the corporation; Mr. J. Bancroft, on behalf of claimants; and Mr. George Pownall, as umpire in both cases.

In the first case claimant produced eleven valuers, whose estimates varied from 21,800*l.* to 35,000*l.*, the average of the whole being 27,420*l.* The corporation brought forward four valuers, the average of whose estimates was 3,211*l.*, and the umpire awarded 5,882*l.*

In the second case, namely, Rodgett's, the average value as ascertained by the array of witnesses called by claimant, was 13,470*l.*; the average of the four corporation witnesses was 3,169*l.*, and the award of the umpire, 3,936*l.*!

ARCHITECTS' RESPONSIBILITIES.

SIR,—On the subject of the responsibilities of architects for defects of workmanship, which the most careful supervision will not always adequately provide against, I send you herewith a copy of a clause which I have for some year past uniformly introduced into my contracts to meet this particular contingency; it is as follows:—

"Provided, nevertheless, that no final or other certificate shall, under any circumstances, cover or relieve the contractor from his liability for any fraud, default, or wilful deviation from his contract or works described in specification; but he shall always remain responsible for any such fraud, default, or wilful deviation, and for the consequences thereof, whether the same be discovered or noticed previously to the granting of such final or other certificate or not."

This should, of course, be introduced after the clause specifying the payments and certificate. It is perfectly equitable and most admirably adapted to the cases against which it is particularly aimed. It has, moreover, this special advantage; that retaining the responsibility of the contractor after the certificates are given, does away with one of the main inducements to bad work.

H. B. G.

ARCHITECTS AND "QUANTITIES."

SIR,—As there was a long discussion in your columns some few months back, relative to the desirability of the architect supplying his own quantities for new workhouse at Hereford, or in fact of any architect supplying his own quantities, perhaps it may interest your readers to know the result, and to warn architects against adopting a similar course of procedure.

From the *Hereford Mercury*.

NEW WORKHOUSE.

A report, dated January 1st, was put in from the building committee, who met at the new house on New Year's Day; present, Mr. Abel Smith, Mr. Mortlock, Mr. Cooks, Mr. Squires, Mr. Baker, Mr. Robinson, and Mr. Brandram.

It stated that the committee had inspected the new workhouse.

Mr. Peck had made a statement respecting the extra brickwork, and had expressed himself satisfied with the construction of the tank to which Mr. Cousins had objected.

Mr. Peck attended, and said, with regard to an alleged error in taking out the quantities of the brickwork, that he did not wish to get rid of his responsibility, but that there was an error of 84 rods 17 ft., and the amount of extra brick was equal to 1,018.

The Chairman asked if it was necessary to take action on it.

Mr. Brandram said he thought not; the Board had nothing to do with it. Mr. Peck had guaranteed the accuracy of the quantities, and the error was stated to have been caused by an omission of a clerk in Mr. Peck's office.

Mr. James asked whether Mr. Peck had received any money on account. Mr. Sworder said, No. A SEAFYTOR.

NEW MODE OF TOLLING GREAT BELLS: WORCESTER.

THE 44-ton bell lately cast by Messrs. Taylor, Loughborough, for Worcester Cathedral, has been hung on a new plan, which, with the bells clock on the model of the Westminster one, designed by Mr. Denison, Q.C. and gives a very effect to bells which are too heavy to be rung in full swing. The gudgeons or pivots are wedge-shaped, like those of a scale-balan, and are on hand-brasses very slightly hollowed: the motion is thereby so little that the bell can be moved by one man with one hand, and was so used after afternoon service last Sunday (Jan. 17), by the Rev. H. T. Eilacombe, of Devonshire; it is a small man, and nearly 80, as well as by Mr. Denison himself, and the Rev. R. Cattley, the author of the scheme for the peal of 12 bells and the clock. It is actually much easier in pulling the clapper by a rope, besides being unlikely to crack the bell; and the tone of the bell came out much more grandly than with the old plan. There is no doubt that the heaviest bells in England might be made tollable in this way at a very small expense, some of which are never heard now, except very inadequately struck by a clock hammer, or by hand. No bell is required, only a long lever fixed to the bell.

The gudgeons must not be lower than the top of the bell. The bell is half a tone below the half-quarter bell of the Westminster clock. The diameter of the mouth is 76 in. The inscriptions are set in ornamented medallions, copied from some ancient bells in Wiltshire. Round the shoulders:—*Surgens, dormiens, et exurgens martiris et illuminabit te*; below:—*Joannes Taylor, de Loughborough, fudit. In usum ecclesie cathedralis Martini et beate Mariae Virginis in civitate et parochia Wigorniensis. MDCCCLXVII.* Besides the founders' trade-mark, within a circular medallion, there are on shields the Royal arms, and those of the City, and the seal of Worcester, and the Dean and Chapter, besides the names of the donors which encircle the bell.

RECENT NOTICES OF FREEMASONS.

Worcester Cathedral Roll, A.D. 1396-97.—William Gidding and William Geryys, Freemasons. Gidding had a salary of 1l. 6s. 8d.—In 1427, John Wolston and John Harry, Freemasons, were sent from Exeter to Beer to measure stone.

Guilford of Freemasons were in existence in London A.D. 1375, Edward III. A list drawn up in French of the numbers of persons chosen to perform several mysteries of the Common Council in the next year, 1376, show two Freemasons among others elected.

Whitby Abbey Chapel, A.D. 1434.—William Gidding, Freemason, made a contract with the lord of York for the construction of the same.—*Monasticon*, vol. iii, p. 162.

St. George's Chapel, Windsor, A.D. 1507.—William Vertue, Freemason, executed the groined ceiling at St. George's Chapel, Windsor.

Eton College, A.D. 1441, December.—There were thirty-five Freemasons employed.

Tower of London.—The Freemasons' work between the 4th of June "laste paste," into September 7th, 24th year of Henry VIII., is described by a document now in the Chapter-house, Westminster.

Louth Steeple, A.D. 1627-8.—The spire was repaired by "Thomas Englefield, Freemason and steeple mender." E. W. S.

MATTERS THEATRICAL.

Haymarket Theatre.—"Home," a new, if not wholly original, comedy, by Mr. T. Robertson, the author of "Caste" and other excellent dramatic pieces, has been produced here with complete success,—that sort of success which must force all who are interested in stage productions to go and see it. The story, though slight, is compact and "washable." Some of the situations are novel; the language throughout is pointed and good, and it is thoroughly well acted by Mr. Sothorn, Mr. Compton, and Miss Ada Cavendish (the original Venus of "Ixion"). Miss Jane Burke and Miss Caroline Hill fill smaller parts efficiently. A young actor, brother of a gentleman already acting in this theatre, made an agreeable impression. He was wrong to take a name, Astley, so little different from that of an actor beginning to become known at the Adelphi. Mr. Buckstone, in announcing the new piece for repetition until further notice, said to his audience,—"I know you all like home, and I hope you will find it here for many nights to come." In "The Frightful Hair," which is very funny, Mr. Kendal, an actor fast rising in his profession, makes a decided hit. His travestied imitation of the principal actor in Lord Lytton's play, in voice, manner, and appearance, is strikingly good, and is sustained throughout the entire piece. Some of the parodies are exceedingly well sung, and Mr. O'Connor has painted for the piece two or three bright scenes.

"The Princess's"—"After Dark" continues to fill the house nightly; nor need any be surprised at this who consider the matter. It is not alone the story, which is sufficiently interesting, the well-contrived and painted scenery, or the strikingly sensational passage of the express train (one of the cleverest mechanical effects, be the inventor who he may, that the stage has shown); but the acting, too, that has assured this success. As in nearly all Mr. Bonicault's pieces, each part is rightly filled. Mr. George Vining has made of the role of the first drunken vagrant Tom a finished study, elaborating it throughout with the greatest care and efficiency. The resulting picture is calculated to teach as well as interest. The varnished bushranger of Mr. W. Lacy and the Jew gambling-house keeper of Mr. Dominick Murray are equally excellent in their way.

Lighting Theatres.—A correspondent, "M.A.B.," writes thus:—"Perhaps you will allow me to offer a suggestion on lighting theatres and concert-rooms. The excessive quantity of gas in these places of entertainment very much interferes with the comfort of many persons, and in cases in which the great amount of light is not distressing to the sight, the deleterious atmosphere so occasioned is most injurious to the health. I know several ladies who suffer severely from headache whenever they spend two or three hours in these over-lighted places. The effect of subdued light is most agreeable to the majority of persons. There are people who can not only bear a strong light, but like it; they are exceptional, however, and should be better instructed on the subject. There are two London theatres which I need not name where a good example is set in the matter of moderate lighting: the stage effects are very much heightened by this means, for the glare upon the eyes from the chandelier and surrounding lights renders it difficult and painful to see and appreciate all that is passing upon the stage."

Montreal.—A showy theatre, to seat 1,600 persons, has been completed here.

Creusot.—A new theatre, designed by M. Morisot, of Creusot, has been opened at the great ironworks there.

Mr. Henry Leslie's Concerts.—Mr. Leslie has sent out an attractive prospectus of his fourteenth season, which will comprise concerts of unaccompanied music, by Mr. Leslie's choir, and orchestral and choral performances. The first concert will be given on Thursday, February 4th.

PROVINCIAL NEWS.

Nottingham.—The new Mechanics' Hall, replacing the one that was burnt in 1867 upon the same site, is nearly completed, and was opened on the 19th instant. What remained of the old building has been restored and incorporated with the new. The lofty portico fronting Milton-street remains, but the entrances are parallel with the street, constituting an improvement on the old steep flight of steps. Another improvement is the porch at the Burton-street entrance to the hall, which is situated almost on the site of the old entrance to the library. The lecture-hall at the corner of North Church-street is a prominent addition to the institution. The present edifice has improved ingress and egress as compared with the late one, having three spacious entrances from Milton-street and two from Burton-street, in addition to several entrances from the corridors, dividing the hall and the institution leading to the orchestra, green-room, retiring-room, &c., with several additional exits available in case of emergency, while the stairs throughout are fireproof. The old grand hall within was 95 ft. long, 45 ft. wide, and 30 ft. high; the present hall is 110 ft. long, 59 ft. wide, and 40 ft. high, and has a gallery in addition. The superficial floor-space of the old hall was about 4,275 ft., while that of the present hall is 8,100 ft. The cubical quantity of the old hall was about 128,250 ft., while the new hall contains about 258,600 ft., which shows the new hall is more than cent. per cent. larger than the old one. The orchestra is semicircular, and less precipitous than the old one, and able to furnish space for about eighty more performers, with four convenient approaches. The grand hall is oblong in form, with semicircular ends and returns. The building has two tiers of windows to the sides, side and end galleries, with a horse-shoe well-hole. The hall is surmounted by a coffered ceiling, with a coved and enriched cornice. The outer tier of eaves are encompassed by guilloche ventilators, communicating with draught chambers through the roof, having pendants at their junctions, lighted by five 81-jet sun-lights, by Messrs. Verity & Sons, of London. The lecture-hall, abutting upon North Church-street and Burton-street, is 59 ft. long, 43 ft. wide, and 28 ft. high. This room is in one story, and lighted by an 85-jet sun-light. The library is 58 ft. 6 in. long, 31 ft. 9 in. wide, and 16 ft. high, lighted from each end by skylights and three pendant corner gas chandeliers. The reading-room, which occupies the north-western boundary, is 58 ft. 6 in. long, 25 ft. 3 in. wide, and 16 ft. high, having an enriched cornice and empenned ceiling, lighted by a tier of six semicircular sashes from the west, and furnished at the end of the room with pendant ventilating shade-lights, which, together with the sun-lights, were all provided by Messrs. Verity & Sons. The lecture-hall and grand hall are warmed by hot water on the circulating principle, supplied by Messrs. Goddard & Massey, of Nottingham. The principal contractor is Mr. William Slinn, builder, Nottingham. The carpenter and joiner's work has been executed by Mr. George Wheatcroft; the plastering by Mr. Thomas Murdy; and the slating and stonework by Messrs. Marriott & Co., all of Nottingham. Mr. T. Simpson, of Nottingham, is the architect.

Cavendish.—A new lecture-hall has been opened at Cavendish. The building, which has been erected at the sole expense of Mr. J. S. SALTER, Garrett, stands at that gentleman's estate. Mr. Sudbury, was the architect, and the building was erected by some workmen of Mr. Garrett's.

Cannock.—The new market-hall of Cannock has been opened for the inspection of the public. The site and building cost about 1,200l., raised by 1l. shares, which were quickly taken up, in the main by the middle and poorer classes—the landed and money interest giving scarcely any encouragement to the undertaking. The shape of the hall is nearly oblong, with an open roof, supported by eight horizontal rafters, these being connected with a network of tie-beams. Light is admitted from a clearstory, and from a large window over the entrance door. The hall is 100 ft. long, 47 ft. wide, and 42 ft. high, lighted with circular gas-burners of 21 jets each.

Kidderminster.—At a meeting of the building committee of the new market-hall to consider the tenders for the hall, it was found that there were eight tenders sent in, varying from 1,919l. up to 2,650l. That of Messrs. Goodman & Wilks, for 1,949l., was accepted. The vegetable market is to be completed in two months, and the whole of the work is to be finished by May 6.

Books Received.

History of the Fens of South Lincolnshire. By W. H. WHEELER, C.E. London: Simpkin, Marshall, & Co.

THE chief purpose of this volume is to draw attention to the large expanse of fertile land which might be redeemed by home colonization in the fen district, and about the confluence of the Witham, the Willand, the Nene, and the Ouse. The scheme brought forward by Sir John Rennie for enclosing the whole of the Wash, and thus reclaiming 150,000 acres of waste space, Mr. Wheeler considers as one well worthy the attention of Government. The example set here by the Romans of old, who employed their soldiers, aided by convict labour, in forming the embankments by which the Fens are protected, might well be imitated in the present day, even were neither soldiers nor convicts to be employed. And it is not in the fen districts alone that thousands of acres of English land might be utilized, and employment thereby found for our unemployed working classes, but in various parts of the country. Mr. Wheeler gives an interesting account of what has already been done in the fen district, whereby 250,000 acres of land, a space larger than some of the English counties, have been converted from mere morass into one of the richest tracts of agricultural land in the country; so that what he proposes would be no blind speculation, about the profitable results of which there could be much doubt. The volume is accompanied with a plan of the district treated of, reduced from the ordnance map, and specially adapted by the author for his book.

VARIORUM.

THE "Spirit of Education." By Mikado. Wynman & Sons, Great Queen-street, London. Without entering into any of those subjects which the author of this brochure gives simply by way of exemplification of the relationship of the teacher to the pupil, such as the theory of "the three elementary or primitive colours" in light, we must admit that the tone is excellent and worthy of all acceptance, as is the motto which indicates it, namely,—"Though I speak with the tongues of men and angels, and have not charity, I am become as sounding brass or a tinkling cymbal." The author impresses on his readers that teachers should be trained to feel "that it is their duty to regard all who differ with them in religious belief with feelings of charity; to respect the convictions of others, as they would have their own respected; and to feel that each one of the numerous sectarian bodies composing the Christian church might, with equal right, act upon the assumption that all the others were in error, as they that all those were who differed from them in opinion."—"Report of the Sanitary Committee of the Borough of Nottingham, for the year ending September 30th, 1868." The reporters here state that an intimation of the outbreak of the Typhoid epidemic was made to them in September; and that—

"An inspection of the parts of St. Ann's Ward, especially affected by it, was at once made, when it was found that a considerable number of pigs were kept in close proximity to dwelling-houses, without proper drainage, and which were in such a state generally as to induce your Committee to take active steps for the abatement and removal of the nuisance. It was also found that many of the sepulchres in the same neighbourhood, in consequence of defects in the plan of construction, were in a foul state, caused by the accumulation of water. Your Committee caused all the districts affected with fever to be liberally supplied with disinfectants."

The Committee state that four of the twenty three public water-closets "have been converted into dry-earth closets with satisfactory results, and the contents are utilized instead of running into the sewers." Storing-tanks in some of the thirty-nine urinals have also been provided. The means requisite for the utilization of the sewage, and the purification of the river Trent and its tributaries, are exciting attention in the district.

—The *Register and Magazine of Biography*, January, 1869. Nichols & Sons, Parliament-street, Westminster. No. 1. This new shilling magazine is intended as an enlarged record of births, marriages, and deaths, with notes of genealogical and personal occurrences. The present number contains biographical notices of Henry Constable, the poet, Sir Edmund Andros, and members of eminent persons more recently deceased, including Rossetti, with relative matter of a miscellaneous description. It is an enlargement of the idea carried out for many years in the *Gentleman's Magazine*, with which the Messrs.

Nichols were long and honorably connected.—The *Publisher's Circular* (Sampson Low) for January 16, is specially devoted to the educational books of the year. In its advertising pages there are copious lists of school, college, and class books of every kind, aim, and variety, adapted for almost every college or school, as well as for private tuition and self-instruction. Amongst them will be found Mr. John Murray's standard school books, consisting of advanced dictionaries, school dictionaries of Dr. William Smith, Greek and Latin classics by the same author, and others, and even reproductions, King Edward VI.'s First Latin Book and Latin Grammar; another admirable variety is the Student's Manual series, from the same publisher. Messrs. Longman's list includes a great variety: Gleig's School Series; Colenso's Mathematical, Classical, and most valuable Elementary Works; Alexander Bain on Grammar and Composition; the Civil Service Arithmetic; White's Capital Dictionaries; Valpy's Delicacies; and, last and sweetest, educational and elementary works on Music, which has now fully taken its place as an item of a generous education: we must not omit to mention a very useful little series of works, the "Stepping-Stones" to knowledge—instruction in various sciences, wherein music is simply explained and easily retained. In the lists of the Messrs. Virtue will be found the important handbooks of instruction, brought down to the latest discoveries, the *Wendle Series*.—"Troveville by the Sea." Edited by W. Blanchard Jerrold. Bradbury & Evans, Bonverie-street. In the preface the editor says: "The loveliest watering place on the northern shore of France is all but unknown among us; and it is to make a beginning towards rooting out this ignorance that I have watched the following unpretending and light chapters through the press." It is well calculated to send additional visitors in the season to this already much and fashionably-frequented sea-side resort.

Miscellaneous.

The Central Station Hotel, Leeds.—In our necessarily brief account last week of this handsome structure it was stated that the carving, with some exceptions, had been executed by a certain carver. We are now invited to add a line as to these exceptions, and willingly comply. At the corners of the building, which the town authorities required to be rounded off, a corbel figure is carved, representing an athlete supporting, as it were, the angle above, and bearing the railway company's armorial badge; thus surmounting well a somewhat formidable difficulty. These were executed by Mr. Theodore Pnyffers, and deserve to be commended. Mr. Pnyffers, it will be remembered, is executing the figures for the south porch of Canterbury Cathedral.

Sheep-shearing by Steam.—The Melhorne correspondent of the *Alexandra Courier* says:—"I saw a machine at work the other day which is likely to cause a great change in the sheep farming interest; it is no less than to shear sheep by steam; and from what I saw of it, it is likely to be a complete success. The machine is made of brass, something in the shape of a small trowel; the motion is got up by a turbine wheel about three inches in diameter; and this is geared into another wheel on which is fixed a cutter; in front is a comb, which serves as a guide, and against cutting the skin of the sheep. The steam is conveyed from the boiler by a tube of india-rubber; this tube or pipe is double, having one inside the other; the inner one is the injection, and the space between the two is the ejection. The machine can be handled quite easily, and will be used just in the same fashion as the shears, but will cut much quicker and far cleaner, without the least danger of injuring the fleece or the sheep."

Liverpool Architectural Society.—The seventh meeting of the twenty-first session of the Liverpool Architectural and Archeological Society was held on Wednesday, the 13th, in the Royal Institution, Colquhoun-street. Mr. F. Horner presided. Mr. Boulton exhibited a plan of some tunnelling discovered in excavating the foundations of the New Exchange; and the paper of the evening was read by Mr. H. P. Horner, "On Characteristic Design in Architecture." A sub-committee, consisting of the president, Mr. Boulton, Mr. Wm. Picton, and the secretary, was appointed to consider and report upon the subject of architectural education in Liverpool.

Death of Sir Henry Ellis.—On the 13th inst., Sir Henry Ellis, late principal Librarian of the British Museum, died in his 92nd year. He was appointed to that post in 1827, and was for many years Secretary of the Society of Antiquaries. In middle life he was indefatigable as an author. Among the most valuable of his publications are his "Original Letters and Illustrations," mainly from the autograph originals in the British Museum, the State Paper Office, and other sources. Sir Henry Ellis was also the responsible editor of an enlarged edition of Dugdale's "Monasticon Anglicanum," in several volumes folio. He also was the author of the "General Introduction to 'Domesday Book.'" Only a few weeks ago we found him assiduously examining the accounts of the Literary Fund, and heard from his lips many stories of long long ago. Directly after this, the fall of a stack of chimneys into the room where he was sitting gave a shock to his system, and there is reason to fear expedited the event we deplore.

Exhibition to further Domestic Economy in Utrecht.—Meetings are being held in London to further the proposed exhibition in Utrecht to be held in the months of August and September, 1869. The principal object of this exhibition is to bring to the knowledge of the workman such articles of household use, furniture, dress, food, work, and instruction of different countries, as at a low price, combine usefulness and solidity, so that he may be enabled, by judicious economy, to improve his condition. Articles of luxury as well as of elegance, strictly so called, are excluded. The exhibition will include house &c. (a) Plans of dwellings for married and single men; (b) Plans of lodging-houses, eating-houses, boarding-houses, baths, rooms for reading and recreation; (c) Details of construction; (d) Materials for such buildings. Household necessities, &c.: Furniture, clothing, food, workmen's and gardeners' tools, means of moral, intellectual, and bodily development, and reports, statutes, regulations of different associations for promoting the well-being of the working classes. All the articles to be sent in between the 15th and 30th July.

Society for the Encouragement of the Fine Arts.—On Thursday, the 14th inst., the annual general meeting of this society took place in 9, Conduit-street.—Mr. James Edmondson in the chair.—When the annual report was read by the hon. secretary. The report stated that the session of 1868 had been a successful one, evidenced by the increase in the number of members, the warm interest taken in the proceedings of kindred societies, and by the continued support it had received from those professionally connected with the fine arts. The revival of art exhibitions, at which the merits of such men as Dore, Barry, and Constable had been discussed, had given general satisfaction; and these, with the *conversations*, musical, and of lectures, had formed a centre of artistic social enjoyment.

Saw-hardening Furnaces.—Mr. John Rogers, builder, Hereford-street, Sheffield, patented an improvement in the building and constructing of saw-hardening furnaces; it is said to be applicable to steam boilers and brick-pans, and will consume its own smoke. It is estimated that the invention will save 30 cent. in fuel.

Exhibition at Bath School of Art.—Lately noticed the distribution of Government prizes by the Mayor, at the Central School of Bath. We may now add that there is an exhibition of the works executed by the pupils during past year, in chalk, colour, and monochrome. There are in it original sketches by the members of the Sketching Club, a club formed up through the suggestion of Dr. Puckett, I. master of the school, for the purpose of encouraging pupils in original compositions.

Encroachment of the Sea.—A special meeting of the corporation of Hythe has been held to consider the present dangerous condition of the sea wall, caused by the recent gales; was resolved that the clerk should request Courtenay Honeywood, the Lords Commissioner of Romney-marsh and the War Department co-operate with the corporation in some effective measures for mutual protection. It was resolved that the mayor should procure such quantity of rough rock and other material as was necessary for the temporary protection of the sea wall at the Parade.

The Licensed Victuallers' Asylum.—This Asylum, founded for the benefit of licensed victuallers who have been reduced to distress, an institution which is regarded with peculiar interest by the body to the wants of whose necessitous members it is intended to minister. Of late years its sphere of usefulness has been gradually extended, until it now comprises 170 bays, accommodating 211 people. This work is maintained at an expense of about 6,000*l.* per year. The annual hall was held on the 14th inst. at St. James's Hall, and was attended by about 600 people.

Australian Meat.—On Wednesday a dinner was given by the manager of the Australian Meat Agency to a large number of working men and their wives, selected from the principal establishments in which the various working people of the metropolis are employed, for the purpose of making those most interested in the importation of cheap meat thoroughly acquainted with what is sought to be accomplished by the promoters of the movement. The dinner was served at the central depot of the agency, 31, North Folgate, and was partaken of by some 100 persons, who were said to represent as many as 70,000 working people of London. Dr. W. Richardson presided. The question taken up and put to a practical test by the Australian Meat Agency is certainly worthy of the best attention of the public. What is sought to be done is simply to utilise the surplus food of our colonies for the purpose of reducing the price of it in the mother country.

Mr. Arthur Ashpitel, Architect, F.S.A.—I mention with extreme pain and regret the death of Mr. Ashpitel, which took place on Monday last. We shall make an early opportunity to speak of him more at length. He was highly cultivated and estimable man.

Sanitary Board of Health.—Great complaints have been made as to the demand by the Board of one set from each competitor, for the "finished sketches, &c." The amount should be returned to all who send in a *bona fide* production.

Ready Raft.—I beg to suggest a plan for saving life at sea from foundering ships in violent storms. A portion of the deck to be reserved to the ship's frame (two thick bands of lumber to be laid between to prevent vibration) by three stout bolts on each side. In an hour of danger the nuts to be partially screwed, and at the critical moment the bolts knocked out. It would then float off and sink with its livin'; freight; the hullwarks at each end would afford some protection to the crew thereon, and it would not upset.

Gas-light on Shipboard.—The lighting of steam carriages with gas is about to be followed up by gas-light in ships. The *Monarch*, a turret ship, preparing for sea in Chatham Harbour, is ordered to be fitted up with a gas apparatus, every portion of the deck between decks being intended to be lit by gas, which will be manufactured on board. The estimated expense of fitting up the ship's apparatus is about 300*l.*

Parish-house, St. Pancras.—The parsonage of the parish of St. Pancras have erected a parsonage-house, with *post-mortem* room, in the ground adjoining the workhouse. The parsonage has been built under the superintendence of Mr. Dent, architect, by Mr. Turner, with Horsely.

TENDERS.

For building two houses, Herolds Park-terrace, &c., for Mr. G. Harpell, Mr. J. H. Smith, &c. —
 J. Smith 21,337 0 0
 J. Smith 4,320 0 0
 J. Smith 1,200 0 0
 J. Smith 452 0 0

We are compelled to decline publishing out books and giving addresses.

All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

IMPROVED MACHINERY, combined with STEAM POWER, is employed by J. W. BENSON in the Manufacture of Church, Turret, Stable, and Tall-tale Clocks, Sun and Wind Dials, Perpetual Calendars, and every description of Clock and Watch Work. Architects, Builders, Committees, &c. can be promptly supplied with estimates. A descriptive Pamphlet on Church and other Clocks, post-free, 2d. J. W. BENSON, by special appointment, Watch and Clock Maker to His Royal Highness the Prince of Wales. Steam Factory for Clocks and Watches, 58 and 60, Ludgate-hill; Showrooms, 25, Old Bond-street, London.

DWELLINGS FOR WORKING PEOPLE.

The Society for Improving the Condition of the Labouring Classes have just published, at their Office, 27, Essex-st., Strand, a Revised and greatly enlarged Edition (Sixth Thousand) of THE DWELLINGS AND SANITARY REFORMER'S GUIDE, &c. &c. THE ESSENTIALS OF A HEALTHY DWELLING, and an Historical Sketch of the Efforts made for extending its Benefits to the Working Classes, particularly in the Metropolis; and likewise on the Continent. With his Plans and Sections, and the Royal Warrant, signed by the numerous Illustrative Plans of external Designs, as well as Designs adapted to Towns and to Rural Districts.

By HENRY ROBERTS, Esq. F.R.S. Price 7s. cloth. Also, by the same Author, New and Revised Editions of HOME REFORM; or, What the Labouring Classes may do to Improve their Dwellings. An Address to Working People. Price 3s.

THE PHYSICAL CONDITION OF THE LABOURING CLASSES, Resulting from the State of their Dwellings, and the Beneficial Effects of Sanitary Improvements adopted in England. Price 5s. Working Drawings, on a large scale, for Labourers' Cottages. Each Design, complete on one sheet, price 2s. 1/2. Specifications for ditto, 1s. Bills of Quantities, 1s. 6d.

QUANTITIES MADE EASY. A quick and accurate method of taking out quantities from plans or sketches, with or without a specification. Sent by post for 30 stamps, and by Air Mail, by Express, Twynhill-road, Upper Leamington, New Cross, S.E.

STANNAH'S TABLES OF ANGLE and the IRON give the Weight in Pounds per Lineal Foot of every Section required for Boats, Chimneys, Pipes, &c. and will be found invaluable to any one engaged in Estimating for Wrought-iron Work generally. Price 2s. Publishers, VIRTUE & CO., 25, Ivy Lane, London.

WEALE'S RUDIMENTAL SERIES. THE ORDERS OF ARCHITECTURE and their Aesthetic Principles. By W. H. WEALE, Esq. 7th Edition. Price 1s. 6d.

THE STYLES OF ARCHITECTURE of various Countries, from the Earliest to the Present period. By T. TALBOT BURY, Esq. 4th Edition. Price 1s. 6d.

THE PRINCIPLES OF DESIGN IN ARCHITECTURE. BY EDWARD LACY GARBETT, Esq. F.R.S. Architectural Modelling in Paper. Practical Instructions. By T. A. RICHARDSON, Esq. F.R.S.

VIRYUS'S ARCHITECTURE, translated by J. GWILLI. Price 2s. GREEK ARCHITECTURE, PRINCIPLES OF BEAUTY IN. By the EARL of ARBURNHEIM. Price 1s.

PERFECTION IN BOOKKEEPING. BUILDERS and Others desiring a really good system, can have a SET OF MODELS for BUILDERS BOOKS, by DOUBLET ENTRY, in which was awarded the prize offered in "The Builder," No. 1153, and which has been adopted by many large firms. Also a Modelled Arrangement by Single Entry, suitable for small Builders. Address, E. A. 4, St. George's-road, Bevis' Mark, London.

PENFOLD ON RATING. Fifth Edition, revised and extended, by J. T. KRISHAW, Surveyor.

THE ENGINEER, FRIDAY, Jan. 22. CONTENTS: 1. Working Drawings (No. 13) of the Belted Port and Channel Dock, with Descriptive Article. Mr. Brazier, Engineer. 2. Royal Institution (No. 3), with Drawings of the Lecture Theatre and the Chemical Laboratory. 3. New Bridge over the Trent at Nottingham (Hull's note). 4. Recent Lectures at the Royal Institution. 5. On Electricity and the Correlations of Electrical Force (No. 5). 6. New Railways in France. 7. The Late Geological Expector. 8. The Factory Extension Act. 9. The Engineering and Scientific News of the Week. Full Lists of Patents, &c. THE ENGINEER, price 6d.; by post, 7d.; Office: 158, Strand; and at all Newsstands and Stations.

MR. JOHN DOUBLET'S WORKS ON THE STEAM ENGINE. A CATECHISM of the STEAM-ENGINE, in its various applications to Mines, Mills, Steam Navigation, Railways, and Agriculture, with Practical Instructions for the Manufacture and Management of Engines of every class.

HANDBOOK of the STEAM-ENGINE, price 5s. TREATISE on the STEAM-ENGINE, 4to, 42s. TREATISE on the SCREW PROPELLER, 4to, 63s. EXAMPLES of MODERN STEAM, AIR, and GAS ENGINES, Parts 1. to VIII, 4to, price 25s. 0d. each.

NEBBI'S "PRACTICAL MENSURATION." A thoroughly revised Edition, augmented by a Table on Levelling, price 6s. bound.

A TREATISE on PRACTICAL MENSURATION. The most approved Methods of Drawing Geometrical Figures, Mensuration of Surfaces, Land Surveying, Mensuration of Solids, and the Use of the Carpenter's Rule. Timber Measure, in which is given the Method of Measuring and Valuing Standing Timber. All these Works, illustrated by the Dimensions and Cuttings of a House.

BY ANTHONY NEBBI. New Edition, enlarged and much improved. To which is added, a Treatise on Levelling. The two Treatises, illustrated by above 700 Practical Examples and about 300 Woodcuts.

KEY to NEBBI'S PRACTICAL MENSURATION. Containing Solutions to all Questions which are not answered in that work, & with References to the Problems, Rules, and Notes, by which the Solution are obtained. Corrected & re-written throughout, with the Improved Edition of the Treatise. 12mo, price 5s. bound.

LONDON: LONGMANS, GREEN & CO. PATERNOSTER-row.

LAXTON'S BUILDERS' PRICE BOOK FOR 1869.

For the use of ARCHITECTS, ENGINEERS, BUILDERS, CONTRACTORS, SURVEYORS, and all the Building Trades. It comprises the PRICES for Materials and Labour, in each of the following branches: — Bricklayer, Joiner, Plasterer, Glazier, Slater, Sawyer, Painter, Paperhanger, Builders' Ironmongery, Smith, Coppermith, Decorator, Carpenter, Mason, Zinc Worker. Contains above 70,000 Prices, carefully corrected and revised; with various important memoranda; a Form of Estimate; numerous useful Tables; an excellent Plan of Contract connected with the Builders' Trade. The present issue has been carefully revised and improved, and will be found as valuable as ever. For fifty years this book has retained its position with the Builders' Trade. London: MORGAN & CHASE, 38, Ludgate-hill; and may be ordered of any Bookseller in the Kingdom.

MONUMENTAL DESIGNS.—The Advertiser is now publishing "A SHEET OF MONUMENTAL DESIGNS FOR CEMETERIES," and also "A Sheet of Designs of Marble Tablets for the Interior of Churches, Chapels, &c. with a Descriptive Index for Prices to each." The designs, got up by a monument maker of great experience, and printed by an eminent firm of lithographers in London, are the best ever offered to the trade; they require only to be seen to be thoroughly appreciated. A single specimen sheet of either (please say which) with index, will be sent post-free on receipt of eight postage stamps (the two sheets sent post-free for fifteen stamps), by S. H. GARDINER, 2, Gloucester road, Lower Kentish town, who will also send, with name, trade, and address, printed out of each sheet and price list.—N.B. A Book of Epitaphs for Tombs, &c. post-free 4s. stamps.

PARTNERSHIP.—A very old-established Firm of Builders and Contractors have an opening for an active PARTNER with Capital, or would be willing to amalgamate with another firm of equal standing, increased capital being desired with a knowledge of mechanical drawing. A man of letter, 204, St. Giles's, London, will be liberally considered.—Apply by letter, stating "Midland Counties Herald," Birmingham.

CLERK.—WANTED, by a large Manufacturing Firm of Cooking Apparatus in the Midland Counties, a head BOOKKEEPER and CORNER. He must be a good penman, precise and correct at accounts, and proficient given to one with a knowledge of mechanical drawing. A man of letter, 204, St. Giles's, London, will be liberally considered.—Apply by letter, stating "Midland Counties Herald," Birmingham.

FOREMAN.—WANTED, by a large Manufacturing Firm of Cooking Apparatus in the Midland Counties, an experienced FOREMAN who will have to superintend the management of a small boiler, and also being desired with a knowledge of mechanical drawing. A man of letter, 204, St. Giles's, London, will be liberally considered.—Apply by letter, stating "Midland Counties Herald," Birmingham.

CHILDREN, thoroughly experienced in House Work, Domestic Furniture, and Milling in all its branches, may be OBTAINED at the House of 101, Marlborough-st., Birmingham, Oxford-street.—Address to the Secretary.

SHOW-ROOM CLERK WANTED, at an Upholsterer's at the West-end. None but very competent men need apply.—Address, Messrs. C. Wignam-street, W.

WANTED, immediately, a good active WORKING FOREMAN of MASONRY, used to Church work. Must be a good hand.—Apply, by letter, stating age, &c. to A. Z. King's-cross-lane, D. or see.

WANTED, by a London Firm, a clever, practical MAN to take the entire Management of the erection of an extensive BUILDING, about 50 miles from town.—Address, giving references, where first engaged, and salary required, to No. 115, Office of "The Builder."

WANTED, in an Engineer and Land Agent's Office, a CORRESPONDING CLERK. A neat disputer and short-hand writer would be preferred.—Apply to D. H. Office of "The Builder."

WANTED, a first-class FOREMAN, Carpenter and Joiner by trade, who must have a thorough knowledge of Machinery.—Apply, stating age, references, and salary, to H. LOVATT, Contractor, Waterman-street.

WANTED, immediately, by a London Firm, on an extensive job in the City, a thoroughly efficient MAN KEEPER—Active, by letter only in cost book-keeping, with full penmanship, stating age, salary required, references, &c. to A. A. 133, Abchurch-lane, S.E.

WOOD-CARVERS.—WANTED, a first-class WOOD CARVER, thoroughly experienced in the figure and the Romanesque style.—Apply by letter, giving experience and wages required, to Mr. FORSYTH, 8, Edward-street, Hampstead-road, London.

WANTED, a WORKING FOREMAN, Must be competent in setting out, and used to work a General Joiner and other Machines for preparing Lumber.—Apply, by letter, stating terms, to W. T. P. 24, Ball's Vine-gate, Seven Sisters-street, London.

WANTED, a first-class FIGURE PAINTER, Constant situation. None need apply who are not fully competent.—Address, W. HOLMAN & SONS, Stationers' Hall, Decorative Works, Warwick.

WANTED, immediately, a respectable WORKING PARTNER, with from 2000 to 20000 capital, to join an old-established Tradesman in carrying out premises, rights, building operations in brick & iron work.—Address, No. 5, 103, St. John-street-road, Clerkenwell.

WANTED, TWELVE GOOD MACHINE HANDS, to work a Tapping Machine and General Joiner. None but those who can furnish first class references need apply, to 122, Albany-street, Regent-st., E.C.

WANTED, by an experienced PLUMBER, a SITUATION, Thoroughly understands Gas and Hot-water Fitting, Bath and Closet work, &c. Good references can be given.—Address, PLUMBER, 3, Parker-street, Kingsland-road, London, N.E.

WANTED, in the neighbourhood of Holloway, a thoroughly practical MAN, who will be engaged to set out and lay down a road and soft stone.—If suitable, must understand the use of the level and soft stone.—Address, stating age, terms, references, &c. to No. 38, Office of "The Builder."

TO STATIONERS. A SITUATION and COOKING APPARATUS MAKERS.—WANTED, by a thoroughly practical Man, a SITUATION as FOREMAN, having obtained the same for fourteen years in stores, all kinds of cooking apparatus, both for steam-boilers and work in general.—Address, 38, Office of "The Builder."

WANTED, EMPLOYMENT on a Job, by a respectable Young Man, age 23, as PLUMBER, PAINTER, GLAZIER, and PLAIN ZINC WORKER, well able to make himself generally useful in anything required, provided with a jobbing work of any sort. Wages no object.—Address, H. H. 3, Fadington-street, Portman-square, Marylebone, W.

WANTED, by an experienced BRICK-MAKER, a JOB, to dig, make, and burn brick, in the 1,000, G.O. character can be given.—Address, R. H. W. No. 6, Kennington, West-street, Hackney.

WANTED, by a Young Man, a SITUATION in an Office, to keep Books, Men's Time &c. Can prepare accounts, and put up his time in the Receipt, if required.—Address, S. A. 2, Kelvin-street, Sydenham-hill, S.E.

WANTED, a RE-ENGAGEMENT, as WORKING FOREMAN of JOINERS and MILL, to take charge of a plant or work a machine, and also to direct the builders' machinery, setting out work, &c. Terms moderate. Unexceptionable references.—"The Builder."

WANTED, EMPLOYMENT, by an Experienced PLUMBER, Thoroughly understands fitting iron, hot water and gas pipes. Will take a job by the piece.—Address, 75, Old-street, The Builders.

WANTED, a SITUATION as IMPROVER, by a respectable Young Man who has served four years at the trade. Good character from the best masters.—Address, B. BROOKS, Lambeth-place, St. Dunstons, Kingsland-road, London, E.

WANTED, by a steady, energetic Man, a SITUATION as WORKING FOREMAN, or otherwise. Well references. Age 29, Old-street, Clerkenwell, Clerkenwell-square, St. Pancras, N.W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a thoroughly practical, steady Man, a RE-ENGAGEMENT as FOREMAN over water works. Will take a job by the piece.—Address, P. 1, Tanton-terrace, Finsbury-square, Kings-road, Chelsea.

WANTED, by a thoroughly practical, steady Man, a RE-ENGAGEMENT as FOREMAN over water works. Will take a job by the piece.—Address, P. 1, Tanton-terrace, Finsbury-square, Kings-road, Chelsea.

WANTED, a RE-ENGAGEMENT by an experienced Bricklayer and Plumber, who has had upwards of thirty years' practical experience with one of the first Architects in the City, and has a good knowledge of drawing, surveying, &c. He can give excellent testimonials of his ability and of his respectability.—Address, C. T. C. care of Mr. Charles Hebbert, 41, Lupus-street, South Belgrave, S.W.

WANTED, by a respectable Man, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

WANTED, by a Man of good practical experience, a SITUATION as MANAGER of a BRICK-FIELD, or as a placer, or as a foreman of work of many years' experience (age 39).—Address, J. M. J. 4, the Mall, Kensington, W.

The Builder.

VOL. XXVII.—No. 1356.

St. Mark's, Venice.

RETURN we once more to this remarkable shrine.* The enrichment of the division that we have called the upper story—the interval of vertical surface between the level of the gallery and the springing of the vaults—is comparatively moderated: it thus forms in a manner a frieze to the plain wall below, and constitutes a term of transition. Above this frieze-like band all the surfaces are covered with a general ground of gold mosaics, which follows every curve, and is folded level over every angle of band or archivolt. No interruption to it is allowed by interfering projections of mouldings. Indeed, except for the few string-courses below already noticed, and a somewhat more decided cornice round the base of the cupolas,

there is a negation throughout of such ordinary architectural features; in the general effect of solid piers and unbroken continuities of masses, there is nothing to intimate that the whole structure might not be monolithic,—that it might not be cut out of single solid rock with merely such well-adjusted allowance of thickness relatively to weight and cohesion, that the material is free from danger of being self-crushed and easily supports itself.

The glory of the gold ground tells, of course, with peculiar effect upon the curved, still more upon the coved, surfaces, and throws up in brilliant distinctness the subjects and borders of patterns many-lined with which it is charged.

This is not the place to dissert upon the system with which various subjects from sacred, legendary, and even historical lore were distributed. The designs are of various dates and various excellence,—from the archaic, which are sometimes grand and sometimes grotesque in their quaint proportions, to the modern, which comprise contrasts as vital, between refinement and sophistication. The Academical style is, no doubt, as remote from purity in taste as the grimly barbarous; but they who would exalt the merely quaint into the only truly reverential, do small honour to the architecture that is far indeed removed from artificial quaintness. To criticism, however, with such proclivities, it may be recommended as matter of consistency to assert the right of the associated rhyming legends to give the norm of poetry;—

* Sic actus Christi describunt quatuor isti.
Marconi firantes, —Kantaris vociferantur," &c.

The subjects are for the most part left to be divided by the free unoccupied space of gold left between them. This much may be said as justification of the principle underlying the scheme of their distribution: the centre of the first cupola as we enter is occupied by the dove as symbol of the Holy Spirit, from which rays descend to fiery, or, rather, scarlet tongues, upon the heads of the twelve Apostles, who alternate

with the twelve lights that pierce the cupola. The four evangelists occupy the four spandrels of the centre, and in the points below them are the four rivers of Paradise; the cupola above is assigned to God the Father; and the third, with its apse, is given in completion of the Trinity, to the glorification of the Son. Throughout the whole series, both in vestibule and church, we observe the intention to comprise a complete cycle of the sacred scheme as understood by the designers, and to distribute its various divisions to appropriate positions in the sequence in which they would be architecturally arrived at,—in order of conspicuousness and dignity, and in relative connexion or parallelisms,—while leading up at last to the great culmination of all interests, human and divine, in the eastern apse.

The presbytery is raised above the level of the church, at the line of the eastern margin of the central square of the crossing, and there can be no doubt, from the plan and section of the crypt below which are given by Cicognara, that the rise was originally fixed at this point; the row of small arches in front may once have been always open, affording a view into the crypt, and have extended clear across. The entrance would then have been to the right and left by the continuations of the aisles. At present the small arcade is covered in the centre by semi-circular steps, giving admission through a surrounding barrier or parapet that is the base of a highly-enriched screen. Four polished columns upon this on either side of the entrance bear an entablature that runs through from side to side, and on the entablature are seven statues over columns and intervals, on either side of an elaborate archaic cross that rises in the centre. The style of these columns, and their capitals, and the colours of the inlaid and encrusting marbles of the whole, are quite in harmony—beautifully so, indeed, with the chroch at large; but nevertheless it is a most unfortunate and damaging innovation. The wall of separation, the screen, is so effectively a screen that it interferes seriously with that completion of the cross on the lower plan by visible dependence on the eastern arms upon the centre, that was certainly counted on in the original design for bringing the more complicated upper plan together. Still more unbaptly it secludes the entire eastern division of the church from the main body to an extent that is at variance as much with architectural effect as with the certain traditions of local ritual. Even at the present time the separation marked by so absolute a line is habitually disregarded, and the ordinary congregation enters, and on occasion crowds without let or distinction beyond the barrier, and takes their seat and station. By other certain signs there can be no doubt that the portion originally secluded was marked off by the western line of the dome of the choir. Only when the screen is at least moved back in imagination to this point, if not—still better—beautiful as it is, obliterated entirely, can we stand in Saint Mark's and recognise with full satisfaction how noble and self-coherent is the plan and distribution of the temple that has received through a succession of ages enrichments so ever unstinted, and with scarcely another exception so uniformly in harmony. At present the long entablature of varied marbles bolts abruptly at either end against the plain marble incrustations of the piers, which exhibit no modifications announcing that it is expected, no lines nor mouldings responsive to its attachment.

The pair of eastern piers, on the other hand, receive an enhancement that marks their line as specially terminal. Their interval is reduced by the diameter of coupled columns placed in advance of them; above these the marble-encrusted pier is advanced, and bears like a podium the still smaller coupled columns of the upper story, upon which descends the

architrave of a transverse arch, presenting below the barrel vault, an enriched face to the westward. This is a repetition of the same treatment that is applied in the arms of the transepts, of which the span is contracted by the like arrangement that subserves enhanced enrichment by secondary columns and presentation of architrave fascias. The levels of the horizontal divisions are also preserved throughout, but with the difference that the elevation of the floor of presbytery and choir reduces the height of the lower range of columns to the great advantage of concentration of effect; the greater richness of their materials harmonizes with the preciousness and minuter elaborations of the fittings of the sanctuary, as their size with the reduction of its spacings generally. A gradual approximation in scale was thus introduced to the stature of the celebrants, on whom attention is most concentrated, and from whose position the eye is led by easier transitions through a series of magnitudes expanding at last most impressively to the largest dimensions of the structure.

The lower half of the height, intermediate between dome-base to pavement, remains to be distributed. One more most important horizontal line is given here by the heights of the nave columns, to which we have already adverted. Detailed measurements only would make it worth while to dissert on the principle observed in the proportions and spacings of these. It must be enough to notice that they seem so far to adhere to classical precedent as to show a commensurableness of height with divisions of plan.

There is nothing more thoroughly artistic in the composition than the easy and accurate articulation of the eastern termination of the church with the design of the flanks, consistently at the same time with the introduction of novel enhancements and enrichments to give appropriate distinction to the focus of the choir work. It is here that we too often have to regret,—if we do not weakly permit ourselves to slur over,—shortcomings on the part of Mediæval architects, in whose favour patriotic associations plead in conjunction with many others. In many an abbey church,—let it suffice to specify Whitchy,—and even in cathedrals, the transverse walls both of transepts and even of east ends are too frequently simply built across,—either with no acknowledgment of allegiance to,—no assertion of control over the horizontal divisions and string-courses of the sides, or at best with vain and to be commiserated endeavours to tie the two compositions,—each admirable in itself,—together by some straggling, incompetent, and misdirected moulding.

The relative heights of the upper and lower arcades—that is, of the nave lateral arcades and the lower perforations of the piers, as compared with the upper, are most effectively, and we have no right to presume otherwise than deliberately and artistically, decided. Here, again, was put in practice at an early date a principle that the Western architects were long in appreciating, but never lost sight of when once they had grasped it. One of the greatest advances in Gothic was achieved when the architects learned to correct the proportions of their predecessors in this respect—to give lightness, loftiness, and dignity no less, to their compositions by throwing a predominance of height in favour of the pier arches, and yet not entirely to sacrifice the importance of the arcades above them. The architect of St. Mark's might seem to have been in danger of forfeiting the grandest effect of the magnitudes he commands in consequence of the comparative fewness of his points of main support, and the unbroken largeness of the spaces he spanned; but even in this respect he is not so far behind his competitors as we find the later builders of Italian Gothic, and he recovered his effect by an adaptation that is all his own—the free interposed arcades.

* See p. 37, ante.

No one who is familiar with the interior of St. Mark's, to whom its ever-varying effects, and its ever-abiding and unchanging effect, have been daily delight, will easily wish that it were other than it is; the liberal spaciousness appropriate to the public worship of a collected population of a great city, is made compatible with the requirements of secluded devotion, and the self-communing of the contemplative; massive grandeur and minutest finish, simplicity and magnificence, meet and are reconciled, and the wealthiest resources seem for once not to have corrupted taste, or distorted judgment, which still can hold the balance even between admiration of rarer materials and gorgeous processes, and the better attractiveness of refined design. When we review the design, however, at a distance and in memory, regret will arise that no worthy attempt was ever made in the ages of vital Gothic architecture, to reproduce and rival its characteristics as a domical structure in union with the perfected details of the Gothic style. Apart from marble incrustations and mosaic covering, the plain unrelieved surfaces of the structure must be oppressive to a degree, which only painting of the very highest character could relieve. But all the lines of the construction would lend themselves most happily to expression and enrichment by Gothic profiles and mouldings; the cupola by its constructive nature would seem to proffer its capabilities of elegance and grandeur to the pointed style, as spontaneously as the elongated hollow pyramid of the spire. The very dome of St. Paul's gives us, in section, a pointed arch; and the concealed cone which is its core, and that having no affinity to the semicircular arcuation, is now advantageously withdrawn from visible association with it, might have been honestly patent in the rival style.

One translation of St. Mark's into the Pointed style took place early, and had considerable influence on a provincial school of architecture; this was the well-known example of St. Front, at Périgueux, in Aquitaine; but here, no less than in the Italian modification in St. Anthony's, at Padua,—

The builder was with want of genius cursed—
The second temple was not like the first.

How different it could be with so many points of accurate agreement is indeed a warning to those who copy badly where the one problem worthy of study is how to recast with masterly independence. Of the intention to copy there can be no doubt; even the slight difference in dimension has been ingeniously traced to the Venetian foot having been read off in the somewhat shorter French dimension, but the workmanship is too much at variance for us to admit the assistance of Greek or Venetian workmen.

The pendentives by which in St. Mark's the square plan of a crossing is reduced to the circular of the dome, are known to be formed by a succession of discharging brick arches bearing on the archivolts of the great arches; at Saint Front it has been found that the courses of the pendentives have horizontal beds; and this may induce us to believe that it was mistrust of construction that caused the transverse perforations of the great piers to be so contracted that they cease to be continuations of the aisles, and become mere disproportioned passages. The aisle colonnades are omitted, the gradation in diameter or area of domes is neglected,—blankness, barrenness, sameness rule throughout, and so the germ that should have taken new developments in a new climate degenerated hopelessly in process of transplanting.

The tessellated pavement of St. Mark's is of marvellous unevenness; in the open space under the chief dome it has been replaced by large slabs,—which, however, are broken,—they are rejoined curiously so as to seem almost bent,—to follow the undulations of the more perfect portions adjacent. One writer has been soberly quoted as authorising the opinion that the inequality was intended to symbolize the power of Venice over the sea; elsewhere the wavy footing, dangerous enough at times, has been interpreted as a refined type of the tempests that trouble the church or the world. It is certainly curious that the floor of the church should have been so ill-founded, while the lines of piers and walls remain so wonderfully accurate; a very small proportion of the subsidence beneath our feet would have started the mosaics and cracked the incrustations in all directions. The case of subsidence is clear by the proof, if any were wanted, of the sinking of the plinth of the left-hand pulpit since its erection, and the consequent

readjustments of the heights of some of its supports; that the crypt when first reopened was full of water to mid-height of its pillars, would explain more serious infiltration.

Before we pass on to remark on the architecture of the vestibule and façade, let us look once more round the interior. The span of the transepts, and consequently the diameter of their domes, is contracted by the insertion of coupled granite columns set against the outer piers on either side, and carrying an archivolt turned below the barrel vault of the main crossing; this vault therefore, which in the nave is carried forward unbroken westward, is superseded over the arms of the transept by one of lower level; the pairs of free columns also, and their arched epistylia, are also set in and range north and south with the granite pair, while the triplets of the nave east and west lie back behind the piers, and do not encroach in any way on the nave spacing.

Again, the barrel vault beyond the transept domes, and above the inclosed chambers at the north and south walls of the church, are still further lowered and contracted by an advance of the line of wall and springing, and exposes the plane of another vertical fascia with an inscription on its mosaic ground.

Even in the nave, where the full grandeur of the vault is otherwise uncontracted, a sub-vault is introduced and shows a plain fascia, at the line where its extension begins over porch and vestibule. In the upper order or story of the transepts the small paired octagonal columns over the granite pair below, bear the contracting archivolts east and west; over the inclosed chambers on the south the second still more contracted archivolt descends again upon another pair parallel to the others, but somewhat in advance; on the north these second pairs are omitted,—their place and function being taken by an advance of the pier.

In the division under the eastern cupola the same treatment is repeated, but with enhancement above the transepts, as those received differentiating details in respect of the more simply ordered nave. Here the eastern and western archivolts of the choir-dome descend upon coupled columns parallel to the axis of the church,—four pairs in all, therefore, instead of two pairs only, as in the transepts. Four single columns, again, of like design and adjacent, each upon a plan at right angles to the coupled pair, receive the transverse archivolts, and make up rich angular groups; the fronts and soffits of these archivolts are enriched with especially-elaborate and resplendent mosaic patterns—the westernmost with an impressive inscription; albeit, in a rhyming Latin verse.

It is with excellent feeling that these upper paired columns throughout the church—the only columns on this line—are exceedingly, indeed, for anything that appears to a not very close scrutiny, are absolutely alike. They emphasise the principal turning-points of the design, and by their prominent correspondences lead the eye easily round the building by a simplified series of stages that might be otherwise confused in the general union of metallic surfaces and un-moulded projections. By their response, again, to larger paired columns below them they provide a link that unites the lower plain marble surfaces with the upper system of exuberant ornament and more complicated construction.

We have already adverted to the fact so important for appreciating the true artistic style and finish of the interior of St. Mark's, that the columns employed have, for the most part, every appearance of having been designed for their positions, of being matched absolutely, or at least with parallel divergence, from a common type. The chief exceptions are the larger and ruler shafts that are attached in pairs to the walls of the western arm of the church and receive archivolts that cross the aisles from the great angular piers; in these we may with probability recognise the columns that are stated to have been left standing from the old church founded in 831.

At the angles of the wall at returns of nave and transept there are groups of three, giving a paired presentation either way. The column at the angle, of deep red granite—like all other columns in the church, the shafts are monolith—stands free; the other two, which are of lighter colour, are partly engaged in the wall, possibly only from encroachment of the later incrustation: the bases are particularly rude in profile and coarsely executed, and the capitals, except for the line of black and white inlaid pattern, scarcely less so. The shafts in the right hand

aisle are so much taller as to dispense with the architrave that on the opposite side is interposed between shafts and spring of the archivolt. The pairs of columns that flank the western door are of nobler materials; they have capitals to a certain point similar to those of their granite fellows, but range with them by a special adaptation; the member which is architrave in one aisle and omitted in the other, is here modified to become an integral part of the capital, below the mouldings that it has in common with the other two. The exceptional irregularity thus managed and modified, kept in the background as far as maybe, and broken in any case into a certain consistency, becomes the highest expression of the resolution of the artist, so fully carried out elsewhere, to give no licence to mere brute magnificence of material to the detriment of orderly refinement.

"Such, then, is Rome!" so concludes Strabo, in his endeavour to give a succinct description of the magnificence of the capital of the world under the first Caesars. "Such, then, is St. Mark's," we hesitate to say, when indeed it is hopeless to say more; it is for poetic faculty, and not for critical or simple artistic appreciation to attempt to convey to those who have not stood below its domes the impression that this glorious temple makes,—deeper than logical thought, more lively than excited imagination, but satisfying both at the same time, as exciting a fund of sentiment that has its headspring beneath them and beyond them. Passing from it, but not forgetting it, we contemplate with a communicated interest its less perfect adjuncts and completions. The western arm of the Greek cross of the church is invested externally on the north and west with a covered portico, vestibule, ambulatory, and on the south side to almost equal width, that is, to more than half the spread of the transept, with chambers that accommodate a baptistery, and at the south-west angle the mortuary chapel of a cardinal: this, however, is a comparatively modern intrusion. Data are not accessible at present to enable us to discuss with any hope of an accurate result the several dates of these external compartments. Considered on their own merits as they are before us, they announce themselves equivocally—on the one hand, as exhibiting archaisms in their mosaic decorations as crude as any that we meet within the church; on the other hand, such incongruity in general artistic and decorative principles as apparently to preclude the idea that they, or the general façade they are attached to, can be due to the same architect or the same period.

As regards construction, the leading principle is indeed the same. Issuing from the church through the central door and its recessed porch, we find a square opening overhead in the roof of the portico, giving a view through to the continued barrel vault of the nave, as already described, and admitting light from the west window which terminates it, over the advanced wall of portico. To the right and left of this opening, barrel vaults extend to squares opposite the doors to the aisles, and these are roofed by small domes upon pendentives.

Along the north flank there are four such domes, including one at the angle, which is common to the front,—but so near each other that the intermediate vaulting is reduced to a handed archivolt; and opposed to each in the outer wall is an external coved recess. It is observable that the arcuation of the portico north and west is slightly, let us say obtusely, pointed; all above the line of spring is clothed, as within the church, with a gold mosaic ground, bearing Scripture stories; the walls are marble-coated; the pavement is a mosaic tessellation. The most eastern hemicycle is pierced for an entrance door from the northern piazza dei Leoni, and is in immediate communication with an entrance into the north transept, coved, and with pair of niches on either side, marble pillared, marble lined. Along the exterior of the church wall runs a marble seat, between the paired pillars, which receive the rectangular transverse archivolts. In the front portico eadems are suppressed; recesses that take their place are occupied by tombs of antique dates,—and there is greater luxury of columns and capitals, which in double tier quiche clothe the face of the west walls and inner portions. This is the first appearance by the route we have taken, of a system of enrichment that is extended to extravagance on the fronts; a crowd of shafts, or pillars of confused marbles, convey at first a feeling of confusion after the staid orderliness of the interior,—nor does this feeling wholly vanish even when we

have had time to observe that the multifarious, not to say motley, collection is in truth not left unmarshalled. Pair, we then find, answers with considerable accuracy to pair,—the assemblage is no mere utilization of fragments at any cost of uniformity; but still the symmetrical principle does not only announce itself,—it requires time for being observed,—not to say attention for detecting it, and there is a hard fight at last with the disturbing differences in details.

Again, when we glance over the plan there seems a marked contrast in some points of construction that are in favour of the church rather than the portico. On the exterior of the north porch advanced piers answer to the boms of the hemicycles of the interior, and compose with them such immense masses of solid masonry that they have been constantly referred to as abutments in favour of the stability of the domes. A glance at plan and section shows that they can subserve no such purpose, and improves, moreover, our appreciation of the economy of solid support by which this stability was really effected. On the whole, we are disposed to pronounce in favour of the probability that the investing porticoes are much later than the church, and that neither in leading lines nor in detail do they belong to the original design. The more artificial treatment of the coved recesses of the portico seems to us alien to the taste and spirit of the artist, who only advanced by gradations of enhancement to the still dignified enrichment of the western apse. As regards the naïvely archaic mosaics, we doubt, must be posterior to the erection of the portico; but so they may be also to the church itself, and even to the decorations within it, that seem to assert themselves as contemporaneous. The style of hieratic decorations is, of all others, most difficult to date. We shall find at this day, it is said, on Mount Athos, a monk painting a wall with a saint of a characteristic grimness that should be thought a resurrection from under the whitewash of Santa Sophia.

But "it is too tangled a knot for us to untie;" keep we more steadily to the point of view of simple architectural propriety and beautiful effect.

The western arm of the church is invested not merely below, but by an upper story on all three sides; the result is, that the proper crucial form of the church is entirely masked and the domes rarely can be caught sight of in such a combination as to recover the expression of the plan,—in any case, it would only be to declare an incongruity with the distinct enunciation of the façade.

The façade, as seen from the grand piazza, exhibits a line of five recessed porches, with segmental heads; the piers closely clothed with pilasters in double tiers; a free single column is added at the north-west angle, to extend the front as far as the line of the northern projecting piers; the small open square that it completes at the angle has a low mosaic coved vault; and here alone throughout the structure, and in an addition at the southern angle, given for uniformity, have we found even a faint indication of groin vaulting.

The wider central porch answering to the nave is semicircular in plan; the next on either side opposite to the aisles are narrower, rectangular on plan, and with less important doorways, and these three in themselves would complete an agreeable composition; but on either side again the front is extended by recessed arches and doors on the same line, answering to the flanking porticoes; by the greater span which is assigned to these, the law of sequence is reversed; and still once again our sense of order is destined to receive a further shock by the sharp contrast of the small and narrow stilted open arches at either extremity.

The archivolts of the aisle-porches, like that of the centre, are true semicircles; but those of the flank porticoes have a flattened appearance, a greater width of segment being obtained with equal height by striking them from a centre below the level of springing. Placed as they are, between two narrower openings, they become in a manner secondary centres, to the disparagement of the true centre, and with no proportionate advantage to themselves, unable, as they declare themselves to be, to assert control over their irregular—their unequally narrower, flanking supporters.

Close above the archivolts of the side porches runs the pillared balustrade of a gallery, which has a width extending over the porches and their advanced piers. The balustrade is broken

in the centre by the loftier sculptured archivolts of the central porch. The result again is most unfortunate to the composition taken with reference to the main expression. The aisle porches are still further dissociated from the central porch, which they would most harmoniously support, and attached more intimately to those of the flank porticoes that are only pushed to the front obtrusively and interferingly. In the upper story the composition goes far to recover itself, and its merits have sufficed for centuries to mask the ill-impressions of the disorderly series below. The line of this upper front is only set back behind the gallery so far as to the line of outer wall of the investing porticoes. It follows the same line on the return along the north wall, and the gallery which returns also along this wall is carried by the advanced piers of the exedra.

Five large archivolts above answer to those of the porches of the façade; but here the proportionate sequence is happily corrected. The central arch occupied by the great west window retains its full predominance, and the adjacent arches answering to the lines of the aisles, are now consistently wider than the outer which correspond to the flank porticoes.

Here we become entangled again in another chronological *nodus*. The elaborate finishings of this upper story are due to the Renaissance artists. In fact, the style is so exactly that of the gateway which connects the church with the Doge's Palace that it is probably the work of the same Bartolommeo Buono (obt. 1529), whose name appears there inscribed on the architrave as its architect. Was it due to his taste that the design is recovered here to sequent coherence, or did he but reduce a well-prepared design of earlier date, which had become confused at a lower stage by the inaptitude of an intermediate artist? However this may be, we cannot be too thankful that the disarray of the lower story, in which the outer arches make an unseemly straddle to compass justly the axis of the side portico, was not allowed to propagate its norm abnormal to the upper. The upper and lower designs are thus, no doubt, in discord; but it is well and better, indeed, that all should not be out of joint.

The height of the upper story has a happy subordination to that of the lower,—its enrichment is as happily as appropriately enhanced. This is due to Renaissance artists, who created each archivolts with a low hood of a curve returned to an elevated apex; the edges are brilliant with white marble crocketing of exuberant foliations supporting worshipping figures; the more elevated central apex is surmounted by the blessing Saviour in place of final above the embazoned lion of St. Mark, and the four lower on either side by triumphant saints. Over the four piers intermediate between the five arches are high canopied tabernacles; the conical canopies are doubtless incongruous here, but it were in vain to try to pause to quarrel with them. Statues of the four evangelists are housed in the pointed arch shades, and below each is an elegant figure with pitcher on shoulder perforated for storm waters from the roof,—personifications again, but here by no means grotesquely archaic, of the rivers of Paradise that are below the evangelists of the dome. A somewhat larger tabernacle is over either angle of the front: in that corner left kneels between twisted colonnettes the Virgin of the Annunciation; in the other the announcing Angel. The distance of separation is not unusual in representations of this subject; so on the bridge of the Rialto the Virgin kneels in bas-relief on one spandrel of the bridge, and the hastening Gabriel appears in like position on the other side.

The upper design, thus, it must be admitted, no less than the lower by loading the plain expression of the nave and aisles of the church with co-ordinate expressions of the outer corridors that are mere external adjuncts; sins, indeed, more seriously, for moderation in this respect in the upper design would have gone far to contravert any trespass in the lower—if not to establish it as justifiable. The architects, however, seem at last to have a little left aside their regard for the church itself, in anxiety to spread out the front to an extent that would make it a proportionate occlusion to one full end of the grand piazza.

Some observations yet remain to be made on the treatment of the lower portico. While we should ascribe the ground plan of the façade to an architect other than the designer of the church, we feel inclined to recognize again an interfering and inferior hand at a certain point of

the elevation; a change of taste, and a change for the worse, seems to supervene at the spring of the archivolts. The boldly advanced piers are clothed in front, and on the recessed sides, with closely set shafts of most varied material and colour, and irregular in diameters, finish,—in almost every respect. Still they are disposed by no means at random, clumsily, or independently of a system deliberately thought out. On the lower range especially, dark and light shafts alternate, and are opposed with marked symmetrical purpose. These larger shafts have a podium of good solidity, and support an architrave, that in its turn serves as a podium to the upper order. These smaller shafts are so closely set, that their capitals and bases are in contact, and so that six above are included in the dimension that takes only four below. At this point ensues the transition that is made so awkwardly. The merest ledge scarcely thicker than an abacus appropriate for a shaftlet, is interposed between the capitals and the springing of the great archivolts. These are too large to respond directly to individual capitals, and the intermediate course is far too slender to even seem to bind several solidly together. The decorative character of the shafts is abruptly superseded by a constructional demand upon them, for which no adequate support is afforded. In the smaller porches there is more appearance that the outer arches were intended to fall as truly on the capitals at the angles of the piers, as is the case, but still not universally, with the recessed architraves that descend on nook-shafts on either side of the grand entrance. But the aim is missed, and sometimes a capital is only half covered, and in other instances they stand free. There is a general unluckiness prevalent through the entire series, the more glaring from occasional examples of the happiest agreement. Barbarian here is self-betrayed and obtensive. Have we before us, we inquire, a work of better intention, that has been carried forward by bunglers? Surely so, rather than rudimentary developments of tentative genius.

We spare to enter in detail into the treatment of the exterior on the north and south. Here, as decidedly as on the façade or still more decidedly, the church itself is masked by the investing chapels and porticoes below, and by a story above them, of which the interior is discovered neither from church nor porticoes, and has no correspondence whatever with the grand interior.

In itself the investing portico appears to be a happy and appropriate addition to a church of importance; it replaces the ancient narthex; it softens with more happy gradation than the atrium of St. Ambrogio at Milan, the transition from the worldly to the sacred atmosphere, and supplies for the general congregation an invitation to the same tone of feeling that the cloisters may be supposed to have generated in reflective denizens of an abbey. Such an extension of it, however, to façade and upper story as we have commented on at St. Mark's, is in every sense no less than artistically, an encroachment and an abuse.

The four horses of gilded bronze from Constantinople stand on free pedestals in the centre of the gallery, and disadvantageously low over the main porch. Behind them are four loftier pedestals; we could almost believe that these marked their original position, and that space was found for them lower by abolishing a super-archivolts of the main porch, which seems so much missed by the heavily-sculptured arch, and for which there is foot-space blankly forlorn over the middle colonnettes of the piers. Otherwise these four higher pedestals might seem intended to accommodate upon the usual scheme, the three feet and foot-supported bow of a colossal lion of St. Mark.

Of the richness and quality of the various marbles employed enough has been said by others and elsewhere; others also have noticed the insertion as exterior ornament of a slab on the north side with a pagan subject,—Ceres in dragon car, with torques, in search of her daughter. But a still stranger subject is that has-relief on a slab set in the north angle of the façade, which shows Hercules returned to Argos with the captured Erymanthian boar, and Eurystheus as we see him on the ancient vases, retreating in alarm into a huge vessel as a hiding-place. It is not easy of conjecture, to confusion with what incident in sacred lore such group can have owed its position.

Thus much, then, we have said in qualification of the enthusiasm that not inexcusably is excited

by the first—nay, sustained and fed by long familiarity with St. Mark's; thus much we have said in vindication of the genius of some earlier architect, perhaps architects, whose work, from the very admiration it excited, attracted some sedulous extensions, that though sometimes apparently inspired by very contact with the original work, in other cases unfortunately defaced, overloaded, or overlaid it.

After all discriminations have been weighed and accounted for, the final impression which we would report from the whole, taken even as it stands, is far more in sympathy with that of its uncritical worshippers, to whom whatever there is in it is right, than with strictures we meet with from a writer more sober, but whose consistent endeavour is above impeachment. The late Joseph Woods, writing in 1816 (see "Letters of an Architect," published 1828), says truly enough of the Orologio or clock tower to the left of the church:—"It is not good in itself, and contributes nothing to the whole effect." He proceeds—"I do not say this of the campanile, though it is merely a great square tower, above 300 ft. high, terminated by a pyramid, and having no intrinsic beauty; its power of pleasing is owing to the strong contrast it affords, running up so high upon a narrow base, to the long-continued horizontal lines of the piazza, and to the lumpy forms of the cathedral." Be it observed in passing, that the admitted merit of enhancing a large general effect—a merit which extends far beyond the limits of the piazza, is of noble nature and more worth than any such beauty as might be styled intrinsic, but which should only be beautiful while looked at by itself, and helping to disgrace and discredit everything around. "The exterior of this church," the criticism proceeds, "surprises you by its extreme ugliness more than by anything else. It is of two perfectly distinct styles. The lower belongs to that degraded Roman which we call Norman, adorned with numerous little columns, and abounding in ornament; but the ornaments are merely such, neither forming nor interrupting the lines of the architecture, but entirely subordinate to them," &c. Presently we read again of these columns that they "are mostly good and ill-made; some are of their original length, others have been shortened; the capitals are almost all different—all in bad taste, and disproportioned to the columns, being not so much in height as in diameter, some being too large, and others as much too little."

It is hard to say that these things, and there are more such imputations in reserve, are not so; it may seem a bad task after such admission to have to justify to ourselves and others our admiration, our enthusiasm; it is to the behoof of a truly hardy and healthy criticism that it should be endured to recognising fairly whatever of truth however unwelcome, and so confront it fairly. Whether we badage our own eyes or cover up our facts out of sight,—whether we are silent upon a fair half of our subject or involve it by our utterance merely in a haze of metaphors and nebulous wordy extravagance, we do equal injustice and expose the most ingenious exposition to deserved disaster. "The Duca palace," says Woods, "in the next page, is even more ugly than anything I have previously mentioned." This was not in 1816 so bold a paradoxical speech as it might be held now; but precisely because such judgments on the great architectural combinations of Venice would now be unpopular it is desirable to revert to them as they were enunciated before present influences came into play. The result, we believe, will be that after the most candid recognition of blots and blunders we shall revert to our original impression—that in architectural design, as in heroic natures, there may be a value in the larger scope of character that will atone for very grave accumulative errors in detail. "Has your master no virtues then," said Henri Quatre to the Spanish nobleman who wanted his king's exemption from some kindly weaknesses, "has your master no virtues that he must take his stand upon superiority to peccadillo?"

In justice to Woods, it must be said that he has a true feeling for the prime virtue of this great architectural centre, though misled by too technical hesitations, to depreciate its primacy. This grand and decisive excellence is found in a successful union of a display of power and riches with a certain justness of proportion in the masses and in the distribution, so that a moral grandeur dominates at least the mere material magnificence; and minor inaccuracies and carelessness are superseded by the dignity of the whole,

THE PRINCE CONSORT MEMORIAL, HYDE PARK.

We have from time to time mentioned the progress of this monument, and given particulars of its details in the order in which they have been erected. We are now about to add a short account of the designs of the mosaics which are to fill the spandrels of the arches forming one of the principal stages of the memorial, and of the figures, also to be executed in mosaics by Signor Salviati, that are to fill the gables over them. It will be remembered that these figures, four in number, are to represent Architecture, Sculpture, Painting, and Poetry, and that the two spandrels of the arch beneath each figure are to be occupied with a design carrying out a delineation of the subject over which it presides. Thus, under the figure representing Architecture, the two spandrels will contain mosaics giving an idealised presentment of the details of the practice of architecture; under that of Sculpture are to be placed illustrations of sculptural manipulations; and so on.

We must further premise that this series of designs is from the pencil of Mr. J. R. Clayton. He has treated his subjects with poetical as well as pictorial feeling. His figures, Greek in their proportions, in their small well-poised heads, in their regularity and general similarity of feature—low brows, straight noses, full eyes, prominent chins—are Mediaeval in their handling. He seems to have treated them with the privacy and severity of the ancient Greek models, yet clothed them with the warmth and life of Mediaeval associations. Looking first at the spandrels representing Architecture, we see two draughtsmen seated at a table at work, with compass and pencil. Their heads and limbs are Greek, youthful and graceful; especially the hands are well formed, the fingers long and slender; their drapery fitting, yet sufficiently flowing to fall in folds conformably to the movements of their limbs. Not a line or a fold could be spared from the reticent purity of the composition so far. Then we note the spirit of the Mediaevalist making its mark. The foremost figure is shown, full length, seated with one leg bent under the opposite thigh on an open wooden stool, resting his elbow upon the table, his head upon his hand, drawing, abstractedly. The second figure, owing to the exigencies of the spandrel form, is not shown below the waist. He is represented as intent upon a measurement of a drawing spread upon the table before him. In the opposite spandrel we see the stalwart workmen of the Middle Ages; they who dexterously placed the mighty stones in their appointed places, and they who lifted the heavy burdens and carried them to and fro. A mason, with upturned sleeves and close-fitting cap, standing on scaffolding over an arch, the centering of which is not withdrawn, trowel in hand, is preparing a bed of mortar for a stone ready before him, to be put into position. His brawny arm, his wide thick hand, are in marked contrast with the slenderness and delicacy of those of the draughtsmen, as are his broad shoulders and air of docile strength. Behind him, close to a ladder, stands a labourer older, more worn, with uncovered head and close-cropped scanty hair, tightening a rope about the point of junction of two poles; older, as we said, and hollow-eyed and hollow-cheeked, but still able to twine the great cordage about his arm, and with a good grip make it fast and safe beyond chance of slip.

The youthful female figure that represents Poetry is seated on a cushioned throne, the canopy of which rises over her head in the apex of the space filled by the composition. In her right hand she holds a lute, the lower part of which is resting on her knee; with her left hand she is unrolling a scroll, the end of which falls over her arm in bold curves. Her robe is drawn about her neck by a band which crosses her breast in a straight line, and rises over her shoulders at right angles, and thence descends below her waist, till it is hidden by a second mantle thrown lightly over her knees, and which falls, in its turn, about her feet upon the steps of the throne. Part of one foot only protrudes from this last-mentioned vestment. The head, slightly turned towards the left shoulder, is crowned with a garland of flowers and spiked leaves, fastened with a knot of ribbons. The features are small, clear, and refined; the expression mild, dreamy, and longing. In the spandrel on the right of this beatific impression are two youths, the one entrancing, the

other entranced with the subject and sound of a lyric. The first figure, or that occupying the perpendicular space of the spandrel, is seated, and with extended hand striking the strings of his instrument, which is resting upon a portion of balustrade; the second faces him in a leaning posture with a clever arrangement of attitude that follows the curved line. An expression of soft rapture beams from both faces. In the left compartment a third figure is seated beneath a tree, in the act of composition; a scroll lies spread before him, and a quill is in his hand. At the moment of representation he has rested his head upon his disengaged hand, and is looking wistfully into the realms of thought. A fourth figure, full of years in an attitude of meditation, as of one who has seen into the orbic of experience, with drooping eyelids and folded hands, fills in the horizontal portion of the spandrel.

Painting is seated, palette and brushes in her left hand, her right firmly upholding a panel, or canvas, standing on edge at her side. Her hair is bound closely to her head by a band; besides this ornament, a second circlet encompasses it, from which leaves spread themselves out in a ready coronet. Her robe is ample, covering her neck and arms, drawn in at the waist by a double cincture, and falling in massy folds over her knees and upon the ground. The expression upon her features is that of resolve. No suggestion of languor, tenderness, or wistfulness in her lineaments mars the impression of high ability and stern determination to act. We feel, as we gaze upon her bright, resolute face, that the most sluggish of painters would acquire vigour under her banner. There is more fire, too, or more earnestness, in the countenances of the painters filling the spandrels, of which this energetic figure is the central crown. In that on the right a youth holds a panel, upon which an artist, seated with his back to the spectator, his heart and soul in his occupation, is sketching in an outline. Purpose, genius, and skill are apparent in this last figure, and well contrasted with the hand, vague, scarcely awakened curiosity of his less-gifted assistant.

Sculpture, grave and thoughtful, uncrowned, bare-armed, with an implement of her art in her left hand, and a product of it, in the shape of a small draped figure, in her right, is seated with her arms resting upon the low sides of her chair. Her air and attitude are alike indicative of well-earned repose. Her mien is that of a contemplative worker intent upon creations of power and beauty. The folds of her drapery are, like her purpose, bold, well-defined, grand, and certain; neither light nor petty, not profuse nor overcrowded. In the spandrels are more delineations of industry and allusions to creative will. On the right a sculptor is seated between a female figure holding a tazza, upon which he is at work, and his model. His back is turned to us, his mallet uplifted, his chisel placed in the fold of the drapery he would deepen; vigor and determination are apparent in the tension of his arm, in the position of his head, in his concentration of thought. In the spandrel on the left a second sculptor is giving the last touches to the drapery of a model. A third figure, probably that of the chief of the studio to which this last belongs, reverent and bearded, yet in the prime of manhood, overlooks his progress from the background, resting as he does so an arm upon the base of a colonnade and clasping his pendant wrist with his otherwise unoccupied hand.

Those whose sympathies are with the revived art of the mosaicist will enjoy this portion of the details of the gradually growing monument.

THE HOUSES OF PARLIAMENT.

SINCE last session, several works at the New Palace at Westminster have advanced towards completion, under the direction of the architect, Mr. Edward M. Barry, A.R.A., and workmen are at present busily engaged in making some new arrangements in the House of Commons, with a view to provide additional sittings for Members and others. Below the bar there have hitherto been three rows of seats on each side of the House appropriated to Peers and other distinguished strangers. In consideration of the inconvenience often experienced by members from a want of room, the two front rows of these seats have been thrown into the House, which gains

by this means thirty-six additional seats for members. The strangers disposed of by the change will be accommodated in the gallery behind the clock, facing the Speaker. This gallery, known as the Diplomatic Gallery, has hitherto contained seats for twenty persons; but, by the addition of an extra seat, it will now accommodate forty-six strangers; and, as the number removed from below is twenty-eight, there is only a loss by the new arrangement of two seats for strangers, and a total gain of thirty-four seats within the present walls of the House.

In St. Stephen's crypt the baptistery has been finished and decorated. The floor is paved with Minton's tiles, mixed with marble of different colours, and squares of white marble incised with outline heads of the evangelists and other saints. A font occupies the middle of the baptistery. It is of alabaster, with marble columns supporting it, and is placed on two steps. The sides of the baptistery, which is octagonal, are lined to about 5 ft. from the ground, with alabaster incised with grotesque patterns; and above this dado there is a holdy carved cornice of alabaster. The groined roof and upper part of the walls have been decorated by Messrs. Clayton & Bell, a figure of the Saviour in a vesica facing the door, and a nearly full-length figure of St. John the Baptist facing eastwards. The window opposite the latter is filled with grisaille glass by Hardman. The baptistery is placed at the south-west angle of the crypt, and is entered from it. It will reward a visit.

Mr. Grace is at work in the Royal Gallery completing the decoration, which had been left unfinished by Sir Charles Barry. The stonework is elaborately painted and gilt, and four out of the eight statues, for which niches are provided, are finished, and are now being fixed in their places. The statues are in stone, by Mr. J. Birnie Philip, of the following monarchs:—Alfred, William I, Richard I, Edward III, Henry V, Elizabeth, William III, and Anne, who have been selected as representing the great wars of English history, according to the principle indicated by the choice of the subjects of Waterloo and Trafalgar for the pictures by Maclean painted on the side walls. The statues are to be gilt with dead gold, varied in shades, and toned down by picking out with dark colour parts of the dress and ornaments. In the adjoining apartment, the Queen's Robing-room, Mr. Dyce's frescoes have been repaired by Mr. C. H. Cope, R.A., and the decoration of the room has been completed. The ceiling, which is panelled, has been painted and gilt, statuettes of English princesses have been placed in the niches, and a panel behind the throne has been filled with embroidery representing the royal arms, with the cyphers V. R., on crimson velvet. The upper panels in the wall framing were left unfinished at the time of Sir C. Barry's death, and they are now about to be filled with bas-reliefs in oak by Mr. H. H. Armsted. The bas-reliefs are about 2 ft. high, and of various lengths. They represent scenes from the "Morte d'Arthur," in accordance with the subjects of Mr. Dyce's frescoes of the exploits of the Knights of the Round Table. Nothing has yet been done to carry out the recommendations of the select committees of last year on the House of Lords or the enlargement of the House of Commons.

In new Palace Yard the iron entrance-gates, made by Hardman, are being fixed, and a drinking fountain of plain polished grey granite has been placed near the cabstand, for the use of the cabdrivers and others. The statue of Sir R. Peel has been removed from the angle opposite Parliament-street. The turf border on the side next Bridge-street is being laid out with beds for flowers and overgreens. In Parliament-square, where Canning's statue formerly stood, the two turfed spaces are being laid out in a dissimilar way, and trees and shrubs are about to be planted in the inclosure opposite, behind the present site of Canning's statue. The iron railing round this inclosure is being set back to widen the footpaths, and the corner next George-street is cut off, so as to have Mr. Burton's octagonal drinking-fountain isolated, and approachable from all sides. The plots in Parliament-square are being inclosed with a wrought-iron railing about 3 ft. 6 in. high, made from the architect's design by Messrs. Skidmore. All the works above described are being rapidly pressed forward, that they may be completed as far as possible before the meeting of Parliament next month.

THE LATE MR. ARTHUR ASHPITEL, ARCHITECT.

LAST week we briefly recorded the death of a valuable and universally esteemed member of our profession. Mr. Arthur Ashpitel died on the 18th inst., at his residence, 2, Poets'-corner, Westminster Abbey, at the age of sixty-two years. He was never married.

Mr. Ashpitel was born in Hackney, and educated at Dr. Burnett's celebrated school. When about twelve years old he met with a serious fall, and dislocated his hip, which crippled him for life, and laid the foundation of serious illness.

He was a man endowed with vigorous intellectual power, and, probably in consequence of the fall which debarred him in a great measure from very active bodily exertion, he was from an early period and through life a careful and laborious student of ancient and modern literature.

He received his professional training in the office of his father, who was a pupil of Mr. Daniel Alexander, and had a considerable practice in partnership with Mr. Savage. Mr. Arthur Ashpitel commenced work on his own account about the year 1842 in Crown-court, Old Broad-street, where he conducted a considerable practice as an architect and a large business in compensation and reference cases. Among his architectural works are the churches of St. Barnabas, Homerton; St. John's, Blackheath; of Ripple, Ilford, Verham Dean, Aldborough, and others, as well as some schools at Hoxton. Illustrations of the church at Homerton, and of a tomb more recently designed by him, will be found in our pages.

In the year 1850 he entered into partnership with Mr. Whichcord at Carlton Chambers, and subsequently at Poets'-corner, Westminster; and for several years was engaged in large general practice. Amongst his works at this period may be enumerated several private mansions in Surrey and South Wales; the clock tower, London Bridge; establishments of public baths and washhouses at Lameth, Maidstone, Bilston, Kidderminster, Llanelly, &c., one or two blocks of dwellings for artisans, and the Kent Ophthalmic Hospital.

His health failing, he left England for Italy in the year 1854; travelled for a considerable period with the late Mr. David Roberts, R.A.; and resided some time at Rome, where he made the intimate acquaintance of the late Cav. Canina, and entered upon a course of study that resulted in his "Restoration of Ancient Rome," which he exhibited as a drawing at the exhibition of the Royal Academy. He also made a drawing, "Rome as it is," and the two were reproduced in chromolithography by the Messrs. Kell.

Of late years Mr. Ashpitel had retired very much from the active exercise of his profession, and devoted himself to literary pursuits. His pen was constantly employed, and his studies were directed to the elucidation of archæology; his contributions have been frequent and valuable to the Society of Antiquaries; the Archæological Association; and to the Dictionary of the Architectural Publication Society. In connection with the British Archæological Association he contributed papers on the Cathedrals of Worcester, Chester, Lincoln, Rochester, and others. He also edited an edition of Nicholson's "Carpentry," and quite lately edited, under the title "A Treatise on Architecture," papers on Architecture and the Arts of Construction, originally published in the "Encyclopædia Britannica." These papers, as we mentioned in our notice of the book when it appeared, he supplemented in various parts.

In more general literature Mr. Ashpitel, who was a Tory of the old school, wrote early in life several political pamphlets and satirical poems, which at the time attracted considerable notice. Some of the *vers de société* and translations from the Greek Anthology, which, published in the *Obit*, gained attention, were from his pen. He was a frequent contributor, also, to *Notes and Queries*.

Mr. Ashpitel took a very active interest in the affairs of the Royal Institute of Architects, and when he was in sufficient health he was a frequent attendant at the meetings. He was elected a vice-president of that body in 1862, and on the resolution to initiate a voluntary Examination for proficiency was appointed one of the examiners, in which position his matured learning was found of great value.

His death will be felt in many quarters as that of an amiable and accomplished scholar,

and the profession will regret the loss of a disinterested and kindly colleague.

His remains were interred on Monday last in the family vault, at St. John's, Hackney. In the first coach were (his only brother) the Rev. F. Ashpitel and his son; the next was occupied by the Rev. W. Denton, and Messrs F. and O. Denton; and the third by Messrs. B. B. Woodward, A. White, J. Whichcord, and Olding. In the last coach were Messrs. James Edmeston (who began professional life with the object of our notice some twenty-five years ago), Wyatt Papworth, W. Gritten, and T. H. Porter.

We are able to add to our notice the announcement that Mr. Ashpitel has bequeathed the greater part of his rare and valuable books, and his collection of antique and Etruscan vases, brought by him from Italy, to the Society of Antiquaries; that the two drawings of Rome are left to the National Collection, South Kensington; and that provision is made for founding a prize at the Institute of Architects.

ON PRINTING AND GRAINING FROM THE NATURAL SURFACES OF STONES.

At a meeting of the Society of Arts, held on the 27th, Mr. George Godwin, in the chair,

Mr. W. Dean described his patented process for taking impressions from the grain of wood, and transferring those impressions on to other surfaces, and which he has called "Xylography."

Before entering on a description of this process, he made a few remarks of a personal character. He said,—I think it was about the year 1833 when the late Mr. Minton added to his other large operations that of making encaustic tiles. From the first it was felt that pattern sheets of the tiles—which in those days were all of one size, 6 in. square,—would have to be printed, to send to architects and others, for the purpose of illustration. These were printed from wood blocks, the size of the tiles, and were engraved, I believe, by Mr. Barr, of Birmingham. They were printed on huff paper, which represented the groundwork of the tiles, in red and black, which represented the ornament, these being the only colours then in use. The practical inconvenience of patterns of this size will be obvious, and so it was felt at the manufactory, and Mr. Minton decided to reduce the size of the patterns, and to have them printed from stone, under his own superintendence. But at that point he met with this difficulty, there was not a lithographer in the county. With his accustomed energy and promptness, he determined that he would have a lithographic press in his own town; and, in the arrangements which were made to carry out that decision, it so happened that I was selected to go to London to learn the lithographic printing, and, early in 1835, I entered the establishment of Mr. Hullmandel, of Great Marlborough-street, as a pupil. After a residence of some months in London, I returned to Staffordshire and commenced operations. In working on these pattern sheets for Mr. Minton, I received valuable aid from Mr. Hullmandel, and I remember well, when Mr. Minton introduced the deep blue on buff ground on the tiles, the difficulties I had to contend with in printing blue on huff paper; for as you are all aware, no doubt, that the result was huff and green, and not huff and blue. Trials almost without end were made. I was greatly perplexed, and Mr. Minton became very impatient, for it so happened that he was engaged in getting up a design for the floor of a church for the Marchioness of Lodiham, in which tiles with a blue ornament on a buff ground were introduced, and we were within three days of the date when the design had to be forwarded. In a state almost of desperation, and while casting about for help, in a happy moment I thought of Mr. Hullmandel, and decided to write to him by that night's post, in the hope that he might possibly help me through the difficulty. The return post from London was due on the day the design had to be forwarded; the morning came, and with it a letter from Mr. Hullmandel. It was very brief, but very characteristic of the man, and was as follows:—

"DEAR SIR,—Print in varnish, and dust with dry colour. Yours truly,

C. HULLMANDEL."

I need scarcely add that the design was forwarded in time, greatly to the delight of Mr. Minton. To some present this may seem strange enough; but it must be borne in mind that, at

the time I am speaking of, chromolithography was not introduced.

I proceed to remark that in showing my own patented process in different places, I have often heard it observed, "How very remarkable it is that this has never before been discovered;" and indeed in that light I myself regard it, especially when I reflect on the fact that pieces of oak, such as I now hold in my hand, called by letter-press printers "reglets," have been in use by them for, I should say, at least a century, and probably for a much longer period, and that there never occurred to the thousands of masters and workmen who, during that period, must have seen imprinted the veining of those reglets, the idea of turning the fact to practised account, and giving to it a commercial value. Yet such appears to be the fact.

Before I enter on a detailed description of the process, I will glance at the range of the patent, and point out those branches of industry to which it is specially applicable. These are as follows:—for transferring impressions from wood to plain deal, or to painted surfaces, either flat or moulded, in buildings of all descriptions, where an accurate transcript of the more costly woods is desired, and for bonse and bedroom furniture generally; for japanned goods, made in metal or papier mâché; for enamelled parquerie tiles, and for articles in earthenware, such as garden seats, oyster and flower tubs, spirit cases, flower-pots, tea-urn stands, &c.; for enamelled slate, for paperhangings, and for oil cloths.

Having thus briefly indicated the nature of the patent, and the range of its application, I proceed to state the methods by which these results are arrived at. Select a piece of wood of fine quality about 5 ft. long, 12 in. wide, and a ¼ in. thick; it is, to use the technical phrase, cleaned up by the cabinetmaker on both sides, and is well sand-papered down. By having both sides of the board cleaned up, two patterns are obtained from the same board. A chemical preparation is then applied to it, which has the effect of opening the pores of the wood, and, at the same time, of hardening the surface, and, when the board is thoroughly dry, it is ready for use; and is, in fact, a wood-plate, "not graven by art or man's device," but by the Great Designer and Architect of the Universe, whose works, the most stupendous as well as the most minute, are all perfect. The material used for taking the impression is prepared in oil, and is specially adapted for the purposes of transferring. The paper, too, is manufactured for the purpose, is very thin but tough, so that it can be successfully applied to any irregular or moulded surface, and is sized to prevent the colour from becoming incorporated with the body of the paper. A small wooden roller is used for spreading the colour on the board, and a large, broad, flexible palette-knife is used for taking the superfluous colour off. That being done, the sized paper is placed on the board, and both are passed through a small machine having turned iron cylinders, the upper one being covered with double-milled flannel; the paper is then taken off the board, its printed surface is applied to the article to be decorated, the back of the impression is lightly rubbed with a piece of soft flannel, the paper is removed, and an exact *fac-simile* of the board from which the impression is taken is given. But that is not all, for a second and a third transfer is frequently obtained from the same piece of paper, and sometimes a fourth, a fifth, and a sixth. This is one of the remarkable features of the process; and, as you will not fail to perceive, must have a very marked influence on the rapidity of its application, and, consequently, on its cheapness. The thought may occur to the minds of some present, "but in taking off the impressions do not the boards get foul, and the pores of the wood clogged up?" The thought is a natural one. My answer is, that with the colour properly prepared and adapted for its purpose, they do not, no more than does the plate of the copper and steel plate printer; but such a result would occur in both cases if the material used was not suitable for its purpose. When a board has been used it is treated as all other plates are,—a cheap material is used for dissolving the printing colour, a handful of fine sawdust is then rubbed over it, which most effectually draws out of the pores of the wood the dissolved colour, and leaves the board clean and ready for further use when required. Another question may arise in some minds,—"But what about the durability of the boards?" The answer to that question at

first sight may appear startling, but I am satisfied it is correct, notwithstanding, that under the same conditions, provided no accident happen to it, the board will be far more durable than either the copper or steel plate. I have arrived at that conclusion, not only from close observation, but from actual experience; for it is a fact that there are boards at Messrs. Thomas Simmonds & Sons', Manchester; at Messrs. Minton & Co.'s, Stoke-upon-Trent; and at the carriage works of the North Staffordshire Railway Company, which have been in something like regular use for nearly three years, and my conviction is, that they are in as good a working state at the present time as they were the day they were first used. Nay, more,—I believe that some boards, with careful and constant use, improve rather than deteriorate. This is one other point I will allude to before passing to the other important branch of the subject, and that is with respect to variety of pattern. That question has sometimes met me in a very hurtful form. I have been told that there would be either great sameness in the work, or I must take a timber-yard with me. My answer to this is, not necessarily either the one or the other. For example, I take a board of the size already named (5 ft. long and 12 in. wide); this I use on both sides, and from one such board I obtain 10 ft. superficial variety of pattern, and in applying the impressions I do not follow that they should all be applied precisely in the same way; so that half a dozen boards of the sizes named would give 60 ft. superficial of variety of pattern, and that variety would be trebled by judicious application, and would give ample variety for the largest room in a nobleman's mansion. But there is no necessity to limit the number, if greater variety is desired, the boards being cheap enough, only costing about half-a-crown each.

The second division of the subject, and the one to which I shall now direct my attention, is the important one of quality and cost. In dealing with them, instead of giving my own opinion, I shall give that of others—persons of refinement and taste, and of large practical experience.

I have taken considerable pains to bring my specimens and process under the notice of architects, both in London and in the provinces; in some cases an audience has been denied me; by some I have been told plainly enough that they hate all imitations; but by others I have met with a very courteous and, sometimes, a flattering reception.

Messrs. Thomas Simmonds & Sons, of Manchester, were among the first to adopt my patent, and, after three years' experience of its practical value, have had the spirit to arrange with me for an exclusive licence for the city of Manchester and Salford. Shortly after they introduced it they were employed to erect a mansion for a gentleman who had seen my specimens, and who wished to have the graining done by this process. The architect objected to it, but the proprietor persisted, and carried the point. When the mansion was completed, the architect, the proprietor, the builder, and the patentee met to look over the work. After the inspection, I took the architect to the entrance-hall, to a point where the imitation was worked up to the solid oak, and where we had a good view of both; and, while looking at the work from that point, I asked the architect whether he thought there was more than one person in a hundred who would be able to say where the solid ended and the imitation commenced. He replied very frankly that he thought there was not. I replied, that being so, I thought my patent process ought to have fair play, and it ought not summarily to be put out of court. He said he quite agreed with me, that it had worked out much better than he thought it would do, and if I would call on him at his office, he would give me an hour to talk over its application elsewhere. You will readily imagine that I was perfectly satisfied with the result. I had fought the battle of imitation and won. The next illustration I shall cite took place in one of our largest provincial towns. The architect has attained to considerable eminence in his profession, and the case afforded me some amusement. After a careful examination of my specimens, and listening to what I had to say in their favour, he called his chief assistant, and, pointing to the specimens, asked him what he thought those were. He replied, very promptly and emphatically, "I suppose, sir, you will call them shams." "No reply was," "No, I shall not; these are not shams, they are a transcript from the wood itself, and, therefore, must be both true and natural."

The building firm whose opinion of the quality of my specimens I shall now have the pleasure to quote, are the builders of the new Foreign Office, Messrs. George Smith & Co., of South-street. Judging from the solid oak-work inside that building, I may safely say, that if any persons in the kingdom are competent judges of quality of work, they are; and I esteem the opinion expressed by Mr. Taylor, of that firm, of the utmost value to me. While Mr. Taylor was examining my specimens, Mr. Smith, jun., of that firm, came into his office. Mr. Taylor, after directing his attention to them, remarked, "This is what we are got to now; we cannot tell the solid from the imitation of it. I think I know as much about wainscoting as most men, and I defy any man to tell these specimens from solid wood."

As to the question of cost, I may remark here that there are plenty of painters, in London and the country, who say that they can get graining done at 5d. and 6d. per yard. I do not deny the statement, for I heard one gentleman say that the men who did his graining got through a great deal of work, for they did it with white-wash brushes, and, for aught he knew (or perhaps cared), it answered as well as if it were more costly. There are others, however, who are candid enough to admit that, for good oak-graining, they have often to pay 2s. or 2s. 6d. per yard. Among the latter I have pleasure in mentioning Mr. Foxley, of London. I have it on the authority of Mr. Crossley, of Newark, that he paid to a London grainer 50s. for graining fifty doors for him, in a house he was decorating in the metropolis, for, I believe, a Nottinghamshire gentleman; but Mr. Crossley declined to affirm that the hand-graining he paid so high a price for was equal in quality to my specimens.

A painter in Burslem was anxious to see some work done by the process in his own house; a man and boy were sent over to do some, and they grained two six-panelled doors in twenty minutes by the clock. The wife of the painter told me she watched the clock with the special object of ascertaining how long it took to do them. The same man and boy grained an octagon pulpit for another painter, about three miles from Burslem, in an hour and twenty minutes. Both these painters purchased licences. When Messrs. Simmonds & Sons, of Manchester, purchased a second machine, I gave one of their men instructions in working the process, and, after three days' practice, I asked him about the quantity of work he could do as compared with hand-graining, and he informed me that he was quite sure he could do one-third more than by hand, and much more easily and pleasantly to himself.

The question of durability has been raised, and properly so, as that is a point of great importance to the public. To enable you to judge, I may say that the hand-grainer works in distemper, I in oil-colours, and it resolves itself into the old question, which is the more durable—water-colours or oil-colours? After all, the test of experience is the most conclusive and satisfactory; and here again I must refer to my specimens, as the large one has been done more than three years, and has had a good deal of knocking about at exhibitions, and travelling through the country. If a good sound varnish is used, such as is manufactured by Mr. Williamson, of Lancaster, I have no hesitation in saying that the work will be very durable, and more so than work done by hand.

The letter-press printer reproduces old and scarce books, and the chromolithographer reproduces rare and costly pictures, and they do so at a price that places them within the reach and means of the general public. So this process is designed to make accessible to the community in general copies of the more than artistic beauties of a part, though it be but a small part, of the glorious works of God. I flatter myself that I can, even at this early stage of the process, produce as fine a copy of a choice piece of Baltic hillek oak as the chromolithographer can produce of Stanfield's "Venice," Turner's "Polyphemus," or any other fine work of art.

At the conclusion of the paper a discussion ensued, to which we may refer on another occasion.

Discovery of a Crypt in Hungary.—A fine crypt of the twelfth century has just been discovered at Gran, near the cathedral. Eight granite columns support the roof, and each has a different capital. The monument is to be thoroughly restored.

INDIAN PUBLIC WORKS DEPARTMENT.

The Indian Public Works Department is attracting some attention at present, and it may be of interest to afford a description of how works are carried out by it; and what advantages it offers as a career. Before 1853, military roads and buildings were almost the only undertakings of the East India Company, of an engineering kind. Expensive wars were waged continually, absorbing the surplus revenue. Such things as loans for productive enterprises were not thought of; but a considerable debt was gradually incurred for warlike purposes, and with great readiness. Millions are at once forthcoming for a war, but to irrigate the country, for instance, where similar sums are wanted, there has been the greatest disinclination to borrow.

The public works were managed by the military boards, as they were termed, in the different Presidencies, constituted of the commandant of artillery, the commandant of engineers, the Commissary-General, a paid member, and a secretary. The Military Board had the regulation of the commissariat, clothing, and stud departments, as well as the Public Works Department. One of its main objects was, to check, not to encourage, expenditure; and while it is often obviously beneficial to reduce military charges to a minimum, it is utter destruction to a country to draw as much revenue from it as possible, and give it nothing in the shape of roads, canals, and other useful works in return; only fortifications and barracks, constructed in the cheapest way practicable. It was found out that a board to check expenditure was not the best for the Public Works Department to be under, and the Department was rendered independent of it. But the profession of engineering had no weight in India. Men like Sir Arthur Cotton spoke in vain. The influential service in India is the Covenanted Civil Service. By it the revenue is collected and justice administered, and the legal and general councils are formed chiefly. In its eye it is sufficient if the revenue from land-rents and salt and opium is high and increasing, and if the courts of law work smoothly. The improvement of the country is a secondary consideration. Indeed, the civil servants living on large salaries in considerable estate do not see that so much is wanted. Most of the year they are in spacious houses, well furnished, attended by numerous servants, with an excellent table every day, and their attention taken up with work that is, in its way, really important, and far from uninteresting. Much of it is of absorbing interest. They have pleasant society in the stations, a church, and often a band; and the only differences, perhaps, between their being at home and in India is the heat, which is most disagreeable and debilitating, and the monotony only relieved by the daily round of work.

In the cold season, after the rains have subsided the rigour of which aspect the country wears at most other times, they go into camp, making a round of their districts. They then have ample sets of tents, a troop of servants, abundant carriage, the best provisions that are to be got, supplemented by preserved articles, and the best wines and liquors; so that the period of their tour passes with great pleasantness, and India is voted not such a bad country, after all. In the same manner, there is no part of the world, even the driest, that could not be gone through to leave a favourable impression behind it. The civil servants therefore go back to their stations with the idea that the neighbourhood is prospering. They got about quite easily, consequently the roads must have been good enough. They did not feel any scarcity of provisions, for everything was plentiful and of average quality. It cannot be expected they should be very ardent advocates for public works; and, occupying the most commanding places, it is about the last thing they think of, their thoughts being occupied with the moral rather than the material interests of the country.

Next to the Civil Service, the most influential body are the representatives of the army. The Indian army is in no way situated to sympathize with the condition of the masses of the population. The heads of it live in much the same fashion as, and associate with, the civilians. The social staff of the army reside in cantonments, in the midst of a class essentially European in their mode of thought. They have little or nothing to do with the country at large, and see very little of it, except in marching from one station to another. It so happens that from old days have

come down tolerably good communications between the principal stations for troops; and, except in high prices, the state of the country does not present itself to their notice. Of late the placing the European force in India under the Horse Guards, and having the native troops a separate branch of the service, has tended further to disconnect the army interests from those of the empire itself. Queen's officers have no stake in it at all; pay does not go so far as it used to do; all having independent means exchange out of India as soon as possible, and each as have not wait patiently for relief. The mode of life is exactly similar to that of any other colony, Indian allowances compensating for the discomfort of the climate. The old East India Company's Officers used to take a much more hearty interest in the country, because they were engaged to spend their whole service in it, were sent to garrison many of the out-of-the-way posts which were never tenanted by European troops, and had opportunities of getting away from their regiments to civil appointments, where they got nearly as good salaries as regular civilians. Indeed, young officers of ambition never looked upon military duty as their sphere, but set to work to study the native language, and quitted their regiments as soon as ever they could. The company's native regiments had always more officers on the list than were required, except in actual war; as is proved by, in these days, the number being a third what it used to be. When engaged in it is a moot point still whether the revised scale is sufficient. India being under a government conducted by a few officials in every way alien to the population they govern, must be held by a vast army of Europeans.

In this way the bulk of the European society in the interior is military, and the sentiments are not the same as those of a commercial community would be. To an army inaction is perfect misery. There is nothing in drill and filling up returns to relieve the dullness of living among barracks. Consequently in India the main, though perhaps not reiterated, wish is for a rumpus,—some war by which medals, and brevets, and prize money may be won. Discussion takes this shape far more readily than bettering the country. Much of this feeling is reflected by the higher officers, who administer the army, to the Government. The cause of which they are the exponents is powerfully advocated, and this advocacy, though beneficial to the army, is virtually antagonistic to the other claims upon the attention of Government.

Military operations in India are of a very simple character. Success depends upon the mettle of the troops, and the infusion, if not of as large a body as possible, at least of their spirit, among the native soldiers. It also hinges upon the enemy being neither so well armed nor provided as the imperial force. Scientific expeditions, therefore, are not often called for, and military engineers are not the necessity they are in civilized countries. Good European infantry and artillery, with a mere sprinkling of sappers, and a small engineer staff, will win any battle in the East Indies. But as a precaution, and in the event of a contest being not altogether with Oriental strategy, the East India Company maintained the full complement of engineer officers in a fixed proportion to the rest of their army. But they only retained a few companies of sapper rank and file in each Presidency, to man which a title of the engineer officers on the list would have answered. The remainder had no express military duty to attend to, except to build and repair the barracks, and make and repair the roads, from one principal station to another. As things stood, then, we had the Civil Service in no way particularly disposed to promote public works, having their other and more engrossing duties of collection of the revenue and enforcement of the law, and seldom opportunity of forming a due conception of the backwardness of the country; and the army, by position desirous of turmoil, and exerting its influence for anything but works of peace; the mercantile community confined to the presidency towns, and with very partial knowledge of the wants of the vast interior; and the only class left to represent the need for all kinds of public works was that portion of the corps of military engineers not required in garrison, they being by qualification and habit almost the only officials in India capable of talking with authority on the subject and dealing with such questions. Practically control of the public

works fell to them. During the continuance of the East India Company they were in each Presidency the Public Works Department. The rule was they had the prior claim to all other candidates, and though other officers were admitted to the Public Works Department, it was solely because the engineers could not numerically undertake more than a certain amount of work. Indeed, just as the civilians trained at Hatterbury were presumed to have the monopoly of all the revenue, judicial, and political appointments under the Indian Government, the Bengal, Madras, and Bombay engineers were considered to have the Public Works and Survey Departments as their exclusive sphere. With this privilege in a fashion secured, the engineers ranked next to the civil service in popular estimation, as offering either a military or civil career of a very attractive kind. The source of supply was the military seminary of the Company at Addiscombe. About forty cadetships were given away by nomination half-yearly, and the nominee at the end of two years could present themselves for examination for the three branches of engineers, artillery, and infantry. The number of appointments given away to each branch depended upon, first, the vacancies in the engineer and artillery lists; and, secondly, the proficiency of the candidates. The education imparted at Addiscombe was excellent. The mathematical standard was high for engineers, and about half the hours of study were allowed to it daily, the others being taken up with Hindustani, drawing, fortification, and a few other things of minor importance. But classics and history were almost excluded from the curriculum. No candidate could get into the Engineers who had not read advanced mathematics, and if one failing to do so stood well in the final examination, he not only did not get into the Engineers himself, but prevented those below him who had from entering. By this every one did his utmost to acquire a competent knowledge of the test subject. The Artillery ranks before the Engineers in the army, but the latter service was the prize of the cadetship.

The competition for the junior service was very severe, and the severity is a measure of its popularity over the artillery. There were many reasons for this preference, and they are worth adducing. In the first place, it was always thought the engineers had exclusive right to places in the Public Works Department. This, of course, was a fallacy, as in India officers from the line were admitted almost for the mere asking. Then there was the public esteem in which a corps, formed entirely of men who had gained a high college proficiency, must of necessity be held in. There was also the prospect of obtaining civil employment at once, without going through the drudgery of military duty, which to a mind fond of study and hooks is very repellant and unprofitable. In short, the notion was abroad that, next to the covenanted civil service, the engineers was the best thing going. So parents and guardians kept their sons and wards for years beforehand at schools which taught mathematics in preference to classics; and inculcated upon them the putting out all their strength to become engineers. It was an immense thing for the East India Company having obtained such a good reputation for its engineer service, one greatly in excess of its deserts as compared with the civil service, the emolument being in the ratio of say 3 to 1. But there would never have been such competition excited by the intrinsic merits of the service alone. It is well known that those who entered the Company's military service as cadets, were not men of fortunes generally; and that whichever line was best paid was the one for them to try for. Even as cadets they were aware that as engineers they would have advantages they could not look for, at the commencement at any rate, in the other branches. The engineers could spend two years nearly longer in India than the artillery and infantry, who had to go out to India at once. They would also come into receipt of a staff salary on landing, whereas if posted to the artillery they would not only have no chance of more than the pay of a lieutenant, for ten or fifteen years, but have to buy expensive horses and equipment into the bargain, and be for years, perhaps, a pull on their relatives; so that it was an immediate object to avoid falling into no hopeless predicament, to all who could read high enough, and had no private resources. The semi-civil nature of the service also commended itself to many who did not care to accept the subordinate position of a regimental officer for a long term of years. This

A PLEA FOR IRON.

SIR,—Your recent article entitled "A Plea for Stone" bears so strongly against the use of iron as a material for building purposes, that you will doubtless permit some protest to be made by one of those who would give to iron an important place in modern architecture. Your severest strictures are directed against those who are endeavouring to give to iron a precedence over stone in situations where the latter has hitherto been used alone; and in much of what you say on this innovation you will have the concurrence of those who are the warmest advocates of iron when legitimately used. But it is the misfortune of every new project, and of any suggested improvement, that they are judged more by the mistakes made with them by the unskilful than by the real services they are intended to perform, and which they succeed in performing when properly applied. There is, no doubt, a tendency at present to take an extreme advantage of the great tensile power of wrought iron, and to produce the "spider-like framing" to which you refer; but this is generally in purely utilitarian cases, where the architect has no discretion given him, economy being the sole consideration, and in those cases also where the distance to be spanned is impossible for any other material.

But it is with the hidden use of iron that you find the greatest fault; and every man of taste will join with you in decrying the shams which profess to be stone, but which are secretly held together by iron ties. These false pretences, however, are not peculiar to iron, and the architect, in adopting them, merely follows a too common practice of his art. In a theatre, or any large hall, he considers it necessary to show a ceiling with elaborate cornices and brackets, on which apparently rest the beams of his roof. Really there exists out of sight an entirely independent trussed principal, on which the ceiling hangs. But assuming the existence of the sham roof, why should it not be of iron, which will allow a large span with moderate weight?

For the new Central Hall at Kensington an iron roof is being constructed, below which will hang a ceiling having a different outline. The iron roof over the courtyard of the new India Office shows an attempt after fitness which is praiseworthy, but which might have been improved. That the roofs of this kind are sham at all is the fault of the architect, not of his material; and iron roofs, with no detail of their construction hidden, could be constructed which need shock no true canon of taste. Iron is peculiarly adapted as a substitute for timber in roofs, and will allow large spans otherwise unattainable.

The æsthetic taste which would despise iron as a material for architecture is a false sentiment, which will disappear as we become more skilful in giving the appropriate form to iron-work, and in those countries and situations where stone and brick are scarce and expensive the new material is studied more than is yet the case in this country. Important buildings, with imposing elevations, entirely of iron, have been erected in America and in the cities of the Continent, which would alone prove the truth of the present assertion. The feeble attempts to imitate in cast-iron the traditional moldings and ornaments of stone deserve fully the reprobation they obtain; but if iron is heated properly it will allow a fineness and delicacy of ornament which, perhaps, may be possible in marble or alabaster, but which are quite impossible in stone.

The remarks in your article as to the endurance of iron raise a most important issue. The mistakes continually made in the application of iron arise very greatly from the confusion of ideas which often exists with regard to the difference between cast and wrought iron. During the last fifty years great mistakes have been made with the use of the cast metal, and accidents and failures, occurring partly through the use of inferior iron, and still more from its unskilful disposal, strong prejudices are felt against its use by many architects; and it is a common boast by many that they will never introduce it except where strictly in compression, as in the case of columns and stanchions. Without entering further into this question, I will merely remark that cast iron possesses many qualities which render it often preferable to wrought iron, and it is therefore for certain situations used by those who are better informed. In the matter of endurance against weather it is far superior to wrought iron. Rust does not scale from it; and the oxidation, when formed, is of a much

less dangerous kind than in wrought iron. Iron-work should either be accessible for painting, or should be entirely protected from the air. Box girders of wrought iron are often inaccessible inside for painting, and where ironwork is thus neglected the period of its existence may be calculated pretty surely. Iron hedded in lime will last for centuries; and some bars lately taken out of the walls of the Chapter-house at Westminster are perfectly sound and strong. Who knows how long the bars which help to hold the aisles of the Abbey together have existed? Mr. George Gilbert Scott, who is now engaged in restoring the Chapter-house, is having a pointed roof of cast-iron (as most likely to endure) constructed above the groined stone ceiling. In bridges I presume iron holds an undoubted preference, or else I would point out that the early cast-iron structures show no signs of decay. The Coalbrookdale bridge over the Severn, erected nearly a hundred years ago, first showed what could be done with iron; Southwark bridge, which has been standing so many years, exhibits no symptom of failure, and will in all probability long survive its more modern and elegant rival at Westminster, which is constructed mainly of very light wrought-iron. The engineer of the city of London is most wisely constructing the large bridge for carrying the Holborn Viaduct over Farringdon-road entirely of cast-iron.

I am content if I have shown that those of us who believe in the capabilities of iron, at any rate, have a case, and will leave able champions to dispute the strong position which we maintain for it, whether the question be one of taste or mere utility,—two qualities which should go hand in hand together.

EWING MATHESON.

THE LIVERPOOL ARCHITECTURAL SOCIETY.

At the last meeting of this Society, on the 27th ult., Mr. J. A. Picton alluded to the loss the architectural profession had sustained in the death of the late Mr. Arthur Asplial, whom he characterised as not only an accomplished architect and writer on architecture, but a man of very varied literary acquirements and of most amiable character. He also drew attention to some old specifications for the building of the old Liverpool Exchange (then the *new* one), and some other buildings, which had come into his hands, and which were remarkable for their brevity and concentration in comparison with more recent documents of the same kind, as it appeared that in those days the specification for a large building often occupied only one page of manuscript. It appeared that, for the old Exchange, the arrangement with regard to the architect's Commission was that Mr. Foster, the architect, was to receive 5 per cent. on the work if it did not exceed 80,000*l.* in cost; but if it did exceed that amount, the per-centage was to be paid on that amount only; and if the cost should be less than 80,000*l.*, per-centage was to be on actual amount expended. At the building of St. George's Hall a similar arrangement had been made, with a result most disastrous to Mr. Elmes, as the expenditure in that case vastly exceeded the amount on which the commission was calculated.

Mr. W. H. Picton then read a paper, entitled "Gleanings from the Architectural Field of 1868," chiefly suggested by the views of new edifices which had appeared in the *Builder* during the past year, a number of the illustrations from which were exhibited in further elucidation of the subject. Among these were the mansions of Possingworth, Sussex, and Hunewood, county Wicklow; St. James's Church, Kidbrooke (Messrs. Newman & Billing); the Town-hall, Melbourne (Messrs. Reed & Barnes); St. Patrick's Cathedral, Melbourne (Messrs. Wardell & Co.); the London University (Mr. Pennothorne); and also photographs of various new buildings in Australia. Mr. Picton referred specially to Possingworth, Sussex, built by Sir Digby Wyatt, which he considered a plan well worthy of study, especially as to the manner in which the various classes of rooms were grouped together, and the admirable planning of the offices; though the intrusion of a flight of steps into the large hall would, he thought, materially interfere with its use as a hall-room, if that should be desired. He highly commended the style of the external design as suitable for an English gentleman's house; and referred, as a contrast, to Hunewood, Wicklow, by Mr. White,

as an example of what might be called the "Romantic" style of house-building, and which, whatever the undeniable merits of the design, was far too archaic in its expression for a modern dwelling-house. Mr. Picton commented also on the design for the London University, by Mr. Pennothorne, as a very well-considered elevation, and a timely protest against the eccentricity of design which characterized so many modern buildings.

LOUTH GRAMMAR SCHOOL AND BEDI-HOUSES.

The Grammar School of King Edward VI., in Louth, Lincolnshire, was founded in 1552, being one of the earliest foundations of that reign. The management of the school was vested in the Corporation of the town, which was founded by the same charter, with the style of "The Warden and Six Assistants of the Town of Louth, and Free School of King Edward VI., in Louth." This body escaped total extinction on the passing of the Municipal Corporations Act, through the favour of the late Lord Lyndhurst, who paid a debt of gratitude to some of the inhabitants of Louth by procuring the insertion of a clause in the Bill containing the existence of the warden and six assistants as governors of the school only. Before the time of railways, and the establishment of the large proprietary schools, when a scholar was thought to travel far if he passed the confines of his native county, Louth school enjoyed a high and well-merited reputation. It not only ranked as the Eton of Lincolnshire, but successfully competed with similar foundations in the neighbouring counties. The seal of the old corporation is a curious piece of antiquity. It bears the legend "*Qui parit virgo odit filium*," and represents the interior of a school-room, with one of the scholars receiving bodily chastisement at the hands of the pedagogue, who wields a formidable sprig of betula over the form of his erring disciple. The estates of the school are considerable, and at present under the control of the Charity Commission.

Attached to the school are Bede-houses for the accommodation of twelve poor persons.

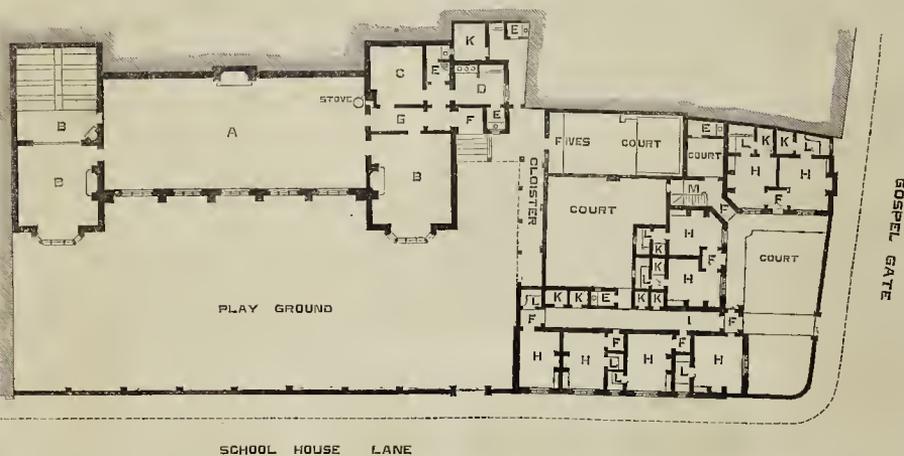

The fund for the erection of the new buildings has been provided partly from the estates itself, and partly from a subscription raised by old *alumni* of the school, among whom are found the names of Alfred Kempton, the poet laureate, and his brothers; Sir John Franklin, Dr. Hentley (Canon of Christ Church, Oxford), Governor Eyre, and other persons of distinction. The school is at present in a flourishing state, numbering about seventy boys. Together with the rise of Mr. Fowler's handsome and spacious building, the hopes of the numerous friends of the school have revived. In the new race about to be run by the old grammar-schools of England, they think that Louth will have, all things considered, an excellent start; and that its ample funds, its old glories, and its present popularity entitle it to take its place as one of the great county schools foreshadowed by the recent Royal Commission. It is expected that the new building, the foundation-stone of which was laid in August last, by the visitor, the bishop of the diocese, will be opened by his successor in the course of the ensuing summer.

The principal school-room is 57 ft. long, 23 ft. wide, and 30 ft. high to the ridge. It has an open-timbered roof with arched principals, and is lighted by a range of traiered windows on the side. At the north end of the school is a room 40 ft. long by 16 ft. wide, with a gallery at one end to be used as a lecture-room, and by means of a folding partition it forms two good class-rooms. At the south, or entrance end, is the library, 19 ft. by 16 ft., with a large bay window in addition, and there is a similar window at the other end. These rooms are 13 ft. high. Near the entrance on the east side are cloak-room, lavatories, &c. The ventilation of the school-room is effected by means of fresh-air channels near the wall-plate and behind the cornice, 15 ft. from the floor, with foul-air flues at each end of the room in connexion with the heating arrangements. The entrance to the school is sheltered by a lean-to roof, which is continued along the south side of the playground, forming a kind of cloister, and from this access is gained to the Fives-court.

The Bede-houses, as before referred to, adjoin the school on the south. The land available for them required considerable care in their arrangement. Eight are on the ground-floor and four

KING EDWARD VI'S GRAMMAR SCHOOL AND BEDE-HOUSES, LOUTH, LINCOLNSHIRE.
MR. JAMES FOWLER, ARCHITECT.

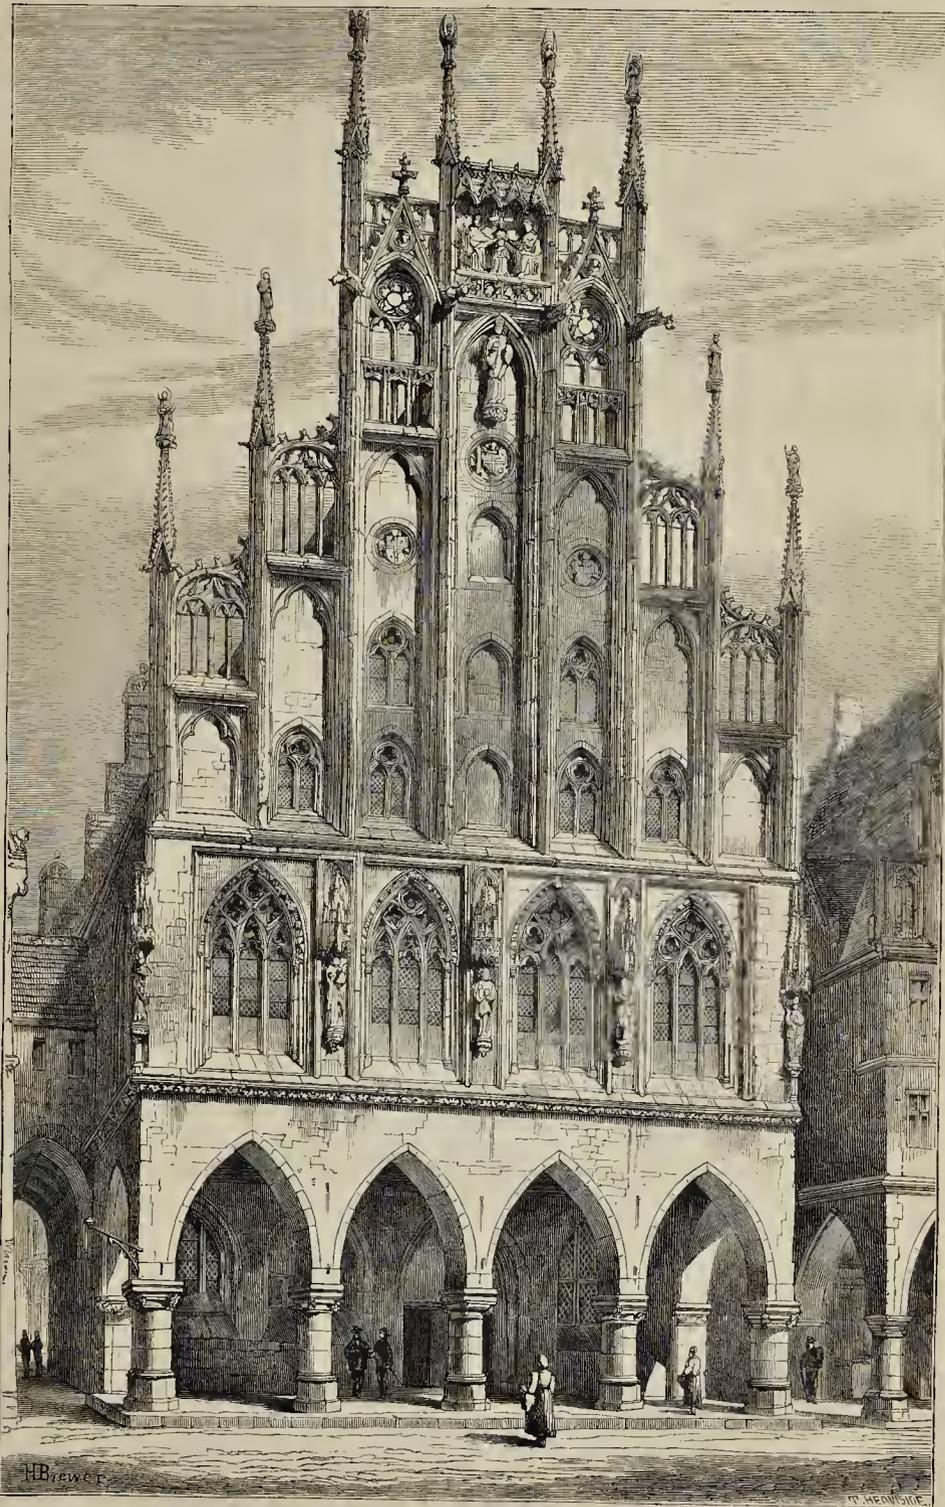

above; the latter are approached by a stone staircase, and by a balcony in front. Each room is about 12 ft. by 10 ft., and 10 ft. high, and has a separate pantry, coal-store, cupboards, and so on. The buildings are of red brick in narrow courses, the windows being of Ancaster stone, and when completed they will form an agreeable addition

to the attractions of the town, seen as they will be in connexion with the noble and well-known spire of the parish church. Mr. Fowler, of Louth, is the architect employed by the trustees; and his designs have so far been well carried out by Mr. Thomas Morey, a local builder.

THE RATHHAUS, MÜNSTER, NORTH GERMANY.

RATHHAUS, MÜNSTER.

WHETHER looked at from a historical or archaeological point of view, Münster is certainly one of the most interesting towns in Northern Germany. It was originally the capital city of a very powerful prince-bishopric, and to this fact it probably owes the number and beauty of its churches, and the solidity and picturesque quality of its houses.

The situation of Münster cannot be called beautiful, as the town occupies the centre of an immense flat plain; but it is, nevertheless, pleasing from the richness of the cultivation and the number of trees seen in all directions. The beautiful towers of the churches group well over this foreground of rich and varied foliage. The entrances to the town are not prepossessing, as it is surrounded by a *stinking ditch*, which is a disgrace to any civilized community, and the river into which this abominable drain empties itself is little better than another ditch. The ancient walls and ramparts were destroyed at the commencement of this century, and their place is now occupied by a fine avenue of trees, which entirely surrounds the town, and would form an agreeable promenade were it not for the before-mentioned ditch.

Many of the streets are not uninteresting; but the high-street, or, as it is here called, the "Prinzpal Markt," is one of the most picturesque in Europe. The houses on both sides are built over arcades of acutely-pointed arches, supported upon octagonal and circular columns; some of these arcades are as early as the commencement of the fourteenth century, and the details of the capitals and bases are often highly original and ornamental. Each house has a gable towards the street, some of which are ornamented with pierced Gothic tracery pinnacles, panelling work, and other enrichments. The house which originally belonged to John of Leyden is a singularly beautiful specimen, and in a very perfect condition. At one end of this noble street stands the Church of St. Lambert, a highly ornamental Gothic building, upon the tower of which are seen the cages in which the bodies of John of Leyden and his companions were exposed after their execution.

Near to the opposite end of the street, and on the east side, stands the Rathhaus, of which we give a view, engraved from a drawing made on the spot for us by Mr. H. W. Brewer. Its gable forms a striking object from whatever point it may be seen; it is of great size, and built entirely of stone; it is 104 ft. high to the top of the upper pinnacles, and 51 ft. broad. The date of this portion of the building is late in the fourteenth century. It is difficult, however, to decide whether it is all of the same date, as the open flying buttresses pierced with flamboyant tracery certainly appear to be of a later date than the simple "geometrical" windows. However, in Germany the two kinds of tracery were often used in the same building to an extent which is not to be met with in either England or France; and in Westphalia this appears to have been particularly common, for in the before-mentioned church of St. Lambert, the side windows are filled with the same kind of curvilinear tracery, and the windows of the tower, which are of the same date, have very simple geometrical tracery.

The four large windows on the first story give light to a large hall, which has been renovated; and although it is a fine apartment, the old arrangements have been entirely disregarded, and the details are hardly removed from "Carpenters' Gothic." The "Freidensaal," in which the "peace of Westphalia" was signed in the year 1648, is a much more interesting room; it was fitted up in the year 1575, and all the panelling, ceiling, and other ornamental portions are of that date. Perhaps a more beautiful example of a Mediaeval chamber of large size does not exist in Europe. The gable to the rear of the Rathhaus is of the same date as the "Freidensaal" hut, although highly picturesque, is not remarkable for its architecture.

RIGHT-HAND AND LEFT-HAND LOCKS.

A CORRESPONDENT writes:—"May I beg you to favour me with a definition of the terms 'right-handed' and 'left-handed' as applied to locks on doors? I find a difference of opinion among professional men upon the subject."

A lock which, when the hevel of the spring-catch is in front of the observer, shoots towards the right, is a "right-hand lock;" if it shoot towards the left, a "left-hand lock."

STRENGTH OF WAREHOUSE FLOORS.

At a recent meeting of the Liverpool Architectural Society a report was received from Mr. Newlands on the cause of the accident in Bighy-street, Liverpool. The writer says,—"I have carefully investigated the failure of the fifth story floor of the warehouse, No. 25, Bighy-street, which involved the partial destruction of the next three floors under it, and now report the result. The building was erected originally as a lard-refining establishment, and was not intended to be used as a warehouse in the usual acceptance of the term.

The warehouse consists of seven stories, the floors of which, with the exception of the first, which is of brick, are constructed with girders and bridging joists of timber. There are four rows of girders, each 15 in. by 7½ in. in section, supported on two rows of cast-iron columns, placed so as to make the clear bearing of each section of the girder 14 ft. long. The area of the bay of the floor, supported by each of these sections of the girders, is 122½ ft. superficial.

A girder of the size and bearing above mentioned should, if perfectly sound, break with a load of 40 tons uniformly distributed over it. It is a rule of practice, however, to limit the actual weight to one-fourth of the breaking weight, and this is called the safe load, which, in the case stated, would be 10 tons.

The timber of the girder of the warehouse is of a wonderfully small specific gravity; a cubic foot weighs only 25 lb. The girder is, moreover, reduced in strength by the mortises out for the joists, and by knots, and its breaking weight is reduced to 33½ tons, and its safe load to 8 tons 7½ cwt.

In order to ascertain whether the usual formula could be safely applied in calculating the strength of the girders in question, I had three pieces, of 7 ft. long, 6 in. deep, and 3 in. wide, out from the broken girders; these I loaded until they broke, which they did on the average with a load of 6,714 lb., which is somewhat less than the average of the formula. I used the results thus obtained in calculating the breaking and safe load already given.

The weight of a cubic foot of line-seed was next ascertained for me by Mr. Johnstone, of the Weights and Measures Office, by repeated experiments. The result was, that when the line-seed was compacted together by being well shaken in the box, a cubic foot weighed 46 lb. 11 oz. 10 dwt., but when it was allowed to flow in through a hopper it weighed only 41 lb. 7 oz. 6 dwt.

I am indebted to Mr. James Samnelson, however, for the means of ascertaining, with great accuracy, the weight of the line-seed per cubic foot when distributed over a floor to the depth of 4 ft. 3 in., when it may be supposed to be nearly as densely compacted as by shaking.

In the case adduced by him 7,429 cubic feet weighed 150 tons, which gives as the weight of a cubic foot 45½ lb. nearly; I have assumed 45 lb.

It was stated, in evidence, that there were 60 tons, or thereabouts, of line-seed on the floor that gave way, and that it was spread uniformly to a depth of 3 ft. 6 in. Now this must be a mistake for the net area of the floor, deducting 114 ft. 1½ in. for the areas of the left, the stairs, the chimney, and the shoot is 1,788 ft., and the weight upon it would be 126½ tons.

It is, however, sufficient for the present inquiry that we find the quantity that may be presumed to have been sustained by one bay of the flooring, that is, by one section of the girder which gave way.

Now the area of a bay of the floor supported by one span of the girder is, as has been stated, 122½ superficial feet; and if line-seed were spread over this to a uniform depth of 3½ ft., its weight would be 8 tons 13 cwt., or 6 cwt. more than the limit of safety.

But the hay might be loaded by heaping up the material to a height of 7 ft., with a weight of 17 tons, which is more than half the breaking weight of a sound girder of the dimensions of the one in question.

There are now no means, unfortunately, of discovering the extent of the load; all we know is that, unhappily, the girder broke, and broke under a load far less than its assumed breaking weight.

I had therefore to look for some special cause of failure, and my first supposition was that some settlement of the building might have taken place, and that a greater load might have been thrown on some part of the girder than it

was calculated to sustain. The fact that the point of rupture was only 4 ft. from one of the supports, and not in the middle of the span, appeared to justify this supposition. A careful levelling of the building showed that no settlement had taken place, and the conclusion was forced upon me that the condition of the girder at the point of rupture must have been the cause of the accident.

At this point there is found a large knot, extending diagonally across the section. The fibres are much twisted from their normal direction, and the timber is very much shaken and otherwise injured. It is impossible, of course, to say now how this condition of things was brought about; but it is to this condition, in my mind, that we must look for the cause of the accident.

Had the timber of the girder been all of the same strength as the scantlings which were sawn from it, and broken as a test, there should have been no immediate failure, even if the room had been loaded with line-seed from floor to ceiling; but in such a case there would have been a gradual deterioration of the timber, ending doubtless in its eventual rupture, and this shows the necessity for never exceeding the safe load. There does not, however, appear to have been time for this deterioration, and the accident must be attributed, as I have said, to the existence of an unseen evil, which unfortunately betrayed its presence by causing injury to life and property."

THE PROPOSED BUILDING ACT AND THE INSTITUTE OF ARCHITECTS.

A SPECIAL meeting of the Institute will be held on Monday evening next, to consider a report of the committee on the Metropolitan Buildings and Management Bill, adopted by the council, 22nd June, 1868. We have the report before us, together with one drawn up on the same subject by the District Surveyors' Association.

The committee of the Institute say,—

"We, the committee, appointed by the Royal Institute of British Architects, to examine and report on the draught of a proposed New Metropolitan Buildings and Management Bill, having duly examined the same, and considered the provisions therein contained, both in their relation to those set forth in previous Acts of the same nature, and in relation to the necessities of current practice in the metropolis, beg to report as follows:—

Having reference to the present state of the Bill, and the probability of its being extensively altered, we have only dealt with it at the present time in general terms, leaving the minute details to a future time.

We observed that its scope differs from that of the existing Building Act in the extended powers given to the Metropolitan Board of Works. Not only has that body, by the proposed Bill, power of authorizing any deviation from the conditions of structure laid down in the Act, but it remains the sole and absolute court of appeal in all matters or questions arising out of the Act, having at the same time such despotic rule over the position of the district surveyors, as to render them entirely powerless, if the Board sees fit to exercise its authority. Our chief objections to the Metropolitan Board of Works, as holding this great power, are not of any personal nature, but rest on the following considerations.

Questions arising out of this Act are generally on matters of detail of an altogether technical nature; that is, technical either from an architectural or a legal point of view. While the variety and importance of other duties already devolving upon that Board, are not likely to leave them time to properly investigate complicated questions of construction, and the numerous other matters which must necessarily arise out of the working of the Bill; and the number of members of which the Board is composed, must neutralize to a great extent the sense of personal responsibility which is essential for the due administration by it of such matters of detail. Your committee would have preferred to have seen the authority conferred by the draft Bill upon the Metropolitan Board of Works, vested in a smaller tribunal, appointed, it may be, by the Board, and adequately remunerated, especially selected for possessing the necessary legal and constructional knowledge, and directly responsible for their judgment of all questions upon which any power of discretion is

left by the Act. Such tribunal should, we think, consist of one or more architects or surveyors of repute, and of one or more magistrates or barristers.

We would further observe, that the draft Bill, as compared with the existing Metropolitan Building Acts, contains various provisions, founded in the main on the Building Act in operation at Liverpool, with respect to fire-resisting buildings, more particularly of the warehouse class; and the conditions under which goods of greater or less combustibility may be stored therein. The introduction of these clauses (subject to some remarks, we shall hereafter offer in detail) will, we consider, confer a benefit both upon the public, and upon those especially connected with the use or erection of such structures.

The Bill comprises various clauses, more particularly affecting metropolitan local management, which we consider tend to complicate unnecessarily an Act for the special regulation of buildings—a kind of Bill which, from its very nature, must always be somewhat complicated. We consider, therefore, that any such clauses would, with great propriety, be included in a Bill for the Revision of Metropolitan Local Management.

We find so many clauses and provisions relating to the prevention of fire, that we think more general prominence should be given to the subject in the preamble of the Bill.

We think, also, that the attention of the Metropolitan Board might with advantage be recalled to the suggestion already made by this Institute, that the introduction of a part (similar to Part VI. for party walls), having reference to questions of light and air in the metropolis, would be a great public boon, as tending to diminish and prevent litigation on that difficult subject, and to simplify procedure, when damage is caused by the erection or alteration of buildings.

We proceed now to refer to certain details of the draft Bill, which, we think, call for special remark, desiring to observe at the same time, that we leave many other points without comment at present, but which will require more or less revision, before the draft Bill can become law with any prospect of public usefulness. Some such points have already been noticed in the 'Remarks and Suggestions' submitted for the consideration of the Metropolitan Board of Works, in November last, by the District Surveyors' Association.*

The remarks and suggestions on the Metropolitan Buildings and Management Bill, already submitted by the District Surveyors' Association, for the consideration of the Metropolitan Board of Works, commence with these general remarks:—

"They do not consider that there exists any sufficient reason for such sweeping changes as are proposed by the Bill, or that they are demanded by the public. They believe that it would have been more convenient to correct the known imperfections of the present Act, leaving unaltered all the parts to which no objections had been discovered.

They consider that the general character of the Bill is one of too much minute detail, which they believe will be found inoperative from the impossibility of providing for all the various circumstances which arise in practice; also in many clauses the detailed regulations are technically and practically obscure. This is a defect which, in the present Act, has been found frequently to defeat the object of some of the provisions. By laying down minute regulations as to details, not universally applicable, and which must necessarily be framed with reference to presupposed cases, the officers who are charged with the execution of the Act will be prevented, in cases where the circumstances are different, from exercising that practical knowledge which they may be supposed to possess.

Important alterations have been made in the Bill since the former remarks of the District Surveyors' Association were submitted, in consequence of the report of Captain Shaw, the Superintendent of the Fire Brigade. These alterations require further careful consideration; some of the provisions as they stand at present are quite at variance with the results of practical experience. Captain Shaw's remarks refer chiefly to the case of a building actually on fire, but one of the great objects of the regulations of a Building Act should be the construction of buildings in such a manner as to reduce the liability to catch fire; and with this object,

materials which are incombustible, though not 'fire resisting,' may be used with advantage. With reference to fire, it is also important to distinguish between the construction of ordinary dwelling-houses and buildings of the warehouse class, which has not been hitherto sufficiently the case.

Some modifications are required in the rules for the thickness of walls, but they could only be pointed out by means of detailed diagrams, and it may be sufficient here merely to direct attention to the subject.

The district surveyors feel compelled again respectfully to urge that the clauses relating to the duties and emoluments of those officers would, if they became law, be unjust to the existing officers, and inexpedient even with reference to those who may be appointed in future.

They believe that the interests of the public will be best considered by so framing the Act as to insure the appointment of men of ascertained practical knowledge and experience, and of such professional position and standing as to give weight to their opinion."

NEW NATIONAL SCHOOLS, TWEEDMOUTH.

The new national schools at Tweedmouth were opened on the 11th inst., when 167 children presented themselves to the vicar, the Rev. Thos. Procter, for admission in the course of the morning; additional applications eventually swelling the number to a still more considerable one. The new schools have been built upon the site of a small group of buildings formerly used as a vicarage and school. They consist of two school-rooms placed one above the other, each 52 ft. long by 20 ft. wide, and both furnished with class-rooms 20 ft. long, and lobbies, besides separate residences for the master and mistress. The lower school is 14 ft. high; and the walls of the upper one are 20 ft. high, spanning which is an open timber roof. This last is apportioned to girls. They are both well warmed, lighted, ventilated, and furnished with all necessary appliances in the way of Siddeotham's reversible desks, &c. The class-rooms have galleries. In each school 180 children can be accommodated. A central feature of the exterior of the schools is a belfry surmounted by a cross. On a panel in the front of the lower school is inscribed:—"Tweedmouth National Schools: rebuilt, 1868. Bring them up in the nurture and admonition of the Lord." There are two gateways inscribed Boys' School and Girls' School respectively. The expenditure upon the new schools has been 1,150*l.*, to which sum must be added the value of the vicarage-house incorporated with them, and of the materials on the site, which have been re-used wherever practicable, and which bring up the value of the new buildings to 1,650*l.* The vicar, under whose auspices the work has been inaugurated, carried on, and completed, has been assisted by a grant from the Privy Council of 407*l.* 14*s.* 10*d.* Grants have been also made by the Dean and Chapter of Durham, the Diocesan Society, and the National Society. The architect was Mr. F. R. Wilson, Alnwick.

THE PROPOSED LAW COURTS AND THE THAMES EMBANKMENT.

At a meeting of the Board of Works, on the 22nd inst., Mr. W. Tite, M.P., brought forward the motion, the words of which we have already printed.*

In moving it, he said it was a great mistake to suppose that the Metropolitan Board of Works had any great amount of vacant land on the Thames Embankment, the principal part of it had already been disposed of. At Blackfriars-bridge the land taken from the river had been given to the gasworks. The next piece was of very little value, but that following it, 800 ft. long, had been given to the Temple for the actual or imaginary damage done to them by taking their water frontage. They then came to a piece of land of 120 ft. in length, which was given to Waterloo-bridge, and was at their disposal. This was to be appropriated to a station for the Metropolitan District Railway, for there would be no use in having a station at Blackfriars-bridge. He then got to Somerset-house, where there was nothing to deal with; but between Somerset-house and Hungerford-bridge there was a piece which was given to the Crown in exchange for the foreshore of the river. He then came back to the embankment, where he made it in the House of Commons, that, as he had been assured by a very competent authority that the land already obtained for the New Courts of Justice would be insufficient, and not equal to their wants, they should go again to Parliament for additional land, marked red on the plan, unless they were to put some portion of the offices in connection with the Law Courts on the Thames Embankment. He would state a few facts on the plan

which was then on the table. The land already purchased would cost 750,000*l.*, and the additional land proposed to be acquired would cost about 668,000*l.*, so that altogether the site according to the estimate, which was a very liberal thing from the actual cost, would be about 1,418,000*l.* and a half sterling. Then they were to take the buildings, architect's fees, furnishing, &c., which would bring up the total cost to 24 millions, of which sum 8,000,000*l.* was to be advanced by Government at 4 per cent. on the security of a redeemable annuity. About three-quarters of an acre on the Thames Embankment might be appropriated to some of the offices, for it would be advantageous that they should be divided from the general business of the law courts. For instance, persons who came to examine wills in cases before the Probate Court would be in the way, although it was necessary that the courts should be so situated that access should easily be had to barristers attending to them. Having alluded to the plan of Sir Charles Trevelyan, who had brought to bear a great amount of intelligence and talent, which had made a great impression on the public mind, he had proposed that the site should be changed, and that it would be a great mistake to put the buildings on the site selected in the Strand. His plan was that they should put the buildings on a site near the Thames Embankment, but that would not take a single foot of the land that the Metropolitan Board of Works might have to sell, as it kept all the buildings beyond the Thames Embankment line, although it would have a frontage towards the Thames.

Mr. Le Beau, the gentleman who presented a little too far, and objected to the proposal to have the Probate Court separated from the other courts. He moved, as an amendment, that he be referred to the Works and General Purposes Committee to confer with the Government or the Law Courts Commissioners, as to the acquisition by them of any land that can be obtained on or adjacent to the embankment for the purpose of affording additional space for any law offices it may be deemed expedient to erect thereon.

Mr. Tite consented to accept the amendment, which was accordingly adopted, notwithstanding an argument strenuously urged by Messrs. Roche, Cooke, and Eit, that they should not interfere with the open space near the embankment by disposing of it for building.

OPENING OF LUTON PLAIT HALLS AND CORN EXCHANGE.

These new buildings were formally opened on Monday in last week, by Lord Cowper, in the presence of the American Minister and a large assemblage. The opening was followed by a dinner and the usual speechifying, in which Mr. Johnson, of course, took a lion's share. The day was kept as a holiday in Luton.

The Plait Halls are in Cheapside and Waller-street. They open into each other, but have separate external entrances. These buildings are of simple construction. The dimensions of the Plait Hall in Cheapside are 100 ft. by 90 ft., and of that in Waller-street 130 ft. by 60 ft. The roofs are supported by iron columns, and covered with galvanized iron; the windows are filled with plate-glass; the walls are panelled; and the floors are boarded. In the Cheapside Hall there are forty centre stalls, and there are to be nineteen "shops" 12 ft. square and 12 ft. high. In the Waller-street Hall there are forty plait-stalls fitted round the sides, and there are to be thirty-two stalls or stands in the centre. The buildings are lofty and well ventilated. The cost of erection, including the purchase of the ground, is about 8,000*l.* The building was designed by Mr. R. W. Ordish, of London, architect, and erected by Messrs. Smart, Brothers, of Luton.

The Corn Exchange, which stands on the top of the Market-hill, is in the Venetian-Gothic style, with a tall clock-turret. The building is of red brick, with hands of other coloured bricks, and Bath-stone dressings. In the basement is the huteburs' market. The Corn Exchange proper is about 60 ft. by 30 ft., and is reached by a flight of steps from the Market-hill. There is a gallery at one end of the building. The light is chiefly obtained through a bay window. The Corn Exchange was erected by Messrs. Smart, Brothers, from the designs of Messrs. Grundy & Messenger, of London; and has cost about 8,000*l.*, which, we suppose, includes the demolition of old buildings.

HOT-WATER PIPES AND THE BUILDING ACT.

Sir,—Can you afford any information as to what in the eye of the law is to be considered a hot-water pipe, viz., at what temperature? For surely nothing can be more absurd than to consider those warm cast-iron pipes, now so much used in heating, as the hot-water pipe named in the Building Act, the water seldom or never boiling in the boiler that warms the water.

There is certainly an oversight somewhere; and, as I perceive by the *Builder* that the clauses of the Building Act are to be revised, I should be glad to have some practical information as to what a district surveyor can designate a

* See p. 53, ante.

(dangerous) hot-water pipe requiring to be kept clear of woodwork. Has there been any law-suit which can give a precedent as to what is a hot-water pipe or a warm pipe?

It seems to me that all restrictions about heating apparatus constructed with cast-iron pipe should be solely regulated by the height of the open supply cistern above the level of the boiler, as it is absolutely impossible (drive the boiler as much as you will), where there is an open supply cistern or air vents, to raise the water in such apparatus above the boiling point for such pressure as the number of feet taken vertically between the highest and lowest levels would give, viz., in church work, about 225" in the boiler, and, of course, much less in the pipes.

A SURVEYOR AND ENGINEER.

*** The Metropolitan Building Act (sec. xxi.) says nothing about "dangerous" hot-water pipes. It provides that "no pipe for conveying hot-water shall be placed nearer than 3 in. to any combustible materials," and extends to all water-pipes that are used for heating buildings, whether the boiler be a close one or not. Magistrates on more than one occasion have confirmed the district surveyors in their view, and rightly enforced adherence to the rule with penalties for previous non-attention to it.

The matter may deserve the consideration of the framers of the amended Act; but we are by no means prepared to say that pipes from an open boiler should be exempt. By any accidental stoppage of the pipes their temperature might be raised sufficiently to set fire to wood-work resting against them and already dried by the contiguity, should such be permitted. We are informed of some "hot-water engineers" who systematically withhold notice from the district surveyor whom employed to set up hot-water pipes. We need scarcely say that by such a course they incur a very serious responsibility, independently of the special penalty provided by the Building Act.

DIMENSIONS OF ST. PAUL'S.

Sir,—Respecting the height of St. Paul's great deception is constantly set before the public, as the height given is usually 404 ft., or twice the height of the Monument. Now, I cannot think why such a height should be stated, for in examining the sections given under A. Pugin's measurement in "Public Buildings of London," published in 1825 by J. Taylor, High Holborn, and under A. Pugin's directions, from the vaults or crypt to the top of the cross is 381 ft.; the crypt being 21 ft., leaving 360 ft. from the pavement of the nave; from the western steps to the east end, 550 ft.; from the top of the steps to the pine-apple of the western turret, 210 ft.; diameter of the walls supporting the outer dome, 107 ft.; length of north and south transept across the area of the dome, 240 ft.; from the inner doors north and south; height to the top of the ridge of the roof from the pavement, 112 ft.; from the base of the steps of the north and south transept, 313 ft.; from the springing of the outer dome to the top of the cone supporting the cross, ball, and lantern, 53 ft.; inner measurement of the nave and side aisles, 93 ft. 8 in. Now, if any accuracy may be placed in A. Pugin's measurement, I think it is high time such blunders were corrected; and that the publication of this through your columns would set at rest many inquiries which from time to time appear in almost every paper.

J. W. F.

*** Our correspondent is much too sanguine. Errors are very long-lived. The correct height of St. Paul's has been given even in our own pages many times, and will be asked many more.

THE NEGLECTED CHILDREN OF EXETER.

It is very gratifying to us to observe that this subject, which, as our readers know, we have much at heart, is making way in the provinces. A largely and influentially attended public meeting has been held in the council chamber, at the Guildhall, Exeter, convened by the mayor, by circular, "to consider the best means of employing the poor and destitute children of the city during the winter evenings."

The good attendance of clergy and citizens shows that the mayor of Exeter has taken up a subject which the public generally will feel a warm interest in, and be willing to help forward by pecuniary support and personal effort. Let a judicious scheme be devised for rescuing neglected children from the contamination of the

streets, and for providing instruction and employment for boys and girls whose parents either cannot or will not care for them aright, and it will not lack assistance. Police reports afford sufficient proof of the existence of a shocking amount of juvenile criminality; the large number of young people who infest the thoroughfares at night, supplies evidence of the fact that hundreds are lapsing into evil courses for want of proper direction and restraint. With these the mayor and those who are acting with him wish to deal, and so to deal that many who would otherwise acquire vicious habits may be made honest and virtuous, and many who are left to the bad training of the streets may be brought under influences calculated to render the idle industrious and the rude and immoral well-behaved and respectable.

On the motion of the Doan, it was resolved,— "That in the opinion of this meeting it is most desirable that measures should be adopted immediately for the purpose of providing additional instruction and well-devised amusement for the juvenile population of the city during the winter evenings."

Many gentlemen spoke, and it was resolved afterwards,— "That a committee be appointed to report to an adjourned meeting what steps it may be in their opinion desirable to take to give effect to the foregoing resolution."

The committee was then named and appointed. It included the mayor (Mr. Ellis), the dean, the ex-mayor, and several other influential men.

INSTITUTION OF SURVEYORS.

At the ordinary general meeting, held on Monday, January 25th, Mr. John Clutton, the president, in the chair, the adjourned discussion on Mr. Grantham's paper on "Arterial Drainage" was continued. Messrs. E. J. Smith, F. J. Clark, F. Vigers, J. W. Barry, F. Fuller, and others, took part; and the question chiefly discussed was that of the mode of rating the improved properties. The president summed up, and Mr. Edward Ryde then read a paper on "Parochial Assessments." A vote of thanks was passed, and any discussion adjourned to the next meeting on February 8th, when a paper will be read by Mr. J. Bailey Denton, on "The Extension of the Railway System, with special reference to its influence on Landed Property and Agriculture."

CHURCH-BUILDING NEWS.

Waddeton, Torquay, Devon.—The new church in the grounds of Waddeton Court House, the seat of Mr. Henry Studdy, was used for the first time on the first Sunday in the new year. It comprises nave, chancel (with apse), vestry, and porch, and will seat about eighty persons, being intended for the hamlet of Waddeton only; and rebuilt in memoriam of the Rev. R. Holdsworth, late vicar of Brixham. The works were designed and carried out under the superintendance of Mr. Thomas Lidstone, of Dartmouth, by whom the Mansion House was constructed some few years ago. The former chapel was consecrated in the twelfth century.

Hexham.—A vestry meeting was recently held in the vestry, Abbey Church, Hexham, for the purpose of adopting such measures as may appear necessary for enabling the rector and churchwardens to make application to the proper Ecclesiastical Court for a faculty to empower them to make certain alterations necessary in the restoration of the transepts. The meeting was of a formal character. The chairman having submitted plans prepared by Mr. Johnstone, architect, Newcastle, it was unanimously resolved that the meeting approve of such plans, and that the rector and churchwardens adopt such measures as may be necessary. The alterations, additions, and reparations will be made by voluntary contributions. It is intended to lower the floor of the transepts and their aisles to the original level; to repair the stonework of the piers, arches, clearstory, triforium, arcades, and other parts of the transept and their aisles; to close up the present north door of the transept, with a view to the restoration of the arcade to its original state, and to adapt, as may be considered necessary, the south door for the entrance to the church; to open out any windows that are blocked up; to build a new vestry on the part of the site of the old nave between the hut-tresses to the west of the tower; to take down the wall at present filling up the western arch of

the tower, and rebuild it within or without the intended vestry; and to do other minor works connected with the church.

Coventry.—The two new churches—All Saints' and St. Mark's—which have been erected respectively in Far Gosford-street and Stoney Stanton-road, have been consecrated by the Bishop of the diocese. These churches have been built for new parochial districts taken out of the parishes of St. Michael's and Holy Trinity, the funds having been contributed by societies connected with the church and by subscriptions in the county and city. About 7,700l. have been subscribed, and there is still a deficiency of about 700l. Both churches are as near as possible alike, and have been built by Mr. Lovatt, of Wolverhampton, from the plans of Messrs. Paull & Robinson, of Manchester, the diocesan architects. The buildings are in the Early English and Gothic style, and the exterior wallings and dressings are of local sandstone. Each church consists of nave, aisles, chancel, vestry, organ-chamber, and porch. The inside dimensions are, aisles and nave, 79 ft. 6 in. by 12 ft. 6 in. and 23 ft. respectively; chancel, 32 ft. by 20 ft.; making a total internal length of 111 ft. 6 in. The pews are all open, and are made of stained wood. In St. Mark's Church a stained-glass window amounts to the communion-table, the gift of Mrs. Darlington, of Meriden Hall.

Bristol.—A meeting of members of the congregation meeting in the iron church, Tyndall's Park, has been held to consider the desirability of taking steps for laying the foundation of the permanent structure. Plans for the building (prepared by Mr. St. Anby, of London) were submitted, and the architect's opinion was that when 1,000l. were forthcoming they would be justified in making a beginning.

South Walsh, Essex.—We are requested to state that the architect of the restorations of St. Peter's Church was Mr. Tenlon, not Fenton, as misprinted.

Lowestoft.—An adjourned vestry meeting has been held, the rector presiding, to receive a further report of the committee, and plans and specifications for the repair of St. Margaret's Church. There appeared to be three plans for consideration—the original plan, that now proposed by the architect, and the removal of the church into the town. The bishop had suggested to the churchwardens and committee that they should obtain from their architect a plan for the thorough restoration of the Church, with all that was requisite in the way of fittings, &c., and then make an appeal to the public for aid by donations either towards a particular object or a general fund; to be given at once, or distributed over a term of three or more years. The committee recommended that a work of so much urgency should be at once proceeded with. The report was adopted. The estimate for the additional work is 650l.

ART-WORKMANSHIP COMPETITION.

The works sent in competition for the handsome rewards offered this session by the Society of Arts are now on view in the Society's room, Adelphi. The number is but sixty, fewer than might have been anticipated. The adjudication of prizes will be made next week.

ARCHITECTURESQUE AND PICTURESQUE.

Sir,—It appears to me that Professor Kerr does not precisely set the painter's value on the word "picturesque." If he did, and the term "architecturesque" were proposed to be used in a parallel sense, it would, I think, be readily understood and accepted by them as well as by architects. The painter would not apply the word "picturesque" to the antiques, or the finest works of Michelangelo, Raffaele, Giotto, &c., which correspond with the classical examples of architecture; but to the works of the Venetian, Spanish, and Flemish schools. "Picturesque" by painters is applied to that kind of art which deals with the more florid, varied, and intricate in effect, in contradistinction to that which is more temperate, balanced, and simple. The word "architecturesque" to be parallel with "picturesque" should stand thus:—

Painting.	Architecture.
The Grand Style	The Classical
The Picturesque	The Architecturesque
The Unartistic	The Unarchitectural.
	A PAINTER.

COMPETITIONS.

Walsall.—It is proposed to erect a new church at Galdmore to seat about 500 persons. A design by Mr. Veall, architect, Wolverhampton, was selected in a limited competition.

Harly Winney Church.—For this competition the committee received more than forty designs. They have chosen those marked "Fides," by Mr. E. A. Lansdowne, architect, and have given him instructions to carry on the work.

Elton.—A short time since designs were received by the committee in a limited competition for St. Stephen's schools, Elton, near Bury, Lancashire. After examination of the drawings, the committee selected those sent in by Messrs. Farrar & Syan, and also designs sent in by Messrs. J. M. & H. Taylor, for consideration. Ultimately the designs of Messrs. Farrar & Syan were adopted, and the works will be carried out under their direction.

SCHOOLS OF ART.

The Nottingham School.—Mr. W. F. Webb, of Newstead Abbey, distributed the prizes gained by the students of this school during the past year, in the large room of the Institution. Mr. Alderman Birkin presided. We have already given an account of the distinguished success of this school during the past year. The meeting was addressed by the chairman and by Mr. Webb, Mr. Rawle, the head master, Mr. Muddella, M.P., and other gentlemen.

A School for Swansea.—The public of Swansea and its vicinity are about to have the advantage of a School of Art. An advertisement appears in the *Cambrian* that a School of Art, in connexion with the South Kensington Museum, is about to be opened in the large rooms above the Post-office, Mr. Hooford being the head master. The school is warmly supported by a large number of the principal gentry, who are the managing committee, whilst the situation is central and convenient, the rooms being well lighted and furnished with classical figures and all necessary adjuncts.

METROPOLITAN BUILDING ACT.

CAUTION TO BUILDERS.

ON Tuesday last Messrs. Tonson & Williams were summoned to Clerkenwell Police-court by the district surveyor of South Islington for neglecting to give notice previously to cutting away a chimney breast and flue, also forming front window into doorway, at their premises, No. 336, Goswell-road, Islington.

Mr. Cooke, the sitting magistrate, fined them 3l. (afterwards reduced to 2l.), and expenses, 12s.

SANITARY TRACTS.

Sir,—I see that you decline to point out books, yet I venture to avail myself of a woman's privilege to ask if you could point out to me where I could procure some sanitary tracts. I have the task of arranging a quarterly packet of tracts for our Ladies' Sanitary Association in Manchester; and having exhausted every available source here, I am compelled to try elsewhere for something new. As I am writing contrary to the notice in the *Builder*, I shall not of course expect an answer, but shall be glad if you give me one, as I am really in difficulties about my packets of information for our meetings.

M. D. Manchester.
* * * Apply to the Ladies' Sanitary Association, 8, Pont-street, Belgrave-square, S.W.

THE TESTIMONIALS OF CANDIDATES.

Sir,—There is a matter connected with public competitions for surveyorships, assistants, and other offices relating to municipal affairs, to which, with your permission, I will draw the attention of those who are concerned. It is that of testimonials.

It has come to my certain knowledge that in one or two public appointments of late applicants have been thrown out and rendered ineligible because they had sent copies and not original testimonials.

That this is scarcely a consistent course for authorities to follow, I will endeavour to show. The persons so rendered ineligible may be the best qualified for that particular appointment. Original testimonials, in addition to the risk of being lost, soon become worn out from frequent handling; and this is no small risk, for although some authorities courteously return papers to unsuccessful candidates, I regret it is not constantly the case. As these cannot always, in fact very seldom can, be renewed, it is of serious consequence to the unfortunate individual so losing them.

It will sometimes occur that at the same time more than one appointment is made, and in different parts of the country; in this case it becomes impossible to transmit "originals" for several appointments, and perforce copies only can be sent, and so the applicant becomes ineligible, and his time is wasted.

When copies have been forwarded, it would be an easy matter for notice to produce "originals" to be given to those most likely to be appointed.

Whilst drawing attention to this subject, let me add, how much better it would be in the interests of all for municipal authorities to select, in the first instance, some half-dozen from among 50 or 100 applicants—being considered the most competent—to appear for personal examination, instead of having the whole batch coming forward at great expense and loss of time. The appointment of Surveyor of Pavements to the vestry of Rochester is a case in point. The matter just ventilated, I trust, will be taken up by some able pen in the interests of many of our subscribers.

COMPETITOR.

THE LATE MR. GEORGE SMITH.

Sir,—I have received a letter from the Rev. Sydney Smith, who informs me that his mother was not the daughter of the water-bailiff. Will you have the goodness, therefore, to notice this error in your next number? I felt as certain of the supposed fact as I did of the anecdote touching Abernethy; the latter I was in the office some forty years ago by George Smith, Mr. Smith's eldest son, and felt sure that he had coupled the statement with his mother's name.

H. C. BALLOW.

A CAUTION.

Sir,—About six o'clock on Saturday evening last, a Mr. "Roberts" was shown into my room. On my going into the room a few minutes later, he mentioned my father's name, and that his object was to obtain some assistance from the Architects' Benevolent Society, referred him to my father, who was not then at the office, and he left, carrying with him a valuable illuminated work that, with excellent taste, he had selected from my book-shelf. To put architects on their guard against such people, I beg you will be good enough to insert a note of this in your next issue.

T. H. W.

CHARGES FOR QUANTITIES.

Sir,—Will you favour me with space in the *Builder* for the following statement of a surveyor's claim for quantities? And if you will add to the favour by stating your own opinion whether or not the claim is a proper one and in accordance with the practice of the profession, you will confer a benefit on all connected with building operations.

A house near this town (Perith) having to be enlarged, an architect from another town was employed, who advertised for tenders, and deposited his plans, &c., in a convenient place for inspection; but neither in his advertisement, specification, nor otherwise did he refer to any bills of quantities. About the same time, however, placards on the walls informed me that bills of quantities might be obtained at 2s. 6d. for each of my departments of the work, on application to a surveyor, at D— (the same town where the architect resides).

I rendered 7s. 6d. and received three schedules; but as these quantities had not been authorized or alluded to by the architect, I had no guarantee that other competitors would use or even obtain them. I therefore thought it desirable to check the quantities, and finding some important items too much, I set the whole aside and took out my own. My tender, amounting to 100l., was accepted, and I have since received a bill, making the claim of which I now complain. It is as follows:—

To Commission	£2 8 0
To Lithographing	2 0 0
	£4 8 0

making, with the previous payment, 4l. 10s. 6d. per cent. on the amount of my contract. The placard advertising the quantities it was stated that they "could be guaranteed on certain conditions;" but no mention was made of any further payment than that which I rendered; but when I got the schedules I found appended to each an intimation to add 2l. per cent. for quantities and other items for lithographing; but this I did not do, not seeing, under the circumstances, the justice of such an addition to my tender.

I enclose my address and other particulars for your own information.

J. S.
* * * If the facts be precisely as stated, our correspondent is not bound to pay the charge made, which, moreover, is excessive.

MASONIC BUILDINGS.

Sir,—Will some of your correspondents point out a publication or anything which would lead me in the way of acquiring the "ritual of building adopted by the order of Freemasons for the extent and peculiarities of accommodation required for the working of the higher degrees of Masonry," as I am engaged in constructing a hall connected with the Masonic body.

H.

THE BOSTON CHIMES.

Sir,—In the correspondence that has taken place in your paper, we have the late epistle of the Rev. H. T. Ellacomb, who went to Boston as an amateur, to examine and see novelties. He confesses the work was unfinished, but at so magnificent was the machinery, he felt convinced such beautiful work must produce the sweetest music. He did not see the barrels work, neither heard the bells together, consequently he can know but little of the question in dispute. He speaks heartily, and says the fault may be with the founder; acknowledges that he knows not where it is. The issue, after all, is very simple. The chimes are not satisfactory, and all mortals that make them so have failed. I confess I am mortified that my invention of raling and discharging hell-hammers should suffer from the incompetence of others. I repeat that the bells can be made to act perfectly; the whole thing is simple and practicable; and when my detractors confess they are beaten, I am ready to carry on their failure to success.

D. Linnor.

* * * We allow Mr. Imhof to speak, being personally interested; but we must decline printing two or three other letters on the subject since received. Additional work is being done, we are informed; and until that is finished and the chimes reopened judgment may be suspended.

Books Received.

Quantities Made Easy: a quick and accurate Method of taking out Quantities in Buildings.

By H. A. CREASEY. F. Shaw, Dockhead.
THESE pages consist of lists of the items in an ordinary dwelling-house, so that an estimator may not forget or overlook any in taking out his quantities. Instead, however, of keeping all the trades separate, the writer puts each room separately, so that the same headings would have to be written over and over again, and the resulting sum would be very much higher than the same estimator would bring it if he pursued the more customary, expeditious, and common-sense mode.

Practical Remarks on the Principles of Rating, as applied to the proper and uniform Assessment of Railways, Gas-works, Water-works, &c. By H. JAS. CASTLE, assisted by EDWARD JAS. CASTLE, Barrister-at-Law. London: Maxwell & Son, 1869.

THIS work was originally published in 1863, and we have simply to announce the appearance of a new edition, in which additional judgments are quoted. A chapter is given on the rating of mines, brickfields, and cemeteries. The subject is better understood now than it was when Mr. Castle first wrote.

Atchley's Price Book for Architects, Builders, &c. 1869. By P. THOMPSON, Builder.

THE new issue of this price-book includes some sensible observations on "Building Materials," by Mr. F. J. Rogers; a short paper on "Concrete," and "Observations on the Law of Strikes and Combinations," by Mr. J. P. Godfrey, solicitor. The correctness of the prices we do not pretend to check; but we may ask on what grounds builders are to be allowed to charge 9d. an hour for a bricklayer (7s. 11d. a day), and 5d. an hour for a bricklayer's labourer, when they are told they must only charge 9d. an hour for a mason and 5d. an hour for his labourer?

VARIORUM.

THE "Journal of the Historical and Archaeological Association" of Ireland (late the Kilkeny Archaeological Society), for the July quarter of last year, has been issued (McGlashan & Gill, Dublin). It is a remarkably interesting number, and contains various papers and proceedings of special interest on the antiquities of Ireland, including those of the islands of Aran, the Suckinan Ogham inscriptions in the county of Waterford; the Cyclopean churches at Loughs Corrh, Mask, and Carra, and at Gill-Sleibh-Caillian; incised rock markings at Ballybann, county Cork, &c. The rock symbols referred to are identical with some of those on the rocks of England and Scotland, and include concentric circles, with a break in each circle, just as in some of the Northumbrian, but without the central cup, which, however, is repeatedly inscribed by itself, as is also the case on the English rocks. It is a remarkable and interesting fact, mentioned in "Fiji and the Fijians" (2nd ed., vol. i, p. 220), that on a sacred monolithic pillar, emblematic of a Fiji God, or his resting-place, where offerings are made, there are incised three separate series of ring and cup markings, consisting, in each case, of two concentric circles with the central point or cup. This fact may bear on the suggestions made by Mr. J. E. Dove, in his letters on "Rock Symbols" in the *Builder*, that these symbols referred to the relationship between the divine and the human, or the radiative and concentrative principles of life, to which he suggested a key in his letters on Geometrical and other Symbols, also in the *Builder*. The occurrence of the selfsame system of ancient symbols in parts of the world almost wide as the poles asunder, is very remarkable, but not unprecedented.—"Transactions of the Institution of Engineers in Scotland: twelfth session, 1868-9." This part of these Transactions is occupied with a lengthened discussion on the important subject of water distribution and the regulation of the supply, with especial relation to Glasgow.—"Report on Projects before Parliament affecting the City of London." By William Haywood, Engineer and Surveyor to the City Sewers Commission. Printed by Lowndes, Fenchurch-street. This report relates to the Eastern Metropolitan Underground, the Islington, the London, Chatham, and Dover, the Hyde Park and City, or Oxford-street Underground, Railways; and to the Courts of Justice Concen-

tion and the City of London Subways. Mr. Haywood recommends that the Commission dissent from the whole of the projects, so as to obtain its *locus standi* before the committees of the Houses of Parliament, to which the Bills probably will be referred.—Bates, Hendy, & Co.'s "Mercantile Handbook for India, China, and the Colonies." 1869. Old Jewry, London. This Handbook contains a good deal of matter useful in India, China, and the colonies to all who wish to transact business with this country. It comprises a Diary and Directory of British Manufacturers, said to be specially adapted for the use of merchants abroad; but upon what principle the names are selected, as those of the leading manufacturers, we do not know. Writing, as we happen to do, with a Perryan steel pen, we looked up the list of leading steel-pen manufacturers, but we do not find Perry amongst them, although the list contains several of whom we never heard before. So of other manufacturers. However, the book is a very useful one in its way.—Mr. H. H. Vale has printed in a separate form his paper, "The Antiquities of Iona," read at Liverpool Architectural Society (Watts & Co., printers, Liverpool).—"Sprague's Pocket Diary and Architects' and Surveyors' Memorandum Book for 1869" is a neat ordinary little pocket-book, with tables and memoranda, compiled for the use of architects and surveyors. It is not intended to compete with the diaries with which every one is familiar, the special feature rendering it of use to the profession exclusively.

Miscellaneous.

Manchester Art Society.—A numerous attended *conversations* of the members and friends of the Manchester Art Society was held on the 19th inst. in the large room of the Masonic Hall, Cooper-street. In the unavoidable absence of the Mayor of Manchester (who, however, wrote at some length, expressing his sympathy with the objects of the society), the chair was taken by the Mayor of Salford, who briefly addressed the meeting. Mr. J. A. Deane gave an account of the society since its organization in 1836. Its chief object was to supply a demand felt by a large number of artists in Manchester and the district for a greater scope for independent action in bringing their works before the public than had been hitherto obtainable either in connexion with any of the established institutions for public exhibitions in Manchester, or through the agency of the dealers. It was also thought desirable to assist artists generally to exhibit their productions when they might otherwise be unable to do so by reason of the overcrowding of contributions to the Royal Institution's exhibitions.

Cheap Cottages for the Poor.—Attention has lately been directed to an attempt towards solving the problem of building satisfactory residences for the poor on terms to offer a fair remuneration for capital. The cottages in question are at New Hampton, near Twickenham, and have been built by Mr. Benjamin Nicol, and his mode of proceeding in constructing the framework was suggested by an invention he had made for giving increased power to the ordinary sewing-machine. Slabs are used composed of several layers, forming a thickness of 3 in., "the centre of which consists of a fabric of straw sewn together by a large sewing-machine, compressed at the same time by rollers to 1 in. in thickness, and steeped in a silicate to render it incombustible, while for the external part iron, gravel, Seyssel asphalt, and Portland cement are employed in certain proportions." In the report of the Commissioners on the Employment of Children, Young Persons, and Women in Agriculture, a full description is given. Plans have been submitted showing that by this mode of construction a cottage with living-room and three bedrooms "of ample size, and fulfilling all the requirements of health, decency, and comfort," can be constructed for £85, and which the Commissioners consider "likely to be of great service to all persons connected with agriculture."

Nonconformist Church, Huntingdon.—You will confer a favour if you find room to state what Messrs. Maile, Richardson, & Wrighton, of Huntingdon and Godmanchester, were the contractors for the Nonconformist Church at Huntingdon, which appeared in your pages recently.—C.

Statistical Society.—The usual monthly meeting of this society has been held, Colonel Sykes, M.P., in the chair. Amongst those present were Mr. Lowe, Chancellor of the Exchequer; Mr. Childers, First Lord of the Admiralty; Mr. V. Harcourt, M.P.; Dr. Farre; and others. A letter was read from Mr. W. E. Gladstone, the president of the society, regretting his inability to be present. Mr. K. Dudley Baxter read a paper on the taxation and capital of the United Kingdom. He first considered the resources and territories of the United Kingdom. The lecturer contended that direct taxation by one tax was impracticable, and that a system of taxes was necessary. He examined the various methods of taxation, giving a slight sketch of their history, and proposed the following classification:—1. Taxes on income and capital; 2. Licences on taxes or trades and professions; 3. Taxes on consumption of food and stimulants; 4. Rates on occupation and tolls.

Woolwich and Deptford Dockyards.—Woolwich Dockyard will be finally closed on the 1st of October next, and banded over to another department of the State. The yard at Deptford is to be cleared by April 1, but it is understood must be kept useless. The greater part of this yard is held on a peppercorn rent, under the will of the well-known John Evelyn. In the time of Evelyn, land at Deptford was of but little value; and being anxious to encourage ship-building, he gave land to Government at an annual rent of a peppercorn, on condition that there should always be a ship on the stocks; and during the twenty-six years it was closed up to 1833, the letter, if not the spirit, of Evelyn's will was carried out by the keel of a vessel being laid down and left in No. 1 building-ship. Here, as in educational legacies, we see how injuriously the stipulations of donors often act.

Gift to the Parishioners of Bromborough.—The inhabitants of Bromborough have had formally handed over to them a new building, which has cost upwards of 2,000*l.*, and which has been erected at the sole expense of Mr. Robert Rankin, of Bromborough Hall, and is intended for national schools in connexion with the parish church. The new building will contain accommodation for at least 250 children. It consists of three large rooms—one intended for boys, another for girls, and the third for the infants' school. There is also a class-room, and a playground a full acre in extent. Attached to the schools is also a residence for the master and mistress. The building is of red sandstone. The architect was Mr. John Douglas, of Chester. The land upon which this school is erected was given by Mr. Mainwaring, of Oteley Park.

Bell-founding in Birmingham.—The "opening," a few days ago, of the new peal of eight bells which have been placed in Bishop Ryder's Church, has drawn attention to an interesting business which once flourished, then died out, and has recently been revived in Birmingham. The merit of restoring one of its lost industries to the Midland capital belongs to Mr. W. H. M. Blews, New Bartholomew-street, who has placed in the tower of Bishop Ryder's Church a peal of bells, which has elicited praise from competent judges.

Sheffield Architectural & Archaeological Society.—A meeting of the members of this society was held on the 20th, in the School of Art, when a paper "On Architecture and Archaeology," was read by the president, the Rev. J. Stacey, governor and chaplain of the Shrewsbury Hospital. At the outset, the rev. gentleman thanked the members of the society for the honour they had recently conferred upon him, in electing him as their president. He then spoke of the necessity of architecture and archaeology being studied together, and concluded his paper by alluding to the fact that a great improvement had taken place in their street architecture, several creditable and handsome buildings having recently been erected, which were not unworthy of the wealth and importance of Sheffield.

The Ornamental Windows in the Parish Church and St. James's Church, Doncaster.—The stained glass memorial windows in these churches have been broken by mischievous youths with the catapult. In the Parish church the window erected by Sir Isaac Morley to the memory of his father and family, and the one erected by Messrs. Cooke & Co., bankers, to the late Mr. James Dunhill, have both suffered.

Irish Railways.—The second report of the Irish Railway Commission has been issued. The Commissioners state that they have carefully examined the effect which the reductions in railway fares in Belgium have had on the traffic in that country, but they do not consider the circumstances of that country and of Ireland to be analogous. They propose that the fares on the Irish Railways should be reduced to 1-25*d.* per mile first class, 75*d.* per mile second class, and 50*d.* third class; and they also recommend a considerable reduction in the charges for goods. These reductions, they are of opinion, would create such a large increase of traffic as would confer a great boon on the public, and largely develop the general industry of the country. The Commissioners also express an opinion that a saving of 32,000*l.* a year would be effected by the concentration of management under one administrative department.

City District Surveyor.—According to the *City Press*, the Metropolitan Board of Works has appointed Mr. G. W. Williams, of Frederick's-place, the District Surveyor of Pimstead and Eltham, to be Interim Surveyor of the southern division of the City, the appointment being vacant through the death of Mr. G. Smith. The income of the office for the last year amounted to 143*l.* 18*s.* 9*d.*, and the Building Act Committee have now under consideration the subject of the proposed re-arrangement of the several districts in the City, the income of the whole of them being below the average of other metropolitan districts.

Machines for Dovetailing.—Machines for mortises and tenons have long been in use among carpenters and joiners; and now a "dovetailer" has been constructed, which does its work so thoroughly that more than 2,000 of the machines have been sold and are in use in the United States. It performs the operation, it is said, with remarkable rapidity, leaving nothing to be effected by hand, and the saw is so contrived with a flange that the entire dovetail hole is cut out as easily as the pin which is to fill it. Its construction and mode of operation are described and illustrated by plates in the last number of "Proceedings" of the Institution of Mechanical Engineers.

Transparent Colourless Lacquer.—Under this name, says *Scientific Opinion*, Messrs. Brodie & Middleton, of Longacre, offer for sale a preparation which promises to find its way very generally into domestic use. Every one knows that the lustre and polish of ordinary brasswork are due to the thin coating of ordinary lacquer with which it is covered, and which, by excluding the air, prevents the process of oxidation. But frequent cleansing removes this lacquer from microscopes, door-plates, Medieval chandeliers, and so forth; and the re-coating with the lacquer is both a troublesome and expensive process. The new preparation obviates these difficulties. It can be laid on by any one with a common camel-hair brush, the object need not be heated, and the action of the air is effectually prevented. This new substance is quite liquid, dries with some rapidity, and is readily removed by turpentine.

Death-rate of Swansea.—According to the report of the medical officer of health of the borough (Mr. Ebenzer Davies), taken over the three months of the past quarter, the annual death-rate was only 15-8 per 1,000 of the population; while the death-rate for the past month of December was as low as 12-6 per 1,000. Seventeen persons died above 70 years of age, of whom five were above 80 years, and one woman died at the age of 101 years. The lately-constructed system of sewerage and the abundant supply of water, both carried out by the local board of health, may have contributed to this satisfactory state of things.

Rediscovery of the Dungeons of Guildford Castle.—After a great deal of excavation an entrance to the subterranean vaults and dungeons of Guildford Castle has been made. The largest room is open, and measures 60 ft. by 57 ft.; height, 9 ft. to 15 ft. Six others have yet to be found. In these dungeons, upon one occasion no fewer than 600 persons were tortured, and killed in a day or two.

Education of Workmen in Belgium.—The Municipal Council of Brussels, aided by a vote of the Belgian Chamber, has reorganized its industrial museum, and opened a school for the artistic education of workmen.

The Sanitary Condition of Chesterfield. The number of deaths in and around Chesterfield, which have resulted from scarlatina is creating much alarm amongst the inhabitants. It is not an uncommon circumstance to hear of five or six children being affected in one house, or of two or three in one family dying of the malady in a few hours. It is hoped these circumstances will stir up the authorities. The corporation have horrified 3,000l. for the purpose of completing the deep drainage, and also for erecting slaughter-houses outside the town.

Funny.—Amongst other American "factions" deadly and industrial (says the *Levant Herald*), which have been recently offered to the Porte by General Mott, the enterprising brother-in-law of Blaque Boy, and ex-officer of volunteers, who is still here, is a steam brick-making machine, which, it is said, not merely dispenses with "straw," but throws out clinkers ready burned, builds, furnishes, and all hut peoples, houses of any size or style of architecture the Minister of Public Works may desire.

The French Atlantic Cable.—The first instalment of this cable—125 miles in length—which will be stowed in the fore tank of the *Great Eastern*, arrived at Sheerness, in the hulk *Iris*, a day or two since, and the process of shipping it commenced.

Proposed Tramway on Thames Embankment.—The stoppage of the works necessary to the completion of the roadway arising from the delay of the District Railway Company, has given rise to a proposal to proceed at once with the roadway, laying a tramway along it for the public convenience.

Bath Stone.—Messrs. Randall & Sanders write—Referring to Mr. Cross's letter on "The Decay of Stone," which appeared in your last number, we beg to say that all the Bath stone used in the Grosvenor Hotel was supplied from our Corsham Down quarries. Will you do us the favour to notice this in your next publication?

TENDERS.

For additions to Messrs. Gainsford & Co's premises, High-street, Southwark. Messrs. Henry Jarvis & Son, architects:—

Richardson	23,750 0 0
Thompson	3,615 0 0
Tarrant	3,496 0 0
Macey	3,430 0 0
Hemshaw	3,299 0 0
Kidder & Son	3,250 0 0
Downs	3,193 0 0
Fitchard	3,183 0 0
Turner & Sons	3,067 0 0

For rebuilding No. 43, Strand. Mr. J. Nicholls, architect. Quantities supplied by Mr. Manning:—

Benders	1,640 0 0
Laurence & Baugh	1,617 0 0
Macey	1,540 0 0
Abrahams	1,429 0 0
Richards	1,399 0 0

For sewers, roads, and kerbing, Walford Estate, Stoke Newington. Messrs. Hannam & Lamb, surveyors:—

Nicholson	23,030 0 0
Wood	2,935 0 0
Found	2,797 0 0

For finishing house at Stamford-hill. Mr. Chester Cheston, jun., architect:—

Webb & Sons	21,693 0 0
Lewis	1,900 0 0
Rivett	1,833 0 0
Ennor (accepted)	1,421 0 0

For the erection of one detached and two semi-detached houses at Clapton, for Mr. Charles Jacob. Mr. Chester Cheston, jun., architect. Quantities by Mr. William Oakley:—

Detached House	Pair of semi-detached Houses	
Wood	23,259 0 0	23,243 0 0
Rivett	2,354 0 0	2,153 0 0
Asby	2,133 0 0	2,273 0 0
Lewis	2,061 0 0	2,136 0 0
Myers & Sons	2,304 0 0	1,829 0 0
Ennor	1,675 0 0	1,982 0 0
Webb & Sons (accepted)	1,859 0 0	1,859 0 0

For the erection of Clapton Parsonage for the Rev. G. P. Irby. Mr. Chester Cheston, jun., architect. Quantities by Mr. William Oakley:—

Ennor	23,420 0 0
Rivett	3,333 0 0

RECENT EXAMPLES OF DOMESTIC ARCHITECTURE.

Specialists, etc. half bound in Morocco, 20. 7s.
VILLA and COTTAGE ARCHITECTURE.
SELECT EXAMPLES OF COUNTRY and SUBURBAN RESIDENCES, recently erected.

With a full Descriptive Notice of each Building.
Thirty Villas and Cottages, of the Works of Nineteen different Architects, are illustrated by Plans, Elevations, and Sections, together with occasional Perspective Views and Details. The buildings are fully described, and in nearly every case a statement of the actual cost is given.

This is a volume that those about to build villas or cottages may usefully study. The combined work of sixteen architects can scarcely fail to furnish information that will be a gain to the architect, and a valuable and useful handbook for any one who wishes to see what is to be done in its many valuable suggestions. - Builder.

ANCASTER STONE QUARRIES COMPANY, GRANTHAM, LINCOLNSHIRE.—The Proprietors have been enabled to improve their method of working since the principal Quarries have been under one management, and offer blocks of much better average.—Address Mr. J. ELLIOTT, Ancaster, Grantham.

LIZARD SERPENTINE. The variety of rich colours obtainable in this beautiful Marble makes it specially adapted for Architectural Works, such as COLUMNS, SHOP FRONTS, CHIMNEY-PICES and FENDERS, PEDESTALS, &c. and for Exterior Decoration it is invaluable, as it never loses its polish from exposure to the atmosphere. Estimates and Designs forwarded on application to the LIZARD SERPENTINE COMPANY (LIMITED), 9, GARRICK STREET, COVENT GARDEN. An extensive Stock of Chimney-pieces on view.

The Builder.

VOL. XXVII.—No. 1357.

"Père La Chaise."

N the year 1347 a wealthy grocer of Paris, it is recorded, as most readers know, one Regnault, built for himself a magnificent private residence, which he named La Folie Regnault. When this grocer died, his heirs sold the place to a devout lady who presented it to a convent of Jesuits. Louis XIV., in 1705 appointed as superior of the convent Père La Chaise, his confessor, to whom the monarch was much attached. The Père was a subtle and powerful man, and Mont Louis, as the convent was now called, became the favourite haunt of courtiers,—the focus of ambition, luxury, and intrigue,—the centre of Jesuitical power in France. On the suppression of the order, about sixty years afterwards, the mansion and grounds were sold to pay debts, and in 1800 they were purchased for 160,000 francs by the municipality of Paris to afford a site upon which to form their first cemetery. Such was the origin of the renowned Père La Chaise, which, as every visitor to Paris knows, occupies the slope of a hill on the north-east of the capital, beyond the Boulevard de la Bastille. Originally the grounds extended to forty acres, and the work of laying them out was entrusted to M. Brogniart, who now sleeps at the foot of one of the cypress trees which he planted. The cemetery was consecrated in 1804, and, on the 21st of May the same year, the first grave was opened. But, not long after, Père La Chaise was turned into a fortress. This was in 1814, while the armies of the allies were approaching Paris. Formidable barriers were erected in the cemetery, which, from its elevated position, commands the plain extending to Vincennes. The walls were pierced with loopholes, and the pupils of the Veterinary School of Alfort occupied it on the 30th of March, and successfully resisted two attacks of the Russian troops detached by General Barclay de Tolly. On the third day, however, the Russians succeeded, and made themselves masters of the cemetery. Paris capitulated the same evening, and here the Russians bivouacked. The worst use which they seem to have made of the place was to cut down a great many of the trees for fuel. Next year, on the second visit of the allies, the interments were again temporarily suspended. The work was once more resumed. To render access easy to different points, winding paths were formed, a wide paved road was opened to the ancient mansion of Père La Chaise, and the grounds were planted with shrubs, cypresses, and weeping willows. The mansion itself was demolished in 1822, and it was intended to erect on its site a colossal pyramid, the base of which was to serve as a chapel for the performance of the burial service. But this part of the

design was abandoned. The neat chapel, which stands in the middle of the cemetery, was erected instead. The present extent of the cemetery is 212 acres, and nearly 5,000,000. have been expended on it. Since the first grave was made, it is estimated that the remains of more than 200,000 persons have been interred here. The number of tombs amounts to about 16,000, of these upwards of 3,000 have monuments. There are three descriptions of graves. Those for the poor (*fosses communes*) are situated in the northern part of the ground. They are 4½ ft. deep. The dead are gratuitously hurried in coffins placed close to each other, without any intervening space, but not upon each other. These trenches are reopened every five years, that term being sufficient for the decomposition of the bodies in this soil, which is very clayey. Then there are the temporary graves. These are held for ten years upon the payment of a certain sum, but are revertible at the end of that period, notwithstanding that monuments may have been erected over them. The remainder of the graves are perpetual; that is to say, they are acquired by the purchase of the ground, and families have the right to sink vaults and to raise monuments at pleasure. At the extreme end of Père La Chaise stands a Moorish mosque, designed by Vely Pasha, Turkish ambassador, for the use of Mussulmans. The Queen and a prince of Oude are interred here. On the right, near the entrance of the cemetery, is situated the Jews' burying-ground. There lies Rachel, the celebrated *tragedienne*. The rest of the extensive tract of ground is devoted to the interment of persons without distinction of rank or religion. The monuments in this great necropolis are of every architectural character and design. Here we see elegant temples and chapels, solemn vaults, and massive pyramids; there tall obelisks, graceful columns, and altars, and urns of diversified forms. No other public cemetery contains the dust of so many celebrated men and distinguished women as Père La Chaise. Bunhill Fields, the "Campo Santo" of Dissenters, is interesting, since in it rest glorious John Bunyan, and Daniel De Foe, John Owen, George Fox, and Isaac Watts. The Edinburgh cemeteries are famous. In the Dean lie Francis Jeffrey, with David Scott, the greatest Scottish painter of his time, and "Christopher North." Dr. Chalmers and Hugh Miller sleep in that pleasant garden the Grange, and Greyfriars Kirkyard is the resting-place of George Buchanan and Allan Ramsay, and all that brave army of martyrs—the old Scottish Covenanters. In Montmartre, Paris, are the graves of Henri Heine, the German poet; of Pigalle, the sculptor; and of General Cavaignac. The remains of the patriot Manin were recently removed hence and conveyed home by his loving countrymen. In the Cimetièrre du Nord lie Paul Delaroche, and his wife, the daughter of Horace Vernet; but Père la Chaise can show a longer glory roll than any of these; it possesses an interest greater even than Kensal Green,—last home though it be of Thackeray, Thomas Hood, Leigh Hunt, Sydney Smith, Allan Cunningham, Mackworth Praed, Douglas Jerrold, John Leech, and other bright spirits who have gone, leaving the world better than they found it.

Let us glance at a few of the great ones whose names are recorded and whose praises are sung in the favourite and most famous of French burial-places. In point of general interest the names of Abelard and Heloise must head the list. The story of the unfortunate lovers, as told by Pope, is a fascinating piece of biography, and it is hardly any wonder that their tomb should be the first to attract the visitor to Père La Chaise. A brief description of their remarkable memorial may be not uninteresting. It consists of a rectangular chapel, in the thirteenth century Gothic style, formed by M. Lenoir out of

the ruins of the celebrated abbey of the Paraclete, founded by Abelard, and of which Heloise was the first abbess. It is 1½ ft. in length, 11 ft. in breadth, and 24 ft. high. An open-work crocketed pinnacle, 13 ft. high, rose out of the cruciform roof, and four smaller pinnacles terminated the gables, but owing to their ruinous state these were some time ago removed. Fourteen columns, each 6 ft. in height, with foliated capitals, support trifoliate arches with open spandrels unmounted by cornices wrought in flowers. The four pediments are pierced with trifoliate windows, and decorated with bas-reliefs, roses, and medallions of Abelard and Heloise. The principal one presents two busts, and a bas-relief in three compartments. In the centre is Mount Calvary; on the left Abelard, in his monastic habit; and on the right an angel holds in his arms the soul of the lover. The opposite one is adorned with two roses, and a bas-relief representing Abelard's funeral. The two lateral pediments are ornamented with roses of beautiful workmanship. Inside the chapel is the tomb built for Abelard by Pierre le Vénéralle, at the Priory of St. Marcel. He is represented in a recumbent posture, the head slightly inclined and the hands joined. By his side is the statue of Heloise. The bas-reliefs round this sarcophagus represent the fathers of the church. An inscription on one side of the tomb runs as follows:—

"Hic
Sub eodem marmore jacent
Hujus monasterii
Conditor Petrus Abelardus,
Et Abbatissa Heloïssa,
Olim studiis, ingenio, amore, infansatis nuptiis
Et penitentia,
Nunc aeternâ, quod speramus, felicitate
conjuncti.
Petrus Abelardus obiit x. primâ Aprilis, M.C.XLIII.
Heloïssa xvij. Maii, M.C.XLIII.
Cursu Carolus de Roney Paracleti Abbatissa
M.D.CC.LXXIX."

A second inscription refers to the retraction of errors regarding the doctrine of the Trinity, attributed to Abelard. At the angles of the monument are four short inscriptions, stating its origin, its removal, and erection in the Musée des Monuments Français, whence it was transported to Père La Chaise. The complete restoration of this interesting relic is now being effected. A plain tomb of large dimensions, surrounded by palisades, bears the name of him who has been called the French Virgil,—Jacques Delille. Near to it is an altar to the memory of the eminent composer, Grétry. Not far off lies Marie-Antoinette-Josephine Raucourt, who died on the 15th day of January, 1815. The opposition of the priests to the interment of this celebrated actress in consecrated ground was carried to such a pitch that it had well-nigh created a popular tumult. In a plain tomb sleeps Madame Cottin, the author of the ever-popular narrative, "Elizabeth, or the Exiles of Siberia." A lofty pyramid, on one side of which is a bas-relief bearing his portrait and name, and the date of his death, commemorates Marshal Massena; and close by are deposited the remains of his friend and companion in arms, Marshal Lefebvre, under a sarcophagus of white marble, with his bust. A large number of French soldiers of distinction rest here. We find the names of Marshals Kellerman, Grouchy, Berthier, and Suchet; Generals Gohert, St. Cyr, and Foy, the idol of the French people. Foy's monument consists of a splendid sepulchre surmounted by a temple containing a marble statue of the general in Roman costume. It is the work of David, and was erected by national subscription. Here also is the grave of the unfortunate Marshal Ney, who, upon Bonaparte's return from Elba, swerved from his allegiance to the king, was condemned to death on the 6th of December, 1815, and shot at nine o'clock on the following morning. This monument was removed soon after its erection, in consequence of the numerous pencil inscriptions written upon it, which were renewed as soon as effaced. The

spot is now laid out as a small garden, enclosed by an iron railing. Among the most imposing memorials is a statue erected by public subscription to Casimir Périer, the Prime Minister, who died of cholera, 1832. A still more costly mausoleum has been raised to Countess Demidoff. Ten Doric columns of white marble support an entablature, under which is a sarcophagus, accessible by a double-branched flight of stairs, the whole resting on a vast basement of sculptured masonry. The tomb of Count Lavalette is ornamented with a bas-relief, representing his escape from prison. There is a neat cenotaph to David the painter, and a massive tomb of bronze is the "In Memoriam" of Balzac. Near to the distinguished novelist rest Delavigne the poet, and Judith Pére, the original of Beranger's Lisette. The grave of the great song-writer himself, he who has been called the Burns of France, is some little distance to the right. His dust mingles with that of Manuel, the patriotic statesman of 1832. One monument serves to commemorate both. Molière and La Fontaine also lie side by side within one enclosure. Their remains were transferred to Père La Chaise in 1804. Racine, another genius, and the friend of these friends, sleeps not far off. Pradier and Dantan, the sculptors, are here, with David d'Angers, whose chisel supplied so many of the finest memorials in the cemetery, is himself commemorated by a tomb of the simplest kind. A little way beyond the gate, and to the left of it, we come upon the name of Alfred de Musset. In obedience to his wish, a weeping willow droops over the head of this lamented poet. Next to him lies Visconti, the architect of the new Louvre. A reclining statue, in white marble, finely executed, forms his tomb. Interesting also is the grave of the Marquis de Clermont-Calleraude who, on the memorable 10th of August, 1792, placed himself between Louis XVI. and the mob to defend his sovereign. But a record of all the famous personages gathered to their fathers in Père La Chaise, would fill many pages. Besides those we have mentioned, the visitor will find scores of others, some of them the greatest ornaments of their age. Among mathematicians and philosophers, be will find Arago, Curvier, Poinso, Delambre, Geoffroy St. Hilaire, and Larmougueire; Laplace the astronomer; Lavoisier, Fourcroy, and Gay-Lussac, chemists; and Dupuytren and Baron Larrey, surgeons (the latter esteemed by Napoleon as the honestest man he ever knew); Bnat, and the Duke Decrès, naval commanders; Bellini, Rubini, and Weber, the composers; Beaumarchais and Scribe, dramatic writers, with Martain, the Spanish dramatist; Duchesnois, the tragic actress and Talma; Lebrun the poet, Dacier the critic, Madame de Genlis, Angodo the financier, Lafitte the banker, and Fourier the Socialist, in the company of Volney of "Ruins of Empires" notoriety. Garnier-Pages is here, with Benjamin Constant, the benevolent, Abbé Sicard, Lalande, Souvestre, Janet, Davonal, Targot, Winsor (who introduced gaslighting into London and Paris), and the Duke de Morny, the faithful friend and servant of the present ruler of France. Of the more recently erected tombs Morny's is by far the most conspicuous and elegant. In Père La Chaise repose the ashes of a few English notables. Here are the names of Sir Sydney Smith, the admiral; General Macdonald; Mr. Ricardo, the writer on finance; the Earl of Stair; Lord Cochrane; Patrick Keene, who was assassinated on the Boulevard des Italiens in 1815; Philip Astley, of the Amphitheatre; also those of Mrs. Fitzherbert, and Mrs. Jordan. Strange, by the way, that the favourites of two English kings, brothers and immediate successors, should find a grave in the same spot, and in a foreign country!

In some respects Père La Chaise is unlike every other public cemetery. It bears but a slight resemblance to the humble and retired Scottish kirkyard, with its narrow footpaths leading to the "place of worship" in the centre, and the plain, modest headstones, with their matter-of-fact inscriptions scattered over its green sward. Of much greater extent, Père La Chaise is not so tastefully laid out or so carefully kept as the Highgate or Kensal Green, as the Dean Cemetery of Edinburgh, or the Clagow Necropolis. These are beautiful gardens, where you scarce can see the graves for flowers. In the Parisian cemetery you see very few

"Marigolds on death-beds blowing."

Looking at the reputation of the French in matters of taste and design, the place does not fulfil the expectations formed of it. There is

little uniformity or regularity in the plan of the cemetery. Thickly-planted trees overhang the principal pathways, making them very gloomy and nearly always damp. In autumn, the walks are literally covered with dead leaves, which it takes much time and labour to clear away. Then the poor quarter of the cemetery detracts greatly from its picturesque appearance. The graves here cover a large space; they are placed close together, each grave being partitioned off by a tiny railing of wood, painted black. Hundreds of small black wooden crosses, with wreaths of flowers and *immortelles*, themselves fast crumbling into dust, are deposited on these graves, and the whole of this valley of dry bones is overrun and choked with ferns and long grass. Altogether this place is dismal and the sight sad. The custom the French have, in common with all Roman Catholic populations, of decorating the graves of departed friends with stucco statues of the Virgin, painted portraits of saints, wax candles, crosses, rosaries, and glass cases of artificial flowers, and other mementoes of affection, is here indulged in to excess. The custom, it need hardly be said, little accords with English notions. But what spoils the beauty, as it disturbs the solitude of Père La Chaise, more than anything else, is the manufacture of monuments continually being carried on within its gates. At the time of our last visit bricklayers were everywhere busy building vaults, and stone-cutters hewing cenotaphs. One-half of the cemetery presented the appearance of an extensive stuary establishment in full operation. These workmen were erecting the perpetual class of tombs already alluded to, and the work will go on from year to year until the ground is completely occupied with graves. Owing to this great extent, the number of interments that takes place in Père La Chaise is very large—from two to three thousand a year, we believe. But of course the number varies. You may see at the same moment half a dozen funeral processions winding their dolorous way up the wooded slopes of this "golgatha." And these mournful errands continue to be made all day long. All day long, too, you meet a tide of mourners and visitors entering and leaving this city of the dead. Yes, Père La Chaise is a city—a vast, ever-increasing city—the metropolis of departed Parisians, whose present population numbers upwards of 200,000, men, women, and children, who have quitted the busy world outside, and, in the significant language of the old Roman, have "gone over to the majority."

LIVERPOOL LABOURERS' DWELLINGS.

More than a year ago the Corporation of Liverpool offered a premium for the best plans for a block of dwellings which they proposed to erect on a site, purchased by them for the purpose, adjoining Vauxhall-road, one of the main thoroughfares to the north end of the town, parallel to the line of docks, and which traverses, perhaps, the most thickly populated of the poorer districts of Liverpool. The premium was to be awarded to the plan which should afford "at the lowest cost (having regard both to expense of building and quantity of land occupied) the greatest number of healthy and convenient dwellings, substantially built, and suitable to the wants of the labouring classes." As usual in such cases, a number of designs were sent in having no reference to the conditions to be attained; designs accompanied by alarming perspective views giving to the proposed block of humble dwellings the aspect of a lordly mansion, or a group of substantial dwelling-houses for the comfortable middle-classes; and further recommended by imaginary balance-sheets, fearfully and wonderfully made out, giving promise of returns of 7, 8, and even up to 10 per cent.; computed at available rentals being matters easily manipulated—on paper. The council, shunting their eyes to these golden prospects, gave the first premium to a modest and carefully-planned set of drawings by Mr. J. E. Reeve, which appeared best to fulfil the joint conditions of salubrity and moderate cost; but having reserved the power of employing any other competitor, they ultimately entrusted the work to Messrs. Redman & Hesket, whose plans, on further investigation, appeared likely to yield larger accommodation and consequent return for the sum to be expended. These buildings, which are now nearly ready for occupation, are arranged in three rows longitudinally on the site which is an oblong parallelogram of about

two to one; the whole being again divided transversely by an asphalted road, 30 ft. wide, which runs across the centre of the site and opens into the two streets, Sylvester-street and Ashfield-street, which bound the site on the south and north sides respectively. The two longitudinal roads, between the centre and side blocks of dwellings, are 25 ft. wide, and the entire aggregation of dwellings is thus partitioned into six blocks, four outer ones of five stories, and two inner ones of three stories in height. The only objection to the general plan is that, as the ends of the site are bounded by existing buildings, each of the longitudinal courts of course forms a *cul-de-sac*, closed by a high wall at one end, which must materially interfere with light and thorough ventilation, besides possibly lowering the rental value of the houses near the upper ends. Among the plans originally exhibited in competition, several other ways of arranging the buildings were shown; and there can be little doubt that the plan which found favour with several competitors, of placing the blocks of dwellings transversely across the site from Sylvester-street to Ashfield-street, so as to have a succession of clear openings from side to side, would have been preferable in a sanitary point of view. The present arrangement was selected as affording space for a greater number of dwellings than any other; and as the number of applications for tenancy is said to have been already more than double the number of houses (which are 146 in all), we must refrain from quarrelling with a plan which provides what there is evidently such a very great demand for, especially remembering that this is to be looked upon only as an experiment before entering upon future undertakings of the same nature. In detail, there is much to commend in the planning, which is very compact, and loses as little as possible of available space. The houses are in three classes; with three, two, and one bedroom respectively, in addition to kitchen and scullery. Access is given to the different stories, at the requisite intervals, by staircases of Yorkshire stone, with landings of the same carried on iron beams; the landings at one side of the building being open to the air, and the alternate landings at the other side affording space for two water-closets on each, with Guest & Chrimes's apparatus. From the outer landings a door opens on each side, giving access to a set of rooms complete in itself, so that each tenant has its own outer door opening on to the staircase, and each has its own water-closet, a few steps up on the next landing. Between the two water-closets an ash-shaft descends, with an iron door on each floor, for discharging the ashes into the ashpit in the basement. Each room is fitted with gas, and a meter is placed in the basement for each staircase. We should have liked to see the water-closet a little less prominently and publicly placed; the seat is opposite the door, which opens directly opposite the street entrance on the lower floors. Of course it may be said that the class for whom such houses are built have not the same fastidiousness about such matters as is found among what are called the "upper classes;" but as one of the ends of improved dwellings is to raise their occupants, the more the latter are encouraged towards that refinement of habits which forms so large an element in civilization, the better for them. Another slight defect in the plan is the darkness at the bottom of the stairs leading to the basement dwellings, which might have been lessened by a glass riser in one or two of the steps above. The work in general has been very well executed by the contractor, Mr. Hugh Yates, of Liverpool.

The rental of the houses will be from 6s. to 3s. per week, the latter amount being only for the smaller houses in the interior blocks. These are about the current rents of house property of the same class in the neighbourhood, and upon this scale it is expected that nearly 54 per cent. will be realized. This will not be considered a very paying speculation, yet even this has not been attained save by rejecting what would probably have been a better sanitary plan, and by putting more houses on the site than it will well bear, considering the proportion of open ground to ground built on. The interior streets or courts will be little less close and crowded than some of those in the neighbourhood; and as no special provision could be made for a washhouse or drying ground, these courts will, at weekly periods, doubtless be crowded with clothes hung out to dry, than which there is surely not a more comfortable sight to be seen between two rows of dwellings. Is not "washing-da"

proverbial among the lower classes as a day of discomfort? And if anything like pleasantness and attractiveness is to be given to the aspect of our town homes of this class, we opine that a separate place set apart for washing and drying will be a *sine qua non* towards that end. In some houses of this kind built a good many years ago towards the south of Liverpool, drying-rooms were provided in the roof, as an attic, but it was found that the tenants would not take the trouble of carrying a large bundle of clothes so far upstairs. These same houses did not pay 5 per cent., if we remember rightly, nor anything like it; and possibly the addition of such a room, even in a more accessible position and with a slight charge for the use of it, would suffice to reduce the return below that moderate per-centage. But the result of this Labourers' Dwellings Competition in Liverpool goes far to convince us that those who undertake to provide for the labouring population in our towns, dwellings where life may be in some degree an enjoyment, and not a mere fact of existence, must be content for the present to mix a little philanthropy with their per-centage calculations. Political economy is a great science, but it does not abrogate the claims of humanity. When we consider the great amount of so-called wealth which is at present turned over amongst the richest classes, in a perfectly unproductive manner, on the one hand; and when we contemplate, on the other hand, the masses of population who, in such districts as that between Scotland-road and Vauxhall-road in Liverpool, are living crowded together in ill-ventilated and ill-drained houses looking out upon dirty alleys which are the receptacles of perennial filth and refuse—districts in which even such a large block of new building as it has been alluding to seems like a drop in a bucket—it becomes evident that to make any tangible improvement in this state of things we must not wait too warily for large per-centages. Money laid out, even with but a small per-centage return, upon such an object as this, will in the end repay the community, inasmuch as it will give a chance to the lower classes to live like men and not like animals, and to be more helpful to the general good. It is to be hoped that the Corporation of Liverpool, having made on the whole a fair first experiment, will not stop in so desirable a work.

fish's success by not making his "Foul Wards" a detached building, as requested, capable of supervision by one nurse. The ward which is divided into three seems to want Nurses' rooms. The mode of getting over the difference in levels needs explanation. As a means of escape from fire, the author gives his corridors terrace-tops. The design of "Experientia," which seems very complete and well considered, has an advantage over the latter in setting the administrative block forward, before the wards; and over "What is worth doing," &c., in the position of the foul wards building, which could by the plan of *Experientia* be served by the same administration. This could scarcely be the case in "What is worth doing." In this latter, too, the wards come very close to the railway, and the administration block to the proposed new street. The value of a double corridor to the administration, which renders supervision difficult, seems questionable; and we are not certain, looking from the same point of view, if a staircase at the end of the wards is desirable. However, all we wish to show by these observations, in the interest of the competitors generally, is the necessity for the most careful examination and comparison of relative advantages and demerits.

A NEW EXPERIMENT FOR THE POOR.

DURING the course of last year, while writing on the nature of the risks to which human life is subjected, we promised to discuss on a future occasion the principles of a new society which had then but recently started in Edinburgh for the purpose of improving the condition of the poorer classes. We have not been able to overtake the subject sooner; and indeed it is always well to postpone treating of any institution in the northern capital as a thing accomplished. For even in the present case an unquestionably benevolent and disinterested movement seems likely to turn out a failure, owing, as it would seem, to the strong and determined opposition of the local authorities. They may or may not be right. Our readers, however, may judge for themselves. There are circumstances connected with this experiment, as we must still term it, which are, at all events, worthy of the consideration of those who are interested in the progress of society.

In that valuable part of the "De Argumentis," where Bacon touches upon moral science, he lays particular stress upon that principle which he calls the *bonum communis*, or social good, considered as a source of happiness to the state or to the individual who pursues it; and he shows by a reference to various systems of antiquity that in this neglect lay their radical deficiency. For those systems placed happiness in the *bonum suitatis* alone, or in that principle of which self is the only direct and ultimate object. We need not illustrate Bacon's philosophy by a reference to the celebrated Poor Laws of Elizabeth. But it is clear that Bacon considered that the "social good" could only be ameliorated, and, if possible, improved, under the direct and positive control of the state. In our day greater scope has been allowed to individual benevolence; and to such an extent has this idea prevailed, that some people begin to hold the opinion that all existing charities may be as well and impartially administered by private individuals or associations as by local authorities or even by the State itself.

The "Edinburgh Association for Improving the Condition of the Poor" belongs to this category of private benevolent associations. In fact, it is one of those modern experiments in "sociology," of which the success will exclusively depend upon the manner in which it is carried out. As we have already characterized it, it appears to be an attempt to eradicate poverty and extinguish crime on the principle of voluntary association. But, although the Scotch are unquestionably the best volunteers under the sun, the idea does not seem to have germinated in the northern capital. Either Paris or New York is entitled to the honour of being regarded as the birth-place of the present highly popular theory of amalgamating existing charities, or at least of opposing a united and articulated organization to the inroads of poverty, disease, and crime. Since, however, Edinburgh has been all along abreast of the movement, and more particularly has supplied us with the most voluminous reports on every phase of the subject, we cannot do better than give some account of its progress as developed and at present exhibited in that ancient city.

It is first of all necessary to explain that for some years past much attention has been directed to the deplorable condition of the industrious poor of Edinburgh. The late Dr. Chalmers made strenuous efforts to arouse the attention of his backsliding congregation to the utterly abandoned state of the Cowgate and West-port; Dr. Guthrie's eloquent denunciations of the sins and sorrows of the city fell upon the astonished ears of his fashionable congregation like a thunder-bolt; and Dr. Begg's able and more practical efforts at amelioration are well known to our readers. At the same time the ecclesiastical reformers were ably seconded in their efforts by the more scientific and better regulated researches of the medical men. The late Professor Alison's discoveries on the origin and causes of contagious diseases were chiefly made in the dismal cellars of the Cowgate and Cannongate; and these discoveries were tolerably well applied some years later, by one of his quondam pupils, Dr. W. T. Gairdner. Dr. Foulis, a philanthropic physician, actually purchased an old close, and after repairing it, renovating it, and supplying it with water and other necessities, succeeded in demonstrating that the existing evils, had as they were, could be diminished, if not entirely prevented. This school of medical reformers at length brought to light Dr. Littlejohn's admirable report on the sanitary condition of Edinburgh, from which report we believe have sprung the subsequent city improvements inaugurated so ably under the auspices of the Lord Provost (Mr. Wm. Chambers). Of course, it is unnecessary to state that all this time the press was not idle. The *Scotsman*, the *Edinburgh News*, the *Scottish Press*, the *Evening Courant*, and even the poor old and now defunct *Calonian Mercury*, made important special inquiries, and published long articles on the condition of the poor. Many private citizens, such as Mr. Charles Cowan and Mr. Thomas Knox, published pamphlets, and otherwise threw themselves with great earnestness and zeal into the practical questions of reform.

At length about three or four years ago the *Scotsman* undertook to expound at great length and, as we remember, with much ability the subject of the constitution and operation of the "Charities of Edinburgh," which had long been in an unsatisfactory condition. Irrespective altogether of the Poor Law Boards, it was found there were no less than thirty-six different charitable associations in Edinburgh, all engaged in the same common cause, and mostly supported by the same class of benevolent individuals. The sensible conclusion to which the writer came was this: that those various charities, from their isolated character, lost much of their usefulness; that their cost of management and administration was wasteful and extravagant; that, after all, they failed to meet their intended purpose; and that some method of combining them and organising them was urgently needed.

It happened very opportunely, about the same time, that public attention and curiosity were excited by an American gentleman, who was at that time residing in Edinburgh, and who pointed to certain well-organized charitable measures which had been employed with remarkable success in different Continental and American cities. By means of several private lectures which he gave, and by the publication of a pamphlet on the subject (in which he was ably assisted by a lady who is interested in the scheme), public interest was deepened and extended. Upwards of one hundred influential citizens of Edinburgh, ministers and laymen, together with all the leading newspapers, cordially concurred in lending their names and commending the charitable measures and intentions displayed in the pamphlet.*

To sum up the author's conclusions, the plan is based on three great principles:—

1. Thorough systematic investigation of the actual conditions and wants of all the poor in a city.

2. Suitable relief given in every case of need, in ways which tend least to abase, or to degrade and pauperize the receiver.

3. Relief given as far as possible by methods which enable the poor to help themselves, the great object being to prevent cases of temporary destitution from becoming cases of permanent pauperism.

The author proceeds to support this scheme by

* "How to Relieve the Poor of Edinburgh, and other great Cities, without increasing Pauperism; a Tried, Economical, and Successful Plan." Edinburgh: Edmondson & Douglas, 1867.

THE PROPOSED SICK ASYLUM FOR NEWINGTON.

The architects who have submitted designs for this asylum are Messrs. Berriman & Son, Messrs. Giles & Biven, Messrs. Jarvis & Son, Mr. Knightley, and Mr. Leppard. Mr. Burton was also invited, we believe, but did not send in drawings.

In the previous competitions of this kind, the names of the architects were affixed to their drawings; but in the present case they are not so, the drawings being simply identified by mottoes,—a delusion and a snare! We cannot applaud the change. The estimates of cost, as this list shows, differ enormously:—

"Junius"	£33,500
"What is worth doing at all is worth doing well"	33,600
"Experientia"	34,500
"L'Esperance"	51,000
"Expectans"	68,000

The competitors have all set forth their designs very creditably, one of them sending no fewer than a dozen drawings, to show alternative designs. The last on the list, "Expectans," has made the mistake of "well" lighting and ventilating his administrative block, which means ill lighting and ventilating; building round an internal area. This, and the general crowding of the buildings, will make his chance small. The plan by "L'Esperance," too, clever as it is in some respects, will not compare satisfactorily with the first three on our list, and from these we have little doubt the selection must be made. In general arrangement of the blocks these resemble each other very much at first sight, but this resemblance is lessened on looking at the appropriation of the several portions, and comparing distances. Stock bricks, with a few red hands, are the materials chiefly adopted, and all have three stories in height. We had made a list of objections to each, with the view of comparing; but we prefer to use them as simply showing how carefully the designs should be examined before the decision be arrived at. "Junius," with a capital plan in many respects,

references to the methods of systematic benevolent distribution in Paris and New York; to Liverpool; to Elberfeld, on the Rhine; to Calcutta, and to Bombay, as conducted under the auspices and supervision of Dr. Duff. The French and American systems, however, are those upon which he chiefly builds, and which, he tells us, "are totally independent of all church or congregational organization." It is easier, he adds, to form a visiting society quite independent of all churches rather than one dependent on their co-operation with each other, and a good deal more to this effect. Our readers will, of course, recognize at once the principle of absolute secularization in this American scheme of benevolence. The churchman to the cure of souls; the layman to the cure of bodies. We will not stay to notice it at present, further than to point out the fact that the visitors, to whatever church they happened to belong, would necessarily require to be sincere and benevolent Christians! In the city of George Combe and his disciples the principle seems to have met with general approbation, more particularly with that of the Lord Provost, who, we are informed, had long meditated some kind of similar organization on the subject.

The preliminary proceedings were conducted with great administrative skill. As a first step the Lord Provost issued numerous invitations to take part in a meeting to consider the "practicability and expediency of adopting measures to simplify, economize, and concentrate the action of the public charities of Edinburgh, as well as to improve the condition of the really deserving poor." The invitations were cordially responded to in every quarter; and a large number of ministers and doctors, as well as men of all parties and denominations, assembled in the council chambers. The Lord Provost presided; and in explaining the object of the meeting, drew attention, in very emphatic terms, to the unsatisfactory organization and results of the present charitable institutions. Without for a moment inferring that those charities were badly or recklessly administered, and while giving their managers all honour and credit for their efforts to succour want and infirmity, he deplored the absence of all systematic action. He also pointed out how it was possible that, by insufficient and unsystematic arrangements, they might be absolutely nourishing the diseases which it was their intention to assuage; and that in consequence of the present desultory system it was to be feared that they encouraged imposture on the one hand, while, on the other, many of the really deserving and modest poor were left in obscure holes and corners to suffer the pangs of misery and neglect. He further illustrated the need of more united action and of well-organized and systematic measures, by explaining what serious evils result, not only to the poor, but to all classes of the community, from the deficiencies of our existing charitable arrangements; and he finally declared that the whole system now pursued was fraught with consequences alike painful and reproachful; and that it could not possibly fail, if its operation were continued, to damage the best interests of the city. The proceedings were brought to a conclusion by the appointment of a large committee, consisting of upwards of seventy clergymen and laymen, representing every shade of theological and political opinions.

This meeting in the Council Chambers was held on the 15th April, 1867, and the first practical result of the meeting was the production, ten months afterwards (28th February, 1868), of a voluminous report on the whole cognate subjects, written by Dr. Alexander Wood.* This gentleman, it appears is one of the medical school of reformers which we have already indicated.

We will not criticise a report which is written gratuitously and for benevolent purposes. To those who have not studied too minutely the various phenomena and the innumerable circumstances of which it professes to treat, this report may be justly considered valuable. Certainly it contains a large store of facts, and a perfect labyrinth of statistics such as they are. Its practical conclusion may be expressed in three lines: "The only one of these schemes which the committee would recommend to take up at present is the thorough and systematic house-to-house visitations of the poor" (Introduction, p. 15) and also to this end, "that a central office must be established in connexion with it."

And accordingly a central office was established

at 25, York-place; active operations immediately commenced; district visitors volunteered; a manager was appointed, at a salary of £201. a year; and the Edinburgh Association for Improving the Condition of the Poor is at this moment in full working order. But, as the national poet Burns has it, the best laid schemes of mice and men often "gang agley." The apothegm would also appear to include the most benevolent schemes. For only last week, on applying to the town council for their reasonable share of the preliminary expenses—guaranteed as they had thought by the Lord Provost and magistrates—the association were bluntly told that they were doing more harm than good; that they were teaching the whole poor of Edinburgh to seek alms; that before they began expending money at such a wholesale rate, they should have paid their printer's bill; and, finally, that the members ought to be aware of the old proverb, that charity begins at home! Well may the association retort on the town council in the memorable lines of Tom Hood:—

"Oh, for the early
Of Christian charity
Under the sun!"

GLEANINGS FROM THE ARCHITECTURAL FIELD OF 1868.*

ONE great advantage which the architectural practitioner of the present day enjoys over his predecessors in the art, is that of having brought constantly under his notice the works of his own time, as they are going on around him throughout the world. One hundred years ago it was absolutely necessary for the architectural student, if he would gain any competent knowledge of the state of his art prevailing even in this country, to travel extensively to the various cities and centres of industry. It is true, nevertheless, that the present easy acquirement of current architectural knowledge has had some evils connected with it, and these of a serious kind. The active and enterprising spirit of the age which has developed the cheap illustrated architectural periodical has brought along with it more weighty demands than ever upon the skill of the architect, and has given him shorter time for his tasks. Time for thought being denied him, and having treasures gathered round him from all quarters, his works have become rather adaptations than original productions; and, drawn hither and thither by the rival attractions of various styles, he has often attempted them all, and thoroughly worked out none. With his accumulated knowledge he has been like the man who was said to have so many books on his head that his brains could not work. This drawback is, however, one which may, and should be, overcome by the man who wishes to become a true architectural thinker. Let him select what style he chooses, in the first instance,—one in which he can labour with delight, *con amore*,—and, bringing all his knowledge of that style, and all his artistic feeling, to bear upon the work, he will gradually, without fail, expand and develop his adopted style in a natural manner, and with a success which will be of the highest value to the cause of art. I think that I am fairly borne out by the facts, when I assert that this has been the case in the career of the greatest architects. Brunelleschi, Palladio, Wren, Chambers, and, indeed, Sir Charles Barry (as his best works were Italian), were men who spent their lives developing one adopted style; and such are Pugin, Scott, and Street. No style monopolizes every beauty any more than any type of scenery in nature; and where we detect a beauty lurking in the features of any other style than our own, we are perfectly free to follow and adopt it so long as the new beauty will not agree with the old. But rival beauties are proverbially dangerous in art as well as in social life, and it is therefore necessary to do our spiriting gently. For instance, you see a beautiful picture in the artist's studio, deep-toned and subdued in colour; everything, indeed, about it being made subservient to the forcible telling of the story, say one of the late C. R. Leslie's, and you admire it exceedingly. A few months after you visit an exhibition, and seeing the name in the catalogue, look out at once for your favourite. "Alas, how different, yet how like the same!" The glory has departed! How? By the presence of a rival beauty beside it in the shape of a richly-coloured glowing landscape by Turner & Linnell. The one picture has killed

the other. Two notes in music may be beautiful when each is sounded alone, but when brought into rivalry how great the discord.

Notwithstanding the above remarks, the advantages of a constant view of the architectural field around aro, I repeat, great. Example is better than precept. As we view the works of others from week to week, we are thereby incited to emulation and strenuous endeavour; and by the manner in which difficulties have been worked out and overcome, we are encouraged to grapple manfully with our constructive necessities in order that we may ensue them in a form of consistent and truthful comeliness. From the abundant harvest of our art during the past year, 1868, as chronicled in the pages of the *Builder*, I have gleaned for my paper this evening a few illustrations of buildings on which to comment, trusting that the subjects thus brought under our view may afford us food for discussion. As distance is said to lend enchantment to the view, we will commence, if you please, at the Antipodes, with—

St. Patrick's Roman Catholic Cathedral, Melbourne.*

This important edifice was begun in the year 1855. The plan comprises nave, transepts, and choir, with aisles to each on both sides. The choir has an apsidal end, and five chapels open out from the aisle which surrounds it. There are two towers with spires, each 220 ft. in height, at the south-west end of the nave, and a lantern tower and spire, 330 ft. high, at the intersection of the nave and transepts. The extreme length of the church interior is 315 ft. The width inside the nave and aisles is 76 ft. The interior length of the transepts is 160 ft., and the height to the ridge of the roof is 92 ft. At the time the *Builder* writes, the nave and aisles, and two western towers, had been commenced; the nave and one aisle had been roofed in, and nearly completed, and the stone vaulting of the second aisle was making rapid progress; one of the towers was up ready to receive the spire, the other being complete to the floor of the upper belfry, and a portion of the helix had been hung in the western tower. The architects are Messrs. Wardell & Co.

The brief account of the building which I have extracted, will show that it is a church of a class which is rarely built in these days, although there are not wanting signs just now of a return to the old enterprise for building cathedrals, displayed so nobly in the Middle Ages. The new Roman Catholic cathedral at Westminster is likely to be of first-rate proportions. Here, in Liverpool, we have had a good deal of talk and correspondence in the papers about a Protestant cathedral, which I trust will not be allowed to rest till it result in the matter being accomplished. But to return to our subject.

The general external effect of the church is pleasing, reminding one much of Lichfield, with its three spires. The disproportion between the western and central towers is, I submit, too great. The same fault is observable, I think, in York Minster, where I always feel that the end towers look dwarfish when compared with the great central tower. In the body of the building the architects have lavished the most work upon the north transept elevation, which has three large doorways, in the Continental manner, with a magnificent rose-window above, the gable being occupied by three windows. In contrast with this front, the west end is kept too plain, and is scarcely, I think, worthy of the rest of the building. In justice, however, to the designers, I think it is evident that the transept doors have been made for some reason or other the main entrances to the building, a reason which would justify the designers to a great extent in devoting so much attention to them. The flying buttresses in their design are scarcely characteristic enough of stone. They resemble too much roof timbers, and one is reminded by them of a series of ornamented props, stuck up against the building. The top of the central tower appears somewhat crowded, in consequence of the canopies over the belfry windows running into the battlement above. The un-crocketed spire above this tower is not in harmony with the richly crocketed pinnacles around it, and the contrast between the two gives a baldness to the spire which otherwise it would not have. In the case of the west towers, the crockets are omitted with much better effect. There is a feature about these towers to which I wish to draw attention. The angles formed by the buttresses at the

* Report on the Condition of the Poorer Classes of Edinburgh, and of their Dwellings, Neighbourhoods, and Families. Edinburgh: Edmonstone & Douglas, 1868.

* Read at meeting of the Liverpool Architectural Society, Jan. 27.

* See *Builder*, vol. xxvii. p. 594.

three corners are filled up with a splay, the wall being built out from the level of the belfry windows. This is a good idea. The towers are not large enough to allow of broad faces to the buttresses, and the architects by this means are enabled to project them out boldly without their having a meagre appearance, the great disparity between the faces and the sides being concealed by these projecting splays. Another good feature about the church is the way in which the line of the parapet surmounting the clearstory is carried round the western towers and across the west front, where the ornamental pierced work of the flank elevations might have been again introduced with good effect. However, even as it is, this feature gives much unity to the design. Taking the church as a whole, I consider that it displays a good deal of "character," the element so ally insisted upon by Mr. H. P. Horner. There is a dignity and repose about the design well fitted for the sacred purpose to which it is to be devoted. By all that we can gather from the description and the illustration, it fulfils very fairly Sir Henry Wotton's three requisites—"Stability, Firmness, and Delight."

My next illustration is the interior of St. James's Church, Kidbrooke, near Blackheath: Messrs. Newman & Billing, architects. This church, we are informed, was consecrated by the Bishop of Rochester, in July, 1867. It contains accommodation for 1,000 persons, and cost, exclusive of the organ, reredos, pulpit, fences, lighting, &c., about 7,000*l*. The tower and spire, 160 ft. high, are at the east end of the north aisle, and a vestry at the opposite side. The organ-chamber is formed on the ground-floor of the tower. The reredos, pulpit, reading-desk, and font are wrought in Caen stone, with alabaster and marble columns introduced. The church is built of brick, with Kentish ragstone facing, and Bath stone dressings. The pewing and stalls are of deal, stained and varnished. The chancel is laid with encaustic tiles. The whole of the windows are filled with geometric tracery. The interior is chiefly noteworthy for its carving, and the novel mode of lighting by means of coronas surrounding the piers above the caps. The carving was executed from designs furnished by the architects. It is very elaborate, but not, I think, sufficiently conventionalized. In the large-sized view of one of the pier capitals it will be seen that the small sprigs introduced just above the necking look stuck on, like sprigs of holly in Christmas decorations. This opens up a nice question as to how far the use of natural foliage may be indulged in in architectural decoration. For my own part, I am of opinion that it may be laid down as a sound principle that all carving ought to be conventionalized to some extent before being used in connexion with architecture. This extent must depend very much upon the character of the buildings in which it is employed. In the Greek edifices, which were as far removed from any connexion with Nature as any buildings have ever been, we find the carving severely conventionalized, only still retaining the beauty of form and plan of structure derived from the natural model. In the Norman we find much of the same severity; but in the Gothic Pointed architecture we come upon a much closer imitation of nature, yet still conventionalized. This relaxing of the severity of the earlier style was only consistent with the architecture, which became itself much more closely allied to nature:—

"The pillars with clustered shafts so trim,
With base and with capital flourish'd around,
Seem'd bundles of lances which garlands had bound."

But in all this change the workman was much more than a mere clever copyist. He took, it is true, the plans and details of his leaves and flowers from the band of Nature, but nothing more, following her only in those elements of general form and contour which were common to both. The brackets under the shafts supporting tiers of timbers in this church are, I think, taken in their general form from the well-known examples at Lincoln. The east window is of good design. The filling-in of the arch over the organ with open tracery is an idea worth noting in the present day, when there is scarcely anything in the shape of an organ-case provided. The tracery will help to hide the tops of the large wood pipes, the swell, and other excrescences.

With regard to this method of lighting, I can testify that it has a most beautiful effect. About two years ago I stayed at York over the Sunday, and attended evening service at the cathedral,

which is now lighted in this manner, and a more striking sight I have seldom seen than the long nave, with the line of brilliant rings of gas jets illuminating the soffits of the immense arches. By this method the piers cannot cast any shadow over the pews, and the light is equally diffused through aisles and nave.

Again leaving England, I must ask you to return with me to Melbourne,* where the new town-hall is now being erected. The foundation stone of this structure was laid by his Royal Highness the Duke of Edinburgh, on the 29th of November, 1867.† This building is another evidence of the magnificent way in which they build in the new colony. There is a good deal about the general treatment of the whole which resembles our Liverpool municipal offices. In both buildings a large Corinthian order is employed, with attached columns and pilasters, and a lofty attic above. In both we have pavilion roofs at the corners. The position of the tower, however, in both is different,—in the municipal offices being in the centre of the front, while in this example it is at one angle. As far as the tower itself is concerned, this may be perhaps the best place for it; but, taken in connexion with the rest of the building, it appears misplaced, as it destroys the balance of the whole composition, which is one of the leading charms of the Classical style. The towers of both buildings are composed of much the same elements—viz., a columnar order—a clock-face story and a terminating story, which in the Melbourne structure consists of a slated dome and lantern. The clock-face here forms a base for the columnar order; in the municipal offices it is above. Here, although the clock story is somewhat bald in design, it still forms a pleasing contrast to the lighter and richer story above. Here the architects have taken considerable liberties with classical traditions in making the pedestals of the columns and the breaks in the entablature above circular in plan. This is certainly a mistake in the case of the pedestals, as they have lost thereby the effect of contrast presented between the square pedestal and the circular shaft above. The circle in the entablature gets over the difficulty of having a square break at the angle, and is therefore much less objectionable. The attic between the pavilions is too much broken up, and is scarcely severe enough in character to harmonise with the Classic order beneath. The large Venetian windows lighting the upper story appear to be of good design, and will have a fine and bold effect with their deeply-recessed arches. The composition of the two heights of windows beneath the tower is very happily managed. The architects here have wisely substituted a pedimented head over the upper window in place of the round arch, which would have looked weak and unsatisfactory. As it is, the large pilasters at the angles of the tower, with the deep entablature and the smaller pilasters and entablatures of the windows, are in accord one with the other, as they are both doing precisely the same kind of work in a precisely similar way. The harmony would have been complete had the large angle pilasters been coupled like those of the upper window.

*Passingworth Manor, Sussex, the Seat of
Mr. Louis Huth.‡*

This house is situated on ground rapidly falling to the south, commanding extensive views, and is screened at the back by a belt of fir trees. The materials used in the construction of the house are red brick with Bath stone dressings and slated roofs. The principal rooms on the ground-floor are the hall, dining-room, morning-room, drawing-room, picture-gallery, and conservatory. In the centre of the building is a quadrangle, entered under a gate-house, by which access is gained to the porch, forming the principal entrance.

The hall, which forms the south side of the quadrangle, is 50 ft. by 20 ft. in the clear, and 40 ft. to the underside of the ridge-piece, with an open timber roof. In the hall are the principal staircase, entirely of oak, with carved panels, an ornamental chimney-piece, 15 ft. high by 9 ft. wide, and several stained-glass windows, the one at end of the hall having representations of the Seasons, the bay window on the north side the Months, and the other windows various subjects. At the end of the hall is a gallery for musicians, or for lookers on. The dining-room is 38 ft. long by 22 ft. 6 in. wide by 15 ft. high

and is entered directly from the hall. In this room are a large bay window, 17 ft. by 8 ft. inside; a recess, opposite the bay, in which is a carved oak sideboard, specially designed by the architect; a chimney-piece carved in stone; and an elaborate ceiling. From this room leads the southern turret, forming a recess on the ground-floor, and from the top of which a fine view of the country is obtained.

To the west of the dining-room and south of the hall, from which it leads directly, is the morning-room, 25 ft. by 22 ft. On the south side are steps into the garden. The drawing-room is 43 ft. by 30 ft., exclusive of two bays, each 17 ft. wide by 7 ft. 6 in. deep. The walls are all panelled in oak, and the ceiling is elaborate. Between this room and the picture-gallery is a fine flight of steps leading into the garden, the balustrading to which is of pierced stonework. On the west of the quadrangle is a corridor; next which is the picture-gallery, 60 ft. long by 23 ft. wide by 22 ft. high. The ceiling is trabeated, the panels being of open ironwork between carved and moulded oak beams, supporting the glass, forming the inner ceiling of the gallery, which is lighted from above; the beams rest on ornamental brackets, which are supported on corbelled heads, carved. The gallery leads from a triple-arched doorway on the west side into the conservatory, which is composed solely of glass and iron. The roofing of glass is supported on iron columns, with ornamental capitals, and is crowned by a light glass and iron dome. To the north of the picture-gallery and conservatory is Mr. Huth's room, 43 ft. by 20 ft., with a bay at the west end, and a polygonal bay on the north.

The whole of the east wing of the building, about 100 ft. by 70 ft., is occupied by the kitchen and its offices. The kitchen itself is 36 ft. by 18 ft., by 24 ft. high, with an open roof crowned by a lofty turret. It is fitted up with cooking apparatus, plate-warmers, ovens, &c. Round it are placed the larder, scullery, dairy, yard, servants' hall, and so on. There are four water-closets on the ground-floor.

The first floor is devoted entirely to bed and dressing rooms, with a bath-room over the porch, and various domestic offices. The principal bedroom, with its two dressing-rooms adjoining, is about 50 ft. by 30 ft. by 12 ft. 6 in. high, the other rooms in like proportion. The second or attic floor is also used for bedrooms; the rooms are 10 ft. high, and of various superficial areas. In the basement are extensive coal, wine, and beer cellars. At some distance to the east of the house are the stables, containing coach-houses, stalls for four horses, six loose boxes, harness-room, open sheds, carpenter's shop, &c., forming a complete block, and a stable-yard 80 ft. by 70 ft. At the different entrances to the estate are three lodges. The cost of the building, including the stables, was slightly in excess of 60,000*l*., and the whole was erected from the designs and under the superintendence of Sir Digby Wyatt, F.S.A.

On the arrangements of this house, which are well worthy of study, I have a few criticisms to offer. In the large hall the Medival idea has been followed out, with the bay window at one end; but a good portion of its length is occupied by the first flight of the stairs. This militates very considerably against its use as a ball-room or entertaining apartment, and I cannot help thinking that when so much space was sacrificed for the sake of carrying out the idea of the heronial hall, it would have been better to have had it thoroughly detached. Though nothing is said about it in the description, I should judge that it is very likely used as a billiard-room, as no other is provided in the plan, and the space left clear of the stairs is just about the area required for the purpose.

One great merit of the plan is the manner in which each department of the house is compacted together, and is complete in itself. The principal rooms, which face the south and west, are very admirably placed. First, we have the dining-room nearest to the domestic offices, so as to be conveniently served from the kitchen. Then the morning-room, with a door near the foot of the stairs, having a ready communication with the garden by means of an outer door, and flight of steps; and then the drawing-room, facing south and west, thus having the sun throughout the day. All the space that could be spared on the south side of the room is given to large mullioned windows, the best out-look being in that direction. A feature worth notice is the screen around the door, an arrangement to be seen in many of the Elizabethan mansions, and of great value in rendering the room free

* See *Builder*, vol. xxvi., page 765.

† The architects are Messrs. Keiv & Barnes.

‡ See *Builder*, vol. xxvi., pp. 712, 713.

* See *Builder*, vol. xxvi., pp. 869, 861.

from draught—a desideratum where ladies in evening dress are assembled. The picture-gallery leading from the drawing-room, together with it and Mr. Luth's room at the other end, form a noble suite of entertaining-rooms, 120 ft. long from north to south. The arrangement of Mr. Luth's rooms is very complete, having gun-room, strong-room, water-closet, &c., with a separate entrance, so as to be readily accessible.

The domestic offices are an excellent example of thoughtful planning. Notice, for instance, the position of the housekeeper's apartments. Situated at the angle of the block, she has complete control over the exit and entrance of the servants; on one side is the china-store, on the other the kitchen; and a little further off the butler's pantry and servants' hall. The passage from the kitchen to the dining-room is a little circuitous, though as a compensation it gives ready access to both of the dining-room doors. On the upper floor, we find the principal bedroom, with its dressing-rooms, forms a complete suite by itself, having a private passage. The other bedrooms are gained by means of a passage lighted from the upper portion of the entrance-hall; while another passage over the cloisters communicates with the north wing of the house, where the space is divided into three rooms for men-servants attendant upon visitors. The upper plan of the servants' portion of the house is equally good with the lower. The housekeeper's bedroom is at the corner, over her sitting-room, having the linen-store close at hand. The butler has a bedroom above his pantry, with a flight of stairs up to it from the pantry. Above the lutey is a lift for dishes. It will be noticed, on looking closely at the plan, that there is a double wall, with a cavity between the W.C. and the housekeeper's room, to prevent the noise caused by the closet from being heard. Externally, judging from the view given, the house presents a highly pleasing appearance and has no affectation of antiquity. It looks what it is, the mansion of an English gentleman, not "of the olden time," but of modern days, degenerate though some may deem them. The long lines of balustrading and formal terracing help gradually to nite the work of the architect with the works of Nature around. One satisfactory thing about the elevation is that it is honest. There is no studied irregularity here; all the breaks and excrescences are accounted for naturally in the requirements of the plan; and, despite these breaks, which are many, there is a general symmetry and balance which gives much dignity to the whole. What pleases me more than anything else about the whole exterior is the very clever arrangement of the picture-gallery and conservatory. When you think of it you will allow that a picture-gallery, 60 ft. long by 23 ft. wide and 22 ft. high, in which there are to be no windows, is an awkward feature to have to deal with externally. And now observe how well it is done here. One side is made to serve for the back wall of the conservatory. (Some may think the architect should have had the conservatory on the other front, and which is decidedly a better aspect; but, considering the fine view on that side, I do not think that the space for it could well have been spared.) But to return. The conservatory, with its raised centre, breaks up the long line of the gallery, just leaving sufficient of it in view to show the connexion between the two sections of the house. But then on the other side was the other long wall, 22 ft. high, to deal with. This, again, has been overcome by the introduction of a corridor, one story in height, with an open arcade, which is useful as connecting the two wings of the mansion. Above there is a similar passage, but narrower, which is lighted with three windows, and so the whole difficulty is mastered. The doorway opening on to the flats above the large bay windows is a novel idea which I do not remember to have seen before.

Humestown, County Wicklow, Ireland.*

The view of this house appeared in the *Builder* of August 8th, in which we are informed that it was then in course of erection for Mr. W. W. Fitzwilliam Dick, M.P. for the county of Wicklow. It stands in a commanding position, well surrounded with rich woods and mountain scenery. The walls are entirely of granite, and the roofs covered with tiles. The kitchen offices are in the basement a few feet below the ground-level, giving considerable elevation to the ground-floor, which is approached by a stone staircase from a vaulted hall about 40 ft.

in height. This hall forms the base of the tower.

The fittings of the interior are being constructed of various coloured woods, the staircase being in oak. Provision is made in various ways for defensive purposes, if necessary.

The house being intended chiefly for a short summer residence, provision has been made for a system of warming and ventilation throughout during the time that it will be unoccupied. The whole of the basement is vaulted in brick. The ceilings and floors over the dining-room, drawing-room, &c., are supported by massive oak beams, and finished with cornices of wood. The kitchen is open to the roof, and well separated from the habitable part of the house. There is a lift for coals and luggage from the bottom to the top of the house, and dinner is to be served by a traversing wagon passing up the stairs to the serving-room. The windows of the hall and staircase and upper portions of those of the living-rooms will be filled with stained glass, containing armorial bearings. Mr. William White, F.S.A., is the architect.

The exterior of this mansion is eminently picturesque, the architect rightly considering that the romantic scenery in the midst of which the house is situated demanded the use of what may fairly be called the Romantic style. The sentiment of affection for "the good old times," as they are very wrongly called, has inspired the conception of the whole; but this feeling is kept well in check, and is not allowed to interfere seriously with the comfort or convenience of the dwelling. Yet after allowing that much ability is shown in the design, it is after all an acted style, and in this respect contrasts badly with the truthful expression of modern wants and requirements, shown in Possingworth Manor, which I last noticed. Such a building as this is a piece of architectural scene-making, which does not advance except in a very limited degree, the true interests of the art. The clever way in which the whole mass of building is grouped together shows the hand of a capable architect as well as an antiquary. The manner in which the lines of the tower are gradually brought with an easy flow to the ground is well managed, and the carriage porch, with its massive buttresses and deeply-shadowed portal, is in perfect keeping with the pseudo-donjon keep behind.

And now let us turn to an edifice of a very different nature to the above, viz.,

The New University of London.*

by Mr. James Pennethorne. The *Builder* observes, "After long endeavours a building is being provided for the London University at the public expense. It occupies the northern portion of the ground in which stands Burlington House, and fronts in Burlington-gardens. Of this elevation we give a view, together with a plan of the ground-floor. The design at first selected was objected to after the works had been carried on to a certain extent, and a fresh design, that now illustrated, and which is being proceeded with, was made. The plan shows the arrangements of the building and the principal apartments. The accommodation provided will be as follows:—

Upon the Ground-floor.	f.	ft.
Entrance-hall or corridor	33 by 33
Public staircase	72 by 56
Hall for conferring degrees	72 by 56
Ditto for public examination	61 by 32
Small hall ditto	61 by 32
Waiting-room for candidates	61 by 32
Two examiners' rooms, each	22 by 16
General waiting-room	18 by 14
Clerk's room	23 by 18
Room for specimens and apparatus	18 by 14
Messenger's room	18 by 14

Upon the first floor are senate-room, committee-room, registrar's official room and private room, room for clerk of convocation, library, laboratory, anatomical room, and two professors' rooms. Upon the second floor will be apartments for the housekeeper, &c., and on the basement-floor rooms for the lithographer, for muniments, for stores, for the housekeeper, and so on. The principal front of the building is, as we have said, towards Burlington-gardens, and will be faced with Portland stone and red Mansfield stone intermixed, the enriched string-courses being of Hopton Wood stone. The estimate submitted to Parliament for the building was 65,000*l.*, exclusive of fittings, and this amount, it was stated to the House of Commons, will be considerably increased by the change of style."

The facade given in our illustration is a good specimen of Mr. Pennethorne's ability in the

Classic style. The raised centre of five bays flanked by the two clock-towers, is advanced out from the line of the front, and attains thereby a distinct completeness of its own independently of the rest. The arrangement of the columnar order at each end of the centre, where it abuts on the tower, is worthy of note. Many an architect would have been content to have had here merely a half-column in the angle; but Mr. Pennethorne, with excellent judgment, has finished the arcade with a full column at each end, the pilasters at the angles of the towers, giving the required finish to the order which is thus arranged like a temple in antis. Having a long front to deal with, and of no great altitude, the architect has endeavoured by every means possible to give height to the facade by breaking up the front and introducing perpendicular lines in the shape of pilasters, long and narrow windows, and statues on the summit. By these means the effect of too great horizontality is avoided very successfully. The treatment of the wings is particularly happy. The solid masonry of the lower portion, sufficiently relieved from heaviness by the stuated niches, affords a pleasing contrast to the open colonnade above, a pleasing variety very similar in idea to that of the wings on the east front of St. George's Hall, only that here the effect is obtained without such a serious sacrifice. In this upper portion of the facade the round shafts dividing the windows, contrast with the flat pilaster very pleasingly. Indeed, throughout the whole elevation there is a delightful play of contrast which fully occupies the eye without distracting it. There is no apparent striving for effect, so frequently a fault in our modern buildings, no crude half-conceived novelty impertinently thrust in; but, taking the old classical elements, a harmonious, dignified, and highly-effective composition has been wrought out of a slightly monumental character very appropriate to the purpose of the institution. There is only one feature in the building which does not thoroughly satisfy me, and that is the attic terminating the towers, which is treated in a similar way to the story below it, and the angular and heavy when contrasted with those beneath. A broad face of masonry was quite necessary here, no doubt, to carry up the line of the towers, but it might have been done with better effect, either with coins or simple unbroken projections. The dwarfish character of these pilasters is made still more apparent by the line of the balustrade being carried across the towers beneath the clock.

In concluding this paper I gladly express my belief in a glorious future, which is before our art. In spite of much weakness and numerous failings in the architectural works of our countrymen at home and abroad, no one can deny that great progress has been made in the last twenty years. That progress I attribute in a large measure to the greater liberality and breadth of thought begotten by the extensive circulation of the architectural newspaper, and the keen discussion of art subjects which has taken place in the numerous architectural associations throughout the land. The public mind is more interested in the subject year by year. A proof of this is afforded in the interest taken during the last few years by the public journals in the fierce "Battle of the Styles." But perhaps the greatest evidence of the rapid changes which our art is making is given by the extraordinary transformation in the revived Gothic style since the period of its resuscitation by Rickman and his followers. Compare some of the ultra-Medieval edifices of the present day which occasionally startle us with one of the early revived Gothic designs, and you hardly recognise the relationship. Abroad, in France, on the other hand, great advance has been made in the development of a Classical Renaissance style, which in the elegance of its details and severity of its mouldings has emulated the ancient Greek. The fact that eccentricity and fanaticism accompany this forward movement only shows that the rapid stream is swollen and so deeply agitated as even to tear up the natural channel through which it speeds in its onward course to the distant ocean.

"Not in vain the distance beacons. Forward, forward, let us range.
Let the great world spin for ever down the ringing grooves of change.
Yet I doubt not through the ages one increasing purpose runs,
And the thoughts of men are widen'd with the process of the suns."

W. H. PICTON.

PUBLIC WORKS DEPARTMENT, INDIA.*

The course pursued is as follows:—The chief engineer lives at the seat of Government, and being secretary for public works as well, takes the general direction of works on behalf of the civil administration. He is assisted by superintending engineers, who reside at some central station, and regulate all works in a certain area, which is usually very large, some circles being the size of Scotland, and others the size of Wales. The superintending engineers disburse no money, and keep no accounts. They do not even draw up designs or estimates unless they like;—simply receive schemes for check, and exercise a supervision more or less loose over those who are engaged in carrying out works. They have it very much in their power to settle down into a steady-going routine, varied by what is called their cold-weather inspection. At the same time, superintending engineers are seldom, in the efforts they make, behind other Indian officials; and that they are not as useful as they might often be, is owing to the system, and to circumstances. The superintending engineers, who are few in number, there being only sixteen for the Bombay and Madras Presidencies put together, and about thirty for Bengal, have under them from four to eight executive engineers apiece, by whom, and their assistants, the work of the Department is virtually done. That is to say, if the superintending engineers were eliminated there would be little change perceptible in the progress of public works. The executive engineers and their assistants prepare as a rule all the designs and estimates, and spend and account for all the money. There are some 400 or 500 executive engineers in India, and through them the entire grant for public works may be said to pass. Their present salaries for civil engineers range from 6,000 to 11,000 rupees a year, the equivalent of 300*l.* to 540*l.* a year in England, or even less. Executive engineers have, if their division is big enough, one or more assistants on say half their own pay, and several European and native subordinates. They are also furnished with an office establishment, and draughtsmen as required. Now supposing these agents were really zealous and efficient, as they are presumed to be by Government, the Public Works machine would go tolerably smoothly; but as it is, the only person really able to conduct very plain-sailing work at reasonable rates in so peculiarly constituted a situation as an Indian district, is not seldom the executive engineer himself, who gets the blame if anything goes wrong. Executive engineers are placed in charge of what are called divisions, which may be only a large military station; or a military station, with a hundred or two miles of road tacked on to it; or so many miles of road; or of all works military and civil in a particular district. If the latter, which is most common, there is generally a principal town at which the European community, the troops, the magistrate, doctor, clergyman, &c., reside, and which the executive engineer makes his head quarters. The works are very much scattered about over the district, and the assistant engineers and subordinates are pushed out to superintend them. They get plans and instructions furnished them, and are occasionally visited by the executive engineers. As a rule, contractors on any scale do not undertake work for the Indian Public Works Department. In the words of the Department itself, "they are not to be got," yet it is strange that almost every railway work is done, and well done by contractors and sub-contractors. The fact is, that the Public Works estimates are framed upon the results given by daily labour or job work, executed under favourable departmental supervision; that is, by careful superintendents, whose pay has been separately provided for. So that as no contractor can hope to work so cheaply, and obtain a profit, none of any standing will come forward to tender; and such as may, look to securing one by getting bad work passed, and when found out discredit the system. If an executive engineer cannot obtain contractors, he has to employ daily labour. The additional anxiety and attention this requires is enormous. The subordinates in the district may be careless or unpractised, and either the executive engineer has to be constantly moving about, or else has to hear the brunt of the excess expenditure they incur. But if they are diligent, the daily labour principle takes up an undue amount of their time. Indeed, to get good results from labour hired by

the day, and outasked, and to get money's value in the purchase of materials for a large work in small quantities, demands a great deal of experience and knowledge of what prices are in a locality, that it must take some considerable time for either assistant engineers or overseers to acquire; yet they are set to this difficult duty of managing daily labour without much personal control from the executive and superintending engineers, who are, perhaps, alone experienced enough to work the system economically, and catch it if they break down. If the Department is taken from the point of view of an assistant engineer, newly set to conduct works in India, it will show its weakest side; and that is the one which, if amendment is to take place, should have public opinion turned upon it. A newly appointed engineer lands at one of the presidency towns, where he finds civilized English society, and a mode of life not so very dissimilar to that of home, except that the extreme heat confines people all day to the house unless they go about in a close carriage. There are all the evidences of great wealth, and the bustle of an immense trade. All the professions are represented, and exercised in much the same way as in European towns. On the whole, the appearance of the presidency towns is such as to give a favourable impression of India to the new comer. An assistant engineer is posted somewhere in the interior very soon; it may be to a large military station, where he will still have European society; or to a wild district, in which Europeans are to be counted by the half-dozen, and are miles and miles sunder. He is paid the same in both situations; but in the one he can live in a respectable manner, while in the other, if not ravenously fond of sport, the style of life that has to be adopted on small allowances is little short of disgusting, ordinarily good food being hardly obtainable. The greater part of the interior of India is poverty-stricken to a degree. The people have few or none of the appliances of civilization. They inhabit hovels of mud and thatch most of them of the size of an English cottager's pigsty, and an agglomeration of these forms a town or village. They have few notions of cleanliness. Their carpet is a thin wash of cow-dung and water over an earthen floor. Their furniture a few brass or earthenware vessels. The animals herd in the small courtyard of each house, if not in an adjoining apartment. The streets run with sewage, and the air is charged with smells. About their ordinary vocations the greater part of the male population go nearly naked. The diet is either flour or rice flavoured with salt and pepper, relished with onions, and washed down with tepid water. So extremely filthy are all native towns and villages that no European could exist in close proximity to them, far less in them. Yet, be it in Calcutta, or in Madras, the natives themselves prefer such neighbourhoods and residences to anything cleaner and better. The rains in India are periodical, and while they fall the country looks rather fresh and green; but in the dry months which succeed, the surface is scorched, and in colour a dull brown varied by the yellow of the withered grass. Agriculture is very hawkdaw, being pursued under great difficulties. The plough is of wood, drawn by oxen. The cattle in India are miserable, dwarfed, ill-fed, and lean. In the rainy season there is grass for them, but in the dry weather they have to pick up a subsistence how they may. In consequence, they are stunted and incapable of heavy draught. The cows, again, belong to the same order, and have much the make of an English calf. The milk they give is of inferior quality, and even in European stations these animals are given stable litter to eat: on the coast they eat fish, so that Indian milk will not bear inspection, and tracing it to its source is enough to turn the strongest stomach. The fowls are not better tended than the other animals, so that their eggs have a taste, and the flesh is particularly spleen and uninviting. In the districts butcher's meat is not to be had to buy, as the people seldom use it. Milk, eggs, and fowls are the articles of food that go by the name of supplies; and it is a singular proof of the extreme destitution of the country that a traveller—and an assistant engineer is always more or less a traveller—has generally to arm himself with the order of a Government official, directing the villagers along his route to sell him provisions, which for mere money's sake they will not do. In many places where the assistant-engineer is sent to, he has to subsist almost entirely on preserved provisions brought out from England, and it is rarely he can anywhere do without

some of them to supplement the scanty nutriment the country affords. The employment of an assistant-engineer is so various that it cannot be minutely described here. He is supposed to be furnished with designs by the executive engineer, and to have the carrying of them out. If he can get contractors, he has merely to measure their work; but, if not, he has to hire labour, keep the accounts, and disburse the pay. To assist him in this he has sometimes a European overseer or two, and always a certain number of natives. These latter have usually no theoretical knowledge, and very little practical information. They have most of them probably never seen good workmanship in their lives. Their pay is as low as their position, and they are of course naturally ever on the watch to make it up by peculation. If intrusted with petty purchases, as they must be now and then, they take a percentage systematically. Government have a great dread of entrusting capable men on liberal salaries. An assistant engineer who offered 10*l.* a month to one superintendent would run a risk of being turned out of his appointment; but he might take on ten persons, on 1*l.* a month, without any question being asked, or, still easier, five on 2*l.* a month. The duties of an assistant engineer are often not of a very high order, and many of them are beneath a highly educated professional man. He has, besides his surveys and designs, to direct workpeople, compile accounts, and disburse pay. As a rule, also, he is given more to look after than one individual can, without being constantly on the stretch, satisfactorily superintend. So that to perform what is set him at all fairly his constitution must be excellent, and he must have what is more rare,—a willingness to in all weathers go about the country, foregoing society and amusement, lodging and feeding in a poor way, while discharging functions that very often require little more than common sense and common honesty. At first starting it is almost impossible for an assistant-engineer not to be beset with an idea that a service of this nature was not what he was trained for, or suited to him; and it may be questioned whether, when he has overcome this feeling, he has gained anything to speak of. The whole arises from Government giving a lower salary to an engineer than to a young civil servant, and letting native subordinates into the Department before they are thoroughly educated, and also in the general state of depression in which the country is sunk. The upper subordinates of the Department are now, for the most part, European soldiers, who have gone to one of the four civil-engineering colleges, and there received a brief preparation. The course is mainly one of surveying, and when they leave the college they have of necessity to be taught the details of masonry, carpentry, and the like by those whom they are sent to assist. If not put to too heavy or too scattered work, and they can be instructed by any one above them, they answer very fairly as a class, and many are excellent subordinates. But in the case of men sent out into the districts, where with their scant allowances they cannot procure decent shelter or nourishing food, and are debarr'd from all associates of their own rank or colour, there is much temptation to unsteadiness. Where European overseers are chiefly found to fail is, however, in skill; for never having served a regular apprenticeship to the practical crafts, they have no standard to guide them, and want incessant watching and direction. There are very few upper subordinates natives. The charges are so large that an ordinary native is not physically capable of managing them. The travelling and exposure are too severe for him. He is also not so accurate, and not so persevering as a European, who gives his mind to a piece of work, and goes about what he is doing mechanically. Besides, in the Public Works Department, in the case of posts worked more than a small sum, the opinion aoted upon in Lord Cornwallis's time in all departments, that no native is to be trusted, seems to survive. It is not altogether unfounded, because there are few natives in the position of subordinates who will not take per-centages from contractors and on purchases, and connive at those beneath them doing so as well. The practice is of long standing; and in the independent territories of feudatory princes all officiate take bribes and have perquisites, from the Prime Minister downwards. A native overseer intrusted with the payment of gangs of labourers can, if he choose, appropriate a large amount to himself with hardly any risk of detection; and if

* See p. 83, ante.

he permits similar inroads by those under him, the cost of establishment becomes very high. The European overseer is found out at once if he attempts to misappropriate, on the other hand, and is, besides, disposed to rest satisfied with his salary, which the native is not. Another reason why natives are not numerous in the Public Works Department is that they do not think it a desirable line to take to. Engineering as a profession has hardly naturalized itself yet in India. The natives see, for one thing, that it is the worst paid kind of service, considering the responsibility, under Government; that most of the members of the Department are always travelling about the country in a most uncomfortable way; that the duties are more financial than scientific; and as their fellow countrymen have scarcely learnt to appreciate roads or bridges, or public buildings, which the general run of them say our forefathers did very well without, their engaging in their construction will bring them no honour or advantage. In fact, there are in India master masons who do most of the works, such as houses, bathing-places, temples, and wells. They are low in the scale of caste, but have a rude practical notion of building, and the rules of thumb as their caste secrets. These men are generally made use of by the Public Works Department in actual construction, but they are too illiterate to make designs or organize a large series of works. However, the natives see most of the work done by the Department of so simple a kind as to be within these men's capacity, and European engineers are tacitly set down as the equivalents in their own country of the master-mason degree.

Natives and other candidates for the Public Works Department are educated at civil engineering colleges, established at Roorkee, in the north of India, and at Calcutta, Poona, and Madras. Roorkee is on the largest scale, and prepares the bulk of the subordinates for the Bengal side. These facilities are, however, far too few for the enormous extent of India. It is as if the engineers of France were all trained at Moscow. Did such a practice prevail in Europe, the profession would be filled with Russians. There are immense tracts of India, say between the Nerhudda and the Ganges, all Durmah, the Nizam's dominions, and other districts, where public works of magnitude are in progress, or sorely required, and there are no colleges at which the natives of those localities can receive a scientific education; and in consequence the agents of the Department are all strangers, and the service can never be popular because it excludes as unqualified every one belonging to the indigenous population, who is not willing or able to go hundreds of miles away from home to attend a civil engineering college. Natives are very fond of their own neighbourhoods, and dislike removing, unless actually driven to migrate in search of a subsistence. Though India is generally talked of as one empire, it is very composite; being made up of a number of provinces differing in climate, customs, wealth, and mode of government. Much of the central part of India, for instance, is thinly peopled, unhealthy, or desolate, and even to a native it is not the same thing living there as in the rich, and cheap, and for him salubrious, plains of Lower Bengal or Oudh. Salaries, however, except in a few notoriously deadly localities, are exactly the same all throughout the service, where provisions are moderate in price, as where they are twice as dear. Only in the three presidency towns is any difference made. It would tend to improve the Department, if colleges of instruction were multiplied, so as to bring them within reach of the inhabitants of every district. In the less important, they of course need not aim at so high a standard as in the colleges already established. These, however, especially Roorkee, turn out far too many half-educated subordinates; partly because the demand is so great, and partly in hopes that they will pick up a further amount of knowledge on works, which, as opportunities are not abundant, and the stock of it upon which to build is limited, not one in ten perhaps does. This is particularly noticeable in the class of draughtsmen. The men sent out in this capacity, are the most miserable performers possible. They know nothing of free-hand drawing or perspective, and can do little more than trace from plans that have been pencilled in for them. This is entirely due to the course they have gone through being too hurried, and to the very small salaries offered in executive engineers' offices. The illustrations in the colleges' own publications show that, with proper instru-

tion, good limners can be produced. The theory is that, once in an executive engineer's office, a draughtsman will improve; just as that subordinates who have never seen a stone quarried or the inside of a carpenter's shop, will learn all that is necessary while they are nominally assisting him, but whilst in reality that officer has to stand the brunt of their mistakes, which his superiors, who must hold some one to blame, invariably visit upon him. The duties of an executive engineer, who is, as it may be termed, the working man of the Public Works Department, are defined as follows by Government. The executive engineer, it says, is the officer in immediate charge of a division. In him is vested the management of all public works within that division. He arranges all the details of their construction; he superintends the works and accounts; he receives all cash advances and distributes funds to his subordinates; he is responsible for the proper custody and efficient repair of every work or building; and is answerable for the exact performance of all duties of whatever description connected with the Department. It is part of the duty of the executive engineer to suggest public improvements, and to prepare detailed designs for them; he is also to report on and suggest measures for the protection of any public monument or building of architectural or historical interest which appears likely to fall into decay. In addition to his other duties, he will consider himself to be *ex officio* the professional adviser of all departments of the administration within the limits of his charge. Executive engineers will prepare designs and estimates under the orders of the superintending engineer, and they are responsible for the accuracy of all drawings they submit. It is the duty of the executive engineer to pay strict attention to economical application of all labour and materials; he should also strive to bring economically into use, on all occasions, the articles procurable in the local markets and the natural resources of his district. He is held responsible for the good quality of all work done under his orders. He will afford his assistants every aid in acquiring professional knowledge, and must exact from his subordinates a correct performance of their duties, furnishing them with working drawings and written instructions as to the execution of any works they may be entrusted with.

Considering that a division may be the size of Yorkshire, his assistants new to India, and the subordinates college educated in theory alone, or corrupt, or intemperate, these qualifications expected from an executive engineer are pretty comprehensive. He has, let it be observed, not only to design all works, but to carry them out, and make most of the payments, and keep all the accounts connected with them. He is responsible for everything. If stupidity is shown by his subordinates, Government immediately says it is his fault, for not looking sufficiently closely after them;—if fraud occurs, that he has been too easy-going;—if prices are high, that he ought to have kept them lower, because three or four hundred miles off some one else does so;—if an estimate is exceeded, that it is very discreditably to him; and so on. At any rate, it would be thought that an official from whom so very much was asked, and who had so large a charge, would be very well paid in India. The remuneration, however, is thus arranged:—There are four grades of executive engineers: the civil engineer's salary in the lowest is 50*l.* a month, and in the highest 90*l.*, the intermediate grades being 60*l.* and 75*l.* These grades have no necessary connexion with the extent or importance of the division of works held. They depend upon length of service chiefly. Thus an engineer of the fourth grade may be exceeded in the same district or station by one of the first or second grade, and two engineers may be side by side with equal functions to fulfil, and yet the one receives about double the pay of the other.

Government dislikes making a promotion from grade to grade oftener than once in two years, so that there is little encouragement to merit,—in fact, everything to stifle rising merit. For civil servants, that is, collectors of revenue and district judges, the successive steps are 47*l.*, 53*l.*, 112*l.*, 180*l.*, 230*l.*, 250*l.*, and 300*l.* a month; while, for civil engineers, they are 20*l.*, 30*l.*, 40*l.*, 50*l.*, 60*l.*, 75*l.*, 90*l.*, and 100*l.*, and very few appointments of a higher description. It is not generally known in England, that for a married man to live in India in respectability 50*l.* is the very lowest sum required. It need to be less, but of

late years the necessities of life have almost doubled in price. About 80*l.* a month income would just enable a person in the position of an executive engineer to pay his way and maintain a tolerable status. With less he would be far better off in England on 350*l.* a year. Hitherto Government, treating the Public Works Department as connected with the military service, have argued that if they get officers to remain with regiments for twenty-five to thirty years on pay not rising above 60*l.* or 30*l.* a month, and for half that time not above 25*l.* or 30*l.* a month, they ought to get first-class engineers on the same terms, and do not take into account the essential difference between a scientific and civil, and a purely military service; one which demands a mere school-boy's education, and one that calls for considerable culture and ability. The situation of an officer with his regiment, an hon'r morning parade, billiards during the day, and a pleasant mess party in the evening, no travelling, or no anxiety, except making two ends meet, is slightly different from a civil engineer out by himself in lonely seclusion, feeding how he can, charged with difficult works, burdened with accounts, and exposed to sun and weather.

Besides there being little in the grading, or in the salaries themselves, of executive engineers to really reward efficiency, especially in the case of young and rising men, the lift to the rank above is, pecuniarily speaking, a small one. The step from executive to superintending engineer is only worth at first 10*l.* a month. When, however, the duties of that class are recounted, it will be seen what further value it has. A superintending engineer, says the Government, is the officer next in rank in the executive branch to the chief engineer. A superintending engineer shall have nothing to do with the actual execution of public works, or with the disbursement of public money on account of works, nor with the provision or custody of any materials for the construction of public works, otherwise than as an officer of control. The permanent residence of the superintending engineer will be at some central point within his circle, which will be fixed by the local government. It has been already observed that there is in almost every province or considerable district a chief town at which there is some comfort and an agreeable European society to be obtained; while, on the other hand, without it, the country is destitute of everything of the kind, and often even of the commonest supplies. The consequence of this is that there is every temptation to be in the stations as long as and as much as possible. Subordinates and assistant engineers are pushed out to do the hard work, and have the solitude and discomfort, while those above them take it as their earned privilege to be able to remain at their cheerful head-quarters. The superfluous amount of routine and office work is a further tie on the side of executive engineers, who do,—or, at least, the tendency must be for them to do,—as much as they can by correspondence, and as little by personal contact with their subordinates. It is not at all pleasant to leave family and friends and snug home, to go out and live in tents and huts and far distant places, for the sake of imparting elementary instruction to subordinates and workmen. The temptation is great to make occasional and rapid runs, bestowing a few words of caution and invecive on the way, instead of that continuous and painstaking progress which anticipates all their omissions and errors. It does not follow that every executive engineer sniffs his convenience; but the climate and nature of India are such as to deter officials from being out in their districts as much as perhaps they ought to be. Superintending engineers especially, when they have to wide a circle to move over, and the means of communication are slow, are apt to stay at head-quarters, in place of diffusing their experience. They then slide into post offices between their staff and chief engineer, sometimes forgetting, in fussing about works lying near them, much that would be well worthy of a visit. Another feature of the Department is that a man may be a good architect and set to lay out roads; or he may be in charge of a canal one day and of barracks the next; or may be a fair mechanical engineer and at home in a workshop, and given bridges and drains to build. An engineer also with a desire to improve himself, has so seldom the opportunity. He is left alone if at an outpost, and scolded when he is supposed to have, or has, done wrong. Sharp, stinging, now and

then abusive, censure is unfortunately the characteristic tone of the Department, brought about by the unyielding economy of Government, which before all things exacts the cheapest rates, and the little superior officers know of the difficulties that the agents of the Department have to encounter in the prosecution of works. When it is not so bad as this, the attitude towards an engineer is always one of suspicion. A large share of the professional experiences of the departmental officers is got from their mistakes. The accumulated stock handed down from one member to another is very small. The process of this individual acquisition is painful not less than the performance of functions more or less of an office clerk and having to lead a vagrant vagabond sort of life, on allowances from a third to a half of those of the civil service. Now, this is not an overstrained depiction of this Public Works Department, as it will be found by a large proportion of the civil engineers who come out to India. As far as payment is concerned, the Indian Government always assert that economy must be studied; but why it is necessary to apply it to the Public Works Department more than to any other department does not appear. Economy is not very rigidly looked to in India, for there were the other day in a single military station in the south of the peninsula no less than forty majors and colonels drawing from 644, to 821 a month for doing literally nothing, or what is known as "general duty." Possibly there are throughout the Indian army 150 officers of high rank on the active list in receipt of these emoluments, and giving no equivalent; 150 civil engineers on the same pay would be a signal addition to the Public Works Department. The domestic drawbacks to India can be met to a certain extent by increasing the number of engineers. The amount of space to be travelled over would not be so great, and the lessening of human nature to civilized society would be indulged without sacrifice of efficiency. On the railways the resident engineers are much nearer each other, and have many advantages over the civil district engineer in Government employ. The profession, above all, needs raising. Neither in the eyes of the natives, nor most assuredly in the estimation of the authorities, is the Public Works Department much thought of. The civil officials have seen too often young men taken from regiments and drabbed engineers, and have also seen the consequences of want of a theoretical and practical training too frequently to entertain much respect for it. They take note of the inner working of the Department, and see that most of the energy, time, and ability of the establishments go in the preparation and rendering of accounts, and that the powers of the local superintending engineers are so restricted that what they most want done cannot be done. The most detestable structures rise up in spite of them, and the most impassable roads are made under their noses; yet they can do nothing, as the Public Works Department has its own heads and rules, and is out of reach of criticism and complaint. The work objected to is a sanctioned and a hudget work, and must go on. They also cannot but remark the secondary sort of place given to engineers in the scale of remuneration, which does not come up to that of police-officers, or of natives in the Judicial Department sometimes. The grand remedy for all this resides, however, in the Government of India spending two or three times what they now do in public works.

THE NEW PRIVATE BILLS.

ILLUSTRATIONS by maps and drawings convey, concerning many affairs, whether the progress of a campaign in Abyssinia, the rearrangement of the representation of the people by a Reform Bill, or the improvements projected in a great city, more vivid and accurate impressions than can be given by any quantity of letter-press. Mr. Stanford, the geographical publisher, of Charing-cross, is enterprising in taking advantage of the capabilities of his art, as the public and those specially interested may be reminded by the issue of his annual map, showing the railways and other public improvements affecting the metropolis, for which plans may have been lodged at the public offices on or prior to the 30th of November in each year, and for which Parliamentary sanction is to be asked in the ensuing session. The new map just published contains an extra portion, showing the environs of London on a smaller scale, and embracing the greater part of Middlesex, with portions of the counties of Surrey, Kent, Essex, and Hert-

ford. The extra map was needed to display the schemes of the four projects by which it has been proposed to obtain power to provide above 100 miles of street tramway in a single session. Only a small proportion of the mileage originally contemplated by these schemes is likely to be asked for, one of the most imposing, which proposed to lay sixty-two miles, having been already dropped. In addition to the four tramway schemes, which take four-fifths of the red lines in which proposed new works are shown, the map shows works proposed by fifteen existing or proposed railway companies, and nine miscellaneous schemes, such as markets, gas, and water Bills.

The new railways proposed to be constructed, according to the plans lodged on the 30th November last, embrace about fifteen miles within the metropolitan district; but the schemes likely to be presented will not probably ask for more than a fraction of that extent, several of the most important of them being already dropped, including the Hyde Park and City, the Eastern Metropolitan Underground, the Clapham and London Bridge, and others. Some useful works are proposed, not for the greater part of very great extent, by the London and North-Western Company, a new approach from Euston-square; by the London, Chatham and Dover Company, station walls at Ludgate-hill; by the Metropolitan Company, station works at Westminster and at Brompton; and by the Metropolitan Company, alteration of station at Gower-street. Notices are given of a Courts of Justice Concentration Bill, for the Strand site already fixed, not adjoining the Thames Embankment; and for a Public Offices Concentration Bill at Westminster. The lodged plans include markets for Belgrave, and for Belgravia and Chelsea, adjoining each other in the Chelsea Bridge-road; a Bay-water market and baths; and a Westbourne market. Plans are also lodged for the long-proposed Park-lane improvement, at the end of Piccadilly; for a metropolitan improved water supply; and for certain new works of the Imperial Gas Company at West Ham.

NEW WAREHOUSES AND OFFICES, ST. JOHN-STREET, WEST SMITHFIELD.

DURING the night of the 10th of March last the premises belonging to Messrs. George Farmiloe & Sons, lead and glass merchants, in St. John-street, were consumed by fire. The "devouring element" left little more standing than the external walls, and those were so injured by the combined action of fire and water that it was not deemed advisable to re-use them in the new structure. A considerable time was occupied in removing the debris and salvage. Amongst the latter were hundreds of tons of lead and glass fused into one common mass. Tenders having been invited for the new building forming the subject of our illustration, that of Messrs. Brown & Robinson, for 12,916*l.*, was accepted.

The size of the building necessitated its division into two parts, so that the requirements of the Building Act might be complied with as regards the cubical contents of the buildings. A court-yard, 45 ft. long by 30 ft. wide, to which access is afforded by a gateway in front, serves the double purpose of forming the necessary division of the buildings, and of loading and unloading goods without inconvenience to foot passengers in the street.

A noticeable feature in the construction is the massive character of the foundations and floors to bear the enormous weights that will be placed upon them. This is especially the case with the ground floor of the hack warehouse, designed to receive the lead kept in store, which has been constructed of rolled iron joists and girders, calculated to bear a working load of 10 cwt. on every foot superficial. The ironwork in these joists and girders, and throughout the building, was applied by Messrs. W. & T. Phillips, of the Coal Exchange. The loading and unloading will be performed by means of steam-cranes supplied by the Newington Ironworks Company, the steam being generated by gas.

The front is composed of Portland stone and white Suffolk brick, the bases of the piers and the columns of the centre windows being of polished Aberdeen granite from the quarries of Messrs. Manuelle; the carving being entrusted to Mr. Seale. The whole has been executed from the designs and under the able superintendence of Mr. Lewis H. Isaacs, architect, Gray's-inn. Mr. Boulden acted as clerk of the works.

THE NEW ROOMS OF THE ROYAL ACADEMY.

As the new galleries and schools of the Royal Academy are fast approaching completion, our readers will be glad to know their arrangement and the precise accommodation they will afford. We therefore give plans showing the two floors. The buildings have been erected from the designs and under the superintendence of Mr. Sydney Smirke, R.A., and consist of a large oblong block, parallel with Burlington House, and separated from it only by a few feet, but extending on both sides considerably beyond its frontage.

The exhibition-rooms are on the first-floor, and are divided into three lines or rows; five, each, in the north and south rows, and four in the middle. The central room is a domed octagonal sculpture-saloon. Occupying the whole space westward of this is the "Great Room," where the annual dinner will be given. Eastward of the central saloon is a lecture-hall; the remaining space eastward affords a room intended for water-colour drawings, and the gallery south of that will be set apart for architectural drawings.

All the exhibition-rooms communicate with each other, and the circulation is complete.

These are the precise dimensions of the apartments:—

	Ft.	Fl.
The Picture Gallery at top of stairs ...	43	by 31
Central Sculpture Saloon, diameter ...	43	
Sculpture Room	43	„ 32½
North Picture Galleries, each	40	„ 32½
The Great Room	82	53
Water-colour Room	43	26
Architectural Room	40	31
South Picture Galleries, each	40	31
Hall for distribution of prizes, and for lectures	55	43

The floors are fireproof, being laid on brick-vaulting throughout; they are covered with Arrowsmith's solid *parquet* work of wainscot and walnut wood. The doors and their dressings are of the same materials, with the moldings carved, except at nine of the principal doorways, where they are of marble of various colours, chiefly from Belgium and the Pyrenees. The ceilings are for the most part coved, having the enrichments gilt. The walls of the picture-galleries are being finished of a deep, subdued red (with a sanded pattern), down to a dado of black wood and walnut. The choice rested between this and "phœnix's egg" colour.

The octagonal vestibule will be for the larger works of sculpture, and the upper part of the walls will be ornamented with busts of the most eminent artists of past times.

The ceiling decorations of the Great Room are somewhat more elaborate than those of other apartments, and include a series of demi-angels, holding emblems, as corbels. The lighting is by means of a large central skylight in each gallery, excepting the sculpture-room, where there is a side light.

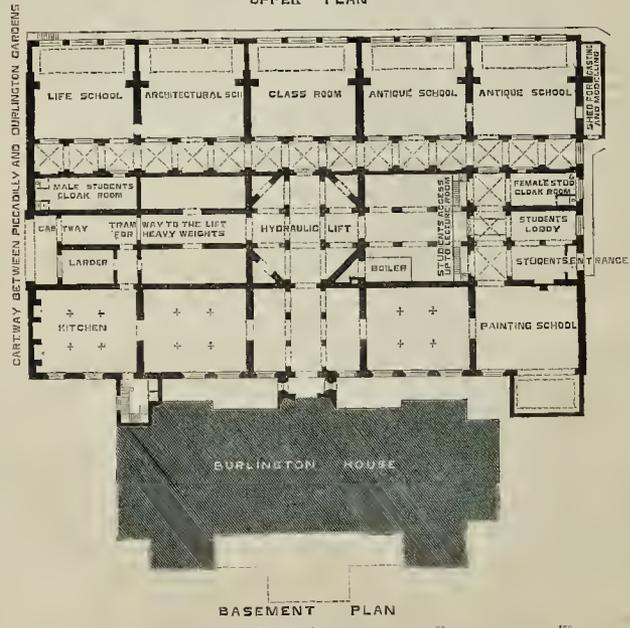

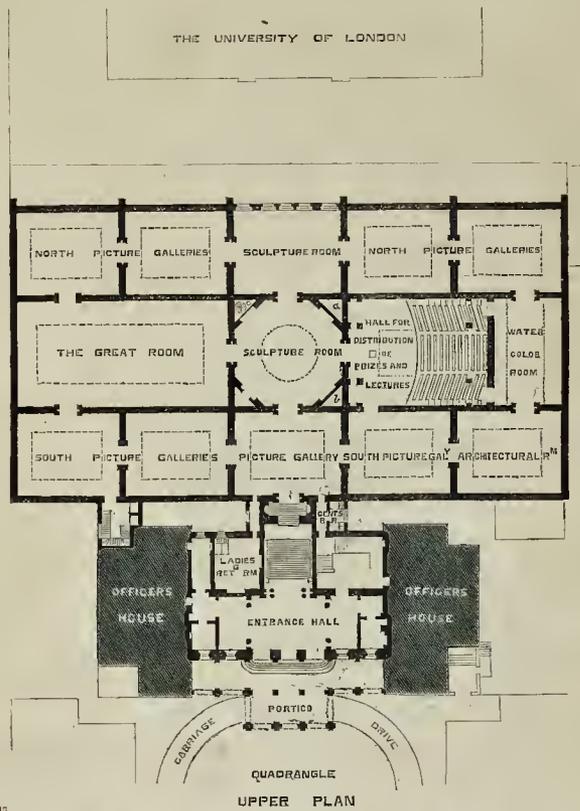

The height of the walls in the Great Room to top of cornice is 27 ft.; the cove occupies 11 ft., making the height to the underside of lantern 38 ft. In the lesser rooms, the height to the top of the cornice is 23 ft., and the cove occupies 9 ft.

We may add that the galleries promise to form a very handsome and well-lighted range. The central saloon will probably be less light.

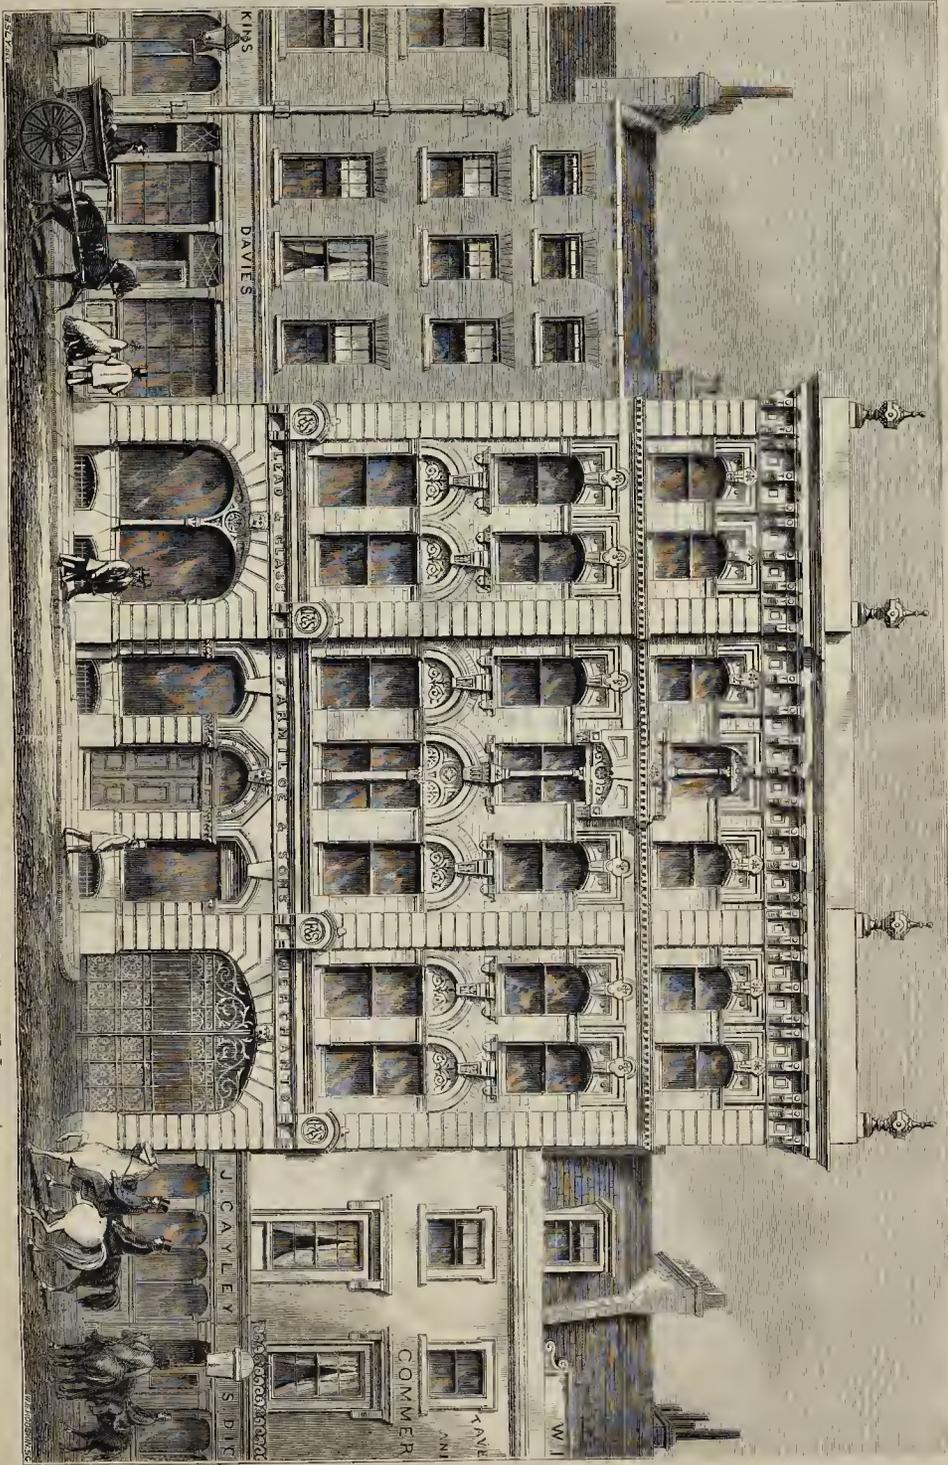

The schools are very spacious and airy, being 19 ft. high. Their appropriation is shown on the plan. The corridors, 10 ft. wide, are lined with white glazed tiles. The male and female students have separate apartments, of ample size. The whole of the schools, as well as the exhibition galleries, are warmed by Messrs. Haden's warm-water apparatus, the channels for warm air being rendered available for the introduction of cool air in summer. The access for the students will be from the Burlington Gardens entrance, where also all works for exhibition will be received. The general contractors are Messrs. Jackson & Shaw, and the decorations are being executed by Mr. Leonard Gollmann, in his usual good manner.

The foundations are being put in for the houses of the Learned Societies, next Piccadilly, and along the east and west sides of the quadrangle, under the direction of Messrs. Banks & Barry. Until these buildings are up, visitors to the Academy who ride will set down in Piccadilly, and proceed by a temporary corridor, now nearly completed, right across the quadrangle to the entrance-hall of Burlington House, where ultimately will be a carriage portico, as shown on our plan.

THE ROYAL ACADEMY, BURLINGTON HOUSE, PICCADILLY.—MR. SYDNEY SMIRKE, R.A., ARCHITECT.

a, b, Ventilating Shafts. C, Iron Stairs to Roof.

NEW WAREHOUSES AND OFFICES, ST. JOHN STREET, WEST SMITHFIELD.—Mr. LEWIS H. ISAACS, ARCHITECT.

THE "SOUTH KENSINGTON MUSEUM."

Sir,—You have doubtless observed that the *Albumen* of Jan. 16 followed the *Builder's* "lead" of the previous week, in protesting against the uselessly long name of the South Kensington Museum. Unlike the *Builder*, it does not suggest a substitute, but contents itself with saying the title is "much too long, even for a museum; it is fast becoming known as 'the S. K. M.," which is at least briefer." Now I, who originated the printed objection to the lengthy appellation, protested most strongly against the S. K. M. [M I L K] abbreviation, and suggested "The Art-Museum" as a substitute; but it has been represented to me that this definition is scarcely appropriate, as it would be ignoring the grand collection possessed by the British Museum of the highest of all art, so far as sculpture is concerned; and to this I may add, ignoring also the collection of highest pictorial art contained in the National Gallery.

It thus becomes a necessity to find some other name for our Museum which shall, if possible, be perfectly appropriate, and shall be acceptable to everybody. To meet this necessity, I would propose that her Majesty's permission should be sought to allow it to be called after her beloved consort, "The Albert Museum."

When we remember that it grew out of the '51 Exhibition, which was fostered, promoted, and brought into being by Prince Albert, and could not possibly have been carried through successfully without him; that he administered the electric spark which has vivified industrial art in England; and that the art-collection at South Kensington was his own idea, and was continually watched over and benefited by his good taste and wise counsels, besides being materially augmented by his generous donations; when, I say, we remember all this, it seems marvellous that the suggestion has never occurred to any one connected with the Museum to call it after the name of its producer and benefactor. I think this little act of grateful, though tardy, justice could scarcely fail to be agreeable to our Queen, and perhaps even she might feel willing personally to bestow upon her dear husband's foster-child, the name that is revered and beloved by all her subjects as well as by herself. Should this suggestion meet with her Majesty's approval, some little "state and ceremony" would of course be arranged, so as to do honour to the occasion and make the day a notable one; and if it could be set apart as a holiday for the people, this would be the better carry out the wishes of "Albert the Good," whose desire it was to make this museum peculiarly the people's museum.

If, then, in future, we should be allowed to call our Museum by such a familiar and household name as "The Albert Museum," this title will get rid of all difficulties: it will be short, euphonious, and pleasant on our lips; will not derogate from other collections of art; and will deliver us from the confusion that arises, especially with country-people and foreigners, between Kensington proper and South Kensington, which latter is really Brompton.

When last I sent you a few "notes" on the loan portion of the Museum, I described the beautiful mosaic table lent by Mrs. Hope. This is no longer to be found where it then stood; during some alterations it has been moved elsewhere, whether to return or not remains to be proved. Another extremely interesting object has also gone: the International Volunteer Trophy. As I have seen no description of this in print, it would be well here to preserve its memory, lest it should not again be publicly exhibited.

The size of the trophy I should judge to be 6 ft. long by 1 ft. 6 in. wide, and 3 ft., or 3 ft. 6 in. high. It is of silver, frosted, and only sparingly burnished in parts; and it was designed by A. Wilms, and executed by Elkington. It is, as your readers doubtless know, held for a year by that nation whose representatives have been most successful in rifle-shooting.

A short wide pedestal supports a column, on each side of which stands a well-modelled statuette, about 1 ft. high: one in Scotch dress, the other clad as an English officer of volunteers; and on the summit of the column stands Patriotism holding a torch and crown. Beneath his feet, and round the top of the column, runs the motto, "*Amor Patriæ*." "Defence, not Defiance," is the admirably appropriate legend beneath one of the statuettes; while under the other is inscribed, "*Si vis pacem para bellum*." These subjects, with gronped

flags, &c., form the centre of the trophy. At the base of the large pedestal are placed four groups of a mother and child. For the sake of explanation, we must designate one portion of the trophy as the War, and the other as the Peace, end. The grouped figures on the War end, then, represent a mother embracing her eager little son, who brandishes his father's sword, and struggles to free himself from her detaining arms; in the other group, the child has returned with the sword broken, and with his tears coursing down his mournful visage, while the mother encircles him with one arm, and hides her bowed face with the other hand. Immediately in front of these figures is placed a chariot—the classic biga—erect in which stands a young warrior, with a firm sad expression on his beautiful features. He holds a sword aloft in his right hand, and his long robes flow in most graceful folds on to the floor of the chariot. The chariot-wheels have a gorgon's head for the nave, and the spokes are wreathed with oak and laurel; garlands of the same, form the harness of the horses, which are led by a small child, who, in spite of his brave helmet, seems ready to burst into tears, as if he knew he had done wrong, and felt he deserved the chastisement which was about to descend upon him.

On the Peace end of the trophy, a female figure and child in one of the groups amass fruits and vegetables; and in the other, note down on tablets the gains of Commerce. In front of them, Peace, crowned with flowers, stands erect in her chariot, which is drawn by two fat, sleek oxen, garlanded with flowers, olive-branches, &c., and led by a smiling little urchin, also garlanded with flowers. The naves of the wheels are formed of bosses of fruits, while a wreath of hops and flowers decorates the spokes.

Two more figures of boys, seated one on each side of the base of the pedestal, bear, the one a telescope and the other recording tablets. These subjects are placed midway between Peace and War, they being applicable to both states.

After this description, it is needless to speak of the thoughtfulness, care, and artistic skill that have been brought to bear upon the design and execution of this Volunteer trophy: it is a very excellent work, and well repays patient examination.

To return to the noble collection of art-objects lent by Mrs. Hope. The large plaque of Limoges enamel—supposed to be by Leonard Limousin himself, date about 1550—containing six acrochats piled together in one group, is a marvelously fine thing. Other grand objects are, the "Cistern on three feet," majolica di Urbino, sixteenth century; and a large vase, about 2 ft. high, of French earthenware, Palissy style, seventeenth century. Two carved jade vases, with perforated covers, are also very handsome; and the large studded tazza of jade, supported on a delicate silver stand of European manufacture, formed of twelve mermaids and interwoven cords, is very beautiful and graceful. There are likewise some fine dishes and plates, enamelled in colours; some admirable majolica dishes; a beautiful, rich-looking majolica jug; two specimens of Henri Deux ware; and one very charming plate—or saucer, for the centre is a deep hole, as if to take the cup—the design on which consists of five little boys, one with the prettiest face imaginable, playing at leap-frog, the colouring of the whole being the most tender and delicate I have ever seen in majolica.

At the back of this case is placed the elliptic jewel of white enamel, bearing the "bloody hand" of Ulster, the only known badge extant of the Order of Baronets. The jewel is set round with large precious stones of various colours, ruby, emerald, and diamond alternately. It is of British workmanship, date 1664, and is lent by Sir George Duckett, bart.

A beautiful Biberon of Faience d'Oiron (Henri Deux ware), date 1530 or 1540, lent by Mr. J. Malcolm, of Paltaloch, has a singular hinged cover of the same material that is worthy of notice; and, because they are placed near at hand, I will here mention the smarg-bowl, cover and spoon of white earthenware and good form, lent by Miss Dale, probably of Leeds manufacture, and also the butter-boat, salt-glazed Staffordshire ware, lent by Professor Church. The hunting group, in white porcelain, from the manufacture of the Duc d'Angoulême, is spirited and graceful; date about 1780. Not far off is a snuff-box, lent by Mr. Beresford Hope, formed of beautiful slabs of "lunachelli," which I take to be matrix of opal; and there is a fine one of spar, inlaid with houses and trees in hard stones; a gold snuff-box, con-

taining the freedom of the City, with the City arms enamelled on the lid, presented in 1811 to Lieut.-General Sir W. C. Beresford; and from the same collection comes the flattened oval sardonyx ewer, mounted in gold, enamelled and jewelled, ornamented with graceful little enamelled figures, and having a wonderful dragon for handle.

In the adjoining glass-case is still to be seen the extremely interesting, and minutely carved, violin of boxwood, given by Queen Elizabeth to the Earl of Leicester. Its date is about 1330 to 1340, so it must have been a curiosity in Elizabeth's time; and we may well suppose it to have figured as one of those costly New Year's gifts which the Queen was so fond of receiving and bestowing. Possibly this violin was given by her to Leicester, in return for the rich present he made her on the New Year's-day of 1571.2—namely, "one armet, or shakell of gold, all over fairly garnished with rubies and diamonds, having in the closing thereof a clocke, and in the fore part of the same a fayre lozengie diamonde without a foyle, hanging thereat a round jully fully garnished with diamonds, and perle pendant weying 11 oz. gr. dim., and farrthinge gold weight: in a case of purple vellat, all over embranderid with Venice gold, and ynde with greene vellat."

Supposing the violin to have been the choice return-gift for this sumptuous bracelet of 1571.2, the "additions" to it in 1579 may have been made by Leicester's order to suit his own fancy; and probably at the same time the shields bearing his arms, and those of the Queen, were placed on the finger-board. It is lent by the Earl of Warwick And here I must close my "Notes" for this present. ART-LOVER.

THE DUBLIN SCHOOL OF ART.

THE distribution of medals and prizes to the students of the Dublin School of Art took place in the theatre of the Royal Dublin Society on the evening of Thursday, the 28th ult., his Excellency Earl Spencer presiding. Lord Strathnairn, the Commander of the forces in Ireland, the Lord Mayor, the Lord Chancellor, and many other distinguished persons were present.

Mr. George Woods Mansell opened the proceedings, and explained to his Excellency that the Dublin School of Art stood first, considering the number of national awards in proportion to the number of students, of all the schools in the United Kingdom.

Lieut.-Col. Adamson, the President of the Fine Arts Department, alluded to the difficulty which the artisan classes of Ireland had in finding time and means to proceed to South Kensington, and under these circumstances he considered that a small museum of ornamental art should be established in connexion with the Dublin School. Col. Adamson then read the report of the Committee of Fine Arts. The attendance of students during the year 1868 has been 519, showing an increase of 87 over the year 1867. Eleven national awards were gained, including one of the two Princess of Wales's scholarships.

The President then distributed the awards to the students, who were introduced to him by Mr. Lyne, the head-master of the school.

Lord Clancarty proposed a vote of thanks to the Lord-Lieutenant and to Lady Spencer, for their kindness in attending on so interesting an occasion, which was seconded by the Lord Mayor.

His Excellency made a long and very able speech. He expressed the gratification he felt in hearing the report of the Chairman of the Fine Arts Committee, and congratulated the society that the head-master of their schools, Mr. Edwin Lyne, had gained a second place amongst the art-teachers of all England for the success of his instruction. Lord Spencer then said:—I do not feel that I have any right to enter largely upon the subject of art, but I feel bound to make one or two observations, which I do with great diffidence. I think it is very often not appreciated how great a power art has upon the history of the country,—I mean in recording the deeds of our countrymen, and the noble acts which they do for the benefit of their country. I believe that art, peculiarly the art of painting and sculpture, takes a great part in educating one generation as to the deeds of another. I believe that in Great Britain, at this time, we have made very great strides towards the improvement of the fine arts, and the part

which Ireland is to play in promoting the fine arts of Great Britain is by no means a small one; for I believe that it belongs to this people to be eminently artistic. I believe that there are qualities belonging to the Irish people which are singularly propitious to the development of high art. We have the poetic imagination, which is so well known to exist among your people; we have that warm-heartedness without which, I hold, true art cannot be maintained, for without it you have not proper sympathies with all the different relations of life. You have the love of the beautiful very strongly developed among your people. It is, then, a noble work, which I feel sure this society will nobly carry out—the development of the artistic feeling among the Irish people.

It is the duty of societies like this to properly cultivate taste among all classes. Let them not pander to the public taste. Let them not be led into pandering toawkish sentimentality or sensational excitement, but let them try to immortalize the great deeds that have been and still can be done in this country, and then they will do a great work worthy of their country.

One thing more I will say, and that is, that I should wish to see a taste for the fine arts permeate the whole country. A taste for the fine arts, in other words, is a taste for what is correct. In old days, in Italy, nearly everything that was used in daily life was remarkable for some hearty, either of form or of colour. Why should not this be so in our days? Why should we not cultivate taste in such a way that everything about us, whether the architecture of our houses, our carriages, our furniture, our crockery, our dress even, should be governed by the excellence of taste? I believe there is nothing that will develop and spread itself so much as good taste; and there is no knowing what pleasure it gives to those who would have everything about them in good taste.

GRAINING FROM THE NATURAL SURFACE OF WOODS.

At the close of the paper on this subject, read by Mr. Dean at the Society of Arts, and printed in our last.*

The Chairman (Mr. Godwin), in inviting discussion, remarked that the mention which had been made of Mr. Herbert Minton and Mr. Hullmandel must have brought to the minds of many present the remembrance of what immense progress had been made within the last thirty or thirty-five years in many of the useful arts. At the period alluded to in the paper, chromolithographs were unknown, at least in England, and encaustic tiles were not in use, whilst the large trade in both these articles was now patent to everybody. Still, there was much room for further development, especially in the matter of encaustic tiles, which were, he had almost said, shamefully expensive in many cases; and were the price reduced, their use would be largely increased. These things, however, were not the only matters in which great progress had been made during the period he had named, and, although their country was often spoken of as Old England, she might be regarded as still in her youth, so far as progress was concerned. They had only had a Royal Academy for about a hundred years, and steam-engines, railways, and the electric telegraph had been introduced within the memory of most persons present. Coming more immediately to the subject of the evening, he must beg leave to take exception to the name that had been given to the process described, for "xylography" (*xylo*, wood, and *grapho* I engrave) meant wood-engraving, as any dictionary would show. He would suggest Wood-Printing as a more appropriate term. He had no great love for graining himself, although he did not go quite the length of some who abominated it as a sham. Graining, under some circumstances, was no doubt defensible, but the inexcusable character of some shams which had been put forward had had the effect of inducing many men who were anxious to associate architecture only with what was noble and honest, to set their faces against all imitations whatever. Putting aside that consideration, and looking at the matter commercially, it appeared to him that this new process had advantages, not the least of which was that it would have, he hoped, the effect of banishing that wretched apology for graining which sometimes was seen dis-

figuring and disgracing people's houses. He should like to hear from Mr. Dean whether the closer-grained woods could be printed from in this manner, as the majority of the specimens appeared to be oak; and he was not certain whether mahogany, rosewood, and the harder woods could be imitated. He should also like to know whether the paper from which the impression was produced must be taken from the original on the spot, or whether it could be taken by workmen at a distance; and he did not understand whether the specified times within which a given quantity of work had been done included the printing of the paper, or only the transferring of the impression to the wood. Mr. Dean had just handed him a specimen of imitated hollywood, which was certainly commendable, as there was a quietness and modesty about it not always seen in grained work.

Mr. J. Blore (taking from the table a tile with a wood pattern upon it) could not quite see the advantage of manufacturing tiles in imitation of wood, though the invention was very ingenious, and would, no doubt, prove exceedingly useful. He would also like to know whether the durability of this system for external work had been tried.

The Chairman observed that this would probably depend on the varnish, and that there seemed nothing in the process itself which would make it differ in this respect from other graining. He thought making the tiles look like wood quite indefensible.

Mr. Bottomley said the process of printing from the grain of wood on paper was not new, as it had been in use some time by the French for paperhangings, which had been imported into this country rather extensively during the last few years.

Mr. Morant inquired whether the graining was applied to the wood direct, or whether a "ground" had first to be prepared.

Mr. Bottomley said, in correction of one statement in Mr. Dean's paper, that the best oak graining was now not done in distemper, but always in oil; the inferior work was done in spirit.

Mr. John Land said the process had been mentioned as being more durable than ordinary graining; but he saw nothing in it to render the effect more lasting than graining in oil. He saw nothing in the specimens exhibited beyond what he had seen produced on paper in distemper, which, when applied to woodwork and varnished, had exactly the same appearance. He should have liked to see more variety in the specimens, and did not doubt but that many other kinds of wood could be imitated.

He hoped leave to call Mr. Dean's attention to the beautiful specimens of wood in the museum at Kew, some of which would be very difficult indeed to imitate by hand, and, therefore, if they could be copied by this process, there would be a real advantage in it. At present they were confined to two or three descriptions of wood for interior work in houses owing to the difficulty of imitating others, which, in some cases, would no doubt render the copy as costly as the original; therefore, if some of these beautiful woods, both English and foreign, could be imitated at a reasonable cost by this process, decorators would have their means of ornamentation much extended. He understood from Mr. Dean that the cost of his process was about a shilling per yard.

Mr. Laing said he had had an opportunity of inspecting the specimens by daylight, and was very much pleased with them: one feature about the work which had struck him particularly was, that the mouldings were as elaborately finished as the plain work, which was not the case with graining done by hand, where mouldings and such like parts were simply run down with the corn. Of course, the men being paid by the piece, their object was to get through as much work as possible in the time, and the more difficult parts, such as mouldings, were accordingly done just so as to pass muster. In the specimens exhibited, however, one part was as good as another. It had struck him that the light and dark specimens were clearer and more distinct than the intermediate shades. To his mind, the great advantage of this process was that graining of first-rate quality could now be executed in the provinces, where it was at present difficult, if not impossible, to obtain the requisite skilled workmen to do it by hand, and thus many country houses would now be decorated in this way where, hitherto, such a thing would have been out of the question.

Mr. Yardley thought there were one or two

inaccuracies in the paper which he should like to correct. It was said that there was a reluctance on the part of architects to employ graining, on account of the bad manner in which it was often done; but, he believed, the real reason was the desire, which had been alluded to by the chairman, to avoid everything in the nature of a sham, and also the question of expense. It was much cheaper to stain deal, which, in many cases, showed a very beautiful grain through the stain, than to have it painted and grained. He should like to know whether Mr. Dean's process was applied to the wood plain, or whether it required painting first, because, of course, if the latter were the case the cost would be increased. Mr. Dean had spoken of 2s. and 2s. 6d. a yard being paid for graining, but he had never known more than 2s. or 2s. 3d. being allowed by an architect, including the preliminary painting, and two coats of varnish afterwards. He should like to know whether the process was applicable to delicate woods, such as bird's-eye maple and satin wood.

Mr. Miller asked if the process could be applied in imitation of parquet flooring, and if so, at what expense?

Mr. Dean, in reply to the questions which had been put, referred first to that put by the chairman as to the transfer of hard woods. A specimen of bay wood was on the table, and there were also specimens of Hungarian ash; and bird's-eye maple was in process of trial. The fact was, however, that he had not as yet been able fully to experiment on many of these kinds of wood, from being engaged in carrying out his patent commercially, and also from the difficulty which was experienced in getting suitable specimens of wood with which to experiment.

He thought the question as to the applicability of the process to encaustic tiles had been made sufficiently evident by reference to the case of Mr. Robson, of Liverpool, who had used nearly 1,000 yards of tiles embellished in this manner in the dados and staircases of the new public offices. Mr. Bottomley had stated quite correctly that for some years past the French had transferred the natural grain of wood to paper for paperhangings, but they had not gone beyond that; whereas he had succeeded in re-transferring the impression from the paper to either a painted or plain deal surface, the latter being specially applicable for churches. He had carefully examined the many beautiful specimens of woods in the museum at Kew, and he had not the smallest doubt that very many of them could be successfully employed in this process; but experiments would have to be made, which would take some little time. He had had great difficulty in procuring specimens of bird's-eye maple and Hungarian ash suitable for his purpose. These difficulties would no doubt vanish by degrees, but still they were sufficient to show that time was required for the perfecting and development of the invention. At Bradford, in Yorkshire, while in conversation with one of the principal painters and decorators, it was suggested to him that his system would be very useful to men who were not in a position to employ first-rate grainers; his reply to that was, that in a week he could put these second and third-rate men in a position to compete with, if not to surpass, those who employed the best grainers money could procure. As to the price, he had given pretty full details in the paper, and he would add that Mr. Crossley, of Newark, had told him he had paid as much as 5s. a yard for graining alone. He did not think the system was applicable to parquet flooring, for floors were intended to be walked upon, and however good might be the varnish the pattern must be rubbed out in a comparatively short space of time. The encaustic tiles in imitation of parquetry had, however, been used to a considerable extent, and for the borders of rooms appeared particularly applicable. It was only right, however, to say that many persons had taken exception to the application of the process to tiles, and he had for this reason mentioned its employment by Mr. Robson, at Liverpool, where it had been considered very successful.

The Chairman then moved a vote of thanks to Mr. Dean, which was carried unanimously.

The Discovery of the Guildford Castle Vaults.—With respect to this discovery, the *Surrey Advertiser* states that a petition has been extensively signed in Guildford to Lord Granley, the owner of the property, asking his lordship's permission to prosecute the excavations.

* See p. 81, ante.

THE WORKMEN'S INTERNATIONAL EXHIBITION.

A public meeting has been held in the Town-hall, Tunbridge Wells, in support of the scheme for holding this exhibition. The Hon. F. G. Molyneux occupied the chair. There was a good attendance of working men.

Mr. Beckmaster, who was present, said that Tunbridge Wells was a very celebrated place more than 100 years ago, when Dr. Johnson drank twenty-seven cups of tea with Mrs. Thralo on the promenade. Every place and every trade has its traditions, but the story of the Tunbridge ware is not very romantic. An Italian refugee, wrecked on the Sussex coast about 100 years ago, made his way to Tunbridge Wells, and there started a trade, which was at that time unknown in England. The work, chiefly in rough mosaic, and much inferior to what we see now, excited great curiosity. The Italian had a monopoly of the trade; he kept the secret to himself, and became wealthy. At last some enterprising man, tempted by the success of the Italian refugee, who was reputed to be rich, climbed to the top of his workshop, took off a tile, and watched the process from beginning to end, and from that time there was free trade in Tunbridge ware. We want you to help with your Tunbridge ware and any other productions, the result either of your skill or invention, or both. And what is the object of all this? It is to make a man feel that there is something noble in labour; to cultivate between the workmen of different countries feelings of good will and kindly brotherhood; to encourage good work, and revive the honest pride and feeling of bygone times. I have seen in common clay a jug made by a potter, years ago, with this inscription, ornamented with birds and flowers: "To my sweetheart, Jane Wilson. Made by my own hands.—George Brown." The writing was the worst part of the work. There must have been a pride and a pleasure of which we know but little when Quentin Matsys looked upon the ironwork made with his own hands. Most working men endeavour to make something. We want to get this work together; the success of our efforts will depend mainly on the working men themselves. They have their full share in the management, and we mean that the credit of good work shall be given to those who deserve it.

MUNICIPAL GOVERNMENT OF THE METROPOLIS.

THE daily papers have made widely known that the Home Secretary, Mr. Bruce, gave a deputation of the Metropolitan Municipal Association, who went to him last week, full assurance that the Government are disposed to aid them in their endeavours to obtain a better form of government for the metropolis. This Association has been established for the purpose of collecting facts and statistics in relation to the present local government of the metropolis, and for diffusing the information so collected by means of public meetings, lectures, and through the public press; and further, to promote by every available means the attainment of a Legislative enactment that will secure a more direct and thorough municipal representation of the ratepayers, and a more responsible, efficient, and economical form of government for the metropolis. All who feel the importance of this improvement should join it. Mr. James Bial, of 209, Piccadilly, is the Hon. Secretary.

HALIFAX.

A VERY important work has just been commenced here—the constructing of a new road to connect the borough of Halifax with the adjoining township of Southowram, and to be called Southoran-road. The road is over a mile in length (including a side branch), and is 30 ft. wide between the walls. It winds along the side of Beacon-hill, whose natural slope is an incline of 1 to 1½, and is supported on the lower side by a dry retaining wall, topped with a 4 ft. 6 in. fence wall, the higher side having a fence wall only, and the ground above cut down to a slope of 1 to 1. The height of the retaining wall, in some places, is over 40 ft. There is an earthenware pipe drain from end to end, commencing at 2 ft. diameter, and tapering to 12 in. The road rises 244 ft. in its entire length, its steepest gradient being 1 in 15, and is intended to replace the existing road to Southowram, which is

an incline of 1 in 6, and not at all adapted for the immense amount of stone traffic that runs over it. Some idea of the magnitude of the work may be gathered from the quantities, there being over 50,000 cubic yards of excavation, and 15,000 cubic yards of stone in retaining and fence walls. The total quantity of stone used will be considerably over 20,000 cubic yards.

It is expected that this road will open out a great tract of cheap building ground, as it goes over what is now nothing more than a barren waste.

The contract is let to Messrs. Chapman & Shaw, for the sum of 8,200*l.*, and is to be completed in eighteen months. Mr. Henry Alty is the engineer appointed by the Halifax corporation to carry out the works.

THE THAMES EMBANKMENT AND THE LAW COURTS.

SIR,—I stated at the Metropolitan Board of Works that it is not possible to place Mr. Street's building, as now designed, on Sir C. Trevelyan's site on the Thames Embankment, inasmuch as the latter is too small by about 40,000 ft. A few figures will show this. Mr. Street's plan at the Institute is 740 ft. by 500 ft., which dimensions give 370,000 square feet. Sir Charles Trevelyan's site is bounded by the Strand on the north, the Temple on the east, the Embankment on the south, and King's College on the west. Allowing for streets for light and air on the east and west sides, this plot is as nearly as possible 660 ft. by 500 ft., or 330,000 square feet, and is, therefore, as I stated at the Board of Works, too small by 40,000 ft., for Mr. Street's present plan, to say nothing of any future extension of it. It is, however, more than sufficient for either the courts or the offices, in a separate building, according to my proposal. I have taken all my dimensions from official plans, and cannot understand Sir Charles's assertion that his site, exclusive of King's College, and without including any portion of the embankment, contains 446,500 superficial feet.

WILLIAM TITE.

THE COLISEUM, LONDON.

SIR,—Can you inform me where I can find any description of the Coliseum in the Regent's Park, with plans and sections of the building? * I am sorry to see that it is to be pulled down. Could it not be saved? It seems to me extraordinary that while this building is available, we should be erecting a very similar one at South Kensington for a purpose for which, if we are to put the slightest faith in the laws of Acoustics, it must be very ill-adapted. However, there must be many purposes to which the Coliseum building would be very suitable, and for which I trust to see it yet preserved. In these anti-Ritualistic days, why should it not be converted into a church? Its great prototype, the Pantheon at Rome, is so used, and Ferguson, in his Handbook, affirms that it is well adapted for the purpose. Neither of the buildings is cruciform in plan, but the light from above would satisfy the lovers of symbolism. Again, there is a great want of a really public library in London. Could a building be obtained, there are hundreds of men in London who would come forward with donations of money and books to stock it, and we should no longer bear the reproach of being behind the other great cities of Europe and America in possessing no free library in London. You have done so much for the working man in London in sanitary matters, help him in this too. J. B. Major.

THE FAILURE OF STONE.

I BELIEVE if the decayed stones in a building were carefully examined a large majority would prove to be face-bedded; yet some good judges tell us that in Portland, Bath, Granite, and some others, it does not matter whether the stone fixed in work is face-bedded or not. I think the contrary might easily be proved, as stone laid on its natural bed, "with its teeth out"—to use a quarry phrase—presents a greater resistance to the effects of wind and weather, than when laid in any other position.

In addition to stone being laid on its natural

* "Public Buildings of London." By Britton & Pugin.—Ed.

bed, I think it ought to be well seasoned, for even our worst stones when well seasoned will stand for a long time before exhibiting any signs of decay, and a careful observer will find in buildings recently erected stones perishing, but after a time the decay is arrested, as it were, by some invisible agency, more particularly so in Portland and Ancaster stone. This is nature throwing out a coating or weathering to the surface.

This coating is most remarkable in the Ancaster stone, as many builders know to their cost who neglect the cleaning-down of buildings till it is formed.

In this age of steam we quarry hy steam, we convey hy steam; we saw and work by steam—I had almost said we fix hy steam—so that the stone has no time to get rid of the quarry sap. To season stone we require some such desiccating process as that to which timber is subjected. Thus, although the stone quarried in the present day is as good as at any former period, the continual outcry is—"There is no good stone to be had now."

What I say is this—When we have made choice of the stone to be used, select the best of that kind, season it well, have a properly-cleansed surface before it leaves the banker, set it on its natural or quarry bed, and we may defy the influence of London smoke or soot; but I hope we shall see many more articles on this subject in your valuable journal, as, in the multitude of counsel there is wisdom. D. H. R.

INAUGURATION OF THE WALSALL AGRICULTURAL HALL.

THIS edifice has been inaugurated by a concert in aid of the Walsall Cottage Hospital. The building, which was designed by Mr. G. B. Nichols, West Bromwich, architect, has been erected by Messrs. Trow & Sons, of Wednesbury, contractors. It provides a hall 80 ft. by 50 ft., with a spacious vestibule entrance, on each side of which, on the ground floor, are placed the settling-rooms, forming arched recesses, which may be used as refreshment-rooms or for other general purposes, over which are placed retiring-rooms for ladies and gentlemen, divided by an arched lobby, arranged to overlook the whole of the hall. There is a stage at the end of the hall, 36 ft. wide by 31 ft. deep, with a platform in front, the stage being recessed by an archway of 21 ft. span, and 21 ft. 6 in. high, on each side of which are lobbies fitted up with water-closets, lavatories, &c., and dressing-rooms for performers. The basement provides an extensive area of vaults, adapted for letting off for storage. The doorway is the chief feature of the front of the edifice, and is executed in Bath stone, having double pilasters, with carved capitals, raised on a moulded pedestal, with a moulded lintel, supported with light ornamental cast-iron columns, and having a plain frieze and cornice, surmounted with a deep blocking course for a large semi-circular window, which lights the gallery lobby. This is the only noticeable feature of stonework in the building, the other portion of the front being executed in red brickwork, the detail being simply worked out with moulded bricks, slightly relieved with hands of white bricks. The style of the building is bordering on Italian. The roof being the chief feature, is constructed of timber, open internally, in the form of half a hexadecagon, or sixteen-sided polygon, of 50 ft. span, without any tie-rod, the angular portions being relieved with wrought-ironwork. The principals, seven in number, are partly supported on cast-iron columns. The whole of the interior walling is executed in panels of red and white brickwork, ornamentation being obtained by a variety of moulded and perforated bricks and quarrics, which perforations afford ventilation. The lighting is effected by means of wrought-iron sky-lights, extending the whole length of the building on either side. The panels of the ceilings, the archways, and the roof-timber are all decorated in distemper, and the ironwork is painted in party colours. The archway forming the stage has been fitted up with a proscenium border; and a painted act-drop, by Messrs. Day & Watson, of Birmingham, has been hung, representing a harvest landscape. The lighting of the hall by night is by means of fourteen star-light burners, which have been fitted up for the contractors by Messrs. Brown & Chesterton, of Walsall. The red bricks were obtained from the Paddock Works, and the white bricks from the works of the Hednesford Colliery Company.

The heating and ventilation have been carried out by Messrs. Haden & Son, of Trowbridge. The interior decorations have been done by the contractors from the designs and under the special superintendence of the architect.

DWELLINGS FOR THE POOR AND THE NEW LAW COURTS SITE.

SIR,—If the publication of Sir C. Trevelyan's letters in the *Times*, and that powerful journal's advocacy of similar views should prevail, and the Thames Embankment be ultimately selected for the New Courts of Law, might not the site near Carey-street be used for the benefit of that class whose wretched dwellings were cleared away to make room for them? It seems to me that our architects have the genius to cover that vacant space with habitations that would be both ornamental and convenient; and I do not believe the country would grudge the cost (that could not be covered by returns in the shape of rent), of thus supplementing the experiments already made.

But supposing this site cannot be thus utilized, will you, nevertheless, allow me this opportunity to say a word on the general subject of the dwellings of the poor in London. As one walks miles and miles between big uniform houses, evidently adapted only for richer people, would it not be a relief to the eye as well as mind, to see in good positions houses of another kind? I feel confident our architects (and it is because I wish them to see these lines, that I ask you to grant the space for them), could, as occasion offered, build streets for the poor, and at the same time add to, rather than diminish the beauty of the metropolis. Fancy a village without cottages! Why a metropolis without dwellings for the poor, except out of the way, in close courts or dingy back streets? F. F.

DISSENTING CHURCH-BUILDING NEWS.

Landkey.—The new Wesleyan chapel here, erected at a cost of nearly 800*l.*, has been opened for divine worship. The design is in the Middle-Pointed period of Gothic architecture. The plan comprises porch, nave, and an end gallery for the school children. It is built of hammer-dressed Swynbridge stone, with dark bands of Venn stone. The side and end fronts are in hammer-dressed Venn stone. The dressings are in Bath stone. A large five-light window forms the principal feature of the front, with traceried head. Below it, the entrance doorway has pillars with carved Bath stone caps and coloured shafts of Marwood Hill stone. The principal feature internally is the open roof. It is divided into five bays, the principals springing from carved circles in Gannan's Down stone. It is ceiled to the collar, and the whole is boarded and stained. Provision is made for ventilation by a row of cinque foil piercing in the centre of collar ceiling and of quatrefoil piercings in the cornice. Fresh air is admitted by regulator valves in the sills of windows and in the ground-floor aisle. It is proposed to warm the chapel with one of Musgrave's slow combustion stoves. The open seating in ground floor and gallery is framed with inclined backs, book-boards, and hat-rails complete. The gallery front is projected on cast brackets, and is framed with pierced panel framing. The windows are glazed with obscured glass and green border, leaded. The glazing and staining have been executed by Mr. John Clarke, of Barnstaple. The corona lights, suspended from the sweeps of the roof, were made by Mr. Harper, of Barnstaple. The contractors were Messrs. Pulford (Barnstaple), Youatt (Swynbridge), and Southwood (Landkey). The works have been carried out according to the plans, and under the superintendence of the architect, Mr. Lander, of Barnstaple.

Barnstaple.—The Wesleyan new chapel here has been opened for divine service. The plan is a parallelogram 70 ft. by 50 ft., and there is a deep gallery round three of the sides. Care has been taken to provide for ready ingress egress to and from the building, the entrance to the galleries being entirely separate. That to the galleries is by two commodious staircases at the higher end of the building, and that to the body of the chapel and the large schoolrooms, at the lower end. A separate staircase entrance is provided for the Sunday-school children. All the doors open outward from the building so as to give the readiest egress in the event of a panic. The style of the edifice is in the fourteenth century period of Gothic

architecture. The side of the chapel being towards the street, gave the opportunity of scoring an effective façade. The elevation is dependent on the internal plan. It is divided in height by a string-course marking the line of galleries, and the sky-line marking the construction of the roof. For the purpose of ventilation, the roof is divided into nave and transept, and this transept forms the principle feature in the front elevation, rising as a gable to the height of 50 ft. from the street line. In it is a large five-light window with traceried head. In the opposite gable is a proportionate "Alpha and Omega," or wheel-window, of geometric tracery. The entrances are marked with indicated porches, the doorways having pillars with carved capitals and shafts of polished Marwood-hill stone. The arches have mouldings of Early English character. The bays between the porches and transept are filled in with triplet windows accentuated within and without, with pillars having carved caps and bars, and polished shafts of Marwood-hill stone. The heads are filled in with tracery of varied designs. The lower windows are three-light windows, with traceried heads of uniform design. All the arches are in alternate bands of Bath stone and Marwood-hill stone. The cornice is of bold and simple design, formed partly of stone and partly of the ornamental ironwork of the shutes. Some of the members are filled in with carved patera, and the sky-line is formed with running iron ornament. The whole of the front rising from the splayed granite plinth course is in brickwork, faced throughout with Bath freestone. This portion of the work has been executed by Mr. Youngs. The roof is an adaptation of the roof timbers of the old chapel. The galleries are carried on coupled cast-iron pillars, with foliated brackets and pierced intersecting panels. These were from the foundry of Mr. Charles S. Willsheire. They are painted a brown colour, the brackets and caps picked out with gold. The gallery fronts are of pierced panel framing, carried out in brackets from the beams, with cornice and architecturae moulding. Extraction pipes are laid throughout under the galleries, which lead to openings over the gas coronas, and at each end to an opening in the outer wall. Pipes for the ingress of fresh air supplied with regulator valves throughout are brought under the aisles of the ground floor, in the steps of gallery floors, and in the soil-boards of the windows. The lighting of the chapel is by a large quatrefoil corona with clustered lights, hung from the large ventilator in the centre of the nave and transept of roof. On the ground-floor are seven four-light coronas, hung from ventilator in the centre of the gallery ceiling. The whole are painted blue, picked out with gold. The whole of these are from the designs of the architect, and the workmanship of them throughout was done by Mr. Claude Rafara, the manager of the Barnstaple Gas Works. The contractors were—Mr. Thomas Brown, for the mason's work; Mr. William Youngs, for the stone-mason's work; Messrs. Oliver & Son for the carpenter and joiner's work; Mr. William Britton, for the glazier, painter, and stainer's work; the carving, by Mr. Hems; and the polishing, by Mr. Arnold. Mr. Lander, of Barnstaple, was the architect.

SCHOOLS OF ART.

The Birmingham School.—The inaugural meeting of the Students' Art Literature Class has taken place in the Library, Midland Institute. Mr. D. Raimbach (the head master) presided. It was unanimously resolved that the statement of the provisional committee and the draft of the rules be adopted, and that the proposed class for the study of literature will be beneficial to the students of the School of Art. The committee has issued a programme.

The Darlington School.—The annual meeting, conversazione, and exhibition in connexion with this school has been held in the Mechanics' Institute, Darlington. The room was enlivened by an exhibition of the students' drawings, together with a collection of photographs, engravings, etchings, and other works of art from the South Kensington Museum. The Secretary (Mr. J. C. Inanson) read the tenth annual report, which said:—

"The committee of the School of Art have much pleasure in reporting that during the last twelve months the school has been carried on with increasing success. The number of students under instruction has been larger than in any previous year, and the number who passed the ex-

amination in March also shows a considerable increase. The total number of students under instruction at the end of the year, including both the central school and the North-road branch, has been 178, as compared with 161 in 1868; and out of the 191 who were examined in March last, 58 were successful, and to 13 of these prizes have been awarded for special proficiency.

There were also 17 awards made for drawings in the elementary section, in the shape of payments to the school, and out of these 4 were selected as deserving of prizes. Three works were also selected for national competition, but did not succeed in gaining this higher distinction."

The Kidderminster School.—This school continues to hold on its satisfactory course, and the past year's work excels that of all former ones. The annual meeting was held in the Music Hall, Kidderminster. Sir Digby Wyatt presided. The report was in the following terms:—

"The Committee have again the satisfaction of placing before the subscribers and friends to the institution an excellent report of the condition and progress of the school during the past year. The total number of students who have attended the school during the past twelve months has been 81 (an increase of 16 over the previous year); of this number 74 comprise the evening class, and 10 the day class. An analysis of the occupations classified out of these 81 persons shows that about two-thirds of the number are designers, who are thus qualifying themselves for advancing the local trade, and are filling or are about to fill important posts in the various carpet works of the town. The examination in the second grade took place in April last, and out of 82 students who were examined 45 were successful. A competition of the works from the London and provincial schools took place at South Kensington in July last, at which this school was eminently successful. One silver medal (out of the twenty medals competed for by 120 schools), one bronze medal, three Queen's prizes, and seven third-grade prizes, making a total of twelve national awards, were obtained by the students of the Kidderminster School. In order to afford a right estimate of the relative position of the Kidderminster School as compared with others at the Competitive National Examination, it should be observed that only three schools obtained more than two Queen's prizes. South Kensington, with its 992 students, obtained three Queen's prizes; Dublin, with 432 students, four Queen's prizes; and Kidderminster, with its 81 students, three Queen's prizes."

COMPETITIONS.

Grand Haven.—A new Congregational church is about to be erected here. It is to occupy a central and prominent position in the town. A design by Mr. Tait, of Leicester, has been selected in a limited competition.

Hartley Winney New Church.—We are asked to say, with reference to the competition in this matter, that certain drawings are at present retained as being amongst the five best designs received by the committee; that one of these five, "Fides" is preferred, providing the author can satisfy the committee that his plans can be carried out for the sum named in their instructions and the other four, namely, "Well Considered," "Fiat Justitia," "Intergate Solâ," "To be or not to be," are retained for further consideration in the event of his failing to do so.

FLAMBOYANT ARCHITECTURE.

At the Friday evening meeting last week, at the Royal Institution, Mr. John Ruskin delivered a lecture upon "The Flamboyant Architecture of the Valley of the Somme." We avail ourselves of a report of it in the *Telegraph*.

Mr. Ruskin said that he would first explain why he chose "The Flamboyant Architecture of the Valley of the Somme" as the subject of his lecture. Gothic architecture lasted altogether no more than 300 years; it began about A.D. 1200, and expired three centuries later. His object was to inquire why it did not so quickly, whether from any faults of its own, or from other causes. During the three centuries it lasted there were three schools of Gothic architecture. The first was the massive school, wherein the heavy stonework was carved in some simple manner at the edges. Next came the school in which the surface is done away with; the carving becomes important and delicate, and perfectly represents organic forms. In the last school the organic forms are lost, and all the surface is chopped away in an intricate manner. Did the Gothic, then, perish by its own fault or by the faults of others? or was it because no more could be got out of it? or did it give way because other styles were better? To give clear ideas on this subject, he wished to show his hearers something of the very last of Gothic architecture; and the latest he could find in Europe was in the valley of the Somme. The churches here are very numerous, and in the middle of the valley are many which exhibit the Flamboyant, or "flame-like" specimens of the Gothic; for Gothic architecture came to the valley of the Somme to die. It perished before the revival of literature, and before the Reformation, which latter was an entirely illiterate

movement. He wished to impress upon the minds of all present that an artist always leaves the impression of his own mind upon his works, and this as decidedly in architecture as in anything else. A foolish person will build foolishly, and an intelligent man will build sensibly. Therefore, in architecture, the characters of the artists, or of the nation, may be read at any time. When the architecture is too ornamental, the artist was too vain; and when it is too plain, he was stupid, idle, or contemptible. Thus the manners and mind of a nation can be read in its architecture as surely as the presence of a spider's web proves that it was made by a spider. Manufacture is the work of the hands only, but architecture is the work of the spirit. That architecture which is born of valour and honour acquires valour and honour, and its effect upon the nation is invaluable; yet English gentlemen of high standing have denied this principle, and the growth of such ideas has much to do with the decline in English art. . . . Flamboyant architecture is not a granite architecture, like that of Egypt, constructed in a granite age; neither is it a marble architecture, like that of Greece. The Flamboyant is essentially a chalk architecture. The designs are cut deeply upon a soft, cheesy substance, which gives way easily under the chisel, so that the finished design is something like lace upon a black ground; and this is its chief fault of the style. The first style of building (he said) was very simple, and consisted essentially of one stone placed on the top of two others; in later times the Greeks added ornament to this, which is a very stable and simple architecture. Last of all came arches high in air, and things which do stand, yet look as if they could not. Thus, when the mind at last is taken up with mechanical details, it necessarily forgets all about human passions. When masonry deals with passion and poetry it is great, but when it deals with mechanical problems it becomes mean and dies. The artists of the Flamboyant school delighted in loose, fluttering lines, instead of those of organic form; and this was a sure sign of decay. Moreover, they threw into their work a strange fear and melody, derived from their ancient Scandinavian religion, with its dread of a physical hell. Then, at last, the stonework took the ague, becoming loose and wanton, and fantastical. The Gothic did not die because it was too rich, for Beethoven is rich, and so are the clouds of heaven; but it fell because its profusion was cold and heartless, and had ceased to be sincere. It died because it had lost sentiment. Good architecture can only be built by a thoughtful and pure people, by a nation with a common pride and a common wealth. In good architectural work the mason must be pure and intelligent, with plenty of art taste; he must not be paid too much, nor must those below him be paid too little. There must be a common wealth and a common pride to produce good architecture in a nation; that is to say, the taste for beauty must be diffused, and beautiful homes erected for the poor. He did not object to happiness and luxury when everybody was happy and luxurious. At the present time the metropolis is spending seven millions a year upon the London poor, yet pauperism is largely on the increase; the payment shows no generosity; in fact, it is a fine paid by the rich for their neglect of the poor. Instead of lighting candles by daylight, it would be better to light and warm the houses of the poor, and to build up tabernacles that will keep out wind and rain from human bodies. When this is done, luxury may be introduced, and a glorious Flamboyant dragon may be carved over every poor man's door.

THE BOROUGH OF PORTSMOUTH DRAINAGE WORKS.

The corporation have called in Mr. Hawley to report upon the efficiency of the extensive scheme of drainage which has been the cause of so much local dispute and vexation. Mr. Hawley reports favourably of the general arrangements, including the outfall works, upon which the greatest difference of opinion existed. Mr. Hawley states,—"In conclusion I may remark, that whilst I see nothing to condemn, I observe much to commend in the arrangements. In this instance, as in all cases in which the physical difficulties of collecting and discharging the sewage are similar, an amount of intelligence, and watchfulness will be demanded from the officers in charge, altogether unknown under more usual and more favourable conditions." The scheme was designed in 1863, by Mr. Lewis Angell, C.E. The upper and lower level main sewers and outfall works were constructed by Mr. F. Furness, under conditions involving great difficulties. The engine-house was erected by Messrs. Light, and the subsidiary sewers are let at a schedule of prices to Messrs. Neave & Fry. Mr. Grottores is the resident borough engineer.

RAILWAY BRIDGES IN THE METROPOLIS.

Sir,—I have just had a conversation with one of the jurymen who sat on the inquest on the body of the gentleman killed by being thrown from a vehicle, the horse having taken fright from the thundering noise caused by trains rattling through the iron tank (it can't be called a bridge) over Westminster Bridge-road. It came out in evidence that other accidents have occurred from the same cause. The verdict was "accidental death;" thus no one is amenable. Surely, Sir, this danger ought not to be allowed to continue. Railway companies must remedy it. Instances will ere long crash down with a train. Hard wood rails (the inner sides) to be sheet-ironed to prevent the rim from fraying the wood) would do the cin. The first rails were wood, and in America they are so now. It is astonishing the wear and weight hard wood will stand vertically. This clattering of iron wheels on iron rails in iron tanks is intolerable. R. T.

SIZE OF OPERA-HOUSES.

Sir,—Can any of your correspondents oblige me by giving the relative dimensions of the operasouses at London (Covent Garden), St. Petersburg, and Moscow? A. W.

THE GREENING OF STONE.

Sir,—I will be obliged if some of your readers will give any information as to the cause of stone greening over, and how to prevent it. A.

ROAD MAKING AT CAMBERWELL.

Sir,—I have read the correspondence in your paper on roads and road-making. The following has been the process just carried out in this locality. After a long dry summer last year, and when the road had become thoroughly dry and hard, four or five inches of coarse ballast were spread over the entire surface, and rain falling immediately after, this was speedily ground up (at a vast expenditure of horse power) into a quagmire, and deep and remained so for about a week, when more ballast was spread on this, which is now amalgamated with the aforesaid, forming a mixture of mud, horse-dung, and crushed ballast, and which only awaits more rain to be carried away by what they call road-sand or drift, or to be crumpled in blinding clouds of dust by the next wind that blows. SIXTEEN.

LANDS AND RAILWAYS CLAUSES CONSOLIDATION ACTS.

DAMAGE TO GOODS.

Knock v. The Metropolitan Railway Company. The house of the plaintiff in this case received structural damage from the works of the defendants, and damage was also thereby occasioned to his goods. An arbitrator awarded the plaintiff compensation for the injury to the goods, as well as for the other damage. The *Solicitors' Journal* says:—"It was objected, in an action upon the award, that the arbitrator had no power under the Lands and Railways Clauses Act, 1845, to award compensation for damage done to goods. It seems therefore to be an authority on this point, although the universal practice is to give compensation in such cases for damage done to goods. The Court decided that such compensation could be given under the words of the Act, and they considered the matter too clear to grant a rule to have the point argued. It is curious that there should have been any doubt on this question, but probably it has hitherto been thought so clear that the objection has not before been taken, and so, until now, there has been no reported case upon the subject."

BUILDING CONTRACTS.

For some time past the unsatisfactory and uncertain state of the relation between the architect and the contractor, in carrying out work, has been attracting the attention of the architectural profession and of the builders in Liverpool; and some months ago a sub-committee was appointed, at the instance of the Liverpool Architectural Society, to consider the question, and to endeavour to frame such a form of building contract as would be likely to be acceptable to both architects and builders; and which, while leaving no loophole by which the contractor could evade any part of his engagement, might nevertheless protect him from any undue or unjust pressure on the part of the architect. The committee, which consisted, on the side of the architects, of Messrs. T. J. Kilpin, J. Bonit, and H. H. Statlam; and, on the side of the builders, of Messrs. J. Jones, T. Haigh, and J. Roberts, though meeting in a most amicable spirit, had considerable difficulty in adjusting clauses so as to meet the wishes of both sides; the principal difference arising on the questions as to the appointment of an arbitrator to whom each party might appeal in case of dispute, and as to the extent to which bills of quantities should be incorporated in the contract. Finally, however, after a good deal of discussion, a middle course was adopted on both these points, and the members of the committee are now enabled to recommend to their respective societies, the Liverpool Architectural Society and the Liverpool Builders' Association, the following form of contract for adoption. The advisability of adopt-

ing this form of contract, and the means for practically bringing it into operation if approved of, will form the subject for discussion at the meeting of the Liverpool Architectural Society next week:—

"This Contract made the day of 1869, between of the one part, and of the other part, witnesseth, that the parties hereto have mutually contracted and agreed with each other; and the said Contractor, so far as the stipulations and provisions of this contract, and the works, matters, and things herein mentioned or referred to, are to be performed and observed by him, hereby agrees with the said Proprietor; and the said Proprietor, so far as the said stipulations and provisions, matters and things, are to be performed by him, hereby agrees with the said Contractor as follows, namely:—

1. In the construction of these presents, when the Contract will admit of it, the term 'Contractor' shall mean the said ; the term 'Architect' shall mean the or other the Architect for the time being employed by the Proprietor to superintend the erection and completion of the works; and the term 'works' shall mean all the works, acts, matters, and things specified and described in the specification, plans, and other drawings, and detailed bills of quantities supplied, hereinafter mentioned, and such other works, matters, and things as are hereby contracted to be done and performed by the Contractor.

2. The Contractor shall well and substantially, and in the best and most workmanlike manner, with the best materials of their respective kinds, and under the direction of the Architect, make, execute, finish, and complete, and deliver over to the Proprietor, on or before the day of the several works, acts, matters, and things mentioned or referred to in the specification, plans, and drawings already prepared by the Architect and signed by the parties, and in the detailed bills of quantities supplied, with such additions, enlargements, and alterations of, and deviations from, the said works (if any) as the Architect may from time to time, during the progress of the works, direct; but further time shall be allowed, if with reasonable diligence on the part of the contractor, such additions, enlargement, alterations, and deviations should be the cause of delay in the execution and completion of the works.

3. The Contractor shall find all materials, labour, services, tools, scaffolding, implements, tents, and machinery, and power of every kind, for the full, safe, expeditious, and proper carrying on and completion of the works.

4. The Contractor shall be answerable for, restore and make good all injuries, damages, re-operations, and repairs occasioned or rendered necessary by accidental causes, or by flood, storm, tempest, fire, trespass, or other means, to the works, previously to the completion and delivery of the same, and hold the Proprietor harmless from any damage to person or property arising from the Contractor's operations or neglect. The Contractor shall insure the works from damage by fire in the sum of £, such damages to be effected in the joint names of the Contractor and the Proprietor. If the Contractor fails to effect such insurance to the satisfaction of the Proprietor, it shall be lawful for (but not obligatory upon) the Proprietor to insure the same, and to retain and deduct the sums paid for such insurance from any money which may be owing to the Contractor.

5. The Proprietor shall pay to the Contractor, for the full and perfect completion of this Contract, the sum of £. But if the Architect shall direct any addition to, or omission of, or variation from, the works, the value of such addition, omission, or variation, shall be added to or deducted from the said sum of £, as the case may be; and if there should be found to be any error in the detailed bills of quantities supplied, such error shall be rectified, and an addition be made to the Contractor, or deducted from him, as the case may be, in respect of such error.

6. The sum payable under the last clause shall be paid by instalments in manner following, namely—Instalment as the works proceed over every month after commencing the works, at the rate of per cent, upon the value of the work done and materials provided and delivered upon the ground, such materials to become the property of the Proprietor, as certified in writing from time to time by the Architect, until the amount reserved by the Proprietor shall equal 100 per cent. on the said sum of £; and when the same shall amount to such 10 per cent, the instalments shall be the full value of the work and materials so certified, and, after full completion and delivery of works, whatever balance may be owing after the payments aforesaid, and the ascertaining the value of any extras and deductions, shall be paid by the Proprietor to the Contractor within from such completion as payable until the expiration of three days after giving the Architect's certificate to the Proprietor, either personally or, by leaving the same for him at his place of business or residence; and no instalment of a less amount than £; shall be required to be paid during the progress of the works.

7. The Contractor shall, during the execution of the works, when directed and required by the Architect, remove from the Proprietor's premises all materials and works which shall not, in the opinion of the Architect, be in accordance with the specification, plans, and drawings, either as regards quality of materials or workmanship; or which he shall consider unsound, ill-seasoned, defective, unsuitable, or improper. And the Contractor shall, when so directed and required by the Architect, remove and take down all work which the Architect shall best opinion is not done according to the specification, plans, and drawings, or otherwise imperfectly executed; and in either case proper and satisfactory materials and work shall be substituted. And if after forty-eight hours' notice the Contractor shall not comply with such direction or requisition, it shall be lawful for the Architect to cause the removal and taking down of the material and works objected to, and to cause materials and works to be found and executed by some other person or persons, and the costs, charges, and expenses of the same or otherwise as he may think fit, shall be deducted from the amount payable to the Contractor under this Contract, or otherwise shall be paid by the Contractor to the Proprietor.

8. If the Contractor shall become bankrupt or compound with or make an assignment for the benefit of his creditors, or shall wilfully suspend or delay the per-

* The words printed in italics may be omitted when the quantities are taken out by a surveyor appointed or agreed to by the contractors.

formance of his part of this Contract for forty-eight hours, after a notice shall be served upon him or left at his last known place of abode by the Architect requiring him to proceed with and perform the same, it shall be lawful for the Proprietor by the Architect to enter upon and take possession of the works, and to employ any other person or persons to carry on and complete the said works, and may authorize him or them to use the plant, tools, materials, and property of the Contractor there being, and the costs and charges incurred in any way in carrying on and completing the said works shall be paid to the Proprietor by the Contractor, or he set off by the Proprietor against any money due or to become payable to the Contractor.

9. The Contractor shall, if the Architect direct, suspend the whole or any part of the works during inclement weather; and if the same shall be suspended by such direction, or shall be necessarily suspended from any cause over which the Contractor has no control, or any local or general strike, then the completion of the works may be delayed for a period equivalent to the time of such suspension.

10. In case the works and things hereby contracted to be done by the Contractor shall not be done and completed at the time hereinbefore mentioned, the Contractor shall pay on demand to the Proprietor, as liquidated and ascertained damages, a sum not exceeding £10 for every week which may elapse between the appointed and actual time of completion and delivery hereinbefore mentioned, or the Proprietor may deduct the same from any moneys payable or to become payable to the Contractor, allowance being made for delay, if any occasioned, in the execution and completion of the works by reason of additions, enlargements, alterations, deviations, and other causes, as provided for in Clauses 2 and 3.

11. The Contractor shall provide and keep on the premises where the works are to be carried on a good and efficient foreman; and if the Contractor shall not provide such foreman, the Architect shall be at liberty, first giving forty-eight hours' notice in writing to the Contractor to employ a foreman, and the costs of so doing shall be paid by the Contractor; and if the Contractor's Architect may dismiss any foreman, and also any workman, for incompetence or misconduct.

12. Should any flaws, cracks, settlements, shrinking, or other defects arise or occur during the progress of the works, or within after the delivery thereof, arising from bad materials or workmanship, the payment of moneys due on the giving of any such certificate as aforesaid by the Architect shall not exonerate the Contractor from liability, but the same shall be rectified by him at his own expense.

13. The Contractor shall give all necessary notice to the Road Surveyors or other Surveyor, and to all other persons or persons to whom notice is required to be given.

14. The Contractor shall not assign or sublet this contract, or any part thereof, without the consent of the Architect.

15. If in any difference between the parties touching the premises, they or either of them shall be dissatisfied with the decision of the Architect the subject shall be referred to a referee; but if he shall refuse to act, or shall die, then to such person as the President for the time being of the Liverpool Antiquarian and Archaeological Society may appoint, it being understood that such reference shall not be opened until the works are completed, without the concurrence of the Architect; and this sub-mission to arbitration, with the award of the arbitrator, may be made a rule of any of Her Majesty's Courts of Record in England. The cost of the arbitration and award shall be in the discretion of the arbitrator.

As witness the hands of the parties the day and year first before written."

METROPOLITAN BUILDINGS ACT.

LIABILITY OF OWNERS FOR FEES.

Mr. G. Wood, of Devonshire Wharf, Camden Town, was summoned before Mr. Dayman, at the Wandsworth Police Court, for the sum of £1 18s, district surveyor's fees due from him as the owner of six houses in Fenchurch-street, Wandsworth-road. The defendant pleaded that at the time the fees came due he was not the owner, being merely the mortgagee; that though he had subsequently fore-closed, he had since parted with the property, and was not now the owner; and that the builder was the proper person to pay the fees. Mr. Dayman decided that any builder, owner, or occupier, is liable under the Act; and that the fees being of the nature of a charge on the property, any owner is liable, provided he is the owner at the time the claim is made upon him; and that having subsequently parted with the property, did not affect his liability. He also ruled that the mortgagee is the owner, though he may not have foreclosed.

ARBITRATION CLAUSES IN CONTRACTS.

The leading builders of London and of the provinces have had under much consideration lately the effect of the Arbitration Clauses in Contracts, and have been in communication with the Institute of British Architects on the subject. As contracts are now drawn, the architect is absolute,—practically he may act with injustice towards the builder, the latter being entirely without remedy. The only plea on which such power can be placed in the hands of any individual is, that he should occupy the position of an umpire or judge without bias on one side or the other, and this is a position which some architects conceive they ought to occupy. But the builders say with justice that an architect is naturally bound up with the interests of his clients, who employ and pay him. Moreover, he has often to decide on matters in which his direct personal interests are concerned. The architects say, "We are quite willing to give an arbitration clause as regards the value of extra or omitted works, but on no other point." The builders reply that this arbitration clause is utterly useless, unless there can

be also a reference as to the builder's right to a final certificate of completion; for, according to the wording of all contracts, the architect's certificate is made a condition precedent to obtaining payment, and although the amount due to a contractor may be definitely settled, he is unable to enforce payment of the same without the architect's certificate, which may be withheld without any reason being assigned. Such is the law.

Two cases may be cited to show the arbitrary unfairness of the working of this condition. In one case, the builder was directed by the specification to use material unfit for the purpose. When the building was nearly finished the unfit materials had to be substituted by other materials. The architect in this case refuses his certificate until the builder consents to deduct from his account a sum equal to the whole cost of the substituted materials, and this he does manifestly in order to save himself with his client. In the other case, the builder was bound in a heavy penalty to complete by a certain date; the architect leaves his office for some weeks, during which the builder is brought almost to a standstill for drawings and instructions; the accounts are made up and agreed to, but the architect says, "I will not give you my certificate (the only mode by which you can obtain payments) unless you consent to take off a large sum by way of forfeit for delay." Here, again, the architect is able to make the contract in his own indulgence, because the contract is so drawn that he is absolute master of the situation. The builders consider it high time that such a state of things should be amended. A. B. C.

YORKSHIRE ARCHITECTURAL SOCIETY.

A GENERAL meeting of the members of this society has been held, in the council-room of the Yorkshire Philosophical Society, at York. The hon. and very rev. the dean in the chair. The attendance was only meagre. The Rev. Geo. Rowe read the report, which was adopted, and which stated that the committee had the pleasure of reporting that the flourishing condition of the society in former years continued, both as to the number of members and the state of the finances. The reappointment of the committee and officers of the society took place; and the Rev. G. Lewthwaite then read a paper "On the Antiquities of the Parish of Adel," about six miles from Leeds. The Rev. Geo. Rowe then, referring to the church at Brompton, Northallerton, said that in digging the foundations for the reconstruction there were found several crosses and cross slabs and other stones. The crosses were of the same age probably as the other stones, having the same interlaced cord as an ornamentation. Of the other stones there were portions of eleven or twelve. These were about 4 ft. 4 in. long, 1 ft. 4 in. high, and 6 in. in thickness. They had stood in the ground on one of the longer sides, and either end had a figure which was most like that of a bear, sometimes with two, sometimes with four paws. It was usually muzzled, but in one instance the paws acted as a muzzle. Out of their mouths proceeded the upper member of a rude characteristic ornamentation, consisting of various forms of fretwork and interlaced hands. In some cases an arch was sunk a short distance into the middle of the lower part of the stone. The Rev. J. R. Lunn then read a paper descriptive of the ecclesiology of the rural deanery of Knaresborough, in the diocese of Ripon.

LIGHT AND AIR.

WHEN DOES RIGHT COME.

Courtoult v. Leigh.—This was a special case, in the Court of Exchequer, in which the facts were stated by an arbitrator for the opinion of the Court, and raised a question both novel and important with respect to the condition as to the completion and fitness for habitation in which a newly-built house must be before the owner of it can gain any right to light and air as against an adjoining proprietor. The plaintiff's and defendant's premises were adjoining houses in Lewes-creecent, Kemp-town, Brighton. In 1830 the plaintiff's house having been recently built, was, after remaining some time in carcase, completed, so far as the structure was concerned, and had windows formed and casements put in, but it was still unfinished internally, and unfit for habitation. More recently, and within the last twenty years, it was finished and inhabited. More than twenty years after this, defendant

added rooms at the back of his house, whereby the access of light and air to the plaintiff's windows was diminished.

Mr. Garth, Q.C. (with whom was the Hon. Mr. Thesiger), for the plaintiff, contended that so soon as the house and windows were completed the plaintiff's right began to run as against the defendant.

Mr. Charles E. Pollock (with whom was Mr. Thripp), for the defendant, contended that so long as the plaintiff's house remained unfit for habitation, there was no such enjoyment as was requisite to acquire a right under the statute.

The Court gave judgment for the plaintiff, holding that the house, being finished in 1830, all but internal fittings, and the windows being put in, the plaintiff's right dated from that period, and consequently that he had enjoyed it for more than twenty years, and was entitled to maintain an action against the defendant for the disturbance of it.

THE CHARGES FOR QUANTITIES.

Sir.—A paragraph in your paper with respect to the Halifax Board charging for sketches, and your opinion thereon, prompts me to say that the architects of a London job, for which I see twenty-three firms tendered, had the modesty to demand a guinea for every copy of quantities, not to be returned, as I positively ascertained, in this case producing very nearly 1 per cent. on the job beforehand. Do you know of any precedent for such practice?

AN INTENDING COMPETITOR.

MONUMENTAL.

The Monument to Alderman Beckford.—It has been resolved by the Court of Common Council to restore the monument to Alderman Beckford, in Guildhall. Mr. Higginbotham, in moving the resolution, alluded to a statement by some clever fellow in one of the daily papers a few days ago, in reference to the motion, that it was very doubtful whether the speech reported to have been made to his Majesty George III. by this great City worthy, on the 23rd of May, 1770, had ever been uttered by him; and he read extracts from the "Annual Register" of that date, and the minutes and journals of the Court of Common Council itself, which, he said, left no doubt whatever that the speech really was made as represented.

The Statue of Queen Anne, in Leeds.—It has now been decided to keep the statue of Queen Anne at the Leeds Town-hall, and workmen have been engaged in placing her Majesty in the niche at the right-hand side of the Great Geopre-stre entrance. There is a vacant niche on the opposite side of the entrance.

Robert the Bruce on a Corinthian Column.—A meeting has been held in the small town of Lochmaben, in Scotland, which claims, together with Turnbury, to have been the native place of King Robert the Bruce, and resolutions have been agreed to by acclamation, that a statue of Robert be placed on the top of a Corinthian column at Lochmaben, the figure to be looking towards Banockburn and Edinburgh, and pointing to Dumfries,—that is, looking in two directions and pointing in a third. One speaker said the Wallace Memorial at Stirling should encourage them to proceed: we should have rather thought it would discourage them. At any rate, anything more ridiculously inappropriate than a Corinthian column with the Medieval Bruce on the top of it could scarcely be suggested.

Books Received.

Metropolitan Board of Works: Ideas of the Streets and Places in the Metropolis. WATERLOW & SONS, Printers, London-walk.

This very comprehensive index of the streets and places in the metropolis, according to the existing nomenclature, has been compiled by Mr. Newall in the department of the Superintending Architect, to assist the Board and its officers in the naming of new streets, under the 87th section of the Metropolitan Local Management Act of 1862. It has been in preparation for several years, according as opportunities permitted. Copies are to be sent to the vestries and district boards, and to the Post Office authorities and county courts, for use and revision, and are to be placed in the hands of the nomenclature clerks and

examined in each locality. By these means it is hoped that the Board will soon be in possession of an amount of information in reference to the existing arbitrary and irregular nomenclature that will render the work of reforming it extremely easy. The present index is simply a proof for revision; we may very shortly expect to have in succeeding issues a standard list. There is great need for such a revision and reform of street nomenclature. The number of streets of the same name throughout the metropolis is extraordinary. There are no less than seventy John-streets, for example, over and above a long list of John-streets North, John-streets South, &c., &c. There are long lists, too, of Cross-streets, Crown-courts, King-streets, and a host of others. The re-naming the whole will be a task of no little difficulty. The Board have already made some little progress, but that is as nothing to what has yet to be done. We may here state that the new street leading from the new meat-market to the top of Holborn-hill has been named Charterhouse-street. The open space of ground at the top of the hill, facing Hatton-garden, will be called Holborn-circus; a new street, called St. Andrew's-street, to connect Holborn-circus and Farringdon-street, will pass at the back of St. Andrew's Church, cross Stonecutner-street, and open into Farringdon-street, near Black Horse-court.

VARIORUM.

The *Popular Science Review* for January, is a generally interesting one. The leading paper is on Flying Machines, by Mr. F. W. Brearey, honorary secretary to the Aeronautical Society of Great Britain. In a paper on the planet Mars, by Mr. Proctor, there are a series of curious and new diagrams and sketches, with a new chart of the planet. "Report on a Project for the Drainage of Bombay. Also Report on Mr. Sowerby's Memorandum on the Drainage of Bombay." By Hector Talloch, Captain Royal Engineers. Bombay: printed at the Education Society's Press, Byculla, 1868. Captain Talloch's project appears to be entirely in accord with the views of the Secretary of State and the recommendations of Mr. Rawlinson. It proposes to utilize the sewage for irrigational purposes at a point distant from the town, and thus in the long run to make the works remunerative. If such utilization is found a failure, the sewage can still be discharged at Colaba or anywhere else at a less cost. The whole island and the city, present and future, would be drained by this project, while Mr. Aitken's leaves, it is said, a great portion untouched. The storm waters would be separated from the sewage, and all the floods on the flats and the town drained. The total cost, including sewage utilization, pumping station, outlets to the sea, and of course the sewers and street drains, sluices, manholes, &c., would be about 75 lakhs of rupees.—North of England Institute of Mining Engineers: On the Hauglage of Coal; being the Report of the Committee appointed by the Mining Institute to investigate the Subject." Newcastle-upon-Tyne: A. Reid. 1869. This voluminous report contains a mass of information as to haulage of coal by endless chains, endless ropes, &c., both above ground and below, including details of many experiments, and upwards of fifty illustrative plates.—Cassell's Primary Series: "The Boy's First Reader, for Elementary Schools." Part I.: "The Girl's First Reader;" Part I.: "An Explanatory Introduction to Geography, for Elementary Schools," by F. Young, F.R.G.S., Cassell, Petter, & Galpin. These are enticing little books for children, well adapted to excite their interest by engravings, which are also useful in illustration of the simple lessons taught.

Miscellaneous.

Communication between Passengers, Guards, and Drivers.—Mr. Weir's atmospheric system has been tested on the South-Western Railway. The whole principle of the plan is the transmission of pulsations of air through tubes communicating with air chambers, and giving motion to a simple arrangement by which a bell is struck. A lever fixed to a rod releases a short sonaphone or signal arm, which, dropping down at the side of the carriage, at once indicates to the guard the spot where he is wanted.

The Science and Art Exhibition for South Staffordshire.—This exhibition, which is to be opened in May next, and closed at about the end of September, will have a building erected for the purpose. Molineux House, which the committee have taken, will be made available, but more as an annex than otherwise, the exhibition being that presented in the main building. That structure will take the form of a large central nave, 150 ft. long by 60 ft. wide, roofed over in one span. The framing will be of timber, covered externally with corrugated iron over felt on boards, and internally it will be lined with boarding. A gallery 14 ft. wide will be framed along the north and south sides, and 19 ft. wide at the ends of the building. Two annexes or wings added on each side the main building increase the ground floor area to a total width of 80 ft. The approach to the building will be under a covered way from the garden entrance of Molineux House. The main building is progressing with rapidity. It was commenced on the 8th inst., and it will be given up for use on the 31st of March. The contractor is Mr. F. N. Clark, of Wolverhampton, and the architect is Mr. George Bidlake, of the same town. Messrs. R. Lowe & Co., nurserymen, are re-arranging the grounds.

General Exhibition of Water-Colour Drawings.—The fifth exhibition of water-colour drawings in the Dudley Gallery, Egyptian Hall, Piccadilly, comprises 721 works. It can scarcely be considered equal to its predecessor, but is nevertheless an interesting collection.

Society of Engineers.—At the meeting of the Society of Engineers, held on the 1st inst., Mr. F. W. Bryant, president, in the chair, a paper was read on "Explosive Compounds for Engineering Purposes," by Mr. Perry F. Nursey. The following candidates were balloted for, and duly elected Associates, viz., Messrs. Charles Cockburn Gibbons, and Alfred Rubery.

Public Mortuaries.—The movement for providing these buildings in the metropolis appears to be progressing. A large number of the north-eastern and north-western parishes have already arranged for their erection in suitable localities, and the eastern districts seem to be following their example with commendable rapidity. At a late meeting of the Poplar Board of Works the plans for the erection of a mortuary for that parish, as approved by the medical officer, were agreed to, and forwarded for the approval of the rector and vestry. A site is being sought for one at Bow. The term "mortuary" is scarcely the right one for these receiving-houses, but seems to be pretty generally adopted.

New Forms of Permanent Magnet.—A discovery has been made by an old contributor to the *Builder*, Mr. F. A. Paget, C.E., which must become a subject of interest among electricians. It is well known that it is impossible to magnetize a plate except in the direction of its greatest length; and that a square one cannot be made to show magnetic action at all. Mr. Paget, however, finds that by cutting slits nearly up to the middle of a steel plate, a square plate in one piece can with such slits be regularly magnetized; and by this means even an oblong square plate can be regularly magnetized and with as many poles as may be required, in a direction transverse to its greatest length. Mr. Paget also suggests that a parallelepipedon or cube may, perhaps, be convertible in this way into a connected series of magnets. It may be said, of course, that it is just separate oblong magnets that are thus made; but they are not separate; and the influence of this Siamese twin sort of connexion is just one of those curious points which require investigation. May not the oblong connexion be in itself a diamagnet? and if so the mutual reactions of the diamagnet and the magnets, may evolve something new in regard to magnetic and diamagnetic laws.

Maldstone Cottage Improvement Company (Limited).—The annual meeting of this useful society has just been held. It was reported that the shares taken up to the 31st of December last amounted to 4,200£. The net income for the year amounted to 298£ 2s. 7d., out of which a dividend was declared at the rate of 5 per cent., the balance (65£ 10s. 5d.) being added to the reserve fund, which now amounts to 250£ 0s. 5d. Since the last report eight cottages have been purchased, making now 55 in possession of the company. Many cottages in the town still urgently require improvement.

The Improvement of the Cam.—The works were commenced on New Year's day. The contractor for the first part of the work—dredging and restoring the river between Jesus Sluice Locks and Baisbita to its original depth and width—has commenced operations with the powerful dredger of the South Level Commissioners at a point nearly opposite Logan's boat-house. When the new dredger, just built for the Conservators of the Cam, has done its work of dredging the river between Queen's College and Jesus Sluice Lock, it will probably be also at the disposal of the contractor. The other measures proposed by the committee, under the advice of Mr. J. Hawkshaw, are—widening the passage through the railway bridge, and reducing the sharpness of some of the most prominent corners. The rough estimate for carrying out all these improvements was 6,000£, of which upwards of 5,000£ have been already subscribed.

Masonic Archæological Institute.—On the 29th ult. the first meeting of this institution, just established, was held at the Freemasons' Hall, Mr. James Glaisher in the chair. Several donations to the library and museum were reported. The inaugural address was delivered by Mr. Hyde Clarke, treasurer, pointing out, as subjects for investigation, the history of Freemasonry in the last century and middle ages; its relations to secret societies and guilds and associations of working men; the possible influence of gnosticism and the ancient mysteries on its symbolism; and its place in the study of the philosophy of the human mind. A vote of thanks was moved by Mr. Glaisher, seconded by Mr. C. H. Gregory. The next paper was announced to be on the ritual used by Frederick the Great when Crown Prince, brought over to this country recently by his Royal Highness the Crown Prince of Prussia.

Buildings in Birmingham in 1868.—The Borough Surveyor has made his usual return of the number and class of buildings erected in Birmingham during the past year, in accordance with plans registered at the surveyor's office. In the total the number is higher than for the four preceding years, as will be seen from the subjoined comparison:—

Year.	Buildings erected.
1861	952
1862	1,359
1863	1,694
1864	1,419
1865	1,056
1866	1,411
1867	1,408
1868	1,513

House building is considerably on the increase within the borough, as compared with the last four years, and the number of houses built in 1868 is much higher than the result given by a long average.

Preparing for Earthquakes.—Some time ago we pointed out the desirability of building with reference to the possible occurrence of earthquakes. The citizens of San Francisco have formed a committee to inquire into the means of preventing or lessening the destruction of property by such disasters. The bricks used in building are reported to be very defective, and it is proposed to adopt a method of bracing buildings with iron rods.

The Chicago River Tunnel.—The tunnel under the Chicago river, known as the Washington-street tunnel, connecting the south and west divisions of the city by a roadway, has just been completed, and was opened to the public on New Year's day. The contract price was 328,500 dollars. The length of the work is about 1,605 ft.; of the retaining walls of the open approach, on the west side, about 320 ft.; and 275 ft. on the east side. The length of the main archway, or covered way, is 952 ft. There are three archways leading through the tunnel; one is for foot passengers, and two are for teams and horses.

Reclamation of Land.—Sir: I am very glad that in mentioning Mr. Wheeler's "History of the Fens," you called attention to the waste land that might be brought into cultivation on our coasts, as it seems to me that no more desirable channel could possibly be found for the surplus capital of the country than in bringing these lands into cultivation. I am aware that you have on many former occasions brought this matter forward, but public attention cannot be too often called to it until something new is done, and it is just one of those measures for the public good that the *Builder* especially delights in advocating.—H.

The Knightsbridge Barracks.—The desirability of removing these barracks, as often urged by us, is further strengthened by a circumstance recently referred to by the *Lancet*. Several of the officers have been driven out of their apartments by an unwholesome smell, as of decomposing animal matter, which has been felt ever since a chimney took fire in one of them. The usual futile endeavour to obtain an authoritative investigation into the cause has been made; but no such investigation has yet been allowed, and the cause is still undiscovered. It has been suggested that the fire may have smoked or burned a colony of rats to death, and that the nuisance may arise from their decomposing bodies.

College Improvements at Cambridge.—Alluding to the late attempt to Gothicise the Hall of St. Catherine's College, as a first step towards the renovation of the whole of the college in the same style, the *Guardian* says:—Most of our readers are familiar with the plain, respectable, but perfectly uninteresting red-brick buildings of this college. Any alteration, they may be inclined to think, must be for the better. This is hardly the case at present. Perhaps when the work is carried further, the effect may be less incongruous. The new Gonville Court at Gains College is rapidly rising, and has now reached the second story. It will be a picturesque building in the Renaissance style, recalling the Chateau at Blois. The architect is Mr. Waterhouse, to whom Cambridge is also indebted for the "Union"—the club, not the workhouse. Trinity is beginning to reface its chapel with stone, and, therefore, we may conclude, is not intending to enter into competition with St. John's, whose new chapel—Mr. Scott's design—is approaching completion. The carved wooden ceiling is being decorated with polychrome; it will exhibit in its eighteen compartments representative men of the eighteen Christian centuries; our Lord in majesty fills the nineteenth compartment over the altar. The designs and execution are due to Messrs. Clayton & Bell, who are also employed on the windows.

The Noxious Vapours in Galvanizing Works.—The Wolverhampton Corrugated Iron Company have adopted a plan of consuming the bath vapour in galvanizing iron, for which they have secured provisional protection, and with which Mr. R. Baker, factories inspector, it is said, expressed his decided satisfaction when he lately saw it in operation. The top of the bath in which the process goes on is surrounded by an open flue, which forms a projecting lip, and from this run one or more pipes, which communicate by a powerful fan worked by a steam-engine. From the fan a large flue extends to a furnace, which in this case is used for annealing the sheets or articles galvanized. The fan, by exhausting the air from the pipes which extend to it from the bath, causes a strong downward current of air to sweep over the surface of the metal, which drives the vapour into the flue, down the pipes, and from the fan to the furnace, where it is entirely consumed.

The Longley Memorial Church at Oxford.—It is proposed to erect a church at Oxford to the memory of the late Archbishop of Canterbury. The site of the building will be in the new ecclesiastical district of Cowley St. John. Cowley was the first scene of Archbishop Longley's pastoral labours. The village church in which he used to labour has been recently enlarged and restored. It is proposed to erect the new church for 1,000 persons within a few paces of Magdalen Bridge, the anticipated cost being from 15,000, to 20,000. The new Archbishop of Canterbury and the bishop of the diocese have promised their support, and upwards of 2,000, have been already promised or subscribed.

Destruction of a Picture Gallery by Fire.—A destructive fire is reported from Exeter. The picture-gallery of Mr. Hodge, near the Guildhall, was found to be on fire, through, it is supposed, an explosion of gas. In a short time about a hundred pictures were destroyed, including one by Rubens, for which 900l. had been offered.

"Masonic Buildings."—In reply to "H.," a one correspondent, "I. B. S." advises him to study a Lodge in Weymouth, built about the beginning of the present century. Two other correspondents offer to advise personally, but to this we cannot be a party.

The Maidstone Sewage Question.—The local Board have decided upon borrowing 9,000l. for the purpose of proceeding with the drainage of the town, leaving the question of the ultimate disposal of the sewage for future consideration. The scheme originally proposed by the Board was of a much larger and more expensive character: the estimated outlay, as submitted by the authors of the plan, fell little short of 25,000l. The Board now throw aside altogether—at least, for the present—the most difficult portion of the subject, namely, the ultimate disposal of the sewage, and confine their proposal to the completion of the existing system of drainage in the town.

The Proposal to Supply London with Water from the Severn.—At the twelfth annual meeting of the Canal Association, held at Birmingham last month, Mr. E. Leader Williams, speaking of the river Severn, and particularly in connexion with Mr. Bateman's project for supplying London with that which he designates "the surplus water of the Severn," to the extent of 200,000,000 gallons per day, observed that nothing was known of any surplus water, inasmuch as the maintenance of the estuary of the river is dependent upon the velocity and volume of the winter floods, without which the estuary and the whole of the lower reaches of the river would become choked with mud and silt brought up by the far too powerful spring tides. The tendency of these tides to choke up the lower reaches of the Severn had, he said, been specially demonstrated during the drought of the past summer, as the deep reaches and pools near Gloucester became so filled with deposit as to prevent navigation, depending upon the top of spring tides.

Birmingham Society of Artisans.—The annual dinner of the Birmingham Artisans' Society was held on Monday evening, at the Acon Hall, Temple-street, Mr. George Dixon, M.P., occupied the chair, and Mr. J. A. Langford the vice-chair. The Chairman, in proposing "The Birmingham Artisans' Society," said that during the past year three papers on different subjects had been read by members of the society, and a memorial had been sent to the Society of Arts, advocating the claims of such towns as Birmingham to Government contributions for local museums. When Mr. Samuelson obtained a committee of the House of Commons to investigate the large question of scientific instruction, one of the members of the Birmingham Artisans' Society was sent up to give evidence,—the only representative of the working men from the whole country which appeared before that committee. The Chairman then reviewed some of the leading questions of the day, in which he desired to see such a society become interested.

The Count de Beerski, Painter.—The American papers record the death, at Rochester, New York, of Count de Beerski, a Russian nobleman, and an artist of considerable repute. He inherited a valuable estate near Moscow, together with 250 serfs, all of whom he emancipated. When Nicholas ascended the throne, the count, in consequence of his liberal views, was obliged to leave his native country and all his possessions. Accustomed as he had been to wealth and luxury, he now found himself obliged to do something for subsistence. He was well educated, and possessed a taste for drawing. He resolved to paint miniatures; and in Hamburg, Paris, and London attracted considerable notice as an artist. Some of his paintings were exhibited in Hyde Park in 1851, and won first-class honours. Count de Beerski was subsequently employed, we believe, to paint portraits of her Majesty and the Royal Family. He emigrated to America in 1859, and was much esteemed by all who knew him.

A New Bath-heating Stove.—Mr. Richard Head has invented and patented a stove so constructed as to fill the usual opening of a fireplace, and act as an ordinary stove, while it is surmounted by a boiler sufficiently large to supply a bath. The boiler has tapering flues running up through it, and it is partly surrounded by hot-air spaces so that the heating of the water is said to be effected in a much shorter time than by other bath-heating stoves. The bath is filled through a pipe, and may be placed anywhere either on the same floor, or a floor below. The filling of the boiler is also effected by a pipe. The arrangements are said to prevent risk of explosion, and avoid filling the room with steam.

Deptford Paving Tenders.—At a recent meeting of the Greenwich Board of Works, the road surveyor presented a plan and estimate with regard to the paving, &c., of Manor-road, Upper Lewisham-road, Deptford. The report having been adopted, Mr. Halsey moved that tenders be advertised for in respect of Manor-road. Mr. Gillespie seconded, and (it being understood that the advertisements would be sent to the local papers as well as the *Builder*) said he considered the former a useless expenditure, for every one likely to send in a tender would read the columns of the *Builder*. He did not wish to disparage the local papers, but believed as a matter of economy it would be unprofitable to send to them. Mr. Bartlett and others were of a different opinion, and it was agreed that the advertisements be sent to the *Builder* and the local papers.

Death of the late Borough Surveyor of South Shields.—Mr. T. M. Clemence, late borough surveyor of South Shields, is dead. The deceased gentleman had been connected officially with the borough some eight or nine years, and by his gentlemanly and scholarly bearing, it is said, won the friendship and respect of all who knew him. He was about forty-two years of age.

Mr. Sedding, of Penzance, architect, read a paper lately before the Exeter Diocesan Architectural Society, upon the interesting churches of St. Buryan, St. Leven, and St. Sennen.

TENDERS.

For alterations to 281, Westminster Bridge-road, for Mr. Page. Mr. W. E. Williams, architect.	
Nixon & Son	4,633 0 0
Ennor	472 0 0
Auley	459 0 0
Marr (accepted)	431 0 0
Fittings, Extension of Front, &c.	
Marr	163 18 0

For alterations and additions to Grapes and Can, Goswell-road, for Mr. May. Mr. W. E. Williams, architect.	
Tracey & Co.	537 0 0
Marr	477 0 0
Auley	425 0 0
Ennor (accepted)	419 0 0

For the erection of Lancaster Buildings, Titebarret-street, Liverpool, for the Liverpool Financial Association. Messrs. Pictor, Chambers, & Bradley, architects. Quantities supplied.

The Builder.

VOL. XXVII.—No. 1358.

The New Law Courts and the Offices.

THE question of the site of the New Law Courts and Offices is now exciting so much attention, that we have thought it right to obtain the means of arranging the plan which we present to our readers to-day.* It shows Mr. Street's enlarged plan of the Courts as exhibited at the Royal Institute of British Architects, modified in accordance with Mr. Tite's suggestion for the division of the building as brought by him before the Metropolitan Board of Works on the 22nd of January, 1869. His observations on the subject we gave

soon after. We intended to give a plan of Sir Charles Trevelyan's site, derived from his descriptions; but as he announced in the *Times* of Saturday last that he is about to publish it himself, we, of course, willingly wait for that document. Our remarks on the present occasion apply mainly to Mr. Tite's proposition. We should be glad if we could go with those who urge that Courts and Offices should all be placed on the embankment side of the Strand; but careful consideration has led us to the belief that this cannot be wisely done; the rigid limits of the site (the Embankment, the Strand, Somerset House, and the Temple) preventing the possibility of any extension hereafter, the enormous extra expenditure it would entail, notwithstanding what has been said to the contrary, and its inferiority in point of convenience for lawyers, are all against it.

The Incorporated Law Society, in a protest just now issued, say:—

"The Carey-street site has been purchased; nearly 800,000*l.* have been expended in its acquisition; nearly all the buildings have been cleared away; a number of architects of eminence were invited to compete for the office of architect; full and elaborate instructions for the guidance of the architects were prepared under the personal superintendence of members of the commission; the several designs underwent a very careful and minute examination; an enormous amount of labour was bestowed on the several plans and arrangements by the several members of the commission; after Mr. Street had been appointed the architect, the commissioners were in constant communication with him, arranging the details of the final plans; and this laborious work of years has been so far completed, that it was confidently expected the buildings would be commenced in the spring of this year.

All the plans and the arrangements for the grouping of the several courts and offices so as to afford the greatest amount of convenience to all who have business to transact there, have been made with reference to the special form of the Carey-street site. A site of any other shape would render necessary new plans and other internal arrangements. In fact, for a site of a different shape, a great part of this labour would have to be undertaken anew.

It is part of the Carey-street design that the courts should be placed on the first floor, in the inner quadrangle, and that, for ensuring to the profession safe and convenient access to the courts and offices, bridges on the court-floor level should be thrown across the Strand and Carey-street, so as to avoid the risk of crossing either of these thoroughfares among the carts and carriages. Hostile criticism has attempted to direct the shaft of ridicule against courts placed so high as the first floor. The critics possibly forgot that the Houses of Parliament are on the first floor, and the court of the Judges, the Committee of the Privy Council also; and that those important tribunals, the committees of the House of Commons, are on the second floor."

* See p. 126.

The comparative advantages of the two sites depend unquestionably on the comparative facilities of access. But the access wanted is for the legal profession, not for laymen, and from the private chambers and offices of the bar and solicitors, and not so much from railway stations.

"The number of jurors, witnesses, and others daily called direct from their own homes or offices to the courts and offices of the law is comparatively small; certainly not 2,000 a-day. A large number of the witnesses go to the attorney's offices on their way to court. But it has been ascertained from accurate observation that in the transaction of the business of suitors from 12,000 to 15,000 visits are daily made by the solicitors and their clerks to the different offices, going and returning several times in the course of the day, and nearly as many visits probably are daily made by them to the several courts. If several hundred yards be added to the distance to be on each occasion traversed in from 12,000 to 15,000 daily visits to the offices, and as many to the courts, it is vexatious to contemplate the miles on miles of wasteful traversing which would be inflicted on the profession, and through them on the suitors, and the weeks and months of delay which will be added to the inevitable annoyances of litigation."

Since this matter came under discussion, another suggestion has been made, namely, to take the Probate Offices to the new Offices, Fetter-lane. But, with the extensive arrangements required for the archives, our figures will presently show that no sufficient space can be found there for such a purpose.

That more land must now be bought if all the Courts and Offices are to be erected on the Strand site appears certain, and the question must be asked, who is to blame for the error of calculation that has been made. When we remember the enormous and costly machinery that was set in motion to obtain all the information requisite to determine what was wanted, the present state of things seems inexplicable, and scarcely excusable.

Let us look now, however, to the plan we publish. It has appeared to many that in attempting to combine in one building the whole of the new Courts and Offices, the zealous advocates of concentration might go too far. Mr. Tite urged this view of the case in the House of Commons last session, and much that has occurred lately has tended to strengthen the impression that the separation of the Offices from the Courts would be an advantage, both architecturally and otherwise. This view has found many supporters in the press, who have advocated the division of the work, and pleaded for a reconsideration of the question on the basis of the suggestion of two buildings instead of one. It will be seen by the plan that Mr. Tite proposes to build the Courts on the present Strand site, and to place the Offices on the Thames Embankment in a building which would admit of ready extension. At present the portion on the Embankment, including the first quadrangle, would be all that is required, as will be seen by a few figures.

The proposal now before Parliament is to spend 600,000*l.* in acquiring additions to the present site; this sum does not include the expense (which must be very large) of forming any new streets for access to the new Courts and Offices. The necessity for this large expenditure would be altogether avoided by the adoption of Mr. Tite's plan, according to which the cost of the site would not exceed 250,000*l.*, while its accessible position would render it unnecessary to lay out anything in forming new streets. The cost of the Embankment site for offices has been estimated by an experienced surveyor, and though it does not include any frontage to the Strand, and only involves the purchase of yards and unimportant premises, it is not considered prudent to estimate it at a lower figure than has been said. Judging by such data the cost of Sir C. Trevelyan's site, with its expensive frontage to the Strand along its whole length, and its compulsory purchase of the Metropolitan District Railway station, and other important premises, would seem to be too sanguinely estimated at only a million and a half.

Considering its position adjoining Somerset House, which is 93 ft. high, in five stories, Mr. Tite proposes that his building should be about

the same height and have the same number of stories, and it would contain more than 320,000 square feet of accommodation. After deducting one half for the thickness of walls, passages, staircases, &c., there would remain 160,000 square feet of accommodation, on all the floors, suitable for offices.

The area prescribed by the Courts of Justice Commission for the Courts and the Offices immediately connected with them is 191,506 square feet, and for the offices not immediately connected with the Courts 148,742 square feet on all floors. The site proposed is therefore amply for the latter class of offices, for which it possesses great advantages, and the present Strand site is sufficient for all the Courts without the necessity for any further outlay. The plan provides for easy extension of the Offices at any future time in the direction of the Strand. The building space on the plan is 64,700 square feet, and estimating the cost of the building at the rate laid down on the authority of Mr. Scott, R.A., by the Royal Commission on the Government Offices for buildings four stories high at 6*l.* per foot, the cost of its erection would be 388,200*l.*, or 485,250*l.* if one-fourth extra be allowed on account of the additional story. The new Courts and Offices connected therewith, four stories high, would require a building space of 96,000 square feet, and this, at 6*l.* per foot, would cost 576,000*l.* for the building. It is probable, however, that the cost of the Courts might be more than the cost of ordinary Offices; and, supposing by a liberal estimate the difference to be as much as 50 per cent., the necessary outlay on the Courts in the Strand, at 9*l.* per foot, would be 864,000*l.*

To the above estimates must be added the cost of the Will Tower for the Probate department.

The cubic space required by the Royal Commission for the storage of wills is 350,000 cubic feet, and would probably cost about 80,000*l.*

The area of the site at present secured by the Royal Commissioners is amply sufficient, as the plan shows, for the erection of the Courts and Offices immediately connected with them.

A very grave question, of course, immediately arises:—How will the interest of suitors and lawyers be affected by the separation of the Offices from the Courts? If we may judge from the remarks of one of the professional papers the change would not be objected to. The *Law Times*, for example, says,—

"A suggestion has been offered which ought to reconcile the differences of the rival sites; it is to use both of them. The Carey-street site is not sufficient, and a much larger area must be cleared, at an enormous cost, for the property that bounds it is extremely valuable. The proposition is, to place the courts on the Embankment, and the offices in Carey-street. This seems to present a combination of advantages. In the first place, it would be desirable to separate the Courts from the Offices. The effect of crowding a multitude of rooms in and about public halls is to stifle the assembly-room in its auxiliaries. It is not only destructive of architectural and pictorial effect, but it is extremely inconvenient in those who have business there. If proof of this be wanting, look at the palace at Westminster—a complete labyrinth, only to be threaded by long practice. Nor can we discover any serious disadvantages in such a severance. There is no necessary connexion between the Courts and the Offices. Their distance apart would be no more than ten minutes in time of transit, and no references from the Courts to the Offices are of such urgency that a messenger could not convey them in good time for all practical purposes. Chambers might be provided for the chief clerks attached to each of the Equity Courts; and a Judge should sit daily in a Practice Court to do the work of the Chamber Judges; and attached to the court should be chambers for the Masters. For this the Embankment offers a site without rival in Europe, while the offices, removed to the Carey-street site, would be conveniently near to those who most want to use them. Lastly, there is the still greater advantage, that the work will be done better and more speedily. The Courts will not be marred without nor cramped within, and they will be completed in a moderate time from designs which, under the improved conditions, may be expected to rival and excel anything hitherto produced.

We trust that Parliament will be induced to reconsider the question on the basis of this new suggestion of two buildings instead of one."

It is obvious that the building on the Embankment might be made, from its position, an ornament to London. It would be conveniently placed with reference to the Temple and the new Law Courts. It would be directly accessible to the public by the Strand and the Thames Embankment. It would adjoin a steamboat pier

and a station on the Metropolitan District Railway, and would thus be in communication with every part of London. The site would be cheaper, quieter, with more light and air, and better in every respect than any other that could be found in the neighbourhood.

Finally, the adoption of this plan would utilize and adorn a large portion of the Thames Embankment, and would save to the public, as compared with the proposed purchase of more land round about the Strand site, half a million of money.

If the scheme be carried out, and two buildings be determined on instead of one, the opportunity should be used (we have no hesitation in adding) to repair a great injustice, by appointing Mr. E. M. Barry as architect for the second building.

IRISH ANTIQUITIES AND THE LATE DR. PETRIE.

THE biography of this eminent man, which appeared at the close of 1868, within a few days of two years from the date of his death, is a most acceptable addition to the science of history and archaeology.* Dr. Petrie's labours in the fields of Irish antiquity and art were altogether of a desultory kind. His long life and incessant occupation in these subjects contributed only one volume to the shelves of the British Museum. The further records of his labours are to be found in scattered tracts in the Transactions of the Royal Irish Academy, and in one or two short-lived magazines, which he was chiefly instrumental in promoting. Dr. Stokes has now brought under notice all his labours in the moderate compass of an octavo volume, and reveals, in addition to what was before accessible to the public, the existence in M.S. of a large collection of Notes and drawings, much of it possessing great value, but unfortunately wanting both in completeness and arrangement.

Dr. Stokes writes of his deceased friend with great simplicity and modesty of expression, but his book is characterised by a tone of eulogy throughout of which it might be urged that so much of favourable expression is premature, and that a decision as to the character and merits of his subject should have been left more to the public judgment. If this be so, it may nevertheless be admitted that the biographer, in the course of a long intimacy, had opportunities of learning to admire, and reasons for loving to do so, which the outside world cannot possess; and it may even be found that his easy and natural expression of his feelings will often carry those of the reader with him, so as to make it difficult to think of the facts put forward as independently as might be desirable.

George Petrie was born in Dublin in 1789, the only child of a portrait-painter of ability. From the first he devoted himself to landscape drawing and painting, and passed his early years in sketching tours amongst the scenery of Dublin, Wicklow, and other parts of Leinster, in the course of which his predilection for writing the antiquarian subject with the picturesque was very soon developed. Dr. Stokes divides his biographical treatise into heads which treat separately of the lines of thought and occupation which engaged Petrie. First of his artist life; then of his antiquarian and historical studies; next of his scientific duties on the great Ordnance survey of Ireland, then of the architectural treatises which he either published or projected; and lastly, of his musical powers and his contributions towards the preservation of the ancient, but still current, national Irish music.

The desultory nature of the work which Petrie has left behind him was perhaps almost the certain result of the profession which both his tastes and the necessity of circumstances led him to adopt. His livelihood depended on the use of his pencil and his brush; and even when his skill and accuracy in this art, united to his archaeological knowledge and acumen, had procured for him a Government appointment on the Ordnance survey, he was only temporarily relieved from this necessity. The thirteen years from 1833 to 1846, during which he held this appointment, drew him out of the sphere of private employment, which made it yet more arduous under advancing years, when his only resource was to return to it for a living. Dr. Stokes combats more than once the opinion which was

often expressed by Petrie's contemporaries, that a certain indolence of disposition deprived the public of the full use of his powers. Dr. Stokes points to his incessant occupation as a sufficient refutation, and tells us that his great patience and caution in investigation, and his anxiety to collect sufficient evidence before forming, much less pronouncing a decision, were the qualities which were mistaken for indolence. That his mind was of the quality described by the biographer cannot, we think, be doubted, whilst we believe that the circumstances under which, through his whole life, he self-trained and self-educated his mind, might have been used to add to the force of the biographer's refutation.

Petrie's talents as an artist gave him a high reputation in Ireland, and he held for many years the post of president of the Royal Hibernian Academy, a society distinct from the Royal Irish Academy, of which we shall often speak presently. On this side of the Channel Petrie's larger water-colour works are but little known, though in Ireland some of his latest are amongst the most esteemed of his pictures. In early life he was largely employed in furnishing illustrations to the tourist volumes then so much in vogue. To Cromwell's excursions through Ireland, a duodecimo book, of three volumes, published in 1820, he contributed the drawings for ninety-six plates. Without overlooking the artistic share which the engraver may claim for any commendation due to these subjects, they will always reflect favourably on Petrie's fame when compared generally with other works, or only with subjects treated by other artists in the same volumes. The writer of these lines has had many opportunities of criticising on the subjects themselves the accuracy of Petrie's representations. None but those who try know the difficulties of truthful limning, where a truthful result is the only one sought; and such will know best how to respect the accuracy which seldom falls in Petrie's work, and the honesty and most independent testimonies to Petrie's faithfulness of representation is to be found in the fact, that one utterly opposed to his antiquarian views has purchased a number of the woodcuts executed for Petrie, and from his drawings, and has applied them to the support of a theory which, if there was anything in it, would subvert every conclusion on antiquity that Petrie entertained.*

When Petrie began to study Irish antiquity, his profession led him first to see and examine objects of antiquity, and next he set himself to learn what light history could throw upon them. At this time Vallancey was still living, who may be regarded as the founder of the Pagan school of Irish archaeologists. In a long life General Vallancey had proceeded in exactly an opposite method to that which Petrie was led to adopt. Vallancey imagined that he understood the Irish language, the Sanscrit and Phœnician, and probably many more as recondite as the latter; or he was never at a loss for a jingle of sounds, or of letters, which would enable him to resort to some remote ages and corner of the world to interpret an Irish difficulty. Dr. Stokes speaks of Petrie as the founder of the opposite school. It is doubtful, however, if Petrie can single-handed hold this position. When 100 years ago Vallancey began to be a dictator amongst Irish antiquaries, and the speculative school flourished in Ireland, we in England were not very differently placed. The followers of Dr. Stukely had their notions in the ascendant; now we can hardly fail to smile at the crudities of either. The ground was not then prepared for architectural investigation. Neither here nor in Ireland had the antiquaries recovered from the false cover thrown over all our national antiquities in the times of the Stuarts by the tendency to glorify everything classic, and denounce all else as barbaric. Early in the present century the more just methods of thought began to prevail here; and Petrie, with others, carried on as it were by the same way, were simultaneously labouring in Ireland. The question of priority amongst those engaged must be a difficult one to solve, but that Petrie ultimately held by far the most important place in his sphere is not to be questioned. The making of his own opportunities led to the creation of opportunities for him, and having pre-eminently qualified himself for research, no man obtained so great a chance for acquiring knowledge as he had from his connexion with the Ordnance

survey. Dr. Stokes laments the untimely severance of this connexion, but it must fairly be admitted that no British Government could have maintained it. Sir Thomas Larcom's conception to add a topographical department to the survey was an admirable one. At its head in 1833 he placed Mr. Petrie. Mr. Petrie drew together a small staff of assistants, and the services rendered by these in naming, with a near approach to correctness, the places to be marked on the Ordnance maps are of incalculable value. In a country so repeatedly revolutionized as Ireland has been, with a native language whose last literary remains were, under well-grounded fears, it was thought, expiring, the recovery, identity, and preservation of ancient names was not only an historical but a real practical necessity. Mr. Petrie's staff discovered and recorded besides on the maps a vast number of historical monuments. Dr. Stokes regrets that the fuller description, the minute memoir of every subject, which Mr. Petrie designed, has never seen the light. The immensity of the design is a mark of the patient power of Petrie's intellect, but the impracticability of its immensity will be apparent to others. One volume only of the memoir was ever published (in 1837), and this is a closely printed quarto of about 250 pages. It deals minutely with the history and antiquities, the present and past state of the population in various statistical and social aspects, the geological and physical nature, and the natural history, of one parish! that of Templemore, in which the town of Londonderry is situated. One other subject only of this vast design has been printed, viz., in the Transactions of the Royal Irish Academy, vol. xvi., an account extending to 216 quarto pages, not of a parish, but only of the group of antiquities on the famous Hill of Tara. Mr. Petrie communicated this production of his own to this learned body in 1837 by permission of the heads of the Ordnance survey. That the subject well deserved to be committed to the Transactions of the Royal Irish Academy is certain, but that it was unfit for a Government state-paper is probably not less certain. No Government could foresee the limits of an undertaking which in minute portions presented such a gigantic mass of detail; and with the prospect of being called upon to exercise similar historical functions in the sister countries if the project were continued in Ireland, we can easily understand why even the recommendation of a commission for its continuance was disregarded, and the Irish topographical department extinguished. It is no small honour to this department that it cultivated such a man as the late Dr. O'Donovan; and it is satisfactory to know that some of the fruits of Petrie's design were realised in the production of O'Donovan's edition of the Annals of the Four Masters, in which he so largely and ably deals with the ancient topography of the country.

Petrie's essay on the Hill of Tara is regarded by Dr. Stokes as one of his masterpieces, and is placed by him alongside of his still larger work, "The Ecclesiastical Architecture of Ireland." The essay on Tara is complete, as Petrie intended it should be, and is one of the few literary efforts which he brought to completion. When the Ordnance surveyors had made a satisfactory map of the remains of the hill, the purpose of Petrie was to see if they could be identified with ancient descriptions of the buildings. This celebrated place, the chief seat of the sovereigns of Ireland, from a fabulous period down to the middle of the sixth century, had its buildings ruined and deserted 600 years before the earliest extant description of them was transcribed. Fables and poems, ancient and modern, had attributed grandeur and splendour to the place, for which no authority existed beyond the imaginations of the writers. The question was whether any traces could be found in the past which could be identified with certainty as marks of the old royal residence, and be harmonized with reliable historical documents. Petrie was prepared with a document from which he did establish the identity of the remains for the most part in a very satisfactory manner; and here we may well imagine, when the treatment of the subject was considered by Government they would think his labours should end. Not so did Petrie think; he marshalled around it a mass of curious inquiry and ancient evidence on matters relating to history, which he deemed it important to elucidate, with reference to Tara Hill. He considered and convinced himself of the age of the various remains, and travelled into many kindred questions. Because St. Patrick had visited it, the Book of Armagh, of hour

* The Life and Labours in Art and Archaeology of George Petrie, LL.D., M.R.I.A. By William Stokes, M.D., D.C.L., Oxon. 8vo, 1868. London: Longmans, Green, & Co.

* See "Keane's Towers and Temples of Ireland," 1868.

antiquity, is explored to produce the best evidence and to reject what is unreliable in the story of St. Patrick; the history of the kings is traced from the remotest ages, a discussion on the introduction of letters, and another on laws, occurs, the whole forming a mass of learning, of which an adequate idea cannot be conveyed in these few lines. In this treatise we see fully the desultory nature of the author's mind, as well as its compass, its anxiety to amass evidence, and in this point the difference between him and many of his predecessors and compilers that it was evidence and not mere dreaming which he amassed. The identification of the mounds and banks, the fountains and the cross, with the raths, castles, and houses, the wells and mill-stream, rested on the authenticity of documents 700 years old, in which mention, and even description, of all of them was found. In one point he seems to have surprised himself, not less than others who hear it now for the first time will be surprised, viz., when he convinced himself that the *Lia-fail*, the *Stone of Destiny* of the Irish kings, is not now in Westminster Abbey, but is still on the Hill of Tara. Finding the stone mentioned in his records, he looked for it on the hill in the place assigned to it, and discovered that until 1793 a pillar stone had stood there. It was then removed to mark the grave of the insurgents buried there in that year. If this be not the *Lia-fail*, as Petrie thinks, at any rate it is a formidable competitor with the stone in the coronation chair at Westminster, brought there from Scone in Scotland, in 1296, by Edward I. Petrie contends that until after this date the story of the stone being carried into Scotland by the Irish princes of Albany was unknown; and finding a pillar stone on Tara Hill, whose place agreed with that of the ancient relic, he stands out for the belief that down to the time of his inquiry the *stone of destiny* never had been carried away.

This paper unexpectedly provoked in the Royal Irish Academy a violent feeling of opposition to Petrie, and led to a schism in the council. The wisdom of that body was loudly called in question, and their justice in awarding their honorary medals amongst themselves was the point on which the most effective thrust was made against them; Petrie, himself on the council, being on this occasion the recipient of his third medal.

His paper on the Ecclesiastical Architecture and Round Towers of Ireland was originally delivered at the Royal Irish Academy in 1833. It obtained for him one of the honorary medals. It was, however, very long before it appeared in print. The Academy had only a few years before awarded their medal to a learned lady, Miss Beaufort, for her essay on the Round Towers, in which she attributed to them an Eastern origin. Petrie, elected to the council of the Academy in 1830, sought, as Dr. Stokes indicates, an opportunity for relieving the council from the responsibility of approving that theory which he conceived their medal to have imposed. His movement led to the offer of a premium and medal for the best essay on the subject, and in the end, as we have said, his own essay was declared the successful one. So beset, however, was the council with the difficulty of distributing their arbitrary honours, that they found themselves bound to satisfy another competitor (Mr. O'Brien) and his friends by creating a lesser premium after the first had been awarded, and giving it in favour of another essay, which went to show that their award to Petrie was for a worthless paper. Petrie's essay was finally printed in 1845. It then appeared in a very much extended form. He had added authorities, multiplied examples, and increased it from an essay on the Round Towers to a book on Ancient Irish Architecture, in which, in fact, the Towers make but a small figure, and we were led to expect another volume on them, which, however, never appeared. Negatively it deals with the Round Tower subject, in exposing what he considered the fallacies of Vallancey, and the weakness of Ledwich, O'Brien, Beaufort, and others, and shows the slight grounds on which they had in turn been believed to be mystic towers of some unknown Eastern races, astronomical indexes, Angin towers, Druidical monuments, anchorite prisons, Danish buildings, &c. Petrie then himself adopts the course of considering the nature of the buildings with which they are associated, and this occupies the bulk of his book, introducing us to an acquaintance with a vast number of early Irish church edifices. The Round Towers he finds to be invariably associated with some of these buildings, and hence concludes that they are church build-

ings too, and the belfries of the churches. To a certain extent he shows that the architectural features of the earliest churches agree with those of the towers, and, with a promise of more on the subject, his belief is expressed that the towers range in date from the sixth to the twelfth centuries. Amongst English students there are very few who will not think the general truth of his conclusion fully established. Mr. Parker, in the *Gentleman's Magazine* in 1864, insisted on his own peculiar tenets, which forbid him to believe in any architecture in these islands before the twelfth century, or in any stone erection before the year 1000, and appears to think Mr. Petrie mistaken only in placing any of the towers before the twelfth century. Some of Mr. Parker's assistants, in his articles on "Irish Architecture," accept, however, a belief in a much earlier date. In Ireland promises of theories which are to subvert Petrie's have not been infrequent; but their nature and grounds have been scarcely broached, except in the extraordinary book by Mr. Marcus Keane, published in 1867. Here we have a country gentleman, whose every sheet (there are nearly 500 quarto pages) declares him to be innocent of any acquaintance with architecture, rushing to decide the age of the ancient Irish churches and round towers. He discovers them to be Cuthite temples! History is set at defiance; the well-known Cistercian monastery at Jerpoint is declared to be a Cuthite temple; a tomb at Cashel, palpably of the fifteenth or sixteenth century, is declared to be Cuthite sculpture; the Irish saints are Buddhist deities; and the Cuthites are a people who inhabited Ireland some two thousand years before Christ, from whose days down to the Norman Conquest arts and architecture were unknown in the country. It is a strange turn in the tide of affairs that the very plates which Petrie designed for the use of his further volume should have been purchased by this gentleman, and used to illustrate his extravagant imaginations. That Petrie was in many respects eminently qualified for the task he undertook must be admitted: he was conversant with general architectural history, and had studied its monuments in Ireland with the closeness which none but a draughtsman can apply; he had carefully sought out not one class only, but, as far as possible, all the architectural monuments of the country; he had familiarized himself with its historical sources of information, and in his acquaintance with ancient Irish literature had fitted himself to distinguish the poetic, and to apply the matter of fact. However just his main conclusion, it is not to be supposed that Petrie was always right in detail. He seems constantly, in fact, to have mistrusted his own decisions, and often made up his mind only on some onward pressure of time or circumstances. As to the age of some particular buildings, his conclusions are certainly not always maintainable, and are arrived at on slender grounds. The chancel of the church of Rahin, or Rathain, in King's County, he thinks of about the year 750; and the only ground for this belief is the fact that a certain ecclesiastic named Ua Snuainigh, who flourished at that time, was afterwards regarded as patron of the place. In respect to his church, we prefer Mr. Parker's belief; and, judging from its architecture, should place it in the twelfth century. That Mr. Petrie modified his opinion as to the extreme antiquity assigned by him to some of the Christian monuments is clear from his letter to Lord Dunraven, drawn from him by Parker's articles, in which he expressly admits that he had corrected his former opinion, and now arrived at the same conclusion as the writer of the article on Glendalough as to the age of the Priory Church (therein declared to be of the twelfth century), as well as of some others of the churches there. Petrie must have found it difficult to convince himself lately of the identity of any existing church which would extend the compass of Christian architectural remains even to the eighth century; and although Dr. Stokes asserts that he did not withdraw from his belief in the existence of work of the sixth century, it is manifest that Petrie's admission with respect to Glendalough will go much further than that particular example, and will apply to a host of others which are analogous to it. In matters of fact, his honesty of purpose has not always secured him against error. His representation of the cross on the door of Antrim tower, so important to the Christian theory, is not absolutely correct. At Duleek he has overlooked the very curious feature of the impression of a round tower which is apparent, and, we

believe, hitherto quite unnoticed on the north side of the existing square church tower. This evidence is important to his theory, because Duleek happens to be one of the few places at which an early belfry is noticed in the annals. At Rathoo he omits to notice the curious ornament of the round-tower door, and falls into the mistake of assigning to antiquity the hasement and causeway of the tower, both of which are well known to be modern constructions.

In his admirable descriptions of ancient metal-work, we find the same anxiety to arrive at the truth, and often very satisfactory grounds for assigning an early antiquity, but still, also, the same balancing of his mind. In the case of that curious book-cover, or shrine, in which is still preserved a most ancient book of the Gospels, formerly belonging to the monastery of Clones, he ably shows the age of the outer cover to be of the fourteenth century. The book itself is too tender to bear examination, but he finds it not devoid of evidence which may make it as old as the time of St. Patrick himself. It is immediately laid in a wooden box, and between this and the outer casing can partly be seen a third cover, designed with interlaced work, such as we see on the Irish crosses: this must be of intermediate age between the book and the external plating. Petrie takes a wide margin, and assigns it to some period between the sixth and twelfth centuries.

The long delay in the production of his volume on Irish architecture discouraged the Academy from any further aid in the prosecution of his work, and hence the promised continuation has never appeared, nor does it seem that any matter had been arranged for it beyond the engravings, which have now passed into other hands. His paper on "Military Architecture," delivered in 1834, was also withdrawn from the Academy, no doubt to be perfected to his own satisfaction, and is still in MS. From Dr. Stokes's account, its chief interest seems to lie in the explanation it gives of the more ancient modes of fortification—the duns, cathais, castles, raths, and mounds. He explodes altogether the popular notion that any of these are the work of the Danes, and reasons to show that they are the work of the Irish themselves, from before the Norman conquest back to times so remote as to make the origin of some of the stupendous walls of Aran and the west coast a matter of conjecture.

We must leave it to others to dwell on the patriotic services of Petrie in his zealous efforts to preserve the ancient Irish music, and content ourselves with giving, in the words of Dr. Stokes, the picturesque scene which he records during Petrie's visit to Aran Islands in 1857. To a cottage near the little village of Kilonan,—

"When evening fell, Petrie, with his manuscript music-book and violin, and always accompanied by his friend O'Curry, used to proceed. Nothing could exceed the strange picturesqueness of the scenes which night after night were thus presented. On approaching the house, always lighted up by a blazing turf fire, it was seen surrounded by the islanders, while its interior was crowded with figures, the rich colours of whose dresses heightened by the fire-light showed with a strange vividness and variety, while their fine countenances were all animated with curiosity and pleasure. It would have required a Rembrandt to paint the scene. The minstrel—sometimes an old woman, sometimes a beautiful girl or young man—was seated on a low stool in the chimney-corner, while chairs for Petrie and O'Curry were placed opposite; the rest of the crowded audience remained standing. The song having been given, O'Curry wrote the Irish words, when Petrie's work began. The singer recommenced, stopping at a signal from him at every two or three bars of the melody to permit the writing of the notes, and often repeating the passage until it was correctly taken down, and then going on with the melody exactly from the point where the singing was interrupted. The entire air being at last obtained, the singer a second time was called to give the song continuously, and when all corrections had been made, the violin, an instrument of great sweetness and power, was produced, and the air played as Petrie alone could play it, and often repeated.

Never was the inherent love of music among the Irish people more shown than on this occasion. They listened with deep attention, while their heartfelt pleasure was expressed less by exclamations than by gestures; and when the music ceased, a general and murmured conversa-

tion in their own language took place, which would continue until the next song was commenced."

Petrie's artistic tours and explorations, and his duties on the Ordnance survey, made him acquainted with the existence of a vast number of the minor monuments of antiquity, the utensils, ornamented trappings, jewelry, and weapons of the past, many of them disregarded and neglected; others in obscure corners, but nevertheless the objects of popular veneration. The preservation of such objects, the elucidation of them, and the assembling of them under an orderly method whenever practicable, were objects which from his early days he never lost sight of. For the furtherance of this design "I sought," as he himself expresses it, "for knowledge in every available quarter, with an ardent and untiring devotion." To this spirit we owe in a great measure the collection of antiquities at the Royal Irish Academy. Petrie pointed out for acquisition most of its most prized treasures, and led the way to the inspiration of others with large views for its aggrandizement. Amongst his projected labours was the compilation of a catalogue of this collection, which he indeed commenced; but faith in his resolution to push it to completion being wanting, the further prosecution of the design was committed to the hands of Sir William

Wilde. Ten years have passed, and it is not now completed.

One of Petrie's latest occupations was the catalogue of his own museum, which must be added to his fragmentary works. His papers on the different shrines and reliquaries, and the ancient bells and minor antiquities, show how attentively he had used his opportunities of research in every corner. Amongst his collections ought to be noticed his series of ancient Irish inscriptions, chiefly monumental.

One characteristic which will not fail to strike the reader is Petrie's small care for his own aggrandizement. To one who had sought so little for himself, and done so much substantial service to the public, it was no more than a just recognition of his public spirit when, in 1849, at the age of 60 years, his name was placed on the Civil List. Dr. Stokes claims for his friend the possession of an altogether amiable nature—a point on which, as strangers, we only wish heartily to agree with the biographer; but it shows how rancorously archaeological disputes have been waged in Ireland when Petrie, usually so mild and moderate, even when decided in his expressions of dissent, could write of the statements of a deceased advocate of opposite views, that "nothing but the artfulness could exceed the audacious mendacity" of their author.

THE COLSTON HALL, BRISTOL.

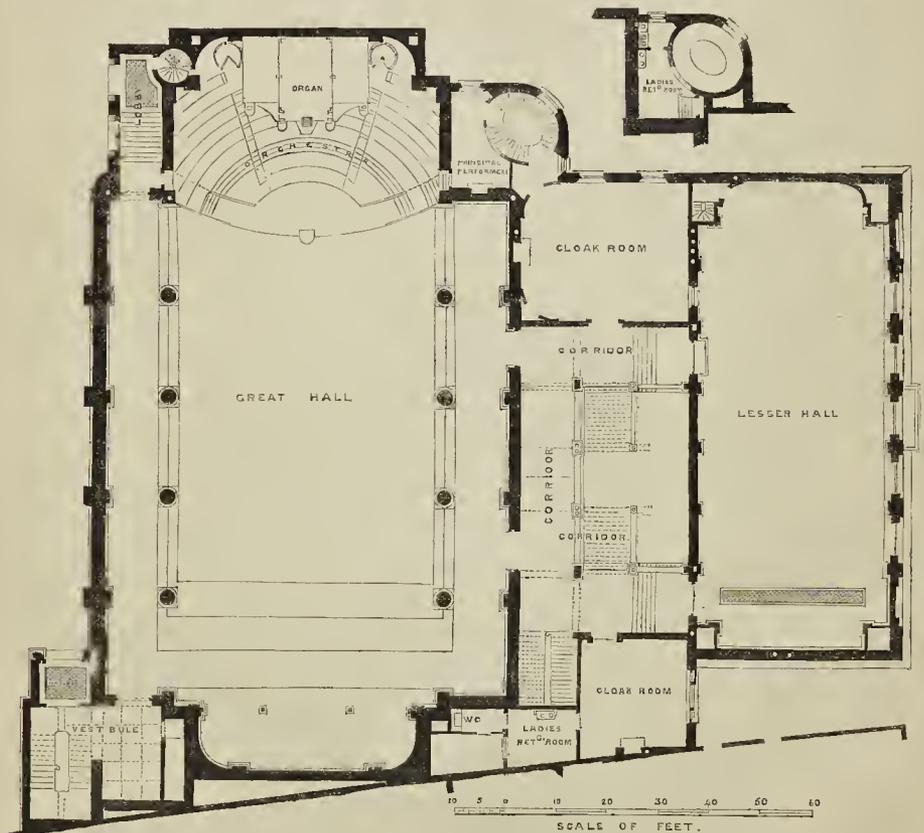

The building illustrated in our present number is the undertaking of a limited liability company. The Great Hall and the two stories of bonded cellars underneath it were completed some time ago. The foundations only have been constructed of the front portion of the building, comprising the principal entrance and staircase, a smaller hall and refreshment-rooms, cloak-rooms, cooking and warming arrangements.

The Great Hall is 150 ft. by 80 ft., and 72 ft. high internally. The central area is 55 ft. wide between the axes of the columns, which are placed 20 ft. apart from centre to centre. The columns, pilasters, door-cases, and balconies are of Bath stone, and there is a dado of Bath stone, 10 ft. high, round the walls. The entablature and the vaulting of the aisles are constructed with brickwork and rubble, and the central vault is formed with bracketing upon the laminated timber ribs of the roof. The form of the vault is elliptical, the height above the principal cornice being 5 ft. greater than the width. The whole of the work above the stone capitals of the columns is finished with plaster. The hall will seat about 3,000 persons, including those in the orchestra.

The remaining portions of the plan will be carried out as soon as the company have made

THE COLSTON HALL, BRISTOL.

PLAN OF MEZZANINE FLOOR
UNDER PRINCIPAL PERFORMERS' ROOM

Plan of Principal Floor.

the necessary financial arrangements. Messrs. Foster & Wood, of Bristol, are the architects, and Messrs. James & Joseph Foster, of Bristol, are the contractors. The gas fittings were supplied by Messrs. Skidmore & Co., of Coventry. The sculptures were executed by Messrs. Boulton, Divall, E. White, Palmer, and Sheppard; and the stained glass was made by Mr. Joseph Bell, of Bristol. The orchestra, which is permanent, was arranged by Mr. Henry Willis, the organ-builder.

Acoustically, the hall, we are told, may be considered successful both for music and speaking, the ordinary conditions being complied with, viz., that the ball be fairly filled and the speaker be fairly skilled in the use of his voice.

A TOUR IN SHROPSHIRE.

HAVING completed a tour of a few weeks in Shropshire at the end of last year my observations, such as they are, may not perhaps be unacceptable to some of your readers. Starting from Cheltenham, you pass through a dull country till reaching Bewdley, whence the train runs by the edge of the valley to Bridgnorth. The situation of this place is extremely picturesque, and though the station is at a very short distance from the town, it has suffered very little change from the proximity; and indeed it may be said of Shropshire towns that such is generally the case. In fact, it may be affirmed that there is hardly any county in England less visited by strangers. The church, dedicated to St. Leonard, which is built of red sandstone, stands on the most elevated situation in the town, and is of course visible from every part of the valley. The precincts, if I may so term them, are picturesque in character from several old houses, the antique-looking parsonage and the grammar-school, rather an extensive building in the Elizabethan style. The church was restored some eight years ago, being in a most wretched condition at the time. The nave is almost a "square," much resembling that of Great Yarmouth. The plaster ceiling in that portion of it having been removed under Mr. Slater's directions, a fine oak roof was discovered underneath. In the chancel also is an oak roof, but much inferior. There is no ancient stained glass; but a modern window on the south side has been inserted from a motive which deserves to be recorded.

"This window and door were restored in the year of our Lord MDCCCXLVII. by a Priest of the English Church, as a poor offering of thankfulness to Almighty God for many means of grace, and good instruction vouchsafed both in this church and at the adjoining grammar-school." The name of this individual, as I learnt, was the Rev. J. Boulton. Equally worthy of commemoration is a brass plate on the north side with an inscription purporting that Thomas Whitmore, esq., who died February 6th, 1846, being patron of both the churches in this town, with exemplary munificence made over the tithes held by his family as lay impropricators to the ministers thereof for ever! The Church of St. Mary Magdalen, not far from the large fragment of the ancient castle, which might not be inaptly denominated the Leaning Tower, was taken down and rebuilt in 1796, and the date alone is quite sufficient to show what sort of structure supplied the place of the old church. As seen, however, at some distance from the town, it groups very well with the fragment of the castle and St. Leonard.

In this place commence the "white and black" timber houses, which are still to be met with in this and the adjoining county Cheshire, and of which the Swan Inn is a good example. Few though they be, they give an antique air of cheerfulness, which pleasingly breaks in upon the monotony of the modern style of building.

The line from Bridgnorth to Shrewsbury, of which there is a branch to Wenlock, enables the tourist to make a morning visit both to that and Buildwas, simply by making a little detour. The proximity of the former to the quiet little town after which it is named detracts but little from its situation and surroundings. It is said to have been founded about 680, by Milburga, of the royal line of Mercia. The remains are of considerable extent, including about thirty acres. The length of the abbey from east to west is 401 ft.; breadth of the nave and aisles, 66 ft. There are some good examples of Pointed architecture, particularly in one of the transepts, where there is a triforium, lofty and elegant; but the gem of the whole is undoubtedly the chapter-house, the walls of which have a series

of interlaced Norman arches, with every variety of detail; but unfortunately I could obtain no photograph which represented these with any distinctness. A picturesque grouping of the ruins is obtained from the adjacent churchyard. This includes also the prior's house, a most curious and interesting structure, nearly perfect, and tenanted by Mr. Gaskill, late M.P. for the borough, and his family. A narrow cloister, with an upper and lower ambulatory, runs along the front, communicating with all the rooms. An author, named Moore, writing in 1787, says, "Many years ago great part of the abbey was pulled down by an agent of the manor, to 'rebuild some houses,' of which he had a lease, though further demolitions were stopped by the then Sir Watkin Williams Wynne." The reproach of making antiquity so very picturesque must not be entirely thrown upon Oliver Cromwell and his troops.

The ruins of the Cistercian Abbey of Buildwas are situated among meadows, a little elevated above the banks of the Severn, environed by gentle eminences, rather thickly wooded, and a more delightful and characteristic spot for conventional retirement is seldom to be met with. The foundation is attributed to Roger de Clinton, in 1135. The nave has seven arches, resting on massive cylindrical piers, and above are clerestory windows, also of an early character. The chapter-house ranges with the north transept. It has an oblong form, is vaulted in nine compartments, supported by four slender columns. The descent is by three or four steps, with a window on either side of the doorway and three opposite. Some portion of the abbey still remaining is occupied as a farmhouse, and was under repair when I saw it. The line to Shrewsbury passes within no great distance.

The view of Shrewsbury from the railway viaduct is very striking, with the two spires of St. Mary and St. Alkmund, and the castle conspicuous above the railway station. Perhaps as a town it has suffered less than many others from the progress of change; and if all the five ancient churches had remained whole and unscathed, it would have been a true gratification to the ecclesiologist. Unfortunately of these, St. Mary and the Abbey Church are alone whole and entire, for St. Alkmund and St. Julian, while they retain the one its spire and the other its tower, are deprived of all the rest. St. Chad has been rebuilt, and may perhaps vie with the most "splendid" London churches of 1792. Its arrangement is that of the "foreign houses of the Legislature," being a semicircle, in which the seats are so arranged that "every one is enabled to see the officiating clergyman" as in the former,—every individual member can see the speaker or president. This was built near the Quarry, one of the finest public walks which any town in the kingdom possesses; and if it had been fated to be reconstructed at the present day, would have harmonized so well with the stately avenues of lofty limes, whose arching branches entwine themselves sometimes into a natural arcade. A portion of the old church was left, and is still in use. St. Mary's is highly interesting in many respects, and among others as affording specimens of style from early Norman to Perpendicular. The lower basement of the tower is of red sandstone, and from its style of windows was, no doubt, that belonging to the original edifice, which is said to have been founded by King Edgar about 980. This is corroborated by the circumstance that during the restoration the foundations of an older structure were found, extending the whole length of the nave. On the base of this tower has been raised a continuation of the same, with a battlement and pinnacles capped by a very lofty spire. The south porch of the nave has a Norman door. The ceiling is a remarkable specimen of the most ancient kind of groined vault, having neither boss nor ornament of any kind. There are besides two other Norman doorways, one on the same side, the south, and the other on the north. The windows of the transepts are early English.

There are few churches of which the interior is, perhaps, more satisfactory. The nave is separated from the aisles by four bays, consisting of semicircular arches resting on Early English columns, with foliated capitals of different devices. This is a singular arrangement, since the pointed arch is sometimes found resting upon the Norman pillar, but quite exceptionally the reverse. Three very fine pointed arches separate the choir from its very wide transepts, and from the nave. Over the choir arch are two triforium arches with enriched capitals, which

give a striking effect to the view as seen from the west end. The view terminates with the east window, the "Root of Jesse," which was presented to the church in 1791, having escaped the destruction which befel the old church of St. Chad. There may be, perhaps, rather too great a predominance of yellow, but yet the general effect is a richness that satisfies the eye. The ceiling of the nave is of oak, the intersection of the beams being formed into panels, richly decorated. That of the chancel is much the same. But one of the great charms of this church is the being completely filled with stained glass, some of no ordinary excellence; and may I be allowed to say, that where the eye is gratified with colour in the windows, that gratification is more heightened, relieved, and diversified by architectural detail than by any amount of fresco painting, however excellent; for then the two impressions do not interfere with one another. The specimens of German and Flemish glass are, indeed, peculiarly good. Of the former may be especially noticed that in an Early English triple lancet window with very acute arches on the north side of the altar. This comprises a series of incidents in the life of St. Bernard, said to have been brought from the church of St. Savin, at Cologne. There are fourteen subjects, in the majority of which the drawing is both correct and spirited, and the draperies very flowing. Of these may be especially mentioned one in which the saint is "healing the blind," and another, returning thanks for recovery from sickness. Both are remarkable for good and effective drawing and excellence of colour. Like the windows at Fairford, they have been attributed to Albert Dürer. Two centre windows on the south side of the nave have special reference to Count Horn and his Countess, and are equally excellent specimens of the Flemish style of glass-painting. They are both represented in attitudes of devotion, the latter with an abbot bearing his crozier, with vestments of peculiar beauty, in colour and detail. The apex, and indeed almost the whole of the upper part of the windows, are filled with elegant frieze work; the lower with coats of arms, including those of the Count and Countess. Both in the north and south aisles of the nave are specimens of German glass, equally worthy of being carefully looked at. In the vestry are also some curious specimens of the Flemish style in "grillades," about the size of that in the Bodleian Library, Oxford.

Being placed nearer the eye, they can be more attentively studied than those within the church itself. As a curious instance of the manner in which Medieval artists adapted themselves to the representation of the most incongruous subjects, we have specimens from a window in the south aisle which represents swarms of flies whom St. Bernard had excommunicated, being literally swept out of the Abbey of Foigny. Besides the figure of Bishop Butler, whose reputation is so intimately connected with Shrewsbury School, there is another which deserves some attention—that of General Cureton. This is placed in the vestibule or open part of the tower, which might have been once a "louvre" or "lantern," and is entered by a "memorial" oak screen. It is a recent figure, in a military cloak, the folds of which are very carefully manipulated, even down to the feet. The countenance possesses that air of tranquillity which those who, like himself, fell on the field of battle are frequently said to exhibit. I may add that the Sunday service in this church is carefully and reverentially performed with a surprised choir. It is also accessible, and constantly open during "every" day in the week. The entrance is "then" by the north porch, and generally at no other.

In the Medieval times the vicars of St. Mary's were "exempted from episcopal jurisdiction" by many consecutive Papal bulls. Whether this privilege, if it may be so termed, is existing at present, I am unable to say.

The Abbey Church of the Holy Rood, dedicated to SS. Peter and Paul, is situated on the other side of the river crossing the English bridge, while very near to it is the line of the Severn Valley Railway. Though now deprived of all the monastic accessories with one single exception, yet the massive western tower of red sandstone, with its large perpendicular window, presents an air of dignified contrast to the surrounding scene. When entire it must have been a stately cruciform structure; but consequently on the dissolution, with others of the kind, it consists at present only of the nave and side aisles, with the western tower above mentioned. The nave having been from a "very

early" period appropriated to the use of the neighbouring inhabitants, was consequently saved from the wanton outrages of the Royal Commissioners, fortunate if they were not obliged to "purchase" the exemption for a heavy sum, as at Tewkesbury. The three windows are all at present of the Perpendicular style; but there are prints of older date which show the two smaller to have been of a different character. The portal is a deeply recessed "semicircular arch," terminating in a pointed doorway. The bell-chamber has two windows on each side; between those of the western front, in a canopied niche, is the statue of an armed knight, having a conical basinet encircled by a crown. This figure is with good reason supposed to represent Edward III., in whose reign the tower was probably begun. The south doorway is plain Norman in character, resting on slender shafts, and adjoining is the ruined wall of the transept. The choir having been destroyed, the eastern end now terminates in a wall run up between the remains or the two western piers, which supported the central tower. Of course, in the interior the altar stands here, above which are placed Norman windows, containing six figures in stained glass of kings and apostles, by Evans, a native artist. They are deep and brilliant in colour, and the drawing is good. Below is a reredos, forming a series of five Norman arches.

The interior of the abbey is a fine specimen of solid Norman work; indeed, I hardly know any to which the term "massive" may be more appropriately applied. The whole is in that style, except what is beyond the three semicircular arches westward, where there is a very wide pier, on the eastern and western extremities of which are half columns of the arcades, and to the middle is attached a flat pilaster. From hence the remainder of the nave displays the commencement of a different style, and the Norman gives place to the pure Gothic of the fourteenth century, as at Gloucester. This terminates in a beautiful pointed arch, 52 ft. in height, which divides the tower from the nave, and by the removal of the organ gallery and screen, the whole extent of the great western window is now displayed, which certainly imparts a very striking appearance to that portion of the building. The entire window is filled with a series of armorial bearings of some of England's ancient peers, as well as a few very modern. It is, in fact, a perfect study of heraldry. There are several monuments of interest, but the most singular is one which stands on the north side of the altar, which at the first view presents the appearance of two tombs, but on examination proves to be only "one," the double appearance being given by a centre buttress, which is not carried over the ledge, upon which rest two figures, the head of the one at the feet of the other. They are supposed to represent the "same" individual who had abandoned the military for the eremitical life, but there is not the slightest clue to the name.

The walls of the nave, with the pillars and arches were, in 1855, cleared of their plaster covering; but such a state of dilapidation was developed as to necessitate a thorough restoration, which appears to have been carefully and effectually carried out. A visit to the vestry will at once show the depth of the incrustation which disfigured the buildings. That has been left in its original state, with the exception of a very small portion of a column behind the door, the lower part of which having been cleared of the white or yellow wash, the remaining portion shows to what a thickness these gradual accumulations had reached. It may be proper to mention that on the fall of St. Chad's, and the demolition of St. Alkmund's, the walls of which "were in such a sound state as to require a very great amount of labour to remove them," several ancient monuments found a place within the walls of the abbey.

Of the monastic remains no traces are now to be met with. The shell of what is supposed to have been the monks' infirmary, but detached from the main body of the abbey, was existing in 1826, as well as a considerable portion of the external wall. If any portions remained they were demolished when the adjoining railway was constructed. Nothing now exists but the stone pulpit on the opposite side of the road, which has been left a solitary relic, surrounded with a wooden railing. It is supposed to have stood in the refectory, and was the "lectern" of the "dining-room." The interior forms an oriel, the roof being vaulted on eight delicate ribs. Some old houses near it have been also cleared away.

Of ancient buildings Shrewsbury possesses several fine specimens. The Market-house is, perhaps, one of the most curious in the kingdom of its kind. The basement is 105 ft. in length, and is used on Saturdays as the corn-market. Over the principal front are the royal arms of Queen Elizabeth, and the date 1596. In one of the nearest streets stands "Ireland's Manston," constituting, in fact, several houses. There is an old black and white timber house on Pride-hill,—and many others, indeed, distributed in various parts of the town. There are also some in the suburb over the Welsh Bridge. The incumbent of St. Alkmund's has made the frontage of his house, once modern, another contribution to these varieties in domestic architecture, being a complete copy of the olden style. The town walls, a considerable portion of which still exists, have been deprived of their battlements. One solitary tower yet remains.

The remainder of my notes will form another article.

A MEMBER OF THE OXFORD ARCHITECTURAL SOCIETY.

CHARACTER IN BUILDING.*

If it were desired to provide a series of puzzles for those who may come after us in Britain, scarcely anything better could be devised than the curious fancies prevailing in the fashions of a large proportion of our buildings, in which the desire to follow in those lines which lead to "business" has misdirected their designers, and robbed their works of that essential element, character, without which our art becomes weak in the present, and of little worth for the future.

Character in works of art, as in their producer, man, is that which most gives individuality; and as the character is high or low, interesting or dull, lifts or depresses each above or below the average mark of ordinary humanity, or of every-day design.

Character in architecture may be entirely independent of style, decoration, or material; but, on the other hand, the indolent selection or treatment of those may be made to conduce essentially to the character desired; while a fashion of adopting one style, or class of styles, for buildings of all natures, tends directly to debar the artist from sources of character in his works, which independence of choice would place at his command.

Character, again, may be quite apart from such qualities as are expressed by the terms beautiful, grand, elegant, and the like, since the qualities these express may be justly attributed to works which can with equal justice be pronounced very deficient in real character.

It may be perfectly consonant with the true character of a building that beauty or that elegance should pervade its features; and yet again these qualities may be felt as very agreeably presented to the eye of the spectator, while he can discover nothing to give him an idea of any special aim in a design; and such special aim successfully attained and indicated is that which alone will really make a building characteristic.

I do not, as you will see, mean such an aim as that simply of making a building beautiful, or even grand, but the purpose of deducing from all the circumstances attending the production of a design—the general form, arrangement of parts, measure of enrichments, and style of finish—which shall be most in accordance with the site, purposes, and cost of the building designed; and as respects such various points, and the due measure of their influence, I propose now to speak.

An independent exercise of judgment in selection of style, in defiance of any prevailing fashion, or even recognised custom, local or general, is a preliminary essential in the architect who desires to give real character to his works; and as a result of the too common lack of such independence of thought we have at the present day a number of meritorious designs in one general, if even slightly varied, style, but which, with all their cleverness—and they evince much—fail to impress us with any idea of special character.

Not first, however, though, in sequence from what I have just said, I have first named it, should the question of style be settled by the architect in beginning a design; the real first

step, in my opinion, is to find the absolute general form which his work must assume to meet the particular purpose of its production, and to do this in the most simple, direct, obvious, and, in most cases, the most economical way.

None, I think, will deny in words—although too many, alas! called architects do in design—that every class of buildings, and each individual of each class, demands from the true artist special treatment consistent with its use. Did this fact dwell with its due weight, however, in the minds of designers, we should not have to sigh over so many hybrids of design as we meet with, in museums like convents, hospitals like hotels, churches like theatres, and many like solecisms; nor should we have to lament, as we must, for so many opportunities lost of giving new interest to our towns, and fresh life to our landscapes, by the production of works really marking their purpose by their form and treatment.

I believe it is best to leave all thought of ultimate style out of sight in dealing in the first instance with the plan of a new work, unless, indeed, a style has been enjoined, or for some overwhelming reason obviously required; and even then I would not allow its consideration more weight in respect of plan than so much as will prevent the adoption of a form flagrantly at variance with the essentials of the style prescribed; since every style deserving that distinctive title will be found to have so much of vitality in capable hands as to adapt itself, when well studied, to most of the many purposes of architecture with which we are conversant, and when so adapted affording often a piquant example in novelty of application as to use or of form as influenced by site.

Out of the pale of our profession the idea is very common that a design which has been found to satisfy its requirements on one site will do so on another, and that it can be transferred again and again to new situations, and always be found suitable. The only case in which this holds true is that of houses built in rows, and with absolutely the same aspect; and an alteration of aspect, in even a moderate degree, will prove the attempt abortive if, in the first instance, the designer has really considered all essential points in laying out his plan.

In regard to isolated buildings of any kind, I question if a single case could be found in which such a transfer of design could work satisfactorily, since it is all but impossible to find two instances of the requirements of accommodation, the aspect, the approaches, and the lines of view being the same, and under no other conditions can such a transfer be well made.

With respect to character, as influenced by site, both the plan and sections of site should be allowed full weight, and of course the points of approach and the aspects and points of prospect belong to the question of plan. The simplest and most direct adaptation of the building plan to these will always be found to yield the best working basis for the superstructure; and it is certain when, for special reasons (generally insufficient), it has been determined to work against these, which may be called the natural motives of plan, that in proceeding to raise the work in whatever style from this groundwork, difficulties will meet us in properly apportioning the more important apartments or divisions of our building, whatever its class or purpose be.

The peculiar sections of site affect secondarily the question of plan; and if individuality and force of character are to be preserved, these must be dealt with not as matters to be artificially masked or changed, but to be met and welcomed, as giving opportunity for escaping from the trite and commonplace in design. Take such examples as Durham Cathedral, Tintern Abbey, Arundel Castle, and say whether they would not have lost vastly in their force and individual character if, instead of adapting the designs to the greater or less varieties of level presented by their sites, the ground had been smoothed over, and they had been constructed on the sober every-day system of a dead flat site.

No class of buildings better illustrate the value of adaptation to actual site than the Medieval castles of this country and the European Continent, since defence and not effect was their chief aim; but in gaining that they eminently realised the latter; and whether in the British Isles, in Germany, Italy, or the Spanish Peninsula, the lover of the bold in character and the picturesque in form will find no more charming studies than are afforded by buildings

* From a paper "On Characteristic Design in Architecture," by Mr. H. P. Horsey, read at a meeting of the Liverpool Architectural Society.

of what we may call the Fortified Domestic styles.

I alluded to Durham Cathedral as an ecclesiastical example of what this principle of adaptation gains for characteristic effect; and I would add, that I hold it wise, wherever a site suggests such treatment, for the church designer to avail himself fully of the facilities presented, and I would cite the very successful example of the church on Hulton-hill, near Rancorn, as a modern instance in point, and I can say from my own experience that no designs have ever seemed to me to grow so naturally under the hand as those which had to be fitted on such irregularities of surface section.

I spoke of adaptation to site not only in the simplest and most direct, but also the most obvious way, and this I mean as applying to the spectator, as well as the designer of an architectural work. It is possible to adapt a building really in a simple manner to the natural features of its site, while these, as the directing causes, may be in great measure unseen when the work is completed, as we know is often done by planting and other devices. This, for the sake of real character, I believe, had better be avoided, unless the natural features yielded to are of an unsightly or disagreeable character. The plea is often advanced of planting for the appearance of shelter; the reality of this is a most desirable aim, of course; but to clothe natural irregularities in foliage seems only to give warmth or protection, is to sacrifice the picturesque to the artificial,—as great a mistake as can be made, but too often fallen into when the completion of grounds or approaches is committed, independently of the opinion or intention of the architect, to some so-called landscape gardener, who is not unlike, happily, some we know of that class, a man of artistic taste and feeling.

I am sure that those professing that charming art who really appreciate the mutual gain from well-associated architecture and landscape will always be found anxious to work with, rather than independently of, the architect; and if this were always done many a failure in effect, many a solecism in taste, many a contradiction in artistic character would be happily avoided. I repeat that the obvious causes of peculiar form in plan should, as far as possible, be kept visible in the completed work, if individual and forcible character are desired to be preserved.

It is seldom that views of strict economy can be safely lost sight of in any architectural project, even those vast and costly ones which seem to stand at the very antipodes of such repressive considerations; and, however real, substantial, and lasting we aim to make our structure, wastefulness even in those respects is a grave error; and thus I hold comes under view one other point on which, with respect to site, it is ever best to aim at the preservation, as far as practicable, of all natural peculiarities. It is, of course, not always possible to avoid even costly displacement of what stands more or less in the way of our particular aim, and especially shall we find this the fact, as I can testify, in the case of extensions or additions to existing buildings; but wherever it is possible to save cost by leaving undisturbed what, even in a slight measure conduces to mark the natural character of a site, such economy of labour will be more than repaid by the gain thus obtained in natural and real effect; and it would be well for architects, in planning their buildings, to look forward as much as possible to the probability of future enlargement, and so to place them with respect to the neighbouring natural objects as to avoid, as far as may be, all risk of heavy and otherwise needless labour in the future.

I have said briefly what seems to me most applicable on this subject with regard to site, and in leaving this part of the matter would only add that, as regards approach, the character aimed at, as of seclusion, dignity, mere comfort, palatial display, or whatever else, the architect should deal with his work so that it shall meet the spectator's view in such direction and at such distance as shall best conduce to the main effect proposed; and I cannot say, in my own experience, that I have ever known a case in which I have found a previous work afford any sure guidance, so varied, so unlimited in variety, are the natural circumstances which we have to consider and adapt our work to in respect of approach and aspect.

As regards Plan, that well-defined foundation from which our work gains its primary vertical outline and sections, the geometrical relations of

form and proportion afford the first and best guide, and we shall look in vain, especially as regards interior effect, for any character so finely and truly marked as will be found in those structures in which this real basis of plan has, happily for the architect, been found possible to preserve.

It must often be the case that this cannot be strictly done; but still regularity of form, justness of proportion, and directness and simplicity of union or connexion (I mean either absolute ad-joinment or communication by passages) in all the principal parts of a design will be found most to conduce to distinctness and strength of character. This must be so if the points I have previously pressed with respect to site have been observed; for supposing that it is true, as I am certain myself it is, that such adaptation to site is the step towards securing characteristic effect, the most direct derivation of solid form from that of site, through plan, will most surely lead a step onward in respect of character.

I may be met by objections on the ground of the picturesque of irregular structures, and of the limitation imposed by the small number of regular figures suitable to plan, if such are to be adhered to; but my answer is, that many of the so-called irregular buildings grow from a strictly arranged and proportioned plan, and it is no irregularity of their basis which gives them the charm to which we give the title of the picturesque, but the treatment of the terminations upwards of their necessary constituent parts, often very materially assisted by that very precision of plan (and by precision I do not necessarily mean absolute symmetry) which may be supposed inimical to such effect.

I would call your attention to the fact that many structures directly planned with the idea of securing effect by studied irregularity of plan prove utter failures as to this special aim, having an appearance of fritter and fluter most disagreeable in so real and solid a thing as a building, and losing comfort and convenience of plan for the sake of an external character which they do not secure.

In treating, however concisely, of so large a subject as I have undertaken to address you upon, it seems impossible to avoid treading on ground which you have before traversed in company with others, or perhaps with myself, and it is in the nature of our Art that its important points of study, effect, consistency, reality, &c., overlap and intertwine with each other; and you will, considering this, be indulgent to me, I hope, if I cannot avoid repeating in a measure things which I have said in some shape or manner before: not that I purposely shall do so, but I am conscious of constantly touching or passing the border of other cognate parts of our general subject.

These buildings in which absolute geometrical arrangement can be preserved gain greatly in dignity of character over such as must depart from it, and little argument will be needed on this point if we but consider the impressions on our own minds of the cathedrals and other great churches of our own or other countries; not of course, that greatness of scale does not conduce to such impressions; but still, even in moderately-sized—yes, even in small—buildings, such geometrical symmetry gives dignity and greatness of character, and no graver mistake can be made in works devoted to the solemn services of religion than aiming by a needlessly irregular form of plan to gain an effect of variety, losing the opportunity of preserving a dignified solemnity, which, as I have said, is consistent even with a very moderate scale, and giving in its place a character which is distracting, not sobering, in its effects, and better fitted for a ball-room than a church—yes, or even than a theatre.

Yeovil Gas-meting.—A Yeovil gas-consumer says he entered a house at Michaelmas last, and on discovering that there was some slight defect in the metre he resolved not to burn any gas for the whole of the quarter. This he adhered to, and during the whole of that period he never lighted the gas once. Very recently, however, to his surprise, the collector of the company presented to him a bill for upwards of 2,900 ft. of gas, consumed between Michaelmas and Christmas, although he was able to furnish the most abundant evidence that he had never used the gas, and that the metre was in exactly the same state as when he took possession of the house. It is to be feared that Yeovil is not the only place where this sort of gas-meting occurs.

BRITISH ARCHAEOLOGICAL SOCIETY OF ROME.

SUBSCRIPTIONS are still asked for by the managers of the Exploration Fund. The following statement of what has been paid for excavations and researches made in Rome during 1868 serves to show what has been done, as well as how the money has been expended:—

Portion of the wall of Servius Tullius	625
Chambers of the Mamertine prison	558
Foundations of the Porta Capena and pavement of the Via Appia	628
One of the chambers of the Fiesina Publica?	250
Castellum Aquæ of Trajan, near the Porta Capena	390
Remains of the Edes Cæsarum?	225
Mouth of the Aqua Appia and course of the Specus	125
The source of the Aqua Appia	125
Reservoirs of Aqueducts in the same vineyard as the Minerva Medica	225
Other reservoirs of aqueducts, south of the Porta Maggiore; and the Specus Vetus on the Cælian	328
Porta Trigemina, and pier of the Sublætan Bridge	125
Cave under the Palatine. Imperial of Augustus?	141
Porta Lateranensis, exterior	125
Porta Chiusa, interior	150
Mausoleum of Augustus, original entrance	250
Templum Urbis Romæ? doorway of the time of Hadrian, on the south side of Ss. Cosmas et Damian	250

Fr. 4,960

At a recent meeting of the British Archaeological Society of Rome Mr. Parker objected to give an explanation in detail of the projects proposed, and the results obtained by those excavations and researches during the first season.

The exact site of the Porta Capena had long been a matter of dispute; volumes of learned dissertations have been written on the subject; but no one had hit upon the real site. Some good antiquaries, the last of whom was Canina, had come nearer to it, but their nearest point was a hundred yards to the south of the actual site. The real site, that is the line where the Wall of Servius Tullius crosses the valley from the Cælian to the Aventine was first pointed out by Mr. Parker two years ago, but neither the Roman nor the German Archaeologists would agree to it. Yet in this exact line it has now been found. Drawings and plans were shown to the meeting, exhibiting the actual sill of the gate with the raised footpaths on each side of it, and the pavement of the Via Appia between them, at the depth of nearly 30 ft. from the surface. One of the square towers of Servius Tullius, by the side of the gate, was also found, and drawings of it were shown. This part of the Wall of the Kings has also been excavated in three other places, and two of them are now left open for inspection. In these the members may stand upon the wall of masonry and see the arcades of two aqueducts, one on either side abutting against the wall. Mr. F. Gori, who was employed by Mr. Parker to superintend the works in his absence during the summer months, went down to Pompeii to compare the principal gate of that city with the principal gate of Rome. He found them exactly the same in every respect. The width of the road is only 8 ft. in both instances, and this is in accordance with the law of the Twelve Tables.

The aqueduct of Trajan was carried on the same line as the older aqueduct across the valley, and his tall brick piers to carry his lofty arcade rest upon the Wall of the Kings. Several of these piers remain in their places in a mutilated state, and these were what first guided Mr. Parker to fix on this line.

One of the reservoirs of Trajan, on the cliff of the Cælian, was excavated, and is left open for the inspection of members; this was at one end of his lofty arcade; at the other end he built another reservoir on the site of the Fiesina Publica, a portion of which has also been excavated, sufficient to show the *signatum* or cement to hold water, the certain sign of an aqueduct or reservoir; one of the seven chambers only has been excavated: the others being all alike, it would have been useless expense to do more. This is also left open for the inspection of members. Various other particulars respecting the buildings in the first Regio called after the Porta Capena were given by Mr. Parker, the site of which may now be fixed with probability. The ideas of the Roman antiquaries that the Porta Capena was at the junction of the Via Latina with the Via Appia near the Church of S. Cesareo, and that this Regio extended outside of the walls is now shown to be erroneous; the length of the Regio from the Porta Capena to the Porta di S. Sebastiano is just a mile, and the number of 2,211 ft. contained in the Regio according to the Regionaries will not admit of a greater length.

CABINET MAKERS OF LONDON.

YOUR correspondent, Mr. Warren, in a recent number, protests against the charge of incompetency brought by the Marquis of Bute against the cabinet-makers of London, and endeavours to fix the stigma on the foremen only, who, he says, are often selected for other qualities than those which tend to promote good workmanship; and further insists that until we have a system of industrial partnerships we cannot expect much improvement. Having for some years filled the positions of journeyman, foreman, and master cabinet-maker in London, up to very recent times, I should like to say a few words on the subject.

In the first place, your correspondent appears to me to fall into the very common error of supposing that his little world is all the world. He is evidently a man accustomed to work in a good, perhaps (and more than likely) one of the best, West-end shops, where every job is made to a supplied design, and seldom repeated; where the work is either done day-work or valued at hook price, and with such work as he mentions an addition of a considerable per-centage above hook price. But he forgets that not one-twentieth, nay, nor one fiftieth, of the work produced in London is made in such shops as these. Let him take a walk through the town, and set down as he passes the number of furniture-shops in which he finds really good work against those in which he sees nothing but scamp work, and I am sure he will be convinced of this. For it must be borne in mind that of ordinary furniture we import none from other countries. Then where is it made? In London. London is the great furniture manufactory for the empire. Round and about Tottenham-court road, Paddington, Clerkenwell, Bethnal-green, Shoreditch, Hoxton, and part of Islington, are the localities where the great bulk of the work is produced. Here you will find workshops, the number of whose occupants vary from as high as twenty down to the solitary individual workman, who, as he often says, likes his liberty and cannot bear the restraint of a big shop. In these places each man has his speciality, to which, in most cases, he rigidly adheres. The one kind of article he begins to make in his youth, he continues through his life, and so he comes to be not a cabinetmaker really, but a wardrobe, or a sideboard, or a cheffonier, or a table, or a chair, or sofa, or a drawer maker, and so on, through all the various articles in use. And in many cases the labour is even more subdivided than this: for instance, take a Davenport. The action, as the rising part is usually called, is made by one man, the desk part by another, and the pedestal containing the cupboard or drawers by a third, besides the carving, which makes a fourth or fifth. Again, the men who work mahogany seldom use rosewood or walnut wood. Deal bedroom furniture is a branch of the trade quite apart from the rest, and is as much subdivided as the others.

Sideboards and cheffoniers are made by as many men as there are varieties of goods. Workshops, too, are divided into two classes—frame shops and carcass shops, frames being such as chairs and sofas; and carcasses such as wardrobes, sideboards, &c.; and these two classes of goods are seldom or never made in one shop. All this work is invariably made by the piece, the price paid being just as little as the employer can get the men to do them for. And as boys' labour soon becomes valuable, the master takes as many apprentices as he can get, especially if they bring a premium, though only a very small one, as 5*l.*, which is a very common sum to pay; and he will think himself extremely fortunate if he obtains 50*l.* to 80*l.* with a boy, as I have known foolish parents and guardians pay to masters, many of whom date their success in life to the advent of such a premium.

In many shops the boys, though paid a fixed wage, are put to taskwork, a certain *minimum* quantity of a *minimum* quality being required of them, any additional quantity done beyond which may increase the pocket-money. The wages which these boys earn when they become men varies as their speed in producing. I have seen a man make two chests of five drawers each, in mahogany, with all partitions, heads, locks, &c. complete, in a week, at the price of 30*s.* each for his labour, while another working alongside on the same work could not complete one in less than nine days. Again, one man will make the carcasses of two large-shaped cheffoniers in walnut or rosewood, in a week, at a price of 25*s.* to 30*s.* each, while another would take ten days to make one.

Of course, the rapid rate is the exception, but if a man finds he can do it, and does it once or twice, a policy of hedges is adopted by the master to keep his wages down, which often ends by his starting for himself. And this is very easy. He can rent a workshop or room at some two or three shillings a week, and can buy a bench for a dozen shillings. With a sovereign or thirty shillings he can buy materials enough at the timber-yard to make his first job, which, when completed, he hawks about in cart or harrow round to the various warehouses or shops, until he sells it; it may be for its value, or it may not: he has to take just as much as he can induce the warehouseman or shopkeeper to give.

If the workman is of an imaginative temperament, he may make a new kind of furniture, or vary an old form so as to give a freshness to his work. This will enable him to sell for a little while, but in a short time other makers see it and copy, and it becomes a neck-and-neck race who can produce at the lowest price. He may then devise another new thing, and for a time he is able to live, till, if he is fortunate and careful, and with premiums from apprentices, &c., he is able to avoid the wholesale warehouses, who cut his prices down to starvation, and does as they do—visits the country shops, and takes orders direct. But as these customers almost invariably require credit, it is uphill work. He cannot buy a stock of timber to be thoroughly seasoned before being made up, and has to get his supplies direct from the retail yards, and make it up at once; so that the work is scarcely put together before it parts by shrinking, and requires to be repaired.

To counteract this evil he uses as little wood in the job as possible; and it used to be a standing joke that the work required to have a big stone fastened to it to prevent it being blown away, so light were the carcasses.

If carving has to be used to decorate the article, it is supplied by the wood-carver, who, like the cabinet-maker, has a workshop with workmen and apprentices. This carving is done at so much per set. It may be appropriate, or it may not. There it is. If the cabinet-maker finds it sells well, he adopts it, and produces the pattern *ad infinitum*. Other cabinet-makers also buy, and with quite a different style of carcass attached, the article is offered for sale.

These carvers also are as journeymen divided into two classes,—those who rough out the work, called howsters, and those who finish, called finishers. These men, in forty-nine cases out of fifty, could not design a very simple ornament differing in a very small degree from the style to which they have been used. The master is sometimes able to use his pencil a little, but not always, and there are some now in business who have been tolerably successful on patterns, on which they have worked since they began years ago. But even among those who can draw at all, the element of design is so wanting, their ignorance of natural forms is so great, that even when they produce flowers or fruit, it is impossible to determine to what order or genus they belong; and I have frequently, when asked the question, replied that I knew of nothing in nature like them, and that I usually called them carvers' fruit.

There was a man, a German, who received a tolerably good artistic education at the King's School in Munich, who afterwards came hither, and worked as a wood-carver, and I have no doubt that that man has made more designs for wood-carving during the last fifteen years than have been made by all the other carvers put together. For if he was hard up, as he sometimes was through drink, he would soon sketch off a number of designs in various styles, all workable, and these he would sell to the master carvers, who were themselves unable to design. This was quite a godsend to the carvers. I have seen that man's designs in every town in England, Scotland, and Ireland, in which I have been; and in India and Australia they are frequently to be met with.

I have entered thus into details, because I believe that it is only by a thorough *exposé* of the whole business, that the public will be able to understand why they do not get better furniture.

At the present time I am thoroughly convinced that the majority of the workmen are quite incapable of producing better, and that if better required they must be educated up to it. This will, of course, take time; but the public have only to determine that they will no longer be satisfied with the results of the very disorganized system at present obtaining, to set the ball rolling in the right direction. Let artists and architects, as well as others who have any

pretensions to taste, declare, as some friends of my own did to me last week, that they would never buy another piece of ordinary furniture; and let there be a demand for good designs as well as for good workmen to execute them, and I have no doubt whatever that both will soon be forthcoming. Let them avoid the great advertising shops, who sell the work made under the circumstances which I have described, and mostly that only; let them avoid them as they would the plague (for they are a plague in an artistic sense), and I shall then have hopes of my countrymen. In the past and present, show and glitter reign supreme;—I had almost said in everything, physical and moral. Let the qualities of fitness and goodness take their place; let our schools of art be multiplied and liberally supported; and above all let there be established without delay trade schools for the young, in which the neophyte may be introduced to the theory of construction as well as that of decoration, and I have no doubt both complaints and protests will then become things of the past.

E. G.

THE RISK OF WINDERS.

GALVEY'S CHARGING CROSS HOTEL COMPANY.

THIS was an action brought in the Court of Queen's Bench, Westminster, by a gentleman, in consequence of his wife having broken her leg by falling down a staircase in the Charging Cross Hotel. The stairs in question are called the "Second Visitors' Stairs." They are 5*ft.* wide, with 12 in. treads and 6 in. risers, and at the quarter-spaces there are winders $\frac{1}{2}$ in. wide in their narrowest parts. The handrail is carried by balusters let into the ends of the steps. It was contended by the plaintiff that the winders were a source of danger, for which the defendants were liable, and the damages were laid at 1,760*l.* The plaintiff's counsel read medical evidence taken in Dublin, to the effect that Mrs. Galwey was injured for life, and that the fracture was of a very bad description, known as "Pott's fracture." Mr. Galwey, jun., Mr. E. Nash, Mr. E. Roberts, and Mr. E. Tasker were called to show that the winders were dangerous, and that there was not sufficient light when the accident occurred. They all admitted, however, that they had frequently used winders in their own practice. For the defence it was shown that nearly 300,000 persons had visited the hotel since its opening, and that about 150 servants were there employed, but that no complaint had ever been made of the stairs. Mr. E. M. Barry and Professor Kerr stated that the stairs are in every way safe, and such as are ordinarily constructed; that they are lighted by a skylight over the well-hole, and eleven windows besides borrowed lights, and that though they are necessarily darker at the bottom than the top, there is no such deficiency of light as to cause danger.

The following members of the profession were in attendance to support this view, but were not called:—Mr. T. H. Wyatt, Professor Hayter Lewis, Mr. Clifton, and Mr. Marrable. Mr. P. C. Hardwick was prevented from attending in consequence of a recent accident. Mr. Plucknett and several practical witnesses were also called. As regards the medical evidence, Mr. Hancock, senior surgeon of Charging Cross Hospital, and Mr. Lee stated that the injury had been exaggerated, that it was not "Pott's fracture," and that in their opinion Mrs. Galwey would soon be as well as she had ever been.

Mr. Justice Lush told the jury that if they thought the company guilty of negligence, the verdict should be for the plaintiff, with proper damages; but that there was such a thing as plaintiff's negligence. The company had a right to expect ordinary care and caution from those who used their premises, and ought not to be punished for their negligence.

The jury withdrew for a short time, and found a verdict for the defendants.

The counsel engaged were Mr. Hawkins, Q.C., Mr. McAlvey, and Mr. Griffiths, for the plaintiff; Mr. O'Malley, Q.C., Mr. Theobald, and Mr. Lanyon for the defendants.

Malvern College.—The Council's annual report states that application has been made to the Malvern College Building Company to build one or more boarding-houses for the College, and to this the company have assented. It appears that 34,000*l.* have already been expended in buildings, besides 34,000*l.* on the College. During the past year the number of pupils has increased from 130 to 170.

THE FIRE-PROOF PROPERTIES OF ASPHALTE.*

We have before us a communication recently made to the French Société des Ingénieurs Civils by M.M. Flachot and Noisette, detailing experiments made by them to ascertain the extent of the fire-proof properties of asphalté. They relate that five fires had occurred in different buildings that contained asphalté flooring, in which all the floors and other wood-work were destroyed except that covered with the asphalté, it occurred to them that this material, hitherto only used as a flooring on which to store ovens or stables, could be further utilized as a fire-proof material. In each instance the fires mentioned were arrested at the story laid in with asphalté, whether it covered the stables on the ground floor, or had been used on the upper floor of the granaries above them. The asphalté in some portion of its thickness softened or liquified by the fire, but when help arrived and it was covered with water, it hardened again and returned to its original condition. The wood shafts which communicated from floor to floor were in each case sources of extra damage, a fact that leads to the suggestion of a fire-proof material for this part of such structures for the future.

The first experiments detailed were made in the workshops of the Compagnie des Omnibus. Five tables, covered with white deal of 0,027 millimètres in thickness, resting upon four feet, about 1 mètre in height, were coated with the following materials:—1st. Asphalté from the stores of the Compagnie Générale des Asphaltés, of 15 millimètres in thickness; 2nd. Plaster of 30 millimètres in thickness; 3rd. Béton Coignet of 40 millimètres in thickness; 4th. Portland cement of 25 millimètres in thickness; 5th. Asphalté of the same nature and thickness of No. 1 spread upon a bed of baked earth 25 millimètres in thickness. Table No. 1 received the contents of two grilles of incandescent charcoal, upon which groundwork wood was piled and supplied afresh, till the fire had burnt for an hour and three quarters, during which time no indication of the fire communicating with the planks below the coating of asphalté appeared. On the removal of the fire it was found that the asphalté had liquified towards the centre, and also scorched the plank below it, which was also slightly carbonized to a thickness of from 1 to 3 millimètres. The experimentalists considered it was proved that a bed of asphalté 0,015 millimètres thick preserved the planks from ignition for an hour and a half. Whether it would do so for an indefinite period after fusion and the exhaustion of the combustible vapours contained within it, has yet to be ascertained.

A similar proceeding upon the second and third tables showed that the plaster and Coignet's concrete had perfectly preserved the planks from fire. The water contained in the last-mentioned was transformed into vapour, with several superficial explosions, which caused a slight reduction in the thickness of the concrete, but no further damage.

The coating of cement in the fourth experiment, like that just mentioned, altered in some places by explosions arising from the water it contained. The cracks were larger here, owing to the thickness being less, 25 millimètres instead of 40. The planks below it were carbonized where the heat was most intense.

The fifth experiment gave a most satisfactory result. The fire was renewed twice, and prolonged for an hour and a half. When the ashes were cleared away, and the asphalté cooled by water, it was found that it retained its toughness, that its thickness was not sensibly diminished, that the burnt earth remained intact, and that the planking was as completely preserved as under the grille and béton Coignet. In all the experiments the fires were more intense than they could be in a conflagration; and the results show that the obstacles the several coatings present to the progress of the flames, would give the necessary time to obtain help after the discovery of a disaster.

Another experiment was made to ascertain the combustibility of asphalté. Some fragments of it were placed in a brazier of burning charcoal, open to the air on all sides. A certain amount of gaseous matters was burnt, and an inconsiderable amount of the asphalté melted

round about the grille; but in less than a quarter of an hour the fire became powerless to pierce it, and gradually went out.

The authors of the experiments next consider the price, weight, duration, and appropriateness of the different materials as floorings for large granaries, with stables below them. Portland cement they price at 3 francs the square mètre; béton Coignet at 2 francs 80 centimes. Both of these have the drawback of yielding a dust that is pernicious in its effects upon the horses' teeth. The plaster costs but 95 centimes the square mètre, but it labours under the disadvantages of prolonged desiccation, is not so durable, and yields a dust that is bad for the forage, and renders it unfit for the storage of oats; and neither of these articles adapts itself to the shrinkage of the boards of the floor. The asphalté upon the burnt earth they price at 2 francs 90 centimes, and consider that its surface is suitable for the storage of both grain and forage; that it adapts itself to the deformation of the flooring; that it is dry, and can be washed; and, in cases of fire, beyond either of the other materials, would be serviceable in preventing water from filtering through the boards, and destroying grain garnered in stories below it.

Additional experiments were made by the Compagnie des Omnibus, in the presence of members of the Conseil d'Administration and chiefs of the Corps des Sapeurs Pompiers de la Ville, and other interested persons, in the court of the dépôt at Montmartre. Two tables were prepared as before, and covered with a bed of asphalté of 15 millimètres laid upon one of the terre à four of 25 millimètres in thickness. Fire was applied to one of them, as in the other investigations, for an hour and a quarter; and there was a brisk wind blowing upon it. The softening of the asphalté, the vaporization of the essential oils it contained, the eruption of little jets of white vapour, all proceeded as before; and when the cinders and débris were removed it was found that the slight thickness of the asphalté that had been altered by the fire formed a crust over the rest that quite protected it. This was lifted up and the earth below uncovered, which was found unaltered in any particular, and the planks below this were so little affected by the intense heat that had been raging about them that the hand could be kept upon them. The upper surface of the asphalté, although deprived of some of its essential oil, was not so altered but that on cooling it returned to its former degree of hardness. The fire was lighted under the other table, and was soon at work upon the joists of the boards and upon their lower surface; but not being able to ascend through the hermetically sealed planks of the bed of asphalté above, it remained inactive; and when the feet of the table were consumed, the top sank down, and put out its own fire, and that upon the hearth below it at the same time. The last experiment was but a reproduction of a fact first observed in a conflagration at the asphalté works at Seyssel. A cauldron, one of eight, full of bitumen, cracked, and this inflammable matter, escaping on to the hearth, caught fire. The flames began to lick the joists and beams of the floor above. As it happened that the upper floor was intended to receive heaps of asphalté dust, which would have filtered through the planks after the heat below had caused them to shrink, the floor had been covered, at the instance of M. Malo, with sheets of strong grey paper, and a layer of bituminous mastic laid over it. This imprisoned the flames, and would have kept them powerless but for the circumstance that it did not extend over the whole floor. The flames, making their way from joist to joist, came at last to the unprotected place, and the roof was soon in a blaze. The firemen played upon the roof, without much result, for the fire from the basement fed that above; till at last the beams of the floor carbonized gave way, and the floor sank, carrying with it the bed of asphalté, which extinguished the fire instantly.

The Compagnie des Omnibus have adopted the asphalté and earthen flooring for their granaries when they are of wood. Where iron is used, the intervals will be filled with plaster in the Italian manner, and the earth and asphalté laid over the plaster. The authors of the communication recommend this mode of flooring for all industrial establishments and magazines containing combustibles. Private houses, they say, might apply the asphalté between the joists under the boards. They give particulars of a fire which broke out in a

row of workmen's dwellings at Soyssel, where a bed of asphalté completely preserved the floor, with the ceiling below it, notwithstanding that the furniture standing upon it was consumed.

THE SOCIETY OF ARTS REPORT ON TECHNICAL EDUCATION.

As already noted, the report of the committee appointed at a conference held at the Society of Arts, in January, 1868, on Technical Education, has been published (by Bell & Daldy). The report is too long for us to give any comprehensive abstract of it; but we quote some of its conclusions:—

- (a.) For the purposes of dissemination, technical education should be deemed to exclude the manual instruction in arts and manufactures which is given in the workshop.
- (b.) That the term 'technical education' is understood by the sub-committee to mean general instruction in those sciences the principles of which are applicable to various employments of life.
- (c.) That technical instruction, as defined above, should not, as a rule, be given in separate professional institutions, but in institutions established for general education.
- (d.) That, with a view to the development of a system of scientific education, it is desirable that schools be established having for their main object the teaching of science as a mental discipline. These science schools should prepare some youths for the higher courses of a college, and other less ambitious pupils for their professional pupillage.
- (e.) That the subject of secondary instruction having been reported upon ably and deliberately by the Schools Inquiry Commission, the Committee do not feel it necessary to enter into the details of this subject, while they desire emphatically to express their opinion of the necessity for the introduction of scientific teaching in all secondary schools.
- (f.) That it is desirable that the higher scientific instruction should be tested by public examinations, and that the proficiency of persons who pass these examinations should be certified by diploma.
- (g.) That the preparation for the business conducted by the Committee is not sufficient until due scientific instruction has been followed by practical pupillage in efficient works.
- (h.) The Committee recommend employers of labour and others in the habit of taking pupils, apprentices, and clerks, to give the preference as far as possible to those adding evidence of the possession of adequate instruction in the sciences applicable respectively to their professions or occupations.

The reporters are of opinion that it is desirable that Government, colleges, and the leading civil and mechanical engineers, architects, merchants, ship-owners, chemists, manufacturers, and agriculturists, should encourage systematic scientific instruction by certain specific measures set forth in the report; the Government, for example, by aiding in the establishment of science-teaching in schools, colleges, and universities; by providing free libraries, night classes, and prizes for workmen, &c.; and professional men and others by creating scholarships, and recognising and privileging diplomas, &c.

The report reserves for separate consideration the technical education of those who are producers of works of fine or decorative art; or directors of art manufactures. The Committee are of opinion that:—

"Provision should be made for the teaching of drawing in all schools, primary and secondary, as a branch of general education, in order to train the eye and hand, and in order to cultivate habits of observation. It is essential that drawing should be part of the regular school course, and not an extra lesson; and, further, that it should be taught intelligently, not from mere copies, but from real objects.

The art-workman needs, in addition to a power of free-hand drawing, an acquaintance with geometrical drawing, in order that he may be able to execute work correctly, in accordance with the designs of the artist who directs him.

For artists, designers, and directors of art manufacturers, the education should be a liberal one, in order that they may understand the feelings of those on whom they desire to make an impression. Their education should also be, to some extent, scientific, in order that they may have a knowledge of the properties of the materials they employ, and be able to adapt those materials to the structure of the objects produced, and those objects to the uses for which they are intended.

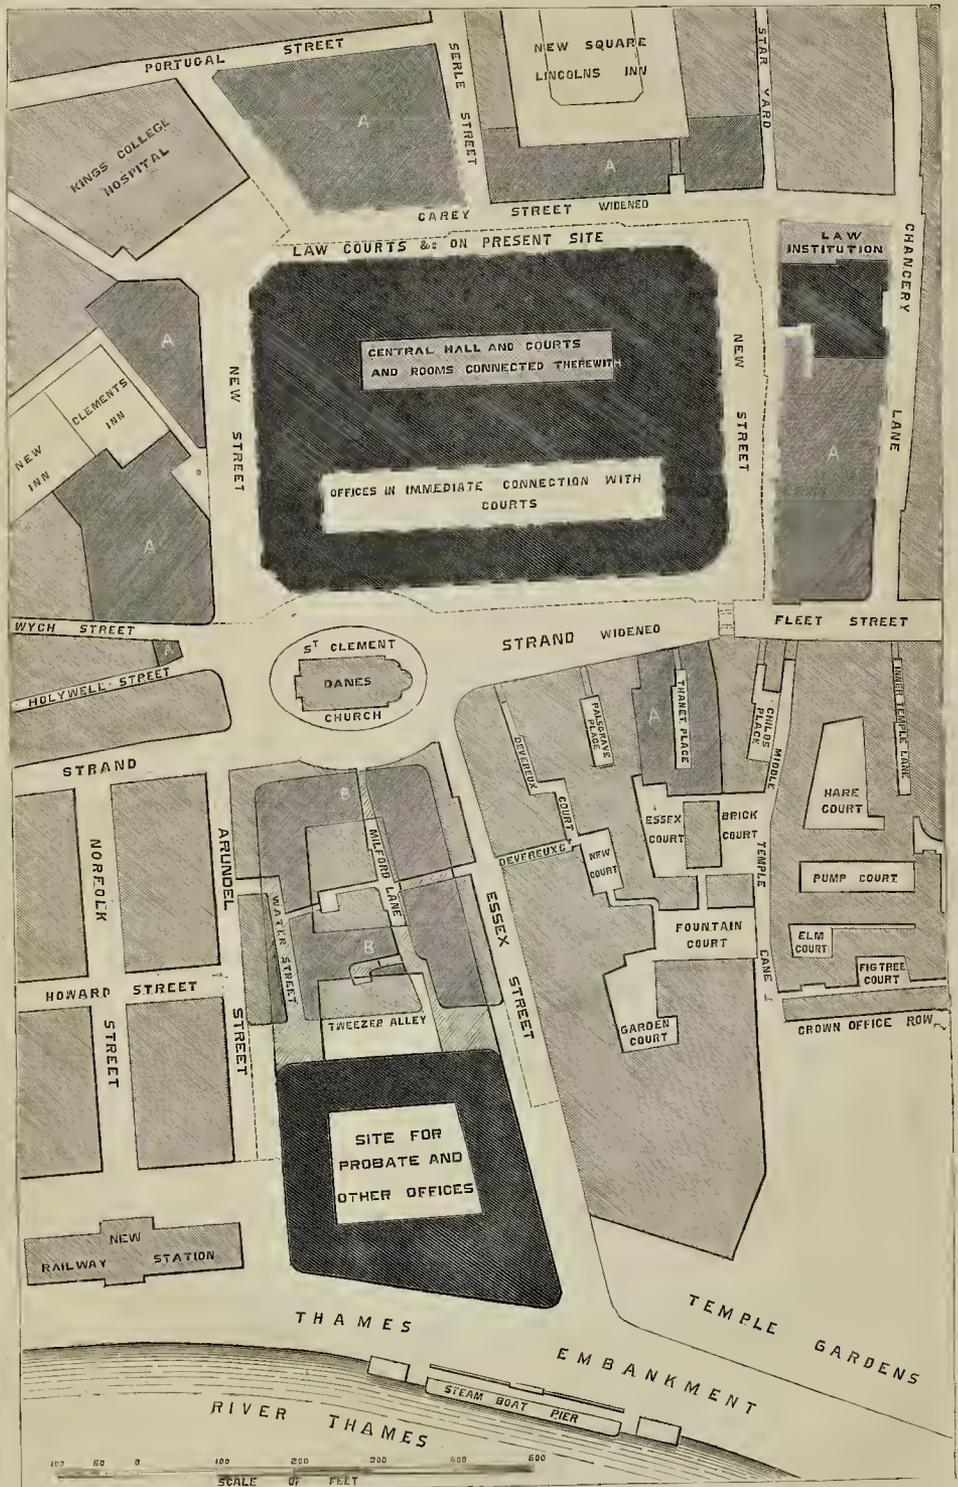

It is desirable, both for the artist-workmen and for those engaged in the highest branches of art, that opportunity should be given, by access to museums and to evening classes, for the study both of the theory and history of art.

Your Committee are of opinion that the universities may render great service to the technical education of those engaged in artistic pursuits, by the recognition of art as an element in general education, and by professional lectures. Some steps in this direction have been taken, by the regulations attaching importance to drawing in the local examinations; but your Committee would gladly see the practice carried further, and applied to the higher stages of academic education. They cannot doubt that the study of works of ancient and modern art would have a tendency, in connexion with literature, to diffuse culture throughout the nation, and to raise the standard of education.

The report is signed W. Hawes, Chairman of the Sub-committee; and P. Le Neve Foster, Secretary.

Preparing for Earthquakes.—A Californian has applied for a patent for an earthquake-proof chimney.

TREE AND SERPENT WORSHIP.

At the Royal Institution on Friday evening, the 5th, Mr. Jas. Fergusson, F.R.S., lectured "On Tree and Serpent Worship, as exemplified by recently discovered Indian Monuments." In the course of his discourse he called attention to drawings and photographs of parts of three temples in different parts of India, especially that of Sanchi, whereon trees and snakes were largely sculptured. He said that Buddha was born of royal parents in the year 623 B.C., in a district at the foot of the Himalayas; he had a happy childhood and a happy marriage, but, being struck with the miseries of humanity, he resolved to reform society, and, leaving his home and friends, he spent six years in secluded prayer and thought, at the foot of a tree which is called to this day the "tree of knowledge." There he preached and made many converts, till, in the year 543 B.C., he died, at the age of 80. Buddhism was afterwards sometimes favoured and sometimes persecuted, till, in the year 250 B.C., Asoka did for Buddhism what Constantine did for Christianity, and made it the state religion, after which it also spread rapidly in the countries surrounding India. At the present time there is probably not one single Buddhist in India, although this religion is prevalent in the neighbouring countries, and is followed by a very large proportion of the inhabitants of the earth. It is, therefore, interesting to inquire how these changes took place. India, more especially in its southern portion, was in very early times inhabited by the Turanian race. They were then conquered by an Aryan Sanscrit-speaking race, who mixed and intermarried with the Turanians, and planted the Vedic religion among the people. Finally, both the Vedic religion and the Aryan gradually became corrupt, and then Buddha urged the natives to rise, and to drive out the Aryans and their religion together. The Turanians are a building race, and this character distinguishes them from the Aryans. Buddha seems to have revived the ancient religion of the country, and not to have started an entirely new one. It was not till after his days that the Turanian element gained the ascendancy, which is probably the reason why no temple in India is older than the time of Asoka. This king erected pagodas, monasteries, and churches, the latter being very much like our own, with an altar, and a place for the choir, besides other resemblances. The serpent, and sacred trees, and Buddha are carved in most of these churches, one of the most remarkable of the temples being that of Sanchi, built about the year 200 B.C. There is evidence that, after a time, snake worship became more prominent than Buddhism itself. As far as he could trace it, tree and serpent worship spread all over the world, wherever there is an underlying Turanian element in the population. In the opening chapters of Genesis, the "myth" which has troubled many, is probably a curse upon serpent worship. The brazen serpent, uplifted by Moses, is the first healing serpent on record, though there have been many since, even in Greece and Rome. Hezekiah is narrated to have turned the serpents out of the temples, and to have destroyed the groves; so it would appear that tree and serpent worship was then followed among as the Jews, though the habit was looked upon as a heathenish by their priests. In Assyria, as shown by the monuments, tree worship was very common, but serpent worship was followed to a lesser extent. The Egyptians can hardly be said to have been serpent worshippers, though the serpent is often used allegorically in their monuments; but the case was different among the ancient Greeks, who were of the Turanian and not the Aryan race. The Homeric myths, and most of the ancient traditions, give evidence of the prevalence of this superstition; the oracle at Delphi was pythonic; and at last the partial serpent worship of the Greeks spread to Rome, till tans snakes became so plentiful in the latter city that they were a nuisance. Wherever there is an underlying Turanian element in the population, there will traces of tree or serpent worship be found. The Germans in ancient times worshipped trees, and in Scandinavia, among the Finns and Laps, who are of Turanian origin, tree and serpent worship is an important element in the religion. In Esthonia trees were worshipped down to a very late date, and some of the prayers to them which are yet preserved show that the religion is evidently an offshoot of the Hindoo mythology. He thought there was a little evidence that tree and serpent worship once reached the North of Scotland, as indicated

by ancient stones and legends, met with more especially in the Orkneys. In England only the faintest shadow of such a worship is found; and if it came here it must have been introduced by some southern route. What are possibly traces of it are found mostly in Wales and its borders. In Africa tree and serpent worship prevails largely at the present day, more especially at Dahomey, where it forms the sole or chief religion of the country, and where thousands of snakes are kept, all descended, it is said, from one primeval serpent. In parts of America, especially in Mexico, serpent worship was once common, and seems to have been of Turanian origin. In fact, remnants of this old religion crop up everywhere, and are found nearly all over the world. Conjoined with it is found the custom of building up rude stones into cromlechs and circles. In India many of the tribes are building cromlechs at the present day, just like those found so plentifully in Wales, Brittany, Southern Europe, Asia Minor, Syria, and nearly all over the world. Very recently an Indian officer, while breaking through some jungle in that country, came upon thirty or forty ancient cromlechs, and, strange to say, in company with them were twenty or more large rough stone crosses, evidently Christian; so he photographed the scene and sent home the pictures.

THE TRADES MOVEMENT.

The Trades Union Commission have at length brought their labours to a close. The report—which is understood to be not wholly unanimous—is agreed to, and will be published as soon as practicable.

A conference of trades unions is to be held in Birmingham in June next, and the following twelve subjects have been selected as those on which papers would be allowed to be read or resolutions proposed:—1. Justification of trades unions. 2. Legislation of trades unions and the commissioners' report. 3. Trades unions, political economy, and foreign competition. 4. Reduction of the hours of labour beneficial to the nation. 5. Limitation of the number of apprentices. 6. Strikes and lock-outs; their cause and effects. 7. The necessity of assimilating the Factory and Workshops Act of 1867. 8. How far will co-operative production and industrial partnerships assist in settling the conflicting interests of capital and labour. 9. The absolute necessity of trades unionists having representatives at the meetings of the Social Science Association. 10. Primary education. 11. The best means to secure the direct representation of labour in the House of Commons. 12. The necessity for working-class newspapers, and the best means for their establishment.

A free labour deputation, from nearly all the manufacturers and merchants of Manchester and its vicinity recently presented an address, signed by upwards of 300 of them, to a meeting of the local building trades, held for the purpose. The address was of course in favour of free labour, which the Free Labour Society urged upon the attention of the builders, as an essential part of free trade. Mr. Alderman Bennet said, that unless the architects would specify machine-made bricks, builders were almost powerless in the matter. Thanks were given on the part of the builders by Alderman Neill. A paragraph was read from the operative masons' fortnightly report, stating that strikes existed at the present time among the masons in nearly forty towns, against the introduction of machine or quarry-worked stone, and that the masons were spending nearly 500*l.* per fortnight, or upwards of 12,000*l.* per annum, in fighting against machinery. This is little less than madness.

The eight hours' law in America is now acknowledged by the Republican press to be a complete failure. The framers of the Act are said to be quite satisfied with the result of its trial. They threw out a bait just before an election, and the working-classes took it without suspicion. But although a law may say that eight hours shall constitute a day's labour, it cannot regulate the rate of wages. Employers paid for eight hours, and no more, and the workmen were obliged to ask for the privilege of completing the regular day.

The London Trades Council, through their secretary, Mr. G. Odger, are endeavouring to gain the co-operation of the various trade societies throughout the kingdom in their movement for the establishment of Boards of Arbitration for the settlement of trade disputes. Mr. Odger has just received a letter from Mr. Dronfield,

secretary of the Association of Organized Trades of Sheffield, enclosing the following resolution, unanimously passed by that body:—"That the delegates respectfully recommend the trade unionists of Sheffield to consider the importance and desirability of taking steps to establish Boards of Arbitration in their respective trades with as little delay as possible."

METAL WORK.

MANCHESTER ARCHITECTURAL ASSOCIATION.

The fourth ordinary meeting of the session was held in the Rooms of the Association, Lord's Chambers, Corporation-street, on Tuesday evening, January 26th; the president, Mr. Isaac Blackwell, in the chair. After the election of members, and a discussion on the Architectural Education question, which was referred to the council, Mr. Angelo Tyler, of Birmingham, read the paper for the evening on "Metal Work."

In the course of his remarks the author said,—From the Classic and Pre-classic periods the desire and power to treat works in metal artistically has continually been apparent, the vehicle of working varying according to the idiosyncrasy of the nation. Among the ancient Greeks we find the practice of working through the agency of sand-casting more prevalent, though it is probable that they equally excelled in hammered work. The civilized nations of the ancient East were undoubtedly great workers in the sheet metal; at least we may so infer if we take into consideration the skill in hammer-raising displayed by their descendants, which is indubitably of native growth.

Coming more nearly to European history, we find a powerful fostering and development of art-metal working by the congenial home and profitable market for the reception of Eastern methods of working and design existing amongst what I may call the Christian orientalism of Early Byzantium. When I say Eastern methods of working, I mean the practice always extant of rendering design subservient to facilities of working, a practice which was eminently a characteristic of Byzantine metal work. From Byzantine metal work and its equally vigorous Runic sister we have a varied character, culminating in the twelfth century to a peculiar grace and beauty, though still carrying a barbaric tinge, inherent no doubt from the want of power in the age to cull and develop, or at any rate adhere to and perpetuate its Eastern peculiarity of touch and expression until Western Ecclesiasticism gradually dominated, when we find the production of a crabbéd Mediævalism, as shown in the metal work of the fourteenth, fifteenth, and sixteenth centuries, meritorious in some points, as must necessarily be on account of the protecting influences of a collegiate though circumscribed age.

The extraordinary impetus given to art metal-working through the wonderful manipulating excellence and grace of design of the school of Ghiberti and Cellini has extended its civilizing influence to the present day; the present so-called Mediæval revival (which, by the way, is more archaeological than artistic) gradually becoming toned by its power, and yielding to its many beauties, in spite of an interested manufacture. I am of opinion that the principle involved in the single word revival is incorrect, because obstructive, through setting up the idol of a bygone merit as a goal of perfection: hence we have our metal-workers ignoring the beautiful in one style, to exalt it in another, developing into spiral extravagances and jewelled deformities of design, instead of taking up the staff of art metal progress as it fell from the decrepit hands of a yielding past, worse than slavishly imitating, because parodying, by idly adapting in iron the gold and silver work peculiarities of examples of the twelfth century, such as the Reliquary of the Virgin, Aix la Chapelle. We have, amongst others, a fourteenth and fifteenth-century crocketed railing after examples unfortunately resuscitated by the late A. W. Pugin, in his moments of, let us hope, transition to pure and less bigoted art; brightly polishing their work because it was a fifteenth or sixteenth century canon to do so, and in which they have been ably seconded by the rest of the Mediæval metal work revival school, blossoming into maple and ivy-leaved productions, and religiously adhering to that most convenient, a cusped and traecored filling. I do not see why we should ignore principles of manufacture, many of which were generated in Italy during the Cinquecento, and also are our, I think, modern advantages. Why exclude all

bronzing and parcel relief? Why so persistently exclude that most beautiful vehicle cast on chased surfaces? A most valuable medium is cast malleable on account of its non-oxidation, strength, and ductility; and yet architects who will patronise common cast-iron because known in Mediaeval times will purposely exclude cast malleable, because those interesting contemporaries of the swash-bucklers were in a state of ignorance as to its making. Amongst decorators (Mediaeval revival) we find their guiding inspiration is the Byzantine *herba benedicta*, which is undergoing some remarkable developments, parallel, I am sorry to think, with some of the extraordinary architecture of the day, which shows much more of licence engendered by an invention running riot than a correct appreciation of true art.

LIVERPOOL ARCHITECTURAL SOCIETY.

At the ninth meeting of the present session of this Society, held on Wednesday last, the secretary announced that the council had received thirteen sets of drawings in competition for the Students' Prize; the subject being a design for a row of street-houses, to be executed in brick, with terra-cotta or ornamental tile decorations. The meeting then proceeded to the consideration of the proposed form of building contract (printed in our last number), the clauses being gone through *seriatim*. Various points of objection were raised, and amendments proposed, with reference to several of the clauses, and an additional clause was adopted by the meeting, for insertion after the third clause of the original form, providing that after the architect had furnished one complete set of copies of the drawings for the use of the contractor, the latter should be responsible for furnishing all additional copies necessary for the use of the workmen or the sub-contractors. Owing to shortness of time, the consideration of the form of contract was not carried further than up to the sixth clause, and no definite resolution was arrived at upon the subject, the further consideration of which was adjourned till such period as the Council of the Society should determine upon.

SOCIETY OF FEMALE ARTISTS.

The thirteenth exhibition of this society, now open in the Conduit-street Gallery, comprises 484 pictures, contributed by 183 lady artists. It is a very agreeable collection, much superior to that of last year; and Miss Warren, Miss Adelaide Burgess, Miss Gastineau, the Misses Swift, Mrs. E. M. Ward, Madame Bodichon, Miss E. D'O. James, Mrs. J. W. Brown, Mrs. Lee Bridell, Miss Margaret Bayner, Mrs. Robertson Blaine, Miss Stannard, and Miss Louisa Starr materially contribute to make it so. Two special features of the exhibition are a dozen very clever drawings, by Miss Louise Rayner, of buildings in Chester; and sixteen by Mrs. Marrable, illustrating the Engadine, Switzerland. Two views of the Roseg Glacier, amongst the latter, are particularly good.

PARIS.

The project of a law relative to the works at the heights of Trocadero has led to a slight difference between the Corps Legislatif and M. Haussmann. The prefect of the Seine demands from the Chamber the small trifle of 132,000*l.* to pay for the earthwork. The Chamber replied that the inhabitants of Paris must pay for the whims of M. Haussmann, and that the departments have nothing to do with them. At the Place du Chateau d'Eau, the new fountain proceeds but slowly, and the huge bill-stuck amphitheatre of hoarding is all that is to be seen after years of labour. Various are the conjectures daily put forth as to the future destination of the pile of buildings on the north of the place, called the Magazins Réunis, built by a company who took upon themselves to reimburse integrally to all purchasers of articles of whatever nature they might be—from a rat-trap to a *Sèvres vase*—the sums laid out by them in their establishment. But they did not, preferring bankruptcy. At the south side of the place a new monster shop, "Panvro Jacques," has been located in a well-built and commodious pile. This is one of the monster houses of Paris which have been of successful duration. Other houses worthy of the site are being erected on the south-west side, so that the place will shortly be regularised.

Accidents have frequently occurred in Paris

from the falling of cornices of houses owing to the decay of the stone or the plaster, and a few days ago one was very nearly rendered fatal. At the Place de la Concorde a portion of the cornice of the Hôtel de Crillon fell upon the street with a loud crash, and was broken into a thousand pieces; owing to the early hour (8 a.m.) there were few passers by, but a pastry cook's boy had a narrow escape from destruction as the mass fell at his feet just as he was passing.

The French association for preventing the abuse of tobacco has named the following officers for the year 1869:—M. Blatin, president; Dr. Jules Guerin, first vice-president; Dr. Vermeil, second ditto; Decroix, general secretary; Rassel, secretary of meetings; Beaupré, secretary archivist; Crivelli, foreign secretary; Dr. Joly was named president of honour.

A frightful tornado passed over Paris on the 1st of February. Several workmen were injured by being blown off scaffolding, &c. The trains of the circular railway passing over the Anteuil viaduct on the Seine were nearly shipwrecked: one engine lost her chimney, which fell into the river and sank a boat. One of the open-roofed carriages was stripped, to the great alarm of the passengers. A horse was decapitated in the Rue de Vivienne by a fragment of metal plate which fell from the roof of a house into the street.

ST. EDMUND'S CHURCH, RIBY, LINCOLNSHIRE.

This church has undergone a complete transformation; those who remember it in former days would hardly recognize the building now. The interesting portions of the ancient fourteenth century church which remained were the centre tower, the walls of which battered considerably; the transept, and nave, with a good arcade. The original chancel had been replaced by a wretched structure, with round-headed windows, and otherwise entirely devoid of architectural character. The north aisle of the nave had been similarly treated. The transepts and chancel had been cut off from the nave, and were never used for divine service. The nave was filled with high square pews, and a ponderous pulpit and desk were piled against the screen, which divided the nave from the eastern portion.

By the munificence of Mr. George Tomline, M.P., this state of things has been completely changed. The modern chancel has given place to a new one, designed in the Decorated style. The interior has three bays of groining, springing from triple vaulting shafts. The ribs and bosses are of Ancaster stone, and the groins filled in with chalk, banded by courses of Ancaster stone. The east end has a triplet window, and the sides are lighted by triplet windows, with tracery heads. The chancel is fitted up with oak stalls, and the walls are lined with oak, having an ornamental brattishing. The tower has been groined, and the nave and all other parts are ashlined with Ancaster stone. The nave and transept ceilings are of polygonal form, with oak panels, divided by ribs and ornamental bosses. The nave is fitted up with oak open benches. The ancient portions of the church, which have been most carefully preserved and restored, are the centre tower and nave arcade, of good Decorated character. In the north wall of the nave a very early Norman doorway had been embedded; it was not *in situ*, but had probably belonged to the original church. The works have been executed by Messrs. Dove, Brothers, from the designs of Mr. Ferrey, F.S.A. The entire cost, amounting to about 5,000*l.*, has been defrayed by Mr. George Tomline, M.P.

THE MILITARY STATIONS IN KENT.

The Army Medical Department Report has just been issued. It appears from this report that, taken as a whole, the stations for dépôt battalions appear to be more healthy than those in the large seaport towns, dockyards, or London and Dublin; their mortality being in the year 1866, 8.66 ratio per 1,000 of strength, and the sick 43.10. As regards the army on the home stations generally, fevers of an eruptive kind have not prevailed to any great extent.

The medical and sanitary officers gave a favourable report of the South-eastern District and Shoreliffe Camp. Respecting these the report says:—"Nothing has transpired during the year affecting their sanitary condition to any material extent. The various defects connected with the barrack buildings at Dover have been

referred to in reports of previous years. The latrines and urinals at the Western Heights, and some of those at the casemates in the citadel, are very objectionable; their positions alone at the latter place being sufficient to render them so."

Woolwich is also favourably mentioned in the report as follows:—"No sanitary changes, beyond those of a minor character, have been carried out during the year. The barrack accommodation has nearly equalled that recommended by the Army Sanitary Committee. The accommodation for married soldiers is, in many instances, indifferent, and the condition of the brick cottages is said to be unsatisfactory in drainage and other respects." In the Chatham district objections are made as to the site and construction of some of the barracks. The buildings are said to be generally old, and not all in accordance with modern views, although they may be improved by the alterations in progress. A few remarks of the Deputy Inspector General of Hospitals may be worth quoting.

As regards ventilation, in 1854 Dr. Fraser recommended the more or less entire removal of the partition wall separating the front and back rooms in Chatham barracks. The latrines are, in his opinion, ill-drained, the floors not being sufficiently sloped, and, in consequence, always damp and sloppy. He recommends their reconstruction on improved principles. He urges that measures be adopted for providing a certain amount of hot water weekly in every corps, especially in winter, as a sanitary measure of importance in relation to cleanliness. The surgeon of the Royal Engineers pointed out that both the position and the construction of the latrines in the Royal Engineers' barracks are objectionable, and recommends their reconstruction on modern principles, and their further removal from the rooms. A part of this measure was in progress. Dr. Fraser suggests the entire removal of the school latrines from such objectionable proximity to the Female Hospital. The Milton barracks at Gravesend consist of brick-built huts, and are reported by the medical officer as very good in respect to position, construction, and arrangement. An ablution-room is attached to each hut. There is also an excellent bath-house, with separate baths. At Tilbury there is an ordinary ablution-room. An excellent bath-room has been built during the year. At New Town Fort there is an ordinary ablution-room, but no bath-house. Bathing parades are not possible at this station. Ventilation has been improved at Tilbury and New Tavern Forts, by the erection of fresh air inlets, fan air outlet shafts, and warm air grates; but the barracks at both places are old and ill-constructed. Intermittent fevers have, as usual, prevailed to a certain extent among the men stationed at Tilbury. The cause is, of course, the flat and marshy nature of the surrounding country. There has been no overcrowding, nor any defective ventilation or drainage, and no diseases attributable to such causes have occurred.

Upon the whole, the military stations in Kent present favourable contrast, in a sanitary point of view, with many others in different parts of the kingdom.

CHURCH-BUILDING NEWS.

St. Wendron, Helston, Cornwall.—The church of St. Wendron, near Helston, has lately undergone a restoration. The edifice is situated in one of the highest parts of West Cornwall. Previously to its restoration, the roofs were in a very dilapidated condition. It was found necessary to put new roofs to the nave and chancel, and the other roofs throughout the church have been opened and repaired; new copings and crosses have been added to the gables; some portion of the walling, including the nave-arcade, rebuilt; a vestry added; and the doors, windows, &c., repaired wherever necessary. In the place of the broken-down pews, open free seats have been provided throughout the church. Improvements have been effected in the chancel by the rearrangement of the step levels for the new tiled pavement; the raising of the east window, which will now allow of a new reredos at some future time; and by the marking off of the chancel from the nave and aisles with screens, now being decorated by the architect, Mr. J. D. Sedding, as also the boarded roof over the sacristy. On an covering the face of the wall in the north transept, a series of holes with occasional corbel were discovered at a uniform height of about 5 ft. from the floor, and it has been suggested with some appearance of probability, that it was in this portion of the building that the stag

was erected periodically in Medieval times for the performance of miracle plays. It is well known the portrayal of religious mysteries was common in these parts; and there is in this church of St. Wendron one of the low recesses known by the name of Easter Sepulchres, where the figure of our Lord was placed on Good Friday at the hour of His death. The work of the restoration has been carried out by Messrs. Boue & Son, of Liskeard, builders, under the direction of Messrs. Edmund and John D. Sedding, of Penzance, architects.

Ruiford.—The foundation-stone of St. Mary's Church, Ruiford, has been laid by Lady Arabella Fermor-Hesketh, with full Masonic honours. The new edifice will occupy the place of the present church, of which the outer walls and roof alone are at present standing. It is to be in the Gothic style of architecture, and much larger than the old structure which it replaces. Messrs. Dawson & Davison, of Liverpool, are the architects of the new church; and Messrs. Sale & Hnrst, of Southport, the contractors; the brickwork having been let to Mr. R. Gregory, also of the latter town.

Ripon.—The choir of the cathedral has been re-opened. Since July, 1862, the choir has been in the hands of the workmen, who have carried out the restorations under Mr. G. G. Scott; public worship, in the meantime, having been celebrated in the nave. In this interval the appearance of the choir has been greatly changed. The galleries which disguised the aisles have been removed; the whitewash has disappeared from the stonework; the carved oak screens of the aisles, and the canopies of the stalls, have had the ravages of time repaired; the sedilia have been removed to the easternmost bay of the chancel, south arcade; the whole of the choir and its aisles have been re-seated and re-floored,—the pavement within the chancel rails in a design of various coloured marbles; the arcading behind the altar altered so as to harmonise with similar work in the aisles; and the whole of the choir restored and beautified so as to make it correspond as nearly as possible with its original condition. The towers, which were previously in a very insecure condition, have been strengthened. In the transepts, and beneath the central tower, oak ceilings, panelled and relieved by designs in colour, have been put in. The old ceiling of the nave as yet has not been touched, but there is every probability of this portion of the edifice sharing in the work of restoration and embellishment.

Stalbridge.—The new tower of the parish church has been formally opened. The tower has been built at the sole cost of the Rev. Henry Boucher, of Thornhill. The architect was Mr. E. Hicks, of Dorchester; and the builder, Mr. G. Green, of Blandford.

Padiham, Lancashire.—The new church of St. Leonard which has just been completed is a stone structure, designed in the style which prevailed in the former part of the fifteenth century. The plan consists of nave and nave aisles, chancel and chancel aisles, north and south transepts, tower, south porch, and vestry. The tower rises to the height of 115 ft., finished by eight crocketed pinnacles, the centre ones being broken by large grotesques. Access is gained to the galleries in the transepts by spiral staircases in octagonal turrets. All the windows have tracery heads, with moulded capitals, and beneath the porch entrance is a carved head of the patron saint. The church is finished internally with chiselled stone. The shafts bearing the ornamental curved brackets of the nave roof are supported by carved angels in stone. The curved ribs of the chancel roof rest on blocks carved in representation of the twelve apostles. The benches have framed tracery heads. The choir seats have open tracery backs, the ends being carved; those in front are finished with carved angels, in a sitting posture, bearing musical instruments. The reredos is carved in Caen stone. Ten of the principal windows are already filled with stained glass, small (except one by Messrs. Edmondson, of Manchester) being from the works of Mr. Wailes, of Newcastle-upon-Tyne. The lighting is effected by brass coronas suspended from the centre of the nave, and chancel arches furnished by Messrs. Thomson, of Birmingham. The heating apparatus has been supplied by Messrs. Bacon, of London. The reredos and the other carving has been executed by Messrs. Williams, of Manchester, and the rest of the work by local contractors. The church will seat about 1,000 people, and will cost over 8,000l. The architect

is Mr. William Waddington, of Burnley and Padiham.

Sheffield.—All Saints' Church, Brightside, has been opened for divine service. The church stands on the top of a hill, and its spire is hence a conspicuous object for a great distance round. It has been erected at the sole expense of Sir John Brown, and the cost is said to be nearly 12,000l. Messrs. Flockton & Ahhot were the architects. The edifice is cruciform, and has a tower and spire at the west end. The tower is 120 ft. in height, and consequently is about 10 ft. higher than the tower of the parish church. The extreme dimensions of the church are 130 ft. by 76 ft. in the transepts, and 56 ft. in the nave and aisles. It will accommodate about 720 adults, and 259 children, the sittings of the latter being in a small gallery in the tower, and in two galleries, one on each side of the transepts, which are approached by distinct entrances. There are three aisles, and all the pews are open. The chancel decorations are the work of Messrs. Rodgers, of Sheffield. In an archway just beyond the reading-desk there is an organ, which has been built by Mr. J. Stacey, and the organ case and the reredos are the work of Messrs. Mannel & Son. The pulpit and reading-desk, which are also of wood, are by Mr. G. Shaw, of Manchester. The masonry work has been done by Mr. G. Wade, and the carpenters' and joiners' work by Messrs. Ash & Clayton. —The new church, dedicated to St. Silas, at the crossing of Broomhall and Hanover streets, in what is known as the Gillcar district, has been consecrated. The church is the gift of Mr. Henry Wilson, and is the second church he has built in Sheffield within the last ten or twelve years. The cost is between 7,000l. and 8,000l. The church consists of a nave 80 ft. long, by 27 ft. wide, north and south aisles, and chancel, on the one side of which are the organ chapel and the vestry, and on the other seats for the Sunday-school children. The tower is at the corner of Hanover and Broomhall streets, and is terminated by eight pinnacles, the total height from the ground being 94 ft. The heltry stage is ornamented with eight windows, the arches of which are supported by clusters of columns. The cornice is foliated with conventional ornaments, and there are gargoyles at the angles; the lower part forms a porch. There are no galleries to the church, but the floor furnishes accommodation for 800 persons. The nave arches are simple, carried on circular columns, with shafts of conventional foliage. The pews are of red deal, stained and varnished, and the free-sitting plan will be adopted in regard to them. The chancel is paved with black and red tiles, manufactured by Messrs. Maw; the roof is wagon-headed in form, with the view of bringing out the voices of the choristers. The church is lighted at the west end by a five-light window, and at the east end by a four-light window, but the clearstory windows were mainly relied upon. The roof is of open timber-work—red deal and pitch pine, hoarded and stained. The height of the church from the floor to the apex of the roof is about 55 ft. Artificial light is afforded in the nave by gas brackets upon the arches, in the aisles by small coronas, and in the chancel by two wrought brass standards. The church is warmed by means of Messrs. Stuart & Smith's (Sheffield) Gill stove. The architects are Messrs. Blackmoor & Mitchell-Withers, and the contract for the whole of the work was given to Messrs. Badger & Holmes.

SCHOOL-BUILDING NEWS.

Lightcliffe (Bradford).—New schools at Lightcliffe, erected at a cost of nearly 5,000l., have been publicly opened as national schools. The building, which has a situation on an elevated piece of ground opposite the railway station, is the gift of Mr. E. C. Sutherland-Walker, formerly of Crow Nest, Lightcliffe, and consists of boys', and girls', and infants' school-rooms, with class-rooms, reading-rooms, and a residence at each end for master and mistress. There is also attached to the school a piece of land of about 3 acres, to be appropriated as a recreation-ground. The ground in front of the premises is divided into terrace-walks and ornamental shrubbery.

Northampton.—New Sunday-schools have been erected and inaugurated in connexion with the Commercial-street Chapel, in this town. They consist, on the ground floor, of a lecture-room, measuring 28 ft. wide by 36 ft. long; two class-rooms, capable of being thrown into one; a minister's vestry, and also a vestry for the

deacons. There are separate staircases (of stone) for boys and girls, leading to the upper floor, where there is a school-room, 28 ft. wide by 51 ft. long; also two class-rooms, and a small room for the superintendent. The building being contiguous to the chapel, access is given to each gallery by a door in the upper school-room, and there is also a connexion between the lecture-room and the chapel. The upper room has an open roof, with light iron trusses; the windows have cast-iron casements, with ornamental horders. There is a platform at one end of the room. The woodwork is principally of deal, stained and varnished. The exterior is designed to harmonize in outline with the chapel. The cost amounts to 1,300l. Mr. T. Heygate Vernon, of London, was the architect.

Hanley Castle.—The new grammar-school here for the middle and indistrious classes has been opened. The building is a plain one, in the style of James I., 76 ft. by 22 ft. It has an open timbered roof with arched braces, the open wood-work being stained and varnished. Adjoining the principal room, which is furnished with a movable wooden partition for separating the two schools, is a small class-room. The architect was Mr. Cheek, of Upton; and the builder, Mr. James Griffiths, of Malvern.

Wakefield.—The new parish schools have been opened. The new buildings have frontage into Vicarage, Zetland, and Frederick streets, and comprise boys' school, 61 ft. by 20 ft.; girls' school, 66 ft. by 20 ft.; infants' school, 52 ft. by 21 ft.; two class-rooms, each 16 ft. by 16 ft.; and lavatories and cloak-rooms adjoining the entrances. The principal entrance is from Vicarage-street, by which the girls and infants reach their respective rooms. The boys' entrance is in Zetland-street. The buildings are of Gothic design, externally walled with pitch-faced wall stones in courses, and tooled stone-dressings. The roofs are of high pitch, covered with alternate bands of blue and purple slates, surmounted with red tile ridging, and having at the intersections and gables foliated iron terminals. The roof-timbers inside are exposed to view, planed, and stop-chamfered. On the apex of each school roof are fixed two ornamental patent syphon ventilators. Internally the walls are all plastered, and the woodwork all stained and varnished. The boys and girls' rooms are so arranged that they can be used as one, by throwing open large folding doors. Separate playgrounds are provided for boys and girls, enclosed with walls; that for the girls being surmounted by ornamental iron railing. The various works, which will cost about 2,000l., have been executed by Mr. George Fawcett (mason's work), Mr. J. R. Goldthorpe (woodwork), Mr. C. Driver (plastering), Mr. J. P. Hill (slating), Mr. Drake (plumbing), Mr. S. Kirk (ironwork), and Messrs. Hodgson & Son (painting and staining), from the designs and under the superintendance of Mr. William Watson, of this town, architect.

HOT-WATER PIPES AND THE BUILDING ACT.

SIR,—With reference to the inquiry of "a Surveyor and Engineer" in a recent number,*—The hot-water pipes which are dangerous are those known as "high-pressure hot-water apparatus." In this system there is not only a close boiler, but the pipes themselves, after being filled, are hermetically sealed, leaving only a certain limited space for expansion. High-pressure pipes are frequently worked at a temperature of 400°, and sometimes considerably higher. They have been known to become luminous in the dark, and fires have certainly sometimes been caused by interruptions to the circulation, generally arising from frost. It was with reference to these pipes that the late Mr. Braidwood suggested the restrictions which are very properly imposed by the present Building Act.

Ordinary cast-iron hot-water pipes, such as are generally used under a low pressure for warming public buildings, houses, conservatories, &c., are not dangerous; and there is no reason why they should not be fixed, when convenient, in contact with woodwork. No regard is ever paid in this respect to the provisions of the Building Act beyond the metropolitan area.

The pipes of an ordinary low-pressure hot-water apparatus seldom attain a temperature above 180°, and even where the height of the feed-cistern above the boiler, which is the

* See p. 99, ante.

circumstance that determines the temperature, is as great as it can be in any ordinary house,—say, if it were at the top of the building, and supplying a furnace in the basement,—the boiling point under that head would rarely exceed 240°, and the temperature of the pipes would generally be several degrees lower.

Low-pressure apparatus, as well as high-pressure, have close boilers, although of different construction; but the real safety of the common apparatus arises from the pipes and boiler being supplied from an open cistern at a moderate elevation. This arrangement allows of an unrestricted expansion of the water, the want of which is the cause of danger from the high-pressure pipes.

Speaking as a practical man, and in the habit of erecting both kinds of the apparatus, I would venture to suggest that the existing provisions of the Building Act should be confined to wrought-iron hot-water pipes, hermetically sealed; and, consequently, liable to be worked under an unknown pressure, and that they should be altogether waived as regards the ordinary cast-iron pipes used for warming.

HOT-WATER ENGINEER.

Sir.—As the remarks with which you favoured my letter cannot refer to hot-water apparatus for dwellings, &c. as fitted with expansion-pipes, I, therefore, write to call your attention to the fact, believing that now you have allowed the subject to be mooted in your journal some definite and practical rule will result.

I have myself had more or less to do with several hundred apparatus, and in those where the largeness of the cooling surface to that of the boiler did not render it impossible for the water to overheat, an expansion-pipe has been used, viz., an open pipe placed on the apparatus near the boiler, and rising higher than the level of the cistern, it having a clear opening to the exterior air of from 10 to 19 square inches. Now, sir, I feel sure you will perceive that no description of accident could happen that could hermetically seal up a 3-in., 4-in., or 5-in. pipe so as to stand the pressure of steam, which might otherwise be supposed to occur by the accidental fouling of the supply-pipe from the cistern. And in some very extensive apparatus there should be an arrangement of expansion-pipes, but to describe these would be entering upon another subject.

A SURVEYOR AND ENGINEER.

Sir.—Thinking that a practical illustration of the dangers attending the fitting up of hot-water pipes, as commonly practised, may be useful, I have ventured to trouble you with the following:—

After many years of practice as surveyor and assessor of fire losses, I have had but one case (that I remember) of accidental burning resulting from hot-water pipes, and this took place some few months since.

At a gentleman's residence, in London, a warm bath on the first story was supplied by means of a circuit of hot-water pipes from a boiler in basement. The pipes in the several stories were enclosed by a wooden casing, placed at a distance of 3 in. from the pipes as required by the Act.

Notice of a fire loss having been given, I attended, and learnt from the inmates that the hot-water pipes had ignited the woodwork, in proof of which a portion of the charred woodwork of the casing removed by the fire brigade was shown to me, who reported to the inmates that the works had been properly constructed.

On minutely examining the grain of woodwork offered for my inspection, I found a fibre of hemp adhering to it. I required that the whole of the debris resulting from the fire, which had been carefully removed to the house to me; and on descending to the dusthole in the basement, to which place it had been taken, I quickly discovered the probable cause of the fire.

The casing and hot-water pipes had been packed with hemp and tow, in addition to a coating of felt. There had been probably a leakage of water, which had caused the hemp to ignite. This had probably been smouldering for some hours, as there was little or no draught of air, and thus timely notice of danger was obtained, fortunately in midday.

Had there been a delay of a few hours, or had the fire acquired a draught and mastery of the building during the hours of the night; or had the early intimation of danger been unheeded by the inmates, a very serious destruction of property would have ensued.

A FIRE OFFICE SURVEYOR.

SCHOOLS OF ART.

The Worcester School.—The sixteenth annual meeting of this school, for the distribution of prizes, has been held in the Music-hall. The attendance was both numerous and influential. In the absence of the Earl of Dudley, the chair was taken by the Rev. David Melville, rector of Witley. The report said:—

"Your committee have much pleasure in reporting to the subscribers and friends of the School of Art, at its sixteenth annual meeting, that the progress of the institution during the past year, with respect to the attendance of students and their advances in work, has been satisfactory. 194 students have been under instruction during the past year, which number includes 53 in the day classes and 141 in the evening classes at the central school. The system of teaching, as directed by the Department in London, continues to be adopted, and the examinations in free-hand drawing, practical geometry, perspective and model drawing, were conducted as usual under the direction of the committee. In the examinations 30 papers were successfully taken and 6 prizes. 32 works were sent to London in March last, and prizes were obtained in the national competition by George Evans and Frederick J. Jones."

The chairman distributed the prizes.

The Nottingham School.—The annual meeting of the governors of this school has been held, for revising the report of the committee for the past year, confirming the accounts, electing officers, and transacting the general business of the institution. Mr. R. Birkin, president, occupied the chair. The President, in opening the proceedings, remarked upon the sparseness of the attendance, which he attributed to the fact of the meeting following so closely the one held for the distribution of prizes. He was glad to observe from the report that the institution was in a more satisfactory condition than last year, and hoped that soon they would be out of the difficulties. The reports of Mr. Rawle, the head master, and of the committee, were then read, and the master's zeal and efficiency were acknowledged by special resolution.

COMPETITIONS.

St. Paul's Girls' School, Tottenham.—Designs were submitted in a select competition for this building, by Messrs. Cook, Franklin, Eytan, James, and Warren. The design by Mr. Joseph James was selected as the best, and will be commenced immediately; it has received the sanction of the societies giving grants to the building fund.

ACCIDENTS.

A NEW building for an undertaker's coach-house and joiner's shop, in course of erection, in Hunslet-road, Leeds, has collapsed, hurrying four labourers, one of whom has been seriously injured.

At Coatham, Redcar, the west end of a new chapel has been blown down by the wind. The loss, about 150*l.*, will fall upon the contractors, Mr. T. Wilson, joiner, Redcar, and Messrs. Scott & Lord, builders, Middlesbrough.

At the Northampton Gasworks a new tank has given way. It was 102 ft. in diameter and 30 ft. deep, and was completed about two months since. It is suspected there is a quicksand on the site, which is within the old bed of the river.

At Birmingham there has been a landslide, in George-street, bringing down a 9 in. brick wall, built on arches to aid in supporting a bank of soft red sandstone. The wall fell on adjoining premises, doing them considerable damage. The late rains are blamed.

At Liverpool a slip has occurred in a sewer work in Kerford-street, Everton, the earth falling on a sewer contractor's workman, and killing him. He had neglected to shore up the excavation as directed. An old drain seems to have caused the earth to slip.

RIGHT- AND LEFT-HAND LOCKS.

SIR.—In answer to your correspondent, the bolt of a right-hand lock always shoots from left to right, and a left-hand lock from right to left, as you stand on the outside of the door. Mistakes with respect to the hand of locks are of daily occurrence. What the carpenter calls a right-hand lock, the locksmith calls a left-hand, and vice versa. Standing on the outside of the door, and locking the lock by turning the key in the right hand locks to the right, and in the left hand locks to the left. If the bolt comes out to the left it is a left-hand lock; if to the right it is a right-hand lock; the level of the latch-bolt will be towards you. This is the locksmith's rule.* It may be well to notice that for a closet in a room in which the door of the closet is constructed to pull towards you, if a rim-lock be required to be fixed on such a door so as to be inside the closet when the door is closed, the bolt or latch would require to be bevelled just the contrary way to the ordinary locks, as in closing you push the lock away from you instead of pulling it towards you. Such a lock is called by locksmiths a reverse lock, and it requires to be fitted with a striking-plate for the door-case instead of ordinary box staple of the other locks. If the knob or the keyhole is required to be any particular distance from the edge of the door, always measure from it to the centre of spindle-hole and the centre of keyhole respectively.

In ordering locks, never run down the price, because whatever reduction you may get from the regular and fair price is certain to be made out to you in so much less security, so much less

strength, and so much less finish. By the way, you may think you have saved, the maker will have got more, as there is always more profit in proportion attending the manufacture of a common article than one of a superior quality.

To illustrate this fact we may state a circumstance which is of frequent occurrence. A small manufacturer takes a pattern of a certain sized lock to the wholesale buyer, and names a certain adoption of such a system, however much you price per dozen; this pattern is kept by the dealer, and on another maker calling, the pattern is produced, and the latter maker's price is asked for a similar article. The first, perhaps, was low enough, but the second maker's is still lower; an order with the pattern is given to him, and he sends the several parts to the brass-founder to be cast from. The locks are made and delivered, and the second maker has made quite as much profit out of the reduced price as the first maker would have got from the higher price; and this arises from the circumstance that the limbs which formed the lock having been cast from the limbs of the pattern lock were, after dressing, so much less in size, and consequently so much less in weight. By this mode 3-inch till locks in time measure but 2½ in., and all the parts are light in proportion. Whoever the grinding "system" is adopted, the work in the language of the workshop is "devil'd" just in the same ratio. We believe this holds good in every other trade.

CHARLES AUBIN.

SIR.—May I venture to submit a more precise definition of the hands of door-locks than that given in the *Builder*?

1st. In all cases, whether a door opens inwards or outwards, if, when you stand outside facing the door, the lock shoots towards the right hand, it is a right-hand lock; if towards the left hand, it is a left-hand lock. This rule applies equally to dead, spring, or two-bolt locks.

2nd. For two-bolt or spring locks, when the doors open outwards, apply the same rule, and add the words "reverse bolt."

Any locksmith can supply locks of the proper hands if these rules be adhered to.

JOHN CHUBB.

INAUGURATION OF BELLS AT BIRMINGHAM.

A NEW peal of eight bells has been opened at Bishop Ryder's church, Birmingham. The peal, which is the first founded in Birmingham, consists of eight bells, the tenor weighing about 13 cwt., and the aggregate weight being 55 cwt. The total cost is about 600*l.* At the conclusion of a special service on the occasion, Canon Cattley, the Rev. H. T. Ellacombe, and Mr. E. Denison, Q.C., with the assistance of several Birmingham campanologists, rang a series of peals upon the new bells, the result of which was highly favourable report of the entire work.

In the evening, the Rev. H. T. Ellacombe, rector of Clyst, Devonshire, an old correspondent of the *Builder*, as our readers know, and the author of several important campanological works, delivered a lecture on bells. The art of change-ringing, he remarked, was greatly admired by all who understood it; for there was no amusement so conducive to health, employing as it did so many faculties both of body and mind; and there was no music, when performed by skillful hands, which could afford more agreeable or more melodious sounds than bells,—eight, ten, or twelve. Church bells had a language which was capable of very definite and appropriate meanings; but to secure these, a toll or a chime must be rung at proper times, and in a manner which would properly discriminate between what was joyous and what was solemn and mournful. The art of change-ringing, however, was in many instances so used—or, rather, abused—as to mean everything, or nothing at all. The reason that bells were often so badly rung, was that they were entrusted to the hands of persons who never took any trouble at all to acquaint themselves with change-ringing, and to whom, as a matter of course, the practice was mere drudgery. The lecturer described the process of manufacturing bells, and the elements necessary for perfect musical intonation, illustrating his remarks by models. The oldest peal of bells in parish churches, he said, was to be found at Beverley. It was established in the ninth or tenth century.

* As we have already said.—E.N.

RESPONSIBILITY FOR GAS ENGINEERS' CHARGES.

A CASE of importance to gas engineers, architects, and others, has been tried before the Sheriff, at Dunfermline, on Saturday. Plans had been prepared about twenty years since for the erection of gasworks, at Inverkeithing, in Fifeshire, but had been laid aside, and a small portion of them lost. A new committee had resolved to carry out the plan, and one of their number to obtain a new plan to replace that which was lost. He applied to the pursuer, Mr. Macaulay, of Dunfermline, architect, who prepared new plans altogether, which the committee rejected, and returned to the pursuer. Ultimately the gasworks were erected for 418s., the contract price, and about 50s. of extras, from plans prepared by Mr. Christie, of Newburgh, Fifeshire. Pursuer had made out no specification, but had stated the cost of carrying out his plans at 700s., for which the usual charge of 5 per cent., or 35s., would be made. The action was raised against the members of the committee. The Sheriff, having taken the case into consideration, found (1) that the defender William Thomson called on the pursuer, and employed him to prepare a design for a gasworks; (2) that the pursuer accepted said employment, and, in pursuance thereof, prepared a plan, with relative specification and estimate of cost; (3) that the charges contained in the account libelled are reasonable; (4) that the defenders, other than the said William Thomson, did not authorise, or afterwards homologate, said employment, they having instructed the said William Thomson to employ the pursuer to supply a portion of an old plan which had been lost. The Sheriff further found that the defender, William Thomson, is alone liable to the pursuer in the account sued for, and therefore decrees, in terms of the conclusions of the summons, against the said William Thomson, and finds him liable in expenses; assizes the whole other defenders, and decrees, and finds them entitled to expenses from pursuer; and being fixing the amount of said several expenses, allows the pursuer and the defenders who have been assized to lodge a note of expenses claimed by them.

SALE OF ST. MARGARET'S CHURCH, LIVERPOOL.

SIR,—Liverpool has been much surprised to learn, by an advertisement and letter from Mr. Horsfall, that for the reasons therein stated, he has determined to sell his church and parsonage. These have been erected from designs by Mr. Street, in native brick, with stone and red brick dressings, by a builder from Wolverhampton, a Mr. Horeman, a stranger to the town, who was appointed contractor without competition. The public very naturally inquire whether a clergyman of equal ability to Mr. Clark (whose refusal to come has led Mr. Horsfall to advertise the church for sale), could be found to fill his place; or whether if Mr. Clark had not declined to do so, but death had intervened, the same course of action would have been pursued? G.

DRAINAGE OF TOWNS.

SIR,—Can your correspondents give me any instances where two towns or districts, under separate and distinct local government, have united for the purpose of constructing for their joint use a main intercepting sewer? and if so, the particulars as to apportionment of charges? Is there any town of magnitude in which a main sewer has been carried under a river, such as the River Sever, upon land embanked from the river? With any particulars of cost, size, and efficiency of working. ENGINEER.

GRAINING FROM SURFACE OF WOODS.

SIR,—In the *Builder* I notice a report of a paper read by Mr. Dean, sen., before the Society of Arts on this subject. Without any desire to deteriorate the value of the invention, I would wish to make a few remarks. In the first place, "Xylographic" graining I believe to be over twenty years old, and, if I mistake not, the invention of a Belgian. The specimens shown to me by Mr. Dean were only partially produced, being mostly finished by hand; as for all close-grained woods, such as maple, satinwood, &c., it is simply useless. The prices paid for best oak graining put forward by Mr. Dean are ridiculous, and calculated to mislead people unconnected with the trade. Grainers to the trade are not always fairly dealt with, those who employ them often requiring too much and paying too little, thereby obtaining work according to price. If fault be found, it will be visited upon the unfortunate grainer; if praise, it will be pocketed with the cash. I am happy to say British imitators hold honour that few branches of English industry can boast, having obtained first-class prizes at all international exhibitions. Xylographic graining will have to make immense strides, and show vastly different results, before it can even compete with graining by hand. A LONDON GRAINER FOR THE TRADE.

TAKING OUT QUANTITIES.

The committee for the enlargement of the Poplar workhouse have reported on the utilization of the Town-hall for indoor paupers. They instructed Mr. Morris to make the requisite alterations, and gave instructions to the architect in reference to the alterations to be made in the present workhouse. They authorized Mr. Morris to prepare the necessary drawings and specifications for the builders; and in their report to the Board they suggest that he should be allowed to take the quantities required, and be responsible to the builder whose tender may be accepted by the Board for the correctness of these quantities. The committee further recommended that Mr. Morris be allowed a commission of 1s. per cent. on the value of taking out these quantities. Mr. Bracebridge, at a meeting of the Board, said he did not agree with that portion of the report which recommended that Mr. Morris take out the quantities, and he should not himself accept it. He objected such a thing to himself, and it was not the business of the surveyor to do it. No respectable surveyor would think of doing it. He proposed that that portion of the report be omitted.

Mr. Cole seconded the proposition, and after a lengthy discussion on the question, it was resolved that the suggestion of the committee be not approved. Mr. Bracebridge then moved that Mr. William Dobson be appointed to take out the quantities at 1s. per cent. The Rev. Mr. Driffield having gone into figures, gave it as his opinion that 1 per cent. was too much for taking out the quantities, and proposed as an amendment that 1 per cent. be paid. Some discussion having taken place, the amendment was carried by a majority of four. Mr. Robey proposed that Messrs. Hills & Fletcher be appointed to take out the quantities in lieu of Mr. Dobson. The Rev. Mr. Driffield seconded this, and on its being put to the vote, there appeared for— Messrs. Hills & Fletcher 4 Mr. Dobson 6 The committee's report was then adopted, with the exceptions specified.

Books Received.

Smoking Fires: their Causes and Cure. By the Rev. ALEX. COLVIN AINSLIE, M.A., Vicar of Corfe, Somerset. London: Longmans. 1869. The Rev. author may well say that it is a saddening sight to see, from the fifth or sixth floor of a London hotel, the host of distorted and hideous chimney appendages there displayed. His volume contains many practical suggestions, with all of which, however, we do not agree, as, for example, where he recommends the opening for fresh and cold air to a fire which he speaks to be placed at the side of the hearth. A perpetual draught of cold air to feet and ankles is not likely to promote either the comfort or the safety of a seat by the fireside. The opening could easily be placed so as to be nonobjectionable in this respect. In the concluding chapter, addressed to architects and those engaged in house building, the author says:—

"Men who know their business will find little or nothing new in these pages, nothing that they have not successfully carried out in their practice; but it is not always the fate of those that huld to fall into the hands of men who know their business, and a little more knowledge of true principles will often be useful to those whose practice runs in the old groove, who design and build houses as their predecessors did, and trust to good luck for their being comfortably habitable.

1. Avoid, if possible, chimneys in outer walls, especially in walls with a northern aspect.
2. Especially avoid chimneys passing up through the eaves of high-pitched roofs. If such chimneys must be built, carry them up higher than the ridge of the roof.
3. Let the masonry of chimneys in external walls be as thick as possible.
4. Let the flues be large, and of circular section to secure their being thoroughly swept. Glazed drain-pipe, 1 ft. in diameter, is excellent for the purpose.
5. Avoid all unnecessary heads and elbows.
6. Carry up the chimney-stacks as high as possible. Make them a principal feature in your design, and take pains with their proportions and positions, relatively to one another and the general design of the building. The architect is to blame if it becomes afterwards necessary to disfigure his building with zinc tubes and wind-guards.
7. In chimney-stacks containing many flues let their outlets be at different levels.
8. Let the flue of the kitchen fire be always at the north or east end of a stack.
9. Take means to supply every fireplace with its own air drawn from the coldest side of the house. This may be done by one general wind trunk to supply all the flues in one stack, or by a separate arrangement for each fireplace. But no house can be considered scientifically built in which this is not provided."

Miscellaneous.

The "Builder's" Fire.—A correspondent, Mr. C. Warner Lewis, writing from the Temple, informs us that he has applied to "The Builder's Fire," which he has found useful, a hinged iron plate, so that he can either close up the bottom of the grate with the plate, as in "The Builder's Fire" when rapid combustion is not wanted, or let the plate fall down so as to open the bottom of the grate, and allow a free access of air below as long as may be desired. The hinges would thus appear to be a convenience. The plate can be easily put up or down by means of a poker.

The Prevention of Floods.—This is a subject which occupies much attention in France at the present time. Engineers are generally convinced that the best and only satisfactory solution of the problem of moderating the effects of the sudden overflowing of large rivers, is in forming reservoirs along the banks of the more dangerous tributaries by means of transversal embankments. The waters may be thus collected, and after the flood has passed away, may be turned to account for irrigation during dry weather, and for supplying water to mills or canals. *Galignani* says that the embankment of Pinay, thrown up under Louis XIV., at a distance of 80 kilometres above Roanne, has preserved that town and the valley of the Loire, by supporting 100 millions of cubic metres of water and upwards. A recent paper, by M. Graff, addressed to the French Academy of Sciences, speaks of the reservoir of the Gouffre d'Enfer, on the Frens, above St. Etienne (a work of his own construction), where a dyke 50 metres in altitude, incloses a basin 2,500 hectares in surface, which will contain 1,500,000 cubic metres of water, to ward off inundation in that district.

Poor-rate Valuations.—A return prepared by the Poor-Law Board shows that in April last the valuation lists had been completely revised and returned approved in 588 Unions in England and Wales. The rateable value of those Unions upon which the contribution to the common fund were calculated at Lady-day, 1867, was 77,775,305*l.*; the rateable value in 1868, as settled by the assessment committee in the lists approved, was 79,962,956*l.*, an increase of 2,187,651*l.* The increase in Middlesex is from 4,771,780*l.* to 5,085,230*l.*; in Surrey, from 2,545,702*l.* to 2,682,479*l.*; in Lancashire from 7,493,747*l.* to 7,759,599*l.* In July last the lists in all the Unions in 44 counties had been completely revised. The expenses incurred by the Guardians in the year 1866-67 amounted to 32,890*l.*; and in the year 1867-68 to 35,176*l.* The costs of appeals in the former year were 4,912*l.*, and in the latter 9,091*l.*, but the return may be incomplete under this head. The amount of compensation paid to the clerks was 19,899*l.*

City District Surveyorship.—At the meeting of the Metropolitan Board of Works, on Friday, the 5th, Mr. Silas Taylor, on bringing up the report of the Building Act Committee, recommending that steps be taken to fill up, on the usual conditions, the vacancy in the district surveyorship of the southern division of the city of London, caused by the death of Mr. Smith, stated that the income of the office last year was only 143*l.* 18s. 9d., and the committee had considered as to re-arranging the City districts; but as the new street from Blackfriars to the Mansion House was in the district now vacant, and there would be much building going on for the next few years, they would not recommend any alteration, but that the office be filled up in the usual manner.

Discovery at Godalming.—In a field at no great distance from Busbridge Hall, known as the Chapel Field or the Old Minster Field, some digging has disclosed the foundation of what must have been a small up-angled building, 41 ft. in length by 21 ft. in width. The area is divided into two compartments by two inner foundation walls running parallel to the shorter sides. A number of skeletons in good preservation were found within the inclosure. These were huddled up in different postures, some in a crouching attitude and some lying flat, the legs of some of the latter extending under the stonework. Further excavations have been going on. In "Brayley's History of Surrey" it is stated that in the "Old Minster Field," near Busbridge, was formerly a chapel and burying-ground, which in the reign of Edward VI. were granted to Laurence Eliot, to hold during pleasure, as, by description, "a chapel in Godalming called Old Mynster."

The Proposed New Corn-Exchange, Rochester.—At a meeting of the Estate Committee of the Corporation, it was decided to invite six architects to send in designs for the new corn-exchange which the corporation intends building in this city, at a sum not exceeding 5,000*l.* The length of the proposed new building is to be at least 100 ft. by 68 ft. in width, with the usual suites of smaller rooms for committees, meetings, and offices. The new corn-exchange will be erected at right angles to the present building, which will be used as an entrance to the new exchange.

Monument in Commemoration of Dutch Independence.—A public monument is to be inaugurated at the Hague in the course of the present year. It is to commemorate the revolution which gave independence to the states, and will be more than 70 ft. high, and carry seven bronze figures of colossal dimensions. A circular flight of steps, surrounded with candelabra, will form an approach to the monument, the basement of which will be ornamented with bas-reliefs and inscriptions. On pedestals projecting from the basement will be placed the following statues:—In front, a statue of Guillaume I.; on the sides, two figures representing Religion and History; and at the back, a group of three figures, representing the Counts Hogendorp, Limburg, Stirum, and Van der Dayn van Maasdam, the heroes of the War of Independence, and members of the Provisional Government. On the summit is to be placed a female figure symbolical of Liberty and Independence. At the foot of the figure will be the Dutch lion freed from his chains.

Moving a House.—The process of removing bodily the boatman's house on Caversham Bridge was successfully accomplished, under the superintendence of Mr. Neat, who is managing the works on behalf of Messrs. Head & Co., the contractors; and to those who merely saw the conclusion of the process it did not appear such a formidable undertaking as might have been imagined. An inspection of the necessary preliminary operations, however, dispelled this idea. The house, which was nearly square, with four rooms on the ground floor, and two stories above, was first of all underpinned; but an additional difficulty had to be overcome from the circumstance that the bridge itself had been made use of as the foundation for the front of the house, and it was therefore necessary to support the upper rooms with a number of upright timbers. A strong piece of timber, extending from front to back, and side to side, was then adjusted under each wall, the framework, when completed, forming a square divided into four compartments. The timbers from front to back were protected at bottom by a partial coating of iron; under these were laid similar timbers, protected likewise with strips of iron, but only on the upper surface, and between the two were placed at intervals of about 6 in., some small iron rollers, 1 in. or so in diameter. The building itself was fastened together beyond the possibility of slipping by strong bars of iron, and the bottom framework was securely fixed by diagonal timbers. Everything being ready, some hydraulic engines were tried, but were not quite in working order, and recourse was then had to three "screwjacks" placed against the wooden framework opposite to each of the sliding timbers, with the buttress of the bridge as a fulcrum. Each "jack" was worked by two men, and almost imperceptibly the building commenced its retreat without the slightest sign of resistance. The rate of movement was about 6 in. in four or five minutes, but as the "jacks" were worked out they had to be removed, and the intervening space filled with blocks of wood, when the screw was again put on, and this was repeated until the building reached the destined spot. The whole operation of moving, from its commencement, occupied about two hours and a half, the distance traversed being 8 ft.

A Curator for the Architectural Museum. Here is an appointment open, wherein the right man could do much good to others besides himself. The committee will meet in a few days to make the selection.

The late Mr. Pettit's Architectural Drawings.—Arrangements have been made to exhibit 250 of Mr. Pettit's best sketches at the forthcoming architectural exhibition.

TENDERS.

For finishing two arcades, at Park, Tottenham, for Mr. W. Bairr. Mr. S. Cooper, architect:—

Cook & Greu	£498 0 0
Marion	490 0 0
Yates	465 0 0
Hill & Co.	439 0 0
Stone	415 0 0
Houghton	399 0 0
Hart & Brown	367 5 0
Warr	359 5 0
Rowe & Co.	345 10 0
Smith	339 0 0
Allen	338 0 0
Godwell	329 0 0
Abraham & Sons	308 0 0
Chapman	275 0 0
Davies	275 0 0
Norman	250 0 0

For alterations to Messrs. Parton's premises, Dimlico. Messrs. Jarvis & Son, architects:—

Thompson	£827 0 0
Turner & Sons	791 0 0
Banley	750 0 0
Tarrant	749 0 0
Henshaw	726 0 0
Richardson	669 0 0
Stimpson	695 0 0

For the erection of offices and stores, Victoria-street, Liverpool, for Messrs. Fowler, Brothers, Messrs. Pictou, Chambers, & Bradley, architects. Quantities supplied:—

Roberts & Robinson	£28,318 0 0
Henshaw	6,180 0 0
Boroughs & Son	6,174 0 0
Jones & Sons	6,141 0 0
Callie	6,114 0 0
Urmsou	6,066 0 0
Ray	6,055 0 0
Hugh & Co.	5,866 0 0
Hughes	5,995 0 0

For fitting up lavatories at Southall Schools. Mr. H. Saxon Smith, architect:—

G. Jennings	£347 6 6
Jeakes & Co.	320 0 0
Keane	275 0 0
Gibson, Brothers	225 0 0
T. Jennings	222 0 0
Potter & Sons (accepted)	185 0 0

For the erection of a pair of villa residences, in The Grove, Redford, for Mr. Thomas Lester, Mr. Usher, architect. Quantities supplied:—

Winn & Foster	£1,506 6 0
Corby	1,459 0 0
Lawsen	1,450 0 0
Di keus	1,433 0 0
Moore	1,431 0 0
Hull	1,429 0 0
Curvill	1,435 0 0

For main sewers for the Welthamshaw South-Eastern District. Mr. John T. Bressy, Surveyor:—

Smith	£2,383 14 6
Smart	2,375 10 0
Parker	2,754 17 6

Cartor	1,840 0 0

For building a pair of houses at Putney. Mr. E. Wyndham Tarn, architect:—

Adams	£1,500 0 0
Ebbage	1,455 0 0

For re-instatement of damage by fire at the premises of the Religious Tract Society, Palmerston-row. Mr. E. Wyndham Tarn, architect:—

Holland & Hansen	£519 0 0
------------------	----------

For building church at Newton-upon-Awcliffe, near Pickering. Mr. E. Wyndham Tarn, architect:—

Tusley	£279 0 0
Watson	162 0 0

For building four pairs of houses, in concrete, at Acton. Quantities supplied. Apparatus for concrete building provided by the proprietor. Mr. E. Wyndham, architect:—

	Per Pair.	Fence Walls per Yard Lineal.
Holmes	£690	
Ebbs	649	6s. 6d.
Drake & Reid	635	3 0
Watkins	574	3 0
Corpe	697	2 0
Turner	619	3 0
Hewson	590	
Wright	565	

* Fence wall of concrete, 6 in. thick, and 5 ft. high, with foundation, 9 in. by 9 in.

For nine houses at Loughborough Park, Eriston. Mr. Aldred R. Pite, architect:—

Suton & Dudley	£5,014 0 0
Cowland	5,257 0 0
Baker & Constable	5,179 0 0
Kilton	5,059 0 0
Manley & Rogers	4,977 0 0
Watkins	4,879 0 0
Riley	4,847 0 0
Johnson	4,105 0 0

For erection of church, at Balderstone, Rochdale. Messrs. Medland & H. Taylor, architects:—

Clay	£9,089 0 0
Ellis & Hinefield	8,317 0 0
Rogers & Booth	8,230 0 0
Bullman & Son	7,668 0 0
Thompson	7,568 0 0
Storia	7,555 0 0
Foggett	7,522 0 0

For four shops at New Swindon, Wills, for Messrs. Pateman, Mr. T. Lansdown, architect:—

Dyer	£2,615 0 0
Wheeler	2,580 0 0
Levyatt	2,617 0 0
Kimberley	2,400 0 0
Newcombe	2,370 0 0
Smith	2,300 0 0
Barrett	2,220 0 0
Drew	2,214 0 0

For four cottages for Mr. Fisher, Swindon. Mr. T. S. Lansdown, architect:—

Wheeler	£807 0 0
Drew, of Highworth	792 10 0
Dyer	725 0 0
Drew, of Chalford	697 10 0
Newcombe	690 0 0
Barrett	653 10 8
Willsdrie	558 0 0

For re-building the King's Arms Hotel, Swindon. Mr. T. S. Lansdown, architect:—

Wheeler	£1,210 0 0
Dyer	1,200 0 0
James	1,198 0 0
Levyatt	1,183 11 0
Kimberley	1,100 0 0

TO CORRESPONDENTS.

Chimney Sails.—Sir: I should feel very much obliged if one of your correspondents would give me the exact measures of the largest chimney stack in Great Britain; its height, largest and smallest outside diameter; and where a description of it can be found. I have found out the height of Messrs. Towns' in Glasgow, from a copy of the *Builder*; but I believe there will be one still higher, either in Manchester or Birmingham. I have, however, found no means to ascertain this.—A. K.

SEWAGE and its GENERAL APPLICATIONS.

GRASS, CEREAL, and ROOT CROPS, showing the Results obtained by actual Expts taken down to the Present Date. With Plans and Sections illustrating the method of forming the ground for the different systems, and for discharging the sewage over irrigated fields.

By THOMAS CARROLL, Civil Engineer, A.B.C.D. M.R.E. Published by ROBERTSON, BROOMAN, & CO. "Mechanics' Magazine" and Patent Office, 160, Fleet-street, E.C.

Partnership. - An ARCHITECT wishes to PURCHASE a SHARE (not less than 500l. per annum) of a well-established PRACTICE. Possessing a practical knowledge of the profession, the advertiser has a considerable commercial experience. Address, ALPHEA, 4, Grafton Place, the Grove, Hamersmith.

Partnership. - A Gentleman, of considerable experience, desires an ENGAGEMENT, with view to above. Would invest from 5000l. to 1,0000l. Address, M. 250, Pentonville-road.

To ARCHITECTS and SURVEYORS.

PARTNERSHIP. - The Advertiser is desirous of entering the Office of an Architect and Surveyor, in the first place as a salary, but afterwards to PURCHASE a SHARE of the PRACTICE. Has served his articles with an Architect and Surveyor (London) - Address, SYMPANUM, care of Mr. Mildred, Gooch's, Ludbrook-grove, Notting-hill.

BUILDERS' CLERK WANTED. - Must

be accustomed to measuring timber, lumber and receiving stock, keeping such other materials and workman-ship, in a large structure shop. Apply to the Genl. Intendant by letter, stating salary required, to R. J. 40, South Lambeth-road, P.W.

BOROUGH of PORTSMOUTH. - The Cor-

poration of the Borough of Portsmouth require the services of THREE or FOUR INSPECTORS of WORKS to superintend the construction of sewers and other Works in the said Borough, and to act in such duties, and be able to keep a record of their progress. Applicants by letter, to be preferred. - Apply, stating references, and previous experience, to Mr. J. E. GREATBROS, Southampton, Lambeth, Strand, Strand.

CAMBRIDGE IMPROVEMENT ACTS. -

WANTED, by the Commissioners, a SURVEYOR who possesses a competent knowledge of measuring and valuing such public works as may come within the scope and provisions of an Improvement Act, and a knowledge of drawing, practical engineering, surveying, and mapping. He will be expected to devote the same exclusively to the duties of his office, and not engage in any other occupation or business. His salary will be fixed by the Board of Commissioners on Lady day next. The Surveyor will be required to enter into a bond of 1000l. with two sureties in 500l. each, for the due performance of his duties. Return a post, with respect to charter 1.1 and qualification, and stating the age of the candidate, to be sent to the Genl. Secy, Andrew's Hotel, Cambridge, on or before the 1st of MARCH next. It is to be expressly understood that a contract or negotiation for the purchase or value of any immovable estate, either directly or indirectly, is forbidden, and any infringement of this injunction will be deemed a disqualification of the candidate, so that his nomination cannot be a void.

The following are the duties to be performed by the Surveyor: -

1. He shall inspect and superintend the laying down and making the Pavements of the Carriage ways and Footways, and the putting in and repairing Drains, and all works done by the Gas and Water Works Companies, or private persons.

2. He shall estimate the cost prices of completed New Works.

3. He shall measure and certify the Works, and report upon the manner in which they have been executed.

4. He shall take all Levels, and make Sections or require Works.

5. He shall measure or weigh, materials purchased by the Commissioners for Roads and Parks.

6. He shall superintend the employment of all Labourers engaged in the Sweeping, Watering, and Repairing Roads and Parks, and see that such Works are properly executed.

7. He shall examine and sign Bills relating to Pavements, Drains, and Materials, previously to their being submitted to the Finance Committee.

8. He shall attend the meetings of the Board, and of such Committees as may require his attendance.

9. He shall go out with the Landy Committee, and see the instructions of that Committee carried into effect.

10. He shall do such other duties as may be required by the Board, and that the parties erecting them relate and take the same to the Pavements, and shall receive and report the same to the Committee.

11. He shall perform these and all such other duties as are required by the Improvement Acts, to the satisfaction of the Chairman of the Improvement Board.

12. If from any cause whatever the Surveyor shall be unable to attend to his duties, he shall cause to be appointed, by the Board, a person, approved of by the Chairman, to attend on his behalf during the execution of all such duties.

13. He shall have discretionary power to expend in repairs any sum not exceeding 20s. per annum above that amount, the Surveyor shall be empowered to write to the Chairman of the Board, and the Commissioners of the parish in which the work is to be done; and he shall report at every meeting of the Board the power he has exercised. - By order, FRED. BARLOW, Clerk.

FOUNDRY CLERK. - WANTED, a DE-

STROYING CLERK in a large Foundry in London. - Apply by letter, stating qualifications, to C. one of W. H. Dawson & sons, Stationers, 151, Cannon-street, E.C.

The Builder.

VOL. XXVII.—No. 1359.

Miss Coutts's Market, Bethnal-green.

DOZEN years ago and afterwards, the conductor of this journal described the condition of Crab-tree-row, Bethnal-green; Nova Scotia-gardens, and other parts of the neighbourhood. In Nova Scotia-gardens was a mighty mound of refuse, of which a view was given.* Afterwards Miss Brdrett Coutts, prompted by head as well as heart, became possessed of a considerable tract of the land there; erected first some large blocks of buildings, divided into residences (which, we may say, in passing, are fully tenanted); and more recently has formed a market, with surrounding shops and costly market-hall. With a view to this, powers were granted by Parliament in 1866 to make a new leading thoroughfare, 40 ft. wide, and to improve Crab-tree-row,

the existing south thoroughfare, both communicating directly with the Hackney-road.

The buildings, designed by Mr. H. A. Darbishire, were begun in May, 1864, and are now so nearly completed that the market will be opened for business by a public ceremonial in May or June. The works, we may at once say, have been exceedingly well performed by the firm known as Messrs. W. Cubitt & Co., Mr. Wheeler being their representative on the spot, and Mr. Weller the clerk of works.

The objects Miss Coutts has in view in establishing the market are to supply the surrounding poor with wholesome food at a fair rate; to bring the producer and consumer into closer communication with each other; and to promote habits of industry and thrift among the humblest class of traders. To secure these objects it is intended that the wholesale dealers shall be selected from those who have already established a position and character for respectability in other markets; that the shops shall be occupied by farmers or their agents, who will be their own esleemen, and thus free their customers from the penalties inflicted by their dealing with the middleman; and, lastly, that the costermongers and hawkers shall have the option either of selling in the open market-square, seen in the plan we give, or of hiring their barrows and carts from the market stores upon such terms as will secure to them a better profit than that which they now receive on their hard day's work.

Another object was considered desirable, namely, the provision of better lodgings for City clerks, who complain with reason, that while model dwellings are provided in various parts of London for the working classes, they are still left to the discomforts and expenses of inferior lodgings, far away from their daily occupation. It was thought, therefore, that their interests might be advanced and an important want supplied, if a certain number of convenient dwellings were provided having private entrances and other arrangements which should render them entirely independent of the traffic of the market.

These residences occupy the wings which flank the east and west buildings, and they are arranged in flats. It is thought not unlikely that an entire wing may be taken by one City firm and re-let to its principal assistants.

The market is situated between New-street and Crab Tree-row, close to Shoreditch Church. These thoroughfares bound it on the north and south, and two private roads connected with them are its limits on the east and west. The space thus enclosed is nearly square, and covers about two acres.

The plan, it will be seen, consists of four blocks of buildings with arcades, surrounding an open quadrangle. The buildings, which occupy the east and west side of the quadrangle, are similar in design, and are each 210 ft. long by 45 ft. wide. They each comprise six shops and two wings, flanking a central archway leading to the quadrangle.*

The shops are four stories high, including their basements. Their accommodation consists of kitchen, cellar, store, and closets in the basement; shop, parlour or office, and private entrance on the ground-floor; and sitting-room and four bedrooms, with closets, &c., on the two stories above. They are intended for first-class dealers. The wings are four stories high, exclusive of their basements, which are cellared for market purposes. One wing is occupied as a tavern, and the others are intended as residences for clerks, as already referred to. Each residence occupies a separate story, approached by a common staircase, and contains parlour, kitchen, scullery, store, closets, and four bedrooms. The residences in the east building are called "Georgina Gardens" those in the west building, "Angela Gardens;" the former look over Columbia-square; the latter over an ornamental plantation of plane trees and flowering shrubs.

The central archway, which leads to the quadrangle, has stores and cellars in its basement, and a suite of rooms above, intended, like those in the wings, as a residence for clerks and tenants of the same class. The third or topmost story is carried up as a tower, and contains large filtering cisterns, which supply the entire building with water.

The tavern occupies the entire north wing of the east buildings, and contains in the basement—kitchen, scullery, larder, cellars, stores, &c.; on the ground-floor—coffee-room, bar, two parlours, public and private entrances; and on the two upper floors—first and second class bedrooms, &c. Near to this, still further north, is the Watchman's House, with public closets and stopping places.

The buildings which occupy the north side of the quadrangle consist of the market-hall, the corridors affording access to the quadrangle from the market-yard and New-street, and the staircases leading to the several basements and vaults below.

The hall, of which we give an interior view,† is only one story high, exclusive of its cellars. It measures within the walls 104 ft. in length by 50 ft. in width, and is 50 ft. in height. Its length is divided into seven bays by clustered granite

pillars (Aberdeen and Peterhead) 2 ft. in diameter and 35 ft. high from the floor to the top of their capitals, which are of bronze and of varied design. Each cluster of columns is bound together by bronze bands at certain heights, four in number. From the capitals spring the moulded ribs of the roof, which is groined throughout with pitch pine. The space in the centre of the hall, affording an area of about 2,600 superficial feet, will be unobstructed by fixtures of any kind, as it is intended for the accommodation of small dealers, but in the aisles, immediately behind the pillars, are ranged twenty-four small shops, 13 ft. deep, 6 ft. 9 in. wide, and 8 ft. high each, supplied with office containing fireplace, desk, &c., and furnished with sink, counter, and other fittings necessary for the sale of meat, fish, and poultry. They are lined on all sides with polished Irish marble. These are intended for second-class dealers. Above the shops are galleries, each affording an area of 676 superficial feet, for the sale of flowers, roots, and fruit, and these are approached by staircases adjacent to the principal entrances of the hall. The hall is lighted on all sides by large mullioned and tracery windows, which extend from a few feet above the galleries to the groining of the roof with which their heads are concentric. Two compartments in each window are furnished with casements, which are made to open outwards for ventilation. The building has four entrances: that on the south side, fronting the quadrangle, is the most important, and consists of a groined porch of considerable depth, forming the lowermost stage of a clock-tower and heltry, which rise to the height of 115 ft. above it; two entrances lead from the corridors at the ends of the hall, already mentioned, and the fourth is on the north side leading from the market-yard and New-street. Its basement story contains twenty-six cellars, situated on either side of a central passage, 7 ft. wide, which traverses it from end to end, and communicates with two staircases leading from the corridors and entrances in the market-yard above. This yard covers about 8,000 superficial feet, and, though connected with the central quadrangle is independent of it. In it carts will unload, and most of the wholesale business of the market be carried on, so that the retail traffic which, from the character of the neighbourhood is likely to be the most important, will not be interfered with.

The buildings occupying the south side of the quadrangle, and fronting Crab Tree row, are of the same length as those on the north side just described, viz., 160 ft. Their width, however, is nearly uniform, and does not extend beyond 35 ft. They consist of a gate-house and two arcades, connecting it on each side with the east and west buildings.

The gate-house is three stories high, exclusive of its basement, which is cellared for market stores. On the ground story a lofty archway, with ornamental iron gates, forms the principal approach to the quadrangle, and leads to a public and private staircase connected with the upper floors: the former communicates with the market-office on the first floor; the latter is for the use of the clerk of the market (Mr. Russhent), who occupies the floor above.

The arcades on each side of the gate-house are only one story high. They are intended for dealers of the third class, or those who do not require the accommodation of a shop. The area of each is 2,275 superficial feet. On the side towards Crabtree-row the arches are furnished with very handsome folding iron gates, which double back, so as to clear the openings during the day, and serve as efficient protection when the market is closed at night. Each arcade is supplied with a granite washing fountain, 6 ft. in diameter, and contains eighteen stores for vegetables in its basement.

The central quadrangle which is surrounded

* A view of the West Elevation, and a plan of the buildings, will be found in our volume for 1869 (xxv. pp. 796, 797).

† See p. 147.

* See also "Town Swamps and Social Bridges," by George Godwin, 1859.

by the four blocks of buildings above described occupies an area of about 14,000 superficial feet. It is paved with a bluish-coloured granite divided by lines of red granite into spaces 6 ft. square, which are intended as stations for dealers of the fourth class, or those who require the least accommodation for the sale of their goods. A large lamp, surrounded by four granite washing-basins and hydrants for the supply of water will occupy the centre of the quadrangle. Underneath the whole area are vaults 11 ft. high, communicating with the market-yard by staircases near the hall. These have been so arranged that they may be let to wine merchants, brewers, and others, and they now wait for tenants. Lighted up with gas, they present a remarkable appearance. They are constructed with iron uprights, carrying iron girders and brick arches. The surface above is formed with concrete, asphalt, and paving.

It will be seen from this description that the market buildings have been designed to meet the requirements of five different classes of occupiers, viz., clerks, who will occupy 14 residences in Angela and Georgina Gardens; first-class dealers, who will occupy 12 large shops and residences in the east and west buildings; second-class dealers, who will occupy 24 small shops and offices in the market-hall; third-class dealers, who will occupy 9,850 superficial feet, apportioned into 273 spaces, 6 ft. square, on the ground floor, and in the galleries of the market-hall, and in the south arcades; and, lastly, fourth-class dealers, who will occupy 14,000 superficial feet apportioned into 400 spaces 6 ft. square in the central quadrangle. The rent at present asked for each shop, with office in the market-hall, is 10s. a week. The rent of the houses east and west of the quadrangle, each comprising a shop and nine rooms, is 52l. 10s. per annum each. Several of them are occupied.

The buildings are enriched with carvings and details characteristic of the style prevailing in the early part of the fourteenth century. Their construction is substantial. The walls are of yellow brick, terra cotta being employed for their external angles and for much of the moulded work of the doors, windows, and arcades. All the copings, strings, oills, cornices, capitals, traceries, and carvings, which are exposed to the weather, are of Portland stone. Granite pitching is employed for paving the private roads and large open spaces. Yorkshire stone is used for all corridors, footways, and internal passages, and plain tiles serve for kitchens, sculleries, and minor offices. The roofs are covered with Cumberland slates of a green colour. Almost all the external woodwork, such as the top story of the turrets, is executed in teak.

The endeavour here nobly made to establish a market, and to bring order and elegance, as well as economy and comfort, into the midst of poverty, squalidness, and misery, deserves the warmest wishes of all who are interested in the improved condition and welfare of their fellow creatures. We sincerely hope that it may be as successful as its admirable founder can desire. Much will of course depend on the means which exist for the supply of the market.

THE TERM "ARCHITECTURESQUE."

The claims of the new word "Architecturesque" to a place in our language, with a well-defined meaning attached to it, have now been urged with such fluency, force, vivacity, and ingenuity, that a student of the vicissitudes of language generally may well watch with interest the fortune that awaits it. Many will be curious as to the result of its struggle for existence who do not feel called upon to interfere actively with the conditions of the contest. Will it make good its ground as effectively as the officially sanctioned *telegram*, or will it share the fate of *vicissitudes*, which seems to have been strangled in its birth,—a word that would have had a better chance of life had its originator not missed its applicability,—supposing, as it would seem, that "vicissitudes of fortune" only mean "persistent neediness" in which case "necessitous" would have served his turn equally well?

For a new word to gain currency with welcome and advantage, it must happily meet a want,—supply usefully and agreeably a defect of language; the word must be demanded to furnish a new name for a new thing,—as in the case of *telegram* or *hangaroo*,—or a name for a thing which, however old, has inconveniently been destitute of a name. Who will be the benefactor to endow the English language with a word that

will signify either brother or sister indifferently, as "child" is applicable to either son or daughter? A new word may be required to take up the duty of an old one that by accident or abuse has become "ill sorted," vulgarized, or, to share functions with another word as a synonym of contrasted sound, and useful therefore in conjunction with a varied set of words, or supplying relief to the ear when otherwise repetitions are inevitable.

In any case, if the purpose of the new word is to be effected happily and agreeably, it must be elegant, expressive, unequivocal.

"Architecturesque" is proposed as the title of that quality by which a structure has claim to be an example of fine art and artistic effect, and so to be distinguished from a mere building. On the ground of elegance, and agreeableness of sound, there can be no objection—seldom, indeed, can there be to any word that directly affiliates on a language so fastidious in its laws of sequent *consonation* as the Greek. The question whether it can be held strictly and unequivocally to the meaning it is proposed to express presents itself somewhat differently.

To any word that does not present itself as—*intus et in cute*, "hido and hair o't"—a complete new coinage, meanings and reflections of meanings will cling that it hovers an uteror thereof to take wary account of; meanings and shades of meanings that depend upon its relationship to antecedents, competitors, analogues—in a broad way of stating it—on its history and its derivation. In the present case there can be no uncertainty or cavil as to the main stem of the word, but everything turns upon the analogies of its termination, which has a root meaning of its own, and its historical accretions of association equally.

The tenacity with which the original meaning of a root will hold on to a derivative and influence application long after it has ceased to have an independent existence, is one of the guiding principles of the etymologist. Thanks to this principle, words can be used with the strictest accuracy by those who are perfectly ignorant of their derivation, and the hospital nurse has as definite an idea of a "paroxysm" as the M.D. Cantab. to whom she reports its manifestation; and tradition would no doubt accurately carry down the application, though the traditional derivation should be lost. It is on the strength of this fact that an uncertain root is confidently verified only by consented habitual associations. Derivation corrects use in such a case as "paroxysm," but in a dispute as to such a word as "buoyancy" we must inevitably fall back upon the leading notion in popular usage to determine between one or other of the derivations in the languages through which it may be tracked. Diverge a word or a characteristic termination of such associations we cannot; such nature we vainly shall endeavour to repel under any penalty whatever: the penalty will be braved, he incurred,—but nature will be recurrent.

How stands it then with "architecturesque" and its congeners; we have the artistically analogous, Pictorial and Picturesque, Sculptural and Sculpturesque, and why not then complete the ternary by Architectural and Architecturesque?

Reason there is none whatever, but a condition most stringent: this is no less than that the new word shall complete a pair analogous in their relationship to the pairs that are in established acceptance; for these it will scarcely be sufficiently strong to fight with,—to thrust into disuse or altered use, or to resist in their conjoint determination to enforce it to conformity.

Thus, new as the word "architecturesque" may seem, we are soon made conscious that we are not exactly free to consider what meaning we shall resolve to attach to it; we are indeed much less so than enforced to consider what it means independently, what sense it will inexorably assert for itself, and by hereditary right and by the vigorous aid of its natural kin and alliances compel us to allow or to take the alternative of leaving it alone.

The terms "picturesque" and "sculpturesque" conform with true fraternal loyalty. We do not speak of a painting as picturesque, nor of a group in marble as sculpturesque; these qualifying terms apply to the subjects of the respective arts, not to the works, in which justice even the most worthy has been done to the most appropriate subjects. Nay, even with reference to subjects, we describe them in such phrases rather perhaps from a sense that they in a manner simulate the effects of the respective

arts than as lending themselves most aptly as models. We may say of a child that she is a picturesque little being,—of a district of country, that it is marvelously varied and picturesque,—and yet be disinclined to carry our sketch-book to the hills in one case or to recommend the girlish face we so admire for a fancy picture. There is no inconsistency: the subjects in either case are picturesque because they comprise not only much that a painter would value in a subject, but a semblance moreover of much of the peculiar treatment he would be expected to superinduce; a semblance, not a completion; a commencement so far advanced as to hamper him, not so far nor so purely as dispense with that air of pervading originality that must spring from a germ of true artistic thought, and govern selection throughout and treatment absolutely.

It is thus that experiments with models that are originally too picturesque rarely succeed. If a well-bearded mendicant is transferred to the studio to be ennobled on canvas as a hamished lord, he will be likely but ill to become his elevation, unless the painter has known how far to recast his features by the suggestions of the ideal that but little likeness of the original picturesqueness remains. A landscape of high pictorial capabilities is one thing, a highly picturesque landscape is another; preference for a subject of the latter class would not prepare us for recognizing pre-eminently in the finished work the qualities which should essentially determine it as a work of art.

Picturesqueness is thus not the best quality of a picture in a picture, but the guarantee of some striking characteristics of a picture in what is not,—perhaps ought not to be, or could not possibly be,—a picture. The sculpturesque has exactly the same relations to sculpture; if sculpture is sculpturesque, it is not something more, but something less than truly sculptural, and the term therefore could only be applied in disparagement, and better not at all. The terms become truly applicable and useful only when we would indicate defects, or at least characterize some of the less legitimate modes in which the genius of one art makes inroads upon another. The Nightingale monument of Rouhiliac is rather picturesque than truly sculptural, yet who desires a transference of the subject actually to a picture? On the other hand, the processional triumph of Andrea Mantegna is rather sculpturesque than pictorial. What picturesque language implies is understood by all, and even here the antithesis to sculpturesque would hold, if we compare the characteristics of florid Ciceronian eloquence with the nerve of Demosthenic.

The contrast might be further pursued between picturesque architecture and architecture that is sculpturesque; but that we may more appropriately inquire now how far reciprocity of antithesis applies to architecturesque. There is little question of bow we may apply the term, but very much indeed of how we must. A view down an avenue of tall straight trees meeting at very regular height overhead, with gracefully-curved branches, reminds us necessarily of architecture; the same is the case with a defile between walls of rock marked with very level lines of stratification, and overhanging in parts with ledge-like projections; such views are assuredly not architectural,—are they not as assuredly architecturesque? Does not the word lend itself, impose itself as descriptive by all the analogies of its derivation, to aid in specifying, not architecture, but what is like architecture,—not art in its best realization, but art that is hinted at— at most mimetic intimation of art in natural accidents? The word thus accepted on its own conditions seems a good word, and susceptible of large application. We have spoken of the possibility of qualifying eloquence as sculpturesque, in some other forms where the flow of invention is dominated by an exact observance of balance, by regularity of subdivision, by scrupulously proportioned members—exordium, peroration, and so forth, we might with at least equal appropriateness—always assuming some worthy dignity pervading the whole, qualify it as architecturesque. Sculpture becomes architectonicsque in the caryatides of the Erechthium, unless we say that it is architecture that becomes sculpturesque. Where shall we recognise an example of painting that can fairly challenge the title "architecturesque?" What pictures have the semblance of architectural almost as much as of pictorial works? The built-up scenes of a theatre, or such combinations of modelled perspective and background as the Olympian Theatre of

Palladio, perhaps claim the title less appropriately than more proper pictures, which, like the "Last Supper" of Leonardo da Vinci, but with expression more hardened, are designed with a certain strictness of symmetrical formality, for the direct purpose of blending harmoniously with symmetrically-arranged architecture around. In this sense many of the vast paintings of Paul Veronese—as the "Marriage of Cana," now in the Louvre, or others somewhat smaller, as his fine reflecting picture at Vicenza—may be appropriately styled architecturesque. Can we again find another term,—can we find a better,—for the characteristic style of the sculpture of the Parthenon, in so far as it is modified with direct intention to relieve the rigidity of architectural lines, and to combine harmoniously into balanced masses responsive to architectural symmetry, than the architecturesque?

In what sense, then, architecturesque will insist upon being used, if it is used at all, appears pretty clearly: it is decided by the foregoing precedents of common usage, and will persist in spite of whatever ingenuity of argument or remonstrance, whether soft or vehement: usage has taken firm hold of the family of vocables it pertains to, and will not revolutionize its code to accommodate a claimant that has a fair enough position, as matters stand, to thrive in currency—

— ut vult usus

Quem pene arbitrum est, et ius, et norma dicendi."

There is then most certainly a common notion that clings to the common termination *esque*, as qualifying an adjective, and whether this has no deeper roots than the established and possibly accidental habit, of which we have seen the strength, or has spread from an original germ of consistent derivation, matters not much. So far as the analogies of language present themselves to not very deep research, they are all in favour of established usage. The termination comes to us along with many words imported from Italy by the route of France,—as *pittoresque*, *pittoresco*,—grotesque, *grotesco*,—burlesque, &c.; and it seems in these combinations to be at almost equal distance from Teutonic forms on the one hand, and Greek on the other. The Greek diminutive *iscus* appears in such words as *asterisk*, a little star; *obelisk*, a small, a fine spit; *Paniscus*, a little Pan,—such a companion as trots through Titian's picture dragging a calf's head by a string; the relation seems to be to *iskos*, to make like,—and beyond that again to *iscos*, "equal" or "like." Likeness, however, has seldom to be adverted to without an intimation of characteristic tendency, as among others, of aspiration neither vain nor ignoble, as when we say godlike, manlike, or manly, the same word; or of futile imitation, as when Rosalind talks of "mannish" towards,—

"That do outface it with their semblances."

The termination *ish* in English (= Anglo-Saxon *isc*), carries with it usually along with likeness the implication of disparagement,—first in respect of magnitude or degree, and then of moral value. There could be little mistake if such gibberish—this word itself is an illustration—were permissible, how much less than a compliment would be implied by picturish, sculpturish, architecturish. The termination *esque* scarcely escapes from some shade of like imputation; the thoroughly architectural word *Romanesque* at least can only be understood as antithetical to Roman, as significant of Roman with a difference in the direction of the corrupt and provincial, if not absolutely debased, in the first instance; an embossed Romanesque style developed itself, no doubt, at last; but then it becomes entitled to be distinguished by a new name from the corrupt Romanesque and from the Roman also.

There are ethnological as well as etymological secrets latent in the form *English*, which here we can only commend to the study of those whom it may concern. As regards our proper subject, the conviction, after whatever fluctuations due to the ability of the advocate, comes back decidedly enough at last, that architecture on the whole may be well content, even at her very highest flight, to remain architectural. If there is any cognate term whatever that she might be excused for passing upon as an alternative expression for the noblest quality of her noblest aspirations,—achievements,—it is that Architectonic that both Aristotle and Plato have recourse to when they would characterise the function of organizing energy in its most dignified social exercise. But here, again, the appropriation is made and cannot be set aside,

and the authority of Peripatetic and Academician apart, the analogies of language are as decisively exclusive of the Architectonic as of Architecturesque.

ON THE FUTURE EXTENSION OF THE RAILWAY SYSTEM.

At an ordinary general meeting of the Institution of Surveyors on February the 8th, Mr. John Bailey Denton read a paper on this subject with special reference to the influence of railways on landed property and agriculture.

Earnestly (he said in the course of it) as I advocate the internal improvement of landed estates, I may at once state that, in a commercial sense, I consider that there is no improvement so economical to the landowner as that which railways secure. Whether we regard them as a means of raising the rental or income from cultivated land or woodland, or from minerals, upon which the fee-simple value may be calculated by pure arithmetic, or view them as a means of enhancing the residential enjoyment, or developing the capabilities of estates, the return from which is neither so positive nor simple, it cannot be denied that the selling value of rural property, when brought within the full influence of railway communication, is raised at least 10 per cent. above what it was in its former state; supposing all other things to be equal, and viewing this rise in connexion with the means by which it has been hitherto obtained, the advantage stands in bold relief above all other estate improvements. This statement has been confirmed by some of the first authorities in the country, who have, however, always qualified their opinions by explanations pointing to the differences which necessarily regulate results. [Some of these opinions Mr. Denton read.]

Many authorities have kindly supplied me with corroborative evidence, showing that the improvement which landowners gain from railways, in one way or another, varies from 5 to 20 per cent., or from one and a half to six years' purchase, according to the proximity of station, and the character and amount of accommodation afforded. It may hardly be necessary to adduce to you evidence of the advantages which railways afford to the owners of rural property, though, as they have now come to a complete stand-still and can only be revived by the action of land-owners themselves, it may be well to make prominent a few facts and figures which may draw attention to the object.

The first Railway Act authorized for the conveyance of passengers was passed in the year 1825, more than forty-eight years ago. It was from Darlington to Stockton-on-Tees, and it was upon this railway that George Stephenson first introduced the steam locomotive, for the working of which powers were given by an Act obtained in 1825. The population of England and Wales in 1825 was 12,000,236, and Mr. Porter, in his work on "The Progress of the Nation," estimated the number of persons who travelled daily, by coach and like conveyances, at 82,000 in the whole of Great Britain. The population of England and Wales, to which it is desirable to confine our attention at the present moment, is estimated by Mr. Foulhanque, in his Report to the Board of Trade on Agricultural Statistics, to be 21,649,377, which shows an increase of 80 per cent. in forty-eight years, while the desire for travelling has increased at a much greater ratio than the population itself. The number of persons who travelled in England and Wales in 1867 amounted to 250,598,982, exclusive of season-ticket holders, who numbered 84,418, many of whom travelled twice a day for six days in the week, raising the daily average, according to the *Quarterly Review*, to 850,000, or upwards of ten times as much as Mr. Porter had represented to be the travelling population in the whole of Great Britain before railways existed. To comprehend the magnitude of these figures, it should be stated, that the result is equal to a journey by every man, woman, and child, in England and Wales, fifteen times in the course of the year.

From these facts, it can be well understood how the competition for land, and the demands for country occupations, are on the increase, and, as a necessary consequence, how the value of rural property has advanced to the amount stated. The desire for living in the country, while engaged in the businesses of towns, is shown by the annual Board of Trade

returns, to be vastly increasing with all professional men and tradesmen; and the suburbs of all our large towns are, consequently, extending in a manner to surprise the most sanguine advocates of railway enterprise, and explain how land, within a moderate distance of towns, has been raised from an agricultural value, calculated by tens of pounds per acre, to that of building and accommodation value, which hardly stops at hundreds.

All classes of society now connect their town life with country occupations, and many of our legislators, peers, and commoners, evade the expense of a house in London, and run up from the country with the members of their families, whenever Parliament, court, or fashion calls them thither. It is much the same with the merchants and tradesmen of Liverpool, Manchester, Birmingham, Bristol, and all large towns. For a distance of from 15 to 20 miles the suburbs of this metropolis extend, and to get to business in London for the day, and back to the country for the night, have called into existence regular services of trains which make this amphibious sort of life easy of existence. In the morning there are those trains to arrive in London at 9 o'clock for the "early birds," those at 10 for the "daily breads," and those at 11 for the "lazy dogs;" and in the evening there are corresponding trains which deliver the "early diners" at home at 6, the "late diners" at 7, and the "snapper passengers" at 8 or 9 o'clock.

On this point the Registrar-General tells a pithy truth. He says, in his Report for the year 1867, that "the population within the registration limits is, by estimate, 2,995,513, but beyond this central mass there is a ring of life growing rapidly, and extending along the railway lines for a circle of 15 miles from Charing-cross. The population within the circle patrolled by the metropolitan police is 3,463,771." If these figures apply truly to the neighbourhood of London, and only in a less degree to other large towns, it is unnecessary to show how railways, having converted agricultural into suburban land, bring the more backward farms into a forward position, and thus equalize the character of properties, and raise the value of the whole. These figures, in fact, fully support the opinions I have quoted from our leading authorities, as to the extraordinary increase in value of building and accommodation land, and the less but certain improvement in farming land. To appreciate, however, the full benefit which railways confer upon agriculturists, we must again have reference to Mr. Foulhanque's recent agricultural statistics, published by the Board of Trade, by which it appears that the total number of live-stock in England and Wales was, in the year 1867, as follows:—

Cattle	4,013,564
Sheep	22,025,498
Pigs	2,778,672

By comparing these figures with those given in the returns furnished by the railway companies to the Board of Trade of the same year (1867), representing the number of live stock that travelled by railway in England and Wales, we find the following results, which would almost lead us to question the accuracy of the figures I quote. First, it appears that the total number of neat cattle that, in spite of the restrictive influence of the cattle disease, travelled by railway was 2,310,368, which is equal to more than half the total quantity possessed by the farmers of England and Wales; second, that of sheep, 7,171,412 travelled, which is equal to one-third of the whole number of sheep they possessed; and, third, that of pigs there were 1,389,582, which is as nearly as possible equal to half the number that belonged to the farmers when the returns were made to the Board of Trade.

Of course, it should be understood that in these railway returns are included all the animals imported from foreign countries, as well as the native stock which move from one part of the country to the other, and sometimes make two or three movements in a year.

As a set-off to advantages from railways we often hear of the loss of land to agriculturists, which results from the absorption of the quantity taken up by them. According to the most recent returns, the number of acres already purchased by railway companies for authorized lines open and not yet open, in England and Wales, is 121,120 acres and 37 poles. This quantity does not, however, include all the lands in the country which railways have absorbed

but only those of which the directors have made returns to the Government. The omissions form but a very small proportion. It is probable, therefore, that the total acreage in England and Wales, when the omissions are supplied, may reach 130,000 acres. This quantity includes the land in towns and enburbs. It would not be far wrong to assume that 100,000 acres have been absorbed by the railways made and making through rural districts alone. This quantity is arrived at thus:—the length of lines already opened in England and Wales is 10,037 miles, and the quantity of land per mile has been ascertained to be 12.97 acres. Of this length I estimate that one-fifth, or, say, 2,037 miles, has passed through towns and suburbs, leaving 8,000 miles as the length passing through rural districts. If we take 12 acres per mile, including village stations, as the average mileage quantity through rural districts, 96,000 acres will be due to the 8,000 miles, to which 4,000 acres may be added for lines making. Now, if we compare these 100,000 acres with the waste of land which exists all over the country, we shall see how insignificant it is. It is not many years since it was the practice with surveyors to allow 1 acre in 16 as a loss in cultivated farms, of average condition, arising from waste in hedges, farm roads, balks, &c., and what we now consider slovenly farming. This loss, however, is now yearly becoming less, and may average 1 acre in 20, instead of 1 in 16.

The total quantity of land under crops, bare fallow and grass, in 1867, was, according to Mr. Fonblanque:—

In England	29,982,366
In Wales	2,415,139

Making a total of ... 25,347,495

Now, if one-twentieth part of this quantity, which is 1,267,375 acres, is still wasted, or lost to cultivation, it follows that there is twelve and a half times the space occupied by railways, a great part of which is within the power of the farmer to recover and make productive, though, at the present moment, it is producing nothing. Thus the agriculturists of England and Wales have only to save from waste less than two-fifths of an acre in every 100 acres they occupy, to make up the quantity which railways, so essential to the commerce and comfort of our common country, have taken from them.

Having disposed of this drawback, there can but remain one general acknowledgment of the vast benefits which railways have conferred upon all branches of industry; yet in spite of this there seems to have been no limit to the demands which have been made upon railway shareholders, whereby the amount of money actually applicable to works has been reduced to a minimum, and the cost of use and maintenance raised to a maximum.

The reader then traced the causes of the present stagnant condition of railway enterprise, dividing them under the following heads:—

1st. The heavy Parliamentary expenses which have been inflicted on all railways, more or less.

2nd. The excessive cost of land.

3rd. The heavy cost of railway works and maintenance, and the wasteful mode of raising capital.

Under the first head he said,—Putting these more flagrant cases of waste out of view, it may serve our present purpose if I give the particulars of certain lines, which, by the courtesy of the secretaries of the several companies interested, I am enabled to do. The figures they present may be accepted as a fair sample of what railways through rural districts have hitherto paid in Parliamentary expenses, although it will, no doubt, be objected that the lines specified bring into communication certain large towns, and, therefore, cannot be strictly called "rural railways." To meet such objection I have endeavored to get the same information respecting lines which are indisputably and wholly rural, and, although I have not obtained figures I can precisely quote, I have ascertained that in most cases they have been made bones of contention between large opposing companies claiming the territory they traverse; and that though conceived by their promoters in the chivalry of competition or independence, have almost invariably become the property of one of the contending large companies, after causing an expenditure of which the average mileage amount would probably be found to be even greater than that which the following tabulated railways expose:—

Name of Railway	Length in miles.	Acres per mile.	Total acreage.	Total outlay of capital.	Parliamentary Expenses.			Land for Line.		
					Total cost.	Cost per mile.	Cost per acre.	Total cost.	Cost per mile.	Cost per acre.
Furness Railway... Manchester, Sheffield, and Lincolnshire	93	15	1397 0 0	£. 2,529,365	£. 88,870	£. 630	£. 42	£. 159,233	£. 1,712	£. 114
North Staffordshire (pt.)	249	11½	2804 1 22	12,373,978	628,690	2,555	224	827,015	3,362	295
Whitehaven, Cleator, & Egremont	123	12	1476 0 0	6,266,274	141,172	1,148	95	658,388	5,353	446
Cockermouth, Keswick, & Penrith	21	9½	200 0 0	335,000	5,740	273	28½	49,845	2,373	222
Maryport and Carlisle	31½	7½	237 1 30	322,967	3,850	124	16	50,500	1,629	239
.....	38	12½	487 3 13	707,705	15,070	397	31	84,064	2,228	173
.....	5524	—	6692 2 28	22,565,289	853,101	—	—	1,729,645	—	—
Average on the whole	—	12	—	40,879 per mile.	—	1,546 per mile	129 per acre.	—	3,133 per mile.	262 per acre.

The acreage is obtained from the Board of Trade Returns, and the outlay from the Secretaries of the different Railway Companies.

If, as I am disposed to assume, these lines of railway convey results fairly representing that part of the existing railway system which we have now in view, it would appear that the outlay in Parliamentary expenses has been, on an average, 1,545l. per mile, which, for the 8,000 miles I have considered was the extent of the railways made through rural districts in England and Wales, up to the end of 1867, would amount to 12,360,000l., of which the 12,000,000l. at least would have been saved if the Legislature had adopted, in the first instance, that course which every one now admits would have been the best, of investigating, through a competent medium, the requirements of districts, and have predetermined the position of those railways which were necessary.

Cost of Land.—With respect to the outlay in the purchase of land, I am able to give a few more particulars, in consequence of having been very kindly assisted by the secretaries of several of the railway companies and by many of the members of this Institution, who have had large experience in railway purchases. The following tabulated statement exhibits past experiences in the purchase of several lines, which will serve as an index to the remainder. In most cases the acreage cost includes surveyors' charges on both sides, but excludes the solicitors' costs of conveyancing:—

added for severance and compulsory sale. The readiness with which landowners will sell their land at a very moderate cost, or even give it, for railways, if they cannot get them without, quite sanctions this assertion. In the Isle of Angelsea the land for the Central Railway, eighteen miles in length, was purchased for 5,000l., and this was done by the secretary himself applying to the landowners before any other steps were taken. Again, the land for the Ringwood and Christchurch line, 7½ miles in length, was purchased for 1,200l., or 15l. an acre; and at this moment the greater part of the land for an extension in North Devon is very wisely offered for nothing, if by such means the parent company can be induced to make it. I cannot give many instances of this sort, for, unfortunately, though great professions of liberality have frequently been made to induce the promoters of railways to make them, directly an Act has been obtained for the purpose, legal reasons have been found for discarding preliminary professions, and the obligations of trustees and of persons under disability have been made the pretext for squeezing out of railway companies as much as could possibly be got. If experience had shown that the prices obtained by landowners were only such as would qualify them to make a proper abatement of rent to their tenants, the statements I have made would utterly fail in truth and fair-

In several of the above costs the compensation to the occupiers is excluded.

Having regard only to those lines in the foregoing schedule which may be called rural, and taking off from the remainder a fair proportion of the length of those in which lands of mixed character were purchased, 240l. may safely be taken as the average amount of money paid per acre to landowners exclusive of the occupiers' interest. This amount, it cannot be denied, has been paid in four cases out of five, where the land would have been well sold at thirty years' purchase on its rental, without anything being

ness; but I feel sure you will agree with me that the cases are very few in which landowners have not gained considerable profit—i. e., increased income—by the sale of their land, after making such abatement as they may have made to their tenants. Isolated cases, no doubt, could be found where injury has been done for which no adequate compensation has been given; but, fortunately, they are few. In a very large majority of instances no abatement has been made to the tenant, and none has been asked beyond

the simple proportionate amount per acre for the land taken,—generally calculated on the bare rent of the farm; though the inconveniences which a tenant-at-will suffers have not always been fully compensated by the money he has received of the railway company.

I am now speaking before an Institution the members of which have the most perfect knowledge of facts, and I would ask whether this statement is at all exaggerated? Mr. Beadell writes, "As a general principle, I think a landowner might well afford to sell his land at its bare value, giving up all claim for overvalue and compulsory sale; but taking care that, so far as accommodation works are concerned, he is properly protected." This is precisely my view of the question; and, in order that we may appreciate the full extent and effect of the over-payment to landowners, which has donehitherto had something to do with the present condition of railways, and the dead-lock to which they have come, we may assume that an average of 60l. an acre—i.e. 2l. (tithe-free) × 30 years' purchase, would have been ample payment for the 100,000 acres which railways have absorbed in rural districts. If this be so, and 240l. an acre has been paid for this quantity of land, the total amount must have reached 24,000,000l., when 6,000,000l. should have sufficed. Hence it follows that 18,000,000l. have actually been lost to the railways, and gained by those individuals of the landed interest who have been lucky enough to possess lands required for making them. I will illustrate the way in which the landowner's profit has been gained, by three cases within my own experience, believing them to be typical of others. In one case, acting for a landowner, I was instrumental in obtaining the sum of 1,700l. for 3½ acres of land. The case was one of very bad overvalue, there being upwards of 250 acres of productive arable land cut off from the homestead by the railway, which crossed on a level. The statement made to the tenant was 20l. a year, and the landowner having applied the money obtained in the redemption of the land-tax, and in the purchase of additional land, obtained nearly 60l. a year, so that he gained a profit of nearly 40l. a year. In the next case, a noble marquis, now deceased, sold between thirteen and fourteen acres of land, on a branch railway (purely agricultural), at 120l. an acre, for which he was receiving about 25s. tithe-free rent, and represented the proportion of the land-tax as merely nominal, while he pleaded great generosity in selling the land at the price. The railway was taken on lease, during construction, by one of the great parent lines, and though effort was made to apportion the land-tax, difficulties were found in doing so, and it was postponed until the lease was perfected. The noble marquis then demanded a re-apportionment of the land-tax, *ad valorem*, on the ground that agriculture was depressed, and the railway interest on the ascendant. The case was taken before the local Commissioners, and they being unable to resist the law, fixed on the railway each an amount of land-tax that, when redeemed, the price of the land purchased was raised to 175l. an acre. As a large part of the land in the parish belonged to the marquis, he, of course, gained by the increased amount apportioned on the railway. The third case is one in which a line was promoted by the landowners of the district. It passed through a property, under trust, for which an eminent solicitor, much connected with railway enterprise, was acting. He, being versed in such matters, opposed the Bill in Parliament, and came to terms in the committee-room. I refrain from mentioning the amount agreed upon, though it was a large one, but it is certain that the tenant, from that day to this, has received no abatement of rent; on the contrary, he has re-hired the farm on lease, without desiring any reduction, being satisfied that the accommodation the railway affords compensates him for the loss of the land taken. While referring to this latter case, I am reminded of the observation of our highly-esteemed friend and Associate, Mr. John Horatio Lloyd, on the evening of our first meeting, when he said, speaking of our position as surveyors, that the zeal for the interests of our employers not infrequently warps our judgment and puts a strain upon our consciences. Now, my experience leads me to the conclusion that though many surveyors are led in their zeal to do the best they can for claimants against railways, whose cases are put into their hands, there seldom is wanting, in the worse cases of exaction, a legal adviser who, with a full knowledge of the value

of the accommodation railways afford, instructs the surveyor employed to obtain the very utmost he can, and frequently adopts the most paltry expedient to grasp it. Great reliance is placed on the disposition of juries and juries to split difference, and it is not an uncommon practice for solicitors and surveyors so to prepare their cases, after having ascertained the very outside to which the railway company will go, as to furnish figures, in evidence, so much above the sum they really hope to get as the company's offer is below it.

Every purchaser for railway companies is alive to these tactics, and will acknowledge that, so long as the only alternative to yielding is an appeal to jury or arbitration, with all the expense of counsel, solicitors, and witnesses, it is doubtful whether it is not better, on the ground of expediency, to succumb to exaction rather than to resist it on the ground of principle. Though exposure of the manoeuvre by which money is squeezed out of companies oftentimes acts advantageously in checking for a time the greed of individuals, it cannot be denied that, on the whole, recourse to jury, and, not infrequently, arbitration, results in a lamentable failure of justice; and if the railway system is to extend, by branch lines and additional connecting lines, to those places and districts which are still without them, I think it will be found necessary to adopt a very different mode of proceeding for the acquisition of land. It is believed by many that, wherever a turnpike road now exists, a railway of some description or other should be made, and if made at a cost not exceeding 5,000l., will pay a fair dividend; and the Legislature, by the Act of last session ("The Regulation of Railways Act, 1868,") delegated to the Board of Trade the power of granting licences to construct and work *light railways*, which may be suitable for the majority of lines still remaining to be made. To reduce the cost of land, therefore, by an acceptable mode of proceeding is a primary consideration. With a view to raise a discussion on this point, I will now venture to place before you some suggestions for that purpose. I have already proposed that no payment should be made for compulsory sale nor for severance, but that a fixed number of years' purchase on the annual value, with proper accommodation works, should be the only basis of compensation when the land is simply farming land. It then remains to be considered whether the land should be paid for outright. It is the opinion of some persons that a very long lease or easement at an annual rental, say for 999 years, such as exists in the case of the Blyth and Tyne Railway, would be the better mode of acquiring land; and, if this latter plan were adopted, subject to a revision of rental at certain periods, so as to give the landowner the benefit of a general rise in value, it is not open to much objection. It would have this advantage, that many legal expenses would be avoided which appertain to the purchase of land. The question would then be, by what means should the annual value of land be ascertained?

An opinion has been expressed that the Board of Trade, who now, in the place of justices, appoint surveyors to value for possession where any land is required by railway companies before settlement can be made, are fully competent to appoint an umpire, whose decision shall be final, to determine the amount to be paid or the rent to be fixed, where the landowner or his agent and the agent of the company cannot agree; and it has been suggested that it should be entirely within the breast of such umpire to decide whether any evidence beyond that of the agents on both sides is necessary to enable him to form a proper judgment. Whether or not, there should be a power of appeal against such decision is a matter worthy of consideration; but, under any circumstances, it is conceded that some such inexpensive process should regulate the future price of land for railways in rural districts, and that one and the same person should be appointed to act as umpire throughout the entire length of any future branch railway.

Discoveries in St. Mary's Church, Rochester.—During the alterations in St. Mary's Church, two Norman arches have been brought to light, both of which had been previously walled up. They are at the western end of the edifice, and are supposed to be all that now remains of the old church.

ART-WORKMANSHIP AT THE SOCIETY OF ARTS.

THE council of the Society of Arts offered last year, to art-workmen, a large number of prizes, ranging from 15l. each, under two heads,—namely, first, for specimens of art-workmanship in prescribed processes, such as enamelling on metal, painting on earthenware slabs, the execution of "filigrani" in glass, damascening on gold or silver, the combination of marquetry with carving in low relief, and the inlay of hard woods; and, secondly, for specimens of the application to ordinary industry of prescribed art processes. Under this second heading prizes, for example, were offered for the most beautiful dial-face for a clock, the most beautiful frame for a miniature, the most beautiful set of fire-irons, the most beautiful earthenware slab, painted in enamel colours and fired, for insertion in a chimney-piece; a pedestal for a base of carved marble combined with mosaic; ornamental ironwork for the balcony of a window, and so on. There is also the North London Exhibition Prize (the interest of 167l. 7s. 3d. Consols.) to be awarded for the best example of skilful workmanship amongst the specimens sent in. And when, in addition to these prizes, it was known that the Department of Art have always purchased a number of the rewarded works, extending 50l. or 60l., according to circumstances, there were surely strong inducements for men anxious to advance themselves, if not their art, to submit works showing what they could do.

The response is not equal to what might justly have been expected. It is all very well for workmen to say they wish to elevate themselves: "Show us a road?" "How can we do it?" and so forth; but something more is needed: they must do as those above them are forced to do,—work long hours on an occasion, and do as well as talk.

In competition for the prizes offered under the first head, there are but eight works; for those under the second, seventeen. In addition to these there are forty-one subjects sent in for exhibition, not in accordance with prescribed processes. The most meritorious under the first head are a Clock-Case in amboyna and purple-wood, with inlay of ivory, neat and freely cut, by Thomas Jacob; the centre of a chimney-piece, with mosaic inlay, by J. E. Daly; and a carved and inlaid panel by Thomas Codfrey. In the second division J. B. Evans deserves, and will doubtless get, reward for his painted slab, for insertion in a chimney-piece, a most praiseworthy work. A frame for a miniature, and a ring tray, of strongly gilt gilding metal, and enamelled, by Frederic Lowe, are very creditable. A slab, by W. H. Slater, "Pluto" painted on blackware, and some Book Covers sent by C. Ffardor, deserve notice. E. Millard's Set of Fire-irons are certainly not "beautiful," whatever other merit they may have. Two or three of the Clock Dial sent by J. Thwaites are very good; we do not include the one of quasi-Gothic pattern.

Amongst the subjects not in accordance with prescribed processes, though eligible for rewards, the most excellent work of its kind is a piece of Porcelain painting ("Giving a Bite," after Mulready), by W. P. Simpson. Some of the colours are excellently hit, in the face of difficulties. Some stone carving by John Barker, a Boy's Head in relief, marble, by W. X. D., and a relief in boxwood, by Thomas Wills, deserve praise. As do, in even greater degree, the Head of a female, modelled from life, and a steel die from the same of reduced size, both by G. Morgan.

THE EAST WINDOW, ST. PAUL'S CATHEDRAL.

ON Wednesday, the 10th instant, St. Paul's Cathedral received a painted window, representing the Crucifixion, and occupying the principal opening of the central compartment of the apse. This magnificent donation of the Drapers' Company was uncovered in the presence of a large gathering of the members of the company, and as many of the cathedral clergy as could attend. The donors are recorded in the window, with the addition, "Unto God only be honour and glory."

The design, in common with that of the other principal painted windows intended for the cathedral, of which one (the west window—Mr. Brown's gift) had already been for some time in its place, represents the historical subject enclosed in an imaginary architectural framework. The justification of this style of treatment is founded on

the almost universal practice of the Renaissance artists of France and Belgium.

The window was executed in Munich, at the Royal establishment, under the superintendence of the Chevalier Max. Aimmiller, to whose care and skill the recent success of the Munich establishment are mainly due. The fault which in former times deservedly attached to the Munich school of glass-painting—namely, the unjustifiable use of enamel colour, has been laid aside in the windows recently executed for St. Paul's, as well as in those sent to Glasgow and Edinburgh, which are as completely mosaic as the Mediaeval examples.

The fine old veteran painter, Julius Schnorr von Carolsfeld, designed the figures, which, in their expression of deep feeling and solemnity, may be classed with any of the works by which his reputation has been established. The full-sized cartoon was made by his pupil Strübiner. The architectural decoration was designed by the surveyor to the fabric of St. Paul's, Mr. F. C. Penrose, who also prepared the general scheme of the windows in concert with two members of the St. Paul's committee, whose loss will not soon be replaced, either in that committee or in the world of art in general—Charles Winston and John Lewis Petik.

This window, in consequence of the amount of labour and thought which has been bestowed upon it, deserves to be carefully examined, and we anticipate that, however little acceptance it may receive from those who have made up their minds strongly in favour of a different style of treatment, it will nevertheless enlist a sufficient number of admirers to justify the donors and the committee in the belief that they have not only introduced a great ornament into the cathedral, but also have rendered an important service to the British school, by inciting the public to demand a more artistic description of glass painting than is now in too many instances put up with.

The cost of this window, irrespective of home charges and fixing, is about 900*l.* The fixing was intrusted to Mr. Miller, of Brewer's-street, who appears to have executed his task with great care.

Two other windows for the apse are in progress, being respectively the gifts of the Goldsmiths' Company, and of Dr. Rogers, in memory of his martyr-ancestor, Canon Rogers; and one for the end of the south aisle of the choir, in memory of the late Mr. William Cotton.

ON THE SCIENCE OF COLOUR.*

THE results which I have endeavoured to deduce from the study of the prismatic colours are fully confirmed by all sorts of experiments made with the colours of pigments. For instance, we may test the colours of pigments with the prism in a beautifully simple way. We have merely to cover a small part of a strip of white paper with the pigment, and view it over a dark cavity through the prism, and we see the spectrum of the pigment-colour adjoining to that of the white, and detect at once the rays which are absorbed or extinguished by the pigment, and those which it sends to the eye, to which its colour is due. Thus, with respect to yellow, which many will still maintain, I suppose, to be a primary colour, unconvinced by the experiments on the combination of the prismatic rays (which show that the best yellow is produced by throwing together all from the first red to the last green ray); if we analyse the colour of anemolin, of chrome yellow, or of king's yellow, or the petals of any bright yellow flower, we uniformly find that, the better and clearer the yellow, the more perfectly the object reflects all the red and all the green rays, absorbing only the blue. Hence, if blue is a primary colour, it is difficult to see how it can be supposed that a colour produced by all the other rays of the spectrum is not made up of both the other primaries combined, whatever those primaries are. Some strips of paper, coloured in parts with different pigments, will be found on the table amongst the objects for prismatic observation.

Again, we may determine correctly all the intermediate colours between any two given colours, and ascertain the accurate mean between two given colours, without the slightest difficulty or possibility of error, by the beautiful method which was first used by the celebrated Lambert in the

last century, and which I have, in my late treatise on the science of colour, endeavoured to improve and apply to this purpose. We have merely to hold a slip of clean polished glass, perpendicularly, between spots of the given colours, so as to see the near spot reflected from that part of the glass through which we see the other spot. If spots of white and black are placed opposite to each on alternate sides of the given colours, the position of the eye, in which half the light is reflected and half transmitted, is readily found, and the result there observed must be the mean of the colours. When the reflection is more oblique, the reflected light will be in higher proportion than the transmitted, and the contrary with a less oblique reflection.

Those who suppose that they can get the colours intermediate between the colours of two pigments by mixing the pigments, should compare the results obtained by that fallacious method with those obtained by this elegant and easy experiment. Gamboge and Prussian blue, for instance, make, by mixture or superposition, a green, darker than either the yellow or the blue of those pigments; the scientific method gives, as their intermediate colour, a gray of mean brightness, in agreement with the results obtained by our experiments on the combination of the prismatic rays. So, also, it does with the colours of king's yellow and cobalt, or lemon yellow and French blue or ultramarine.

If we avail ourselves of the well-known property of Iceland spar to give double images of two coloured spots, and arrange the spots so that one image of both shall fall together, which is easily done, we obtain the same results. And so, also, if we excite the sensation of the two colours in rapid succession on the same part of the retina, as by the well-known method of rotation. But neither of these methods is so convenient in practice as that of the slip of glass; and I only mention them to show that, in whatever way we can mingle two different colour-sensations, we obtain the same results. Small spots of the colours of vermilion, emerald green, and cobalt, of verdigris, rose madder and king's yellow, with the requisite appliances, have been prepared for the purpose of illustrating these methods of finding their means; and any one who will examine the matter will see that the latter three pigments are very nearly complementary in hue with the former three; that is, the means between vermilion and verdigris, between emerald green and rose madder, and between cobalt and king's yellow, are very nearly neutral grays. The results of all our experiments with colours of pigments, therefore, plainly agree with those of our former experiments on the combination of the prismatic rays, and confirm the opinion that red, green, and blue are the primary, and sea-green, pink, and yellow the secondary colours.

In perfect agreement with the facts I have stated about the complementary colours, are all those apparent changes of colour which are perceived when the retina, having been strongly excited by some one or other colour, becomes less sensible to it than usual, and every object to which we direct the eye appears, therefore, more or less tinged with the complementary colour, as if a wash of that colour had been laid over it. For it is always found that in an eye excited by red, by green, or by blue, objects appear tinged with sea-green, with pink, or with yellow; and the reverse; and that by intermediate colours intermediate effects are produced.

I am aware that some of these effects have been otherwise described by several writers: it is usual, for instance, to hear it said red tinges the adjoining colours with green; but this is not correct, unless the one be a pink-red, or crimson, and the other a sea-green. So again, it is usual to say, that blue and orange mutually depon each other; but for this to be true, the blue must be of a sea-green-blue or azure hue, and the orange must be yellowish.

The most careful experiments, made by looking steadfastly at spots coloured with those pigments which best represent the principal compounds of the prismatic colours, and brilliantly illuminated upon a black ground, and then suddenly directing the eye to a perfectly neutral gray ground, will always clearly show the gray surface darkened and modified in hue in accordance with what I have already pointed out as the real or natural complementaries. Thus, an eye affected with bright red or scarlet, like that of vermilion, turns the gray into a grayish sea-green of the hue of verdigris; one affected with green, like that of emerald green, turns it a

grayish pink, of about the hue of rose madder; one affected with blue, like that of cobalt, turns it into a grayish yellow, of the hue of king's yellow, and the reverse. The same effects are seen in the shadows cast by a sunbeam which has passed through strongly-coloured glass, upon a gray surface otherwise illuminated by a neutral light; and in many other ways, if due precautions are used. And no doubt the peculiar improvement in depth, which is evident in truly complementary colours when viewed in juxtaposition, the eye glancing rapidly from one to the other of them, arises from the same cause. It is evident, therefore, that the eye itself is so constituted as to agree in this respect with the deductions of science concerning the actual relations of colours.

The attempt to reconcile these obvious ocular effects with the common doctrine as to what colours are complementary to each other has led some to regard the deep prismatic blue, which Newton called indigo, as being violet in hue, and the deep prismatic red as being an orange red. It is a great incidental advantage in the system I advocate, that it abides by the invariable colours of the spectrum as the standard by which all the colours of natural objects are easily tested; for if we depart from these, we may widely alter the hues of our simple colours one way or another, and be quite uncertain what is right, having nothing but the general vague idea of redness, blueness, &c., to guide us. The terms used to distinguish colours are among the most indefinite in all languages; and the loose way in which they are applied, and the different meanings attached to them by different authors, would lead one to suppose that our colour-sensations are so different in different persons, and so variable in the same, that they are more fanciful than real, and that no certainty is attainable in them. Yet, in fact, if we except the comparatively few persons who are only capable of the sensations of yellow and blue, and those whose eyes are less sensible than they should be to red, there is a wonderful uniformity and certainty in the sensations excited by light. Only let the rays which enter the eye be the same in quality and quantity, and let the eye be in the same normal condition, without any present or very recent strong excitement, and we may rely upon the results being the same.

But the difference between the new doctrine and the old is more than a difference of terms, for the utmost latitude of interpretation cannot reconcile them.

In a diagram, intended to represent in its lower part the effect of three luminous beams, red, green, and blue, falling in partly overlapping circles upon a reflecting screen otherwise dark, I have endeavoured to imitate as well as I could the natural complementary colours, as seen in the spectra of white and black bands and edges, which perfectly accord with the ocular effects I have just alluded to. These colours lights produce, where the red and green lights fall together, a yellow of double brightness; where the green and blue fall together, a sea-green of double brightness; and where the blue and red fall together, a pink of double brightness; and, lastly, where all three overlap, a white of triple brightness. The upper part of the diagram, on the other hand, exhibits the effects of taking away from white the same three colours, as if by laying over the white, in three overlapping circles, transparent washes of some perfect sea-green, pink, and yellow pigments, producing red where the pink and yellow washes overlap, green where the yellow and sea-green overlap, blue where the sea-green and pink overlap, and, lastly, black where all three overlap.*

By comparing the colours in this diagram with the commonly received primary and secondary colours, as shown in the accompanying large and small diagrams sold for the use of the Schools of Design, which give the best representation of them that I could find, the essential differences between the two systems are made very apparent. Except red and blue, which both admit as primaries, all the other colours differ materially. The middle primary is deep green in the one, and bright yellow in the other; the first secondary is bright sea-green in the one, and yellowish green in the other; the second is bright rosy pink in the one, and dark bluish purple, or even violet, in the other; the third is bright yellow in the one, and a very red orange in the other. In the one it is endeavoured to

* From a paper by Mr. W. Benson, read at the Institute of Architects on the 15th inst. Mr. Benson's views have already been set forth at some length in our pages.

* This diagram was an enlarged copy of one in the author's treatise on the "Science of Colour," page 11.

get all the colours as nearly as possible of their full strength, in which they must be as nearly as possible of equal strength, so as to neutralize each other in equal quantities. In the other, their strengths are supposed to be proportioned according to certain arbitrary rules laid down by Mr. Field upon no sound reason whatever, and which moreover are not and cannot easily be fulfilled. In the one, by the enlightened study of the prismatic spectrum, and the use of satisfactory methods of testing the lines and the strengths of the pigments used, we make a tolerable approach towards correctness, or at least can ascertain pretty nearly how far we err; in the other, by following rules which a mistaken theory derives from the results of mixing pigments, or superimposing coloured glasses (regardless of the fact that such a process gives neither the sum nor the mean of their separate colours), not one of the pairs of nominal complementaries neutralize each other; for the red and green compound a dark orange yellow or citrine; the yellow and purple produce a reddish mixture; and the mean between the blue and orange is a good purple—much stronger and better than that given as the colour complementary to yellow.

The comparison of the natural and conventional systems of colour seems to me to be much to the advantage of the former. There is a certain beauty in combinations of colour devised under the latter, such as those in the diagrams for the Schools of Design; but this is attained without completeness of range or compass;—without including the most powerful colours of all the several kinds, which surely ought to be included in a scheme for showing the relations of colour;—and no reason is apparent in the included colours themselves why they should be placed in that particular order. The peculiar congruity of the true primaries in darkness and depth, and of the true secondaries in brightness and clearness, also tends to give, as it seems to me, a chastened richness and charm to any orderly combination of those colours which must be essentially wanting in similar combinations of the conventional primaries and secondaries.

I think, then, I am not wrong in asserting that an approach to scientific truth will be advantageous to art, and that the best natural taste may be directed and improved by understanding and observing the laws of nature. But in colour true science has hitherto scarcely been in the field at all, and taste has in fact had the battle to itself, not only unaided by true science, but even misled by false or pretended science. No wonder, then, that writers on taste in colour should be inclined to repudiate science altogether; and that Sir J. Gardner Wilkinson, for instance, in the beginning of his valuable work on that subject, should make such remarks as the following:—"Every one willingly admits the great utility of rules; but we must first make ourselves masters of the subject, and be contented to seek for facts to guide us in their formation." . . . "It is of more importance for the proper arrangement of colours to ascertain which harmonize in juxtaposition, than to occupy ourselves with abstract questions respecting their properties, or the laws by which they ought to be regulated; which, though they may display great thought and scientific knowledge, are here of little practical use, and which, like the constitutions of certain wise professors, appear as plausible on paper as they are impossible in practice. From facts and actual experience we may obtain something positive and useful: from theory nothing can be expected, so long as the subject itself is not thoroughly understood, except the most vague and contradictory conclusions."*

As to the impossibility of rightly treating red, yellow, and blue, according to the same rules as primary colours, the same writer also well observes (pp. 61, 62):—"Though red and blue in juxtaposition have the appearance of purple, and yellow placed next to red gives it an orange hue, the same illusion is not caused by the contact of the other two primary colours, blue and yellow, and these do not look green when in juxtaposition, except in certain cases. Nor is the change then so marked as when blue and red, or yellow and red, are in contact. And this is one of many proofs that all the three primary colours are not under the same conditions in relation to each other. It is not, therefore, necessary to lay down the same general and invariable rule respecting the three primaries, that "in making new patterns or ornaments, red and blue

should not join, nor yellow and red, nor yellow and blue," as though the three combinations were exactly similar, and subject to the same laws. For yellow and blue do not deceive the eye to the same extent as the others, when in juxtaposition. Nor has red with green the same effect as red with blue and yellow, and still less have red blue and yellow the same effect as these three colours when united in one;—that is, according to the theory which the author received, they have not the same effect as white.

Such anomalies as those noticed in this extract are the necessary consequences of an erroneous theory. Of course, blue and yellow cannot be treated in the composition by the same rules as blue and red; for blue is complementary to yellow and not to red. Still less can yellow and red be treated by the same rules as yellow and blue; for yellow harmonizes with red, itself containing the full red in conjunction with the full green, whilst it contrasts as the opposite colour to blue. No wonder that red, yellow, and blue together have not the same effect as red and green together, nor yet the same effect as white; for the mean of the first combination is always reddish, and of the second yellowish, and neither of them white or neutral, whatever proportions are taken.

I believe, however, that if we dispense with false theory and admit scientific truth we shall lose these anomalies, and introduce no new ones. We shall be enabled to treat red, green, and blue under the same rules as primary colours, and sea-green, pink, and yellow under the same rules as secondaries, if only we bear in mind the differences in the depth and clearness of the pigments we use to represent them; these, of course, modifying the effects in a large degree. Two primaries of similar depth may please the eye when side by side, while the same two, equally true in hue, but not alike in depth, may fail to do so. A great step will assuredly be gained if we establish correctly the hues of the three simple colour-sensations, and of their complementaries: for these, together with black and white, will give us the eight principal colours upon which to work, and will enable us to determine all the intermediate colours correctly, and to arrange them all with due regard to their natural gradations and contrasts of every kind.

Did I not fear to exceed the limits proper for this occasion, and to stand in the way of that expression of the views entertained by others which I hope this paper will elicit, I would add some remarks on the true limits of colours in strength of hue, which, when ascertained with some approach to correctness, might be substituted with great advantage for Field's doctrine of chromatic equivalents; on their limits in depth and clearness; also on gradations and contrasts of colour, and on the means which I have proposed as a key or directory to the endless natural harmonies of colour; combinations of which, in one form or another, must be (if I am not greatly mistaken) the groundwork of all that naturally delights the eye in colour-compositions, and makes them praiseworthy as works of art.

MEANS FOR THE IMPROVEMENT OF THE PEOPLE.

ENGLISH REPORTS ON THE FRENCH EXHIBITION.

FIVE of the six volumes in which it is proposed to include the reports on the Paris Universal Exhibition, prepared for the Science and Art Department, in accordance with the directions of the Lords of the Committee of Council on Education, have been issued.* The first volume, which is to contain a general report and tables of statistics, has yet to be published. We hope Mr. Cole will speak out in it. The sixth, or last issued, contains so many useful plans and so much information, that it deserves to be made widely known, and to be consulted. It is unlike the other volumes, not in its character, it is exclusively English. The third, which, for the sake of order, we will proceed to notice first, on the other hand contains notices of foreign methods of manufacture of various goods, carrying out the instructions the reporters received to turn their attention to the objects exhibited by the British colonies and by foreign countries, rather than to those shown by the United Kingdom. Passing over the reports re-

* Reports on the Paris Universal Exhibition, 1867. Presented to both Houses of Parliament by command of her Majesty. London: Printed by George E. Eyre & William Spottiswoode, for her Majesty's Stationery Office, 1867.

lating to cotton, linen, worsted, silk and lace manufactures, we come, in this volume, to a series of subjects belonging more to our own provinces.

Foremost in this series we must place Mr. Chadwick's amply illustrated report upon examples of dwellings characterized by cheapness, combined with the conditions necessary for health and comfort. It has already been noticed in these columns; but in its present completeness deserves further comment. The result of his survey of all the means and appliances for improving dwellings gathered together on the occasion of the exhibition, is a conviction that there are, already at hand, many plans and contrivances for very important advances. We give the items on which he considers progress has been made in the order in which he states them:—

In the means of relieving houses from the cesspool smell, or the bad drain, or sewer emanations and smell,
From the foul wall smell, and from the wall vermin.
From the damp wall.
From the smoky nuisance.
From a great proportion of the waste of fuel, and the loss of heat.
From stagnant and vitiated air.
From the deterioration of good water supplies.
From much of the exclusion from sunlight.
And in appliances by which they are made warmer in winter, and cooler in summer.

As he states, by way of heading to his report, that he considers the exhibition presented "evidence of only incidental, and an utterly incommensurate amount of attention to the great subject," we feel it is a source of congratulation that so many details can be picked out as having been improved. We also feel justified in being sanguine in our estimates of the advances yet to come when the matter receives more extended consideration. France, who did not open the question at all in 1856, constructed six models in 1867; Prussia and Austria appearing also in the field for the first time with one model each. The next exhibition will doubtless show these countries putting forth further strength, other nations taking the subject up, and progress made corresponding with the immense importance of the subject in reference to the comfort of the great mass of mankind. Informed as we are that the best class of cottage construction now in use among us, such as that on her Majesty's estate at Osborne, reduces the death rate of the occupiers by one half, it is clear that additional strides towards perfection must still further reduce the chances of premature death. We have turned from the items Mr. Chadwick has strung together to his consideration of the improvements effected in each, and find that he thinks the step in advance made in the matter of cottage walls is shown in an eminent degree in those devised by M. Ferrand. These, it will be remembered, are built double, and formed of hollow bricks, held together and the bearing power obtained by what Mr. Chadwick calls the Crystal Palace principle, a system of iron columns, beams, and crosspieces. This form of wall is thinner, it is urged, than a common brick wall, therefore takes up less space, warmer in winter and cooler in summer, because of the couch of air between the two surfaces, and it is a better non-conductor of sound than an ordinary one. At first M. Ferrand faced his wall with soft plaster and paper, but having his attention directed to the great desirability of a washable face, he has invented a new surface, that is nearly as white as alabaster, having that property. Furnished with this fine impermeable surface, which would do away with many of the offensive smells, and much of the dirt found in some houses, the cost of M. Ferrand's wall is still said to be less than that of an ordinary brick one. As to hollow walls generally, we have no hesitation in saying that, through the difficulty of getting them properly executed, they are five times out of six simply a delusion and a snare. Further experiments and improvements in concrete will probably direct future attention into this channel. A cheap walling, non absorbent, non-conducting, and having a washable internal facing, invented by Mr. B. Nicoll, is spoken of by Mr. Chadwick with praise. We have so frequently mentioned the Emperor's ill-planned concrete-hull houses that we need not again refer to them. There are plans of them, as well as an elevation, in the report; besides plans and elevations of the houses designed by the associated workmen who, assisted by a grant from the Emperor, undertook to build the accommodation they considered, perfect, sans architects et sans entrepreneur; and of those designed for the Co-operative Society of Paris. The last-mentioned body adopted M. Ferrand's

* Sir J. G. Wilkinson on Colour and Taste, pp. 6 and 8.

walling, sections of which are given. Referring to the dislike expressed by Parisian workmen to be *caserné*, or barracked, and to the fact that the associated experimentalists secured well-to-do neighbours by forming the lower part of their dwellings into shops, Mr. Chadwick remarks he has noticed a similar preference for neighbours of a superior class in England.—

"A *cité ouvrière* exclusively—a dead level of society—is not good for them. Their wives prefer to have high instead of exclusively low neighbours, and to see, and have their children see, what is going on about and above them. This feeling is also widely prevalent in England. The cottager's wife would prefer being near the Hall, or the Mansion, or the Parsonage, or to people of high rather than those of low degree. Cottagers' wives and children, occupying cottages in wares or by-ways, always lose in cleanliness, tidiness, and in other respects, by being out of the observation of "my lady," or of the clergyman's wife, or of the squire, or of the clergyman. Go where you will the occupiers of cottages in out-of-the-way places are of inferior social condition."

From the wall he passes to the window. In this item the improvement possible is the use of thick plate-glass instead of the thin glass, in small panes, in general use. The Austrian dwellings were furnished with double windows; with this exception, all the others in the Exhibition were glazed with the heat-wasting thin glass. One-third of the heat of the fire in a room escapes by means of this really extravagant article, and a great deal more goes up the chimneys. Mr. Chadwick dwells upon the three smells commonly perceived in an inferior dwelling—the cesspool smell, the wall smell, and the smoky-chimney smell. The last-mentioned, he considers, is nearly vanquished in some of the French model dwellings, by means of the capital cooking-stoves in use. Many experiments, or experiences, as the French phrase it, have been made by General Morin, in the matter of cottage ventilation, which our readers, interested in the question should look over. The leading principles which Mr. Chadwick mentions as having been recognized by the General are, "first, the superiority of the principle of ventilation by suction—by the method of the hot-water tank acting on the vitiated air-flue—over the existing method of ventilation by driving fresh air into rooms by steam-power; second, the principle that the vitiated air should be taken out as closely as possible from the sources of vitiation; in hospitals, near each bed; third, that the avoidance of the inconvenience of draughts, fresh air should be brought in from a distance to the place of supply. These principles may now be applied to the removal of air in exactly fixed quantities and temperatures; and fourthly, that the heat in entrance-halls, passages, &c., should be kept up to the same heat as the inner chambers." A deep underground covered tank for the reception of rain-water is the best plan proposed for keeping this indispensable article clean and cool. The water supply in France is notoriously impure, being brought by hand from wells and fountains to the houses. The Emperor's model cottages at Vincennes, Mr. Chadwick observed, were without a proper provision for collecting and storing rain-water; and yet this article, which in first-class condition, is so superior for ablutions and laundry operations to hard water that the heat houses must be considered short of a luxury when without it. For drainage, water-closets of the syphon type, properly connected with a self-cleansing and trapped drain made of concrete, are the best means yet devised. After discussing all the items fully, Mr. Chadwick submits that what is now wanted is a series of public trials of the different materials available for construction. He also suggests that "complete manufactures under one head" were also wanted, where the first cost of moulds would be spread over such a mass of productions as not to make them costly. We have contented ourselves with simply indicating to our readers the kind of information of which they can avail themselves, and now pass on to notice the leading features in Mr. R. H. Soden Smith's report on household furniture.

An examination of the furniture and clothing of nations showed Mr. Smith that the more civilization claimed by the people the more complete the absence of anything like art-beauty in the objects of their domestic use. The rude household goods of Oriental nations, tribes of Northern Africa, races in the distant parts of the Russian empire, he says, show an understanding of colour that renders them models for the study of the skillful European. The only department that gives him any consolation is that of ceramic ware, where he perceives taste is getting to be more and more recognized. Perhaps, of all the objects exhibited, some

Spanish matting gave him the most satisfaction; for out of the humbly materials grass and rush a pleasing object was produced, good in design and harmonious in colouring. Canadian household furniture, unpainted and unvarnished, made of oak, light pine, and hickory, stood out well by the side of that of other countries, for a chair of hickory could be sold for 1s. 6d., an armchair for 2s., and a chest of drawers, of the same woods unvarnished, for 15s. It is for the good of manufacturers to know the comprehensible figure their productions make when they are ennobled by artistic feeling. Mr. Smith says:—

"It is scarcely possible to conceive anything more false in taste, more absurd in the application of what is called ornament, than the majority of the objects displayed in Class 91; nevertheless, in many cases the application to these articles of a very little true art would instantly raise their mercantile value. Houblic's drawings and Flaxman's designs gave money value to Wedgwood's pottery even at the time when it was produced, and Wedgwood well understood this. As far as the requirements of cheap manufacture go, it would be almost impossible to find carpets, rugs, and mats, at least, offensive to the eye as to weave things that are hideous; an Oriental workman using his inheritance of art-practice goes right, as it were, by instinct; at this side of the world art-education is needed."

The Rev. Canon Norris, in his report on means for instructing children, gives the different forms of desks and seats in use among other points. In Sweden each child has a desk and seat to himself, thus admitting of the free passage of the teacher in any direction. In Spain, instead of a form running the whole length of a desk, with the attendant inconvenience of stepping over it, each seat, though attached to the desk is round like a music-stool. When required to stand the child does so at the side of his seat. The Rev. M. Mitchell's report on libraries and apparatus used in the instruction of adults gives some hopeful information. In the first French Exhibition there were but 180 exponents in this department: in 1867 there were 500, and twice as many were refused space. The improvement of which this increase was the visible sign consists both in buildings and materials of construction, and in the methods of instruction. In France, education that was before only recommended is now, in several branches, made compulsory. Agriculture, horticulture, gymnastics, the living languages, commercial geography, laws relative to workmen and industrial economy have been thrown open to students. In the two years previous to the Exhibition France erected 1,202 schools. It is clear we must now enter into a different kind of rivalry with this great country from that of our forefathers.

There is, too, a report on toys, by Mr. G. C. T. Bartley, which we must not overlook, because we have frequently urged in these columns the usefulness of improving these sources of primary ideas in children. The chief French toy is a doll, not a representation of an infant for a child to fondle, but a model of a lady attired in the height of fashion, a leading manufacturer changing the costume every month to ensure accuracy. As an excuse for this apparently early inoculation of childhood with a love of finery, it is explained that these dolls serve as models to colonial and other extra-Parisian milliners before they are handed over to their children. French dolls, unlike our wax-faced natives, have china heads. Mechanical toys, made in tin out of such refuse material as empty biscuit and sardine boxes by M. Desein, are, however, in more commendable taste. This ingenious toymaker manufactures a train, consisting of a locomotive, tender, and carriage, in separate compartments, with a finish that admits of their running smoothly, packed in a cardboard box, for twopenny halfpenny. His economical genius is rewarded with an annual sale of a million railway-carriages. Another train, having clockwork movement, which enables it to run round a table, he sells for less than three shillings. The mechanical singing-birds of M. Bontemps, shown in the Exhibition, attracted much admiration, but were too costly to become general favourites. Military toys, too, in France, command a large sale. M. Andreux manufactures 70,000 toy guns per annum, besides immense quantities of cannon, gun-carriages, swords, and other military equipments. The taste for military toys is, however, on the decline, owing, Mr. Bartley says, to the present notion of giving children objects suggestive of the arts of peace. Nevertheless, M. Andreux sold 38,000 toy imitations of the Prussian needle-gun in three months, when that weapon was under public consideration. Prussian toys, as represented in the Exhibition, were not belie-

guns, but the furnitures of dolls' houses, horses and carts, sensible dolls open to caresses without certainty of destruction, and glass marbles. Mr. Barclay gives the palm to Biberach for tin toys. Messrs. Rock & Craner seem to manufacture every description of carriage, cart, cab, omnibus, and perambulator of every nationality; our own insular peculiarities being catered for in the shape of Hansom's cabs, with little wheels on the feet of the horses as well as on the vehicles. Bavaria has an original idea or two about toys. One of these is the popular model of a shop, manufactured at Nuremberg. The kind of shop that commands the largest sale is a grocer's,—a selection accounted for on the ground of its having the most drawers to open and shut, fill and empty. Another toy, not domiciled with us yet, consists of pictures of men, animals, carts, trees, painted on stiff cardboard, and furnished with a block of wood, to enable them to stand upright, which children can arrange in different combinations, and which appear likely to exercise their taste and ingenuity. This Austrian conception of a toy appears to be, that it should be a musical-hox internally, whatever form it may take externally; the Danish, that it should be an implement; the Moorish, that it should be either a trumpet or a top; and the Russian, that it should be made of india-rubber.

We must content ourselves with drawing the attention of all interested in means for instructing the blind to Mr. E. C. Johnson's report upon the subject, which has several illustrations of the different systems of writing and musical notation. Mr. B. Jerrold's report on articles of all kinds manufactured by skilled workmen has a wider though perhaps not more intense interest. We are reminded of the many workmen from foreign parts who pursued their occupation in this class; the Arabs embroidering slippers, the Algerine embroidering purses, the Tlemcen jewellers making flagree-work, the cameo-cutters, and others. Mr. Jerrold says the object of forming this new class was generous and lofty. We must refer our readers to his report for the reasons the result was not satisfactory.

The whole of the sixth volume is devoted to the returns relative to the new order of reward. And to this we will give attention in our next.

INUNDATIONS.

SIR,—In the last number of the *Builder* the problem of freeing lands from inundations is again mooted. I beg to take up the question, beginning with Eton, "the water glade," where I resided two years (unfortunately). The floods there are sudden and impetuous, augmented by winter snows from the Cleaven Hills and upland streams. I will relate an incident. While at dinner one day the waters came in at the back door very fast (ceasestating the finishing of the meal upstairs); the water rose high enough to quench the fire in the grate; the water and thick sedimentary deposits remained beneath the flooring, causing, for months, dampness and effluvia, producing sickness and death. The inhabitants believe it to be an inevitable evil: generations have endured it, and they must grin and bear it. Ambitious dolls! Provided a premium were offered, would not a remedy be devised? I think so. I will endeavour to explain a plan of mine:—Past the aits the torrent rushes in great force. From one of these aits to the shore I would erect a large and wide water-wheel (or two) to work a powerful set of force-pumps to impel the water through pipes (earthen, iron, or brick) of the largest bore, to a point below weirs and locks: this, whenever these mighty rushes of waters came down, the wheels would commence revolving, and cease when lower. Greater the flow, quicker would the wheels revolve. Many thousand tons per hour, night and day, would be expedited on its way seaward, instead of overflowing low lands.

Churchyards in these districts are very moist. If they do not drown their dead, many meet with a watery grave.

R. T.

P.S.—Locate Dutchmen here, and they would soon dam the place.

A District Surveyor for this City.—The election of a district surveyor for the southern division of the City of London took place last Friday, at the offices of the Metropolitan Board of Works, when Mr. Edward Power, jun., was elected by a majority of six votes.

IMPORTANCE OF VENTILATION TO LIFE AND HEALTH.

REGISTRAR-GENERAL'S RETURNS.

UNDER the title of "A New Reading of the Returns of the Registrar-General, on Life, Health, and Disease," and with the motto, "For the life of the flesh is in the blood," Mr. E. T. Craig writes a long and able letter, of which we give an abstract, merely remarking, beforehand, that it affords no new reading to us, who have so long pioneered the way to better health and lessened mortality, by urging the importance of better ventilation in dwellings, especially in bedrooms, and by night, with less overcrowding.

"It has been justly observed that in some branches of knowledge great errors may be made with little loss to society, but this is not the case when dealing with the principles that lie at the very foundations of the laws of life, health, and disease, and their relations with the principles and practice of medicine. Any error in estimating the laws for the preservation of health and vital force may daily be the cause of death to thousands. If the laws that affect the first germs of existence, and throughout life govern the conditions of health and disease, be not understood, or their teachings not wisely applied, then the premature deaths of vast multitudes must be the result, as is the case at present in all our great struggling manufacturing centres of existence. Consumption, for instance, always annually, in England alone, some 60,000 persons, and every year, throughout the civilized world, some 600,000 human beings. Diarrhoea, fever, and other spreading diseases are also the immediate causes of an incalculable amount of suffering and sorrow, and a rate of mortality which might to a very great extent be reduced by attention to a few laws essential to health.

The Registrar-General's statements, however, have an importance far higher than that of the mere statistics of death. In the returns for the spring and summer quarters of 1868, we are supplied with some very striking contrasts; reasons are assigned for the varying numbers of the killed, and counsel offered as to the future line of action required to reduce the death-roll. Here it is that the ground is weak. While many writers are at a loss to account for the high rate of mortality, the registrar-general fails to embrace the whole question in his counsel to the authorities of towns, and hence the necessity for reviewing the proposed line of action, to ensure success in future contests with disease and death. We have facts in abundance.

There is, however, but little hope that the millennium of perfect public health will ever be attained by the suggestion of the Registrar-General, comprised in the mere removal or interment of every kind of fermenting impurity, so that 'the diarrhoea, cholera, and analogous diseases, which spoil the finest summers, will then be as rare in those days as migrating birds; for, finding nothing to feed upon, they will no longer infest our cities and villages.'

As this state of matters would be desirable, we are naturally induced to turn over the pages of the Registrar-General, and the 'notes' of his useful body of District Registrars, to ascertain if any other means of preventing disease—diarrhoea, and death—are advocated, and find none; while the remedy suggested has been the prevailing prescription as a sanitary cure for many years; and, although true in part, fails to grasp the whole question as to the origin of a class of diseases that yearly constitute very prominent items in the bills of mortality. The plans proposed are those which have been acted upon by many towns, and yet the mortality from some diseases, such as in consumption, is as high as before the enormous expenditure of public funds had been incurred. The truth is, the public authorities are put on a wrong course, and, as they seek a false issue, they are all disappointed.

While admitting the full influence of judicious and effective drainage, and ready to advocate its completion wherever required, we contend that great disturbing causes of ill-health and mortality would not be removed by the most efficient sewerage system that could possibly be devised while the present crowded and defective conditions of dwellings exist. These disturbing causes and defective conditions must be better understood and altered, or there will be a constant recurrence of these variations in the conditions of public health. We differ, therefore, from the Registrar-General as to the efficiency of

'the works' which the authorities are advised to accelerate as a remedy for consumption, or even for diarrhoea, 'the malady so fatal to the population.'

While admitting the fullest advantages that may be claimed for efficient sanitary measures, I contend that whatever system of sewerage may exist, the prevalence of consumption and other diseases would be developed and aggravated by disturbing causes arising exclusively within the dwellings.

If we so construct our dwellings, offices, schools, and places of public assembly, and so arrange our bedrooms that the pre-breathed air cannot escape into the outer air, we shall, at all times, have present a sufficient cause of disease whether the sewerage works are perfected or not.

Therefore, to go on year after year, advocating an extension of sewerage works, without perceiving or appreciating the power which other measures would exercise in arresting the cause and the progress of diseases, such as consumption and diarrhoea, is to misdirect the public, and to incur a grave responsibility in urging the authorities in a course which must in the end prove but a fool's errand, and lead to disappointment.

The temperature of the atmosphere was very much raised, there was little wind, and during a part of the summer but little rain. There would be less oxygen in the same volume of air than in the previous quarter; the ozone would be abstracted more rapidly or more effectively by the decomposition of putrescent materials; the carbonic acid gas thrown out by animals and the inhabitants would pervade the air, while the upper sashes of the windows of hundreds of houses in a town were not made to open, to afford the half-stifled inhabitants any relief from the poisonous influences arising from heated pre-breathed air from their own lungs; so that they were literally surrounded, night and day, with an atmosphere only a few degrees above of being deadly destructive.

Now, as we have seen the constructive arrangements of dwelling-houses are such as to prevent the escape of pre-breathed air, the result is an additional cause for the increase of diarrhoea, consumption, functional disease of the heart, as well as a source of fever and other spreading diseases.

I have shown that in the great battle of life the main cause of the heavy catalogues of disease and death from diarrhoea are mainly due to the destructiveness involved in our health-destroying system of house construction and the absence of efficient ventilation."

The only remark we need add to Mr. Craig's letter is, that to the stolid public it is not sufficient to insist that they ventilate their dwellings, and especially their bed-rooms, more thoroughly; but they ought to be pointedly and explicitly informed that by ventilating their bed-rooms better, is meant that such ventilation is most of all requisite by night, and while they are occupying these bed-rooms. In thousands of instances they will willingly throw open their bed-room windows and air their bedding by day, while they will as carefully close up every crevice by night. And the poor, with their miserable supply of bed-clothing, are, in winter, especially liable to do so; but, from the lowest to the highest, the desire to be snug and safe from draughts overrules all consideration of ventilation. Nor is it easy to ventilate bed-rooms by night thoroughly, while keeping them free from draughts, far less for the poor in winter to keep sufficient warmth about them along with ventilation, even when safe from draughts.

The whole subject is one which well merits continual agitation.

NEW CEMETERIES.

Leamington.—The Bishop of Worcester has situated a portion of the new cemetery, consecrated in the Whitnash-road, near this town. The grounds comprise a strip of land on the north side of the old graveyard, fronting the road, a large portion at the west end, and a piece on the south side. Mr. Candall, of Birmingham, who under the late Mr. Squirhill superintended the works in connexion with the old graveyard, is the architect. Plans and specifications of the buildings to be erected were prepared by him, and the Board advertised for tenders for carrying the same into effect. The tender of Mr. W. Green, of Leamington, was accepted for the erection of the chapel, the construction of the necessary walks, the execution

of the drainage, and other work; and that of Mr. G. F. Smith, of Milverton, for the boundary fences and all the ironwork in connexion with the building. Each chapel is in the Norman style of architecture. It is built of red pressed bricks, with blue brick plinths and Bath stone dressings. The roof is covered in with red Staffordshire tiles, with a triple band of black ones introduced half-way up the roof. The principal entrance is at the west end, by a doorway of Bath stone, with a circular moulded arch, supported by light annulated pillars with carved capitals. The whole of the windows have circular moulded heads, with light pillars and Norman capitals of Bath stone. The principal feature of the interior is the arch of which is of pressed brick in the form of a dog-tooth Norman carving, with an inner moulded arch of Bath stone. The floor is laid with Minton tiles. On each side of the tier are movable seats of stained deal, and in the body of the chapel are four other seats, two on each side of the building. The Episcopalian is somewhat more ornamental than the Dissenters' chapel.

Diss.—The site of the new cemetery is on the road leading from Diss to Burston and Diss Heywood. The area of the ground comprises about five acres. The style of the architecture adopted for the chapels is Early Perpendicular, both being 32 ft. long by 16 ft. wide, and each having a vestry 9 ft. by 7 ft. The Episcopalian chapel stands east and west, and the Nonconformists' chapel north and south, the two being connected by porches with an arch between, the entrances being at either side of the archway. The walls are built of flint from Mr. Bishop's pit, at Roydon, near Diss, faced with split, varied with whole flints in the arches, the interior being lined with red brick, relieved at intervals with bands of black; the floors paved with Minton's black and red tiles, and raised at the ends so as to form a dais, on which stand the reading-desks. The roofs, which are not celled, are constructed of open-combed rafters, stained and varnished, being boarded at the eaves, and covered with dark Staffordshire tiles, and ornamented ridge tiles. The windows and door-jamb, arches, and tracery are executed in Bath stone, as also are the coping to the gables, weathering to buttresses, and the bell-turret. Sitting accommodation is provided in each chapel for about twenty-four persons, the benches being constructed of deal, stained and varnished. The lodge for the residence of the keeper of the cemetery is built at the north side of the entrance-gates, of the same material, and corresponds in character with the chapels. The work of the chapels and lodge has been executed by Messrs. C. Bishop & Son, Diss, and the front wall by the same firm, and Mr. J. Ward, stonemason, Diss, the iron-work being executed by Mr. W. Bishop, Diss. The whole of the work has been carried out from competitive plans under the superintendence of Mr. John Thomas Musket, the architect and town surveyor, Diss. The total cost of the chapels, lodge, and wall is about 1,750*l.*, exclusive of the price of the land.

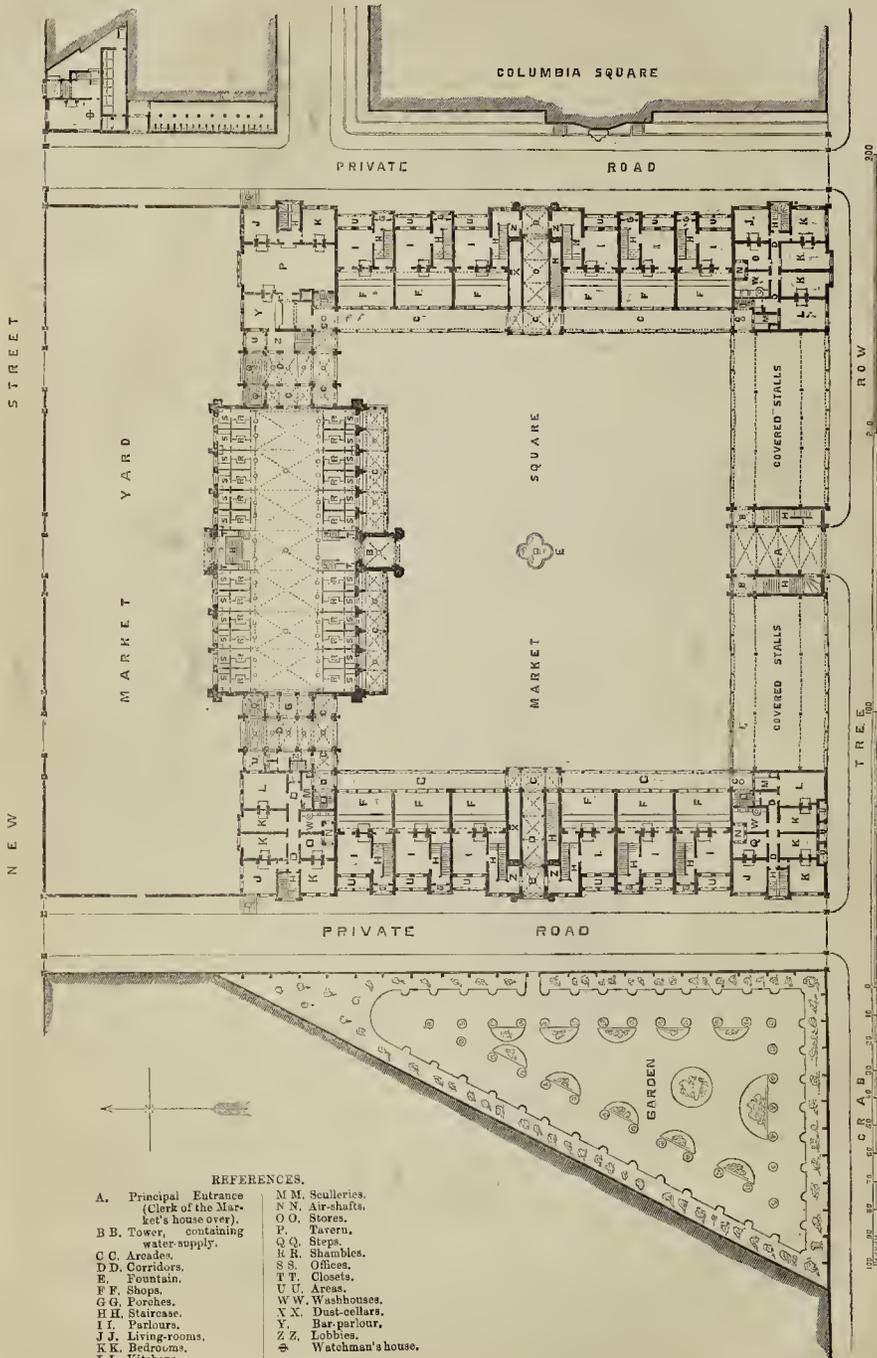

A PLUMB BOB.

A CORRESPONDENT signing himself "A Working Joiner," writes:—"Will you inform me in your next issue whether practically speaking a plummet, or plumb-bob (commonly called) can be made of any other material than lead? I find in my dictionary that *plumb* is from the Latin (*plumbum*), and therefore conclude, as *plumbum* means lead, that a bob made of brass cannot be a plumb-bob."

A piece of lead attached to a string and used to attain a perpendicular line, or test the perpendicularity of a line in building or otherwise, was called a plummet or plumb because of the lead—*plumbum*. As in other similar cases, the name now attaches to the use rather than to the material. A wall standing perpendicular is correctly described as "plumb;" the French for "upright" is *aplomb*; and we apprehend it is now perfectly correct to term any weight used to ascertain a perpendicular position a plumb-bob without reference to the material of which it consists. Milton uses the word "plumb" as descriptive of the sudden downright fall of a man; and the sea is often plumbed with a weight that is not lead.

The Borough Architect, Liverpool.—Mr. Robson has resigned this office.

COLUMBIA MARKET, BETHNAL-GREEN: INTERIOR OF MARKET HALL.
MR. HENRY A. DARBISHIRE, ARCHITECT.

[See p. 137, ante.]

THE FORTHCOMING INDUSTRIAL AND OTHER EXHIBITIONS.

The Utrecht International Exhibition of 1869.—The council of the Society of Arts, on application to the Court of Common Council, has obtained permission to intending exhibitors at the Utrecht International Exhibition of articles of domestic economy, in the ensuing summer, to hold a preliminary exhibition in the Guildhall, London. From the specimens there exhibited those most suitable in price and quality may be selected and sent over to Holland. In addition to such articles there would also be sent the plans, drawings, and specification of model dwellings for the poor. In order to carry out the suggestion, funds will be required; but the sum need not be large; and the council think that this might be raised by a subscription among those who take an interest in the undertaking: the council undertake to contribute. The court were unanimous in according the use of the hall.

Postponement of Workmen's International Exhibition until 1870.—A circular has been issued, announcing the determination of the council of the Working Men's Club and Institute Union to hold this Exhibition in 1870 instead of 1869. They have received many communications from home and abroad as to the difficulty of preparing articles of the best workmanship in time for an Exhibition to be held in the present year.

South London Working Classes Industrial Exhibition.—An aggregate meeting of exhibitors was held in the Lambeth Baths, to choose the adjudicators, the space and vigilance committees, and to transact other business. The following gentlemen were chosen as adjudicators in the artistic department:—Sir M. D. Wyatt, P.S.A.; Messrs. T. E. Butters; Henry Cole, C.B.; George Cruikshank; F. H. Fowler, M.R.I.B.A.; W. Hinchliff; R. Hudson, F.R.S.; W. H. Miller; and R. Redgrave, R.A. For the mechanical: Messrs. T. Beggs, A. Hawkins, jun., G. Jennings, T. Lambert, R. Miller, Norman, Searle, S. S. Taylor, G. Thorneole, and R. Thwaites. For the general, or third class: Messrs. J. Glazier, J. Hill, G. Howlett, jun., G. Pritchard, E. Dresser Rogers, S. S. Taylor, H. Wallace, and W. R. Selway; and a number of ladies for deciding upon the fabrics and fancy work. The space committee and a vigilance committee (composed entirely of exhibitors) were then appointed, all the resolutions being unanimous. The chairman replied to many questions from the exhibitors, the chief query eliciting the fact that protection for designs and improvements had been granted by the Board of Trade under the Industrial Exhibitors Act of 1865.

THE (ALBERT) MUSEUM, SOUTH KENSINGTON.

In the glass case containing the Elizabeth-and-Leicester violin stands a very fine vase of Castellanate make, lent by Mr. John Webb. It is about 2 ft. high, and dates from the middle of the sixteenth century. In the same case is an elegantly shaped dressing-table, formed of satin wood, painted with grisaille medallions, garlands of flowers and fruits in natural colours, and having a border of small cornets, jeweled ribbon, and little green chaplets enclosing jewel-like pendants. On the table, two pedestal cupboards support a shield-shaped looking-glass, crowned with flowers; and the slender legs of the table are held together by gracefully arranged hands that rise in the centre and terminate in a plateau, which supports an oval casket of satin-wood, painted with flowers to match the table.

A corresponding chest of drawers will be found in the first glass case on the left, after entering the loan portion of the Museum; but the drawers are even more beautiful than the table. They are also of satin-wood, painted with garlands and flowers, but the flowers are of larger size, and more care has been bestowed in consequence. On the top, a semicircular rustic landscape of most happy colouring is placed close to the bordering at the back; the space in front is filled by delicate garlands, and a representation of a Wedgwood medallion on lilac ground. The bordering, which runs all round the top of the drawers on the flat, consists of most natural-looking "eyes" of peacock feathers, and is as beautiful as quaint. These two elegant pieces of furniture *de luxe* are of English manufacture, date late eighteenth century, and are lent by Mr. J. James.

By the side of the chest of drawers stands a

grand vase of painted porcelain, lent by Mr. J. Mordlock. It is Rockingham ware, and dates from about 1800. The form is a large egg, divided into three sides by rustic handles of tree-stems, gilt; the egg form subsides into three animal legs, with large paws, white, and the claws gilt; a trellis of gilt oak-branches, acorns and leaves, runs over the legs on to the body of the vase. Each of the three sides is handsomely painted in rich dark colours, with a bouquet of large flowers standing in a vase; on two of the sides a glimpse of a bright landscape, in pale tender tints, is seen beyond the flowers. The neck of the vase has an outer shell of honeycomb-work in white and gold, with three marvellously life-like bees entering the cells; the cover is of a compressed bell shape, with more painted flowers and gilt oak trellis, and it has for handle a rhinoceros, also gilt. The vase stands on a triangular base, the corners of which are rounded off; it is coloured a rich Magenta crimson, and is *semé* with tiny groups of musical and warlike instruments.

In the glass-case immediately behind the one containing this Rockingham vase, is a set of Roundels, the box belonging lying under one of them. Six are exhibited, which, from the size of the box, I presume to be the whole number. They are described on the "temporary label" as of wood covered with painted and gilt paper, with rhyming inscriptions, and it is said they were "used similarly to playing-cards." They are lent by Mr. W. Walker, are English, and of the seventeenth century. If this is known to have been their use, the sort of game played with them is not less the known also; but it is difficult to imagine it could have been one of frantic excitement. To a nineteenth-century observer these roundels suggest nothing so much as tabernacles; and when one remembers the laboriously polished tables that were, in days gone by, the pride of a "dowditch howswife," these roundels seem invented on purpose to counteract the damaging effect of hot-grog glasses. It is difficult to judge, through the plate-glass, of their construction, but they appear to have had the flowers and inscriptions printed on the paper, and then to have been painted by hand. The following are the quaint legends on the six that are open to view:—

"If my goodman will twarthe with me,
He'll finde me some as twarthe as he;
If hee speake faire I do the same,
Then maie we gree, els he is blame."

The logic in this is fine!

"Feede mynde with myrth, thy mawe with meate,
And eate to lyeve, not lyeve to eate;
For gorging doth offende thy health,
Thy god, thy soule, thy witt, and wealth."

A lowring wyfe I woulde not haue,
And from a skoule cure Lord me sane;
A prouing wyfe I woulde lause none,
But godd sende me a merry one."

"At meate and meale make myrth with geast,
Of absent folkes reporte the best;
Mirth pleaseth with civilltie,
The rest is but securillie."

"The hartesse is a pleasant flower, and dothe in garden growe,
So woulde it rest within my harte and were not for a shrowe:
Wyues wyne wo with wilfulness."

"A dowditch howswife such one as gaine,
A world of goods by trauell and paynes;
For what else loesth at night by her playe,
Shee gathes agayne by sleping all day."

The *ad libitum* style of the orthography in the above, is not the least amusing part of the inscriptions; they run round the edge of the roundels on the flat face, and the flowers are daintily painted on a pale yellow ground that is covered with black dots. Nevertheless, these roundels are infinitely superior in point of art to the two packs of playing-cards exhibited by Mr. W. Tate, M.P., and which, just now, are to be seen in the flat glass-case immediately to the left before descending the three steps into the loan portion of the Museum. One of the packs is from Berlin, and dates from the beginning of

* This sort of warning to scolding wives seems to have been a favourite subject with the makers of roundels. On one figured in the *Gentleman's Magazine* for May, 1793, are the following lines:—

"A woman that ys wyfull ys a plague off the worst,
As good lyeve in hell, as wylthe a wyffe that is cursest."

This roundel is one of ten, attributed to the time of Henry VII. or VIII. It has been suggested that roundels were used as "conversation cards," or as fortune-telling cards. The supposition that they were treasurers for cheese or sweetmeats has had supporters. Some interesting notes on the subject will be found in vol. i. of "The Journal of the British Archaeological Association," 1843, p. 329.—Ed.

the eighteenth century; the other is of about the same date as the roundels, namely, seventeenth century, and is from famed Nuremberg, whose "hand goes through every land;" but methinks if the "hand" had not produced better things than these cards, the town had been less famed. The designs are of the roughest; but there's something to be got out of them, as out of most things. On one card a man, looking very like an old witch, is floating in air, and below is the word "Hex," not to be found in Flügel's Wörterbuch, but doubtless the masculine of *Hexe*, witch; then comes a pile of Wurst, sausages; so in Fatherland, superstition and sausages have long held sway. The spiteful cat, with back up, and the word "miau," is perfectly comprehensible in English as well as in German; and on another card the maker did a neat stroke of advertising, when he painted a house and put below it, "Zu finde bey Joh. Heinrich Schenck, Nürnberg."

While writing of cards, there is in a flat glass case, at present on the loan side of the Museum, one that brings a choking sensation into the throat, and well-nigh makes tears spring into the eyes of the beholder, from loving remembrance and hopeless regret. This card lies in a small crimson leather case, lined with green-watered silk, the whole and a short explanation being contained in a larger case of puce morocco and velvet. It is the season ticket of his Royal Highness the Prince Consort for the Great Exhibition of 1851, and is presented by the Queen to the Museum; it bears the well-known "Albert" signature of the noble-hearted, noble-minded "holder." It is doubtless fresh in the memory of most readers of the *Builder*, that when the question was raised as to who should have free admissions to the Exhibition, and there being so many persons who thought themselves entitled to the privilege, that had all claimants been satisfied, the receipts must have greatly suffered in consequence, Prince Albert at once declared his intention of paying for his ticket, thus putting himself on a par with the most private person in the land who had three guineas to spare for a season-ticket. Yet he, after all his uniring exertions and unflagging zeal in promoting the Exhibition, might assuredly have claimed as a right that which he declined to accept, though universally acknowledged to be his due. AAT-LOVER.

THE UNEMPLOYED.

SIR,—As everything connected with the improvement of the condition of the working man is one of the especial provinces of the *Builder*, I beg to call your attention to the following extract from the *Times* of the 11th inst.:

"The London Mechanics' Institution, Southampton Buildings, Chancery Lane, is taking up the question of the unemployed poor, and is about to convene a public meeting to consider the following resolution:—'In the opinion of this meeting the enforced idleness of enormous numbers of the people, their compulsory residence in the filthy slums of large towns, allowing the professional thief and mendicant; the rearing of children in these slums in ignorance, idleness, and dirt, with the ever-present examples of immorality, drunkenness, and a hatred of work, are the chief causes of crime, pauperism, and disease; and that Parliament be at once petitioned to consider the following remedies for these evils and the present scarcity of employment, viz.:—1. An Act authorizing the Government to establish factories and start public works in all parts of the United Kingdom. 2. An Act authorizing the Government to establish schools in all parts of the United Kingdom for the housing, feeding, clothing, and educating the children of the poor and working-classes between the ages of three and twelve years. 3. An Act authorizing the Government to make life insurance compulsory on every man and woman on attaining the age of twenty-one years, no matter what their state of health may be. 4. An Act for a national rate on property of 100l. and upwards for the immediate exigencies of the poor.'"

In framing the above "remedies" for the evils they are hoped to rectify, the meeting omitted one most important item, namely, "An Act authorizing the Government to *assist* on every workman being allowed by his fellow-workmen to take as many conscientious as he may desire, and as he can conscientiously instruct."

It is useless to talk of want of work while there is so much work everywhere waiting to be done, if only the hands and minds could be found to do it properly. As it is, people are obliged to put up with unsuitable and unsatisfactory things, because they can't get better, and frequently do without a thing because they can't have what they want. When workmen and workwomen shall be properly instructed in their respective businesses, we may then hope to have houses built in which we can live with comfort without having to pull them to pieces directly we begin to inhabit them, in order to rectify some blunder of

ignorant or careless workmen; we may then have windows and doors that will open and shut; locks that will fasten; bells that will ring; pipes that will carry off refuse and let water flow; hot-water pipes that won't set the house on fire; chimneys that won't smoke; cooks that can dress dinners; clothes that can be worn without inconvenience; and boots that don't lame us: to say nothing of the more important branches of trade, such as Manchester cottons that won't burn themselves to tinder before they reach their destination, as—with shame be it said—was the case not long ago with various shipploads sent out to India. "Sham" and "want of truthfulness in act" are the bane of this generation.

A THINKER.

THE FRENCH POLAR EXPEDITION.

A FRESH attempt is about to be made by France to reach the North Pole, under the patronage of the Geographical Society of France. This expedition is not on a beaten track. It does not propose to reach the North Pole either by the route of Smith's Straits, proposed by Captain Sheard Osborn in 1865, following up the track of the American explorer, Elisha Kane; or by that named in preference by the *Builder* and Dr. Augustus Petermann, the German traveller, who recommend the passage between Spitzbergen and Nova-Zembla, returning, on Dr. Petermann's suggestion, by the Barentz track. The newly-proposed route is one hitherto unattempted, but founded on conclusions drawn from the best scientific researches. This passage is by Behring's Straits, through which a ready access is obtainable, to reach the free and open polar sea (known by the name of Polynia), and hence the pole itself. In order to carry out this project, the services of a practical traveller, accustomed to the vicissitudes of climate, and fully experienced in the geographical position of the path he is engaged to seek, were necessary. The choice of the committee fell upon M. Gustavus Lambort, whose projected route to reach the North Pole, founded upon practical observations made by him beyond Behring's Straits, and corroborated by remarkable theoretical considerations, was deemed the most eligible.

In 1776 Captain Cook was sent to explore the Pacific, and observed a probable passage thence to the pole; he was on the right track, that of Behring's Straits, which he passed, and reconnoitred land in several places. He was only prevented from returning to his explorations by the untimely fate he met with in the Sandwich Islands.

The French Polar Expedition is to take a direction which has been profoundly studied by M. Gustavus Lambert, but which has never been attempted except by one—Captain Cook. Others who have passed the Straits of Behring have only left us records of facts corroborating the existence of a constantly open polar sea. It is on this sea that the promoters of this expedition place their confidence: it is the basis of their operations.

Subscriptions for this expedition, which cannot fail to interest all merchants and traders, can be effected by sending name and address to the Société Générale pour le Développement du Commerce et de l'Industrie, Bureau G, Boulevard Saut Germain, 79, Paris; or to the Société de Géographie, 3, Rue Christine, Paris. It will suffice to state the amount, which will be collected by a proper agent. The total amounts received are 10,000l.; the ship has been bought for 7,000l.

PRINCESS'S THEATRE.

MR. PALGRAVE SIMPSON, in his new drama, "Marie Antoinette," has given a most effective and truthful picture of the terrible time that intervened between the 1st of October, 1789, and the 16th of October, 1793, when the brave, if not wise, queen made her last toilette. A series of remarkable pictures are presented, and, although, as the author says, "bound together with no more fiction than is necessary to give the coherence and continuity essential to a dramatic form," produce a whole that leaves a strong impression on the mind of the spectator. Mlle. Beatrice, a foreign lady, who first appeared a few years ago at the Haymarket Theatre, exhibits dignity and pathos, and is, from first to last, the great centre of each group. Mr. Vining has put the piece upon the stage in a magnificent manner, and plays the part of the King with great finesse and skill, indicating admirably

his known characteristics. Mr. Rignold has made his first appearance here as *Count de Fersen*, a chivalric lover of the Queen, and promises to be a valuable addition to the company. Mr. Dominick Murray, who plays a semi-comic character, a man of the people led by love for his master to aid the Royalist plots, had scarcely got hold of the part on the first night, and will do more with it presently. The scenery, by Mr. F. Lloyds, Mr. Dayes, and Mr. Matt. Morgan, is admirable. The Gato of Varennes, with the arrival of the Berlines; the Gardens of the Priory of the Temple; and the last scene, the Place de la Revolution, deserve especial praise. The grouping on several occasions recalls pictures by E. M. Ward and Elmore, though we did not observe that any attempt at aerial reproduction was made. Mr. Palgrave Simpson, who has been recently elected secretary to the Society of Dramatic Authors, may be fairly congratulated on a legitimate success.

NEWINGTON SICK ASYLUM COMPETITION.

SIR,—I beg to enclose the correspondence between myself and Mr. Jarvis, two of the competitors in the above matter. The competitors, with the exception of Mr. Jarvis and Mr. Knightley, are agreed that the object for which the Board adopted "mottoes" being defeated, it is only just to the managers themselves that some architects of eminence, or some authority in the Poor-law Board, should select the best plan.

The managers have endeavoured to adopt the motto principle, and its failure cannot be attributed to them. It is, however, now incumbent upon them to show that they are no parties to so flagrant a violation of the rules of competition. These gentlemen are aware of the correspondence in the *Builder* of last July and August, in regard to the Walworth Estate Competition, and will, I am sure, be anxious to see a more pleasant termination to the present one.

JOHN GILES (Giles & Biven).

*** The correspondence is too entirely personal to justify us in giving to it the space it would require. Mr. Giles sets forth very good reasons why the managers should refer the plans to some architect not connected with the district, or to the Poor Law Board. Mr. Jarvis declines to join in such a request, on the ground that the proposition was not made till the eleventh hour, and after the designs had been seen. He agrees with those who, like ourselves, view the mottoes as a delusion and a sham.

Though all the competitors may not agree in the request, the managers, if they are wise, will comply with it.

THE DUBLIN SCHOOL OF ART.

SIR,—I see by your report that it was asserted by one of the speakers at the meeting of the Dublin School, that this school "stood first" among the schools of art in the United Kingdom. I beg to say that the statement is incorrect, Dublin being fourth on the list instead of first.

The highest Government honours were awarded to the masters of the Edinburgh, Nottingham, and Stoke schools, and the fourth honours to the master of the Dublin school. I think it only fair to those masters who have gained such hard fought honours that the truth should be stated. I will not take up your space by a complex tabulated comparison, but, if challenged, can supply the necessary figures to substantiate my statement.

ART-MASTER.

STEAM CULTIVATION.

At the annual meeting of the Midland Farmers' Club, at Birmingham, the subject of Steam Cultivation came on for discussion, introduced by Mr. James Howard, M.P., of Bedford. The interest in steam cultivation, he said, had grown year by year. Nearly all doubts as to profitable employment of steam power in tillage had been removed, and the two great questions to be solved were, how to apply the power of the engine to the best advantage? and the best form of implement to yoke to that power? The cost of the largest apparatus, having two engines drawing two ploughs simultaneously, was about 1,800l., complete, and the daily expenses, calculated upon 200 working days, 4l. 2s. 6d. Taking 40 acres as a day's work, the cost would be

2s. 1d. per acre. Whenever steam-power was introduced upon a farm, deeper tillage is, or ought to be the result. In closing the discussion, which followed the reading of his paper, Mr. Howard remarked that as they could not extend the width of the land in England, they must look to depth for an increase of the produce of the soil. He was free to admit that he thought in those localities where the farms were small, steam cultivation, by hired machinery, would not pay; but it was his opinion that persons with large holdings, and with sufficient capital, should have a cultivator of their own, just as they would have a plough or a harrow.

"SMOKING FIRES."

SIR,—In your notice of a book on this subject by the Rev. A. C. Ainslie, a quotation is given in which "glazed drain-pipes" are recommended for flues. I have known several instances of these being used, and the general complaint has been that the soot is constantly falling into the grate. This arises from the fact of the surface being glazed, as the soot cannot adhere to it. Unglazed pipes should always be preferred. There is, also, another objection to drain-pipes, namely, their liability to crack from the settlement of the walls.*

E. W. T.

PAYMENT FOR "QUANTITIES."

We have received several letters lately from surveyors who, having taken out the quantities for estimates on their own speculation, complain that they often fail to get paid by any one. All we need say is this:—If surveyors take out the quantities for estimates without being appointed either by the architect or the builders, they must of course run the chance of getting no payment for their pains. The remuneration can come only from those individual tenderers who make a special agreement with the surveyor.

The quantity surveyor referred to by our correspondent, "J. S." (p. 92, *ante*), has sent six pages of foolscap, in reply, for which we are unable to find room, especially as they leave the actual facts very nearly as stated. The surveyor goes into a defence of those who take out the quantities without being asked by any one to do so, but we cannot go with him.

ENGINEERS AND CONTRACTORS.

We have received a somewhat curious statement, dedicated to Lord Redesdale, and signed "John Masgrave, Clerk of Works, North London Railway, City Branch," as to the manner in which the works were carried out, and the results which have followed. Old bricks, he states, were used, though prohibited; and arches, he asserts, are falling in consequence. He gives a number of names, but we should probably subject ourselves to an action for libel if we printed what he sends.

THE NORTHERN ARCHITECTURAL ASSOCIATION.

The annual meeting was held on the 9th inst., Mr. J. E. Watson, president, in the chair. The report read by the honorary secretary stated the number of members to be fifty-two. It was agreed that the excursion this year be to Lambton and Lamley Castles and Chester-le-Street. It was stated that the interior decorations of Lambton Castle were now finished. Three years had been occupied over the drawing room. The work had been done by Messrs. Richardson & Coxon, of this town, from designs by Mr. Collmann, London.

The president then delivered the annual address. In the course of it he reviewed the principal buildings in progress or completed in Newcastle and neighbourhood during the past year.

"The restoration of St. Nicholas's Church tower and steeple is one of the most important undertakings, requiring the greatest judgment and skill. The works seemed to be progressing satisfactorily; and he hoped funds would be forthcoming, so that the noble structure of which the tower is justly proud may be completed. So far, all must admire the improvement in the spires, by the clear, sharp manner in which the detail is executed. St. Stephen's Church, Scotswood-road, is an addition to our ecclesiastical edifices, and an ornament to that neigh-

* Mr. Ainslie wishes it said that his suggestion for bringing air to the fire, on which we commented, includes a fender made long enough to cover the opening and confine the air to the fireplace.

hood, as well as an advantage to the residents of that locality, under such an able, intelligent, and persevering pastor as Mr. Lutott. The Orphan Institution, Moor Edge, and the Industrial School, are additions to our public institutions for which (with prominent architectural features) we are indebted to that charitable lady, Mrs. Abbot, who has provided the whole of the necessary funds. The Female Convalescent Home at Whitely is another institution of which we may well feel proud, it being of noble dimensions and appearance, and well worthy of that illustrious nobleman whose memory it was intended to commemorate. The new buildings and streets at Tynemouth, intended to be carried out by the Duke of Northumberland, will be a great addition and improvement, and, no doubt, will have the effect of making it a first-class marine and fashionable watering town. The Gatehead Down-hall is progressing rapidly; and after the many contentions, misfortunes, and delays, and after the wasteful expenditure of money, its completion would give Gatehead a great addition to its architecture, and a higher standing in respect to the quality of its buildings. The hospital at the workhouse, after many difficulties, might, let them trust, be satisfactory in its results. The new buildings at the corner of the Side and Sandhill have just been finished, and the result was a considerable improvement to that narrow and confined place. The Lunatic Asylum at Colodgo is amongst the largest of our public institutions, now nearly completed; it will add to the architectural features of that neighbourhood.

The speaker remarked, that in one of the latest and most extensive competitions a bad precedent was shown by some of the competitors, at the request of the building committee, furnishing detailed working drawings, specifications, and estimates, before the merits of the different designs were decided on, and without any premium being offered for such a vast amount of labour.

Mr. Johnson, as one of the competitors on the occasion referred to, thanked him for the sympathy he had shown in his remarks as to the preparation of working drawings.

Mr. Oliver said they would soon have to pay a premium for competing.

And whose fault is it?

LONDON OMNIBUSES.

The report of the General Omnibus Company, about to be presented, shows that the gross receipts of the company during the half-year ending December 31st, 1868, were 284,077. 5s. 11d.; in the corresponding period of 1867 they were 290,805. 10s. 11d., giving a decrease of 6,728. 5s. The number of passengers carried in the half-year of 1868 was 20,654,306, and in the corresponding half-year of 1867, 20,757,127. The average number of omnibuses working on week-days, respectively, was 593 and 602; on Sundays, 474 and 472. The average traffic receipts per omnibus per week was 17l. 18s. 6½d. and 15l. 1s. 6½d.; ditto, per day of working, 2l. 12s. 9d. and 2l. 13s. 5½d. The average fare received per passenger was 32cd. and 39d.; ditto, earnings per mile run 108d. and 11½d. The total number of miles run, 67,7632 and 6,135,972. The largely-increased extent of accommodation afforded by railways in the metropolis during the past two years has, no doubt, had a certain influence in diminishing the omnibus traffic on certain roads, and has rendered it difficult to find new traffic to compensate for the loss. Some new routes have, however, been opened with promising results, and others of the old-established routes, including some of those partially in competition with railways, continue to produce increasing revenue. The expenses show a decrease of 18,178l., of which 5,279l. are due to the substitution of *matte* for oats. It is proposed to declare a dividend equal to 5 per cent. for the year.

STOCKPORT.

A new bridge, or high-level viaduct, called St. Peter's Gate Bridge, has been erected by the corporation, and recently opened to the public, with a view to facilitate traffic to the Market-place and central parts of the town. The bridge consists of six arches or spans, that cover the street called Underbank being formed of cast-iron girders, with road plates and ornamental parapet railings; the other arches are in brickwork, having stone parapet, with nine bold stone carved pedestals carrying ornamental pillars,—with horizontal parapets, 30 ft. The roadway is paved with granite cubes set in asphalt. Two broad staircases of stone give access from the higher to the low level street, the difference of level being about 32 ft. One feature in the construction of this bridge is the appropriation of the arches to useful purposes. The faces of the piers to Underbank are provided with folding doors, panelled and moulded, with segmental beads, and with circular-headed windows: these form the frontage to extensive

wine and spirit stores and offices occupied by Messrs. Turner, who have paid the corporation 2,000l. for the use of part only of the arches for this purpose. The total cost of the bridge, including land and compensation, will be about 12,000l. The works have been designed and carried out by Mr. Brierley, of Blackburn, civil engineer.

BUILDER'S CHARGE FOR ESTIMATING.

A SURVEYOR writes:—"Will you kindly answer the following query?—Tenders were invited from two builders for the erection of a villa; plans and specifications were supplied, but no quantities; the work was not carried out, but one of the builders puts in a claim for taking out the quantities. Is this right?"

If the builders tendered under the belief that one of them was to be employed, such a charge would most certainly be right. If they were warned before going into the business that possibly neither tender would be accepted, they took the risk, and could make no charge. Suppose two men were led to pay 10l. each for right to rifle for a horse, and when the winner went for his prize he was told there was no horse, would that be right? The least he would ask for would be to have his own money again.

THE GAS SUPPLY OF THE METROPOLIS.

THE president of the Board of Trade (Mr. Bright), has received a deputation from the delegates appointed by the metropolitan vestries and district Boards on the question of the gas supply of the metropolis. The deputation was introduced by Mr. Dilke, M.P. The object of the deputation was to urge the president of the Board of Trade to carry on a Bill of which his predecessor in office, the Duke of Richmond, had given notice, and which provided that if gas consumers were not supplied with good gas at a reasonable rate the Metropolitan Board of Works, or any vestry or local authority might, by agreement or compulsion, purchase the existing works of gas companies and erect additional works. Mr. Bright referred to the probability of the metropolis being divided into municipalities, and asked whether it would not be better to defer the discussion of the subject till the question of municipalities for the metropolis—in favour of which memorials had been received signed by one-third of the inhabitants of the metropolis,—had been settled. Mr. Beale objected to this proposal that the question of municipalities had been under discussion since 1835, and might remain open a long while yet. Besides, many gentlemen present were opposed to municipalities, whilst they were all agreed as to the necessity of some action for obtaining better and cheaper gas. Mr. Bright said the subject would receive the fullest consideration from his colleagues and himself.

A NEW MINERAL PAINT.

MUCH interest has been excited in the United States by the discovery of a mineral which is said to possess the most valuable qualities of white lead, while superior in many respects to the manufactured article. The mine in which it has been found is situate in North Carolina, and has been worked for many years as a silver and lead mine. The vein, however, presents an unprecedented variety and association of minerals. Lead, silver, zinc, copper, gold, iron, and manganese are found in the workings, which are continually varying in character. The ore usually averages about 30 per cent. of lead. The powder manufactured from the ore, when mixed with oil, it is said, forms the most durable paint known, and a yacht upon which it has been tried has been sailing for the past summer without copping of any kind. The works for manufacturing this powder into white lead are situate at Bergen Point, New Jersey. There is something not clear, however, in what is said as to the nature of the paint: it is said to stand a fierce heat without change.

SUN-DIALING.

Sir,—I am about to erect a horizontal sun-dial, and should be glad if any of your readers could state the exact angle at which the gnomon should be placed, and the most correct method for dividing the hours on the dial. The mention of the author's name by whom the best work on the above has been written would prove of equal assistance. S. H. W.

TAKING OUT QUANTITIES.

POPULAR WORKHOUSE.

Sir,—My attention has been called to a statement in your publication of last week, in page 133. It is there said that the Rev. Mr. Driffield proposed as an amendment, that 3 per cent. be paid, and that it was carried by a majority of 47.

The true facts are these:—The Rev. G. T. Driffield considered the payment of 1 per cent., or a sum of 3000l. for this work of taking out the quantities, which was stated would not occupy more than three weeks, was something monstrous. He would, therefore, move, as an amendment, that the remuneration be 3 per cent. only.

This amendment was seconded by Mr. Robey, but on being put from the chair, it was lost by 7 votes against 3.

Mr. Bracebridge moved, and Mr. Hoare seconded the appointment of Mr. Dobson to take out the quantities.

Mr. Robey moved, and the Rev. G. T. Driffield seconded as an amendment, the appointment of Messrs. Hill & Fletcher.

The amendment was lost by 7 votes against 4, and the original motion carried *nem con.*

W. L. DOBSON.

BUILDERS' RESPONSIBILITIES.

GILBERT V. HILL AND ANOTHER.

THIS was an action (Court of Exchequer) by the widow of a carpenter, on behalf of herself and two children, to receive compensation in damages for his death, which was caused by the falling of a building in the Lower-road, Deptford, which was in course of erection by the defendants for a floor-cloth manufacturer.

Mr. Day and Mr. Willis appeared for the plaintiff; Mr. Sergeant Parry and Mr. Beasley for the defendants.

The building fell during a gale that prevailed in July, 1867, and it was said in consequence of the improper removal of certain struts and braces.

The defence was that neither the defendants nor any foreman in their employ ordered or authorised the removal of those supports to the building.

The jury, after having been locked up for some time, not being able to agree, were discharged without giving a verdict.

STONE'S END IN THE BOROUGH.

Is this beyond the care of the Board of Works? Here is a fair opportunity of widening the thoroughfare, I am afraid, going to be thrown away. This spot may be regarded as one of the entrances into London. A plot of ground has been lying unutilised on now some years, where stood the Old Stone's-end public-house. It is reported that a new police-station is about to be built on it. Now, there are houses standing singly on both sides of this way about 12 ft. in advance of the line from Trinity-street, and it is plain that a few years will see them all rebuilt to Horsemen-gate, or as far as the Sessions-house. Would it not be a pity to neglect initiating so great an improvement?

As an old inhabitant of the Borough, I feel ashamed that it should be necessary to point out so manifest a dereliction of duty to all concerned. Do lend your powerful aid, Mr. Editor, to rouse them.

ONLY A TAILOR.

A NEW PIN WANTED.

Sir,—In this age of scientific progress it is not possible to make a coil-headed pin? We have a safety pin, which, in point of fact, is an old Roman fibula, or brooch, or oress; but if you have several children they are always bent and out of order. Now, what is wanted is a pin that could be affixed to a garment by Sir Thomas English-coat of arms, a needle and thread, so as to be affixed thereto for permanent use. On a larger scale, I believe, if made of well-rolled wire, they would be much more useful for training plants than any ordinary cast-iron eyes, being not so brittle. Such iron eyes I well know are sold by florists in Covent-garden Market.

CIVIS LONDINENSIS.

THE LAW COURTS.

Sir,—It is very much to be regretted that when a Government evinces an anxiety to effect improvements in the town by erecting suitable buildings for the administration of justice, it should cause such an agitation among architects and their friends for obtaining the prize of erecting these Courts, as to discourage for the future all attempts to improve the public buildings of London.

I think too much stress is laid on the ornamentation of these new Law Courts. Let them by all means be respectably built, but I see no good reason why money should be lavished on more decorations. Utility should be the aim of architects in erecting public buildings, plenty of light and ventilation, and the simpler the construction the more likely to succeed.

Is it advisable to let the building in one tender? Could it not be divided into four tenders, and a fourth part built first, which would enable the public to judge of the merit of the building as applicable to the hearing of law suits? This cautious way of proceeding would ease the pressure on the fund devoted to the expense of the erections; possibly the caution would not be without its reward; it would afford an opportunity of pausing where an error is to be avoided. Altogether I think no sufficient reasons have been advanced for delaying to begin to erect the Law Courts on the Carey-street site. PRICES.

GRAINING.

Sir,—I cannot agree with any of the speakers at the Society of Arts who opposed "Graining" on the sole idea that it is in most instances badly done. I grant that the graining that is at present done in the new houses that are so fast springing up is positively disgraceful; but that is the reason that the work is done so badly? It is the price that is paid to inexperienced workmen, who are now executing oak graining at the price of 3½d. per yard for several builders at the West-end, a price that no "graver" who is at all entitled to the name would accept if even doubled.

I have tried nearly every invention that during the last twenty-five years has attempted to displace graining and marbling, and have found that in every respect it has failed to give the same pleasing effect as an experienced grainer can give. I trust that in time to the many eminent workmen in the above branch (who have worked their way up to their present high position solely through hard study direct from real specimens) you will insert this note.

Decorative Artists.
P.S.—Another point is, if master painters were to pay a little more for their graining work, it would not spoil the painter's work that often so much time is spent on. They forget that the graining is the work that is looked at when the job is finished, and if well done it would often hide defects underneath it.

CHURCH-BUILDING NEWS.

Bishampton.—The bishop of the diocese, the Duc d'Anmale, and Miss Porter, of Birmingham, have each given 500*l.* towards rebuilding the parish church of Bishampton, and Mr. Freedy, of London, has been engaged as the architect. The present building is ancient, and very dilapidated, the only thing done for it of late having been the re-roofing of the chancel by the Duc d'Anmale, who is lord of the manor. There is Norman and Perpendicular work in the church, but the whole is greatly disfigured, and its dilapidations are disguised by plaster and whitewash, the yellow ochre and the artistic sylvage of black which a village daber formerly put on the outlines of windows and arches having given way to the all-prevailing white. It is hoped that in the renewal of the building care will be taken to preserve the ancient iron frame which held the hour-glass at the pulpit for the preachers in the seventeenth century.

Chester.—The new church of the Holy Trinity has been consecrated. The new edifice is on the site of the old one, but covers the old burial ground, and is on a line with the other modern buildings of Water-gate street. The style of architecture is Decorated. The church consists of a nave, chancel, north and south aisles, two vestries, and a tower with spire at the west end of the south aisle. The length from east to west is 101 ft., the width from north to south walls 68 ft., and the spire is 155 ft. high. The buttresses of the tower terminate in gables, and the spire, with lancet lights, rises from within a parapet of open quatrefoils, which has crocketed pinnacles at the angles. A similar parapet is carried round the building by a tablet of foliage supported by carved corbels. The principal entrance at present is under the tower from Water-gate-street, and is sculptured. There is an entrance at the west end of the nave, in Linen-hall-street, but this is not yet completed. The nave is lighted east and west by two seven-light windows, and also in the clear-story by two-light windows, the tracery being geometrical in character; while the aisles are lighted by two and three-light windows of the same description. The nave is covered by an open timber roof, while the choir and chancel have an inner timber roof, enriched by bosses of carved foliage. The reredos is the gift of Mr. C. T. W. Parry, and is by Mr. Earp. It consists of seven sunk panels, divided by shafts of Balmaloe marble, with carved capitals supporting crocketed canopies, the finials of which rise above the hood moulds. The gables are filled by emblematical subjects, and the space between them and those below is filled up with chaste diaper work. Among other gifts are two stained windows. The one in the north aisle, almost hidden by the organ, consists of three lights, with angelic figures in the tracery and cinquefoils above. In the centre light is the Saviour as the Good Shepherd, and on either side St. Peter and St. Paul. The stained window in the south aisle has also three lights, but a double row of subjects, the tracery having trefoils and quatrefoils. The following texts are illustrated by the artist: 1. "From a child thou hast known the Holy Scriptures;" 2. "I was naked and ye clothed me;" 3. The prayer of faith shall save the sick;" 4. "Ye must be born again;" 5. "I was sick and ye visited me;" 6. "I was thirsty and ye gave me drink." The architects were the late Mr. James Harrison and his successors, Messrs. Kelly & Edwards, of Chester. Mr. Thomas Hughes, of Aldford, was the builder. The seats have been made by Mr. Appleyard, of Chester. The gasfittings, altar-rail, and iron-work were by Messrs. Peard & Jackson, London.

Eccleshall.—The north aisle of the church has been reopened; and, after an interval scarcely exceeding three months, the church has been restored almost as it was before the fire. There is, indeed, little change to notice in the appearance, beyond the addition of a painted window,

given by Miss Buckley. It is a two-light window, at the west end of the south aisle. Two subjects have been introduced: the raising of Lazarus from the tomb by Christ, and the restoring of Tabitha to life, in her sick chamber, by St. Peter. The artists were Messrs. Clayton & Bell, of London.

Bury St. Edmund's.—The chancel of St. James's Church has now been completed. The chancel is 58 ft. long by 23 ft. wide, and 40 ft. 3 in. from the floor to the apex of the roof, and rises in three stages from the nave to the east end, there being one step under the chancel arch, two others in a line with the side doors, and two more at the altar-rail. In all three divisions the floor has been laid with Minton's tiles. Adjacent to the nave is placed, on either side the chancel, a row of ten oaken stalls, in front of which are benches for the choristers; and on the south of the altar are sedilia in three compartments, executed in Caen stone, to be surmounted with carved Gothic canopies and finials. Between the sedilia and the reredos is also a small credence-table of Ancaster stone, supported on moulded brackets. The reredos has been put up at the expense of the members of the firm of Oakes, Bevan, & Co., of this town, and occupies the whole of the eastern wall beneath the string-course. A decorated window, designed by the architect, Mr. G. G. Scott, has been inserted at the east end, and has been filled with stained glass, purchased by subscription, and executed by Messrs. Hardman, of Birmingham, as a memorial of the late pair of the living, Mr. Henry Wilson, of Stowington Hall. The stalls and choir-benches in the chancel have been made by Mr. Darlin, clerk of the works, and the stone sedilia by Mr. Plowman, of this town. The whole of the remainder of the work has been executed by Mr. Jackman.

Manchester.—The church of St. Gabriel, Hulme, Manchester, has been consecrated. The church occupies a prominent position in Erskine-street, midway between the Stretford and City roads. The church is of considerable height, and, although the steeple is still unfinished, rises well above the adjoining buildings. St. Gabriel's is, we believe, the only example in Manchester of a brick church—one in which the facing bricks show both outside and in. The outside of the building is of red brick relieved with blue in bands and patterns, whilst in the interior the walls are lined throughout with white bricks, with arches, strings, and various devices worked in red brick, on a white ground. The outline of the site being a simple rectangle, and of not more than sufficient size, the plan of the church is likewise a parallelogram, terminating tri-axially at the east end, which faces Erskine-street. The north aisle extends to the extreme western limit of the site, but the nave and south aisle stop a little short of it, so as to allow access to and from the central west door. A portion of the western bay of the south aisle contains a brick-built porch, which is the main entrance for the congregation. For other uses and for exit there are in all six doors, three at the western and three at the eastern end of the building. The nave is divided from the north and south aisles by arcades of five arches each. The pillars are of cream-coloured Bath stone, the shafts being banded with red stone. The baptistry—oblong in shape—is at the west end of the north aisle, and is marked off from the aisle by a couplet of tall narrow arches, resting on a central pillar. The chancel, which is 43 ft. by 20 ft., projects a little more to the east than the two smaller apses, and is about double their height. The smaller apses are lighted by an arcade of lancet windows, all round; while the great central apse has three two-light stone tracery windows, divided by circular brick buttresses, terminating with carved and conical caps. Inside and out, the apses have moulded brick cornices. The steeple will come over the western bay of the chancel. The aisle windows are in pairs, with stone cuspied heads. Each bay in the clear-story has a stone rose-window in the centre, with a lancet on each side. The west end is lighted by a three-light window, upwards of 20 ft. high, with a single lancet on each side of it. The roofs are covered with purple slates, with bands and patterns of green-coloured slates. The ridges have red terra-cotta cresting of original design. Want of funds, however, has caused the work to be let in many contracts, and ordered bit by bit as circumstances appeared to justify; and thus it happens that even at the time of consecration much that is desirable is still unfinished. Oak chancel-stalls, and tiling for passages and chancel, are still in preparation.

A few only of the benches for the nave have been made, but it is hoped funds will soon allow more to be ordered. The temporary gas-fittings consist of brackets in the spandrels of the arches above the nave pillars. The heating apparatus was put in by Messrs. Haden. The light is softened by tinted and partially opaque thick glass in two or three colours. The architects were Messrs. Medland & Taylor, of Manchester.

Miscellaneous.

Manchester Architects and Machine-Made Bricks.—In reference to a remark by Alderman Bennet at a meeting of Manchester builders, &c., to receive a free-labour deputation, that "unless the architects would specify machine-made bricks, builders were almost powerless in the matter" of promoting free labour, a letter signed by various well-known Manchester architects says:—"We think that we should not be acting in the interest of any one except the manufacturer of machine-made bricks were we to debar ourselves from that to which we conceive we have an undoubted right, viz., the use of whatever material seems to us the best for the particular purpose intended. To determine that machine-made bricks should be used would certainly be construed as implying the exclusion of those made by hand, and this would be encouraging a monopoly in its most objectionable shape, and depriving the makers of both of that healthy stimulus which competition alone can give. There can be no doubt, on the other hand, that if machine-made bricks could be had in Manchester equal to hand-made ones, but at a lower price, or superior to them at the same price, no protective influence would be required on our part to cause them to be generally used."

Wire-rope Transport.—Mr. Hodgson, C.E., has patented an invention based on East Indian, Chinese, and other Eastern practice, in the formation of a light and cheap mode of transporting mineral or agricultural produce, suspended from a pair of wire ropes, and moved by steam or horse power at one end of the line, through an endless running rope. The goods are conveyed in boxes, which pass the supporting pulleys without interruption. The line is not unlike that of a telegraph, reminding one of the old lady's idea of having her umbrella returned by telegraph. One has been erected near Leicester, and is said to work well. The inventor, however, chiefly intends it for use in the colonies.

Gas and Water Supply Corporations and their Customers.—A case of considerable interest has been heard at the Carlisle County Court. It was an action brought against the Corporation of Carlisle to recover 5*l.* for damage sustained by reason of the defendants cutting off their supply of gas. The Corporation are the proprietors of both the gasworks and the water-works, and the plaintiffs having fallen into arrears of water rate to the extent of 7*s.* 4*d.*, the defendants cut off their supply of gas. The plaintiffs submitted that the defendants had no right to stop the supply of gas for any default in respect of water. The defendants contended that they could cut off the supply of gas at any time. The judge held that they could not. If he said, they agreed to supply a customer, a contract was implied which could only be invalidated by his breaking their rules and falling into arrears for gas.—Verdict for the plaintiffs for 20*s.*

The Value of Land in Bristol.—After considerable negotiation, the Local Board of Health have purchased a narrow strip of ground lying between the inside margin of the footpath and the line of the new City Hotel. The company, it is said, first asked 800*l.* for the strip, but ultimately received the half of that sum. The effect will be the immediate repair of the footpath.

A Cheap and Good Whitewash.—Sir: Seeing a recipe for whitewash last week put me in mind of one that I have been using, which I find is very good, as well as very cheap. It is as follows:—Dissolve 6 lb. of fine white pipe-clay in as much water as will make it as thick as paint; soak and dissolve 4 lb. of good glue; add and mix well; then add ½ lb. of fat or dripping of any kind, put on the fire and boil a few minutes, and use while hot. The fat being boiled with the pipe-clay forms a kind of insoluble soap, which, if used while hot, defies all kinds of weather. It may be coloured to suit the taste.—R.

The Proposed New Chapels at the Chatham Cemetery.—A special meeting of a committee representing the various Nonconformist bodies in Chatham has been held on the subject of the Nonconformist chapel proposed to be erected at the new cemetery, which, as at present proposed, is exceedingly distasteful to Nonconformists, from its presenting an odious comparison to the chapel proposed to be built for the use of the members of the establishment. A resolution was passed directing the Board of Health, acting as the local Board, to make such alterations as would be satisfactory to the general body of Nonconformists. A deputation waited on the Burial Board, when that body, after consultation with an architect (Mr. Young), agreed to make the alterations required by the Nonconformists, and two chapels will accordingly be as nearly as possible alike.

How to Catch Rats.—For catching rats in a cheap and effective manner we recommend the following:—Cover a common harrel with stiff paper, tying the edge around the barrel; use a board so that the rats may have easy access to the top; sprinkle cheese-parings or other "feed" for the rats on the paper for several days, until they begin to believe that they have caught their daily rations from this source; on place in the bottom of the harrel a piece of cake, about 6 in. or 7 in. high, filling with water until only enough of it projects above the water level to rest on. Now replace the cover, first putting a cross in the middle, and then a first rat that comes on the harrel-top goes through into the water, and climbs on the rock. The paper comes back to the place, and the second rat follows the first. Then begins a fight for the possession of the dry place on the stone, the noise of which attracts the rest, who share the same fate.—*Scientific Farmer.*

New Drinking-fountain in the Old Kent-road.—A new drinking-fountain has been erected in the Old Kent-road, outside the Deaf and Dumb Asylum, and nearly opposite the Bricklayers' Arms Station. The fountain has two large drinking-troughs for animals attached to it, and about three months since a local committee were formed, and an appeal made to the inhabitants for the necessary funds. More than 1200 were soon subscribed, and the committee placed themselves in communication with the Metropolitan Drinking-fountain and Cattle-trough Association. A site was granted by the vestry of St. George the Martyr, and the first of two fountains which are to be erected by the Association has now been opened for the use of the public. The directors of the Southwark and Vauxhall Water Company have granted a free supply of water for it. The Metropolitan Drinking-fountain and Cattle-trough Association have 124 fountains and 114 troughs in the metropolis, and as many as 700 horses have been known to drink at one trough in a single day, besides other animals. The society is supported entirely by voluntary contributions, and has offices at 1, Shorter's-court, Throgmorton-street, E.C.

The Sanitary Condition of Bridport.—A meeting of the Town Council has been held to consider the question, and whether some means should be adopted for bringing a supply of water to the town. Mr. H. E. Hounsell having given notice at the last meeting that he would make a motion to that effect. Mr. Hounsell's motion was—“That some means be adopted to bring a supply of water into the town.” They had heard, he said, that the mortality had been very high, but in the last quarter it was heavy because they had had fever. It was because of it that fever that his motion was made, and it was that fever that ought to be prevented by a good water supply as one of the means, and by sundry other precautions. After a good deal of discussion it was finally resolved by 11 against 9 that the matter be adjourned for two months.

The Proposed Tunnel between England and France.—Mr. H. Beckett, F.G.S., the gentleman appointed to report upon the possibility of effecting a communication between the two countries by a submarine tunnel under the Straits of Dover, presided at a meeting of the Midley Geological Society on Monday evening, and read a paper on the scheme. Mr. Beckett is the promoter of the scheme proposed to be two parallel tunnels for a single line of rails, and were of opinion that the total cost would be considerably less than 10,000,000 £ sterling.

Ventilation by Air Fountains.—A mode of ventilating churches, halls, &c., by means of jets of fresh air passing through pipes to the centre of the space to be ventilated, and above reach of the heads of those present; in conjunction with ways of egress for the foul air through the floor, after being cooled by the fresh air mixed with it, is proposed by Mr. R. Moffat Smith, of Manchester, architect. The system of ventilation, Mr. Smith observes, could be combined with warming apparatus. The fresh air would enter the central space through ornamental tube standards, or could descend from the roof, as in a ball-room, although the jets would be turned upwards. By means of valves or taps the air could be regulated at pleasure.

The New Law Courts.—At a recent Court of Common Council, the Remembrancer stated that he had received a communication intimating that the Government had given notice of their intention to introduce a Bill for the purpose of making a bridge to connect the new Courts of Justice and the Temple. He recommended that the communication be referred to the City Lands Committee, with power to confer with the Government and the commissioners employed in constructing the Courts. This was agreed to.

Destruction of the Hull Theatre Royal.—At this fire, of which by this time most of our readers have heard, it was evident from the first that none of the fire-extinguishing appliances at the disposal of the firemen would be of the slightest avail. As is usual with theatres, the flames made rapid and irresistible progress, and within a few minutes from the time that the fire was first observed the entire building was in flames. As yet the cause of the fire, if known, has not been explained. The audience, together with the company and assistants, had all left the building before the fire broke out. Very little property was saved from the flames. The old Theatre Royal was destroyed by fire in October, 1859, and it was six years before this new one was erected, so that it was only four years old. The North British and Mercantile Insurance Company is liable to the extent of 2,000 £.

Report on Expenditure of Boston Local Board.—A report of Mr. W. H. Wheeler, C.E., the borough surveyor, on the expenditure of the local board for 1862-68 has been printed. It states that the average ordinary expenditure has been 3,190 £ per annum, and that during this period a sum of 1,057 £ has been paid for works of permanent improvement, in addition to 3,876 £ paid during the same period in repayment of loan and interest on money borrowed for paving the town, and included in the ordinary expenditure.

The Improved Industrial Dwellings Company (Limited).—The report to the eleventh half-yearly meeting of shareholders states that the properties belonging to the company at present completed and occupied, are as follows:—

	Tenements.
Cobden Buildings, King's Cross-road.....	20
Nelson Buildings, Bridge-street, Greenwich.....	40
Tower Buildings, Brewhouse-lane, High-street, Wapping.....	60
Stanley Buildings, Old St. Pancras-road, King's Cross.....	104
Palmerston Buildings, City Garden-row, City-road 72	
Cromwell Buildings, Red Cross-street, Southwark 24	
Derby Buildings, Brittain-street and Wicklow-street, King's Cross-road.....	168
Gladstone Buildings, Willow-street, Finsbury	84
Total	573
Buildings in course of completion at Willow-street and at the Bethnal Green Estate—to be occupied very shortly.....	102
	674

The company have also a site in Ebury-street, and mean to erect dwellings for about 100 more families; so that this company provides improved dwellings for 778 families, or 3,890 persons, besides 180 ordinary houses at Bethnal-green. A dividend of 5 per cent. has been declared.

Fatal Fall of a Mill Chimney at Glasgow.—A boisterous wind has blown down the square brick stalk, about 80 ft. high, in connexion with the paper-mill of Mr. Robert Bruce, situated at South Woodside, off Park-road, near Kelvin Bridge, Great Western-road. The stalk was blown down literally from top to base. It fell upon the roofs of four houses, the greater part of the debris levelling two centre buildings, which formed the residences of three separate families. Eight persons, mostly females, were killed, and others injured.

Report on Cleansing Newcastle-upon-Tyne.—A report by Mr. John Fulton, C.E., the borough engineer, to the Town Council, on the cleansing of the borough, has been printed. The report, at the conclusion, says:—

“Having recently, under your instructions, visited several of the most important towns of England, I can confidently affirm that, as regards surface-cleansing, Newcastle bears favourable comparison with any of them. It is true that many of our modern streets are not paved, and are consequently in a wretched condition, but the defect is yet in a fair way of being remedied, and, as a proof of this, I may state that upwards of five lineal miles of new streets were severed, paved, and flagged during last year. At this rate of progress two years will suffice to complete all the streets in the town at present unpaved, provided the requisite funds be forthcoming.”

Experiments have been made with chloride of calcium (Cooper's patent) for the purpose of saving expense in street watering, and the report states that “it was found that when used in very strong solution, it had the effect of hardening the surface of the roads, and thus preventing the formation of dust, and the consequent necessity for watering. Further experiments are to be made next summer with this material.”

East London Museum.—On Saturday last the Lord President and Vice-President of the Council for Education (Earl de Grey and Ripon and Mr. Forster, M.P.) received a deputation for the purpose of formally accepting from them the gift to the nation of the title-deeds of the site which the promoters of the East London Museum scheme have conveyed to the Science and Art Department, under the powers of the Act of Parliament obtained for that purpose. Mr. Holms, M.P., introduced the deputation, and Mr. Brady explained that the Government had agreed to erect a museum in East London, on condition that the promoters selected and defrayed the expense and the cost of site. Mr. Brady then proceeded to point out what the promoters' views were as regards the sort of museum they wished to secure. Their leading idea was that it should be educational in the widest sense of the term. As regards fine arts and schools of design, the promoters did not know of any institutions of more importance. They also hoped that the museum might be made subservient to technical education generally. The title was complete, and divested of all prior trusts. A condition of the general proposal was that the museum should be open in the evenings. It would be erected on 43 acres of land in Bethnal-green. Two millions of people resided within a radius of three miles of the site. The Lord President, after formally receiving the title-deeds, said that Government accepted the trust most willingly, and would do their utmost to render the contemplated museum as publicly beneficial as possible.

Hearts of Oak Benefit Society.—The official auditor's report on the financial operations of this society for the year 1868 has just appeared, and it seems to indicate that, in spite of the commercial depression which has prevailed, the year has been in every way most successful. The society began the year with 13,565 members, and finished it with 15,902. The income for the year was 30,249 £. 5s. 9d., or 2,520 £ per month, against 26,801 £. 5s. 7d., or 2,233 £ per month, in 1867. The average quarterly contribution was 9s. 4d., against 9s. 6d. in 1867. The amount received was appropriated as follows:—22,934 £. 0s. 1d. were paid for sickness, funerals, and other benefits; 599 £. 1s. 5d. were spent in postage, reports, &c.; 1,573 £. 2s. 1d. was the cost of management; and the remainder, or 5,153 £. 2s. 2d., was added to the reserve fund, which now amounts to close upon 55,000 £. The cost of management was 67. 4s. per cent. upon the gross income, and it was covered by the fines, thus leaving the whole of the ordinary contributions available for the satisfaction of claims, and for the augmentation of the reserve fund.

The Architectural Museum.—On the 15th the Committee saw four candidates for the office of Curator, and ultimately appointed Mr. Joseph H. Wallis. The new building in Westminster is ready, and the collection is now to be removed without delay.

A Bolton Philanthropist.—The Chadwick Charity trustees at Bolton have had notice given them that Dr. Chadwick, of Southport, and formerly of Bolton, had placed at their disposal a further sum of 5,000 £, in addition to 17,000 £ previously given, making in all 22,000 £, to be devoted to the erection of artisans' model dwellings and an orphan asylum.

The Builder.

VOL. XXVII.—No. 1360.

On some Modern Architectural Work.

WHEN we say that the architectural practice of the present day goes almost entirely according to fashion, we say what is fast becoming a stale truism. We are as familiar with the different types in vogue as we are with the different species of dogs; we can separate them into distinct classes, each with its recognizable peculiarities and markings; if we get sight of a chamfer termination, or a capital from one of them, we can conjecture all the features that go with it, almost as well as a comparative anatomist can compile a body from a single bone, unless it be in the case of those abnormal buildings which occasionally startle us, and which can only be defined as resembling nothing at all, either in heaven, or in earth, or in the waters under the earth. Whether it will ever be possible for us, in the present state of society, with all its varied interests, and with our constantly increasing locomotive and intercommunicative facilities, to be of one mind in our ideas as to architectural style, and to agree in our opinions on the merit of modern designs as we almost universally do agree on the merits of ancient ones, it is impossible to say; at all events, for the present there seems little sign of such unity, and we must be content just now to accept our various current styles, and reproductions of styles, for what they are worth, content if we can see at least good Classic and Gothic, Renaissance and Romanesque, well and artistically treated, and not too captiously reject these, which are at least coherent styles, in the desire for some imaginary and hypothetical form of architecture which is to answer all our needs. We are willing to be grateful to a practitioner of one school for a building showing breadth of composition and elegance in treatment of detail, even though its leading features be borrowed from Greece or Italy, and its delicate contour of moulding seem comparatively ineffective in our climate; and we will give thanks to any one of the Gothic persuasion who will give us a building effective and picturesque in sky-line and appropriate ornament, though it be open to the objection that it recalls a social and intellectual state widely different from that of our own day. But this *laissez faire* criticism cannot be universally applied; there are some things brought out nowadays under the title of Gothic which would be "too cruel anywhere," even in the high tide of the Middle Ages, and a *fortiori* in these our enlightened times,—a class of designs referable in reality to no principles and to no style that ever existed, which are, nevertheless, rapidly getting into a temporary popularity, and which

we can only comprehend under the general title of "Barbarisms."

The tendency to the revival of fashions long worn out and laid by as antiquated is familiar to all who keep their eyes open. We have had various developments of it lately,—revivals of coarseness and irreverent sermonizing and hymnizing belonging to the religion of the early Methodist type; revivals of grotesque and ill-fashioned antique melodies and incomprehensible harmonies under the title of "pure Church music;" and revivals of minstrel galleries, and portentous open fireplaces, and bare stone walls, in mansions supposed to be built for the use of English gentlemen of modern civilized tastes and habits. But with regard to Architecture, with which chiefly we are concerned, matters have gone even farther than this. Mere revivalism of Medieval styles has become too tame and commonplace a source of effect in the craving for novelty which besets so large a portion of the architectural profession,—a craving which is stimulated and excited still further by the system of architectural competitions, where each man feels that his best chance for distinction is to put forth something more wild and startling than his neighbours have done. Consequently, we see designs in every direction passing entirely over the bounds of the picturesque, which was the characteristic of the best of the genuine Medieval buildings, and entering the domain of the barbarous and grotesque. It was the object of the designers, in the finest and most complete of past architectural styles, such as the Greek Doric and the Early English Gothic, to refine the rude material of their walls into elegant and beautiful forms arranged more or less symmetrically in well-balanced masses, connected into one whole by some obvious unity of purpose or treatment, subordinating the various parts to the general design; and while it is quite a misrepresentation to imagine the Greeks as tyrannized over in their buildings by the wish for absolute symmetry of the two halves of a building as a *sine quâ non*, it requires also to be pointed out that the works of the best data of English Gothic are by no means characterized by a meaningless and forced defiance of symmetry. The Medieval builders sought no such adventitious sources of effect: their plans are unsymmetrical only in so far as the requirements and uses of the different portions of a building influenced the sizes and shapes of the various compartments; like the Erechtheion, they are collections of symmetrically planned compartments grouped together in the way most convenient for their various purposes. But look at a large proportion of the drawings sent in for architectural competitions now. They are Gothic, of course; for no one who seriously aims at gaining a prize in a competition lottery would do wisely in sending in a Classic design; his most careful drawing of columns and cornice and window dressings will only result in his drawing a blank. But the Gothic has none of the refinement which characterized its best Medieval prototypes. The plans and the sky-line are studiously and carefully cut up into irregular lines, and jutting corners and odd nooks and hiding-places. The main object seems to be, that no one part of the building should in the least resemble another. There will be a high tower in one corner, with no special object; then a row of low buildings; then a sudden skip up to a greater height, and a more dignified style of fenestration; then another tower or two, and so on; while the roof of the building will present, in the perspective view especially, a wild mazy dance of tarrets and ornamental chimney-stacks, which, perhaps, may be

"Then regular, when most Irregular they seem;"

but which on the whole convey the idea that the top of the building has been bottled to prevent naughty boys climbing over it. If a mansion is to be erected, it will have a frowning machi-

colated tower, with narrow slits for windows, suggestive of dungeons and domestic tyranny, adjoining a modern conservatory; if it is to be a town-hall or Law Courts, towers again on a larger scale and in greater numbers, with outlines like those of an old kitchen clock, corbelled out to an impossible extent at the top, cropping up just where you do not expect them, and terminating with conical roofs suggestive of gigantic extinguishers; and if a new church is in prospect, all the odd "doges" of masonry and heavy piling up of buttresses without any proper finish, and abnormal forms of plate-traceried windows, that can be raked together out of old village churches in France, will be thrown together into one jumble. With this class of designers, all attempt at giving refinement of character to a building, by careful proportioning of the various parts, and by designing each portion and each ornamental detail with reference to its effect on the whole, is apparently scouted as so much child's play calculated to interfere with the "vigour" and pignoresqueness of the design, and to bring the designer down to the level of the wretched and pitiable Renaissance. It is enough that the building represents a conglomeration of all that is most uncount and strange in Middle-age art, all which peculiarly belongs to the Middle Ages as a period of semi-barbarism and uncultivated life, and that all the real beauty and artistic power of the Medieval styles is obliterated; and nothing more is needed than for the "artist" to append his name and address in grotesque and illegible hieroglyphica.

But this spirit of barbarism is even more discernible when we come to consider the details of buildings, than in their general design. Go into a church of the current type, for instance, and see what monstrosities will strike the eye of any observer who is sufficiently independent in his judgment to be able to stand apart from the reigning fashion. One system of obtaining originality has consisted in the perpetual shortening of the shafts employed in Gothic work, so that in designs for pulpits and fonts, the bases and caps of the shafts which support them are only separated from each other by a few inches of shaft, which threatens to disappear altogether presently, and leave cap and base in conjunction; and even in the piers supporting the nave arcades in our churches it has become the fashion to stunt the columns (where columns are need) to the utmost possible extent, creating a heavy and clumsy effect quite at variance with the spirit of Pointed architecture as a vertical style. The font and pulpit, too, are fields for a liberal exercise of barbarism, in the shape of bas-relief designs of stiff archaic figures, such as would at once ruin the chance of any candidate for admission to a "life" school. The roof timbers are ornamented by being striped and dotted round in successive transverse bands of colour, interfering with, instead of emphasizing, their principal lines, and giving a "spotty" and gewgaw appearance, at variance entirely with the repose necessary to dignified architectural effect. The "reredos," as it is called, looks like a sort of lean-to erection, with a sloping roof cut and faceted to imitate tiling, with the same stunted shafts and mis-shapen figures as decorate the font and pulpit, and with a background of inlaid ornament, supposed to be symbolic, and often of the most barbarous and childish type; indeed, it is becoming the fashion now to go for studies of inlaid ornament to those glorious remains of art, the Egyptian hieroglyphics and decorations of mummy-cases. Hints, no doubt, may be obtained from these, and many other antique sources; but it is one thing to work out hints from barbaric design, another to reproduce the same type of thing, with scarcely any modification, in a modern building. Then on the walls of our church we see texts which no one can read, so studiously

are the letters archaized, and windows filled with stained-glass figures standing on the tips of their toes, with no knees or elbows, and showing evidently the anatomy of the period. But the crowning beauty is in the grotesque heads and figures with which the building is decorated at appropriate points. "Why do you architects sculpture devils on the outside of your churches?" said a clergyman to us the other day. "Is it to indicate that they have been expelled from the interior?" This is a happy thought, and we commend it to those Gothic gentlemen who may be called upon to furnish a reason for the hideous and disgusting figures which are perched over the spout-heads of some of their churches: they may sometimes find themselves rather at a loss for a defence. It is to be presumed, on the same theory, that commercial and other pursuits are being much purified from diabolical agency, seeing that these same elegant decorations are to be seen on the exterior of many recently erected buildings for secular purposes; and there are actually to be found wisacres who give great part of their time to the designing and reputation thereupon, or seem to hope to do so. And finally, the barbaric mania has spread to our furniture and private decorations; and we are beset with designs for chairs and other moveable (or rather immovable) furniture of the most clammy and unwieldy type, with studiously ugly outlines; bookcases inlaid with different woods, with an absence of all definite and studied design, just as we might expect to find them in the Sandwich Islands, or among any barbarous people; pianofortes looking as if they would go off into a display of fireworks, and organ-cases, with the pipes splashed over with all imaginable violent colours, in a manner calculated to give one ophthalmia, and perhaps further decorated by inlaid figures of angels "censing," and other devices supposed to represent the spirit of adoration in its latest and most exalted forms.

Now all these sources of effect, or attempt at effect, which we have mentioned as characteristic of much of architectural practice at present (and which are, indeed, before the eyes of our readers), belong to what we may rightly and naturally term the barbaric spirit in art. It is of the essence of barbarism to rejoice in all such gawgaw displays of colour and jumble of intricate form as we have been commenting upon. The spirit of self-restraint in design, so valuable, so necessary to the production of all great and refined works of art, the spirit to choose the good and reject the bad, is just that which is absent from all previous schools of barbaric art. In the art of the Hindoos, and of the Turanian races generally, we see it to perfection: in their copious lavishing of ornament upon every part of a building, their love of bright colour, their indifference to correct drawing of the human form, and adherence to conventional types thereof (especially in ecclesiastical structures), and their love of the grotesque. This is almost exactly the state in which the school of architecture popular among the younger members of the profession now is, with the difference that much of the ornamental detail employed by the ultra-modern Goth of the present day is inferior to that which may be found in Hindoo and Chinese work. There is no more real art, no more consideration of form and proportion, no more evidence of the presence of an educated mind in many of the designs which are sent in for competition nowadays than there is in the most *outré* of the temples on the banks of the Ganges; those who have well studied Indian architecture would probably say, "much less." But, at any rate, the faults of the two styles are of just the same nature, only the Hindoo was the work of people who were doing the best they could, and who had no better models, while the modern abortions referred to are the work of men who have had the opportunity of studying the remains of all the best art that the world has hitherto produced, so far as we know, and have wilfully turned their backs upon these, and elected to be of their own choice barbarians. And so far as the prevailing popular style of church decoration is concerned, the similarity in the two cases is most singularly striking; for a stiff conventionalized style of symbolic decoration, a love of violently contrasted colour, and a contempt for correct figure-drawing, have always accompanied the existence of a slavish adherence to ritual, which imparts a supposed perfection to all things designed for the service of the temple, and judges religious art by a different standard from that used by "externs." And how far the

modern ultra-medievalists are from all which educated men in general understand by Art, we may see at once, if we compare what passes for art with our best artists in the exhibition-rooms with what passes for art in a church, so far as at any rate as the drawing of the figure is concerned. If a stranger from another planet were to visit us, and were shown a painting by Mulready or Maclise, or a statue by Foley, alongside of one of the fashionable designs for a pulpit, or reredos, or stained-glass window, could he for a moment suppose that the two belonged to the art of the same period and the same nation? The young men who are spending their time on these precious productions of ecclesiastical and very Gothic art, may go on and complacently in their own self-satisfied round, and think themselves artists; but the best circle of educated men around them can see the real value of such a class of designs, and regard them with scorn; a scorn which posterity, if it should have the means of knowing anything at all of them, will abundantly ratify.

MEANS FOR THE IMPROVEMENT OF THE PEOPLE.

We ended our first notice of the English official reports on the Free Exhibition of 1867 with mention of the sixth volume, which is devoted to the returns relative to a proposed new Order of reward. This, we need scarcely remind our readers, was a distinct order of reward instituted, in official terms, "in favour of the persons, establishments, or localities which, by a special organization, or special among all those devoted a spirit of harmony among all those co-operating in the same work, and have provided for the material, moral, and intellectual well-being of the workmen;" and it was endowed with prizes to the value of 5,000*l.* and twenty honourable mentions. It was left to each country to collect its own information, and this sixth volume contains that which relates to such establishments or institutions in England. There was at first some little reserve and delicacy, and in some cases absolute refusal to send in any particulars in competition; but, it being pointed out that a knowledge of good was for the general good, these scruples were to some extent removed, though not so far as the objection to money rewards. Forms were accordingly circulated by her Majesty's Commissioners for claimants to fill in, containing a sufficient number of questions to elicit all the leading facts and points of the undertakings under their charge or devised by them. Thirty-seven commercial firms responded; ten building societies; thirteen co-operative societies; thirteen sailors' homes; two localities having special institutions; and thirty-seven institutions of a miscellaneous character, varying from a cripples' home to a working-women's college, and including one of the new boards of arbitration and conciliation, making a total of 102 returns. The mass of information thus gained, and now at everybody's service for a nominal sum, is supplemented with several valuable plans. There is a bird's-eye view of Akroyd, the famous *cité ouvrière* of Messrs. Akroyd & Son, in Yorkshire; and there is another of Copley village, belonging to the same firm, with plans of the houses in them. These are followed by a comprehensive plan of Salthaire, the property of Mr. Salt. Then there are an elevation of Miss Bardett Contts's market, in connexion with Columbia-square; an elevation and plan of the dwellings of the Improved Industrial Dwellings; a view and plan of Gatliff Buildings, belonging to the Metropolitan Association; and a plan, elevations, and section of the Spitalfields Metropolitan Buildings. It is thus easy to mark the differences and advantages of the several plans. Akroyd (previously illustrated in our own pages) is a quadrangular town, forming a hollow square, is a narrow street between them; in a third there are three streets, one behind the other; on the fourth there is a double row again. The blocks illustrated in plans have cellars furnished with coppers for washing, a place for coals, and a sink; above these is a living-room, with a small scullery, with a sink in it, partitioned off, and a staircase leading to a large and small bedchamber above; the latter being over the space cut off from the living-room as a scullery. These houses are

rectangular. Two other blocks have a small projection in the rear, in which the larder and coal-place are located in the cellar, and above these the scullery; and above this a small bedroom; the front of the house, consisting of a large cellar for washhouse, furnished with copper and sink; a good living-room on the ground-floor, and two bedrooms above it; and a small yard in the rear, containing W.C. and place for ashes. In the Copley houses shown we do not find much to admire. They are built back to back, and the ash-places and W.C.s are in front of them; though even here the living-rooms have little sculleries, furnished with sinks, partitioned off from them. Each houselet, or *maisonnette*, as it would be called on the other side of the Channel, has two small bedrooms above stairs. Both Akroyd and Copley are in the enjoyment of many schemes and societies for the general benefit devised by the firm, such as a library, a choral society, a library and scientific society, a horticultural and floral society; but neither, as far as we learn, is in possession of the means of technical education, as supplementary to that primarily afforded by the schools, in this respect contrasting disadvantageously with the establishment of Le Creusot, in France. In the schools belonging to these great iron coal works, there are twenty-three teachers, and the highest classes attain what the Rev. M. Mitchell describes as "a very extended acquaintance with literature as well as science, exercises in style, history, cosmogony, arithmetic, algebra, geometry (descriptive), mechanical physics, chemistry, and the elements of sculpture and drawing." From these schools the factory is furnished with intelligent workmen. Let us hope that the importance of keeping pace with our neighbours on this particular, will not be overlooked by employers, who have shown themselves in so many ways anxious to improve the condition of those whom circumstances have placed in their power to benefit. We have ourselves given particulars of Salthaire. It is here represented by a plan only, which although it shows its extent, the relative position of its church, chapel, dining-hall, baths and wash-houses, literary and philosophical institution, boys', girls', and infants' schools and playgrounds, almshouses, dispensary, allotment gardens, cricket ground, croquet ground, bowling-green, fire-engine house, and offices, does not show the interior arrangement of the 748 houses. The return makes no mention of technical education having obtained footing here; but where a firm exhibits in such a princely manner its determination to do good to its generation, it is unlikely that it will be long absent. Mr. Salt declined to subject Salthaire to the arbitration of the Imperial Commission.

There are other of the firms making returns that have erected houses for the accommodation of their workmen, of which no plans are given. The Messrs. Besbrook, Spinning, & Co., in Ireland, have built 280 within the last twenty years, with kitchen and scullery, sleeping-rooms above, back yards and privies, at an average cost of 50*l.* each; Messrs. Bliss & Son, Chipping Norton, have built 75, at a cost of 5,131*l.* 4s. 6d.; Messrs. Briggs, Yorkshire, have built 170, costing from 70*l.* to 110*l.* each, and when they sent in their return, were intending to erect 62 more; Messrs. Brook & Brothers, Yorkshire, have built 140 cottages, with three rooms in some, and four and five in others, at a cost of nearly 20,000*l.*; Messrs. Campbell & Co., Belfast, built 23 two-storied houses for 60*l.* each, for 90*l.* each; at Cornstall Mill 413 cottages have been built at different times within the last thirty years, at a cost of 100*l.* each; the Consett Iron Company have 1,000 two-roomed cottages; the Dowlaia Iron Company, Merthyr Tydfil, have built 500 Iron Company, Merthyr Tydfil, have built 500 cottages, of which no particulars are given; 200 have been built at Gifford, Wilts; the Messrs. Holmes, Derby, have built 40, varying from 80*l.* to 120*l.*; at Laverstoke Mills 18 detached cottages have been built, with two and three bedrooms, at an average of 160*l.* each; at New Bagley Mills, about 100, built of stone, varying from 100*l.* to 140*l.* each; at the Panmure Works, Dundee, dwelling-houses to accommodate thirty families, and thirty self-contained cottages, of three rooms each, besides some single apartments for single women, have been built within the last ten years, at a cost of 7,800*l.*; Messrs. Ransome & Co., Suffolk, have built fifty cottages of five rooms each, and Messrs. Winfield & Co., Birmingham, thirty, costing about 100*l.*; but without plans it is impossible to learn more from

this list than the bare figures quoted. If we include the Ackroyd and Saltire Dwellings, we here see an aggregate of 4,000 houses. It is difficult to over-rate the amount of comfort and health that might have been conferred upon their occupants if every sanitary provision now available and recognised had been adopted in their construction. Consumption and typhoid fever have still to be rooted out. One piece of information imparted by Mr. Rhind, the surgeon, respecting Saltire, should be repeated in every possible quarter. When, during the visitation of cholera, a system of disinfecting and deodorising, by means of the application of carbolic acid and chloride of lime to the drains, ashpits, privies, and sinks, was carried out, not only was cholera absent, but an immunity from typhoid fever was experienced.

In reply to the question addressed to the building societies, "Has the establishment been remunerative or not?" most of them answered in the affirmative. Columbia-square realizes a return on the cost of 2½ per cent., as nearly as possible; the Hastings Cottage Improvement Society, of 5 per cent.; the Industrial Dwellings, 5 per cent.; the London Labourers' Dwellings, 6 per cent.; the Marylebone Association, 2 per cent.; while the Leeds Permanent Building Society speaks of success in more general terms, and the Metropolitan Association begins to share the prosperity of its fellows. Of Mr. Vance's Dublin Model Lodging-houses, only those for families have been remunerative. All consider themselves successful in other respects, such as their appreciation by tenants, favourable influence on the death-rate, and general prosperity.

Nine of the co-operative societies declare their respective establishments to be remunerative. Their various modes of operations, restrictions, and qualifications are here all seen at a glance. Tracing the career, by way of specimen, of the Rochdale Equitable Pioneers, we are told the principal object of the establishment was to purchase food, firing, clothes, and other necessaries, and to improve the social and domestic condition of its members; that it was formed by some twenty or thirty working men, mostly flannel weavers, joiners, and warpers, in 1844; that it employs 138 males and youths to sell goods and make clothing in its shops; that it has realized a profit of 187,850*l.* up to 1866; its annual income at that date was 249,122*l.*, but increases every year; its annual expense the same year for its nine grocery and branch shops and wages was 7,705*l.* 4*s.* 4*d.*; that its paid officers consist of ten committee-men, who are allowed on an average 1*s.* 6*d.* per week, for attending a meeting to manage the prosperous concern once a week, and various other particulars, not the least praiseworthy being an annual apportionment of the sum of 700*l.* and more to the support of a library and eleven news and reading rooms, and 493*l.* for educational purposes. The fortunes of all the other societies also deserve consultation, and the map of them, so to speak, spread out before the eye, must suggest serviceable comparisons.

On the other hand, none of the Sailors' Homes are remunerative; nor is it intended they should be so. One glance at the bill of fare at the Cornwall House, which tells of eggs and bacon for breakfast; roast beef, beer, vegetables, and plum-pudding for dinner, and beef-steaks with tea, and at the separate hot and cold bath, explains this fact. As a large number of those who avail themselves of its hospitalities are either sick, shipwrecked, hurt, or destitute, this, and of course similar institutions, must provide for very disastrous needs. No plans are given of the buildings.

The minute particulars of the miscellaneous institutions give this comprehensive volume an additional interest. Never before, indeed, has there been such a specification laid before the world of what great-hearted people have devised at different times and in different places, to benefit sections of their fellow-creatures. The two localities claiming to have special institutions were Halifax and Ipswich. To go to Halifax really seems as wise a proceeding as is possible to any one. This proverbially celebrated town was created a borough twenty years ago, and in the interval has laid out 415,943*l.* 17*s.* 9*d.* in improvements, and at the date of the report was expending 133,759*l.* in improving these and making others; these sums, with the cost of the park presented by Sir Francis Crossley, bring up the municipal properties to a value of considerably more than half a million of money. Nearly 60,000*l.* have been expended in sewerage works;

and the amount of money laid out by the wealthy manufacturers upon the building and maintenance of charitable institutions is much more considerable. Thirty-two schools, three sets of almshouses, an orphanage, five relief and friendly societies, five co-operative institutions, six literary institutions, a school of art, a chamber of commerce, a piece hall with 315 rooms in it, and a building society, surely entitle Halifax to say to neighbouring towns, "Do ye likewise."

The Ipswich claim is represented by much smaller figures. The locality is limited to the district of St. John's, California, a tract of unproductive land purchased by a freehold land society, in 1850, and subsequently allotted out in plots, many of which were built upon. The particulars state that about twenty persons occupy houses of a rental of upwards of 10*l.*, about 1,800 persons occupy others varying from 7*l.* to 10*l.*, and about 100 occupy houses of less rental. Of these 320 are freeholders. This industrial settlement is furnished with eight spiritual institutions, such as a church, a chapel, Sunday school, district visitors, &c.; six intellectual institutions, including a working man's institute, a national school, and a library; and five physical institutions, a penny savings-bank, a clothing club, a mothers' meeting, a lying-in charity, and a coal-club. The town of Ipswich enjoys institutions on a larger scale, five-and-thirty of which are mentioned. Let us hope the number of worthy claimants under this heading will, on any future occasion, be much larger.

A French jurymen and artist, M. Dufresne, in one pithy sentence, expressed the pent-up determination for future effort and scorn of all national sloth and slovenliness that must have animated many a breast as its owner strayed through the wondrous courts of the great market that elicited these reports—Miserable is that country which, after this exhibition, cannot comprehend the necessity of progress. We heartily commend our own Department of Science and Art for its attempt to bring many of the lessons taught by it home to those whom they concern.

IMPROVED INDUSTRIAL DWELLINGS, AND INCREASED INDUSTRIAL BURDENS.

FROM either extreme of the social scale we are supplied with forcible illustrations of the magnitude of the revolution which is actually taking place in the country. These indications are not confined to extremes. In every rank and walk of life similar cases occur. But each of us is apt to consider his own case as special, or to hope that his own inconvenience is temporary. In the hurry of daily life it is rare that a man can find time to take philosophical and comprehensive views as to the relation of social phenomena, or to connect the increase of his weekly bills, or the continued want of a tenant for the house he has to let, with any great national change, or secular movement.

Yet, for many reasons, it is highly desirable that such broader views should be at all events occasionally taken; and especially will this prove to be the case when the condition of the poorest and the most helpless members of the community appears to involve unusual, or increasing, hardship. Want is the most eloquent and the most terrible missionary of discontent. The hungry man, still more strongly the husband of a hungry wife, the father of hungry children, is likely enough to question very urgently the justice of that state of society in which it is possible for a stalwart, industrious, orderly man to be hungry. He is apt to lend a very ready ear to those who tell him that political change means the cheapening of the quarter loaf, and work for all who want it. Can those of us who have not his bitter experience blame him very severely? Be that as it may, one lesson is taught by all history, with one consent, and that is—that the great instigator of all violent and disastrous political revolution has been widespread and intolerable want.

The revolution which, with silent and rapid step, is advancing in this country, is not political. At least it is not to the political changes, he they more or less important, that have succeeded the great movement of 1832, that we at all wish now to refer. But there is an impression, right or wrong, in the minds of many, that, amid all the brilliant triumphs of science, march of art, and spread of education, the poor man is becoming daily poorer, and the rich man richer; that the disparity between the two extremes of the social

scale is rapidly on the increase; and that, for all intermediate ranks, the battle of life is becoming, day by day, one in which the combatants are more likely to succumb.

The question is a wide one. It is, however, to one branch of the subject that we will confine our attention; and the chief reason for now bringing the matter before our readers is the wish to call their attention to an instance of which we may call commercial courage and benevolence in the face of considerable discouragement.

A distinct, positive, tangible proof of the increase of pressure upon the poor may be found in the increase of rates. The visits of the tax-gatherer, we are told by those who well know what they are saying, are viewed with undigested dismay by the occupants of weekly tenements. So much is this the case, that there is a disposition to prefer the meanest and most squalid lodging, in which this functionary is unknown, to those more decent, healthy, and commodious dwellings, which a wise and charitable enterprise is now gradually offering to the industrious poor, where the moderate rent is accompanied by the obnoxious quarterly demand. Nor is this to be wondered at, when we glance at the statistics of the case. In the parish of St. Pancras, the local taxation on a five-shilling tenement is 8*d.*, the rent specified being weekly; of this 8*d.*, 3*d.* is an increase due to recent legislation. In St. James's, Clerkenwell, the taxation on a 6*s.* weekly rent is 9*d.*; an increase of a little over 2*d.*. In St. Saviour's, Southwark, for 6*s.* paid as rent, the tax-gatherer demands 10½*d.*, being an increase of about 3½*d.*. In the parish of St. Mary, Islington, both the proportion and the increase of taxation are nearly identical with those in Clerkenwell. The average increase of taxation on all small tenements in these four parishes, consequent upon the enactments of the Reform Bill of last session, is 37½ per cent. A measure that proposed for the first time to give political rights to the working-classes of the metropolis has saddled them with an increase of nearly 40 per cent. on the taxation of one of the first necessities of life. No such increased burden is imposed by the Act on the middle and upper classes.

Such is the testimony of Alderman Sir Sydney Waterlow, M.P., a man whose name is far from being unknown among those who have striven to draw a broad and permanent line of demarcation between the exercise of practical and permanent charity, and the relief and encouragement of mendicancy. Our readers may be aware that a few years ago a company was established, on the limited liability principle, for the purpose of improving the dwellings of the working classes in the metropolis. The leading idea of this enterprise was, that charity would be most efficient if placed on such a basis as to be self-supporting. In other words, so wide a margin existed between the enormous rack-rents exacted by the proprietors of those pestilential and squalid dens in which the very poor are driven to take shelter by the night or by the week, and the payments that would yield a fair return, in the shape of rent, for money invested in the erection of decent and well-considered tenements, that persons who could not afford large donations, might yet render good service to their fellow citizens by investing a certain amount of money, not with a view to actual profit, but, at the same time, without losing the ordinary rate of interest which might be obtained by other safe means of placing such funds.

With this view 50,000*l.* were subscribed in 100*l.* shares. 46,575*l.* have been subscribed in 25*l.* shares, and 3,425*l.* are still required to make up the total proposed capital of 100,000*l.* On the completion of this capital, the company will be able to borrow a second 100,000*l.* of the Government, at the rate of 4 per cent. per annum, making a total available capital of 200,000*l.* The company have purchased estates in the neighbourhoods of Greenwich, Southwark, Willow-street, City Garden-row, Wapping, Old St. Pancras-road, Bagnigge-wells, and Briantia-street; and are in negotiation for a lease of a large plot of land at the end of Ebury-street. On the Willow-street estate, 168 tenements, arranged in six blocks, are half completed, and almost fully occupied. It is expected that the whole will be tenanted by the beginning of March. The Bethnal-green holdings will be ready for occupation in a couple of months. The rental of the finished buildings, after making proper reductions for repairs, and for the redemption funds on account of leasehold property,

allows of a dividend at the rate of 5 per cent per annum, carrying forward an undistributed balance of 800*l.* to credit, that of the former half-year having been 526*l.*

It appears that the different objects of the association have been thus far fully attained. That essential element of civilisation, of morality, and of health, a decent home, has been provided, and is being provided, for 3,890 persons of the working classes, in those great centres of population to which we have before referred. The benevolent work of the company is being gradually, but surely carried out; and this worthy and admirable enterprise is shown to be based on a strictly self-supporting principle. We have here all those elements which are most in accordance with the example of him who showed mercy to his neighbour who had fallen among thieves.

It is lamentable to see the directors of this model enterprise confronted, and almost paralysed, by the enormous increase of rates above referred to. At present, the directors have taken this heavy loss upon the shoulders of the company. In the hope that things would mend, and that the burden would not be of long continuance, they have forbore to ease the pressure on their resources by any increase of rent. They have not as yet thrown the load upon the ultimate point of resistance—the poor man. But while they, perhaps rather nobly than providently, have shunned to discharge their natural function in the distribution of legislative justice, what has been the case elsewhere? What other landlord has made a present to his poor tenantry of an amount equal to an augmentation of local taxation of from 40 to 60 per cent? The effort of the conductors of this company may enable us to gauge the torments amount of pressure, (which the mild winter of 1868-9 has to some extent alleviated) thrown upon the unrepresented and uncomplaining poor.

One cause of this pressure may be found, there can be little doubt, in the cost of those improvements which are now for the first time enabling London to take a respectable architectural rank among the cities of Europe. We naturally feel inclined to regard such expenditure rather with reference to the ultimate reproductiveness of its results, and to the justice of its temporary distribution, than as objecting to its actual amount. But there is, as we promised, a deeper cause at work. Increase of rent, increase of taxes, increase of the cost of food, of firing, of clothing, of every necessary of life, are not peculiar to London. Such increase occurs at Paris, at Florence, at Berlin, at Naples, at New York, at Sydney. Wherever we have any statistical return the same tale is told. In many cases some special reason may be offered for the change. The Parisians will debit the luxury of the Second Empire, and the munificence (with their funds) of their absolute prefect, with the increased cost of the means of living in their gay capital. The Florentines will attribute it to the elevation of their city to the new dignity of metropolis of the kingdom of Italy. So with Berlin. New York may point to the thronging crowds of emigrants, or to the anomalies of the "gold ring." Other places may have little to say except that so it is, that they do not understand why, and that the fact is almost intolerable. A more cosmopolitan reply may be found in the very ugly fact that the 2,600,000 soldiers who were (at least on paper) under arms in 1818, have swelled to no less than 7,000,000 in 1869. But there is yet another cause, and that is the unconscious, silent, steady change that has been wrought in all the monetary relations of the civilized world by the large and sustained influx of gold from Australia and California.

When gold, which measures all things, itself varies in value, disturbance is sure to ensue. In the changing ratio of value that occurs between commodity and commodity,—between gold, for instance, and iron, gold and paper, gold and flour,—matters will sooner or later adjust themselves with more or less accuracy. But in the disturbance which takes place between the price of commodities and the price of labour, this self-adjustment is more difficult. The employer of labour does not see it. Those whom he employs tell him they have to pay higher rents, higher prices for food—more money, we may say, to keep the wolf from the door,—and he replies, "So do I; we are all in the same boat. I do not obtain more labour from you than I did in 1818; therefore I cannot afford to pay more wages."

Very true. But the employer is actually

paying less. He forgets, or he does not know, that the quarter of an ounce of gold with which he remunerates the week's labour of a workman is not now what it was in 1818. It is the same in weight, the same in purity; it bears the same image and superscription; but it is not the same in purchasing power. The workman cannot purchase so many of the absolute necessities of life, turn where he may, with that quarter of an ounce of gold, that he could twenty years ago. Therefore it is not actually, although it is nominally, the same wage that it was at that time.

It is a matter of minute and curious investigation to appreciate the amount of this disturbance of value. We are not about here to attempt it. We may indicate some of the facts which must be collected and compared in order to throw light on the subject. On the one hand, there is the steady increase in the annual supply of gold. The annual yield of all the gold districts in the world at the beginning of the present century was a little over four millions and a half sterling. In 1818, it had risen to nearly nine millions. The importation of gold coin and bullion during 1867, into the United Kingdom alone, was 15,800,000*l.*, or between three and four times the annual product of the whole world sixty years ago. Such a change must, infallibly, tend to stimulate luxury, to diminish the purchasing power of gold, and to increase the difference between the actual and the nominal value of wages.

In articles of luxury and of *virtù* the disturbance of price has been most palpable. Diamonds and some other jewels command three times the price which they would have fetched a quarter of a century since. A yet more remarkable increase has taken place in certain species of china and porcelain. There is an annual addition to the number of jewels, whether that addition be more or less proportionate to the increase of the amount of gold in treasure and in circulation. But if we take objects of which there is not, and cannot be expected to be, any increase in number, while their character as articles of *virtù* is such as to lead to a sharp competition for their ownership, on any occasion of their changing hands, we shall find yet more extraordinary indications of the decline of the purchasing power of gold, or of the increase of that nominal wealth which is displayed by a lavish expenditure. There is a rare kind of earthenware called by the name of *Henri Deux*, ware, of which only sixty-seven specimens are known to be in existence. One of these, of the size of an ordinary dining-dish, was purchased, in 1857, for 140*l.*, at the sale of a French collector, who had given 3*l.* 4*s.* for the article. Another specimen of the same ware, a highly decorated ewer, was purchased, in 1812, for 80*l.*, and is now estimated as worth 2,000*l.* Specimens of a manufacture which is not to compare with the fine porcelains of China in beauty, will now fetch more than their own weight in gold.

It is thus clear that, in any attempt to improve the condition of the poorer classes, in any investigation of the laws for the protection or regulation of labour, and in all questions that relate to the community of interest that exists between the rich and the poor, we shall work altogether in the dark, if we neglect to allow for the important element of the depreciation of money. This has nothing to do, or at least little to do, with the question of the price of money measured by itself; that is to say, the rate of usance. Five per cent. may be the average annual usance for a hundred sovereigns, whether their purchasing power be more or less. But in all quarters we may detect a steady decrease in the purchasing power. In articles of imaginary or of merely æsthetic value, this decrease is the most enormous. In such matters as rent and taxes, it presses most closely upon the poor man. An adjustment, voluntary or compulsory, of the remuneration given for labour, is necessary, under such circumstances, to continue to the poor the means of subsistence. It is the theory of a certain school that this adjustment must be spontaneous, and cannot, with safety, be interfered with by legislative enactment, or by any means that should clash with the working of the law of supply and demand. We are not, now, about to controvert that view. But it is, at least, necessary that the subject should be understood. It is essential to the continuance of any satisfactory relation between capital and labour, that it should be understood on all hands that 1*l.* a week, in the year of grace 1869, is very different from 1*l.* a week in the year 1847. It would even be desirable to know the rate of this

difference. But it is quite clear that the employer ought to be aware that, in paying the same nominal sum, he is not paying the same actual wages. His pay costs him less—it will purchase less for his servant. If the employer of labour choose to say,—“Labour is so much more plentiful now than it was twenty years ago, that I can get plenty of men to do for 10*s.* 6*d.* per week work for which I used to pay 1*l.* a week, and I shall take advantage of that change in circumstances,” his language is perfectly intelligible, and quite accordant with the doctrine of the school to which we refer. But if he says, “I paid 1*l.* twenty years ago, and I pay the same now, although the present value of 1*l.* is, to the former value or purchasing power of the same sum, reduced to the worth of, let us say, 10*s.* 6*d.*,” he is deceiving either himself or his workman, or both. It is high time that this confusion should no longer form one of those numerous evils that render still harder the fate of the poor man. The very noteworthy struggle of the directors of the company for promoting improved dwellings for the poor, against that increase of rent which is one of the effects of this silent but prodigious change in the purchasing powers of the poor man's weekly wages, deserves to be made known to their honour. The attention both of the producer and of the consumer of labour, of the labourer and the capitalist, cannot be too carefully given to this aspect of that never-closed controversy which assumes, ever and anon, some fresh phase. Let us not have to add, some fresh feature of bitterness.

THE ARCHITECTURESQUE.

Nor only am I personally obliged to the learned writer in your last issue for his painstaking treatment of the question I have ventured to raise, but I think the cause involved (for, as I have repeatedly said, I advocate the word merely to formulate the much more important idea) is materially served by such scientific investigation, and therefore I hope there will be more of it.

It seems to me that your article has fixed much more effectively than I had done a definite and separable meaning to the termination “*esque*,” and I think I can fully accept that meaning, and turn it to most useful account. Let us for the occasion take the syllable in question as a separable word, and speak of the “*esque*” (under reserve) as an entity of language, and, of course, of thought and criticism. Now it is this *esque* of architecture for which I claim recognition; and I cordially agree with you that “there is little question of how we may apply the term, but very much indeed of how we must.” Architectural criticism, I consider, has arrived at that point in England when the study of this *esque* as an idea ought to be taken in hand; and I cannot help acknowledging it to be of vital importance to the idea itself that its phraseological formula should have no uncertain sound. Indeed, it is obvious enough that analogy alone has suggested the term I have proposed; and therefore, as I have appealed to analogy, to analogy I must go.

This *esque*, then, means *like*. Pietresque is like a picture. Sarcosque is like a statue. Sculpturesque is like sculpture. Grottesque is like the grotto. Barlesque is like the *barlure*, to like the grotesque, or rather was, like the Roman; Arabesque, like the Arabian; Moorsque, like the Moorish. Structuresque, let me go on to submit, is like structure, and architecturesque like architecture; and, indeed, I see no objection to accept the suggestion which arises, that there may be a good many more of these *esques* (chiefly, if not invariably, matters of art), not as empty phrases, but as substantial facts, worthy of recognition and contemplation, each in its degree.

Now for the analogy. Every one of these *esques* is a “*like*”; but the *likes* are not all one *like*. Translate the word *like* in each case by a perfect synonym, and it will be found that your synonyms are different—not very materially, but no matter how slightly. They will all agree however, in one respect—that in no case will they properly apply to mere superficialism so much as to an occult spirit under the surface. The *esque* is a *soul*. The architecturesque is the soul of architecture, as opposed to the semblance.

Again, there are the *esque* in matter, the *esque* in manner, and the *esque* in product—in artistic subject, that is to say, in artistic treatment, and in artistic result. So we perceive the

first picturesque in the bearded mendicant, the second picturesque in the painter's process of ennobling him, and the third picturesque in the banished lord. Likewise we may perceive the matter architecturesque in the structure-forms of the building, the manner architecturesque in the artistic treatment of those forms in detail, and the product architecturesque in the resulting art-work of a perfect architectural whole.

As a foil to the *esque*, let us take the *ish*, in pursuance of another good suggestion of your accomplished writer. "Picturish" I think formulates a very common fact; I am sure "architecturish" does so. If the *esque* is a soul, the *ish* is a semblance, a *simulacrum*, very much of a cheat. This is a readier way of expressing what I have called the spurious of the *esque*. But, as it savours of a cant phrase, I should not like to apply it practically except in avowed contempt; to everything whose error was more respectable I should prefer to use the more respectful term of spurious, or pseudo, or even fallacious architecturesque. The Brighton Pavilion, and one at least of the Thamea bridges, and a great deal of the shabbier class of our current *Cathartes picturans*, are architecturish; Somerset House, with its superfluous of great columns built up as mere buttresses to a wall; or St. Paul's, with its sham sides and sham dome; or the Duke of York's Column, with a stair in its bowels and a cage on its head, I prefer to treat more in sorrow than in anger, as aberrations of the architecturesque.

The avenue of trees I should scarcely venture to call in any sense architecturesque; its "likeness" to architecture is only in semblance, and incidental, not to say accidental. But Stonehenge I should call architecturesque, although not architectural, for the sake of its array. So also Trafalgar-square is very creditably architecturesque in plan, and Charing-cross very discreditably the reverse. The French are masters of the architecturesque in site: Trafalgar-square is almost on a par with some of their average efforts, whilst Charing-cross is more worthy of the genius of Hotentotland, and is likely ever to remain so. Would that Hansmann had the handling of it!

What is called an "Italian or architectural garden" seems to be an example worth contemplating. A natural garden would be something entirely unregulated by art, however charming in effect; if *naturalesque*, it would be artistic on the basis of being "like" the natural; if *picturesque*, it would be picture-like in the usual sense of the term; if *architectural*, properly speaking, it would involve some smob compositions as terrace-walls and balustrades, pavilions and fountains; if adorned, to whatever extent, with sculpture or statuary, it would be an error to call it either *sculpturesque* or *statuesque*; but, if merely disposed in architecture-like array, although the features may be but plain

curbs and edgings, and clipped hedges and geometrical plan, it is *architecturesque*; and if we would consent for the future so to designate it—an "architecturesque garden"—how much more expressive is the name!

A hasty problem,—an iron bridge; first, strictly structural; then structuresque, like structure; then architecturesque, animated by the spirit of architecture (of which the structuresque or architectonic, as I think, is obviously an important element); then, if you desire it, picturesque, by way of special licence. Observe, in passing, that the architecturesque, in such an example, asserts itself very distinctly as the artistically structural plus the structurally artistic.

Permit me to repeat my thanks to my collaborator, and to express the hope that he will consider me not to have in any way contradicted his excellent argument, but only to have done my best to carry it forward. ROBERT KERR.

THE GUTHRIE MEMORIAL CHAPEL, CLIFTON COLLEGE.

The Guthrie Memorial Chapel, which we illustrate this week, was completed and consecrated by the Bishop of Gloucester and Bristol during the summer of 1867.

The Very Rev. Canon Guthrie, in whose memory this chapel is erected, was the first chairman of the Clifton College Company, and might almost be styled the founder of the College from the great zeal he displayed in its establishment. Dying during the year 1866, his widow resolved to erect a chapel at the College in memory of her husband, well knowing that it had always been his earnest wish to see the chapel built, and for which object he had offered the sum of 500*l*. Before the walls were half up, Mrs. Guthrie also died, and thus the building is in a double sense the Guthrie Memorial Chapel.

The designs were prepared by Messrs. Charles F. Hansom & Son, the architects to the Clifton College Company; and when the college is completed the chapel will be joined to the main building by a continuation of the cloister.

The entrance to the chapel is at the west end, and opposite the door is the archway (now blocked up) which will communicate with the completed college buildings. On the right is the antechapel, over which is a tribune for visitors, approached by the large stone staircase in the tower, immediately on the left of the porch. The remainder of the building consists of nave, 75 by 33 ft.; chancel, 37 by 26 ft.; and organ chamber and vestry, with heating vault beneath them.

The antechapel is divided into three bays by stone arches, has a stone seat all round, and is lighted by an arcade at the west, the whole of

which is filled with stained glass. Each bay has a beautifully carved cornice running all round. In the central bay is the archway leading into the nave. The seats for the boys are arranged on either side, each raised a step higher than that in front, in the proper collegiate form, and a certain number of stalls are provided at the west end for the masters, the one for the head master having a carved canopy. The nave is ceiled in a polygonal form, and divided into panels by wood mouldings. Only one bay is at present decorated. The height of the nave is 50 ft.

The chancel arch is 42 ft. high by 22 ft. wide, with triple shafts and carved capitals. The chancel terminates in an apse semi-diagonal in form; in each angle are stone shafts supporting the ribs of the roof. The ceiling is curved and divided into panels like the nave, the whole being decorated with medallions of gold and colours on a light-blue ground, executed by Mr. John Buggins, of Bristol. An arcade runs round the chancel under the windows, with Devonshire red marble shafts and carved caps. The windows above have also marble shafts and carved caps. The whole of the sculpture and carving was executed by Mr. R. L. Boulton, of Obeltenham, who also executed the pulpit in Caen stone from the designs of the architects.

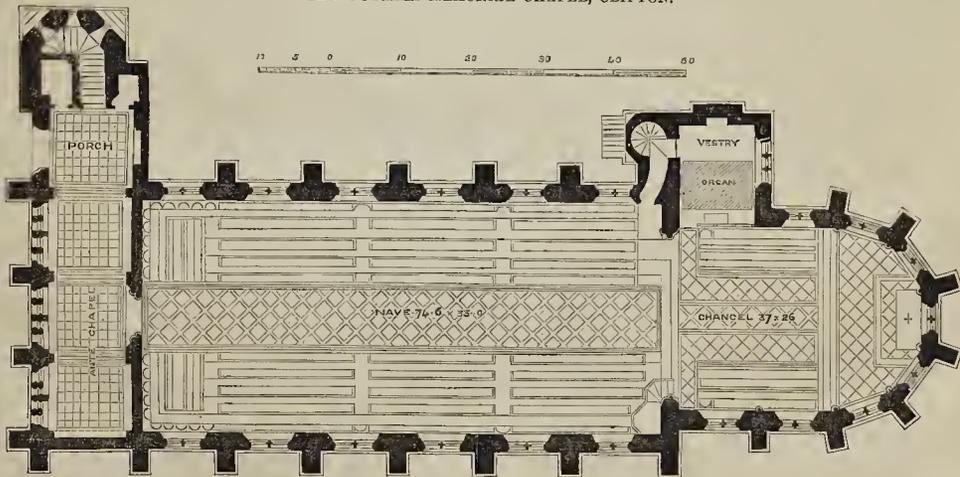

The floors of nave, chancel, and antechapel, except under the stalls, &c., are laid with encaustic tiles by Messrs. Maw & Co.

Stalls are provided in the chancel for the choir, and immediately behind those on the north side stands the organ. A small circular staircase gives communication between the vestry and the outside. The chapel is heated with hot air by Messrs. Haden & Son, of Trowbridge.

Externally, the nave is divided into seven bays by rather massive buttresses, between which are two-light windows. The windows of the chancel are also of two lights, but much longer than those of the nave. The ground falls considerably at the east end, and gives the apse great elevation, being about 40 ft. from the ground to the eaves: a freestone cornice runs all round above the windows, ornamented by carved heads. The west end contains a large circular window in the gable, of very rich tracery; also three carved medallions with angels holding scrolls or musical instruments; in the lower part is the arcade of small windows lighting the antechapel. At the north-west corner stands the small tower containing clock and bells. The clock stands out on a bracket at right angles to the tower, so as to be seen from the college playground. The tower is about 100 ft. high, and this, together with the foundations of the chapel, was built by the council of the college as their memorial to the late chairman, at a cost of about 1,000*l*.

The style of the chapel is Early Decorated. The tracery of all the windows is geometric. The three end windows of the apse contain

THE GUTHRIE MEMORIAL CHAPEL, CLIFTON.

Plan.

stained glass by Messrs. Hardman; the two are filled with stained glass by Mr. Joseph Bell, of Bristol, who also manufactured that of the antechapel, and the nave side window giving upon the tribune. The west circular window contains stained glass by Wailes, of Newcastle. This window has demi-figures of the twelve apostles, with our Lord in the centre circle, surrounded by cherubim, and was especially designed for this subject. There is an oak lectern by Hardman.

This building, without the tower, was erected for the sum of 4,500*l.* by Mr. James Diment, builder, of Bristol; Mr. Charles Lewis being the clerk of works. Several of the stained-glass windows, fittings, &c., have been contrived by the masters, boys, and friends of the college, and more stained glass is now being prepared by Messrs. Hardman.

ON VENTILATION.

On the 24th inst. Dr. Edward Smith, F.R.S., read a paper on this subject, at the Society of Arts. After setting forth, first, general principles, and, second, modes of ventilation, the lecturer stated thus the conclusions to which a consideration of the subject and his official experience had led him:—

1. Interchange of air which proceeds both by diffusion and removal is not instantaneous. The rapidity of the interchange varies with many circumstances.
2. The effects of any natural system of ventilation vary with the season as well as with the special conditions of a building and the number of inmates.
3. There is a relation between ventilation and temperature, which in reference to inhabited rooms is generally an inverse one, and as the human body requires a temperature of the air of from 55° to 65°, according to the season, ventilation in cold weather must be restricted by the lower, and in hot weather by the higher temperature.
4. The movement of the air, although so essential to health, must not be very perceptible, lest it should cause discomfort and disease. Hence the inlets and outlets must not be very near to the inmates, and the current must be divided.
5. The ventilation should, if possible, be self-acting, after the amount required in a given room and under given conditions has been fixed.
6. Any general rule which may be laid down as to the number and size of the ventilators required in a room will demand modification by experience, since the admission of air will depend upon the elevation of the site, the direction of prevalent winds, and the impediments which surrounding walls and buildings offer, and these cannot be the same on all sides of a building.
7. Some differences in the plan, and much in the extent to which the plan should be carried, must depend upon the use of the rooms and the destination of the building, as to whether it be a private house, a public building with a fixed number of occupants, or a building, as a theatre, with a very varying number.
8. There is a relation between space and ventilation, for it is evident that with defective ventilation (not entire absence of ventilation) the larger the quantity of air in relation to the number of occupants the less the immediate evil, whilst at the same time, the larger the mass of air to be moved the greater is the force, or the more extended are the means, required to move it. In private houses the cost is often unimportant, but in general, and particularly in reference to workhouses, hospitals, and other charities supported by voluntary contributions, the aim should be, by providing the best ventilation, to reduce space to the strict requirements of the occupants, and thus to utilize in the greatest degree the money to be expended. That relation must be determined by experiment. Both architects and amateurs are apt to give undue weight to the lofty, spacious, and handsome appearance of their buildings, and too little to the solution of the problem of fitness with economy.
9. The test cannot be the life or death of the inmates, for health may be falling long before it ceases. Moreover, there are various degrees of health, and each person has a separate aspect of health, and it is not at all easy to indicate in particular cases the first period when some injury may have been done to it. A test is required by

which we may infer that injury would result if the cause were continued, and this must clearly be derived from observation. A close-smelling or a foul-smelling room may not be immediately injurious to health, but it is disagreeable at the least, and as such should not be allowed; and although the most injurious emanations from the body are not offensive to the smell, their emission is accompanied by the emission of offensive odours, and the two will co-exist. There is thus a relation between them which may be made useful as a test, so that if in an inhabited room the air be foul to the sense of smell it may be regarded as injurious to health. But the degree of relationship is not exact, since an uncleanly person, or even a cleanly one having the peculiarity of emitting strong odours in an unusual degree, will cause the air to be foul almost as soon as he enters, whilst another cleanly person may stay some time in the same room before rendering it offensive. Hence, in making the estimate, we must strive to ascertain whether the foul smell proceeds from dirty clothes, and particularly dirty stockings and unwashed skins, or is simply that which occurs with cleanly persons. When there is no offensive smell it may be assumed that the ventilation is sufficient; but as a certain amount of want of freshness, or closelessness, is found in our bedrooms or other rooms without known injury to health, I am of opinion that the ventilation is sufficient when the air, after the night's use, is not more offensive than is found in an ordinary private bedroom of the middle classes. Absolute purity of air in inhabited places, whether rooms, houses, public buildings, courts, streets, or towns, however desirable, is not necessary to health, and is not attainable.

10. The test cannot be the means provided to effect the passage of a given quantity of air through a room in a given time, for if the ventilation depend upon natural agencies, it will vary with the force and direction of the winds, the impediments to their action upon a particular ventilator, the frequency with which doors are opened, and other varying causes. If the room were closed, except at particular places, and the air were, by artificial means, conveyed through apertures at a known rate, it would be possible. We do not, however, live in closed boxes, and we cannot separate ourselves from the influence of natural causes.

11. Where persons do not occupy the same room or rooms throughout the 24 hours, but use other rooms, and particularly spend much time in the open air, defective ventilation of those rooms will be less injurious in proportion as they are used for a shorter period of time.

12. The cost of ventilating buildings is usually of importance. None can be so little as that mode which introduces the external air directly, but with proper safeguards, whilst all artificial systems are expensive.

13. No system can be efficient, in a public institution, which depends upon windows, doors, and fireplaces alone; but, for thoroughly renewing the air on fitting occasions, it is desirable that there be windows on both sides of a room, and particularly in public buildings.

14. When air is introduced on one side of a room only, whether by windows or by ventilators, the extent of its influence will vary with the conditions already named; but there is a relation also between it and the width of the room in reference to satisfactory ventilation. It is evident that, with little force of wind, the air will penetrate into the room but little, and with greater force the more; and also that, with a given force of current, the narrower the room the more certainly will it traverse it, and the wider the more certainly it will not traverse it. Hence, with such an arrangement, a wide room will be less perfectly ventilated than a narrow one, and a point may be readily reached at which the influence of such means of ventilation will be nil. Rooms with windows or ventilators on one side only should be very narrow, and still more so if there be no ventilation apart from the windows. A wide room, with windows only on one side, and no special ventilators which act permanently, must be ill-ventilated and unhealthy, as has been shown in the Nightingale Ward of King's College Hospital.

15. When air is introduced on two opposite sides of a room by windows or special ventilators, the current will usually extend further than twice the length of the current from one side of a room; and, as the wind will usually act upon one or the other side, the current will have greater force than with air-openings on one side only. But there is a limit to the width of rooms

so arranged; for, as the current must not be too great to be borne by those inmates who are placed near the external walls, its power to traverse the inner space is restricted. In very wide wards the ventilation in the middle is not so satisfactory as that near the external walls.

16. Where air is introduced into the centre of the floor of the room, a current is produced in the part over which the inmates pass and repass; and is, therefore, very perceptible. Cold air in considerable quantity can rarely be introduced with propriety in that position, but warmed air might be borne.

17. Each room should be so constructed that its ventilation may be independent of that of staircases or any other room; but where two rooms are placed side by side with a partition wall between them, each having windows on one side only, the ventilation of each is improved in proportion as a part of the partition wall is removed. Thus, one room may improve the ventilation of the other, and both be as if they had windows or ventilators on both sides.

18. Ventilators should be placed on opposite sides of a room, be of small size, sufficiently numerous to affect all parts of the room, defended on the inside by finely perforated zinc, and be placed at the floor-level and ceiling-level.

19. Ventilators in a small part of a room only are insufficient for ventilation, since when a current of air passes between two openings the greater portion goes in a direct line, and does not greatly mix with the air lying on either side of it. This may be readily seen when smoke is admitted by an inlet and emitted by an outlet ventilator, or such an arrangement as exists in prison cells.

20. Where the conditions rapidly vary, as in churches, chapels, and theatres, it is impossible to devise a system which will not require modification by an intelligent person. At present the system is universally defective, and only after the heat has become great and the persons very sensitive to cold are the doors or windows opened. The aim should be to regulate the admission of air from the moment when persons enter, so that the temperature shall never be materially increased, but remain at, say 56° in winter and 62° in summer. Cool air without draughts is better borne than hot air with intolerant draughts. In very lofty rooms the apertures for the admission and emission of air should be below the top, not too far removed from the occupants of the seats, the sources of the heat. In addition to this, however, ventilators should be placed in various parts of the ceiling, and be kept under control by a competent person.

21. Such rooms should be thoroughly aired after every occasion of their use, by the full opening of windows. At present, with three services at a church or chapel, this is neglected, and the air is close, heavy, and foul in the afternoon and evening.

22. No artificial means of ventilation should be relied upon solely, which will not act by day and night and throughout the year. Hence with ventilating stoves, which are very valuable, and ventilating air-floes, there should be other and self-acting means of ventilation.

In conclusion, it may be useful that I should sum up the principal errors into which architects are now falling in the systems of ventilation which they recommend. They are:—

1. In not duly estimating the practical limits of the law, that heated air ascends; and the relation of numbers of inmates and size of rooms in the application of the law.
2. In not duly considering that air-shafts, acting under that law, cannot act in all seasons, and with and without fire alike.
3. In not duly estimating the amount of air which can be admitted by windows and doors alone.
4. In not duly estimating the practical limits to which an entering current may be carried, whether from one or both sides of a room.
5. In not duly considering the effects of currents upon inmates, and the limitation thus demanded upon the amount, force, and elevation of currents.
6. In not duly estimating the inverse relation of ventilation to temperature in its effect upon inmates, and particularly upon the old and the young.
7. In not duly estimating the influence of the winds, and the impediments of surrounding buildings, &c., upon each aspect of a building.
8. In having incorrect views as to the direction of the current through ventilators at different elevations.

BLACKFRIARS BRIDGE.

This new bridge, whose progress we have on several occasions noticed, and an illustration of which appeared in our volume for 1862 (Oct. 11), is making progress. Mr. Joseph Cubitt is the engineer-in-chief, and Mr. Bryant is the resident engineer, with whose aid we are able to describe the present state of the work.

The bridge has now arrived at such a stage, especially at the Surrey end, that a very fair idea may be gained of what the general effect will be when the whole is finished and freed from the confusing influence of the forest of scaffolding that now hems it in on both sides.

The axis of the new bridge coincides exactly with that of the old one, but the new structure will have the following great advantages over its predecessor, viz.—first, in having the roadway over the central arch only 10 ft. 6 in. above that of the banks on either side, or half the rise of the old bridge; secondly, in being 75 ft. wide between the parapets (45 ft. roadway, and two footpaths of 15 ft. each) against 12 ft. originally; and, thirdly, in consisting of only five spans or arches, thereby giving greater and more convenient waterway. The length of these arches corresponds very closely with the spans of the London, Chatham, and Dover Railway bridge, which is in close proximity to it on the eastern side, for the purpose of facilitating the navigation of the river.

The central arch is 185 ft. in clear between the piers, those on either side 175 ft. each, and the end arches springing from the land abutments each 155 ft. span. The central piers are 20 ft. 6 in. wide, and the remaining two 18 ft. 6 in. each, making a total length of bridge clear of the shore abutments of 938 ft.

Great care was taken in preparing a good foundation for the piers. Metal caissons were sunk into the bed of the river for about 38 ft. under low-water mark, and filled with concrete for half this height. Upon these foundations solid brickwork was raised to the level of the natural bed of the river, and upon these again was built the pier itself, consisting of solid brickwork faced with granite.

The plan of these piers is similar to that of the adjoining bridge, and resembles a double stemmed ship with sharp outwater. A short distance above high-water mark, these outwaters are played back in two orders, until the sub-plinth and plinth are reached, upon which rests the base of the detached columns. The mouldings of these bases, and also those to the caps, are of an Early Gothic character, and have the lower roll carved with bold conventional leaves, and their under-side is level with the springing line of the arches.

The shafts are of polished red Aberdeen granite, those in the centre being 7 ft. 4 in., and the side shafts 6 ft. 8 in. in diameter respectively, and all tapering slightly towards the cap.

The caps are of stone, octagonal on plan, the bell being carved, and the abacus enriched with the nail-head ornament. Upon the abacus rests the stone parapet, which forms a semi-octagonal balcony or recess from the footway, having seats inside, and raised above the footway by two steps. Each external face of this balcony has two sunk and tracered circles.

The carving of the caps to the columns under the balconies has been entrusted to Mr. J. B. Philip, of Hans-place; and, judging from the models and partially-finished caps, they promise to be the most artistic and attractive features of the bridge.

Mr. Philip has conceived the "happy thought" of brightening the contrast between the two sides of the bridge, by introducing into the carved caps, on the river or western side, birds and plants, such as the stork, bittern, swan, &c., that are to be found in fresh water; and on the sea or eastern side, the sea-gull, sea-weed, &c. *id genus omnia*.

The shore abutments are composed of massive wing walls, which are flanked with pilasters that form the base of large pedestals, and three counterforts of brickwork, the space between being filled in with concrete. These pedestals have a simple moulded base, and carved and moulded capitals finished with a square blocking course, on which equestrian statues might be placed with good effect. From these pedestals a low wall runs landwards, and terminates against circular piers suitable for supporting lamps.

Down the outside of the wing walls will run the stone steps leading to the river and Thames embankment. On the Surrey side a bridge will

lead over these steps directly into the Blackfriars station of the London, Chatham, and Dover Railway.

On the shore abutments the skew backs, from which the curved iron ribs that form each arch-spring are about 5 ft. above Trinity high-water mark; but in the piers they are more elevated, the springing line of the central arch being about 5 ft. higher.

Each arch is composed of nine curved ribs of wrought iron, segmental in form, braced together with short lattice girders, the spandrel being filled in with lattice work terminating against a horizontal girder above, upon which rests the cross girders that support the metal joists to which the iron plates are screwed.

These plates will be laid over the whole of the bridge, and are slightly hollowed in the centre for the better holding of the concrete and asphalt that will receive the paving of the road and footways.

The lattice work to the external ribs is of an ornamental character, having bosses or flowers at the intersections. The external ribs are finished above with enriched corbels supporting a bold cornice, from which rises the plinth to the parapet. This plinth is hollow, and on the inside, next to the footway, is pierced by a small continuous arcade.

The parapet is composed of alternate couples of plain and twisted shafts, on circular moulded bases, resting on square dies. The caps contain foliage formally treated under a square abacus, from which springs a circular moulded trefoil arch, with foliated cusps. The coping or hand-rail consists of a three-quarter round, with hollows and rope mouldings on either side.

The works on the Surrey end are much more advanced than those at the opposite end of the bridge, the pedestals being nearly completed. The caps to these pedestals have the foliage boldly carved and well arranged; but the neck mould, a plain roll, from which the leaves spring, is too large for the finish of the carving. It should be made up of several small members.

A portion of the iron parapet is in its place over the first arch, counting from the Surrey shore, and the joists laid to receive the metal plates. The caps to the first pier are now being carved; on the sea side the subject is sea-gulls, with extended wings and heads turned on one side; the remaining portion of the bell being occupied with seaweed, conventionally treated. In the opposite cap, on the river side, are storks with wings hanging down against their sides, and bills on their breasts, as though watching for fish. These again are separated by freshwater plants.

The second pier has reached to half-way between the springing of the arch and the level of the roadway, the caps being still in the rough.

The third pier, on the opposite side of the central arch, is finished to the top of the skew-back, but the two arches that spring from it have nearly all the cross girders laid.

The first pier on the Middlesex side has the caps *in situ*, but the arch between it and the shore abutment has little more than the curved ribs erected.

The Middlesex abutment is now level with the top of the cross girders, the eastern plaster being of the same height; but that on the western, or river side, has not yet been commenced.

Judging from the amount of work already completed, and the average rate of progress, the bridge and its approaches should be finished by the end of next autumn.

The original estimated cost of the works was 265,000*l.* The mason's work is being executed by Messrs. Thorn & Co.; and the metal work supplied by Messrs. Lloyds, Fosters, & Co., of Wednesbury.

A TOUR IN SHROPSHIRE.*

A PLEASANT excursion of four miles may be made to Haughmond Abbey, which stands on the side of a gentle eminence. The ruins are not very extensive, but from one part you obtain a very rich and extensive view of the great plain in which Shrewsbury stands. The chapter-house is nearly entire, the front of triple arches with a variety of mouldings. These Norman arches are deeply recessed and highly ornate.† In another of the same character, and in a different portion of the abbey, being supposed to be one of the

* See p. 121, ante.

† Some illustrations will be found in another volume of the Builder.

entrances into the church, you have that and the Early English in the same juxtaposition as at St. Mary's, Shrewsbury. The aliot's lodge is in part standing, and the shell of a large hall. In the former an oriel window was to be found some years ago, but it fell in. Among the privileges granted to the abbey was one by Pope Alexander III., A.D. 1172, which allows "that where there should happen to be a general interdict the monks might perform the divine office in a low voice, but with closed doors." The country adjacent is on every side delightfully rural.

Though it is not exactly within the province of this letter, yet I may mention that it being only an easy two hours by rail from Shrewsbury to Lichfield, I took advantage of it to renew my acquaintance with that place, which I had not seen for some years. As my stay was limited to a few hours, I can of course only convey my general impression of the cathedral of the Black Country. I must honestly confess my repugnance to a "three" spired cathedral. It may be that, having for many years admired and appreciated (and who, indeed, does not?) the heaven-borne spire of Salisbury, I could not bring myself to appreciate "three" repetitions of the same architectural feature in all respects inferior. Besides, at Lichfield, the other two churches have also spires, so that to me the unpleasant effect was repeated. It has, I think, been suggested that a feature resembling the dome or cupola, of course with various modifications, would have been a fine architectural substitute for the central spire. The beauty of the nave admits of no dispute, as well as the choir; but here we find carried out *à outrance* the prevailing disposition to render it as little as possible a "sanctuary" for divine service. Stalls there are none, and the backs of the seats are so low that really, if I may be allowed to use a very homely expression, the congregation in the choir and its aisles are all "jumbled together." I was informed that Mr. Scott proposed to raise the backs by 1 ft., which would in some slight degree mitigate the heterogeneous effect. The apse, with its stained-glass windows as seen over the rood-loft, is very striking. I was informed that the old glass (which consisted of splendid figures of bishops and other ecclesiastics) was destroyed during the Commonwealth time. An illuminated MS., in the possession of the Earl of Winchelsea, is said to contain a representation of these. I attended the afternoon service, but I cannot say that the musical portion was satisfactory. The chanting of the Psalms was both loud and indistinct, and the organ accompaniment equally overpowering. I was gratified to find the report that some hitherto unknown substance, vegetable or mineral, had spread itself over the beautiful recumbent figures of the children by Chantry, was quite unfounded. In the afternoon I returned to Shrewsbury.

Church Stretton, which was my next move, is a very small town, perhaps more approaching its village. The scenery around is very delightful as you are close to the "Long Mynd," a range of about ten miles in extent, a style of scenery, though on a smaller scale resembling that in the principality. In the church, which was under repair and enlargement, I did not find anything of interest. The old townhall, with its arcade underneath, was removed in 1833, as the neighbouring gentry are said to have found it inconvenient. The modern structure is plain and unpretending. A very pleasant walk of two miles will take the tourist to the little village, or rather hamlet, of *Hope Bowdler*, pleasantly situated in the valley. The first part of the name is by no means uncommon in this county and Herefordshire. The situation of the church is very delightful. It is a "most perfect facsimile" of the old Norman building which was taken down as being "irreparable;" whether truly so or not I had no means of ascertaining. But, at any rate, the facsimile is a very perfect one. The windows have been filled with grisaille.

The pleasant little town of *Ludlow* stands on an eminence, commanding fine views of the surrounding country. The church and castle, apparently embosomed in trees, are seen to great advantage from the high bank called *Whitcliffe*, to which you cross by a bridge over the river *Teme*. The church, dedicated to St. Lawrence, stands upon the highest ground in the town, the churchyard being supported towards the north by a portion of the ancient wall. A smaller church stood here in the twelfth century, the remains of which, discovered during the renovation by Mr. Scott, was supplanted by that in the Early English style. The present edifice is

cruciform, consisting of a nave, choir, chancel, transepts, side aisles, and two large chantry chapels, with a finely-proportioned and lofty tower in the centre, having at each angle an octangular turret surmounted by a pinnacle. The principal entrance from the town is on the south side by a capacious hexagonal porch embattled, which, with the exception of that at St. Mary Redcliff, Bristol, is unique of its kind. It had become exceedingly ruinous, and the committee who had undertaken the task had given up all hopes of its restoration, when Lord Boyne came forward and undertook it as a memorial to his parents. The view on the north side in the churchyard looking towards the hilly country round Church Stretton is varied and picturesque. In the churchyard itself are some splendid yew trees. The river is seen from every part of the neighbourhood. There are few parish churches in the kingdom of a more imposing interior. The view from the west window is directed to the magnificent arch which terminates the nave, across the lunette or lantern, which is upwards of 80 ft. high, then to the chancel arch of equal dimensions, with its open screen, all terminating in the splendid east window filled with stained glass. The nave is divided from the aisles by six lofty pointed arches on each side, springing from light-clustered pillars, whose only defect is perhaps an appearance of "tenuity" which detracts somewhat from the dignity and solidity of this portion of the edifice. Passing under the screen, we enter the chancel, lighted on each side by five lofty Perpendicular windows, filled with full-length figures of bishops and other dignitaries, while in the great east window, also of the same style, is represented the legend of the martyrdom of St. Lawrence, the patron saint of the church. An inscription, very imperfect, shows that it was the gift of Spoford, Bishop of Hereford, whose episcopacy was from 1421 to 1443. This window, occupying the whole breadth of the chancel, 18 ft. in width and 30 ft. in height, was repaired in a very imperfect manner about a century ago, but skilfully restored in 1828 by Evans, of Shrewsbury. It contains six-five compartments, in which are displayed the life, martyrdom, and miracles of the saint; but the window was at one time so wantonly injured that some of the subjects can with difficulty be traced. He is said to have suffered martyrdom by being broiled over a fire upon a gridiron for having, when a deacon to Sixtus, the Bishop of Rome in 259, refused to deliver up the church treasury to the heathen persecutors. This and other incidents are depicted in various compartments. In the seventh, under which is the inscription, "Lanreus dicitur coram ydolis," he is represented as led by the heathen emperor before idols, who are represented as "falling to pieces through the sanctity of his presence." This legend was, no doubt, derived from that in one of the Apocryphal Gospels, which narrates that the idols of Egypt fell before the Holy Child Jesus when being carried thither by His father Joseph. In the twenty-second compartment is a representation of a cruciform church, with a small octangular turret in the centre, a curious specimen of ancient architecture. Underneath this window was a modern altar-screen of oak wainscot, which concealed the original reredos, elaborately carved in stone, consisting of a series of pointed niches and aculpture, extending the entire length of the wall. This was restored by Lord Dunsannon, with the zealous co-operation of the then rector. On the south side of the altar are, as usual, the piscina and canopied sedilia. The ceiling is of oak, divided into five compartments, resting on corbels. These are alternately painted of a green and red ground. It was not unusual for the larger parochial churches to have stalls in the chancel, especially when there were several chantries in them, the priests of which were bound to assist the incumbent at the divine office during festivals, as at Nantwich, in Cheshire. These stalls remain on each side of the chancel, and were used by the ten priests of the adjoining chantry of St. John. I have before observed that the lofty windows on each side are rich in figures. In the centre compartment of the window nearest the altar is that of a bearded and crowned king, showing how exactly the vestments agree in shape with those of the two archbishops on each side. Nothing can more surely demonstrate that the ecclesiastical is "borrowed" from the regal costume, as we know to be the case. The offering of the Wise Men occupies the lowest portion of the window, furthest from the altar. Two of these are repre-

sented with very high and much-enriched crowns. It will not, I hope, be considered profane, if I remark, that the attitude and general appearance of the one whose garments are red bear a strong resemblance to the *Knave in our packs of cards*. "It cannot be imagined for a moment," as Mr. Winston observes, "that the Mediaeval glass-painters ever drew intentionally ill." Yet, as all must admit, there is a most striking and manifest discrepancy in most of our ancient churches between the "heathenful symmetry" of the architecture and the lank and often grotesque appearance of the figures in the painted windows. The chapels north and south of the choir correspond in size, and are approached from the transepts by handsome carved screens. The chapel of St. John is north of the choir, and is of excellent Perpendicular work. There is some curious stained glass in the east window, but that, as well as the side windows, is in a very fragmentary state, the designs being often carried across the window without any reference to the mullions. On the south side, enclosed by a palisading, are the recumbent figures, in marble, of Sir John Brydgeman, sergeant-at-law, and chief justice of Chester, with his wife.—A.D. 1637. These are very highly finished, and the whole detail of costume is most accurate. I have never seen any faces which convey more clearly the idea of their being "genuine portraits" of the individuals. Unfortunately the hands have been knocked off. They are conjectured to have been the work of Fanelli, who was much employed in England during the reign of Charles I. The windows of the south chapel were once, no doubt, rich in stained glass; but a portion only exists at the east end, which seems to have represented a genealogical history of the Prophets.

During the years 1859 and 1860, the interior of the church underwent a thorough restoration under the direction of Mr. Scott. About that period the magnificent west window was put up, designed and executed by Mr. T. Willment. It represents the eminent persons in the Mediaeval periods who are connected with the history of the town and castle. The surcoats over the armour of some of the royal personages who are kneeling are truly rich and splendid in colour. As a commemorative window of that kind it can have but few rivals.

The service in this church, like that of St. Mary, Shrewsbury, is conducted in the most satisfactory manner. There is not a surpliced choir, but the talented organist, Mr. Bartholomew, takes great pains in their instruction. The castle is entered from the town by a strongly-built tower gateway. Passing under its pointed arch we are introduced to an extensive area, which in former times was called the "base," or "lower court,"—sometimes also the "committed bailey" or "ward," because it was committed to the care of a special officer, and portion of the garrison charged with its defence. It is now usually called the "outer court," and is covered with green turf, which forms a pleasing contrast to the principal front, where a stone bridge of two arches, on which are some remains of an embattled parapet, probably of the age of Sir Henry Sydney, supplies the place of the ancient drawbridge. It is a great defect in this building, that most of the narrow Norman windows have been cut away during the reign of Elizabeth, to make openings for larger ones of the Tudor period. In the outer court, standing at present quite apart, is the chapel, the nave of which now alone remains, "circular in form;" and if the account of its origin be correct, one of the earliest buildings of the kind in this kingdom with the round church at Cambridge, that at Northampton, and the Middle Temple. It is entered by a remarkably elegant Norman doorway, on the opposite side of which is another arch of the same style, which formed the entrance into the destroyed choir. The "state apartments" are at a great distance from the gateway between them, which "was" in existence so late as in 1768. Indeed, the "past tense" is most prominently presented to our mind and feelings when we take a survey of this castle. One writer of a tour through Great Britain observes, "It will be no wonder that this noble castle is 'the perfection of decay' when we acquaint our readers that the present inhabitants live by the sale of the materials. All the five courts, the royal apartments, halls, and rooms of state lie open and abandoned, and some of them falling down." And we need not marvel at this when we learn that soon after the accession of George I. an order came down for

unroofing the buildings and stripping them of their lead. Decay, of course, soon ensued. Other castles, it is true, have suffered in the same way, but to a castle like Ludlow the damage done has been peculiarly detrimental. To some, for example, like Kenilworth, not standing upon an eminence, but nearly on a level with the surrounding country, the "green turf being found everywhere" as we wander among the relics of a past age, "decay and even worse" is not detrimental to the general effect. Ruined edifices and unroofed vegetation are then harmoniously combined. But the very dignity of Ludlow Castle is now its detriment. Viewed from one of the lime-tree walks, which almost encircle a portion of the hill on which it stands, nothing can be more majestic than its general appearance; but when we penetrate the interior the charm is gone. The walls, it is true, remain; but everything which could gratify the eye or soothe the feeling has departed, and we feel this the more keenly as it was not the work of Mediaeval violence, but of modern indifference to the intrinsically beautiful. Who would not have wished to see the hall (not the bare walls only) in which that exquisite and most poetical of dramas, the mask of "Comus," was exhibited? I do not pretend to say that there are not architectural features of interest; but, perhaps, most persons will agree that a visit to the interior of Warwick Castle is far more gratifying. I remarked that in some portions of the wall the interstices were filled up with *cyster-shells*. Descending one of the principal streets in the town, we pass under an ancient gateway which leads us to Ludford Bridge crossing the Teme to the Hereford-road. Lealand, mentioning it in his "Itinerary" says, "There be three fayre arches in this bridge over Teme, and a pretty chapel upon it of S. Catherine. It is about a hundred years since this bridge was built, men passed afore by a ford a little beneath." The chapel of St. Catherine is gone, but there must be few bridges in the kingdom which can lay claim to such antiquity. As in other Shropshire towns, there are some good specimens of white and black houses, especially the "Feathers" hotel, as in modern parlance all substantial inns are denominated. There are also considerable remains of the old wall to be found at intervals on the edge of the hill on which the town is situated.

On my return homeward I remained for a few hours at Hereford, in order to visit the cathedral. The cloisters remain in the same state as when I last saw them. No one can but admire the magnificent screen, and yet I must confess that one of "stone" or "wood" in my eyes would have harmonized better with the building. It is lighted up on a winter's evening, the effect must be very brilliant. When I attended the morning service sitting on the Decanet side, close to the screen, I could not but again remark that every word of the lesson read from the lectern came back to the ear, apparently from the north aisle of the nave. The echo was perfect.

I am not quite certain as to how long the see of Hereford continued to be reckoned among the Welsh, or, to speak more appropriately, the British hipocricks, but that language must have continued to be spoken in Shropshire to a comparatively late period. The author of "Robinson Crusoe" in his "Tome in Great Britain," in 1753, speaking of Shrewsbury, says "Over the market-house is a kind of hall for the manufactures which are sold here weekly, in very large quantities: they speak all English in the town, but on a market-day you would think you were in Wales. The only relics of the language at present are the names of a few places bordering on Montgomery and Denbigh."

A MEMBER OF THE OXFORD ARCHITECTURAL SOCIETY.

A New Paint.—At a recent meeting of the French Academy, M. Sacc called attention to the fact that tungstate of baryta forms an excellent white paint, which has as good a tone and depth as white lead, and has the advantage above this of not getting blackened on exposure to the atmosphere. Zinc white, which was tried as a substitute for white lead, has failed, he said, through wanting body. M. Elie de Beaumont remarked that if this statement was confirmed, it would be of great importance; for we have no need to employ special mining operations for tungsten, as this metal is commonly found in company with tin.

THE (ALBERT) MUSEUM, SOUTH KENSINGTON.

In my last "notes" I mentioned the fine Castel-Durante vase lent by Mr. J. Webb. This gentleman exhibits many other rare and interesting objects, among which the fine cup or tazza of heliotrope—resembling translucent blood-stone—takes a prominent place. It is mounted on a stem formed of a female figure supported on the shoulders of a Triton with horse's fore-legs; the handles are winged figures terminating in masks; the whole is coloured and gemmed enamel and gold. The cup is supposed to be Italian sixteenth century; the enamelled mounting, modern French. Now, it would be interesting to know if this cup were mounted prior, or subsequent to the 1851 Exhibition. Compared with one purchased of the Messrs. Morel, of New Burlington-street, at that Exhibition for the Museum, and which is in a glass case nearly parallel with that containing Mr. Webb's heliotrope tazza, just across the contre-alley, it will be seen to be almost identical in design. Patriotism leads me to say, I am glad to think the English-mounting the more beautiful of the two; irrespective of the costly pearls which enrich the foot, the selection of enamel for the flesh, and gold for the drapery, I consider better taste, as being more suitable than the exactly contrary treatment in the French mounting; also, the faces are much more exquisitely modelled. I suppose both these stems have been designed from some Medieval specimen in the Louvre collection, or elsewhere. Of Mr. Morel's work, the "Report by the Jurors" of the Exhibition is as follows:—"Cup of Oriental agate, made in the form of a sea-shell. The pillar is composed of a female figure, borne by a Triton with horse's fore-legs: at the back part of the shell is the handle of the cup, formed of another female figure sitting upon a dolphin, and holding her flying drapery, the extremities being supported by Cupids: all these figures are enamelled with superior taste." The price paid for this beautiful object was 210*l*.

Respecting the heliotrope stone, many virtues were attributed to it in olden times. Marbodius says, in his "Lapidarium," that it gifts the wearer with prophetic eye, endows him with good fame and long life, checks the flow of blood, protects from poison, and, when united with the herb heliotrope, renders the wearer invisible. It has its name from the fact, that when set in water opposite the sun's rays, it turns their light to blood-colour.

To return to Mr. J. Webb's art-treasures. The covered bowl of lapis lazuli is very rich. It is Italian and sixteenth century. The bowl of white chalcidony, also Italian sixteenth-century, mounted with modern French enamel stand and handles of charming design and execution, is chaste and pure; and the agate vase, likewise mounted in modern French enamel, is excellent. There is a fine plate of lusted Gubbio-ware,—the subject, "Medea and her Children." This is signed by Maestro Giorgio, and dated 1528. From the same collection there is an enamelled ewer, painted in colours on copper,—French Limoges, latter half of sixteenth century; and another in grisaille,—subject, "Passage of the Red Sea," wherein the Egyptians, who are being overwhelmed, are habited like ancient Romans. There are likewise two fine bold figures in Limoges grisaille, signed T. Penevart, 1549, one being St. Luke, the other St. Mark; and a fine tazza and cover,—one of two, by the way, of French Limoges late sixteenth-century in grisaille. On the bowl is a skirmish of cavalry, and on the cover are four classic heads, which are admirable. The handle of the cover is a curious high ornament of scrolls. Some smaller objects are interesting to see, namely, the silver-gilt pomander, with eight distinct tiny perfume-bosses, each falling down by a hinge when open, and closing up into a small ball no larger than a moderate-sized walnut. It is seventeenth century, and is Dutch or German; the Italian seventeenth-century silver-gilt filigree jockey's cap, identical with those still worn at Epsom and Ascot; and the pretty little openwork silver-gilt case, containing two tiny scent-bottles, also seventeenth-century, probably French manufacture.

Very near to these objects stands the votive offering made by the community of Carcassonne during the plague in 1517, and lent to the Museum by Mr. Stephen Bam. It is of silver, gilt and ornamented with stones and enamel, and is labelled "Couronne d'Es Voto à la Madone, pour faire cesser la Peste en 1517, comme l'indiquent

l'inscription visible." It is more interesting than beautiful, and its principal curiosity is—finding it where it is.

Mr. Joseph Bond lends some fine art-objects, from which I would specify the large mug of Persian earthenware or porcelain, bearing a bold design of richly-coloured conventional flowers; also the tankard of Old Dresden, painted with subject of Apollo and Daphne, with silver-gilt mounts and cover, old German medals being let into, and bent to suit the shape of, the lid; date, early eighteenth century; two ewers of Oriental porcelain, the one bearing the cock being so metallic in appearance that it is difficult to believe it is not enamelled on copper; and a beautiful little chased gold *écu*, French, early eighteenth century.

This last object calls to mind the charming miniature stiletto belonging to Mr. T. Dyer Edwards, placed in the same glass-case as Mr. Tite's two packs of cards; it has a gold suspending ring, sheath, and handle, the latter in form of a statuette, and is Italian seventeenth century. This gentleman also exhibits a miniature on ivory of Mrs. Woffington studying the part of Ophelia, dated about 1750; an onyx cameo, profile of Nelson given by him to Lady Hamilton, dated 1801. The gold frame is formed of laurel branches, terminating in an anchor—emblem of Hope, as well as a symbol of the sea. There is likewise a Gimmel ring, each portion of which is set with diamonds that form, when put together, a lozenge-shaped cluster; and in another glass case in the centre of the loan department, are the gold watch made for Benjamin West, P.R.A., ornamented with dark blue enamel, and set with enamel pearls; and the silver watch presented by the Duke of Marlborough to Sir Isaac Newton in 1714, of German manufacture, and enosed in a repoussé openwork cover.

To return to the location of the stiletto and onyx cameo. In close proximity are displayed several interesting objects; namely, a miniature, by Nicholas Hilliard, of Robert Devereux, Earl of Essex, which makes one think there must have been more than his melancholy, dissatisfied-looking face, so greatly to fascinate "Great Gloriana." This miniature is the property of Sir W. C. Trevelyan, bart., as is also the small portrait of Charles I., worked with his hair. Was this the one shown in the loan collection of miniatures some three years since at the Museum?

In the same glass case are three miniatures, lent by Miss Wilson, ascribed to Nicholas Hilliard:—Queen Elizabeth; Mary, Queen of Scots, with her son James VI.; and Henry VIII., with his son Edward VI. They are in large openwork carved and gilt frames. It is singular to see, with all the care and finish bestowed upon the manipulation of these works, how utterly out of proportion are the children; they are diminutive men, not boys; or, rather, dolls. The heads are the most faulty portions, being scarcely more than a quarter the size they should be; whereas children's heads are always much larger in proportion to their bodies than those of adults.

Close to the above lies a noticeable miniature, on copper, of a lady, said to be the Duchess of Baireuth, sister of Frederic the Great. It is lent by Mr. W. Simmons. The wonderful manner in which her, so cleverly painted, grey hair is piled up and padded, quite eclipses the art of our modern helles and coiffeurs, spite of their "chignons" and "ringlets." The duchess wears a grey cap ingeniously chosen to match the colour of her hair, so as not to mar its effect, or clash in any way with Dama Nature's arrangement of neutral tints.

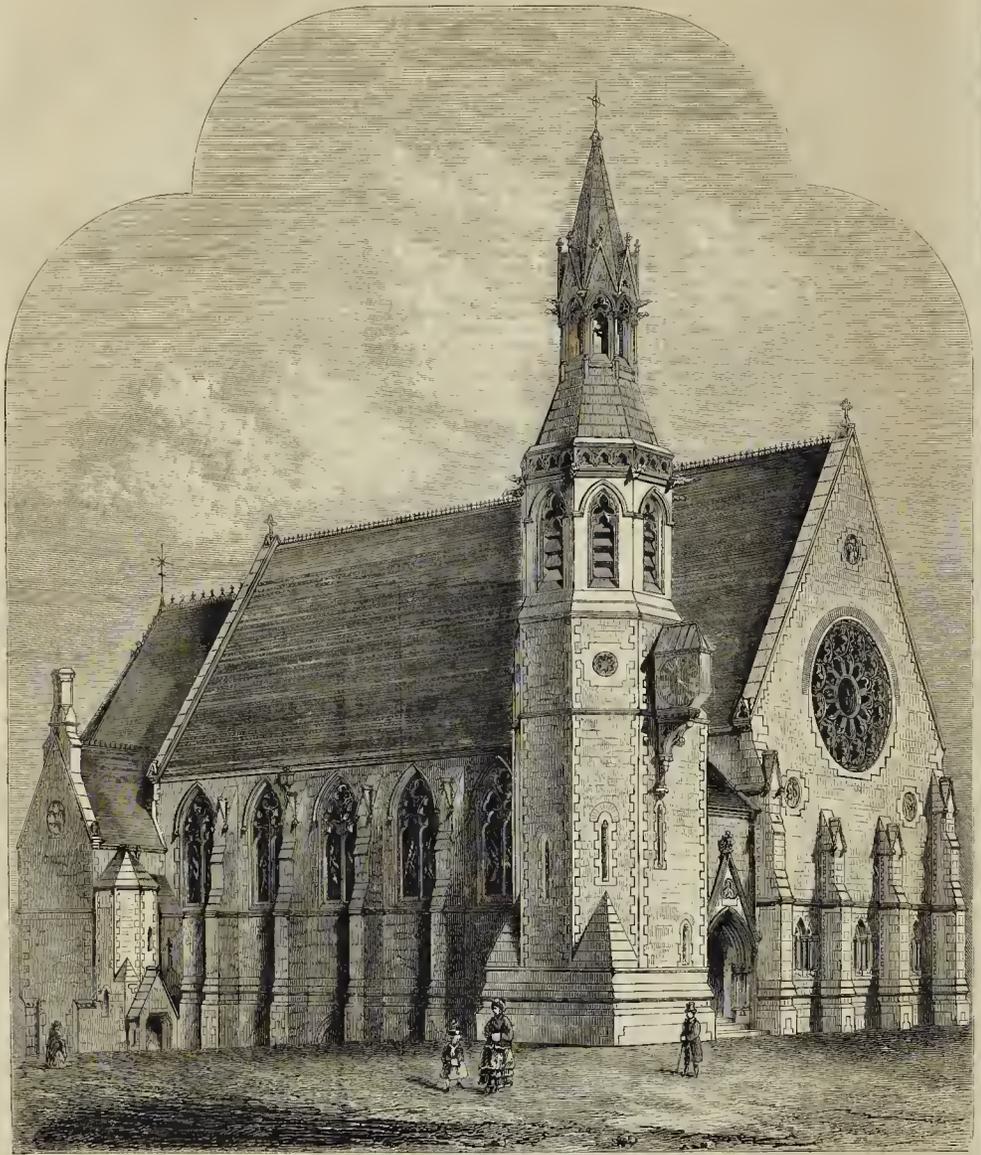

Returning to the centre of the hall, the beautiful amber canister, lent by her Majesty, attracts the eye. It is about 10 in. in height, octagonal in form, is very carefully carved in relief, with figures emblematic of the cardinal virtues, has a silver-gilt foot and cover, and dates from the seventeenth century. Close to the latter, a pilgrim bottle of rock crystal, carved with arabesque flowers and masks, Italian, sixteenth century, is lent by the Earl of Warwick; a large rock-crystal drinking-cup, fluted and carved, by the Hon. A. G. Ponsonby; and the fine-coloured blue stone medallion, suspended to show both sides, which are painted in oil,—subjects, "Christ's Baptism" and "Peter walking on the Sea," is lent by Mr. J. P. R. Godfrey. Close to these stands an octagonal casket of crystal, with gilt and enamel framework, resting on eight terminal figures, Italian, sixteenth century, lent by Mr. Farquhar Matheson; next a small goblet of rock crystal, mounted

in coloured translucent enamel, having a cover with a child seated on it for handle, and for stem a salamander. It is a choice Italian, Italian sixteenth century work, and is lent by H.R.H. the Prince of Wales.

Two Arabic lamps of dusky-coloured glass, ornamented with medallions and Arabic inscriptions, have a strange outlandish appearance among these Western art-works. One of them is lent by the Rev. G. J. Chester, and dates from the thirteenth or fourteenth century; the other from the thirteenth, and is from the Meymar collection in the Paris Exhibition of 1867. Not far off stands a fine sepulchral vase of glass, antique Roman, lent by Mrs. Peircy, the beautiful iridescent colours of which, formed by exposure to the atmosphere, are very lovely. The silver seal with armorial shield, found in the Thames during the building of London Bridge, and lent by Sir W. Jolliffe, bart., is interesting; as are many of Mr. Barker's fine old German engraved glasses and goblets,—notably, the deep tazza ornamented with scrolls, canopies, and arabesques, having a multiform bowl and escalloped foot; another of quatre-foil shape, with cover; a deep tazza, multiform flattened bowl and escalloped foot; a Venetian pear-shaped vase of white glass, painted with green leaves, flowers, and goldfinches; a Gorman glass *gchelt*, painted in oil, with a knight and three coats-of-arms; a wine-glass, engraved with arms and minute scrolls; another, with a spiral pink thread inside the stem; a goblet, with a cut stem, which *unscarves* in the centre; a deep tazza, with multiform bowl, engraved with birds and scrolls, and octagonal foot. Several glasses, with flowers scratched upon them with a diamond, are curious, but are very poor in appearance, and not worth imitating. Dr. Salvini, although they are Venetian; and, with all due appreciation of your beautiful mosaics, allow me to say that, when you were reviving the delicate outlines and quaint conceits of the clever old glass-workers of Murano, it is much to be regretted you should also have revived the dusky-looking "metal," irregular form, and tottering appearance of many of your predecessors' productions. Those fine old fellows did the best they could with the appliances they had at command; but it is not to be believed that if they could have had the benefit of our nineteenth-century discoveries and conveniences of manufacture, they would have chosen to make their own heard, muddy-looking glass, in preference to our clear, crisp refreshing productions, any more than that they would have preferred to go a journey plodding on their toilsome way on foot, or on the back of the only less fatiguing mule, instead of profiting by the comfortable, speedy, and luxurious railway locomotion of our day. To be sure, railways are not of so much consequence in Murano and Venice; but the canal-surrounded position of these places does not nullify my hypothesis,—that the Medieval glass-blowers would have made their glass clear and pure, if they had only known how.

But is it certain that their glass when made, was of the dusky hue we now behold it? That glass does cloud and change colour with age and exposure to the atmosphere, is a well-known fact. Even in our time we have a notable instance, in the beautiful plum-coloured hne assumed by window plate-glass made any some thirty or forty years ago, owing to the particular flux employed in the manufacture; and the use of which flux has, I believe, been since discontinued in consequence. When the duty was taken off glass about twenty years ago, a sudden impulse was given to the trade, and then it was that the exquisitely pure glass which we now see everywhere—and in which I delight—was produced generally, because manufacturers could afford to experimentalize in, and adopt, all suggested improvements.

One of the objections that ultra-medievalists make to much modern glass is, that to "cut" glass is not a proper treatment for such a material: but why not? I contend that any treatment a material will bear, that does not render it a sham nor detract from its usefulness, is perfectly correct and admissible. Cutting does not appear a weakening of the strength of glass, because nobody asks for strength in glass; and even on that head experience is in favour of this mode of ornamentation; for, as every one knows, cut-wineglasses are far more durable than the delicate—though, I admit, very charming—"straw-stems" which make one tremble to touch them, for they seem almost too slight to bear the superimposed bowl. Those persons who extol dusky irregularly-formed blown glass to

THE GUTHRIE MEMORIAL CHAPEL, CLIFTON.

the disparagement of accurate contour, perfect transparency, and upright self-supportiveness of crystal flint glass, would, of course, be consistent, object to have facets cut on precious stones, and would prefer to wear a diamond in the rough.

I should be sorry, however, to have it inferred from what I have said above, that I cannot appreciate old Venetian glass; on the contrary, I admire it extremely, and can rival any dilettante in ecstatic delight over Mr. E. W. Cooke's beautiful collection, now on loan at the Museum. The playful elegance of form, varied outline, quaint conceits, and never-ending variety of design: all these I revel in; besides which there is a delicacy of taste, elegance of finish subdued colouring,

and general harmony of tone—much of the latter due, no doubt, to the blending and softening effects of time—about the old work, which we seek in vain in the modern imitations and reproductions; but what I desire to insist upon is, that having a purer and more beautiful material wherewith to go to work, our modern manufacturers should exert their skill, taste, and ingenuity in turning that to account, instead of ignoring its superiority, and servilely copying failings as well as graces from their "early masters."

Having written so much at length upon Venetian glass, I can scarcely permit myself to return to the subject on a future occasion; therefore, ere closing this notice, I will mention

Dr. Salvisti's mosaic panel, the semi-figure, life-size,—Salvator Mundi,—bought at the International Exhibition for 200*l.*—admirable in feeling as in execution; and the fine howl of old Venetian glass, lent by Mr. Alfred Seymour. The latter has a spiral white thread running all over it, and a twelve-fluted edge; in the centre is painted a female bust in rich full colours, the effect of which is very beautiful, and quite startling from being so life-like. It is a young handsome profile, with straight delicate nose, small mouth, and large soft brown eye; the hair is gilt, and a great jewel-ornament of red stones set in gold, rises from the forehead to the crown of the head. Enough, however, for the present.

MESSRS. C. J. HANSON & SON, ARCHITECTS.

[See p. 161, ante

KENSINGTON DISTRICT SCHOOLS COMPETITION.

Six architects were selected by the Board of Management to submit designs for the proposed schools at Ashford, Middlesex, each to receive 50l.; the successful competitor to be paid 500l., less the beforementioned 50l., for carrying out the works, including expenses of all kinds; the drawings to be without tint, or tinted in one tint of sepia only; the buildings to afford school and living accommodation for 100 infants, 100 casual children, and 500 permanent children; accommodation for certain officers; infirmary for 100 children; and quarantine wards for 24. The designs, suspended in the council-room of the Royal Horticultural Society, are now under the consideration of the Board of Management. The names of the competitors, with the amounts at which they respectively estimate the cost of carrying out the designs, ran thus:—

Mr. Burden	£13,800
Mr. Collins	42,360
Mr. F. Fowler	37,312
Mr. Allom	28,797
Mr. Snell	27,250
Mr. Williams	25,000

The difference is sufficiently startling; comparing, however, the plans of the highest two competitors with those of the lowest two, it seems clear either that the former have provided more accommodation than the instructions and the Poor-Law Board call for, or the latter less.

The long line of front that Mr. Collins adopts, and the general openness of his very complete buildings, have advantages, but are necessarily costly. The elevations are properly kept very plain. Mr. Snell's is a compact plan, and can scarcely be called crowded.

The provision of "closet" accommodation in some of the designs is quite insufficient.

The majority of the competitors have foolishly disregarded the instructions that the drawings are to be without tint, or, at any rate, to have a tint of sepia only. It is not to be expected or hoped that a Board would select a had design in preference to a good one because the latter exhibited a little colour; but if such instructions are given, they should be attended to. Architects who desire strict honesty in their judges, should be strictly honest themselves.

A careful comparison of the various designs with the instructions as to the accommodation required and given should be made before any determination is come to.

THE STRAND GUARDIANS AND THEIR BUILDING OPERATIONS.

The guardians of the Strand Union have been having, what, we suppose, we must, by way of pleasantry, call their little bit of fun with the building trade. Perhaps, should the ratepayers come to think seriously over the matter, they may not see so much fun in it after all.

As has been seen in our columns, the guardians called for tenders for a new workhouse at Tottenham, to be built from the designs of Mr. W. S. Cross, the quantities being taken out by Messrs. W. S. & A. Cross. When the advertisements were out, twenty-three building firms, comprising leading names in the trade, tendered. For our present purpose we may pass over them all but the last four, and with respect to these we have something to say.

The first of the four, being also the nineteenth on the list, was Mr. Howard, of Russell-street, Covent Garden, for 45,800l.; the next was Messrs. Hill, Keddell, & Waldron, for 45,257l.; Messrs. Cooper & Callum, 44,745l.; and Mr. Hart, 43,940l. There is a good deal of very unpleasant talk going on just now, both in the building trade and in the Strand Union, about this very contract, and we may as well give the gist of the murmurings. The tender of Mr. Howard, a respectable local builder, was accepted.

Messrs. Hill, Keddell, & Waldron are well-known men, their present great work being the Holborn Viaduct. They tendered 543l. below the accepted tender, and there can be no question about their power and responsibility to carry out the work properly at the price they offered. If they are good enough and able enough to build an important work for the Corporation of the City of London, they certainly should be considered sufficiently strong to build a workhouse for any board of guardians whatever. The tender following was from a firm—Cooper & Callum—squally well known, and it

was 1,055l. below the accepted one; whilst the last of the rejected three, Mr. Hart, has been an important builder for many years; he tendered below the accepted one no less than 1,860l. The builders are asking, "Why is this?" The whole twenty-two firms who tendered want to know why they should have been put to the trouble and expense of making out estimates and sending in tenders, when the contract was, so to say, predetermined? It appears that Mr. Howard is an old parishioner of the Strand Union, and much thought of by all the guardians, but the ratepayers do not consider that a sufficient reason, in the absence of further explanation, for giving him a bonus of 1,860l. of their money. Nor do the builders think that they ought to have been duped by what they consider a sham advertisement. If the contract was intended for Mr. Howard, why not, in the name of all that is parochial and neighbourly, have given it to him at once; and not delude two-and-twenty other people, by mock invitations, to put themselves to unnecessary cost and anxiety?

THE COURTS OF LAW AND THE EMBANKMENT.

The correspondence in the *Times*, relative to the site for the proposed New Courts and Offices of Law, initiated by Sir Charles Trevelyan, has been published as promised.* It includes plans that show strikingly, what we have already pointed out, the unyielding limits of the insufficient and awkwardly-shaped site next the Embankment. To increase the space, the only road to the Embankment from the Strand is formed under the Law Courts. The buildings would come close up to the noisy part of the Strand on one front, and have a railway station close to them on the other.

Mr. Baillie Cochrane also has published a pamphlet on the subject in the shape of a letter to the Right Hon. A. H. Layard, advocating the site next the Embankment.

On Thursday, the 25th, Capt. Dawson Damer was to ask the Chancellor of the Exchequer if there were any intention of recommending an alteration in the proposed Courts of Justice; and Mr. Gregory has given notice that on the 5th of March he will call the attention of the House to the site of the new Courts, and move a resolution on the subject.

It is to be hoped that amidst this fight as to position, the necessity for a good plan and a noble and fitting exterior may not be lost sight of.

With whom does the responsibility in this respect now rest?

THE BELLS OF ST. MARY ABBOT'S, KENSINGTON.

The tower of the old parish church of Kensington contains a peal of eight bells in the key of E, the weight of the tenor being about 21 cwt. and in a wooden turret surrounding the tower is a comparatively small clock bell.

The bells forming the peal were cast by Thomas Janaway—not Janeway, as stated in various topographical and other works,—of Chelsea, and they severally bear the following inscriptions:—

1. "PROSPERITY TO THE PARISH OF KENSINGTON. THOMAS JANAWAY, 1772."
2. "WHEN FROM THE BARKS OUR NOTES RESOUND, THE BELLS AND VALLEYS ECHO ROUND. THOMAS JANAWAY, 1772."
3. "MUSICA EST MENTIS MEDICINA. THOMAS JANAWAY, 1772."
4. "INACTUM SILBO, PERCUTE DULCE CANO. THOMAS JANAWAY, 1772."
5. "LET ABBOT'S BELLS CONTINUALLY BE RUNG, THE WORD STILL PREACHT AND HALLELUJAH SUNG. THOMAS JANAWAY, 1772."
6. "THE RINGERS' ART OUR GRATEFUL NOTES, PROLONG, APOLLO LISTENS AND APPROVES THE SONG. THOMAS JANAWAY, 1772."
7. "YE RINGERS THAT ARE PUT IN TRUST TO JUDGE OF RING AND RIGHT, BE ALL YOUR JUDGMENTS TRUE AND JUST, REGARDING NO MAN'S RIGHT. THOMAS JANAWAY, 1772."
8. "BE IT KNOWN TO GREAT AND SMALL, THOMAS JANAWAY MADE US ALL. Cast July, 1772, by subscription, Rev. James Waller, D.D. vicar. John Stokes and William Simpson, churchwardens. John Lessingham, Esq. gave Twenty Pounds."

On the walls of the belfry are sixteen tablets, upon which are recorded various exploits of change-ringers from 1774 to 1850.

* J. Day, Savoy-street.

The present ringers are respectable young men, who have been instructed by Mr. G. Morris, of St. Martin's, and whose occasional performances, it is said, have given much satisfaction to the parishioners.

Before concluding, perhaps I may be allowed to state that the present old church having been pronounced unsafe to be used for public worship, is ordered to be taken down, and a new edifice erected within the limits of the churchyard, Mr. George Gilbert Scott, R.A., being the architect.

The Venerable Archdeacon Sinclair is treasurer of the building committee, and the Rev. W. Wright is honorary secretary, and among its members are the churchwardens, Mr. Greenway and Mr. Freem, the Duke of Rutland, and other influential residents of Kensington. The estimated cost of the structure is about 35,000l., and the committee now appeal to the public for subscriptions in aid of the noble work, towards which her Majesty the Queen has been pleased to give 200l., while the vicar of the parish, Archdeacon Sinclair, has made a donation of 1,000l.

With regard to the character of the edifice, the following extract from the architect's report will, I think, be found very interesting:—"I have aimed," says Mr. Scott, "at giving the church a degree of dignity proportioned to the important rank and position of the parish for which it is intended. It would, as it appears to me, be inconsistent to rebuild the parish church of so important a place as Kensington in any degree parallel to that of the cheaper class of churches which are built to meet the pressing demands of an increasing population. Churches of that less dignified class are a great necessity, and it is wise to limit their cost to such a degree that it shall not be a cause of preventing the erection of as many of them as the population demands; but when you come to deal with one of the great parish churches—and that of a wealthy and important parish—the abode of royalty—the case is much altered, and a proportionate architectural dignity becomes needful. I have accordingly, without going into a luxurious or extravagant scale, aimed at giving the church a character proportioned to its position."

THOMAS WALESBY.

THE VIADUCT ON THE EMBANKMENT.

In the House of Commons, the other day, when a committee was very properly appointed to inquire into the roadway and viaduct proposed to be made on the Thames Embankment from Hungerford Bridge to Wellington-street, Strand, and whether the site might not be more advantageously occupied by some public building; also to inquire whether any, and if so, what controlling power over public works in the metropolis was vested in and exercised by any Government department,—

Mr. Tito said he wished to explain that there was no such thing proposed as a viaduct from Charing-cross to Waterloo Bridge, nor had the Metropolitan Board to make any such road at Charing-cross. The road along the Embankment, 100 ft. wide, would be exactly one mile in length, and as it would be ridiculous to have such a thoroughfare running parallel to the Strand and Fleet-street without any intercommunication, it was proposed to connect the two lines at Wellington-street by means of an inclined plane. If the Metropolitan Board were to be released from the carrying out of the work, it would effect a saving of 230,000l. With regard to the control which might be had over such a work, he should be glad to acquiesce in any satisfactory settlement of the question which might seem desirable.

HARGRAVE CHURCH, NEAR BURY ST. EDMUNDS.

This church is situated about seven miles from Bury and one from the village of Hargrave, and adjoins the rectory grounds; and, with the exception of a farmhouse some two fields off, no houses are situated within a quarter of a mile. It stands in a commanding position at the top of a hill, and contains a chancel, nave, and tower; latterly, it has undergone enlargement and partly re-erecting, and has been opened with divine service. The old vestry has been taken down, and a new north aisle, 31 ft. long by 13 ft. 6 in. wide, has been erected. It accommodates ninety adults, and is connected to the nave by three stone arches with circular columns, moulded caps and bases, and three two-light windows, all of Ancaster stone. The walls are

built of Dalham stone, and faced with flints similar to the chancel, and have Ancaster stone quoins, weatherings, and dressings.

The roof is a lean-to against the nave, slated, open timbered, and boarded diagonally, with moulded cornice, all sized and varnished; the seats are open benches, stop-chamfered; the nave has been partly reseated, the old-fashioned pews have been taken down, and open benches to match those of the aisle substituted. The pulpit and desk have been removed from the south to the north side of the nave. The chancel was restored a few years back, with the exception of the seats; these, like the nave, have been swept away, and open benches for the choir have been added, with ornamental iron standards for children's desks. The whole of the woodwork is sized and varnished. A fine old Perpendicular screen, richly carved, separates the nave and chancel; this has been repaired, stained, and varnished. There is also a piscina, and sedilia, &c., in the chancel, restored some few years back.

Mr. Ralph Chamberlain, of London, was the architect employed; Mr. James Drake, of Ousden, the builder; Mr. Hopson, of Bury, the stonemason; and Mr. Shrivell, of London, did the ornamental ironwork.

CHURCH-BUILDING NEWS.

Great Yarmouth.—An appeal for further aid towards the restoration of the church of St. Nicholas has been issued by the vicar and churchwardens, in which they say:—"Four years have elapsed since the restoration of the tower and chancel of this noble church. Meanwhile, the south aisle has fallen into such a state of utter dilapidation, that our architect has pronounced it unsafe, and has recommended us to close it. The seats have accordingly been removed, and the aisle is boarded off from the rest of the church. The restoration, therefore, of the south aisle has become an urgent necessity. We are most anxious to avoid all unnecessary delay, and we earnestly hope to be able to commence the work early in the coming spring. But the funds are at present insufficient to complete a work of such magnitude. The south aisle is in length upwards of 110 ft., by 40 ft. in breadth. No parish church or cathedral in England has aisles of such a size. And the various works to be carried out include the south wall, which is hulged outwards, and must be rebuilt from the ground; an entirely new roof; the exterior west front of the aisle; and two of the four great western pinnacles, each 70 ft. in height. The estimates laid before the restoration committee amount to above 4,000l. In addition to the 6,900l. already expended on the tower and chancel, a sum of 3,400l. has been collected towards the restoration of the south aisle." The restoration committee still require from 700l. to 800l. They solicit aid from the public.

Hardingstone.—The parish church of St. Edmund's, Hardingstone, has been reopened, after undergoing an extensive and very necessary restoration. Externally there has been a general repair of the masonry work; the walls, where necessary, have been underpinned, and a dry area has been constructed round the walls of the church. Internally the whole of the fittings have been removed. The old high pews have been replaced by open deal seats varnished. The old timbers of the roof of the nave have been repaired and cleaned, and covered in with new boarding slightly stained. The roofs of the north and south aisles, which were found to be much decayed, have been replaced with new and more characteristic work. The Early archway in the tower, which, with its stone voussoirs of alternate colours artistically irregular in size, is a feature of the building, has been opened, and a two-light Decorated window has been inserted in the west wall. The window, the painted glass of which was designed by Messrs. Heaton, Butler, & Bayne, is the gift of the vicar. The masonry of the arcades has been stripped and cleaned from paint and whitewash, and the whole of the walls have been replastered. The alleys have been paved with Staffordshire tiles. An old two-light window, in the east wall of the north aisle, has been reopened, and glazed with the ordinary quarries. The old east window of the chancel has been removed, and a three-light Decorated stained-glass window, executed in Daston stone, has been erected in its place. It is filled with painted glass, by Wailes, of Newcastle, which has been put in by the tenants, and other inhabitants of the parish, as a testi-

mony of respect to the memory of the late Mr. and Mrs. Bouverie. The centre figure is Christ carrying a lamb, with the inscription, "I am the Good Shepherd." On either side are Peter and John, with the inscriptions, "Love as Brethren," "God is Love." The roof has been cleaned, and the wall-plates have been replaced on stone corbels. The "Hervey Chantry," with its interesting tombs, remains untouched. The church is lighted with standards and brackets, fitted with reservoirs for paraffine oil. The standards are by Messrs. Richardson & Slade. The church is warmed by an apparatus patented by Perkins & Son, of London. Before the restoration there were two entrances to the church by the north and south porches. These doors have both been blocked up, there being now only an entrance underneath the west tower. The porches have been utilized, one of them being used as a store-room, and the other appropriated to the warming apparatus. The churchyard has been remodelled, and a walk laid out from the entrance-gate to the west door. A short time since new schools were erected, and they form a view from the churchyard. The restoration has been carried out by Messrs. Smith Brothers, of Northampton, from the plans and under the direction of Mr. Robert Palgrave, architect, London.

Blackheath (Rowley Regis).—A new church has been consecrated in this part of the "black country." Mr. Wm. J. Hopkins, of Worcester, architect, designed the structure, and Messrs. Wilson & Son, of Birmingham, builders, have carried out the architect's plans. Mr. Boulton, of Cheltenham, was the carver; Mr. Brayshaw, clerk of the works. The bricks, many of which are moulded, were supplied by Mr. Partridge, of Kingswinford. The builders' contract was for 5,000l., exclusive of extras. The church, which is dedicated to St. Paul, contains 850 sittings, all open and free, and consists of a lofty nave, north and south aisles, vestry, organ-chamber, children's chapel, and a chancel. Nave and aisles are divided into six bays, and the nave is 80 ft. long, 29 ft. wide, and 54 ft. in height to the apex of the roof arch. The arches supporting the clearstory have simple mouldings in brick, resting upon brick pillars. The lights to the six bays of the nave have been varied, few of them being arranged alike. Gallies rise from the clearstory walls of one of the bays, both on the north and south side of the church, having three-light stone tracery windows. All the other windows in the nave are either two or three light lancet-headed windows, the heads of which are worked in brick, and have moulded brick rero-arches. The roof of the nave consists of double-arched trusses, rising nearly the whole height of the roof, and strengthened with wrought, twisted, ornamental iron tie-rods and kings. Over the arches of the nave is a diaper band of ornamental brickwork, and a hand of blue brick runs under the windows of the aisle. The chancel is raised considerably above the nave. On the south side is a chapel for children, opening into the nave and chancel by arches spanning the whole width; and on the north is a corresponding chamber for the organ and vestry. To the east of these arches are two-light stone-tracery windows, the one on the south side having its inner jambs lowered to form sedilia. At the east end there is a three-light tracery window of simple design. A band of brickwork diaper, similar to the one in the nave, runs under the inner wall-plate of the chancel roof. Godwin's tiles are laid on the chancel floor. The wall under the east window at present looks bare, but there is ample space for a reredos, which it is hoped will soon be added. The church is warmed by an apparatus supplied by Mr. Cornell, of Cheltenham, who also provided the ornamental ironwork in the building.

Melford.—The Church restorations recently undertaken have been completed. They have been almost entirely carried out (under the direction of the architect, Mr. Woodyer) by local tradesmen. Mr. Leeks, builder, of Melford, undertook the construction of the screens, &c., and also made half the benches, the other half being made by Mr. Fordham, of the same place; the carving is chiefly the work of Mr. Sprungin. The masonry of the tower arch, &c., was executed by Mr. Keogh, of Sudbury; the glazing was done by London workmen under the supervision of Mr. Almaack; the gasfittings were laid by Messrs. Ward & Silver, of Melford. Although much has been done, there is yet ample scope for further outlay.

Wolverhampton.—Christ Church, Waterloord has been reopened, after having been

enlarged. The first portion of the permanent church was opened as a mission chapel in February, 1867, among a population consisting chiefly of mechanics, and has been from the first overcrowded. The second portion of the edifice has now been added, consisting of a side aisle and extension of the nave. This increases the accommodation from 300 to about 500 seats. Funds are wanted to meet the expenditure that has been and has still to be incurred, and an appeal has been made for donations. Mr. Bidlake is the architect, and Messrs. Higham are the builders. Their contract was for the erection of north and south aisles, and extension of nave, including chancel arch. The north aisle and extension of nave have been opened, and the south aisle is now being proceeded with. The contract is 1,850l. The heating is by hot water, by Messrs. R. L. Jones & Son.

Rossmore (Rotherham).—The contract for the restoration of Rossmore Church tower has just been let to Mr. J. Harper, mason and builder, Mashov'. The plans were made by Messrs. Blacknor & Mitchell-Withers, of Sheffield and Rotherham. The cost of the undertaking will be about 700l.

DISSENTING CHURCH-BUILDING NEWS.

Lower Broughton, Manchester.—A new Wesleyan chapel has just been opened for divine service. It has been built from the designs of Mr. William Waddington, architect, Brnley. It is in the Italian style, has cost about 6,000l., and is capable of accommodating about 950 persons. The contractor was Mr. Mark Foggott, of Cheetam, Manchester.

STAINED GLASS.

Hyde Church.—A memorial window has been placed in the chancel of the parish church, Hyde, near Manchester. The style of the church is late Perpendicular, and the window consists of five lights of unusual height, and hold open tracery, the latter being filled with figures of angels holding scrolls inscribed with texts; and the background and cusped tops filled with canopy work and foliage. The five principal openings are divided laterally in the design of the glass, thus forming ten spaces, each of which is occupied by canopy work inclosing a subject, greater prominence being given to the two central divisions, which contain the "Crucifixion" and the "Ascension." The eight remaining spaces contain the following subjects:—"The Nativity," "Adoration of the Magi," "Baptism," "The last Supper," "Mary and Martha," "Mary anointing the Feet of our Saviour," "Raising Jairus's Daughter," and "Christ healing the Mother of Peter." An inscription at the foot of the window shows that it was put up by Mr. John Sidebotham, of Kingstons House, Hyde, in memory of his wife Elizabeth, and his sister, Jane Lowe Sidebotham. The artists were Messrs. R. B. Edmandson & Son, of Manchester.

Kingsworthy Church.—The brother officers of Mr. C. Turner, of the 60th Rifles, who was killed by an accident, have just caused to be inserted in the south wall of this church a memorial window, by Mr. Alex. Gibbs. The window consists of two lights. The left-hand compartment represents our Lord at the gate of Nain raising the widow's son. In the right hand compartment is a picture of our Lord as the Good Shepherd.

St. Margaret's, Sibsey.—A stained glass window has recently been placed in the chancel of this church, by Mr. Edmund Brown Waite, a former resident of the parish, in memory of his deceased wife. The subject is taken from the 10th chapter of St. Luke's Gospel, the three figures representing Christ, Martha, and Mary. There are now five memorial windows in the chancel of this church.

Arthuret Church.—Messrs. J. Scott & Sons, of Carlisle, stained-glass manufacturers, have completed the first half of the window to be placed in Arthuret Church to the memory of the late Sir James Graham. The design represents the twelve Apostles—one in each light of the window,—surmounted by a row of angels, and the emblems of the Evangelists, with a large dove in the central circular light.

Minty Church.—A stained glass window, says the *Bath Chronicle*, has been placed in Minty Church at the east end of the north aisle by Major Perry-Keene as a memorial of his parents, who lie buried near the spot, and of his eldest son, late of the 2nd West India Regiment, who died off Sierra Leone in 1863.

FROM IRELAND.

Belfast.—The students' chambers at the Presbyterian College have been inaugurated. These chambers have been erected as a memorial of the late Professor Gibson. The building has a frontage of nearly 100 ft. to the south, looking towards the Royal Botanic Gardens and the new residence of the professors. The elevation, whilst designed to harmonise in its main features with the Presbyterian College, to which it forms a wing, has been carried out in a more severe and simple style. The principal entrance, which is at the east end of the range, has its arched head supported on polished red granite columns, having foliated capitals, and the key-stone, which is also a corbel supporting a balcony overhead, is ornamented by a carved bust of the late Professor Gibson. The porch, which has its outer doors formed of wrought African teak-wood, is divided from the entrance-hall by an ornamental glazed screen. Immediately to the left of this hall are the rooms for the house-steward, and beyond them the dining-hall, 63 ft. long, 17½ ft. high, and 15 ft. wide. It is lighted by five large semicircular-headed windows, having a southern aspect, and divided into three bays by pilasters from which spring moulded corbels, on which rest transverse beams, moulded and panelled. The lower part of the walls is lined with pine boards to a height of 4½ ft., and these, as well as the other internal woodwork, are varnished to show the natural grain of the wood. A wide staircase, with ornamental balustrade and wall-side wainscoting, leads direct from the entrance-hall to the first and second floors. On each of these there are eleven single and two double chambers, entered from a central corridor, which receives light and air at each end. Lavatories, baths, &c., are fitted up at convenient places on each floor. There are also housemaids' rooms and nappy closet, and at the rear are kitchens, &c. The builders are Messrs. J. & J. Guiler, and the architects Messrs. Young & Mackenzie. —A new warehouse is being erected in Great Victoria-street. The building is near completion. It is three stories high, with lofty ceilings, and an attic floor in Mansard roof, lighted by large dormer windows. The front is faced with Allan & Mann's white brick, from Glasgow, with cut-stone entrance-doorway, having carved spandrels, perforated parapet, &c. The building is erected on a piled foundation, the beams of floors being supported by metal columns. The roof is finished with wrought-iron cresting of an ornamental design, and on top of dormers are wrought-iron terminals. The work has been carried out from the plans and under the superintendance of Messrs. Boyd & Batt, architects, by Messrs. James M'Cracken & Son, contractors.

FROM SCOTLAND.

Aberdeen.—The Free West Church has been opened for divine service. It has been erected at a cost of 14,000l. at the west end of Union-street. It is built of "freestone," and therefore does not harmonize with the "granitic" Grecian structures in the street. It has been built from plans furnished by Mr. Matthews, and is in a somewhat ornate style. The spire is above 200 ft. high, and is seen all over the west end of the city. The church is seated for about 1,100.

ACCIDENTS.

A FIRE has destroyed the wood and timber yard of Messrs. Arthur & Co., King-street, Goswell-street, and at one time threatened destruction to a large number of houses by which it was surrounded. These houses were inhabited by labourers employed in the Brick-lane Casworks, and the whole of them were much burnt, and the furniture seriously damaged by fire, water, and hasty removal. While the fire was raging, a most formidable gang of thieves and other ruffians had assembled, all acting in concert, and making attacks upon every respectably-dressed person who came near them. For upwards of an hour this scene was continued. Half a dozen mounted constables at last put an end to it. This shows how to deal with such ruffians in future. There should be some restriction on timber-yards in the metropolis and other towns.

At Middleton, near Pickering, in Yorkshire, an old cottage adjoining the day-school house has been completely destroyed by a gale of wind, the entire roof falling inwards. The roof of

the school house was also so much shaken and damaged that it was not deemed safe to use it. This school will have to be rebuilt.

The scaffolding placed inside a vessel at present building at South Stockton, by Richardson, Duck, & Co., recently gave way, and three men were precipitated, a distance of 20 ft. One man was killed.

While a workman was engaged on a scaffold, 70 ft. high, at a new Roman Catholic chapel, at Longton, a chisel, which he had placed on the planks, rolled off, and fell on the head of a man who was stooping immediately under the scaffold. The sharp edge of the tool pierced the head of the unfortunate man, making a fearful gash, from which a portion of the brain protruded.

COMPETITIONS.

Kidderminster Infirmary.—The architects' designs for the new infirmary have been on view in the Corn Exchange for the last few days. The committee threw the matter open to general competition, and this led to a large number of architects competing. Messrs. C. H. Cooke & H. B. Carling, Mr. John Ladds, Mr. J. Toner, all of London; Mr. J. N. Crofts, Liverpool; Mr. G. Bidlake, Wolverhampton; Messrs. Haddon, Brothers, Great Malvern; Mr. J. T. Meredith, Kidderminster; Mr. B. Lawrence, Newport (Mon.); Messrs. Payne & Talbot, and Mr. J. G. Bland, Birmingham; Mr. Sparril, Oswestry; Mr. W. Watkins, Lincoln; Mr. F. Popplewell, Manchester; and Mr. E. L. Evans, are among the competitors. Four of the designs are marked with mottoes, names not being given. A meeting of the infirmary committee was held, when, ultimately, out of the nineteen plans which had been sent in, the committee selected two, between which their choice will lie. The plans selected were those of Mr. J. G. Bland, of Birmingham, and Mr. W. Watkins, of Lincoln.

Newington Sick Asylum.—The Board have awarded the first premium to Messrs. Jarvis, the second to Mr. Knightley, and the third to Messrs. Giles & Biven. Their designs were the three to which we directed attention in our notice.*

MONUMENTAL.

Pegg Monument at Derby.—The erection of a monumental structure has been completed in the Osmaston-road chapel, Derby, in memory of the late Mr. Pegg, J.E., who was mainly instrumental in the erection of that place of worship. The monument is in the Pointed style, in keeping with the architecture of the edifice. It is chiefly of alabaster, and has been executed by Mr. F. Warren, Derby, from a design by Messrs. T. Hine & Son, architects, Nottingham. It is placed in a recess on the north side, and immediately behind the stone pulpit, west of the north transept. The entire structure is over 10 ft. in height, 7 ft. wide, and is attached to the front wall dividing the recess from the baptistery. A dado of Caen stone, 2 ft. in depth, 7 ft. in breadth, comprising three sunken carved panels, and projecting about 1 ft. from the wall, stands upon a base, and sub-base or plinth of Hopton stone. At the height of between 3 ft. and 4 ft. it is surmounted by a deep Caen stone moulding, which forms the basement of four polished red Devonshire marble columns, with carved capitals of Caen stone, finished with an abacus of white polished alabaster, from which spring three deeply-moulded Gothic arches. Over the pillars the alabaster copings above the arches rise from carved bosses, which, like the two side panels of the dado below, show a variety of conventional foliage.

New Monument in Derry Cathedral.—A sarcophagus monument, of polished Aberdeen granite, has just been placed in Derry Cathedral burying-ground, over the grave of the late Bishop Higgin. On each side of the bevelled top is sculptured, in relief, a representation of a bishop's crozier, broken, and a mitre; and on one of the sides underneath is engraved and gilt the inscription. At one side of the sarcophagus are large slabs of Aberdeen granite, to which iron rings are attached for the purpose of raising them when entrance is wanted into the vaults beneath. The monument is enclosed by an iron railing specially cast by Messrs. George Smith & Co., of the Sun Foundry, Glasgow. The low wall by which it is supported is formed of blocks of Aberdeen granite. The whole was designed

* See p. 99, ante.

by Mr. Frederick H. Smith, of Belfast. The working and polishing of the granite were done by Messrs. Mosman, of Glasgow, and the sculptured croziers and mitres on the top were executed by Messrs. Kirk, of Dublin. The putting up and enclosing of the monument have been carried out by Mr. Matthew McOleand, of Derry.

BRADFORD BUILDING TRADES' TECHNICAL SCHOOLS.

A MEETING of employers and foremen engaged in the several branches of the building trades, called by circular, has been held in the newly-erected premises of the Bradford Building Trades' Technical Schools, in Godwin-street, Bradford, the object of the meeting being to explain their arrangements for conducting the schools, and to endeavour to enlist the sympathy and co-operation of all engaged in the trade. Mr. Archibald Neill occupied the chair, and there were also present Messrs. B. Illingworth, John Beauland, J. H. Illingworth, Harland, Wm. Moulson, Wm. Tattersall, and a number of other influential employers.

The Chairman read the circular convening the meeting and also the prospectus of the schools, from which it appeared that it was the intention of the founders that in these schools the technical education of apprentices and operatives employed in the building trades should be carried on by a course of primary instruction in writing and arithmetic; and for the more advanced a course of instruction in practical geometry, mensuration, and drawing. The services of efficient and practical teachers had been secured, who would be aided by qualified assistants as occasion required. It was also intended to form a library of practical and useful works relating to the science and art of the building trade for the use of the members. The terms of payment were 3s. per quarter, which would secure all the advantages the schools might offer. At present the classes met two nights a week. There were now upwards of 120 scholars on the books, whose average attendance was 70 per cent. This was very encouraging, and the interest shown by the scholars was highly creditable. The rooms were comfortable and commodious, and contained ample accommodation for 200 scholars.

Mr. J. H. Illingworth moved the first resolution:—
"That this meeting pledges itself to assist and co-operate with the committee in continuing and supporting these schools."

This resolution was seconded by Mr. Harland and unanimously agreed to.

Mr. John Beauland moved the next resolution, in the following terms:—

"As the schools cannot be self-supporting for some time, the expenses incurred in furnishing rooms and providing class-books being very considerable, and the contribution of 3s. per quarter from each scholar not being sufficient for tuition and working expenses, until we have a large increase of scholars, it is desirable that a subscription be opened forthwith to defray the preliminary and working expenses; and all persons interested in the building trade should be invited to subscribe."

Mr. Wm. Tattersall seconded the resolution, which was also carried.

Mr. S. Wray moved, and Mr. S. Clarke seconded, a resolution, also carried, to the effect that books bearing upon the science and practical art of the trade, models, drawings, &c., being required, it was desirable that any one having it in his power should provide them.

Mr. Wm. Moulson then moved,—
"That all employers present pledge themselves to send their apprentices to these schools."

Mr. Hill seconded the resolution, which was also carried, as was one moved by Mr. B. Illingworth, and seconded by Mr. Isaac Verity, that this meeting nominate representatives from each branch of the trade to serve on the committee.

REVALUATION OF ST. GEORGE'S, HANOVER-SQUARE.

From the revaluation of the parish of St. George's, Hanover-square, by Mr. Charles Lee, which, as we hear, has been adopted by the vestry, we learn that the net rateable value of the whole parish last year was 905,812l., and that it has been increased by Mr. Lee to 1,213,077l., or about 33½ per cent. The revaluation for the basis of the county rate has been fixed by the magistrates at 1,240,827l.

BELGRAVE AND SOUTH KENSINGTON NEW ROAD.

This Bill is before Parliament again for an extension of time for carrying out the works, as the present Act expires in August next. The company by their Act are bound to recon the authorities the whole of the rates now received from the property that may be destroyed by the works until a better property is put on the land. The Bill has a clause by which they seek powers for the authorities of Chelsea to pay them for a period of fifteen years all the extra or improved rates that may accrue by this very important improvement. The road is to be commenced at Westbourne-place, and run across Sloane-street, the Pavilion land, and Quain Field, to the Grange at Brompton, so as to open up a direct communication from Eaton-square to South Kensington, forming a good access to upwards of thirty acres of the best building land in London, on which it is proposed to erect a great number of first-class mansions abutting on a grand boulevard.

The vestry of Chelsea last year approved of the company receiving the improved rates, and an attempt was made to rescind the resolution of the vestry at a special meeting, but it was confirmed by 26 to 18. About a fortnight since a second attempt was made to rescind the resolution, when the opponents of the road were again defeated by 23 to 11, although they required 23 to 12 in order to succeed. The matter now rests with Parliament, and it is hoped the company may succeed with their present Bill, as it is well known that capitalists are ready to furnish the necessary funds, provided the extra rates are allowed to be at the disposal of the company.

The land now lying waste cannot be built upon for the next fourteen or fifteen years, unless by Act of Parliament, as the present lease does not expire till then. Tox.

PROBATIONERSHIPS AT THE ROYAL ACADEMY.

Sir,—Will you kindly allow me a small space in your valuable columns to call attention to the subject of probationerships in architecture, at the Royal Academy of Arts? I confess that I am one of the many who have strictly complied with the council's invitation for the admission of students in architecture, and my drawings have been rejected. I have reason to understand that those I submitted were amply sufficient to show a reasonable degree of proficiency in architecture and architectural drawing. The fact of my not having been admitted has suggested the question—Who decide on admissions to probationerships in architecture? I may be told, the council. But of whom does the council consist? Surely there ought to be architects whose criticism should be invited and recognized. But is such the case? I hope I may be allowed to assert that architecture is an art, and should therefore be subject more particularly to the opinions of those who are professors in that art, when admissions to probationerships in architecture at the Royal Academy are to be decided upon.

ARCHITECTURAL ASSISTANT.

* I admit the query, but have not the slightest doubt that the drawings are usually submitted to a proper tribunal.

SMOKY CHIMNEYS.

Sir,—My house is square on plan. All the chimneys are external. Every chimney in the house smokes more or less. The current of air, instead of being upward, is downward.

When there are no fires in the grates, the cold air descends in a steady current, bringing soot with it, and spoiling everything in the house.

When the fires are going out at night, the hot air, charged with noxious gases, is forced into the rooms by the cold air pressing above it.

I have tried very many varieties of zinc chimney-pots, including some of the best patented ones, but they abate the evil very slightly. The down-draught still continues, although, of course, the volume of air which falls is not so heavy. The chimneys really appear to suck in the air from the top, and to distribute it, laden with soot, over the house. The stoves are the ordinary register stoves.

Opening doors or windows makes little difference. The draught still pours down the chimney and out at the door or window.

Can any of your readers suggest the cause or the cure? R. J.

THE MARSHES OF THE MEDITERRANEAN. INSTITUTION OF CIVIL ENGINEERS.

ON February 16th, the paper read was "On the Lagoons and Marshes of certain Parts of the Shores of the Mediterranean," by Professor D. T. Ansted, F.R.S. The following is a summary of the practical bearing of the facts adduced:—

First. That the malarious lagoons and marshes, of which there were so many examples on various shores, were the result of the interception of waters coming of small tracts of land, or of small and torrential streams, by banks of drifted sand and mud, proceeding from larger rivers, carrying out to some distance large quantities of detritus which was distributed by marine currents.

Secondly. That a study of the existing physical geography of each district affected by malaria, combined with a knowledge of its geology, was sufficient to explain the conditions, and to determine the history of a knowledge that had terminated in the formation of the malarious marshes and lagoons.

Thirdly. That the removal of malaria, whether to be effected by complete drainage or by partial drainage, accompanied by the keeping certain lagoons in free communication with the sea, could only be hoped for by engineering operations, based on the special history of the case under consideration, as determined by a knowledge of the physical geography and geology of the district.

Fourthly. That, in certain cases where small torrential streams had been kept back from the sea by the rapid accumulation of drifted sand, the drainage of the marshes and lagoons might be rendered comparatively easy by keeping open a permanent channel for such streams.

Fifthly. That the principle of breaking up the drainage areas supplying water to the lagoons into smaller areas, each of which admitted of separate treatment, being suggested by the history of lagoons generally, was the principle which should be adopted in all cases where sanitary improvement was called for, and would generally be found advantageous to an economic sense.

ARTISANS' AND LABOURERS' DWELLINGS ACT.

THE district Board of St. Saviour's, South-west, find themselves impeded in their design of putting this Act into operation by the provision for defraying the expense being by a special rate, a provision inserted by the House of Lords. The Board have determined to petition both Houses for an amendment of the Act in this respect.

OFFICES FOR THE POPLAR BOARD OF WORKS.

At the ordinary meeting of the Poplar District Board of Works last Tuesday evening, Mr. Edward Coleman in the chair, the following tenders were received for the erection of new offices for the Board.

The chairman said the approximated sum for the buildings was about 6,700l.

Table with 2 columns: Contractor Name and Amount. Includes Moore, Upper Norwood (£15,007 0 0), Girling, Bromley (10,903 0 0), Perry, Barking-road, Essex (5,775 0 0), Harris, Limehouse (9,663 0 0), Walls, Barking-road (5,921 0 0), Ennor, Commercial-road East (8,779 0 0), Morte, Stratford (8,743 0 0), Myers & Son, Lambeth (8,674 0 0), Crab & Vaughan, Kingland (8,663 0 0), Cook & Green, Kensington (5,386 0 0), Ancombe, Maidstone (5,623 0 0), Winthrop & Co., Lewisham (5,600 0 0), Abraham, Poplar (8,478 0 0), Hughesdon, Deptford (8,600 0 0), Webb & Sons, Bow (8,223 0 0), Sheffield, Poplar (8,387 0 0), Till, Hampstead (8,330 0 0), Hill, Keddell, & Waldron (8,315 0 0), Kilby, Limehouse (8,112 0 0), Wicks, Bangs, & Co., Limehouse (7,975 0 0), Turner, South Hornsey (7,809 0 0), Baker & Constable, Holloway (7,530 0 0).

The lowest four tenders were referred to a special committee, who are to report to the Board at a meeting next Tuesday evening.

GRAINING AND SHAMS.

Sir,—If you think this will not be out of place in your columns will you favour me by publishing it. I think we are hearing just a little too much about shams at present, and judging by the quarter from whence the outcry emanates, there is a simplicity about it that is quite refreshing. If the term sham applied to products of the imagination or ideal representations of nature, I am sure that some of these specimens of realism are perfectly innocent of anything like a sham. As regards to graining and marbling, I will venture to say that when the work is done by a first-class workman there is frequently as much of more ability, refinement, and true artistic feeling displayed than in any other branch of house decoration. Let us see what we get as a substitute for these so-called shams.

In nine cases out of ten we get in form the most elementary examples,—the straight, the indine, and the curve,—without one spark of subtlety or refinement to redeem them from the most hopeless commonplace. And in colour we have blue, red, and yellow,—yellow, red, and blue, neat or mixed, upside down, and inside out. A mere ebulition of the chromatic pack.

Almost the whole of the work is done by journeyman painters, who, by this overdone system of stenciling, are degraded to mere machines. I would ask those who cry out so much about shams, to look into their own art with a more loving eye, and they would possibly learn to appreciate the efforts of their more humble brethren. Also I would ask them to condemn Art only when it is bad, and not because it is not real. Mr. Dean, the Xylographer (I hope that is right), spoke of a gentleman who praised his work because he could not distinguish it from the real. I wonder whether that gentleman ever saw the admirable imitation of a late member of Parliament who was his head daily from 15 to 17 in an establishment in Baker-street? As a lifelike production I think it is unsurpassed.

A PRODUCER OF SHAMS.

GRAINING FROM THE SURFACE OF WOODS.

Sir,—In your paper of January 30th, I find, in a notice of a meeting of the Society of Arts, a description of a supposed new discovery, now christened xylography, and Mr. Dean claims to be the inventor. More than twenty years ago I transferred from prepared paper hundreds of yards of imitation of woods. More than eight years since a Frenchman invented printing from real wood, and thousands of pieces of it were sold in England for paperhanging at 1s. 3d. per piece; five years ago I produced it with an old mangle, a patent one, as follows:—I took ordinary lining

paper, and gave it a coat of size with a little treacle in it, or a coat of size made simply with gum arabic. I then placed the prepared paper on a slab of oak, which was previously rubbed in with oil graining colour. I then pressed it between the two rollers of the mangle, with a piece of molskin between the roller and paper. When the impression was dry, I varnished the work to be grained; and when the varnish was nearly dry I rubbed the printed paper previously damped, and the impression was left clean behind. I can show work done twenty years ago by myself, and you can purchase the French paper at any paper-shop. W. DAVIS.

** We have received a number of letters from grainers for and against the process, but no good end would be answered by printing them.

RAILWAY MATTERS.

As was to be expected, the foolish financiers of the London and Brighton line are being obliged to lower their fares again, the grasping and greedy attempt to raise them having lowered their profits by checking the traffic. How is it that they could not foresee this result as other people did? Surely another sort of management will now be substituted for the purlined one by which the shareholders have hitherto been led.

The dividends on most of the lines making up their accounts to the end of the year have now been declared, and they are upon the whole satisfactory—more so, indeed, than was anticipated a short time since. Railway companies have, during the last half-year, been fortunate in keeping down their working expenses, in consequence of the reduction which has taken place in almost all descriptions of material, and the prevailing lower rate of wages. The railways have gained by diminished charges for labour more than they have lost by the stagnation of trade. Hence the good dividend of the London and North-Western Railway, which is at least a 2 per cent. more than what had been reckoned upon. The completion of the Midland is now, however, beginning to tell severely upon the business of the North-Western, especially so in the item of mineral traffic between Rugby and London.

It is said that application has been made to his Royal Highness the Ranger for leave to construct a railway underneath the parks. The proposed line is intended to join the Charing-cross and Paddington Stations, and according to the plans, is to pass under St. James's-park, parallel with the Mall, thence underneath the Green-park parallel with Constitution-hill to a station at Knightsbridge; then diagonally across Hyde-park, with a station at the barracks to the vicinity of the Victoria-gate, from which it is to pass underneath the streets into one of the Paddington stations. The trains are to be propelled by rope system, and thus the disagreeable and deleterious gases in the underground lines as at present worked will be avoided. It is said that in construction the principal part will be tunnelled, so as not to interfere with the surface of the parks.

THE PROPOSED NEW BUILDING ACT.

Sir,—As a new "Building Act" is under consideration, I send a few remarks on the subject.

I must protest against such frequent changes of the law relating to building. The Act of 1774 lasted 70 years; that of 1844, though a very good and well-considered Act, only existed 11 years; and the last Act (of 1855), has only been in operation 14 years. If we must again be disturbed and inconvenienced by another new Act, I trust that it may be so thoroughly well considered that it will last another 70 years like the old Act of 1774. If it is to be a lasting Act it must not enter too much into minute, petty, and vexatious details.

The principal objects should be—to check the spread of fire; to provide for the safety of the public; sanitary regulations; and to obtain more substantial buildings. I think it would be well to repeal the whole of the previous Acts, and not as in the last Act, to leave small portions of the previous Acts unrepealed instead of embodying them in the new Act. I think the provisions and form of the last Act should be preserved as far as possible with only such alterations as are clearly necessary. A central professional controlling power is very desirable, somewhat after the plan of the Act of 1844.

The proceedings as to rebuilding party walls under revision. There is considerable difference of opinion and practice as to the meaning of several clauses of the present Act relating to party walls; for instance, as to who is the person upon whom the three months' notice should be served. The clauses relating to appointment of owner's surveyors and umpire are secure. No provision is made in case all three surveyors differ. The present Act does not define a "building." It does not mention a prevention of the spread of fire. It does not limit the time within which a district surveyor may take objection to any part of a building, unless erected without notice. It does not expressly require the district surveyor to inspect the drawings, or point out anything amiss in them, before the execution of the work. It does not recognise in walls.

Any absolute restrictions of the height of buildings should only apply, I think, to very thoroughfares.

A READER.

MEDIEVAL METAL CAPITALS.

SIR,—I should esteem it a favour if one of your correspondents would inform me whether metal capitals to pillars were used in any ancient Greek. I am aware that in modern adaptation Greek and Roman forms the capitals, when made of plaster, are often gilt; and if gilt, why could they not of course be made of metal? But I am not aware that capitals were ever used by the Medieval artists, or that metal was employed by them for the capitals. I should like to know.

T. M.

THE NEW CATTLE-MARKET, DONCASTER.

THE new markets, for the plans and designs of which the town council awarded the first premium in an open competition, about three years ago, to Mr. Watkins, of Lincoln, are now, so far as relates to the open markets for the sale of calves, sheep, pigs, &c., and the abattoirs, in a forward state of progress. These markets form a portion of the general system laid out for their enlargement and improvement, which comprises, in addition to those under notice, a new corn exchange (arranged also for large public assemblies), new vegetable and fish markets, a sessions hall and board of guardians' room, which are intended to follow. The style is Italian, freely adapted. The chief entrance is upon the site of the old White Horse Inn, and consists of a central carriage-way 13 ft. wide, and a hand-way on the north side, hung to large ornamental stone piers with carved caps. The sheep market occupies the centre of the upper portion of the open markets, and is arranged in two lairs, having a road down the centre 15 ft. wide. There are 184 sheep-pens, 34 fat beast lairs, and 10 pig-pens. The abattoirs occupy the north-east corner of the markets, and have two approaches therefrom. The quantity of iron used is 10 tons of cast iron, and 10 tons of wrought-iron being. The town council appointed Mr. T. H. Muley, the borough surveyor, clerk of the works, and Mr. Rawson as his assistant. Mr. E. Huddleston, of Lincoln, contracted for the general work, for 4,298l.; and Messrs. Ratcliffe & Muscheler, of the Hexthorpe Ironworks, for the iron pens, 1,544l. 10s.; and for the principal wrought-iron gate and the two side gates, 1,067l. The erection of the market-keeper's lodge, and other extras, will increase the outlay for the works.

G A S.

THE directors of the Gloucester Gas-light Company have proposed dividends to be declared of 10 per cent. for last year upon the class A shares, an additional 5l. per cent. in payment of the balance of the arrears of dividends due to this class of shareholders, and 10s. per cent. per annum upon Class B shares. These dividends absorb 2,573l. 3s. 6d., and leave a balance of 501l. 19s. 2d. to be carried over to the next half-year.—The Ipswich Gaslight Company have declared a dividend at the rate of 7 per cent. for the year, to be paid upon old shares, and 7l. per cent. upon new shares, that are to be placed to the credit of the fund for the depreciation and renewal of the meters on hire, and that a balance of 4,688l. be carried forward to the new profit and loss account.—The directors of the Longton Gas Company have re-

commended a dividend for last half-year at the rate of 6 per cent. per annum, free of income-tax, a balance of 218l. to be added to next account.—The Liverpool Gaslight Company have declared a dividend for the half-year of 5l. on every 100l. stock, and a dividend at the rate of 3l. 10s. for every 100l. for a half-year on the capital paid up in respect of the 7 per cent. shares.

Books Received.

VARIORUM.

"A SYSTEM of Taxation that would be to the Pennyrite Advantage of all." By T. H. Willis. The author of this scheme proposes the repeal and abolition of the property and income tax, Customs dues (reciprocity dues excepted), Excise levies, and all assessed taxes and rates; and the substitution of one general rate or tax, on land alone, covered by buildings as well as uncovered, and from tenants as well as landlords, at per acre, according to its productive character; increasing or lessening the assessments as Parliament may sanction, or as occasion may require. By this simple plan, Mr. Willis argues, a much larger revenue could be obtained, with less taxation to each, and more equal justice to all, than under the present complicated and expensive mode of raising the revenue. The special sources of taxation he divides into covered land; land worked as quarries, &c.; used as nurseries, &c.; employed in tillage, pasturage, &c.; and held for all other purposes. To this would fall to be added customs reciprocity dues, &c., crown lands, post-office, probate and legacy duty, stamps, and miscellaneous receipts. Covered land alone would yield, he calculates, about 35,000,000l. The same principle, he adds, might be applied, and with like advantages to occupying tenants, in respect to parochial rates and all other local rates and taxes. Mr. Willis is an old reformer, as regards rates and taxes, as some of our readers may recollect.—"London Water Supply: Facts and Fallacies discussed." By John Taylor, C.E. London: Spon. This is a series of letters which were written for and published in the *Courier* newspaper in 1866-7, chiefly with reference to the constant service and a future source of supply. The general tone of the whole is in support of the water companies and the quality and quantity of the supply; and Mr. Taylor points to the very exceptional summer of last past as against a constant service for London, although he admits its necessity throughout the slums of the metropolis.—"Sewage, in its general Application to Grass, Cereal, and Root Crops." By Thomas Cargill, C.E., *Mechanics' Magazine* Office. In this very timely-written and important pamphlet, the author shows the results obtained by actual experience down to the present date; with plans and sections, illustrating the methods of forming the ground for the different systems, and for distributing the sewage over the irrigated fields. He confines himself to the utilization of sewage in field irrigation, avoiding the question of the removal of sewage from cities, towns, and villages, as a separate question. Every one interested in sewage irrigation ought to have this pamphlet, which may help towards the solution of the sewage problem.—"On the Rainfall of Cobham and Chiswick." By George Dines, F.R.S. The tables and remarks here published in a separate form are extracted from the proceedings of the Meteorological Society for November last, and they contain the results of forty years' observations. They were made use of by Mr. Dines with reference to a paper on the moon's influence upon rainfall, read before the society.—"The Court Suburb Magazine" is, as its title imports, more especially devoted to Kensington, but is not wholly so. It deals with "General Literature," as well as "Objects of Suburban Interest," is well edited by Miss Aikin Kortright (better known as the author of "The Dean"), by whom also it is issued at 21, Eldon-road, Kensington; and contains much agreeable writing.—A second edition has been published of "Other People's Windows" (Samson Low, Son, & Marston), by the author of "The Gentle Life," Mr. Hain Friswell. This very charming series of sketches, ingeniously and completely tied together into a whole, is now condensed into one pretty volume, and in that shape will, we have little doubt, run through many editions. Mr. Friswell writes like a gentleman, and the spirit of the book is excellent.

Miscellanea.

The New Elephant-house of the Zoological Gardens is thus described in *Scientific Opinion*.—It is a fine building, though a little too red-brick in aspect. It is, however, calculated to provide luxuriously for the comforts and well-being of the pachyderms, and is unrivalled in size and general construction. It contains eight large divisions for elephants and rhinoceri, and is so arranged as to give the animals proper scope for exercise, and the public ample means of watching the habits of the beasts.

Health of Boston, Lincolnshire.—Mr. W. H. Wheeler, the borough surveyor of Boston, in a letter on the Weather and the Public Health, says:—The total number of deaths for the year has been 311, or 15 below the average of the last seven years, the average age being a little over 38 years. 75 were over 70 years of age, and 70 were one year or under. The per centage of the year is 20 deaths to every thousand inhabitants; 20 deaths arose from fever, 1 from diphtheria, 5 from whooping-cough, 2 from diarrhoea (exclusive of infants), 35 from consumption, 12 from lung diseases, 17 from bronchitis, 70 from infantile diseases, 47 from miscellaneous causes, 6 from tumours and cancers, 8 from heart disease, 27 from brain diseases, 5 from accidents, and 61 from decay of nature.

The Maintenance of Parish Churches.

Vestry meetings have been held in several of the parishes throughout Shropshire for the consideration of the best mode of raising funds for the maintenance of the parish churches, hitherto provided for by compulsory rate. At Wem the adoption of the system of a voluntary rate was carried by a large majority. At Newport three propositions were brought before the meeting, one suggesting that all the seats in the church should be made free and unappropriated, and that the congregation should have the opportunity of making "weekly offerings;" the other two proposing the free appropriation of a portion of the seats, and the allotment of the remainder amongst such parishioners as might signify their intention of contributing towards the expenses of the church. The meeting, which was an adjourned one, again separated without arriving at a decision. At High Ercall, Shifnal, Wellington, and Church Aston the system of free and unappropriated sittings, combined with a weekly offertory, has been adopted with satisfactory results.

Society for the Encouragement of the Fine Arts.—On Thursday, the 18th, Mr. Wyke Baylis gave a lecture "On Dante, and Longfellow's recent Translation of 'The Divine Comedy.'"—Mr. Prescott Hewett in the chair,—introducing the subject with a short biographical notice of the poet, who, he said, woke the world to poetry and art, and who had not suffered so much from translation as other poets only because his translators had been so few. He characterized Longfellow's translation as a grave and scholar-like production that was free from Cary's imperfections and impertinences. Mr. Hurlstone, on being called upon, said Cary's was the more poetical, Longfellow's the more literal, translation, the title, "The Vision of Dante," giving the sense of the original far better than "The Divine Comedy," the signification of the word comedy having greatly changed since Dante's time.

The Peabody Gifts to the London Poor.

A statement of progress for the year 1868 has been published and circulated by the daily press. From this it appears that during the year a fourth range of buildings, forming Peabody-square, in Victoria-street, Westminster, has been erected. They contain 235 rooms, and accommodate 389 persons. The total population of all the buildings now completed by the trustees is 1,971. Amongst them are 132 laborers, 62 porters, 22 charwomen, 18 dressmakers, and so on. "The sanitary condition of the buildings shows an entire exemption from endemic diseases, and from those complaints incident to low and crowded localities. Good ventilation and cleanliness are characteristic of the dwellings. An unlimited supply of water, and bath-rooms free to every tenant, together with inclosed playgrounds for the children, have already produced a salutary effect, not only amongst the young, but perceptibly in the increased tidiness and cleanliness of the old." The total amount of the gifts is now 350,000l. The original fund of 150,000l. has already been increased by rents and interest by 23,313l.

TO CARPENTERS AND BUILDERS. WANTED, a SITUATION in a Good JOINING SHOP. Thoroughly acquainted with every branch of the trade.—Address, A. Z. R. 191, High-street, Peckham, London.

TO BUILDERS AND CONTRACTORS. WANTED, a RE-ENGAGEMENT, by a Young Man, to WORK a Moulding Machine, Circular Saw and Band Saw, in connection with a Joiner's work. First-class reference from where last employed.—Address, J. C. 2, Hillen-road, Grove-road, Mile End.

TO ARCHITECTS, BUILDERS, AND OTHERS. WANTED, a RE-ENGAGEMENT as a CLERK of WORKS, or GENERAL FOREMAN of a JOB, Town or country. Capable and junior by trade. References good. Address, S. Q. 4, Upper St. Martin's Lane, W. O.

TO BUILDERS AND OTHERS. WANTED, by a respectable Man, constant EMPLOYMENT. Understands the painting and glazing. Wage, 12 per week.—Address, A. R. M. Webb, near the Duke's Head, Hampton, Middlesex.

WANTED, a SITUATION, by a thoroughly good GREENGLASS and MARBLER. Can do writing, editing and general decorating. Willing to take charge of work or fill up time with any other branch of the business. Can do plumbing if required. Good references.—Address, L. K. 8, 53, Bute-lane-street, Finsbury-street, Hoxton, London.

WANTED, a RE-ENGAGEMENT, by a very experienced BUILDERS' CLERK. Accustomed to all the routine of a London building, especially in the line of business, a good accountant and book-keeper, with first-class references.—L. L. Post-office, West-quay, S.

WANTED, a SITUATION, as BUILDERS' MANAGER or SUPERINTENDENT of WORKS. General knowledge of every part of the business, measuring, estimating, and drawing, purchasing in detail. Thoroughly conversant with Ecclesiastical work. Terms moderate.—Address, L. M. Post Office, Wandsworth-road, Croydon, S.

TO BUILDERS OR QUANTITY SURVEYORS. A YOUNG GENTLEMAN (21) wishes for making up Estimates, and can make finished drawings, &c. Testimonials. First-class testimonials. Moderate salary.—Address, 726, Office of "The Builder."

The Builder.

VOL. XXVII.—No. 131.

London in 1868.

REGISTRAR-GENERAL, in his annual summary of the weekly returns of births and deaths in London, does well in prefacing his usual information of a sanitary and statistical nature with a few figures, which afford considerable assistance in the attempt to form an adequate idea of the present size and population of London. With all the recently-increased facilities for

metropolitan locomotion, a personal knowledge of the nature and extent of the whole of London is, from its very size, a rare accomplishment. It is well, therefore, now and then, to be reminded of such facts as the following:—

The area of London is about 78,000 acres, or nearly 122 square miles. This, it should be understood, is London as defined by the Registrar-General, including Hampstead, Kentish-town, and Stoke Newington, on the north; Wandsworth, Norwood, and Sydenham, on the south; Bow, Poplar, and Greenwich, on the east; and Kensington, Hammersmith, and Fulham, on the west. On this area, including these suburbs, stand over 400,000 inhabited houses, with an average of nearly eight persons to a house, giving a mean density of 40 persons to each acre. It is now nearly eight years since the last census, and we are dependent upon estimates for forming an idea of the present population of London. The estimate based upon the rate of increase which prevailed between 1841-61, gives 3,126,335 as the number of inhabitants of this large area, to the middle of 1868. The county-rate assessment of 1866 placed the annual value of property in London at 15,261,999*l*. The influence of elevation upon human health is now pretty generally known; the Registrar-General informs us that the population of London resides at a mean elevation of 39 ft. above Trinity high-water mark. The elevation of London varies from 11 ft. below high-water in Plumstead Marshes, to 429 ft. above high-water mark in Hampstead. On the north side of the Thames, Fulham, Pimlico, Westminster, and the Isle of Dogs are below high-water mark; on the south side, Battersea, Kennington, Camberwell, Bermondsey, and Rotherhithe. After Hampstead, the most considerable elevations within the limits of London are Shooter's-hill and Sydenham-hill, respectively 411 ft. and 360 ft. above high-water mark.

In the twenty-nine years 1840-68 the average annual rate of mortality was 24.3 per 1,000 persons living; the rate varied between 21.0 and 22.1, the lowest in 1850 and 1856, and 29.4 and 30.1 in 1854 and 1849, in each of which years a cholera epidemic prevailed. The last visitation of cholera in 1866 did not raise the death-rate of England above 26.5, which may be taken as evidence that through the growth and influence of sanitary knowledge the London population was in 1866 in a better condition to repel this hitherto alarming disease. In 1868 the rate of mortality in London was 23.6, and .7 per 1,000 below the average of twenty-nine years. In the fourteen large towns of the United Kingdom furnishing weekly returns, the aggregate

death-rate in 1868 was 25.6, and two per 1,000 above the rate which prevailed in London. In these fourteen large towns the rate of mortality during the year, ranged in order from the lowest, was as follows:—

Bristol	22.8
London	23.6
Birmingham	23.9
Hull	24.4
Dublin	24.6
Newcastle-upon-Tyne...	25.6
Bradford	26.5
Sheffield	26.6
Edinburgh	26.9
Leeds	27.5
Liverpool	29.2
Glasgow	30.5
Salford	30.8
Manchester	32.0

This list shows a difference of no less than 9.2 per 1,000 between the death-rates prevailing during the year in the towns occupying the first and last places. No less than 3,376 persons fell victims during the year to the excessive mortality in Manchester, who would have survived if the death-rate had not been higher than that which prevailed in Bristol. Compared with previous years, Newcastle occupies an improved position, and so does Liverpool, while Manchester and Salford appear lower in the list. Sheffield would have taken a higher place but for the epidemic of small-pox which was so fatal during the latter half of the year. The death-rate in Leeds was considerably below the average in the first six months of the year, but rose rapidly in the last few months, principally through the fatal prevalence of measles, and typhus and typhoid fevers.

In the different parts of London the death-rate during last year was 22.7 in the west districts, 22.9 in both the north and south districts, 24.7 in the central districts, and highest, 25.6 per 1,000 in the east districts. The excessive rate in the east districts must not be attributed to the distress which there prevailed during the greater portion of the year, as the average death-rate in that portion of London (including Shore-ditch, Bethnal-green, Whitechapel, St. George-in-the-East, Stepney, Mile-end Old Town, Bow, and Poplar) the death-rate in the twenty-nine years—1840-68—averaged 26.0 per 1,000, or slightly above the rate in 1868, as was the average rate in the same period for the whole of London. The Registrar-General shows that sanitary improvement has been most striking in South London, where, previously to 1856, the sewerage was especially defective, and the water supply drawn direct from the Thames, was heavily charged with sewage. During the five years, 1840-4, the death-rate in South London was 25 per 1,000, in 1845-9 it was 28, in 1850-4 it was 26, in 1855-9 it further fell to 23, in 1860-4 it was again 23, and in 1865-8 it ranged from 22 to 24. During the cholera epidemics of 1849, 1854, and 1866 the death-rate in this part of London, from all causes, was 38, 35, and 34 respectively. The mortality is now lower in South London than in North London.

The causes of death in London in 1868 do not present many remarkable features: we shall therefore confine ourselves to a brief notice of three classes of death,—those resulting from zymotic disease, those referred to affections of the respiratory organs, and to violent deaths. Of the 74,908 deaths which were registered in London during the fifty-three weeks of last year, 18,893 were referred to all diseases of a zymotic character, showing a proportion of 25.2 per cent. of the total deaths, against 21.3 in 1867, and 29.6 in 1866, when cholera was epidemic. The mortality from this class of diseases is in a great measure governed by the degree of fatality from infantile diarrhoea during the summer and early autumn; in 1860, when the summer season was remarkably cold and wet, both the death-rate in the year from all

causes and the proportion of fatal cases of zymotic disease were lower than in any of the past ten years. Small-pox, last year, was considerably less fatal than in recent years; while the deaths from scarlatina and diphtheria were decidedly more numerous, and those from whooping-cough and measles nearly corresponded with the average of previous years. The various forms of fever (including typhus, typhoid, enteric, and simple) caused 2,483 deaths, which, although showing a small increase upon 1867, were considerably lower than in any of the preceding five years. During the year no less than 4,060 deaths resulted from diarrhoea, of which 3,145 occurred in the three months ending September 30th; in the year 1860, above alluded to, only 1,383 deaths were referred to diarrhoea; and in the thirteen years, 1856-67, the highest number of deaths so caused was 3,557 in 1865. The unusual heat, combined with the remarkable drought of last summer, caused the excessive mortality from diarrhoea, principally infantile, which then prevailed.

Diseases of the respiratory organs, including phthisis, caused 21,203 deaths, or 28.3 per cent. of those from all causes. The heat of last summer scarcely affected the mortality from this class of diseases, and the unusual mildness of January, February, November, and December, was especially favourable to those affections, particularly to bronchitis, pneumonia, and others of an inflammatory nature. We might, therefore, have expected to find the mortality from the diseases of these organs unusually low; this, however, was not the case, although they were below the numbers returned in any of the four years, 1864-7. In 1859 only 16,975 deaths, or 27.5 per cent. of the total deaths, resulted from these diseases. The mean temperature of the air in 1868 was 51.6°, and 2.3° in excess of the average temperature in the 29 years, 1840-68, it also exceeded the average of any one of those years, the nearest approach to it being 51.3° in 1846. The dryness of the atmosphere was 6.8, the average of 29 years being 5.6. The rain-fall of the year was 25.2 inches, against an average of 24.3 inches; the deficiency during the summer being more than compensated by the heavy rains of January and December. The mean daily amount of horizontal movement of the air in the year was 293 miles, whereas the average during the 20 years, 1849-68, was only 247. The full effect of these meteorological conditions upon human health, and especially upon the respiratory organs, is at present scarcely sufficiently understood.

The statement that 2,567 deaths in London last year resulted from external causes, and were what are called "violent deaths," is somewhat startling, and yet such was the case. Of every 1,000 deaths during the year no less than thirty-four were cases of accident or negligence, homicide, suicide, or execution. It is worthy of remark that this class of deaths has steadily increased, with but slight fluctuations, from 1,839 in 1856, to the 2,567 during 1868. Such a waste of life from causes most decidedly within human control, does not reflect much credit upon the humanity of this nineteenth century. While advocating and encouraging sanitary efforts of all kinds, we must not forget to enforce measures for the safety of life and limb from violence; for this, however, we must the rather look to the Commissioner of Police, than to the Privy Council and to health officers. Of the 2,567 violent deaths in London last year, 2,126 resulted from accident and negligence, 112 from murder and manslaughter, 294 were suicides, and two executions. Among the accidents, 891 were caused by fractures, contusions, and wounds, 287 by burns and scalds, forty-four by poisoning, 339 by drowning, 386 (principally of infants) by suffocation, and in the other 179 the causes were imperfectly returned. Of the suicides, sixteen chose gunshot, fifty wounds by cutting or

stabbing, forty-six poisoning, seventy-two drowning, seventy-nine hanging, and in thirty-one the mode of suicides were not stated. The proportion of these violent deaths, it may be observed, is generally considerably smaller in London, indeed in most large cities and boroughs, than in the country at large; this may be accounted for in two ways—first, by the superior intelligence of town inhabitants, as so large a number of these accidents result from careless ignorance; and secondly, by the superior, and more easily accessible, hospital accommodation in large towns.

The 74,908 deaths last year in London included 12,326, or 16.5 per cent, which occurred in the public institutions; of these 6,789 were registered in workhouses, 4,647 in hospitals, 336 in Inebriate asylums, 75 in prisons, and the remaining 479 in other asylums and special institutions. There has been a continuous increase in this class of deaths since 1859, when only 9,633, or 15.3 per cent. of the total deaths, were so recorded. It is scarcely necessary to say that the proportion of these deaths is much larger in London than in other large towns in England.

The Registrar-General naturally deals in his report, at some detail, with the condition of the sewerage, and of the water supply of London in 1868. No one can well over-estimate the importance of these two subjects, or their direct influence upon the public health. We can, however, only, in concluding our notice of this important annual return, just touch upon these two points.

The main drainage system of sewerage for London is approaching completion, but not until it is complete can we judge of its full effect upon the river, and its influence on the health of London. The most important parts of the "low level sewer" are not yet constructed; namely, the part from Chelsea Hospital, including the first lift down to Westminster Bridge, and the part extending from the Temple to the Tower of London; so that many of the large sewers still pour their contents into the Thames." Consideration of this apparently probable purification of the Thames, at no very future date, from contamination of the sewage of London, at the actual outlay of millions of pounds, which have still further raised the already heavy tax burthens of London householders, is somewhat embittered by the knowledge that the result of this gigantic undertaking runs the risk of being in a great measure neutralized through the use of the river by Oxford, Reading, Windsor, Richmond, and other places above London, for the evacuation of their sewage. From another point of view this state of things appears still more fatal. Many years ago Parliament enacted that the London water companies should take their supply from above London, and beyond the reach of the contamination of London sewage. Each of the past few years has shown an increasing contamination of the Thames from the sewage of towns up the river. The public naturally looks anxiously for the long-delayed report of the Royal Commission appointed some years since to inquire into the whole subject. Even Dr. Letheby will have some difficulty in persuading the London water-consumers to consider themselves satisfactorily treated by the present water companies, either in quantity or quality.

The year 1868 was, it must be allowed, most unfavourable for the water supply of London, drawn as it is from a tidal river. The heavy rains of January, October, and December, caused the river to become turbid,—a result observed on many occasions in water drawn from the mains; the long drought of June, July, and August was moreover detrimental alike to the companies and to the consumers. Notwithstanding these circumstances, it is, however, satisfactory to be assured by so high an authority as Dr. Frankland, in his official report to the Registrar-General, that, probably from greater attention to and improved methods of filtration, the sewage contamination in the water supplied by all the London water companies (except the Kent) showed a reduction in 1868 upon 1867. The condition of the water supplied on many occasions during 1869 is reported by the same authority, however, to have been such as to render it totally unfit for domestic use. Chelsea, Southwark, and Lambeth were the principal offending companies, while the West Middlesex is said to stand pre-eminent as regards careful filtration, a matter of such vital importance, considering the source, and quality of the water used. The discovery of an excessive proportion of common salt in the Southwark

water in the autumn, at the latter end of the drought, suggested a suspicion of the admission to the company's reservoirs at Battersea of a proportion of tidal water. The possibility of such a thing, with the intimate relation which was proved between the outbreak of cholera and the East London water supply in 1866, fresh in our memory, is sufficiently alarming. Dr. Frankland furnishes a table showing, from analysis, the total impurity contained by waters drawn from the supply of several provincial towns, and compared with that of London. In 100,000 parts of each water, the "total solid impurity" of the London waters varied from 26.9 in the New River, to 45.3 in the Kent; while in Glasgow, supplied from Loch Katrine, it was only 3.0; in Lancaster, from Bleasdale Falls, 4.6; in Manchester, from Derbyshire hills, 6.2; in Kewick, from Skiddaw, 4.3; and in Whitehaven, from Ennerdale Lake, only 2.2. In each of the latter cases, "previous sewage or manure contamination" was nil, while in the London waters it varied from 1590 to 3842. Comment is unnecessary.

We must, while acknowledging the many satisfactory evidences of sanitary progress in London, and other large towns, in 1868, trust, and not without reasonable cause, for still more favourable results from continued and energetic efforts in the same direction during 1869, and the next few years.

THE CONFLICT OF METROPOLITAN AUTHORITIES AS TO ARCHITECTURAL IMPROVEMENTS.

It is now some eight centuries since the charter of the Norman Conqueror encouraged the citizens of London to form a sort of happy family on a large scale, or a little *imperium in imperio*. The first fruits of the original "social compact" are still existing, in the form of a corporation. But the difficult and anomalous part of the thing is, that this corporation does not now fulfil the originally prescribed conditions. It is not sole—it is not supreme. It has come, in the course of time, to be surrounded, encroached upon, and over-shadowed, by other corporate bodies, under various names. Of these the most general, and perhaps the most formidable, is the name BOARD. Under the direction of various Boards, or compound individualities, the independence of the primary unit, the citizen householder, has been altogether obliterated. He has nothing which he can call permanently his own. Not his house, which is liable to be "scheduled," or expropriated. Not his business, which may be destroyed by the same method, or by turning the traffic of a large thoroughfare from his door, or by a dozen other procedures, emanating from an equal number of Boards. We find Gas Corporations, Water Corporations, Railway Corporations, Paving Commissioners, Poor-law Commissioners, Police Commissioners, Board of Works, and district Boards of Works, all living, and apparently thriving, and certainly acting with the most absolute disregard of one another. They will not part with an iota of their independence, even for the sake of saving money. Why, indeed, should they? The money does not come out of their pockets. There are the police rate, the poor rate, the county rate, the rate of the Metropolitan Board of Works, and the new Metropolitan Asylums rate.

There is scarcely a resident householder of London who is not painfully aware of the truth of this description. Most of them know it to their cost,—their cost in time and in convenience, no less than in actual money. But even the latter item is no trifle. Suppose a certain great thoroughfare to be out of order, and that, after a proper amount of discussion, the "hoard" that presides over the spot has taken the matter in hand, and made good the road at the expense of 250*l.*; the removal of the implements of the servants of this board, which we will call No. 1, is the signal awaited by the servants of the board No. 2. They proceed to fix posts and rails in the newly-finished roadway, to re-open it from end to end, and to re-adjust the gas-main, which had been disturbed by the operations of board No. 1. A long trench, heaped over, when at last it is refilled, like a grave, only with the clay bank interspersed with road-metal, now divides the up and down traffic on the road, or would divide it if the traffic kept to its own side, as it is now becoming accustomed to do. But just about the time when the action of wheels and of hoofs has

nearly levelled this prolonged stumbling-block, the oozy state of the mixture attracts the notice of board No. 3. The waterworks people see that the precious element is escaping, their mains having been in their turn disturbed by preceding operations. Then comes a repetition of the proceedings of board No. 2. By the time that traffic is again allowed to adjust itself to the roadway, the season is so far advanced that the sewer authorities think it high time to perform a little work of their own in the same locality, and destruction No. 4 takes place accordingly. Now if the first proceeding was rightly priced at 250*l.*, we cannot allow a much smaller sum for either of the subsequent operations. We shall have, after six or eight months of interrupted traffic, a very bad road, which has cost the rate-payers, or the gas-consumers, or the water-consumers, or some taxable party, 1,000*l.*, while, by the mere expedient of combination, the work might have been done in two months for 400*l.* And if the only rational provision for laying mains, whether for water, or for gas, as well as for maintaining the sewers and protecting the wires of the electric telegraph,—the subway, had been adopted in the first instance, the original 250*l.* would have covered the entire outlay for maintenance for some two or three years.

In all this, our readers may think, there is unfortunately nothing very new. It was much the same ten or fifteen years ago. It is unpleasant, but it appears to be our normal condition.

But the pressure increases, year by year, with the growth of our vast metropolitan population. And not only does the pressure of old grievances increase, but, year after year, new grievances swell the list. The piercing, and burrowing, and arching, through London, proceeds with rapid pace. New streets suddenly open, like dissolving views, through ancient lines of frontage. Transformations, like those of a pantomime, occur so unexpectedly, that the oldest inhabitant, if confined to his bed for a twelve-month, would wonder where he was when he next went out for an airing. And, over-topping all other boards and corporations by a head and shoulders, stands, or rather moves, the gigantic figure of the Board of Works.

Now, not only have these numerous corporate entities entirely failed as yet to establish the "social compact" among themselves, but they act with a sturdy independence of one another, which has much the same result as the most lively hostility; and they act very vigorously, moreover. The result is, that some anomaly, or inconvenience, or absurdity is constantly threatening us, and nobody is to blame. Every one is right, within their own powers and limits, and from their own point of view. But as there is no combining or controlling agency, nothing to prevent the very admirable plan of Board No. 1, from coming into the most hopeless collision with the very admirable plan of Board No. 2, the Londoners are getting rather the worst of it.

"When things are at the worst, they sometimes mend." That we have arrived at this hopeful point we dare not assert; but it is at least something, that not only men interested in the architectural beauty of the metropolis, but actually some of the presiding geniuses of the conflicting Boards, have been driven, in their despair, to apply for the aid of the House of Commons, in the hope that that which made an unmake, at least a portion of the confusion.

For the marvel is, that nothing but new, *ad hoc*, legislation can avert a mischief which every one deprecates, and which no one advocates. Yet it will wreak itself, unless legislatively stopped. It is some frightful Frankenstein, which the House of Commons has called to life, why, how, and whence, no one seems to know. The Board of Works feel themselves bound to expend a quarter of a million sterling, which they have not by them, and which they do not know how to obtain, in the construction of a viaduct, which no one wishes to be built, which seems more likely to be an obstruction than a convenience to traffic, which would form an intolerable eyecore on one of the best architectural sites in the world, and which would destroy the saleable character of eight acres of land, reclaimed at great expense from the Thames, and which may be estimated as likely to fetch, if sold, at the very least 20,000*l.* per acre.

The whole affair appears to be all but incredible. The First Commissioner of Works says that he "really has nothing officially to do with the Thames Embankment, or with anything which might be erected on that great high-

way." The chairman of the Metropolitan Board of Works, and the Board itself, "are as much opposed to the making of the road" as is the helpless First Commissioner himself, who adds that he feels "assured that they, i. e., the Board of Works, would do all they could to put a stop to its construction." The District Board of Works "had never been consulted on the subject, and had petitioned against the work as soon as its true character became known." The vestry of St. James presented a petition to the House of Commons "declaring the proposed structure unwise and of questionable utility for purposes of traffic." The owners of Salisbury-street and Cecil-street had power given to them by the Act authorising this undesired structure to put up gates, which would intercept the communication with the Strand. The only speaker who made the slightest attempt to defend the scheme, merely made matters worse, by saying that "his chief object in rising was to show that the whole of the proceedings in the matter had been of a most deliberate character." An expensive, unwise, unnecessary, ill-adapted structure has obtained a legislative right to exist: no one knows why, or how, or when, in spite of the ill-will and opposition of every one. Such, at least, is the opinion of five gentlemen, each very competent to form a judgment, as expressed by them in the House of Commons on the 22nd of February.

The House has, very naturally, appointed a committee to investigate the subject, and we suppose there is little doubt that the legislation of 1869 will, in this respect, reverse the legislation of 1868. But what a ponderous, inefficient, haphazard mode of dealing with an important national question is this! How strongly does it tend to support the arguments of those who, either in or out of the House of Commons, urge the propriety of the appointment of some officer of the nature of an *auditor*,—of some central, commanding, impartial, permanent authority, to watch over the architectural welfare of the metropolis. A minister of public works holds the rank of a secretary of State in every European country of the first rank, except our own. Our "First Commissioner," who (Mr. Boreford Hope tells us) constantly sees his name in foreign journals as *le Ministre des Travaux publics*, "has no more authority over public buildings than the headle in Burlington Arcade." The ultimate authority, Parliament, supposing it to discard for once all party or personal motives, and to look at any project brought before it for authorisation solely on its merits, is placed in a most false and unfair position; for the merits of a part may be great, if the part alone is considered, although they may form the demerits of the whole. But at a general, comprehensive view of the bearing of any suggested alterations on the architectural or æsthetic unity of London, how would it be possible for the House, or a committee of the House, to arrive? It is the very highest effort, not only of the skill but of the genius, of the architect or of the engineer, to grasp the true principles of such a unity. How far, how very far, the designers of some of our modern works,—grand enough, it may be, in themselves,—are from estimating the effect they would produce, situated and surrounded as they are, we have ample proof. We may look at the two enormous wagon-roofed stations of Charing-cross and Cannon-street, as perhaps the most striking examples of what we mean. There can be no doubt that these are very skillful structures; triumphs of the talent of the engineer. To a spectator, under either of these roofs, the effect is extremely imposing, and the iron firmament above his head soars skywards with a dignity which tends to dwarf the crowd on the spacious platforms. But none the less do we believe these roofs to be mistakes. A more modest rise, and a division of the entire span into three, would have reduced the cost of the roofing by a considerable amount, and would have been, in every conceivable respect, as convenient for the working of the line. The great risk of damage by fire (already experienced), or by violent storms, would also have been reduced. These, however, it may be replied, are questions for the company alone, to settle with their own professional advisers. Just so. But when we consider that by going to an unnecessarily lavish expense, in the rearing of a disproportionately large roof, a great injury has been inflicted on the architectural character of the vicinity, it is clear that some one besides the company and their advisers ought to have had a word to say on the subject. Let any one differ as much as he likes from our opinion that the inner or under view of

each roof would have been more picturesque, while the structure would have been far cheaper and safer, if built in three spans instead of in one enormous emicircle, there is no room for dispute as to the effect of the outside of these structures. It is simply and unmitigatedly hideous. The proportion is such as even to destroy the sole inherent quality of great hulk—majesty. Who could call these large Noah's arks majestic? Ugly in themselves, they hopelessly dwarf and curh any building that comes near their standard. St. Paul's itself is obscured, from great part of London Bridge, by the unsightly block at Cannon-street. Nor, so long as these roofs stand in their present awkward magnitude, can the noble edifices that line, and that are intended to line, the magnificent esplanade rescued from the bed of the Thames, produce their proper architectural effect on the eye of the tasteful observer.

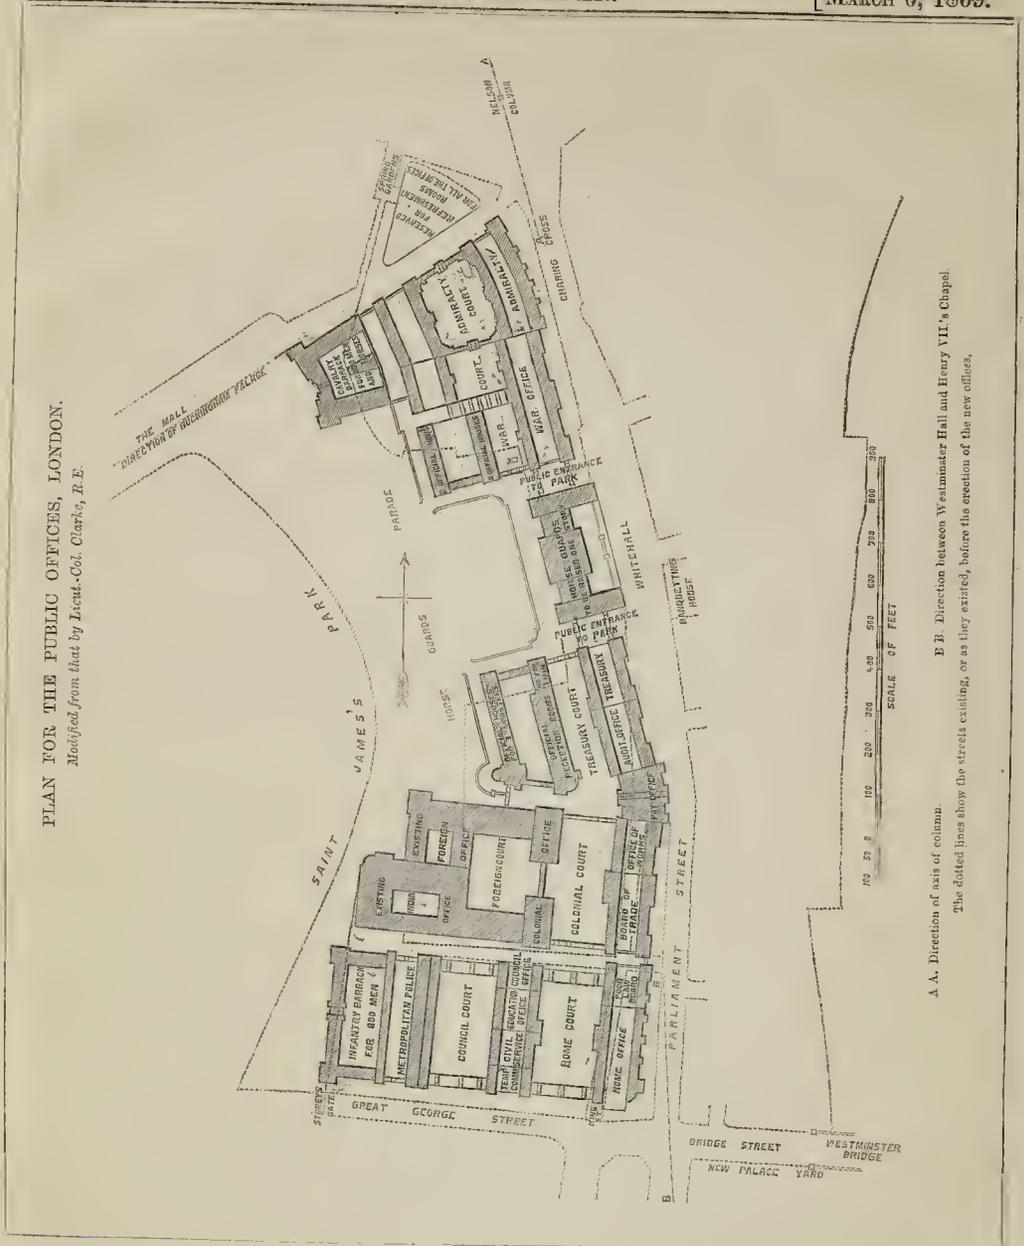

The intolerable confusion caused by the endless subdivision of responsibility and of authority is forcing the introduction of remedial measures. But they are only attempted hit by bit. It has not yet become clear how far any individual remedy may ultimately affect the general malady. The whimsical variety of rating, by which, according to the present system, house property in the metropolis is assessed at a different value, not only in every union, and in each non-union parish, but by each of the five or six rating authorities, whose collectors make their quarterly demands on the nuncley owners or occupiers, is one of those instances of hopeless jumble. So entirely indefensible is the state of affairs, that now that attention has once been clearly called to the subject, the Government finds itself compelled to confess the duty of providing a remedy. And it is more satisfactory to expect this remedy at the hands of the administration, than to look for it from the motion of any individual member, however much the ratepayers and householders of London may have cause to feel grateful to the honourable Baronet, who has obtained the recognition of the necessity.

The plain truth is, that the wise and simple system of local self-government which acted admirably well when London was a city ruled by its lord mayor and surrounded, at gentle distance, by outlying parishes, each with their vestries, churchwardens, wardens, constables, and overseers; becomes nothing but a dead-lock when the City has overspread the province, absorbed all the parishes in one continuous line of streets, and yet left the old boundaries, and the old machinery, with the least possible alteration, and with no attempt at any organization by bringing these different motive powers into union. The question of local government is deferred to another session; the question of equalization of rating cannot be approached, in any serious and business-like manner, while the wider question is left untouched. The concurrent, or rather discordant, rights of City authorities, Board of Works, First Commissioner, and Committees of the House of Commons, seem likely to be left to stumble over one another in the mean time. It will be a signal piece of good fortune if the works now carrying on, and about to be commenced, under the authorization of these heterogeneous powers, neither involve the cost of removal or reconstruction, nor destroy the good hope that sanguine persons were beginning to entertain, that the active rebuilding of the metropolis which is now going on may produce an architectural result worthy of the wealth of the largest capital in Europe, and the picturesque site which that capital occupies by the curving banks of the Thames.

THE RELATION OF SCIENCE TO ART.

At the annual distribution of prizes to the pupils of the Cirencester School of Art, last week, Professor Chmroh made an address, in the course of which he said:—I will take up as they come into my mind a few subjects of artistic moment about which I have often thought. First among these stands the relation of science to art—its help and its interferences more particularly being in my view just now. It has often happened that the period in a nation's history when art has attained its greatest perfection has not been distinguished for special moral excellence, or large literary achievement. Chinese colour is most lovely, its combinations and modes of application afford splendid examples of refinement of taste, yet the stereotyped character of Chinese civilization is a by-word in Europe. In North Africa, again, we have

several rough and half-civilized tribes possessed of a style of ornament which, both as to design and colour, is worthy, I will not say of imitation merely, but of the deepest study. A bit of Arabic inlay, such as some of the Meymar specimens just added to the South Kensington Museum, or a plate of Persian faience, will show us that we must not disdain to learn from people far behind us in general civilization, who know less, but felt more, and commonly achieved, in some art directions, greater successes than are usual amongst us. Looking back 300 years, we find in Western Europe the splendid structures of Mediæval architecture, the grand structures of 1500, together with the perfect products of many kindred arts, coeval with a state of society, of feeling, and of general knowledge which, in some points was absolutely barbaric. Was it, then, I want to ask, the growth of science and the spirit of philosophical inquiry which deadened art then, or must we look to our own era before we can trace any great influence of this kind? I ask this question not because I can here answer it completely, but because it gives me the opportunity of mentioning one point of contact between science and art which leads often, in individual cases, to distinct failure. You know that men of science, who are always questioning nature and learning her secrets, can now do, at their will, and more perfectly than before, many things which men knew not the reason of formerly, and which came as it were hap-hazard, and now and then to the earlier workers. Take an example. When the great French potter, Bernard Palissy, was at work (he died in 1590), no knowledge of the real nature and affinities of the materials of pottery, its colours and glazes, was to be got. He struggled through years of experiments and years of disappointment, and achieved at last a success of no inconsiderable sort. During the last hundred years or more every problem that puzzled Palissy in glazing his ware has been solved by science. Invention and processes and improvements may even have been too abundant. Our manufacturers and those of Europe have done great things: but the ware may be perfect in texture and durability, the colours may be pure and bright as those of flowers, the glaze may have the polish of a jewel, but it there be lacking the artistic spirit to imbue the exquisitely prepared body with true life, the finest porcelain-paste, and enamels, and glazes are worse than dead. Those old potters whose works are now-a-days preserved as precious, did not invent their materials first, and then begin to think of design and colour; the idea of the form and the ornament had wrought itself into order, and then were sought by long-continued trials materials which should give it substance and adequately represent it. Now a chemist, or experimenter, or manufacturer invents a new glaze, and must needs dash it over everything—he makes the vessels to show off the wonderful new glaze, and not the glaze that it may enhance the beauty of the vessels. (See, as example, the Belleek porcelain.) Science has brightened our colours, too, but lay on bright chemical pigments thick as you can, glaze them with the juiciest of glazes, and, if feeling and art be wanting, science has not advantaged you, but done you harm. Most modern majolica with its hues gives you no satisfaction after you have seen it once or twice; while of the old Italian pieces, with their subdued harmonies of it, it may be, poor colours, you never tire. In Josiah Wedgwood you have an illustrations example of a man who pressed into the service of his manufacture all the resources of science, and yet so used them that they served only to exalt the artistic merit of his productions. For to Wedgwood's wares chemistry gave the right composition, while mechanical skill gave truth and perfection of texture and form. By countless trials under scientific guidance Wedgwood improved his materials, not to display them as such, but in order worthy to represent the lovely designs of Flaxman, and to reproduce the beauty of antique art. I have given you illustrations of the way in which science may help or endanger art; hundreds might be cited from painting or from architecture, where especially, mathematical precision and mechanical hardness are often quite fatal to beauty of effect; but I must rest content with having directed your thoughts to a question of such great importance as the right attitude of science to art. 2. I am naturally led to say a few words now on another topic, intimately connected with the last. We have seen or may infer that improvements in manufacture arising

PLAN FOR THE PUBLIC OFFICES, LONDON.
Modified from that by Lieut.-Col. Clark, R.E.

A. A. Direction of axis of column.
E. E. Direction between Westminster Hall and Henry VII.'s Chapel.
The dotted lines show the streets existing, or as they existed, before the erection of the new offices.

from increased knowledge of the intimate properties of the materials used, may often aid and often damage art. If, for example, you make all your pigments pure and bright, you may have no repose as the result—what we may name temperance of colour may become impossible or difficult. Use but do not lavish the gifts that scientific progress offers. Take a Persian diab as an example. On a white ground is a beautiful arabesque of conventional ornaments from leaves and flowers. The designer used four colours only, a pale greenish blue, like the turquoise; a deep rich blue, a grey-like Indian ink; and, lastly, a red—a peculiar tint—very dull and very dirty, not quite unlike that of a half-penny stick of very bad sealing-wax, or a poor sort of red lead. But this colour must not be brightened—only let a scientific man come in and suggest and substitute the last new chemical

red; let him take the dulness out of the red, and the beauty is taken out of the whole combination of colour. And then the Indian ink colour, a similar reason. Often their borders have, besides ornaments in colour, hundreds of little spiral curls of grey, giving at once quietness and solidity to the edge or frame, and thus brightening the central design of the piece. Temperance in colour does not indeed mean dulness and dowdiness of colour; it means proper relief, combination, and modification of colour. Let some of those rarer tints be introduced among your blues and reds and yellows, which you cannot exactly name, but which the watchful student of nature may see trembling on the leaves of the willow, or paving the autumn paths of the forest, or shining at sundown from the depths of the sky.

ON THE ARRANGEMENT OF THE PUBLIC OFFICES, LONDON.

The construction, or rather the completion, as it should be called, of the buildings for the Public Offices of the Government of Great Britain is one of the most important architectural works that has occurred in this country in modern times. They will occupy one of the finest sites in the metropolis, and will be the architectural incarnation of the executive power of the empire, the very seat of government. They may be made to realize, on a grander scale even than the original, Inigo Jones's dream of the palace of the king of England, in so much as the empire of Victoria is greater than that of Charles I. It is somewhat remarkable that the prospect of so great a work should have roused so little action in the educated or even in the art commu-

nity of the kingdom. With the exception of the fiscal discussions of these questions in Parliament, and the somewhat meagre Blue Book we now propose to examine, there has been a notable absence of that ventilating process we pride ourselves so much on in England. Yet it is not from want of interest in the subject itself, for in our country the traffic of the public at large with the offices of Government is so general, that every class of the community has an interest in the matter; they are public offices in the fullest sense. Nor is it because it is only a professional question, for we see that when roused to it, the public does not hesitate to discuss the much deeper professional subject of guns and armour-plating; and the building profession is one particularly congenial to the Anglo-Saxon mind.

This report of a royal commission to inquire into the question of the accommodation of public departments, seems to offer a legitimate opening to the public, to try and learn something about this matter which interests them so much, and to see if they cannot form some idea of what is wanted, and how it can be most satisfactorily provided, notwithstanding the high art mysteries of the subject.

The report itself will not, it is to be feared, give the public much assistance in that way, for it is as slight and crude an affair as probably ever emanated from a royal commission; but, at all events, it affords several starting-points, and a general groundwork for discussion of the subject.

The problem put before the royal commission was not a very suitable one to be dealt with by such a body of counsellors: given a certain number of great departments of State, requiring respectively certain areas of ground for their accommodation,—to fit them all into a site already partly occupied by them, and in a manner which shall combine what Mr. Fergusson would style the three great qualities of the technic, the aesthetic, and the phonetic, in the highest possible degree; or what the uninitiated would style making them as useful and as ornamental as possible. It is a problem that can only be satisfactorily worked out by one master mind; and, therefore, when, having thus given the ingredients to make a certain dish, we find them put into the hands of half a dozen *chefs de cuisine*, it does not require the evidence of a Blue Book to enable us to foretell the result. The ingredients are of course worked up into six independent dishes, each admirable in itself, but each containing the particular idiosyncrasy *de cuisine* of its *chef*. No wonder the unfortunate professional empiric who was called in to taste each of these compounds found himself embarrassed to express his sentiments. It was impossible that so great an architect could be thoroughly satisfied with any plans so concocted; and the Government will have done wisely, if, as is understood, they have put the whole matter entirely into his hands.

That, however, need not prevent a general discussion of the question; indeed, such discussion can hardly fail to assist the architect in some degree; especially as the commissioners managed to involve it in a most curiously complicated knot.

Each member seems to have come with a plan ready made in his own mind, and his aim in taking the evidence seems to have been very much directed to inducing the witness to commit himself in favour of his plan; and the manner of taking the evidence was more suited to a private discussion of the subject between two associates than to a formal inquiry, which, with its evidence, was to form a collection of raw material at some future day to be reduced to order and bear fruit. The evidence of great statesmen and architects upon such a question might be most valuable to all succeeding generations of architects; but of what use could it be to ask Mr. G. G. Scott whether he did not think it desirable to remove existing public buildings which are inconvenient in themselves and architecturally inefficient? And when Mr. Scott naturally gives a somewhat evasive answer to such a thrust, he is doubled upon immediately by the counter thrust,—If, then, you would remove the Horse Guards, where would you put it? and feeling compelled to say something to this, he is further jammed into a corner by,—If you put the Horse Guards there, and the Foot Guards here, what will become of the Horse Marines? The Ordnance map of that part of London was, in fact, a kind of chess-board before the commissioners, with the public offices for pieces, and the commissioners on one side and the witness under examination on the other; each commissioner

playing in turn, and being expected to give check to the witness in three moves.

And what benefit to posterity could it be to know that Sir John Pakington prefers the blue site to the red site? It was probably expected to be a puzzling question to a minister who had just left the Admiralty for the War-office. Sir John showed, however, that he quite appreciated the respective merits of the quarters in question; he stuck to his colours, indeed he may be said to have nailed them to the mast.

The matter contained in the report and evidence—when one does get at it—is not very satisfactory; it reminds one rather of a case of special pleading in a court of justice than of the deliberate wisdom of the counsellors of the nation. There is too much of leading questions put to advocate a foregone opinion, and very little extraction of the real opinion of the witnesses upon the whole question. One salient idea seems to have been, that it is a matter of vital importance to the empire that, when the Minister of War wishes to speak to the Commander-in-Chief he should not be obliged to put on his hat. Probably either of those great persons would think twice about traversing several public streets to ask a question of the other, but neither of them would hesitate about crossing St. James's Park for the purpose. It is not the distance that makes the difficulty of communication between offices, but the impediments in the way. A public street between two offices is like a river between two towns; and a flight of stairs is like a mountain barrier between two countries. A mysterious importance seems to be attached to the idea of being under the same roof; but it would be quite possible to put all the buildings between Charing-cross and Great George-street under the same roof, and yet the facility of intercommunication might be less than it is now.

Another leading idea in the mind of at least one of the commissioners was that the public offices should be as near to the Houses of Parliament as possible; one would suppose, indeed, from the evidence that the perfect ideal of an arrangement of public departments was a great square with the House of Commons in the centre and the offices all round the sides; so that the Speaker sitting in his chair might, by a radiating system of telegraphs, call up any Secretary of State to answer a question put in the House, before the hon. member putting it had resumed his seat. Whether it is beneficial for the general interests of the empire that ministers of State should devote so much of their energies to answering questions in the House of Commons is not for an architect to consider; but, taking the practice as it stands, there seems to be no reasonable necessity for placing any of the offices nearer the Houses of Parliament than a distance that can be conveniently walked in about a quarter of an hour,—or about three-quarters of a mile; so that a minister of State can be quite sure of being in his place in Parliament within that time from his office. What is of much greater importance to the minister is that he should be able to walk that distance with his hands full of papers, and his head full of facts, without interruption. To insist on any closer communication than that is only sacrificing the general interests of the departmental offices to one particular theory of their duties. And to press for it, especially for the department of the army and navy, the two departments of the State which should be most free from Parliamentary interference in their details, looks more like a crotchet than a principle.

Indeed, from the site selected for these two departmental offices near the Thames Embankment, it looks as if there was an idea of giving the First Lord of the Admiralty and the Secretary for War a little practical experience in campaigning, by enabling them every time they went to the Houses of Parliament to execute a sort of combined naval and military operation, by first making a flank march along the underground railway, and then taking a penny boat to the river front of the Houses of Parliament.

Now, let us examine this in an architectural point of view; not in the small ornamental sense of that term, but as an Italian architect, engineer, and patriotic citizen of the fifteenth century would have viewed it.

The first data we have to bear in mind are that there are certain public buildings already existing on and about the sites which it is desirable to maintain. Inigo Jones's Banqueting House at Whitehall is one, about which there is no dispute. The Horse Guards is another, about

which there appear to be conflicting opinions. Some persons appear to consider it as too insignificant in character to be worth preserving; others, among whom must be placed Mr. Scott, think it quite worthy of preservation and improvement, both from its intrinsic merits and its historic interest. When there is a doubt about the destruction of a public institution the instincts of the British public generally go in favour of preserving it. Compared with its new neighbour, the palatial Foreign Office, it certainly might be considered insignificant in its present condition; but, as Mr. Scott observes, it has a picturesque character about it; the Florinsine style in which it is built is one of the most suitable of the modern styles for England, and it is a fair specimen of the handsome simplicity of that style. If the square on its west side had been completed according to Kent's original design, there would probably have been no doubt about retaining it. There is, however, this difficulty about preserving it, that, from its character and position, it should form the central feature of the whole block of public offices; and for that it is hardly fit in its present condition. Mr. Scott seems to doubt whether it is capable of much improvement; but, with great respect for so high an authority, we venture to think that another story can be very suitably added to it, and that with other additions, and by completing the two sides of the square on the west, it can be formed into a very fitting centre for this seat of Government of Great Britain.

The other buildings it is desirable to retain are, of course, the new Foreign and India Offices, and, if practicable, the block called the Treasury Buildings, about which, however, there is considerable doubt, as it was not planned with much thought for further extension; and, finally, the Admiralty, a building which nobody seems to feel justified in pulling down, and yet which nobody wishes to keep. Beyond these there appear to be no other buildings on the St. James's Park side of the site, which if it is at all important to retain if their sites should be required for public offices. On the river side of the site there are, between Northumberland House and Bridge-street, some private buildings of sufficient importance to make it worth while to retain them; but, as they do not come within the area of any one of the present projects, it is unnecessary to consider them.

Bearing these reserved buildings in mind, the first point for discussion is whether the offices shall be massed in one continuous block on the Park side, or whether they shall be concentrated more towards the Westminster end, and placed partly on the Park side, and partly on the river side of the site.

To have a clear idea of the bearings of this question, it must be recollected that Whitehall and Parliament-street form a great highway of traffic between Westminster and London, a traffic which is likely to be increased rather than diminished by the opening of the Underground Railway and the Thames Embankment; and, further, that it appears to be agreed upon all sides, that it is desirable to keep this highway open as it is, and, in fact, to improve it by forming a broad handsome road of it the whole way from Charing-cross to Westminster. This road lies, roughly speaking, north and south; on the west side of it is a site extending from Spring Gardens to Great George-street, occupied chiefly by the existing public offices, and looking on to the Park at the back; on the east side of it, from Northumberland House to Bridge-street, is a site occupied chiefly by private buildings, and looking on to the Thames Embankment at the back.

It may be assumed as impossible to place the whole of the public offices on the eastern or other side, on account of those existing on the river side, which it is desired to retain; therefore there are only the two projects above mentioned that are practicable.

The arguments in favour of the second or divided project are,—

1st. That it is economical, from its requiring a less expensive site, and especially if combined with the idea of a double instead of a single Parliament-street.

2nd. It concentrates the offices nearer to the Houses of Parliament.

3rd. It forms a noble architectural approach to Westminster.

It is on this last point that we must beg to differ strongly from the opinions expressed in the evidence in favour of it. A row of handsome public buildings on each side of a fine roadway produces, in the ornamental view of architecture, undoubtedly a much better effect than a row on

one side only. But to make the effect truly architectural, that is, to make the effect equally good in a technic and phonetic as well as an aesthetic view, it is necessary that the roadway should lead to a definite centre of the buildings, and that it should not be so much of a public thoroughfare as to give the idea of a separation between the two sides. The project in question fails on both these points. Parliament-street leads to nothing. The promoters of the project have sought to remedy this defect by providing a branch street, so that the passenger when about half-way along, can, if he thinks of it, by looking out of his carriage window, get a side view of a side door of Westminster Abbey. Some people have said that that would not be such a very fine sight after all; but at all events it points the moral, which is that the main roadway does not lead to the Abbey. Nor does it to the Houses of Parliament, for, in point of fact, its direction passes just between the two.

But the division of the two blocks of offices by a main thoroughfare is a still more fatal objection in a true architectural view. For convenience of communication it would be a greater barrier than the length of St. James's Park. Think of the Secretary for War dodging boldly through a charge of Hansom cab-alty, or the First Lord taking shelter under the lee of the lamp-post in the middle of the roadstead; think of the poor clerks and messengers, and oh! awful chance—think of the crafty foreigner waylaying the convoy, and carrying off the secret despatch. Then the sentiment of architecture requires that the whole of the public offices should be united in one apparent block; they are not so many independent offices conveniently collected together, but, as before said, they are the seat of the Government. And though a Cabinet may possibly be divided in private it does not do to continually remind the public that at least two Ministers are always on the opposite side.

Nobody would wish to see the Louvre transplanted to the other side of the Place de la Concorde in order to provide a fine approach to the Chamber of Deputies. Moreover, it would be quite possible to produce the ornamental effect by a row of private buildings on the opposite side of the road, but it would be impossible to prevent the inappropriate effect of dividing the block of public offices, and the Horse Guards could not be retained with this project, nothing could bring it into harmony with any such plan. The questionable advantage of a closer approximation to the House of Parliament has been already discussed; and when one hears in mind that the distance of the farthest part of any site proposed, Spring-gardens, is under half a mile from the Houses of Parliament, it seems hardly worth while to have any argument upon the merits of a greater or less concentration within that distance.

The economical advantage is a material one there is no disputing. The chief part of the saving appears to be obtained by leaving the private buildings on the west side of Parliament-street untouched, and forming the new street west of them, to get the view of the north side of the Abbey; and it is calculated that 500,000 will be saved by this, out of an expenditure of 3,000,000. 500,000 is a weighty argument, but the expense of compelling the owners to re-erect their buildings in a manner corresponding to the public offices, does not appear to have been taken into account.

Nor has it been taken into account what will be the result if this middle row of houses do not turn out a satisfactory thing after all. If it should be found out that it is inconvenient for traffic, too narrow and lofty for good effect, and that it totally destroys the unity of the public offices, an unsatisfactory remedy will have to be applied at a greater ultimate expense than any of the proposed projects.

Upon the whole, however, it appears that this project has the merit of economy, but that that is obtained at the expense of fitness and sentiment. But in an improving country like England to establish any institution on a doubtful or defective system for economy's sake, is a mistake which will lead to increased expenditure in the end,—witness the National Gallery, the Treasury buildings, and also others.

Now let us consider the alternative project of placing the whole of the offices on the west side of the main highway to Westminster. It is the necessity, and at the same time the merit, of any such project that the Horse Guards should be the central feature of it. One of the great architectural difficulties of the whole question is to arrange so huge a mass of buildings into one

harmonious group, so that they shall appear to be what they should be in internal arrangement, and what the establishments that occupy them are in reality, an organic body of many parts forming one system with a common centre. The Horse Guards, in its situation and arrangement and with its historic interest, offers this centre. It is no more necessary that the Prime Minister's offices should be there than that a king should sleep in the centre of his palace. The officer who guards the internal peace of the kingdom may very properly be placed there. In another communication we shall examine the plan submitted by Col. Clarke, R.E., and the modified plan that accompanies the present communication. I. B. C.

EXHIBITION OF THE ROYAL SCOTTISH ACADEMY.

The forty-third exhibition of the Royal Scottish Academy, now open, is hardly so interesting as was its predecessor, and that notwithstanding there is an unusual number of works in it which appeared in the exhibition of the Royal Academy last year; of those it will be unnecessary to say anything now in this place. Although there is nothing very striking or remarkable in the works of the local artists, it is satisfactory to observe that there is a steady advance evinced by most of them, particularly as regards colour—a quality in which the Scottish school was rather deficient. Conspicuous in this march of improvement stands Mr. Keely Halswell, who sends several subjects from Rome illustrative of life and character in the Eternal City: Nos. 111, "Dolce far niente," and 660, "Contadini waiting for Hire at the Theatre of Marcellus." Mr. Halswell need not indulge in crude intense local colour, but now his productions are marked by a rich and subdued tonality, accompanied by good texture and vigorous, though in parts loose, drawing. Our attention was arrested by a lovely piece of colour by Mr. G. P. Chalmers (No. 527), "Worn Out." It represents an old lady in a rich and quaint costume, who has fallen asleep beside her spinning wheel. The management of the line and red in the drapery is excellent, and that of the flesh colour equally so. The former works of this artist were deficient in drawing, but in this instance there is no cause for fault-finding in that respect. No. 145, "The Young Trawlers," by W. Macgarratt, is another example of improvement in colour, and the improvement is still more marked in other respects. Mr. Macgarratt has little of the sentimental in his nature, and it was not in his line to attempt to illustrate the works of the Poet Lucrentia. His present works are simple illustrations of everyday life, and yet they are the more truly poetical from the very absence of effort in that direction. The bevy of happy, healthy children, who have taken possession of a fishing boat and not, and are playing at the trade followed by their parents, is delightful to look upon. The accessories are so much subordinated to the figure; to have painted every mesh of the nets hanging on poles, which fill up one side of the picture, would, doubtless, have produced a harsh effect; but the sea and distant shores of the bay are so faintly indicated as to give them an appearance of unreality.

Besides his "Fairy Raid," which attracted a good deal of attention last year, Sir Noel Paton sends (No. 480) "Nicker the Souless." The being represented is a quaint, weird creation—a man, and yet not quite a man. There is something about him that excites a smile, and yet produces a feeling of compassion and sympathy for the lonely creature as he sits among the reeds and water-plants singing his melancholy ditty. The detail is not so elaborately wrought out as is usual with the artist; but the general effect of it is, to our mind, more satisfactory. We cannot in nature count the blades of grass or the leaves on the trees, nor should we be able to do so in a painting. The subject is taken from "Brother Fabian's Manuscript":—

"Where by the marshes
Bootheth the bittern,
Nicker the souless one,
Sits with his bittern;
Sits inconsolable,
Friendless and foolless,
Waiting his destiny,
Nicker the souless."

Mr. Hugh Cameron's scene from humble life are characterized by excellent taste, the colour is pure and delicate, and the individuals and incidents represented are in keeping with it. Contrast his "Responsibility" (No. 434) with Mr. Leggett's "Showing his Earnings" (No. 15),

where vulgarity is rampant. The incident in each is commonplace enough; but in the one case the halo of art is thrown around it; the other is "of the earth earthy."

No. 633, "King James and the Witches," by J. B. Macdonald. Mr. Macdonald is one of the few artists who adhere to historical painting, and the subjects are invariably taken from the history of his native land. The present is a large and ambitious work, representing the "Modern Solomon" trying an old and a young woman for the crime of witchcraft. The very appearance of the old crone is sufficient to have condemned her in the eyes of the superstitions; but it is different with her neighbour, a sensible, comely-looking damsel. Two Presbyterian clergymen stand behind the king's chair, and one appears to be arguing with the other, who seems to have grave doubts of the whole business, and not to place any reliance upon the test by probing to which the damsel is being subjected. Although she does not shrink from the ordeal, the very idea of the fair neck of the young woman being subjected to such treatment produces a disagreeable feeling upon the spectator. There is much character shown both in the expression and attitude of the different figures, and the manipulation is vigorous.

No. 123, "Salmon Fishing on the Tweed," is the best work we have seen from the studio of Mr. R. T. Ross, whose subjects were usually treated in a hard and crude manner; but this defect he has now overcome to a certain extent; were he entirely to succeed in mastering it, his works would be admirable, as they are characterized by good composition and animation.

No. 162, "The Lady and Huidhras," by Mr. Douglas, exhibits a good deal of character in the expressions of Huidhras and his equer, but the colour is harsh and unnatural; the dress of the lady is positively ugly, and yet he can produce both good colour and texture, as is evinced by (No. 610) "Left Behind."

Mr. George Hay must be careful not to run the ludicrous into caricature, as in "Ritchie Monypie in Fleet-street" (No. 589). The character of Nigel's erring-man, as represented by Scott, is not that of a mountebank, but of an exceedingly vain, yet shrewd Scotsman. The street, with the row of open hoots and shopmen offering their wares for sale, are happily rendered, so as to give an air of reality to the scene.

As usual, the exhibition is strong in landscape. Sir George Harvey sends two (Nos. 475), "Ben Ladi" and (493) "Auchmoor—a Stronghold of the Douglas." The first, a grand mountain with the cool breezes playing around it, and the other a lonely moor with small remains of an ancient fortress; there is little in the subject, but the artist has made the most of it,—indeed, to have produced a picture out of so little gives evidence of a master's mind.

Mr. Bough's "Skiddaw from Waterlath" (No. 229) is not so fine a subject as his "Borrodale" of last year, but it exhibits the same effects of distance, air, and sunshine.

What a different picture Mr. Bough would have made of the magnificent scene represented in (No. 409) "Mountain Scenery in Strathlandshire, near Laxford," by Mr. A. Perigal. Mr. Perigal does not seem to know the value of gray in a landscape; the transitions from one point of distance to another are not graduated, but every feature is strongly marked, and even the most distant mountains out hard against the sky.

It is a relief to turn from this picture to (No. 581) "Morning on the Clyde at Dumharton," by James Cassie, the hazy atmospheric effect of which is true to nature.

Mr. Beattie Brown has been very successful in his view of "Caerlaverock Castle, Dumfriesshire" (No. 582); but he has hardly mastered the grandeur of the scene, "Among the Grampans—Loch Avon" (No. 73), one of the wildest and most impressive spots in the Highlands,—one which is little known to tourists from its being out of the ordinary route, and very difficult of access.

The visitor on entering the galleries is confronted with a remarkable statue, of heroic dimensions, of Dr. Livingstone, by Mrs. D. O. Hill. The attitude is spirited, and not over-strained, and the costume exceedingly picturesque; it is admirably adapted for an open-air monument, and would be much more effective and interesting than the generality of our public statues.

We will speak of the architectural drawings in our next.

SOME RECENT FARMS AND RESIDENCES.*

AMONG useful works we must always class those giving details of actual experience in building residences, whether for the great or small. Books of designs have their value, doubtless, for they may suggest how we can improve upon existing examples; but a record of good works accomplished is often doubly instructive. In process of execution many points in a residence are re-considered; a mass of information gradually accrues concerning some of them, which permits the adoption of useful conformation and appliances that would not have been thought of if the building had not passed beyond the stage of design. Hence, as we premised, a reference to works carried out by experienced architects is of use; and we should welcome the appearance of volumes in which the result of knowledge and practice is given. So we think, after looking through the pages of a recent work, by Mr. Dean, containing a selection from the buildings erected by him in different parts of the country. Some of these are country residences, erected on small landed estates, with pleasure-grounds surrounding them, and having lodges and gates; but most of them are buildings connected with the pursuit of agriculture, farmhouses, farm buildings, and labourers' cottages. They are prefaced with a few sensible remarks relating to choice of site, disposition of the premises, approaches, pleasure-grounds, water-supply, ventilation, and drainage; the desirability of employing architects instead of entrusting works to unacquainted minds; and the nature of different materials. The Tudor style is selected for praise.

The first building shown is the steward's house, built in the Home Park, Windsor, with a suite of rooms in it for the use of her Majesty and the late Prince Consort when visiting the adjoining farm. This was not, however, erected in the style Mr. Dean prefers. It has an Italian air, with its wide, low-pitched roof, and semi-circular-headed windows, arranged singly and in couplets. Her Majesty's rooms, three in number, with an entrance-porch giving access to the front, occupy the front of the house, facing the road to the Castle, which is only one story high; behind them rises the two-storied main body apportioned to the steward. The farm buildings are also amply illustrated, with plans, isometrical perspective, elevation, and sections. Those who are not already familiar with the leading scheme in the arrangement of this establishment may here make themselves acquainted with its clever combination of the pastoral, picturesque, and practical. We may give some indication of the ground-plan by describing it as three parallel lines of buildings, with wide yards between each, bordered on two sides by other lines at right-angles with them; the whole forming a quadrangle, the centre of which is occupied by sheep sheds and hulk-boxes. It is, however, so widely known that we need not dwell upon the nicety and finish that appear at every turn; the order and cleanliness meet for Dresden china shepherds and shepherdesses, in the passages behind the languid-eyed cattle, as in the wide open courts where the air seems never able to part with the sweet scent of hay, or in the pens and sties; nor upon the contrivances with which these are attained, and the sources of disorder turned to profit. We shall be giving our readers a better idea of the novelty that is to be found in Mr. Dean's hook, if we make more detailed mention of a farmstead erected by him on a large scale in Hungary, for Count Zelenki. These buildings, our author says, must convince the agriculturists of this country of the importance of presenting an onward course in agriculture, if they do not wish to see foreigners supplying us with farm produce at a cheaper rate than they can do. This Hungarian establishment is at New Arad, a part of the world that does not seem to be in a very forward state of civilization in other respects, for the state of the country renders it necessary that it should be surrounded with a high wall. This defence follows an oblong form; and at the four corners there are watch-towers, on which sentinels keep guard. There is only one entrance,

which is constructed of double walls. On entering through this gateway, which has a clock turret over it, we find all the sheds, pens, and sties for the various animals grouped together in a regular manner, on the right; while on the left lies all the accommodation for the people employed, who consist of married and unmarried men and women: all live within the walls. Looking at the animals first, we see a hundred cows in one long shed—a double row, with fifty in each. Parallel with this, but with a pig-yard intervening, are sheds for fifteen additional cows and forty oxen. Beyond this, with another pig-yard intervening, is a line, of corresponding length, of piggeries, with a shed for forty more supplementing it at right angles; and the first line is bounded with another shed in which are housed the hay-machine, drills, ploughs, harrows, hoes, scarifiers, rollers, and carts, all having their appointed places. The engines, machinery, and most of the implements were sent out from this country. Then there is a shed for sick cattle, placed nearest the side of the farm inhabited by the servants; and there are three provision sheds at opposite distances. The dairy, with its scullery, is also placed at the part of ground most convenient to the servants. In the centre of every yard are manure-tanks. No sheep are provided for. The buildings destined for the home and work-places of the people employed on the farm group round three sides of a square, the fourth side being that which looks upon the sheds appropriated to the animals, which are accordingly in full view. In the centre of the quadrangle there is a large kitchen with a dining-room on both sides of it, and a larder, boiler-house, and wash-house behind it. Beginning at the angle of the quadrangle nearest the gate, we find the rooms for the superintendent, parlour, kitchen, and bedrooms. Close to these are rooms for unmarried servants; and beyond these, again, two cottages for married servants. Turning round into the adjoining side of the square are six more dwellings for married servants. Between the first three and the second, projects a very large workroom, which is well warmed with hot-water pipes; and, over all of them, is an upper story containing ten rooms for "cow maids." On the third side are two more cottages, a hospital, a carpenter's and smith's shop, and another room for the superintendent. Near the hospital is an airing-ground for invalids; and there are drying-grounds, kitchen gardens, and grass plots all around, within the walls: a model colony, fit for a new world as well as for New Arad.

Several of the buildings our author has erected for the Earl of Leicester are illustrated. We will look at two of them; that intended for his lordship's dairy of choice Devon cows, and a pair of labourers' cottages. In the first of these we have a set of buildings, arranged regularly, to run round three sides of an oblong, the outer line of the plan presenting nearly as straight an outline as Count Zelenki's wall. The fourth side of the oblong is occupied by sheds for stock and hulk-boxes, with yards and sheds for other purposes, which project into the centre of the oblong and beyond it; forming, indeed, a second oblong group, placed within the first; with the difference between them that one is hollow, the other solid. The last is arranged very methodically. It is intersected by two straight passage ways, which are divided from one another by the hulk-boxes mentioned, and a continuation of them set out as calf-sheds and spare sheds, with piggeries. On either side of these passage-ways are the sheds for stock, central yards, and a shed for store pigs on one side, and store calves on the other. In the centre of the outer buildings stands the steaming-house, with sheds for roots and cakes on either side of it, and granary and store-room over them. A cow-house on one side, and boxes for show cattle, with shed for hay and straw, on the other, complete this side of the farm-buildings. In the two advancing wings are the horse-boxes, stables, and gighouse, on the one hand; and shed for cutting hay, another for cut hay, cart-lodge, harness-room, chaff-room, and stables, on the other. This is an arrangement Mr. Dean has repeated, with a few variations, at Leamington. The Earl's cottages shown are semi-detached. There is a projection on the front line of the plan formed by the living-rooms of the two dwellings, and carried up to the second story; but for this the outline would be that of an oblong figure. The entrance is through a porch in the side of the house, which does not project, but is carried up to the upper story, where, with some additional space over the larder, it forms a bedroom. There are no less

than four doors into the living-room: one from the porch, another into the larder, a third leading to the stairs, a fourth into the scullery on the rear of it. Above stairs there are three bedrooms. In another pair of semi-detached cottages, built near Warrington, Cheshire, Mr. Dean gives four doors to the living-room, which, we submit, is rather a large allowance.

We will turn now to one of the country residences built in the Tudor style. There are several of them. The first shown is that built for the occupation of one of the Earl of Leicester's tenants at Castle Acre, Norfolk. This, our author says, has been objected to on the score that it is good enough for the earl's eldest son. Without gainsaying this opinion, he adds, that he is sure it is not too good for the enterprising farmer for whom it is intended, nor, indeed, for many of the farmers on the same estate. The next is situated at Moorlands, near York, and presents in an eminent degree that variety of outline of which the author thinks the style so capable. It is, indeed, rather too much out of the principal front being a distinct feature, with a different construction to any of the rest. As Mr. Dean remarks in the course of his prefatory observations, "eminent attainments are not the produce of a day," but rather of diligence, favoured with some encouragement, and the full power and poetry of the style that produced some of our best old English mansions, cannot be grasped without a long study of it. The Tudor residences of to-day are, in reality, far behind the picturesque, pleasant-looking country-houses of Elizabethan times. Mr. Dean's are no exception to this rule. The long experience that he has brought to bear upon farm-buildings, has been so much time taken from more strictly artistic studies; and his Tudor façades suffer in consequence. The charming air of serenity and order, and the modest stateliness of the old houses, are but ill-rendered in our imitations of them. Modern lavishness with angular and eared projections, gables and lipped gables, is no compensation for these missing qualities: the more ins and outs, and odds and ends, the farther we get from the consummate repose of the old places.

In the drawing-room at Moorlands there are no less than fourteen projections and recesses, besides the chimney-breast and a large bow-window; and in the dining-room a similar profusion of corners is to be counted. A handsome feature in the internal arrangements makes some amends for the eccentricity in the principal rooms. Right through the house, at the point of its greatest width, sweeps one wide corridor, with a porch at each end of it. One of these last might have been dispensed with, perhaps, more especially as there is a third entrance from the grounds into a conservatory, projecting from the main front between the drawing and dining rooms, as well as a fourth or back door in the rear of the house. Doors are, we observe, very liberally dealt out again in the kitchen, where we count four more. We do not object to the nine in the corridor, because here they are in their proper place; but an ordinary-sized room with more than two doors in it scarcely retains its domestic character. We think Mr. Dean is happier in the Italian style, which evidently has not, in his mind, so many exigencies. Looking at the next example, which is of a residence in a park of 30 acres, near Lavenham, Suffolk, we see nearly as much accommodation, packed much closer together. Here one entrance-door unites, and one door apiece for the dining, drawing, and breakfast rooms. The kitchen has only three, one of which opens into a pantry, conveniently; but it has the drawback of being separated from the scullery, with which is combined a brew-house, by an intervening store-room and passage. In a line with the kitchen is a combination of dairy and larder. In the rear is a kitchen courtyard, where are the W.C.s and coal-house, built as lean-tos; and beyond this extends a long stable-yard, in which is a provision for six cows besides; a straw-house, a three-stalled stable, a couple of loose boxes, a coach-house, and a harness-room. And here we recognise Mr. Dean's special experience again. These successive accommodations are arranged with skill. The cows are not permitted to enter the yard, although their house is part of the yard-buildings, but are furnished with entrances outside of it; and the straw-house is close to them, and has two doors, from one of which the cows can be attended to, the other opening into the yard; which last door can be closed when the store of straw is being carried in, to prevent any litter in the yard. The

* A Series of selected Designs for Country Residences, Entrance Lodges, Farm Offices, Cottages, &c., which have been erected for H.R.H. the late Prince Consort, the Earl of Leicester, Lord Harris, Hon. G. W. Fitzwilliam, &c., under the superintendence of George Alfred Dean, Lancaster-place, Strand, London; and Messrs. Dean & Jermain, York. By G. A. Dean. Worthing: C. H. Knight, York; J. Sampson, London; Longmans, Green, Reader, & Dyer. 1867.

horses, too, are kept well away from the house by the intervention of the harness-room and coach-house. The front elevation, which is of two stories, is unpretending and pleasing. On the ground-floor are the windows of the dining and drawing rooms, five semicircular-headed lights grouped together, precisely alike. In the distance, extending beyond the block containing these rooms, on both sides of it, like diminutive wings, can be seen a portion of the offices, one story high, and corresponding exactly with one another. Over the dining and drawing room windows are two triplets of semicircular-headed lights, like those below, which belong to the rooms over them. The only break in the uniformity of the design is a low-pitched gable as a finish to the portion of the house occupied by the drawing-room and bed-room over, which, to admit of this feature, is brought slightly out beyond the line of the dining-room wall.

In plate 7 we are shown a Norfolk rectory and offices. This has a singularly straggling plan, affording a marked contrast to that just described. Adjoining part of the drawing-room wall is the pantry; while the kitchen and scullery are built in a rear wing, with a stable-yard beyond them. Altogether, a space of 100 ft. long by upwards of 60 ft. is covered with these buildings, and though the widest part of the ground plan of the house is not quite 70 ft., we are struck with the amount of ground occupied with the very modest accommodation. On the next sheet we have a house, built for a widow lady and her two daughters at Roehampton, Surrey, containing quite as many rooms of very nearly the same dimensions or less than two-thirds of the grounds. But in the design the Tudor style is abandoned. There is a neat, sunken basement to the little residence in which, we perceive, Mr. Dean places the servants' bed-room, again showing himself to be singularly content with an unsanitary arrangement for the human being, which he has not in one instance planned for an animal. With this exception the internal arrangements appear good.

On another sheet the author shows additions he made to a farmhouse in Lancashire, of which he is in charge as receiver, where all the arrangements are in favour of the large number of cows kept for dairying purposes, and of the proper storage of their produce.

We are shown two shooting-houses in Invernesshire,—one at Stratherrick, the other at Strathdean. These are both suited to their purpose. They each contain a small sitting-room, where the host and his friends can hide their hungry and impatient heads, should they arrive home earlier than they are expected from the treacherous, but all the more fascinating, moors; a large dining-room, in which they can compensate themselves; two or three little bedrooms, and a large bathroom; a good-sized kitchen, with a pantry, and a dairy sink in the basement. Both have a bedroom on the ground-floor, and in the first example a closet is cut off the kitchen for a servant's bedroom. The exteriors bring them, as near as possible, within the literal meaning of the term shooting-boxes. No idea of the cost of the respective buildings is given in any case. In most instances the information is not of much value, in consequence of the difference in price of materials in different parts of the country; but in this case it might have been useful, as indicating the possible value of any deduction from, or addition to, similar buildings in the same part of the country.

At Muswell-bill, Hornsey, the author appears to have realised a very popular wish. He has built a miniature farm: so small and compact and prepossessing, that we should not be surprised to hear that several have been since built in its neighbourhood in imitation of it, or that it has been taken to pieces and transported, like a Swiss toy-farm, to be erected elsewhere. Standing at the light iron gate, and looking into the farm-yard, you see a small cowhouse for four cows on the right of you; and on the left, built to correspond with this, another house divided into three compartments, for hens, geese, and ducks. Straight in front of you, across the yard, are two piggeries, with a passage-way behind them to the boiling-house in the angle beyond the cowshed; and that is all. To the left of the poultry-house is a second small yard, into which its doors open, so that the birds do not come into the farm-yard; and in the second yard there is, forming a sort of ornamental turret to the entrance gateway, a large dove-cote. Nothing on so small a scale could be more complete.

Our last selection from Mr. Dean's volume

shall be the buildings for a Cheshire farm of 1,000 acres of arable land. Here every point of vantage that could be gained by consideration and experience seems to have been obtained. The residence for the bailiff, with a garden before the front, occupies one angle of the large piece of ground, some 246 ft. by more, covered by this farmstead. Recessed from the house and hack garden, but containing the boundary line on one side, are the arrangements for the poultry and cows; the dairy open on three sides, and cooled with a fountain; the poultry-houses warmed with hot water in pipes through central tanks; the ducks with an artificial pond; the cow-boxes with feeding passages opening out of the provision-shed between them and the calf-pens. Departing from the house in the direction at right angles to this are the office, men's rooms, tool-house, drill-house, entrance from the public road, horse for wagons and carts, provision-shed, another house for carts and wagons on the other side of this, another entrance from the road, like the first, 16 ft. wide, a dung-pit and liquid manure tank in the corner of it, a carpenter's shop and blacksmiths' shops in succession. Returning at right angles with this is a long implement-shed and engine-house, which brings us up to the barn, which occupies a central position on this outer line of the buildings. Right and left of the forepart of it are the provision-shed and chaff-house. At the rear end are two openings, one to a railway for corn-stacks, the other into the cornstack sheds. There is an upper floor to the barn, with a feeding-place for the thrashing-machine, and there is a granary over the chaff and provision sheds. On the other side of the last-mentioned places is a double row of cattle-boxes, with lofts over them. Mr. Dean explains that he considers lofts over sheds objectionable generally speaking, but in this instance they are not so, as there are an 8 ft. cart passage and tramway between the two rows of boxes. The straw required for littering the cattle is lowered through trap-doors over them, which economises labour. The last of the cattle-houses mentioned is separated from another dung-pit by a paved shoot. This brings us to the fourth side of the enclosure, in which are the accommodation for the horses, the gig-house, and an infirmary. Behind each horse as it stands in its stall is an enclosed recess for the harness. In the centre of the large square that we have now traced stands the boiling-house, with its food tanks, and right and left of this are piggeries, where nearly 200 pigs can be fattened; sheep-pens and cattle-sheds open to yards. A tramway facilitates the carriage of the food from the boiling-house, and in the case of the pigs a further saving of labour is effected by the use of a hose to the liquid food truck. Beneath the sparred floors on which the sheep stand in their pens are powdered gypsum charcoal and burnt clay, for the purpose of utilizing their manure. The calves stand on perforated floors, which their hoofs do not cut. These are removable, like the sparred floors, and are lifted up when the manure has to be removed. But the perfection with which everything is housed would not be completely indicated if we did not mention that an open shed is provided for the cornstacks, which need not, therefore, be thatched. They are placed on frame, and when one is required for the threshing-machine, a lower frame, on wheels, is driven under it, the blocks knocked away, and the stack, with its frame, drawn bodily by a rope attached to the steam-engine, to the feeding place of the machine.

The greater the number of people who are shown such model farms the fewer there will be content with more slovenly, extravagant, wasteful, inferior management and arrangements; and so the world gets helped on a little in one department.

A WORD FOR SUN-DIALS.

About three a year the questions of "S. H. W.," in the *Builder* of 20th February, recur, in precisely the same form: "What inclination am I to give the gnomon of my dial?"—without a hint as to where "I" lives; "and how am I to divide the hour scale?"

Whoever can project the simplest constructions the carpenter requires in solid geometry—those for a hip-rafter, for instance,—may readily construct any kind of sun-dial whatever, for any latitude, on being simply informed of these two invariable rules:—

1. The shadow-casting edge is a straight line,

and must always, everywhere, and in whatever form of dial, be parallel to the earth's axis. Consequently, all the true gnomons in the world are parallel, and with one varying from their direction no true dial could be made, but its time would vary every day in the year.

2. The hour-lines, on whatever surface, plane or not, are the intersections of that surface by planes all meeting at the shadow-casting edge, and making equal angles therewith. Consequently, having found the twelve o'clock plane (which is the meridian), the eleven and one o'clock planes must be inclined thereto 15°, the ten and two o'clock planes 30°, and so on; their common intersection being the gnomon edge.

With a right gnomon then, hour lines may be marked over any surface or surfaces whatever. Whoever cannot do this cannot make the lines for a hip-rafter, or any the simplest matter in carpentry. I am obliged to say "carpentry," not building, because in no branch of building craft but the carpenter's do we any longer attempt more practical science than the builders of Timbuctoo. Four centuries ago, when a nation lived here that could build a Redcliff Church, independent of all timber, we might have said the dial problems were tests that would prove one not only no carpenter, but no mason. It is widely different, of course, in an age of Royal Institutes of Architects, &c., when the idea of requiring, for instance, a fire-proof repository for wills, is held to transcend just as much the science of an isle of Britain as of an isle of Madagascar.

"S. H. W." will perceive then, that the gnomon being required always to be perpendicular to the earth's equator, the divisions of the scale can only be equal (or drawn in a simple and obvious way), when they are on a circle (or other lines) parallel to the said plane, of the earth's equator. In fact, the most natural, most obvious, and best thing to do, is to make your dial with no surfaces but what are either parallel or perpendicular to that plane. The best thing, because all such equatorial dials are equally fitted to any place to which you carry them, as you have only to turn them to the true meridian, and tilt the whole bodily to the inclination answering to the latitude. Moreover, as one instance of the fact that the truest engineering form of everything will be found its most artistic form, I challenge any one to produce a non-equatorial dial of any kind, anywhere, that can be called a decently elegant object; but the elegant forms of equatorial ones are unlimited, from the hollow parts of globes, of ancient Greek design, in the British Museum, to the thick Latin cross, and all manner of Maltese and curvilinear crosses and trefoils, their edges, perpendicular to the equator, forming their own gnomons, with no thin trumpery metal to be always bent out of truth. But makers do not always remember that the minute scales are required, both at the upper and lower edges of these solids, the upper alone serving during the six winter months, and the lower during the summer. Moreover, the thickness requires to be such, that the greatest distance from any part of a scale to its gnomon may not exceed 2.3 times that gnomon's length; otherwise, at midsummer and midwinter the sun's declination of 23½° will carry the shadow entirely off the scale.

Contrasted with these, the hideous inventions known as horizontal and vertical dials, whose drawing the last two centuries exalted into an "art of dialling," with their flimsy unmechanical metal gnomons like caricature noses, must, of course, be each specially made for its latitude and even its particular wall, and useless if removed. Sometimes an architect insists on a vertical one facing almost east or west, of which a peculiarly useless and ugly specimen may be seen on the new school at Highgate.

Most persons, probably, know that theoretic sun-dial time is not, except on four days of the year, the true clock time of the place; which latter again, away from the longitude of Greenwich, is not now railway time. But few are aware, for I have seen no book notice it, that the practical sun-dial time never is, or can be, within one minute of the theoretic, or that meant in all extant almanacs and "equation of time" tables. To make use of the sun-dial at present, it is necessary to distinguish these four kinds of time. Between the railway and local clock time (if the latter he used at all), the difference and its reasons are so generally understood that nothing need be said; except that people must remember the almanac columns headed "clock face, sun," and "clock aft. sun," refer to their local clock time, and could not be given in railway time

without a separate almanac for each town. They must, therefore, combine the numbers thus given, by addition or subtraction with the known constant difference from Greenwich time, due to their longitude.

The *minutes* of the equation of time, for any day, are generally the same every year, but not the *seconds*; and the four times of no equation or of maximum equation may each fall, in different years, on the former or latter of two days (just as the equinoxes may). The only reason the same table will not serve for two successive years is the excess of the year over an exact number of days. Thus, 1868 being a leap-year, was above 18 hours longer than a true year, while 1869 is to be nearly six hours less than a true one. If the excess were an exact quarter of a day, this table would be the same for any year as for the fourth before or after it; and four tables would serve by turns continually. But the defect of the fraction from six hours prevents this, and makes another gradual accumulation of differences, till the tables of two dates 96 years apart differ nearly as much as two successive years. This, again, in our present Gregorian style, is *over-corrected* by the day omitted from the centennial year; and yet again *under-corrected* by the retention of the day in the 400th year; and thus it happens that, practically, while the world stands, each year must have its own table.

In astronomical books, however, you see a practically permanent "equation of time" table made, by omitting days of the months, and substituting the sun's longitude. You may also regard it as dependent on the sun's *declination* only, in this way.—He crosses any given declination circle twice a year, and to each declination belong no more than two amounts of dial correction, one whenever the sun passes that declination in going southward, the other when he passes it in coming northward. (To each tropic, however, and to one intermediate circle, about 10° N., there belongs only one dial error.) Hence the Medicevals got a simple and elegant way of setting their clocks. In some Italian cathedrals the transept has a meridian line marked on the pavement, and a lens in the south window casts an image of the sun, whose centre of course crosses this line every day at *dial noon*; but further north or south each day, as his declination varies. Now do not imagine the Mediceval architect stopped here. They found how to so construct another line, a most difficult curve, lying half east and half west of this straight one, that the sun's image crosses this curve every day at *clock noon*!

This curve, resembling a very lengthened figure of 8, is called the *analemma*. We may see it drawn now on a small scale, but never well, on a vacant part of the ocean of some terrestrial globe,—its lower or big loop standing on the south tropic, and its lesser loop reaching to the northern. If correctly drawn, the resemblance to an *Italic 8* would be so complete that it would *lean* a little from the meridian.

This figure, then, served (as it might again) all the purposes of our "equation of time" tables. Few people know that the two maximum errors, which occur in November and February, when the clock is furthest behind and before the sun, are not equal. One is nearly seventeen minutes, and the other barely sixteen. Now this arises from the *Italic leaning* of the 8, and is increasing, and will increase for many centuries to come. But about A.D. 1250 (from which date our globe-makers would seem to take their "analemma," unchanged) though the loops were more unequal than now, the 8 was *upright*. Before 1250, it had bent the other way, ever since Adam's time. But about his time it was not only upright, but the loops, instead of being at their greatest inequality (as in 1250), were *equal*, as they become only once in about 13,000 years. Throughout these 13,000 years the southern loop continues biggest; and then, for another 13,000, the northern will be highest, and the present changes will all be repeated inversely. Thus I called the astronomers' tables, that substitute the sun's longitude for the months and days, "practically" permanent, but they do not serve for ever.

Tables and almanacs all refer to present or *theoretic* sun-dial time, namely, what would be marked on the dial by an infinitely bright point of light, occupying the place of the sun's centre. Now, most people may have noticed that an electric light, lime light, or even good gas light, when further off than a few yards, casts clearer and sharper shadows than the sun, or than the same lights when nearer. The reason is the smaller amount of *penumbra*. Penumbra is that

space from which the sun's disc (or gas flame or other light) is partly, but only partly, hidden. It forms a border, shading off from the edge of the *pure shadow* (which edge, observe, in the sun's case, is always quite *perceptible*) to another outer edge, which last is always quite *imperceptible*. Now the theoretic shadow's edge is half-way between these, or at the middle of the penumbra. But you cannot estimate this middle, because while, as I have said, the line dividing pure shadow from penumbra is well marked, so that all eyes tolerably good will agree upon it, the limit of penumbra from full light you shall hardly get two to agree upon. There are good optical reasons why this should be so.

Now, the penumbra covers always, on the sun-dial scale, two full minutes of time, unavoidably; and the only side of it, or part of it, that you can practically define is its division from pure shadow. Hence, you see, *practical* dial time must always be a full minute before the theoretic throughout the forenoon, and a full minute after it in the afternoon; or rather the former, whenever you are using the following side of a shadow, and the latter when using its advanced side; for dials may be so made that you employ the same side throughout the day, or variously. This correction may be considered practically invariable in amount, and always one full minute; though strictly it is always a little more, and varies about 2 seconds, the maximum being some 64 seconds in January, and the minimum 62 in July.

If you use a bar for a gnomon, the theoretic shadow is, at all distances, just as wide as the bar; but the pure shadow diminishes till, at 110 times the bar's width, it vanishes, and at that same distance the penumbra is double its width; but no eye would detect it to be so wide.

With these items of information, I will now propose to "S. H. W." or any reader, the exercise, which ought to be easy, of designing a dial, either above or below the eye, to show, by mere inspection, clock time (and no other), either local, or, if desired, railway time, or an approximation never erring 20 seconds therefrom; and this error to be avoided if two gnomons are provided for use alternately, half a year each.

E. L. G.

P.S.—The difference between the almanacs' dial time and that marked by the boundary of pure shadow, is both rather greater and more variable than I stated above. The *Nautical Magazine* has, on page 1 of each month, a column headed, "Sidereal Time of the Semidiameter passing the Meridian" (with a footnote for reducing the same to mean time), showing that this—unlike the semidiameter itself, which has but one maximum and one minimum in the year—has two minima of about 64 seconds, when the sun is in 2° N., on March 26 and September 17, whence it increases to a maximum of no less than 71 seconds at the southern tropic, and another of 69 at the northern. By setting off distances representing these, each way, from the 8-shaped analemma curve (as projected on a cylinder or Mercator's chart), we get two other slightly different 8's, which the sun's image from a lens would exactly touch, so as to be confined between them at the moment of clock noon throughout the year. Remember that the analemma, though always 8-shaped, is not the same when projected on a globe as on a cylinder; and would be quite different again on any plane, especially the horizontal floor of an Italian church, where the inequality of the two loops becomes exaggerated. On the globe projection we should get the new curves by applying the sun's semidiameter merely; but on the cylinder we must apply the times of its passing, as per Nautical Almanac. Now for these curves it would be easy to derive four profiles for halnester-shaped gnomons, which, being applied to an equatorial dial or dials, would mark *mean* time (and that of a different place, as Greenwich, if desired) without one half-second's error throughout the century; and each of the four might do so for above five months: the winter and spring gnomons both serving together from early in January to early in June, and the summer and autumn ones both serving from about the 1st of July to 1st of December. I name them by our northern seasons, but these gnomons would equally apply throughout the globe, and everywhere it is only for a few days before and after the June solstice, and about twenty before and after the December solstice, that we need be restricted to a single gnomon.

Six centuries ago, when the 8 was upright, a single gnomon might have been made to show clock time throughout the year, but I do not see

that it now could for quite six months. At the time of the upright 8, the exact solstices were times of no dial error, but now the corresponding times are a week earlier than each solstice, and at the exact tropics the sun is 1 min. 25 sec. behind, or 1 min. 17 secs. before the clock. These are not quantities that in railway times we can neglect, and as the leaning of the 8 will increase for centuries, it will become less and less possible to make one gnomon serve through the year.

Mean time was only introduced at Paris in 1815, and Arago says riots were anticipated at the workmen finding a noon struck by the clocks that would not truly bave the time between sunrise and sunset; but they seem not to have observed it. Before that date the clocks, though professedly adjusted to the sun daily, were sometimes striking for half an hour. Adjustment each day was quite needless, for James Ferguson showed in his "*Mechanics*" how a clock may, with very slight and quite practical additions, be made to keep apparent solar time. The principle is that of cams. But I am not aware of the problem now propounded, to make *dials* keep clock time, having ever been broached before.

E. L. G.

SIR,—Your correspondent, "S. H. W.," does not appear to know that to make a dial correctly it is necessary to ascertain the exact latitude of the place in which it is intended to erect it, as both "the angle at which the gnomon should be placed, and the method of dividing the hours," depend on this.

Works on dialling are not numerous, but the best I have met with is an old one, entitled, "The Art of Dialling," by Thomas Fale, printed at London in 1626.

There is a useful little pamphlet on this subject,—"*Dialling Diagrams*," by William Watson, of Pocklington, 1854, published at one shilling, by J. Forth, Pocklington.

I have been long looking out for a copy of Peter Nicholson, on Dialling, published many years ago, but now out of print. Should any of your readers know of a copy for sale, I should be glad to hear of it.

If "S. H. W." finds any difficulty in setting out his dial, I shall be happy to assist him, if he will give me the latitude required, as well as the size and shape he wishes his dial-plate to be made.

WM. OSMOND.

Salisbury.

SIR,—In reply to "S. H. W.," the gnomon of a dial must be placed at an angle corresponding with the latitude of the place where the dial is fixed, which will be seen by reference to an Ordnance map, half-inch or 1 in. to the mile. When the gnomon is set up the hour lines can be marked off on a fine day by means of a good clock or watch, provided this is set to solar time, which can be found by reference to an almanac. The base line of the triangle, of which the gnomon is hypotenuse, must point north for which the exact variation of compass must be found for present time. The variation of local time is four minutes per degree of longitude east fast and west slow; this may be ascertained by reference to the map. If your correspondent is well acquainted with mathematics, Hymér's astronomy is the best work to consult.

WALTER SCARBELL.

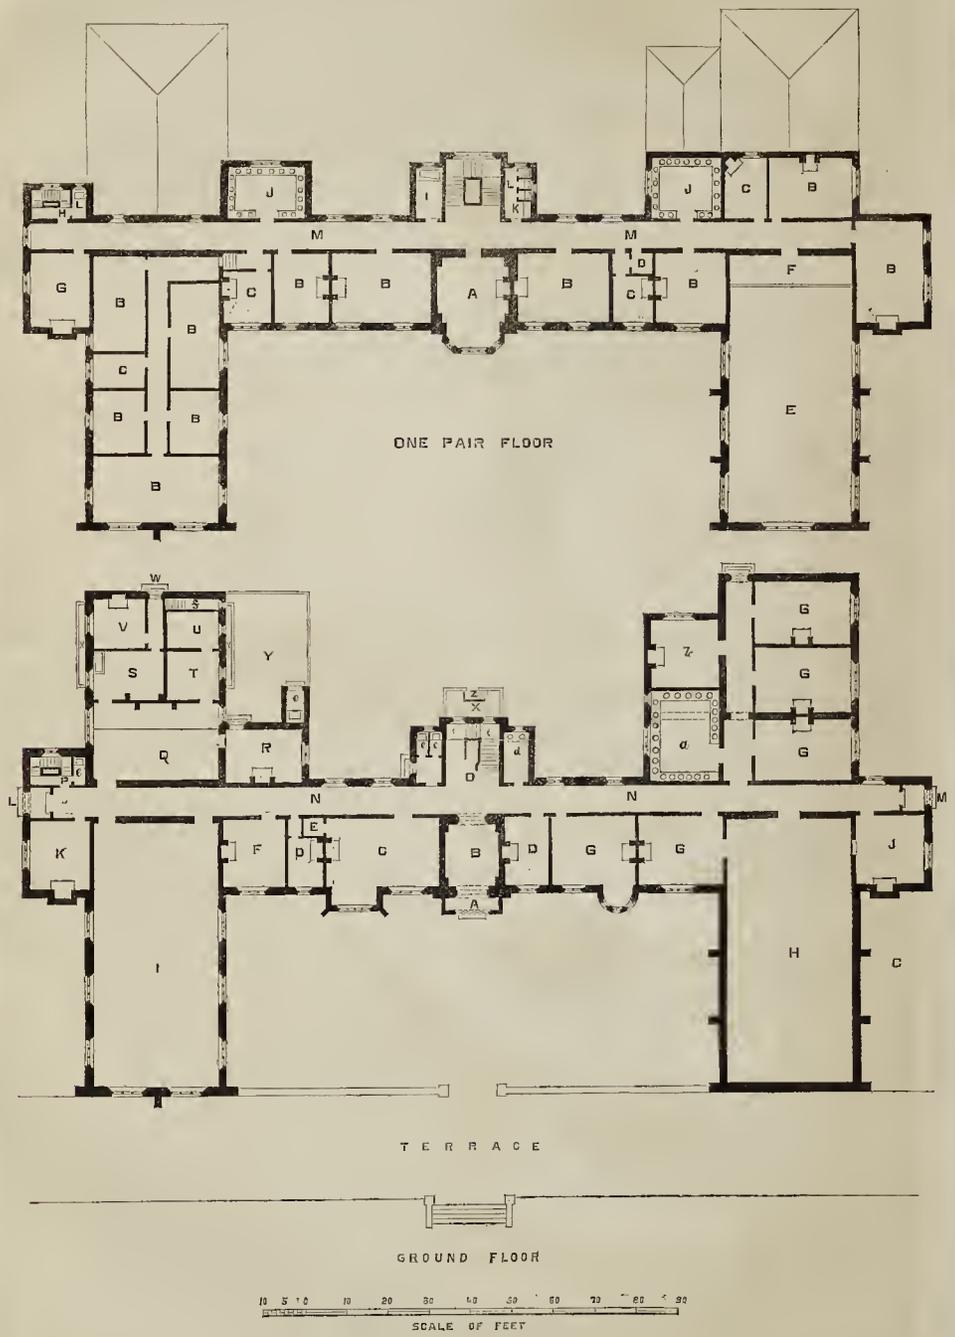

PAYMENT OF DISTRICT SURVEYORS' FEES.

It may be interesting to those concerned to know that, in the case of a claim for the fees of four houses near Queen's-road, Battersea, the owner has been adjudged liable to pay the district surveyor's fee, although an account had more than six months previously been rendered to the builder.

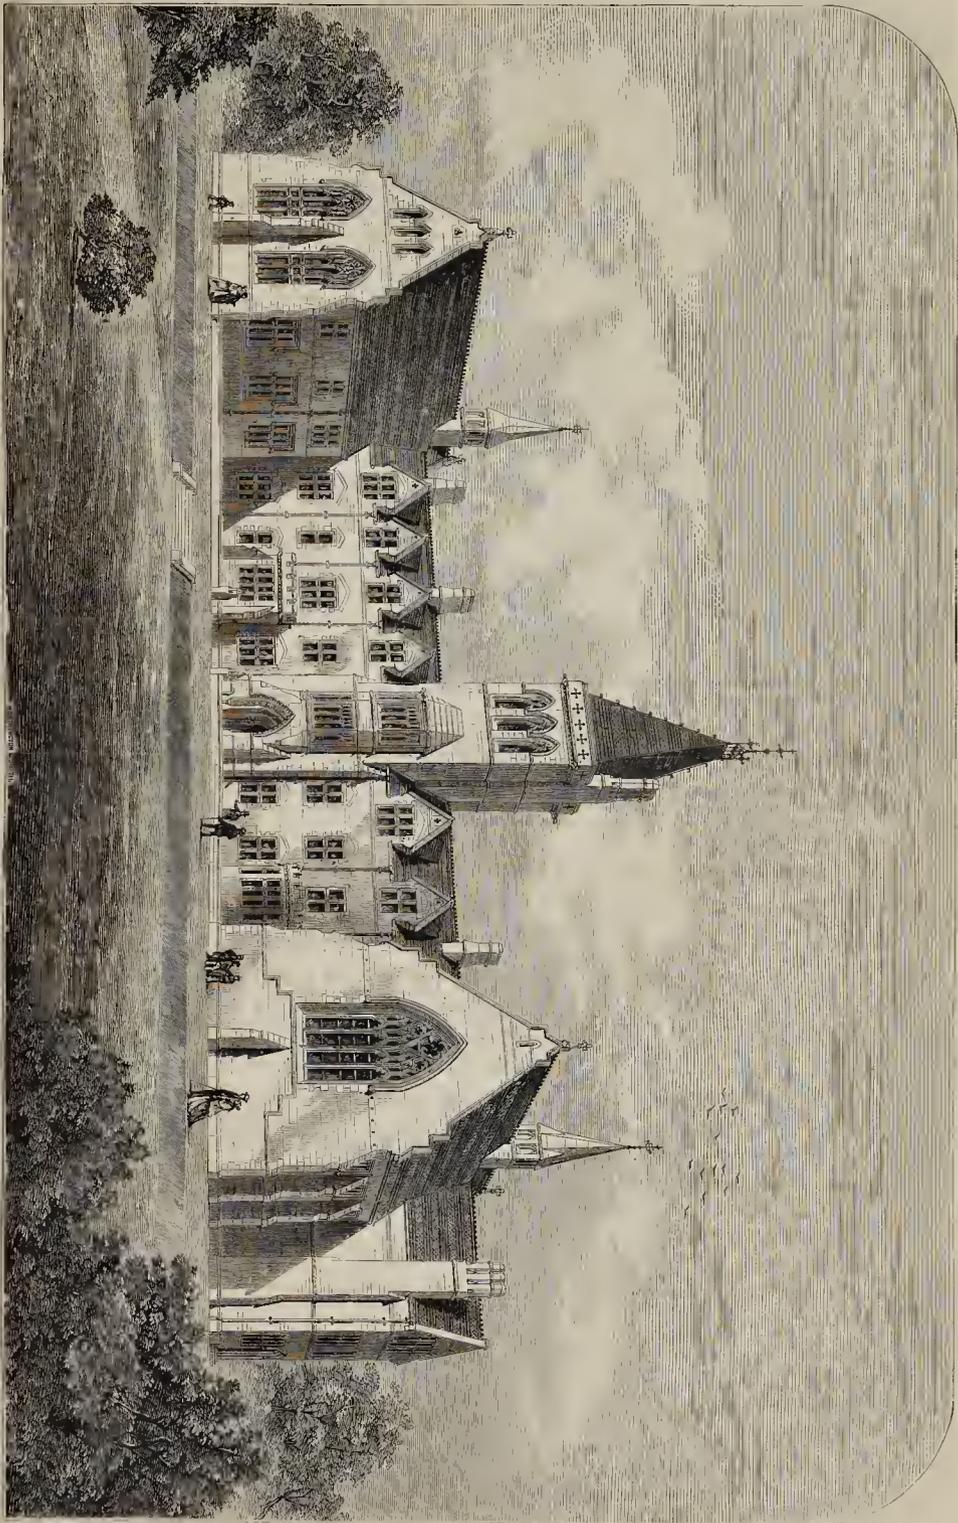

In evidence it was stated that the district surveyor had rendered an account to the builder more than six months previously; that he had applied to the builder, and had failed to obtain his fees from him. The fact of the ownership on the part of the party summoned was not disputed, neither was the account rendered to him; but the owner, through his solicitor, contended that the claim was not against the property, but against the owner; that he had become owner by purchase after the claim for fees was made, and, therefore, was not liable. The magistrate, however, decided that the owner or occupier remained liable until the fee was paid.

This, taken in conjunction with the recent case reported by you in the case of the District Surveyor against Wood, which was also in my district, leaves no doubt as to the liability of the owner, although the claim may have originally been made on the builder.

EDWARD P'ANSON.

THE WEST OF ENGLAND DISSENTERS' COLLEGE.

THE WEST OF ENGLAND DISSENTERS' COLLEGE, TAUNTON.—Mr. Joseph James, Architect.

THE DISSENTERS' COLLEGE, TAUNTON.

The West of England Dissenters' Proprietary School was established at Taunton, in the year 1847, by "men anxious to elevate early instruction by combining it with religious instruction, and who have acted upon the conviction that the success of their project demanded that the education offered should be of such a character as to vie, both in excellence and economy, with the best grammar and endowed schools in the district."

The scheme has been worked with great success, both in regard to the scholars educated, many of whom are now in prominent positions, and also from a pecuniary point of view; inasmuch as, although a good dividend has generally been paid to the proprietors, a large sum has been allowed to accumulate, for the purposes of the new building.

In June, 1866, the committee invited designs from six architects, from which one by Mr. Joseph Jemea, of London, was accepted, and is now being carried out by Mr. Henry Davis, of Taunton, who re-erected the tower of St. Mary Magdalene, Taunton, some years since.

It will be seen by reference to the plan, that the general arrangement is such as to keep each department distinct, but at the same time within easy approach of each other. Accommodation is provided for 150 boys, in separate beds, in moderate-sized dormitories.

The present contract amounts to 10,500., but does not include covered playground, water-closets, heating apparatus, &c.

Advantage will be taken of a stream running through the estate to erect a covered plunge-bath, and ample space will be afforded for playground. There is a large mansion on the estate, which was formerly used as a private lunatic asylum, and which is surrounded by some magnificent trees and shrubberies. This house will be used as a residence for the head master, and as a laundry.

The heating apparatus will be provided by Mr. J. M. Fisher, of Taunton, who has had much experience in this kind of work. Mr. George Salmon is the clerk of the works. The building, when completed, will form a prominent object to travellers by the Bristol and Exeter railway.

THE GREAT VIADUCT ACROSS THE SOLWAY.

THE great engineering undertaking of forming a direct line of railway between the south of Scotland and the west coast of Cumberland by means of bridging the broad estuary of the Solway Firth, is now almost completed. The earthworks are finished throughout, the masonry may likewise be said to be finished, the viaduct has been completed for some time, and the permanent way has been laid for sixteen out of the eighteen miles of the line. The principal work remaining to be done is ballasting, the formation of the junctions, and the stations. An unreclaimed moor on the Cumberland side, over a mile and three-quarters of which the line has had to be carried, has been a great difficulty in the construction, very heavy and extensive draining operations being required, and great labour being occasioned in laying the way over it. The distinctive feature of the line is the viaduct across the Solway. At the point where

the railway crosses the Firth, the distance from shore to shore is 2,544 yards, or a mile and between three and four furlongs. Of this stretch nearly 600 yards are composed of sea embankment, and the remaining 1,950 yards consist of the iron viaduct. The sea bank on the Scottish shore is seven chains long, and 28 ft. deep at the extreme end where it joins the viaduct. On the Cumberland shore the sea bank measures twenty-one chains in length, and at the extreme end it is 29 ft. deep. These banks have been a source of considerable anxiety in making, as the spring-tides rise upon them 21 ft. and 22 ft. The core of the banks is made with clay. The outside is then puddle a depth of 1 ft.; a layer of broken stone and quarry red averaging 2 ft. in thickness is laid over the puddle; and upon the quarry red the pitching is set, the stone being from 15 in. to 19 in. deep. The Seafield bank on the north side of the Solway has been completed for some time, and the bank on the south or Cumberland shore is rapidly approaching completion.

The principle upon which the viaduct is constructed shows simplicity of design. The structure is built of wrought and cast iron. The wrought-iron is used for the girders which span the bays, and likewise for the cross-bracing which stiffens the whole structure. These bays or spans are 30 ft. in length. The pillars that support the girders at intervals of 30 ft. are composed of cast-iron. The foundations are piles about 20 ft. long; but these vary according to the nature of the strata in which they are driven. They are 12 in. in diameter, cast hollow, the thickness of the metal being 1 in. They were cast with a chilled point for driving, and were all driven at low water from barges fitted with patent pile-driving engines, the monkeys used for this operation weighing about 20 cwt. The levels of the foundation-piles vary with the bed of the Solway. The lowest level is in the English channel, where the top of the foundation-piles is within 18 inches of low water of spring tides; and the height from the foundation-piles to the level of the rails is 38 feet. Each pier is composed of six columns, of which the foundation or driving-pile is the lowest; and the height from the foundation-piles to the girders is made up of columns 9 ft. in length, cast with flange at their end, and bolted together at their junction, the face being turned in lathes to ensure a perfect fit. Angle-irons are placed between the columns, and the angle-irons are again tied together by diagonal bracing. Although there are six foundation-piles driven, five only are made use of for the single structure; but the addition of a sixth is all that is required to enable the line to be doubled at any future period, the directors determined to make this provision, the extra outlay being immaterial compared with what it would be to drive a single pile at each pier separately afterwards. The platform of the viaduct is covered with Malle's patent buckled plate, which are riveted to the girders and to each other by strips of iron, this helping to give stiffness to the structure. The permanent way is laid on longitudinal timbers, bolted through to the two middle girders. The longitudinal timbers are secured in their place by ties and transoms at intervals of 10 feet. The rails are secured by cast-iron chairs, spiked to the timbers. A light handrail, supported by cast-iron standards, is fixed on both sides of the viaduct for its entire length.

The total weight of cast-iron in the viaduct is 2,892 tons, and of wrought-iron 1,807 tons. The whole of the superstructure was erected without scaffolding. It is expected that the total cost of spanning the Solway and forming the sea-benke will not exceed 100,000.

LIFE AND DEATH MAPS.

IN an interesting article on the above subject, which appeared in the *Builder*, on the 23rd ult., you were good enough to notice my efforts to illustrate the geographical distribution of disease in England and Wales, and I thank you not only for your having taken the trouble to understand what I endeavoured to show at the Medical Society, but for the many proofs that the article contained of your opinion as to the public utility of my researches.

I have always contended that the geographical distribution of disease is a study of the highest importance, to us islanders especially; for our population is wonderfully increasing, and it is high time that our attention be directed to the

future sites of our new habitations, towns, and cities.

Before, however, entering further upon this subject, I wish to explain my reasons for using two colours instead of different shades of one in the cartographical illustrations of disease-distribution. In drawing and colouring my maps, the first object was to impress the idea of the student at once with the most prominent parts displayed. To do this, I tried the old plan of shading, and many new plans of my own, but found that they all more or less failed to accomplish what I desired. On using, however, the two colours, red and blue, I at once found how much easier my own task became in comprehending the groups. These two colours strike the eye at once, are pleasing to it, and give me an opportunity of using them to aid the memory technically in remembering which are the most and which the least healthy districts in respect of any disease displayed. The red is the healthy, the minus average colour, and is typical of the floridly red arterial or well-oxygenated blood; the blue or plus average colour is the reverse; it represents defective circulation and aëration; it is the colour of roused-up blue venous blood.

The quantity of residual air in houses and streets is greater than is imagined; it is always impure. Streets, therefore, and houses ought always to be so built as to admit of a thorough cleansing from this noxious medium. Streets should not only be built with due regard to the prevailing winds, but the houses should never be so continuous as not to admit of a thorough draught at certain points. Where streets are built at right angles to the current of pure air, the wind passes over them the same as it does over valleys similarly situated; the residual air is, under such circumstances, never thoroughly swept away. It is on this account that a building of a quadrangular form is the very worst for the purpose of a hospital; the same error old air hangs about a quadrangle, and gets in through the open windows day after day, and week after week, even in spite of brisk winds. These quadrangles resemble those valleys in some parts of England, inclosed on all sides, where we find heart disease and the cause of its excess most prevalent.

The map of the geographical distribution of heart disease teaches us a wonderful lesson in ventilation on the grandest scale possible. It shows distinctly that wherever the pure fresh air from the sea can penetrate up the valleys, there the cause of the excess of heart disease is at once destroyed or swept away. The great natural ventilators of our country are our tidal rivers, whose courses are in the axis of the prevailing winds and the tidal wave; the effect of a clean sweep of sea air up these channels is well seen in the map of heart disease; for in the midst of counties whose mortality from this cause is above the average we find wherever these rivers bend their health, so far as this disease is concerned, accompanies them, the riparian districts being invariably minus average, or the red. To build therefore a city or town with such a fact before us, with the streets running at right angles to the healthy wind current, would be to disregard the teaching of nature as we find them written in statistics. Many of our towns and cities are built upon this wrong principle, and therefore many having the natural advantages of a tidal river do not benefit from these advantages to the fullest extent. In reconstructing cities, as we are now doing, take London for instance, that ventilation ought to be one of the great objects of the scheme; no cellars as habitations, no alleys, no quadrangles, no cul-de-sacs, should remain for foul air to reside in and defy the best efforts of the medical man and statesman in their attempts to improve the sanitary condition of the poor. When the old streets are demolished, the new ones that are to replace them should be planned with due regard to the points whence are derived the prevailing winds, our natural air flushers. Were we to look upon our atmosphere as we do on our seas and rivers, and water generally, we should then possess a better idea of its power as a "cleanser." Pure water washes away our solid and liquid impurities, but only in the same manner as a brisk current of the medium in which we live does our aerial sewage. We live at the bottom of an aerial sea instead of swimming about in it as the fish do in theirs, or flying about in it as the birds, and we should find that we are subject to similar currents to those in the sea, and perchance to be regular ones, if we were only better acquainted with their laws.

ALFRED HAVILAND.

GAS EXPLOSIONS.

MANY of our readers have already read of an explosion of gas at the well-known hotel near Castle Howard, Yorkshire, in which two servants had most remarkable escapes, one girl being forced nearly 40 yards. It appears the housemaid opened the bar, a large and lofty room, and lighted a fire, observing at the time a strong smell of gas. It would seem gas had been escaping all night from the chandelier, and that the upper space was fully charged. Contrary to custom, the girl omitted to open the window. She had left the room for a second or two, when, on turning into the long corridor towards the kitchen, a tremendous explosion ensued, and the girl was carried forward as fast as she could run with a sensation of an immense fire behind her right down the outer flight of steps into the park. The explosion had blown out three doors, and through all these openings the girl was carried, the outer door being thrown down the steps into the park, although 30 yards from the explosion. It is believed the accident was the result of a want of water in the slide of the pendant, which permitted the escape of gas from the top. The hotel narrowly escaped being burned.

The science of gas-lighting is one of the great improvements of the nineteenth century; but like railways and steam-engines, its practical every-day working is attended with danger. More accidents, we venture to say, occur with gas explosions than any other casualty to which the art of constructing buildings may be subjected. But, then, this ought to be understood. Every one should understand that gas is explosive. It cannot be denied that it indicates its presence in the most unmistakable manner. Still, how common it is to see an ignorant man or woman rushing with a lighted candle into a cellar or close apartment already filled with one of the most combustible combinations of chemistry? The fact is, they might just as well set fire to a powder-cask. How stale and tiresome to us becomes the repetition of the simple rule, that in the event of a strong smell of gas the first thing to be done is to *shut off the supply* at the meter, and the next, to *open the doors and windows*, and admit fresh air. There are certain more complicated circumstances connected with this particular explosion at Castle Howard, which we may briefly notice, for the benefit of those persons who may be at a distance from a gasfitter, or to whom such accidents may occur during the night; but let us point out and press on the public attention, by all means, the salutary principle, that in all cases of an escape of gas, and under any circumstances almost, a gasfitter should be sent for at once. The circumstances we refer to are these:—"The gas had been escaping all night from the chandelier," and "it is believed that the accident was the want of water in the slide of the pendant." What seems to be meant by the reporter in using the word *slide* here is what we call the water joint. A water joint in a gas lustre, it is worth while to explain, is a very ingenious contrivance. It is simply an elongated lute. It differs from a gasometer, for example, in no other principle than that of possessing a small interior tube for conveying the gas in place of a large internal cylinder, and our conviction is based upon long and practical experience, that those water-joint gas-lamps are highly dangerous instruments in almost any dwelling-house, but particularly where they are under the control of ignorant servant-girls. The recent tendencies of the gasfitter's taste in manufacturing these lamps, is to reduce the size of the water cup as much as possible. Hence the whole lute often consists of the slender column of water that is contained between a $\frac{1}{2}$ in. and a $\frac{1}{4}$ in. metal tube! Of course this soon evaporates, especially in a warm room, and no barrier is then opposed to the escape of the deadly and combustible gas. It seems a simple precaution to pour in a little fresh water into this joint every month, more or less frequent, as the case requires. But alas! how many of our most fatal accidents arise from the neglect of simple precautions. We have found Colza oil a good substitute for water: it does not evaporate so quickly, and does not injure the apparatus by its freezing in winter, as water does. This not suiting the interests of the gasfitter, he tried to prevent us from using it, by croaking about smells and other evils; but many months have passed, and no such results have yet occurred. Even though the oil should begin to smell, it can then be easily replaced by new oil.

We may take the opportunity of adding that

the same dangerous risk belongs to the gas-meters, which from the same neglect of water often permit escape. In fact, most of the explosions of gas take place at the meter, which ought to have the supply-pipes so fitted as to rise from it in a regular declivity. This would allow of the "water in the pipes," which is in fact condensed gas, to flow back into the meter, keeping at once the pipes clear, and the meter additionally supplied with water. Even then it cannot be pointed out too strongly that a systematic inspection and regulation both of gas-meters and water joints are indispensable.

THE VELOCIPEDE MOVEMENT.

In originating this movement, as we think every reader of the *Builder*, even for the last few years, will admit that we are entitled to say we did, our purpose was utility, much more than recreation; and, although our friends, the French and the Americans, seem to have gone crazy about it, they have not yet come up to our mark, either as regards utility or as regards improvement of the vehicle. It is to be hoped that now we have ourselves set about it in England, we shall be able to do something worth while in both of these respects, avoiding much use of the velocipede in crowded streets, and cultivating its use rather in suburban and provincial towns, or country districts. One special improvement which we have all along desiderated is to get rid of the pedaling process by the invention of some other motive power, such as compressed air; and we have before noted that in America such a power is said to have been already applied to cabs or cars; and we do not see why it should not at once be applied to the velocipede. Two-wheeled velocipedes, like "safety" cabs, are by no means safe vehicles; and, at any rate, they are not likely to survive the application of mechanical motive power to these vehicles, whatever they may then be called. Indeed, the two-wheeled velocipede is rather a retrogradation than an improvement. We do not know whether Faraday's, on which he traversed Hampstead-hill, was a two-wheeler; but at all events, the old "dandy charger," if we recollect aright, was usually so, though it was, we think, without treads, the feet touching the ground. The withdrawal of the third or third and fourth wheel, therefore, is no novelty, although for amusement and recreation, and the display of agility and skill, it may still hold its place. On one of these two-wheelers, Mr. Mayall, jun., son of the well-known photographer, is said to have run from London to Brighton, the other day, at the rate of eight miles an hour, and part of the journey—down hill—at the rate of a mile in four minutes. This go-a-head vehicle, as the *Gentleman's Magazine* remarks, is exactly suited to American ideas, and walking, accordingly, is already on its last legs, as Yankee wags allege. Schools, with the imposing name of "Velocinasiums," for teaching the young idea how to gyrate, are being established; races are being run; and men and boys are whizzing here, there, and everywhere, at the speed of twelve miles an hour. Inventors are improving the machines, and manufacturers are making them, wholesale, the supply at present falling short of the demand. The mania is spreading everywhere throughout the States, and Western rhymers are engaged in singing the praises of the "easily-hossed" vehicle. One, Carl Benson, challenged the other day to find a rhyme for "velocipede," made it out thus,—

"There was a man on a velocipede
Who said, I need not give my horse a feed;
Without oats or hay
He will go all day;
It's a cheap thing to keep a velocipede."
Whereupon another poet suggests this,—
"It 's a loss indeed
To give one's horse a feed,
And I can boss a steed
Of such a saucy breed,
Then anre, the boss I need
Is the velocipede."

In France the mania is quite as great as in America, and the last news on the subject is that the Prince Imperial of France is at it, being a great amateur of velocipedes. He has publicly gained a race in the Tuileries Gardens against his comrade, Dr. Conneau's son, and it is said that he has ordered a dozen velocipedes to make presents of to various young friends. The French Government are about to mount the rural postmen, we hear, on velocipedes,—an idea worth consideration at St. Martin's-le-Grand.

When all the novelty-hunters are done with the velocipede, we trust that one result may be that it will be improved in the way we wish, and made useful to those who cannot afford to "keep a gig;" especially in enabling these to live healthfully in out-of-the-way corners of the outskirts of London and other large towns while obliged to be in town all day at business.

LIVERPOOL ARCHITECTURAL SOCIETY.

At the tenth meeting of the present session of this society, held on the 26th ult. last (Mr. F. Horner, president, in the chair), thirteen sets of drawings were exhibited, which had been submitted in competition for the annual prize offered by the society to the student members. The subject was a design for a row of ten seven-yard houses, the materials for the external design being restricted to brick, tiles, and terra-cotta, except for sills or steps. It was announced by the secretary, that the council had awarded the first prize to the set of drawings marked "*Par sit fortuna laboris*," by Mr. Stanley Fox, a pupil of Messrs. Audley; and the second prize to the set marked "*Terra cotta*," by Mr. P. Balmer, pupil of Mr. Wordley. It was observed that a larger number of designs had been submitted on this occasion than had for a long time past been sent in for the students' competitions.

Mr. S. Hoggins (author of the "*Course and Current of Architecture*") then read a paper, entitled "*Letters from Shakspeare*, the new capital of Australia, written by Scamozzi Smith, esq., architect, to his friends in England, in 1915-16." This paper, which was a continuation of one read during a former session of the society, and noticed in our pages at the time, had for its aim to present criticisms on architecture and the other fine arts, in their relation to one another, and to society and social habits the criticism being conveyed in the form of descriptions of imaginary buildings in a future antipodal style. The general tendency of the paper was to inculcate strongly the revival of the refining influence of classic feeling, combined with the freest possible use of all materials which, by their colour or texture, could add any new decorative features to the buildings; and also to plead strongly for the essentially fine-art character of the architect's profession, to be exhibited not only in elevation and ornament, but also in the contrivance of plan and landscape-gardening. The paper was illustrated by a number of original and suggestive designs by its author.

BIZARRE ARCHITECTURE.

Sir,—The best thanks of all our craft who value the fine-art character of architecture are due to you for the very able and spirited article, "*On some Modern Architectural Work*," in the last number of the *Builder*. It angurs well for some reformation of the folly therein exposed when the leading architectural journal takes up the subject in this direct and energetic strain; and to some of us, who have by voice and pen striven in our own localities to stem the muddy torrent of false design, no greater encouragement could be afforded us than aid such as your article gives.

It is remarkable how very insensible to the vices of the styles they affect,—for simple affectation it is,—the disciples of these most corrupt schools are; for you will hear them, as I have frequently witnessed, sneer at and depreciate works not of their own kidney, but, with whatever faults, of far higher art quality, and be evidently entirely ignorant of the real merits of what they deride, and of the points in which their own cannot bear comparison with it. I lately attended an opening service in a costly church which exhibited nearly all the peculiarities you enumerate, and the architect of which, a clever and enterprising young man, had to my own knowledge desired to embody in this work all that be thought best in ecclesiastical design. Well, I declare to you that the one only feature in the least pleasing to the eye was the monogram on the Communion table-cover; all else was crude, discordant, ill-proportioned, and bizarre; yet in the local papers there appeared critiques (!) commenting with unlimited admiration on the knowledge and taste displayed by the rising young architect, and no less on the happily-directed and guided liberality of the founder.

I some time afterwards, with a lady who had accompanied me on the previous occasion, was in a neighbouring church, built more than fifty

years since from a design of Rickman's, of Andor character and with much of what we now justly discard as past in the way of galleries, imitated material, &c. I formed a comparison in my own mind, and then asked my companion whether this or the church of the "new light" Gothic he had been at together were the more dignified architectural and ecclesiastical in effect, and she answered at once in accordance with my own feeling, the one we were then in beyond comparison; so certain is it that just proportions, well-studied detail, and carefully-designed ornament (all of which Rickman's works, as a rule, embody) commend themselves to the mind beyond all the results of affected massiveness, crude phases of form, and forced contrast of colour which these would-be Mediæval structures exhibit; the higher artistic qualities in the earlier revival design more than compensating for the weaknesses belonging to the inherent timidity of such works. This, in the church, I have heard pointed out by the self-constituted local censors of the day as a thing only fit to laugh at; would that they possessed one tithing of the real refinement of the genial old Quaker architect! Unhappily, too, among those who run into no such excess of riot, there are not wanting some, and of metropolitan repute, who, in respect to the Pointed style, seem to act on a maxim which was often on the lips, and seemed a conclusive plea to the approval of a late eminent classical professor of our art, "The ancients did it." If only a precedent can be found for something in an old church or conventional building, it is held as beyond criticism; as if, forsooth, the Mediæval designers never made blunders. I have before my mind's eye now a lately-built steeple attached to a church, which I heard pronounced a perfect model of correct Pointed design, the spire of which (very like one or two old ones I have seen) if drawn by a pupil of mine of six months' standing, I should tell him to rub out and be ashamed of. But if I, here in the provinces, should venture to attach this opinion to the church and designer instanced, I should be simply covered with ridicule.

Let the real principles of art, not the popular affections of the day, rule in the minds of those who have the duty, a noble one if well discharged, of marking for posterity the architectural position of our generation, and we shall soon get rid of the crinities, barbarities, and needless uglinesses of these unhappy caricatures of real architecture; and, whether preferring Classical or Pointed design (uniformity, I believe, impossible), they may give a character to the buildings of our day which shall hold their ground beyond it, which cannot, I believe, be the case with the class of works which, with you, I most sincerely deprecate.

A PROVINCIAL ARCHITECT.

RAILWAY MATTERS.

The report of the directors of the Metropolitan Underground Company states that the gross receipts from traffic for the half-year ending the 31st of December last were 155,769*l.*, as compared with 118,738*l.* for the corresponding half of 1867. The total traffic receipts for the year 1868 amounted to 234,243*l.* The net revenue account showed a credit balance of 150,278*l.* This balance would enable the proprietors to declare dividends at the following rates per annum, viz.: Upon the preference stock at 5 per cent.; the consolidated ordinary stock at 7 per cent.; the preferred stock at 6 per cent.; and the extension stock at 6 per cent., leaving a balance of 4,167*l.* The capital account to the 31st December showed that 6,390,656*l.* had been received, and 6,486,334*l.* expended, leaving a balance of 95,679*l.* against the company. The revenue account for the half-year ending the 31st of December last showed that 162,198*l.* had been received, and 57,989*l.* expended, leaving a balance of 104,209*l.* To this was added 1,674*l.* from the preceding half-year, 14,624*l.* from the new redeemable fund account, 42,600*l.* contractors' payment, 1,250*l.* from the St. John's Wood Railway Company, and 1,793*l.* bankers' and general interest account, making together 166,153*l.* From this was deducted 15,875*l.* interest on loans, and 146,111*l.* for preference and ordinary dividends as proposed in the report, leaving a balance of 4,167*l.* for the next half-year.

The traffic receipts of railways in the United Kingdom for the week ending February 14th, amounted on 13,419 miles to 685,955*l.*; and for the corresponding week in 1868, on 13,216 miles,

to 660,871*l.*, showing an increase of 203 miles, and of 25,084*l.*

Extensive works have been for some time in progress throughout the entire course of the North London Railway. An additional line of rails will be added from Broad-street Station to Camden-town, passing the stations of Shore-ditch, Agar-town, Dalston, Newington, Highbury, and Caledonian-road. Operations have been commenced at the Camden-town end of the line, and from this station to the Roman-road the embankment on which the rails will rest is in a more or less forward state. Beneath the Roman-road an additional bridge, with iron girders, spans the rails. The piers and abutments have been built, and iron girders will span the Great Northern line of rails, near the end of Frederick-street. The principal portion of the small brick arches between the Roman-road and Camden-town have been finished. Several houses have been pulled down in Liverpool-road and Arundel-square. Cumberland-street, lying between the Roman-road and Caledonian-road, and facing the railway, has been lined with plain new buildings of four stories; the greater portion of these are, however, yet unfinished.

The Great Eastern is able to pay a dividend of rather more than 1½ per cent.; but, "in view of the difficulties through which the company has been passing," they do not propose to pay it, but to carry the amount which would be available to divide as a reserve to the accounts of the current half-year. The Taff Vale dividend will be at the rate of 9 per cent. per annum.

A telegram from Lisbon states that the Portuguese Government is treating with one of the railway companies for the purchase of its lines.

FATAL FALL OF AN ARCH ON THE GREAT EASTERN RAILWAY.

A TERRIBLE accident has occurred on the Great Eastern. In Waterloo-town, Bethnal-green, Messrs. Lucas, the contractors, were doing some repairs for the company, and had a number of excavators and carpenters at work under one of the railway arches, which are about 60 ft. in height. A heavily-laden coal-truck passed over the spot where the men were at work, and without an instant's warning the whole structure, which was composed of brick, ironwork, and timber, fell bodily in, burying the men beneath several feet of masonry. One of the trucks in falling through capsized, and providentially was the means of saving the lives of some of the workmen. Forthwith, 100 of Messrs. Lucas's men proceeded to dig out the dying and the dead. Fourteen men were got out alive. The falling timber and iron girders had formed a sort of cavern over them. The dead bodies of five unfortunate men—four of whom were excavators, and one a carpenter—were then dug out from underneath a mass of earth. It is said that at the time of the accident one of the columns underneath the arch was being repaired, and the ironwork being weakened, the train passing over it caused the accident.

TECHNICAL INSTRUCTION FOR WORKMEN.

WE mentioned in our last that a memorial had been presented to the Earl de Grey and Ripon, by a deputation from the Workmen's Technical Education Committee. This committee was appointed at a general conference of operatives, held in London on the 14th of March, 1868. Among the suggestions made, the committee more especially solicit the favour of his lordship's attention to the recommendation, that the same systematic and detailed class-instruction which is given in the day-time at the Royal School of Mines in Jernyn-street, and at the Royal School of Chemistry in Oxford-street, should be given at night. The lectures which for several years past have been delivered in the former institution in the evenings, have been attended by large audiences of working men, and have been of the highest value. The committee feel, however, that more detailed instruction, such as that afforded by the day-classes, accompanied by demonstration and experiments, and giving the student the advantage of frequent examinations in the subjects studied, is now urgently needed, as well as the more popular survey of the physical sciences afforded by the lectures. They recommend that the building where such classes are held should be an "annexe" to the Royal School of Mines and Chemistry, not far

off, say Leicester-square or Golden-square. They are opposed to South Kensington, as being too distant from the residences of the majority of workmen. As to expenditure, it appears to them possible that the public might be induced to provide a site or buildings, if it were known that the State would provide all the expense connected with instruction; and if that view be adopted, the grant might be made conditional on suitable accommodation being provided.

The committee feel that it would be right and desirable that only those should be admitted to the proposed classes who are perfectly competent to avail themselves of the advantage to be derived from such classes; they therefore propose that the admission of any applicant should be rendered conditional on his having passed the lowest standard at the examinations which are held annually by the Science and Art Department, in the month of May.

COMPETITIONS.

Cemetery, Dover.—The first premium for designs for laying out ground and buildings for the new cemetery for the parish of St. Mary, Dover, has been awarded to Mr. Frederick A. Klein, of Cannon-street, London, who will be employed to carry out the works; the second, to Mr. Rowland Ross, of Bishopsgate-street Within.

Hartley Winney New Church.—The design sent in by "Fides" (Mr. Lansdowne, of Newport and Bristol) has been accepted by the building committee; and Messrs. Hibbard & Long, of Bath, have tendered to carry it out for 3,095*l.* The plans drawn by Mr. John Johnson, of Moorgate-street, London, and those by Messrs. W. H. & J. Ward, of Curzon Chambers, Birmingham, have been awarded the second and third premiums respectively.

Lambeth Workhouse and Infirmary.—Thirteen sets of designs were sent in on Monday last for a new infirmary for 600 persons, and a workhouse for 1,500 inmates, for the parish of St. Mary, Lambeth.

Kensington District Schools.—The design by Mr. Saxon Snell has been selected. We sufficiently marked our good opinion of this plan in our brief notice of the designs last week.

Peterborough Corn Exchange Extension.—In answer to advertisements, ten sets of designs were sent in on the 17th of February. The competitors were Messrs. S. Hemming, W. Pattenon, J. Wallis Chapman, and John Ladds, of London; Messrs. J. G. Traylen, Sibson, Edwin Bays, of Cambridge; Mr. J. Meggett and Daniel & James Ruddle, of London and Peterborough; Mr. B. Chubbill and Mr. John Ruddle, both of Peterborough, from whose designs the directors have selected those by Mr. John Ladds, to whom they have awarded the premium, with instructions to prepare working drawings and specifications, and obtain tenders at once.

CHURCH-BUILDING NEWS.

London.—The new church of St. John the Evangelist, St. George's East, has been consecrated by the new Bishop of London. The new church stands in Grove-street, Commercial-road East. It is a small edifice, built of brick and stone, in the Middle Pointed style of architecture. It occupies a site which was formerly a cooper's yard. The church contains about 600 sittings. It has been erected at a cost, as computed by the architect, of 4,300*l.*; although, all things included, the entire expense would amount to a considerably larger sum. The money has been subscribed partly from the Bishop of London's Fund, and the remainder from other sources. The Messrs. François were the architects.—A new church is about to be erected for an ecclesiastical district, consisting of the neighbourhood of Brownswood Park, to be taken out of the parish of Islington. The church will be dedicated to St. John the Evangelist.—Another new metropolitan church has been completed. It is situated in Barnsbury, and the district which is assigned to the new church is taken out of the parish of St. Luke, Holloway.

Bromley (Middlesex).—The church of St. Gabriel, Bromley, Middlesex, has been consecrated. The district assigned to the new church is taken from the parish of St. Michael, Bromley. It has a population of 7,000 of the poorer classes. The edifice has been built from the designs of Mr. R. J. Withers, by Messrs. Dove, Brothers, at a cost of 4,700*l.*, of which 2,000*l.* were given by the Bishop of London's Fund, the Church

Building Society, &c. It affords seats for 753 persons, all free.

Hitchin.—King's Walden Church, which has been closed for the purpose of being repaired and restored, has been re-opened for divine service. The church has been re-seated with benches of polished oak, and the reading-desk is also of oak. The pulpit and font are of stone, carved. The oaken screen, which divides the nave from the chancel, has been restored and redecorated. The works have been carried out by Messrs. Kersyth, of London, from the designs of Messrs. Nesfield & Shaw. An organ, built by Messrs. Waller & Jones, of London, has been put up. It is proposed to insert a painted east window, and to introduce colour in the roof and on the walls of the church.

Fulbourne (Cambs).—The parish church is to be restored by Mr. Tooley, of the "Church Restoration Works" in this town, his tender for the work, 3,100*l.*, having been accepted. Mr. A. J. Blomfield is the architect engaged.

Birmingham.—There is a prospect of a church being erected for the populous and daily-increasing district of Heath-street, in the parish of All Saints. The inhabitants being at a great distance from any church, have taken up the matter warmly, and the Church Extension Society have already purchased a piece of land at the junction of Heath-street and Winson-green-road, for church and parsonage, and made a grant of 500*l.* towards the erection of the church. A building committee has been formed, and plans for the church, which is to be called St. Outhbert's, have been prepared by Messrs. Bateman & Corser. Estimated cost, 5,000*l.*

Ripon.—The chapel of St. Mary Magdalene has been consecrated. This edifice, which is from the designs of Mr. Crossland, architect, Leeds, has been erected through the liberality of Mrs. Mason, the widow of the late Rev. G. Mason, of Copt Hewick Hall. The old chapel, situated not far from the River Ure, contains an ancient pavement in front of the altar, supposed by some to be Roman, but more probably copied from a work of that period, of the date of the twelfth century. The new chapel contains two stained-glass windows, both to the memory of the late Rev. G. Mason. That in the east, representing the six Beatitudes, by O'Connor, of London, was the gift of Mrs. Mason; and that in the south, representing the three Graces—Faith, Hope, and Charity—was got up by subscription among a few friends of the late rev. gentleman. The chapel will hold about 150 persons.

STAINED GLASS.

St. James's, Derby.—The chancel of this church has recently been enriched by the insertion of seven stained-glass lancet windows, each of which is divided into three compartments. Six of the lights illustrates those saviours in the Litany which relate to the Saviour's Redemption, and the most important events in His life, beginning with the Nativity and concluding with the Ascension and the Descent of the Holy Ghost at Pentecost. The seventh light is devoted to the Martyrdoms of St. Stephen, St. John, and the Holy Innocents. The artists were Messrs. Lavers, Barrand & Westlake, of London.

The Abbey Church, Bath.—A stained-glass window by Mr. Hughes, of London, has been placed in the south aisle of this church by Mrs. Brooke, of Malmesbury, in memory of her eldest son. The window contains five subjects, viz.,—The Raising of the Widow's Son, Our Lord addressing the Noblesman and telling him that his Son liveth, Christ receiving little Children, the Prayer in the Garden and the Sleep of the Disciples, and the Payment of Tribute Money. At the top of the window (which was exhibited at the Paris Exposition) are figures of angels bearing banners, on which texts are inscribed.

Marple Church.—A stained-glass window has been placed in the east end of All Saints' Church, Marple. On the upper part are representations of three angels, and near to them appears the word Alleluia, which is twice repeated, as though forming part of an angelic song. On the left-hand side of the central compartment is the representation of the Baptism of Jesus by John the Baptist. On the right-hand of the compartment is the representation of Our Lord's Last Supper.

In the centre compartment is the representation of the Saviour's Ascension. This is the first stained window erected in Marple Church, and is placed there by the eldest daughter of Mr. Skirrow, as a tribute of affection to her parents. The window is from the establishment of Mr. Hughes, of London.

Chichester Cathedral.—We understand that the erection of a new window of stained glass in the south transept of this cathedral has been intrusted to Mr. Wallis, of Newcastle-upon-Tyne, and that it will be immediately taken in hand.

Great Barford Church.—A stained-glass window has recently been put up in the chancel of this church. It is dedicated to the memory of the late Mr. John Arnold, who, on retiring from business as a London merchant, built a mansion in this parish, and here spent the latter years of his life. The window was designed and executed by Messrs. Hardman, of Birmingham.

PROVINCIAL NEWS.

Chatham.—A new wing is to be added to St. Mary's Convict Prison, Chatham, which will accommodate about 300 more convicts. Employment could be found on the dockyard extension works at St. Mary's Island for even a greater number.

Liverpool.—The new offices of the Liverpool and London and Globe Insurance Company, erected at a cost of 11,500*l.*, in Corn-street, are now completed and occupied. The architect was Mr. W. B. Gingell. The public office is a large room, with plastered roof, supported on columns of coloured stone. There are three suites of professional chambers over the company's office.

East Retford.—The first stone of a new Temperance-hall has been laid here. The building will be 54 ft. by 22 ft. inside, and of a plain character, and is estimated to cost 360*l.*

FROM AUSTRALIA.

Malbourne.—The church of St. Mary's, Hotbam, of which the *Illustrated News* of Melbourne gives an engraving, has been opened for divine service, after being enlarged by the addition of transepts and chancel. The style of the building is Gothic, of the Early Decorated period. Its external length is 112 ft., and across through the transepts it is 104 ft. The plan is cruciform. It consists of a nave, with north and south aisles (the portion of the building already in use), north and south transepts, chancel, baptistry, robing-room, and vestry. The church is constructed throughout of limestone, with freestone millions and tracery in the windows, and with Portland cement water-tables to the buttresses, &c. Each gable is terminated with a freestone cross or finial. The nave is a clearstory, and is lighted by windows of circular form, filled with tracery, and situated above the aisle roofs. At the intersection of the nave, chancel, and two transepts, there are four moulded stone arches, 24 ft. wide and 33 ft. high, the space which they enclose being finished with a groined ceiling, with moulded ribs, having carved bosses at their intersections. This ceiling, which hangs like a canopy over the space where the nave, chancel, and transepts meet, is one of the chief of the internal features of the building. All the other parts of the church have open timbered roofs, with moulded hammer-beams, and carved struts thereunder, springing from moulded brackets. The seating-room, when the whole of the interior fittings are completed, will afford accommodation for about 800 persons. The cost of the building so far, has been over 6,000*l.* The tower and spire, which will be 130 ft. high, as yet have only been commenced; and before the whole church is completed an organ-loft and organ will have to be built, as well as interior fittings and stained-glass windows added. At the eastern end of the chancel there is a large window, 12 ft. 6 in. wide by 25 ft. high, intended for a stained-glass design; and it is understood that a local firm have offered to design and manufacture the window for the sum of 400*l.* The architect was Mr. Lloyd Taylor.

The contractor for the new Lunatic Asylum has commenced operations. A large number of men will be employed in the erection of this extensive pile of buildings.

The contractor for the Alfred Graving Dock, Williamstown, has between seventy and eighty men at present employed on that work.

The new Yarra Graving Dock, built by Captains Sinnott and Hughes, has been opened. This dock has been in course of erection for the last two years. The length of the dock is 250 ft., breadth at top 55 ft., and at the bottom 40 ft. It is 16 ft. deep in dock, and has 13 ft. 3 in. of water on the sill at ordinary tides. The pumping machinery consists of a 20-in. centrifugal pump,

capable of raising 5,000 gallons per minute, and was manufactured to order by Mr. William Wright, of Little Bourke-street West. Mr. D. B. Pritchard, C.E., of this city, is the consulting engineer.

FROM SCOTLAND.

Edinburgh.—The Lords of the Treasury, according to the *Scotsman*, have sanctioned the erection of a large new Record Hall, on the vacant ground at the back of the old building, at a cost of about 8,000*l.*, the designs for which have been prepared by Mr. Matheson, of her Majesty's Board of Works. This increased accommodation for the records is rendered necessary by the Land Writs Registration Act of last session.—The directors of the Edinburgh Water Company have received a report from Mr. Hawley, the hydraulic engineer, and from other engineers, pronouncing in strong terms in favour of the Company's scheme for bringing in a supply of water from the Moorfoot Hills. Mr. Hawley estimates the cost of the St. Mary's Looch Scheme at 1,400,000*l.*

OBSTRUCTION OF PICCADILLY.

A CORRESPONDENT, T. H. H., whose letter represents two others on the same subject received by us, says,—The intrusion of a solid brick erection, measuring 27 ft. by 15 ft. and 20 ft. high, completely across the footway of Piccadilly, induces me to inquire whether there is any local authority to protect a public thoroughfare of such importance.

Opposite to the site which is now being excavated for the new buildings for the scientific societies opposite Burlington House, the boarding covers the whole footway, which is 12 ft. wide; but in the centre there is a further obstruction of 5 ft. upon the driveway, and a close porch, which has all the appearance of permanence, projects to the curb; thus cutting off the view of the street line, reducing the carriage-way in this most important street, and necessitating a railed gangway, by detour, for pedestrians. It may be alleged that the long corridor erected as an entrance to the Royal Academy, through the old courtyard, is only temporary; but it is likely to stand in the way for some years, until the new building is complete, to the annoyance and discomfiture of the public.

The architectural effect of this extemporaneous bit of luxury is by no means contemptible; nevertheless, for public use and convenience, it may not be unreasonable to ask that in case a *velum*, or carriage awning, be absolutely requisite for Fellows or Patrons, a pair of pillars only be reserved on the curb to sustain the roof, and that the *transverse walls* be removed, so as to afford free intercourse for pedestrians in this the most important of our West London pavements.

WIDENING THE POULTRY.

SIR,—Nonsense! Abolish the Poultry. Surely they are not going to finish off the end of the new street from Blackfriars to the Mansion-house, and then see what a ridiculous appearance a "Middle-row" left will make.

Here must be the programme. Abolish the Poultry! Let Cheapside be lengthened to the Mansion-house. ONLY A TAILOR.

"MEDIEVAL METAL CAPITALS."

For the benefit of your correspondent "T. M." I would instance the case of Salisbury Cathedral, where the centre shaft of the west doorway has to its capital a bronze abacus. The section of the abacus is the same as the stone abaci on either side of it.

The bronze bands of Salisbury and the copper bands of Westminster are well known; whilst doubtless many other examples exist to ease the mind of "T. M." who appears desirous of making such legitimate use of metal, but is anxious to find a precedent. J. T. P.

SIR,—In reply to "T. M." I think if he will make inquiries, he will find many instances of Metal Capitals in ancient and modern times; to wit, the Pantheon, and St. Peter's (interior), Rome; Nelson Column, London. S. C. F.

THE PROPOSED NEW OFFICES FOR
POPULAR DISTRICT.

At a special meeting of the Popular District Board of Works, held last Tuesday evening, at the Board-room, East-India Dock-road, a report was read from a committee, to whom had been referred the four lowest tenders for the erection of new offices and Board-room. The four tenders were,—Mr. Kilby, 3,122.; Messrs. Wicks, Bangs, & Co., 7,975.; Mr. Turner, 7,890.; Messrs. Baker & Constable, 7,330l. The committee recommended that Messrs. Baker & Constable's tender be accepted. An amendment, to the effect that the tender had exceeded by about 2,330l. the original sum intended to be laid out, was moved, seconded, and persevered in; and after a protracted discussion the Board divided, and the amendment was lost by a majority of eight. A second amendment was then proposed and seconded, that the matter be referred back to the committee, with a view of reducing the sum to be laid out. This amendment was also lost. The report of the committee was then carried, and Messrs. Baker & Constable were informed that their tender had been accepted by the Board. The joint architects are Messrs. Hills & Fletcher, and Messrs. A. & C. Harston.

ROYAL INSTITUTE OF BRITISH
ARCHITECTS.

The President, Mr. W. Tite, M.P., announced at the last meeting of the Institute, held on Monday evening, the 1st inst., that the council proposed to recommend for the Royal Gold Medal of 1869, Professor C. R. Lepsius, archaeologist, of Berlin. The recommendation would come more formally before them at another meeting. Mr. Alfred Strong was elected a fellow, and Mr. W. F. Williams an associate; and then Mr. Wyatt Papworth read a memoir of the late Joseph Bonomi, architect and A.R.A., with a description of some of his designs. A number of Mr. Bonomi's drawings were exhibited.

Mr. Geo. Godwin read a paper on Masons' Marks in various countries, with special reference to the Chevalier Da Silva's work, "Signes qu'on voit gravés sur les Anciens Monuments du Portugal." The paper was illustrated with 43 sheets of marks from Egypt, the Holy Land, Lycia, Italy, England, Ireland, Scotland, France, the Tyrol, Switzerland, Sweden, Denmark, Germany, Austria, Spain, Portugal, and other countries. We shall print it hereafter.

THE ARCHITECTURAL EXHIBITION.

The annual exhibition will be opened on Wednesday, May 5th, and drawings must be sent to the galleries on Monday or Tuesday, the 5th and 6th days of April. The council desire to give to the architectural profession, and the public at large, a creditable and convenient opportunity of exhibiting and inspecting well-executed representations of the work now being executed by individual architects, and others interested in art. In furtherance of these objects, and in addition to the usual attractions of the exhibition, they are desirous of receiving perspective, geometrical, and working drawings of all new buildings, with such particulars as to plan, construction, cost, draughtsman, or artist, as may be desirable. The committee have also decided upon accepting a limited number of purely artistic drawings of architectural subjects, to bring the exhibition into prominence, it has this year been decided to open it free on Mondays and Saturdays.

CABINET-WORK IN LONDON.

Sir,—Your correspondent "E. G." gives a very fair sketch of the majority of the cabinet-makers in London, but he does not show that the remarks made by the Marquis of Eble were justified.

I understand that a statement was made by the noble marquis, to the effect that "there was at a man in England capable of designing a piece of cabinet-work; and if a good design were procured there were no men able to execute it." This is a sweeping charge of incompetency to bring against designers and workmen by a young and I feel justified in saying—inexperienced dilettante. In a few years he may think that he came to a hasty conclusion on this matter, and retract it. He has not, I believe, been in many of the best houses in London or the provinces, where really good designs for furniture are made

and carried out; for, if he had, I think that he would not have made such assertions. Those houses rarely advertise, and they are not much known outside their clients; but they manage to keep a quiet and even course.

One thing your correspondent "E. G.," in his late letter, has not alluded to, is the great number of respectable houses in the upholstery, carpet, and antique furniture trade, that sell furniture, but do not make it. These firms procure good drawings, and give them out to a cabinetmaker, who undertakes to make the piece of cabinet-work for a certain sum, and they do not look to the quality of the work so much as to their full profit; therefore they are satisfied if their customers pass the work, and pay the bills. Yet there are some houses where the furniture is made on the premises under the supervision of the proprietor and designer (very few proprietors can draw), and some furniture is designed by our best architects and artists, and such furniture may be put in competition with that made by any house in the world.

Plain cabinet-work is made in these workshops, and it is as good as men can make, but the price seems high for it when compared, by an inexperienced person, with that made to sell only.

As a furniture and upholstery salesman, I have had to do with the designer, maker, and purchaser; and I consider the cause of so much bad furniture being made is the fault of the latter; for, if the purchaser were content with a neat and simple piece of furniture free from a quantity of wretched carving and inlay or marquetry, satisfaction to purchaser and maker would be the result.

J. S. B.

SOUTH LONDON WORKING CLASSES
INDUSTRIAL EXHIBITION.

On Monday last the third South London Working Classes Industrial Exhibition was opened at the Lameth Baths, the same building in which the two former were held, in the years 1864 and 1865. The exhibitors are mainly of West London, and the working-classes. The number of exhibitors is 450, and of these there is a much larger proportion of skilled workers than in any previous industrial exhibition. The adjudicators, the space committee, and a vigilance committee, have been chosen by the exhibitors from among themselves; and, in consequence of the pecuniary success of the exhibitions of 1864 and 1865, it was thought unnecessary to form a guarantee fund. The adjudicators have awarded the prize of 5l. for the best design for a medal to Marian B. Brook; and that of 2l. 2s. for the best design for a certificate to Helen J. Arndell Miles. Mr. S. Morley, M.P., presided at the opening ceremony, and Mr. Goschen, the Lord Mayor, and other gentlemen addressed the meeting.

TIMBER YARDS.

The late fire in the timber-yard, King-street, Clerkenwell, and its disastrous effects upon some poor tenements, whose tenants were wholly uninsured, again points to the necessity, so often urged in your pages, of placing these timber-yards under strict supervision, restrictions, and regulations.

No timber should be allowed to be stacked against adjoining dwelling-houses, nor within a distance of 30 feet of the external flank, or other wall of any adjoining dwelling-house. By this regulation, timber-yards could only be made in fit and proper situations.

THE DISTRICT SURVEYOR.

A SANITARY GRIEVANCE.

The following letter to the Board of Guardians of St. George's caused some laughter, it is stated. Let us express a hope that it nevertheless awakened attention:—

"Collooney, February, 6, 1869.
I most respectfully beg leave to state, for your information, and the information of the whole board, there is a large heap of manure, the concentrated essence of Mr. Sim's whole concerns, within four yards of my kitchen door. I am an "unprotected female." I mean by that, gentlemen, I have never been married. I live by my industry, so far as keeping an eating-house. A very respectable farmer called in here a few days ago for refreshment; but in consequence of the scent of Mr. Sim's dung-pit up to my door, says he, 'Kitty, I cannot take the second cup of tea.' Gentlemen, I do not want to take any law proceedings against Mr. Sim, but I want him to leave me what the Great Being left the whole human species—the air.—I have the honour to be, your very humble and obedient servant,
CATHERINE M'DONOGH."

THE TREATMENT OF SEWAGE.

Six.—In these times of sanitary improvement many ideas spring up in people's mind as to the best and most economic plan of disposing of the sewage of our towns; and having had many occasions to study and think about it, I have now attempted to bring my thoughts to a practical termination, and trust the following ideas may be profitably imparted.

The ordinary plan of draining our towns into the neighbouring rivers and streams will not be any longer permitted. Sewage works have been established, but sufficient pollution is allowed to escape into the neighbouring rivers and streams, to establish cause for Chancery suits, &c. Earth closets have been made and talked about, but are not without many and grave objections.
